Invasive species have the potential to invade to the exclusion of native vegetation. Natural grasslands, shrublands, and other xeric habitats are more prone to invasive weeds and could affect grizzly bear nutrition and the conditions for their prey. Some invasive species like blackberry invade riparian areas and may provide bear foods. These plan components help ensure that weeds do not invade and permanently alter grizzly bear habitats. Wildfire often interacts with invasive weeds which can change natural disturbance patterns. Objectives seek to treat invasive weeds and prevent spread and establishment. Plan direction for invasive species would have negligible effects on grizzly bears. The guidance in these plan components would help prevent and address invasive plant and animal species to help reduce impacts from wildfire, vegetation management, and invasive species.

Soils

Threats Addressed

- Motorized Access

Plan Component

- FW-DC-SOIL-01
- FW-DC-SOIL-02
- FW-DC-SOIL-03
- MA2 and MA3-GDL-SOIL-02
- MA2 and MA3-GDL-SOIL-05

Plan Component Summary

Establishes desired conditions for soils and provides standards and guidelines to maintain and restore soil function during and after project activities. MA2 and MA3-GDL-SOIL-02 specify that temporary roads, skid trails, and landings should be located on existing disturbed areas before creating new soil disturbance. MA2 and MA3-GDL-SOIL-05 requires that after a road is decommissioned or after cessation of management activities on temporary roads, soil function appropriate to the site potential should be restored using demonstrably effective methods. MA2 and MA3-GDL-SOIL-02 require that temporary roads, skid trails, and landings should be located on existing disturbed areas before creating new soil disturbance to limit additional soil disturbance.

Effect

Ensures that national forest activities do not damage soils and restores them when disturbed. The forest vegetation relies on the integrity of soils to maintain productivity. These plan components ensure that soil conditions are maintained so they continue to support grizzly bear habitat. These would help to minimize creation of new temporary roads and help address unauthorized uses of decommissioned roads. Soil objectives propose restoration activities, which could displace bears or have a small chance of bear-human conflict, but those would have lower probabilities and would have at most short-term local impacts.

Aquatic Ecosystems

Threats Addressed

- Motorized Access
- Vegetation Management
- Recreation
- Livestock
- Mineral and energy development
- Wildfire

Plan Component

All plan components in Sections:

- Water and Aquatic Resources
- Riparian Management Zones
- Conservation Watershed Network
- Infrastructure (Aquatics and Riparian)
- Energy and Minerals (Aquatics and Riparian)
- Livestock Grazing (Aquatics and Riparian)
- Lands and Special Uses (Aquatics and Riparian)
- Recreation (Aquatics and Riparian)

Plan Component Summary

The water and aquatics resources section mostly addresses water quality, connectivity of aquatic systems, sediment, instream flows, and water temperature.

The Riparian Management Zones section addresses the condition and management of riparian areas. They are defined with one of four categories based on whether they are fish-bearing or not, whether they flow year-round, or are still waters. Various activities are restricted within different distances of the edge of the flood plain based on the categories. Restricted activities include vegetation management, timber harvest, thinning, staging of vehicles or heavy equipment, refueling, and fuel storage, fuelwood cutting, and direct ignitions. Additional activities are prohibited in most cases with exceptions and include landings, skidding, staging or decking, yarding, and machine burn piling, new road, trail, and landing construction, including temporary roads. Additionally, a number of fire suppression related activities are restricted or prohibited within riparian areas. Saleable minerals are also restricted within riparian areas.

Plan components in the Conservation Watershed Network emphasize conservation and restoration within watersheds important for at-risk fish species. In these watersheds, activities shall be designed and implemented in a manner that supports or contributes towards the recovery of aquatic federally listed species and the achievement of aquatic and riparian desired conditions. It includes standards that require that when constructing or reconstructing roads, projects shall result in a net decrease in the hydrologic connectivity of the road system and stream channel network unless no further decreases are needed to meet desired conditions for Water and Aquatic Resources or Conservation Watershed Network. Standards prohibit new hydroelectric facilities and water developments shall not be located in the Conservation Watershed Network with exceptions only where the Forest Service has limited authorities.

Plan direction in the Infrastructure (Aquatics and Riparian) section address road and the maintenance of the road system within riparian areas.

Energy and Minerals (Aquatics and Riparian) section includes standards and guidelines that address impacts to riparian areas from energy and mineral activities. These plan components address mineral operations, pollutants, infrastructure, and minimize adverse effects to aquatic and riparian-dependent resources in riparian management zones.

The Livestock Grazing (Aquatics and Riparian) section addresses impacts to riparian and aquatic resources from livestock use.

Lands and Special Uses (Aquatics and Riparian) section address impacts from special uses including hydropower infrastructure.

The Recreation (Aquatics and Riparian) section of the plan addresses impacts from recreation within riparian areas. The desired condition is that recreation sites and developments have minimal impacts to these habitats. Standards and guidelines restrict new sanitation facilities, new facilities, or infrastructure. They also provide guidance on how activities are performed to minimize impacts to water quality and riparian areas.

Aquatic and riparian plan components restrict or minimize motorized access in several sections. These include several plan components that seek to minimize the construction of roads within riparian areas including FW-DC-ARINF-01, FW-STD-ARINF-01, FW-GDL-ARINF-04, FW-GDL-ARINF-08, FW-GDL-RMZ-02, FW-STD-ARINF-01, FW-GDL-ARINF-04, FW-GDL-ARINF-08, and FW-GDL-AREM-02. These are meant to minimize the impact of the transportation system on aquatic and riparian habitats. Objectives FW-OBJ-WTR-02, FW-OBJ-WTR-05, and FW-OBJ-RMZ-01 specifically mention road decommissioning as objectives for riparian habitat restoration.

Effect

The aquatic and riparian ecosystem plan components provide a rigorous framework for the protection and restoration of aquatic and riparian habitats. Collectively, the restrictions on activities within riparian areas would result in the conservation of these areas for grizzly bear use and benefit. Riparian areas provide forage resources, travel corridors, and general habitat to grizzly bears. These plan components are designed to improve fishery resources that may contribute to high quality bear nutrition.

Measures that restrict motorized access in riparian areas represent a substantial restriction because they occur across all management areas and make up approximately 548,284 acres or about 14 percent of the plan area. This includes 233,201 acres of riparian habitats in areas suitable for motorized uses. While these restrictions apply in riparian areas, the restrictions may drive placement of roads and reconstruction of existing roads into upland habitats.

Because of their comprehensive nature, the aquatic plan components address several of the threats to grizzly bears, at least within riparian areas.

Wildlife

Threats Addressed

- Human-Bear Conflicts
- Vegetation management (via landscape pattern)

Plan Component

- FW-GL-WL-01
- FW-DC-WL-01
- FW-DC-WL-06
- FW-DC-WL-07
- FW-DC-WL-08
- FW-DC-WL-07
- FW-GDL-WL-01
- FW-GDL-WL-05

Plan Component Summary

While the needs for most species are expected to be met through coarse filter ecosystem plan components such as those in the Forested Lands, Aquatic Ecosystem, and Meadows, Grasslands, and Shrublands sections, plan component in the wildlife section provide additional guidance for the management of wildlife habitats.

FW-GL-WL-01 is a Forest Plan goal for the Nez Perce-Clearwater to work cooperatively with the U.S. Fish and Wildlife Service and other agencies on conservation strategies, recovery plans, habitat management, and ecological conditions towards recovery of federally listed threatened or endangered species.

FW-DC-WL-01 is a desired condition to provide habitat for federally listed threatened, endangered, and candidate plant and animal species that contribute to their recovery to the point at which listing is no longer appropriate. It also expresses a desire to provide conditions to meet their life history needs.

FW-DC-WL-03 is a desired condition that addresses landscape pattern to provide for connectivity.

This section includes three species specific desired conditions for grizzly bears. They include FW-DC-WL-06, FW-DC-WL-07 and FW-DC-WL-06. These would direct management to provide ecological conditions to support recolonization of grizzly bears within the Bitterroot Recovery Zone and allow travel from other recovery zones to the Bitterroot Recovery Zone. It specifies that allocations identified in the Forest Plan provide connectivity to allow secure passage from occupied habitat into the Bitterroot Recovery Zone.

FW-DC-WL-07 would encourage efforts by the Nez Perce-Clearwater to educate the public on grizzly bears and conflicts. It would encourage providing information and stipulations in issued permits for bear safety to reduce bear-human conflicts.

FW-DC-WL-08 would also encourage education on grizzly bear safety and guide management to equip developed and administration sites infrastructure so that food, garbage, and other attractants can be made inaccessible to grizzly bears to reduce the potential of human-bear conflict.

FW-STD-WL-01 requires that Canada lynx habitat shall be managed in accordance with the Northern Rockies Lynx Management Direction and Record of Decision.

FW-GDL-WL-01 Reduces impacts to dispersal, migration, or critical habitat from communication lines and towers.

FW-GDL-WL-05 is a species-specific component for both elk and grizzly bears. This plan guideline acts as a constraint on new motorized trail construction within Idaho Roadless Rule Areas. It only applies to Idaho Roadless Rule areas that are within a motorized Recreational Opportunity Spectrum (ROS) setting. It would limit the amount and distribution of motorized trails in secure habitat patches 10,000 acres or larger within Idaho Roadless Rule Areas within motorized ROS settings. When constructing motorized trails in areas 10,000 acres or larger, it would require leaving areas 5,000 acres or larger as a minimum after motorized trails are constructed. It would prohibit motorized trails in secure habitats between 10,000 acres and 5,000 acres with the exception that it would not apply within Community Protection Zones (defined in the Idaho Roadless Rule). It does not apply to secure habitats smaller than 5,000 acres in Idaho Roadless Rule Areas that are within a motorized ROS setting. The effects of this plan component were described in detail above. The guideline is not needed in Idaho Roadless Rule areas not suitable for motorized uses because no motorized uses would be allowed there.

Effect

There are three species-specific desired conditions for grizzly bears and one species-specific guideline. There are also plan components for other wildlife species that would indirectly benefit grizzly bears. These plan components are intended to provide management or direction for federally listed species, support recolonization of the Bitterroot Ecosystem by grizzly bears, provide for connectivity, increase public awareness and education about bear safety, and direct management to provide infrastructure for food storage in recreation sites. They also provide for other wildlife species that support grizzly bear prey. FW-DC-WL-01 would provide conditions for federally listed species. FW-DC-WL-03, FW-DC-WL-06, and FW-GDL-WL-05 would promote conservation of secure habitat in Idaho Roadless Rule Areas which will aide connectivity for grizzly bears. FW-STD-WL-01 requires that the Nez Perce-Clearwater follow the Northern Rockies Lynx Management Direction, which could indirectly benefit grizzly bears.

Multiple Uses-Wildlife

Threats Addressed

- Motorized Access
- Recreation
- Vegetation management
- Wildfires

Plan Component

- FW-GDL-WLMU-01
- FW-DC-WLMU-03
- FW-DC-WLMU-05
- MA1-DC-WLMU-01

- MA2-DC-WLMU-01
- MA2-DC-WLMU-02
- MA3-DC-WLMU-01
- FW-DC-WLMU-06
- FW-DC-WLMU-07
- FW-GDL-WLMU-01
- FW-GDL-WLMU-03
- MA3-GDL-WLMU-01

Plan Component Summary

FW-GDL-WLMU-01 is a guideline that ensures that when closing routes to motorized use, to ensure benefits to wildlife habitat are realized, that measures would be included to sufficiently exclude motorized use on closed routes.

FW-GDL-WLMU-02 is a guideline where the intent is to reduce barriers to big game movements when constructing new fences.

FW-DC-WLMU-02 is a guideline that should direct management of habitat to provide conditions to meet life history requirements year-round for ungulates. Additionally, it would guide management to help ensure that habitats are composed of native plants.

FW-DC-WLMU-04 emphasizes that natural processes contribute to the mosaic of habitats needed by ungulates.

FW-GDL-WLMU-03 seeks to protect wintering big game from disturbance activities.

FW-DC-WLMU-06 is the overarching desired condition to provide for elk. It emphasizes maintaining habitat use and nutrition. This desired condition also would direct management to address invasive weeds in elk habitats.

FW-DC-WLMU-07 describes the desired distribution of elk. Elk distribution is often affected by motorized access. It specifically addresses the desire that motorized access does not affect use of nutritional resources by elk.

MA1-DC-WLMU-01 describes how the desired vegetation conditions in Management Area 1 is through natural processes and are composed of native plants.

MA2-DC-WLMU-01 would direct management to provide between 10 and 20 percent of the landscape to provide for elk moderate to high quality forage.

MA3-DC-WLMU-01 is a desired condition meant to encourage providing nutrition away from open motorized access. It specifies that 10 to 20 percent of the management area provides moderate or high-quality nutrition for elk and that a portion of that habitat is occurs greater than 0.5 miles from open motorized routes.

MA2-DC-WLMU-02 is a desired condition that areas at least 5,000 acres in size exist without motorized access open to the public to maintain habitat use by elk.

MA3-GDL-WLMU-01 includes treatments designed to improve elk habitat should focus on one or more of the habitat covariates likely to improve predicted cow elk body fat condition. The guideline has an associated management approach that describes the framework that identifies the four habitat covariates and process that would be used in evaluating project effects on elk habitat and improve habitat conditions for elk (see the elk potential management approaches in the appendix to the Biological Assessment).

Effect

While these plan components emphasize ungulates and are intended to benefit species commonly used by the public for hunting, fishing, gathering, trapping, and other uses, these plan components indirectly benefit grizzly bears. Desired condition FW-GLD-WLMU-02 would encourage vegetation management to provide for ungulates year-round including summer and winter seasons. Early seral conditions would benefit both bears and ungulates by increasing nutrition through both ungulate protein and through improved herbaceous nutrition. Additionally, this direction would encourage the use of natural processes like wildfire would contribute to wildlife habitats. Protecting winter range from disturbance would also benefit grizzly bears from both a disturbance and food source standpoint. Bears often look for carcasses on winter ranges when they emerge from their dens. Essentially providing for ungulates increases nutrition for grizzly bears. Management towards reducing unauthorized motorized uses on closed roads or motorized trails would help reduce the impact of motorized access outside the designated road system.

Elk specific plan components (FW-DC-WLMU-06, FW-DC-WLMU-07, MA2-DC-WLMU-01, MA3-DC-WLMU-01, MA2-DC-WLMU-02, and MA3-GDL-WLMU-01) provide a framework for the management of elk habitats which emphasize habitat use and nutrition. Maintaining habitat use often requires reduction or prevention of motorized access. In addition, these plan components contribute to grizzly nutrition by providing for early successional resources that will provide for both elk and bear nutrition. These measures are intended to improve elk populations which would also result in ungulate protein for grizzly bears. Elk plan components encourage providing nutrition that are located away from motorized access. These plan components provide direction specific to the management areas with particular emphasis in Management Areas 2 and 3.

In Management Area 3 plan, guideline MA3-GDL-WLMU-01 requires improving cow body fat. The Potential Management Approaches provides an integration of four factors known to affect elk habitat use which are: 1) nutritional quality of forage resources, 2) increasing distances from roads (areas one-half mile or more away from open motorized access), 3) habitat factors on slopes less than 40 percent and 4) improved habitat interspersion by factors such as increased edge to interior ratios, a mix of mature and open habitats, decreased distance from nutrition to forest edges, or other landscape patterns that facilitate elk selection. Nutrition must be usable by elk and distance from roads is one factor that allows nutrition to be usable. Additional information about how this is envisioned to work is provided in elk potential management approaches. The basic premise is to evaluate all these factors together during project development and make strategic decisions to increase habitat use and nutrition. In some cases, secure habitat would increase as a result of increasing distance from roads so that nutritional resources would be useable by elk. Elk plan components address motorized access, vegetation management, and would break up contiguous fuels so that wildfires would be less severe.

Sustainable Recreation

Threats Addressed

- Motorized Access
- Recreation
- Bear-human conflicts

Plan Component

- FW-DC-REC-04
- FW-DC-REC-13
- FW-STD-REC-01

Plan Component Summary

These plan components provide direction as to how recreation is to be managed. Those related to grizzly bear conservation are those that enforce recreation opportunity spectrum settings, especially those that address motorized access and the levels of development for recreation facilities.

FW-DC-REC-04 specifies that the type and level of infrastructure and visitor services are sustainable and consistent with the Recreation Opportunity Spectrum settings. This is helpful since vast areas of the national forest are in primitive and semi-primitive settings that would be managed. Since several areas of the national forest are in primitive and semi primitive settings, this desired condition would direct management to be consistent with these settings.

FW-DC-REC-13 specifies that trails including motorized trails not needed to serve management or public needs and purposes are absent. This would help ensure that there is not a proliferation of these features and direct management to remove or close areas that are not needed.

Standard FW-STD-REC-01 requires that construction, reconstruction, and maintenance of recreation facilities and trails shall be consistent with the Recreation Opportunity Spectrum classes designations and specialized plans (for example, such as wilderness, recreation corridor, river management, scenic byway, and trail management plans) as appropriate.

Effect

These are the primary plan components that enforce Recreation Opportunity Spectrum Settings. Recreation Opportunity Spectrum Settings that support less development and primitive or semi-primitive settings would provide lower levels of development, more rustic infrastructure, and a more natural setting that would be better for grizzly bear occupancy. Recreation settings, such as those for non-motorized settings prohibit motorized uses, road construction, and other developments that could impact grizzly bears. Suitability plan component in this section cement that motorized travel, permanent road construction, and temporary road construction are not allowed within primitive and semi-primitive-non motorized settings.

Public Information, Interpretation, and Education

Threats Addressed

- Human-bear conflicts

Plan Component

- FW-DC-ED-01

Plan Component Summary

A desired condition to provide interpretation and educational opportunities enhance the visitor’s understanding and appreciation for the rich natural and cultural history of the Nez Perce-Clearwater. This desired condition specifically mentions wildlife in general but could also include information about grizzly bear ecology and safety.

Effect
Would direct management towards increasing education and interpretation opportunities which may include grizzly bear topics to assist in educating the public about grizzly bear issues.

Infrastructure

Threats Addressed
- Motorized Access

Plan Component
- FW-DC-INF-02
- FW-OBJ-INF-01

Plan Component Summary
FW-DC-INF-02 is a desired condition that roads not needed to serve management and public needs and purposes are absent. Plan direction in the infrastructure section emphasizes the maintenance and condition of roads and structures. These plan components would not increase or cause more roads or trails.

FW-OBJ-INF-01 is an objective to complete road work, such as reconstruction; re-routing; road improvements; decommissioning; or placing roads in intermittent stored service every five years. It also priorities reducing effects on desired aquatic and riparian conditions from chronic sediment delivery or potential future road prism failures, including previously decommissioned roads where drainage features have failed.

Effect
This desired condition should direct management to minimize the road system to only those roads needed for specific purposes and would serve to reduce these features. The maintenance levels of roads are set base upon recreation opportunity spectrum settings and travel management decisions. By themselves, these plan components have little effect on grizzly bears other than when roads or buildings are maintained. In that case, the effects might be temporary displacement. Some plan direction within this section would decrease some roads. This direction would help minimize unneeded roads, which could serve to reduce the impacts to secure habitat for grizzly bears. Objective FW-OBJ-INF-01 would improve conditions for grizzly bears over time and may increase secure habitat.

Suitability

Threats Addressed
- Motorized Access
- Recreation
- Vegetation management
- Human bear-conflicts
- Livestock grazing
- Mineral and energy development
- Wildfires

Plan Component
- Plan components found in the table in Suitability section of the plan

Plan Component Summary
Identifies areas as suitable or not for a variety of uses. Prohibits or allows a variety of activities within different land management allocations such as designated wilderness, recommended wilderness, Designated Wild and Scenic Rivers or areas suitable for timber production for example. If an activity is not suitable within an area, that activity would not be allowed under the plan within the specified area. If on the other hand, the activities are identified as suitable, those activities would be allowed within those areas in the future after a project level analysis and consultation. Activities included in suitability determinations include timber production, timber harvest, permanent road construction, temporary road construction, prescribed fire, livestock grazing, minerals-saleable, minerals-locatable, minerals-leasable, new facilities, motorized recreation, over-snow motorized recreation, and mechanical transport recreation travel.

Timber production and harvest suitability was analyzed in detail in the Timber Suitability, Production, Harvest, and Vegetation Restoration section above and is not discussed further here.

Suitability plan components restrict motorized access via restrictions on permanent road construction, temporary road construction, and motorized travel. These were analyzed in detail in the Effects of Motorized Access Section above.

Prescribed fire is suitable everywhere. This would allow this activity throughout the plan area.

Suitability for livestock grazing was evaluated within the Effects of Rangeland Management and Domestic Livestock Grazing section above.

Suitability for minerals was analyzed within the Effects of Minerals and Energy section above.

New facilities are unsuitable in many areas including the Landmark Historic Corridor, Designated Wilderness, Recommended Wilderness, and Designated wild and scenic rivers within the wild classification. They are also unsuitable in the following Idaho Roadless Rule themes: Wildland Recreation, Primitive and special areas of historic or tribal significance, and backcountry restoration themes. They are only suitable in Idaho Roadless Rule within the Community Protection Zones. They are also not suitable within the primitive recreation opportunity spectrum setting, Riparian Management Zone, Mass movement areas, and Research Natural Areas.

Motorized over-snow travel is unsuitable in designated wilderness, recommended wilderness, and non-motorized winter recreation opportunity spectrum settings.

Mechanical transport includes mechanical activities such as bicycling. These are unsuitable within Wilderness, Recommended Wilderness but are otherwise suitable across the national forest.

Effect
These are broad brush plan components that find activities suitable or not within specific areas of the Nez Perce-Clearwater. An activity can be suitable, unsuitable, or conditionally suitable. Some of these activities are known to affect grizzly bears and their habitat. Effects are closely tied to land management allocations. In many cases, these activities are not suitable and thus prohibited across broad areas. Thus, where activities are unsuitable, threats to grizzly bears are reduced or eliminated.

Threats addressed through suitability include timber, construction of permanent roads, construction of temporary roads, motorized recreation or travel, mineral activities, construction of new facilities, motorized over-snow transportation, and mechanical transportation.

Suitability of uses differs for each activity and each land type as identified in the Suitability section of the plan. However, some generalizations can be made. Designated areas like wilderness, wild and scenic rivers, research natural areas, and the Landmark Historic corridor have fewer suitable uses, or in other words, more activities are not suitable and will not be allowed under the plan. Similarly, areas recommended for designation, such as recommended wilderness and suitable wild and scenic rivers, typically have many uses that are unsuitable. Other areas like the Idaho Roadless Rule areas have a variety of activities that are either unsuitable or conditionally suitable. The elimination of these activities from large areas via suitability plan components prevents effects to grizzly bears.

Timber production is unsuitable on about 73.5 percent of the Nez Perce-Clearwater. Timber harvest of any kind is unsuitable on about 58.7 percent of the national forest.

Prescribed fire being suitable everywhere will allow the national forest to address habitat changes as a result of fire exclusion and uncharacteristic wildfire. Prescribed fire would diversify grizzly bear habitat and provide for better nutrition.

New facilities are not suitable in many areas of the national forest especially those with high value to grizzly bears such as wilderness and most Idaho Roadless Rule theme areas. This would prevent development of new facilities in these areas which would maintain grizzly bear habitat.

Areas where winter-motorized recreation is unsuitable includes areas important to grizzly bears. Wilderness areas and recommended wilderness areas would prevent this activity from occurring within these areas which make up substantial acres within the plan area. This would prevent impacts to denning bears in these areas.

Mechanized transport suitability would protect the grizzly bear Recovery Zone and recommended wilderness areas from this activity. This would prevent impacts from mechanized travel such as bicycles.

Timber

Threats Addressed

- Vegetation management

Plan Component

- FW-DC-TBR-04
- FW-STD-TBR-01
- FW-STD-TBR-02
- FW-STD-TBR-03
- FW-STD-TBR-04
- FW-STD-TBR-05
- FW-GDL-TBR-01

Plan Component Summary

These plan components direct how and where timber harvest and production is to proceed. These plan components would help support ecological conditions for grizzly bears, especially within areas not suitable for timber production. Plan standard FW-STD-TBR-01 specifies that harvest for timber production shall only occur on lands classified as suitable for timber production. Standard FW-STD-TBR-02 specifies that on lands identified as not suitable for timber production but where timber harvest could occur should only be used as a tool to protect other multiple-use values and for salvage, sanitation, or public health or safety. Plan standard FW-STD-TBR-03 would protect soil, slope, and watershed conditions from being irreversibly damaged. Plan standards would ensure that forest stands would be restocked as in FW-STD-TBR-04. Standard FW-STD-TBR-05 specifies that silvicultural treatments shall be selected based on their ability to meet desired conditions and not based solely on economics or unit output of timber. Guideline FW-GDL-TBR-01 specifies that timber harvest within areas not suitable for timber production should only occur for such purposes as salvage, fuels management, insect and disease mitigation, protection or enhancement of biodiversity or wildlife habitat, meeting desired conditions to perform research or administrative studies or recreation and scenic-resource management consistent with other multiple use and management direction. They also identify only a portion of the plan area as suitable for timber production, with the majority not suitable.

Effect

These plan components ensure timber production is conducted in a sustainable manner and only in suitable areas. Areas not suitable for timber production protects grizzly bear habitat from this activity altogether. The effects are that the majority of the national forest would not be subject to this activity.

Additional areas are suitable for timber harvest but not production. Timber harvest may be used as a tool for the purpose of maintaining or restoring other resource values in lands not suited for timber production. Examples include maintaining a healthy, visually pleasing forest in the recreation segment of a wild and scenic river corridor or reducing fire hazard in the wildland urban interface or riparian conservation areas. These plan components should help ensure that grizzly bear habitats are managed in a sustainable manner in relation to timber harvest. Areas suitable for timber harvest but not production include about 586,014 acres total or about 14.8 percent of the national forest. These activities typically restore vegetation to desired conditions.

Energy and Minerals

Threats Addressed

- Mineral and Energy Development

Plan Component

- FW-STD-EM-01

Plan Component Summary

Directs how energy and mineral activities would occur. FW-STD-EM-01 ensures that mining activities shall only be authorized when the associated reclamation plan includes provisions to return disturbed areas to a state of site condition comparable to pre-mineral activity.

Effect

Helps ensures that areas impacted by mining would be restored after mineral activities are completed. This will help restore some areas impacted by mining activities. This would be helpful to restore some grizzly bear habitats.

Livestock Grazing

Threats Addressed

- Livestock allotments

Plan Component

- FW-GDL-GRZ-01

- FW-GDL- GRZ-03

Plan Component Summary
FW-GDL-GRZ-01 directs that livestock salting should be excluded from riparian areas, meadows, designated sensitive plant habitat, seedling conifer regeneration areas, aspen restoration areas, and prescribed restoration areas. FW-GDL-GRZ-03 requires that forage utilization should not exceed 35 to 55 percent.

Effect
Ensure grazing is conducted sustainably, leaving habitat in good condition for grizzly bears.

FW-GLD-GRZ01 would prevent trampling and concentrated uses areas within habitats that may be important to grizzly bears such as meadows, and riparian areas.

FW-GLD-GRZ-03 would ensure that grizzly bear habitats are not overutilized and that they maintain plant vigor and abundance of species despite grazing pressure.

Designated Wilderness Areas

Threats Addressed
- Motorized Access
- Vegetation management

Plan Component
- MA1-DC-WILD-01
- MA1-STD-WILD-01
- MA1-SUIT-WILD-01
- MA1-SUIT-WILD-02
- MA1-SUIT-WILD-03
- MA1-SUIT-WILD-04
- MA1-SUIT-WILD-05
- MA1-SUIT-WILD-06
- MA1-SUIT-WILD-07
- MA1-SUIT-WILD-08
- MA1-SUIT-WILD-09
- MA1-SUIT-WILD-10
- MA1-SUIT-WILD-11

Plan Component Summary
MA1-DC-WILD-01 would direct management to ensure that natural ecological processes and disturbances (for example, succession, wildfire, avalanches, insects, and disease) are the primary forces affecting the composition, structure, and pattern of vegetation.

MA1-STD-WILD-01 requires that management activities within designated wilderness areas shall preserve and protect wilderness character as required by the Wilderness Act, as well as each wilderness area's enabling legislation and its specific management plan.

Suitability was addressed above but essentially timber harvest, timber production, permanent road construction, temporary road construction, mineral extraction (except for those established prior to January 1, 1989), new facilities, motorized recreation, motorized over-snow travel, and mechanized transport are all unsuitable and prohibited in wilderness areas. Livestock grazing is suitable per designating legislation.

Effect

These plan components remove many threats and should maintain ecological conditions to contribute to recovery, especially within the Bitterroot Recovery Zone. Standards that require management to maintain wilderness character would prevent any actions not consistent with wilderness management. These would protect grizzly bear habitats. Suitability reduces or prevents many activities known to impact grizzly bears. These apply to designated wilderness that makes up the Bitterroot Recovery Zone, but also the Gospel-Hump Wilderness Area.

Designated Wild and Scenic Rivers

Threats Addressed

- Motorized access
- Vegetation management
- Wildfires

Plan Component

- MA1-DC-DWSR-01
- MA1-STD-DWSR-01
- MA1-STD-DWSR-02
- MA1-SUIT-DWSR-01
- MA1-SUIT-DWSR-01
- MA1-SUIT-DWSR-03
- MA1-SUIT-DWSR-04
- MA1-SUIT-DWSR-05
- MA1-SUIT-DWSR-06
- MA1-SUIT-DWSR-07
- MA1-SUIT-DWSR-08
- MA1-SUIT-DWSR-09
- MA1-SUIT-DWSR-10
- MA1-SUIT-DWSR-11

Plan Component Summary
Desired condition MA1-DC-DWSR-01 would direct management so that designated wild, scenic, and recreational rivers retain their free-flowing condition, water quality, and the outstandingly remarkable values for which the river was designated.

Standard MA1-STD-DWSR-01 requires that management activities in designated wild and scenic river corridors shall comply with their individual comprehensive river management plans.

MA1-STD-DWSR-02 requires that management activities in designated wild and scenic river corridors shall maintain their free-flowing character, water quality, and outstandingly remarkable values for which the river was designated.

The plan identifies uses that are suitable or not within wild and scenic rivers. These were analyzed in detail above.

Effect
These plan components would help ensure that designated wild and scenic rivers would contribute habitat conditions for grizzly bears because they are managed to conserve free flowing condition and outstandingly remarkable values within the river corridor (one-quarter mile of the river on either side). Outstandingly remarkable values include values for recreation, scenery, wildlife, geology, fisheries, and cultural outstandingly remarkable values. All these values must be protected which indirectly protects these areas for future grizzly bear use. “Free flowing” as applied to any river or section of a river means existing or flowing in a natural condition without impoundment, diversion, straightening, riprapping, or other modification of the waterway (as defined in the Wild and Scenic River Act). The requirement to maintain free flow would prevent alteration of these rivers.

Timber production is not suitable in wild and scenic river corridors, timber harvest is allowed under some circumstances, and road construction is restricted in areas designated as wild but not under recreational rivers. Some mineral extraction, motorized travel, and road construction is limited within wild rivers corridors. Restrictions on these activities would help to protect these areas from alteration and maintain conditions that could benefit grizzly bears.

Recommended Wilderness

Threats Addressed

- MA2-SUIT-RWILD-20

Plan Component Summary

MA2-DC-RWILD-01 is a desired condition that Recommended wilderness areas maintain their existing wilderness characteristics to preserve opportunities for inclusion in the National Wilderness Preservation System.

MA2-DC-RWILD-02 would direct management so that recommended wilderness areas are characterized by a natural environment where ecological processes and disturbances (for example, natural succession, fire, avalanches, insects, and diseases) are the primary forces affecting the composition, structure, and patterns of vegetation.

MA2-DC-RWILD-03 would direct management to ensure that recommended wilderness areas facilitate the connectivity and movement of wildlife species across the Nez Perce-Clearwater by remaining large areas with little human activity.

MA2-OBJ-RWILD-01 is an objective that seeks to ensure activities within recommended wilderness areas are consistent with plan suitability components within five years.

MA2-STD-RWILD-01 requires that summer recreation opportunities shall be compatible with the appropriate recreation opportunity spectrum classification of primitive or semi-primitive non-motorized.

MA2-STD-RWILD-02 requires that winter recreation opportunities shall be compatible with the appropriate recreation opportunity spectrum classification of primitive or semi-primitive non-motorized.

MA2-GDL-RWILD-01 requires that if fire management actions are required within recommended wilderness, the Forest Service should apply minimum impact strategies and tactics to manage wildland fire that protect wilderness characteristics, unless more direct attack is needed to protect life or adjacent property or mitigate risks to responders.

Suitability plan components were analyzed above but essentially, most uses within recommended wilderness are unsuitable or conditionally suitable where the activities are allowed consistent with Idaho Roadless Rule.

Effect

These plan components should help ensure that recommended wilderness areas would remain in a natural and wild state. It would promote ecological conditions to provide for grizzly bear habitat. These areas would provide for connectivity and secure habitat for grizzly bears. They would be managed largely by natural disturbances.

Standards MA2-STD-RWILD-01 and MA2-STD-RWILD-02 and suitability components ensure that these areas remain free from motorized uses.

Eligible and Suitable Wild and Scenic Rivers

Threats Addressed

- Motorized Access
- Recreation
- Vegetation management
- Mineral and energy development

Plan Component
- MA2-DC-E&SWSR-01
- MA2-STD-E&SWSR-01
- MA2-STD-E&SWSR-02
- MA2-GDL-E&SWSR-02
- MA2-SUIT-E&SWR-01 through MA2-E&SWR-22

Plan Component Summary
MA2-DC-E&SWSR-01 would direct management to ensure suitable wild, scenic, and recreational rivers retain their free-flowing condition, preliminary classification, and the outstandingly remarkable values that provide the basis for their inclusion in the system.

MA2-STD-E&SWSR-01 prohibits the authorization or construction of roads, trails, facilities, or airstrips that would alter the classification of the river.

MA2-STD-E&SWSR-02 applies to suitable wild river segment corridors. It prevents authorization or construction of roads outside of the corridor that would adversely affect the wild classification of the river.

MA2-GDL-E&SWSR-02 would restrict new road, trail, and airfield construction so that should be designed to maintain the outstandingly remarkable values, classification, free-flowing character, and water quality of the river.

Suitability was analyzed above but would essentially be managed similar to designated wild and scenic rivers. Rivers in the wild classification have more restrictions and do not allow timber production, permanent road construction, temporary road construction, reconstruction of roads, mineral materials-saleable, major facility construction, motorized over-snow vehicle use, and motorized travel. Activities in other classes of rivers are conditionally allowed such as when needed to maintain a primitive recreation experience or to protect users or to protect outstandingly remarkable values.

Motorized travel is generally not compatible with a Wild classification. Where motorized travel options are deemed to be necessary, such uses should be carefully defined and impacts mitigated. Motorized travel in Scenic and Recreational classifications may be permitted, prohibited, or restricted to protect outstandingly remarkable values.

Effect
Effects are similar to designated wild and scenic rivers. These plan components would help protect habitats one-quarter mile around eligible rivers and would contribute to grizzly bear habitats indirectly through management to maintain free flowing characteristics and outstandingly remarkable values. Similarly, prohibitions on suitability of uses would help conserve these habitats.

Idaho Roadless Rule Areas

Threats Addressed
- Motorized Access
- Recreation
- Vegetation management
- Mineral and energy development

Plan Component
- MA2-DC-IRA-01
- MA2-DC-IRA-02
- MA2-DC-IRA-03
- MA2-DC-IRA-05
- MA2-STD-IRA-01
- MA2-SUIT-IRA-01 through MA-SUIT-IRA-11

Plan Component Summary
MA2-DC-IRA-01. Roadless Areas maintain the roadless characteristics and themes assigned to them in the Idaho Roadless Rule.

MA2-DC-IRA-02. The composition, structure, and pattern of vegetation reflect natural disturbances and follow Idaho Roadless Rule themes, as assigned.

MA2-DC-IRA-03. Roadless areas contribute habitats for wide ranging species and connectivity for movement of wildlife. These areas also provide foraging, security, denning, and nesting habitat for wildlife.

MA2-DC-IRA-05. Habitat configuration, distribution, and composition provide ecological conditions that increase elk herds.

MA2-STD-IRA-01. The provisions in the Idaho Roadless Rule (36 CFR 294 Subpart C) shall take precedence over any inconsistent land management plan component unless and until the rule is amended. Land management plan components that are not inconsistent with the Idaho Roadless Rule will continue to provide guidance for projects and activities within Idaho Roadless Areas and those related to protection of threatened and endangered species (36 CFR 294.28(d)).

Suitability within Idaho Roadless Rule were designed to be consistent with the rule and was analyzed above. Activities that are suitable or not depend upon the roadless rule theme, with Wildland recreation theme areas being the most restrictive while the Backcountry Restoration theme is least restrictive. Some activities are only conditionally suitable.

Effect
Roadless rule areas would be managed consistent with the Idaho Roadless Rule. Vegetation management would seek to maintain the composition, structure and pattern that reflect natural disturbances. Desired condition MA2-DC-IRA-03 would direct management to provide connectivity for wildlife, including grizzly bears, within the Idaho Roadless Rule Areas. Plan direction for Idaho Roadless Rule areas prevents activities like road construction and timber production that can affect conditions for grizzly bears. Direction to increase elk herds would contribute to bear nutrition. Suitability plan components are consistent with the Idaho Roadless Rule and will help provide ecological conditions for grizzly bears.

Research Natural Areas

Threats Addressed
- Motorized Access
- Recreation
- Vegetation management

- Mineral and energy development

Plan Component

- MA2-DC-RNA-01
- MA2-STD-RNA-01
- MA2-STD-RNA-02
- MA2-SUIT-RNA-01 through MA2-SUIT-RNA-11

Plan Component Summary

Desired Condition MA2-DC-RNA-01 would direct management to maintain a representation of natural systems as a baseline for research, monitoring, and education by the agency, academia, and public interests. Additionally, these areas would be managed so that wildfire, insects, and pathogens, along with other processes and disturbances, continue to affect vegetation, reflecting the dynamic nature of the systems they represent. Research natural areas contribute to ecological sustainability and biological diversity.

MA2-STD-RNA-01 does not allow collection of forest products.

MA2-STD-RNA-02 will not allow or authorize uses that threaten or interfere with the objectives or purposes for which a research natural area is established consistent with the desired condition above.

The following activities are unsuitable in Research Natural Areas: Timber production, Timber harvest, Permanent Road construction, temporary road construction leasable minerals, mineral materials, new facilities, and motorized recreation.

Effect

These areas make up a small percent of the plan area but management within them would maintain grizzly bear habitat there. Timber production, harvest, road building, temp roads, mineral extraction, construction of new buildings, and motorized travel are prohibited and thus would protect these areas from those impacts. Management emphasis is on maintaining natural conditions which should maintain habitats for grizzly bears.

Lolo Trail National Historic Landmark

Threats Addressed

- Motorized Access
- Vegetation management
- Mineral and energy development

Plan Component

- GA-GDL-NHL-05

Plan Component Summary

GA-GDL-NHL-05 states; "New temporary or permanent road and trail construction should not be permitted within the Landmark unless the integrity of the National Historic Landmark is maintained, and the purpose of the action is to benefit the National Register integrity of the Landmark."

Suitability plan components find timber production, timber harvest, livestock grazing, leasable mineral extraction, mineral materials, new building construction as unsuitable. Permanent and temporary road construction are only suitable if the integrity of the National Historic Landmark is maintained.

Effect

These areas would be maintained for grizzly bear by this management. Maintain habitats for grizzly bears by preventing some actions known to impact grizzly bears. Management emphasizes managing wildfire to operate as the disturbance regime.

Summary

The overarching theme of vegetation management is to manage the national forest in a sustainable manner based on natural range of variation, with an emphasis on timber production limited to Management Area 3. The plan contains no direction to restrict road or motorized trail densities other than those within the multiple uses elk plan components, or those that apply within specific management areas such as recommended wilderness, recreation, suitable wild and scenic rivers, research natural areas, eligible and suitable wild and scenic rivers, and the National Historic Landmark. Instead, it relies on existing regulations found in law or regulation for Idaho Roadless Rule, designated wilderness, designated wild and scenic rivers, and designated research natural areas to maintain low road densities and secure habitat. An additional layer of management is included in the recreation opportunity spectrum alternatives that were analyzed in detail above, where decisions about suitability of uses are made across broad areas, including motorized travel and recreational development.

Plan Direction that Contributes to Ecological Condition for Grizzly Bear Recovery

Air Quality

Plan direction in the air quality section would have no effect on grizzly bears.

Cultural Resources

Plan direction for cultural resources would have no environmental consequences for grizzly bears.

Municipal Watersheds

Plan direction for municipal watersheds would have no environmental consequences for grizzly bears.

Scenery

Plan direction in the scenery section would have no effect or beneficial effects on grizzly bears.

Public Information, Interpretation, and Education

Plan direction in the public information, interpretation, and education section would have beneficial or no effect on grizzly bears. This plan direction may provide a mechanism for increased public awareness and education about attractants and grizzly bear ecology.

Lower Salmon

Plan direction in the Lower Salmon geographic area section would have negligible consequences on grizzly bears.

Pilot Knob

Plan direction in the Pilot Knob geographic area section would have negligible or no consequences for grizzly bears.

Lolo Trail National Landmark

Plan direction in the Lolo Trail National Landmark section would have negligible or no consequences for grizzly bears.

Connectivity Cumulative Effects

The analysis of cumulative effects provides a larger context in which to evaluate existing conditions and the effects of continuing to implement the Forest Plan. This section discusses the effects of management on adjoining federal, state, and private lands; the potential for connectivity between Recovery Zones; and the ongoing effects of climate change.

The area for cumulative effects is the Bitterroot Ecosystem. This ecosystem occurs roughly approximately from I-90 in the North, south following Highway 93 in Montana and Idaho, West along Highway 23 and I-84 in Idaho, North along Highway 95 in Idaho up to I-90.

Grizzly bear management is guided by the Bitterroot chapter to the grizzly bear recovery plan. That plan seeks to recover grizzly bears in the ecosystem. Originally, the plan was to recover grizzly bears within the Frank Church-River of No Return Wilderness and the Selway-Bitterroot Wilderness via translocation. Since then, the emphasis changed to natural dispersal. The ability of the recovery zone to recover grizzly bears therefore depends on connectivity from other grizzly bear ecosystems.

The Bitterroot recovery zone occurs almost entirely on National Forest System lands and several national forests administer different parts of the recovery zone and surrounding lands, including the Lolo, Bitterroot, Salmon-Chalis, and Boise. These national forests have Forest Plans that support recovery within the ecosystem and cooperate with the U.S. Fish and Wildlife Service in recovery efforts. The designated wilderness areas have wilderness management plans that direct the management of the wilderness areas such that they maintain wilderness character. As most of the recovery zone is designated wilderness, there are few threats to grizzly bears there, other than potential human bear conflicts. Wilderness plans provide strong direction to manage these lands with constraints on many activities. Additionally, Forest Plans provide significant direction for the management of designated wilderness areas. Outside of the recovery zone, but within the Bitterroot ecosystem, National Forest System lands are managed under the direction of Forest Plans, largely to manage lands for multiple uses. Forest plans have constraints or direction to support or manage for the recovery of federally listed species, but the measures used can vary widely depending upon the degree to which there has been a history of grizzly bear presence. Forests that have not previously had a history of grizzly bear presence have fewer measures in their plans for recovery whereas forests in closer proximity to recovery zones have more measures in their plans. Forest in Montana have managed for grizzly bear conservation as a result of grizzly bear occurs from either the Northern Continental Divide, the Cabinet-Yaak, or Selkirk ecosystems. National forests near the Yellowstone Ecosystem have a history of conservation measures for grizzly bears coming from the Greater Yellowstone Ecosystem.

All the national forests within the Bitterroot Ecosystem participates in the Interagency Grizzly Bear Bitterroot Ecosystem subcommittee to make progress towards recovery and implement measures to contribute to recovery. In both the Northern Region and Intermountain Region, forests manage grizzly bear habitat as federally listed threatened species. The Forest Service Manual includes specific direction for the management of grizzly bears. Several forest plans have direction on the management of federally listed species, and each forest consults with the U. S. Fish and Wildlife Service on projects that may affect grizzly bears. The Nez Perce-Clearwater plans include measures to provide for grizzly bears through both the 1987 plans and through this Forest Plan revision effort. The National Forests that administer lands within the ecosystem participate in efforts to provide food storage infrastructure in when funding is available and participate in public education and outreach with their bear aware programs.

The Beaverhead-Deerlodge to the East has amended their plan have revised or amended their forest plans to incorporate habitat management direction from the Greater Yellowstone Ecosystem Grizzly Bear

Conservation Strategy. The Caribou-Targhee National Forest reverts to 1997 direction, which does not directly incorporate conservation strategy recommendations, but follows Grizzly Bear Guidelines from the mid-1980s and access recommendations from the mid-1990s. The Caribou-Targhee is in the process of beginning their Forest Plan Revision efforts. The Caribou-Targhee has specific plan components for maintaining secure habitat in certain areas, phasing out domestic sheep grazing allotments and requiring proper storage of food and attractants.

The Nez Perce-Clearwater is flanked on the north by the St. Joe National Forest, the northeast by the Lolo National Forest, the east by the Bitterroot National Forest, and the south by the Payette National Forest. Management on these national forests is unlikely to disrupt connectivity for grizzly bears. The Nature Conservancy mapped landscape permeability for the Pacific Northwest (McRae et al. 2016), including western Montana, by classifying areas as having high, moderate, or low landscape permeability. Overall, their analysis indicated that the network of federal lands in north central Idaho provides a high degree of landscape permeability for wildlife. Collectively they provide management to contribute to recovery of federally listed species like grizzly bears.

The Nez Perce-Clearwater plan under the Preferred Alternative is part of a larger cooperative effort to provide for recovery in the Bitterroot Ecosystem and Recovery Zone. The plan provides species specific plan components to maintain connectivity and manage for grizzly bear conservation consistent with efforts within the Bitterroot Ecosystem. The Idaho Department of Lands manages lands adjacent to the west of the Nez Perce-Clearwater. These lands are primarily managed for timber production and are heavily roaded. These lands mostly occur to the west of the plan area where grizzly bear dispersal is not expected to occur. In the event a grizzly bear enters these lands, the management of these lands are not likely to pose a barrier to dispersal. However, the higher road densities and increased human activities may cause some bear-human conflict that could result in removal of dispersing bears.

Private Lands

In Idaho, large tracts of private lands are owned to the east of the Nez Perce-Clearwater boundaries. Large portions of these lands are managed for timber production and are heavily roaded but are not populated. A much lesser portion of private lands in these areas are residences or farmlands. These land areas are not located where bears are expected to disperse from the other ecosystems.

The human population in northwest Montana has grown at a relatively high rate during the past few decades and growth is expected to continue. Increasing residential development and demand for recreational opportunities can result in habitat loss, habitat fragmentation, and increases in human-grizzly bear conflicts. Private lands continue to account for a disproportionate number of conflicts and grizzly bear mortalities in Montana. These impacts are likely to intensify, although appropriate residential planning, outreach to landowners about how to avoid conflicts, tools such as bear-resistant containers and electric fencing, and assistance in resolving conflicts can help prevent or reduce these impacts.

Increasing development on private lands and the accompanying risk of human-grizzly bear conflicts has the potential to have cumulative adverse effects on grizzly bears that are moving towards the Bitterroot Ecosystem. Developments within northwestern Montana may pose a barrier to grizzly bear dispersal into the plan area.

Highways and Development North of Nez Perce-Clearwater

In order for grizzly bears to reach the Nez Perce-Clearwater, they must pass one or more highways. Some of these highways have developments that may pose a challenge to the dispersal of grizzly bears into the Nez Perce-Clearwater (Servheen, Waller, and Sandstrom 2003). The combination of highways and developments poses significant barriers to grizzly bear dispersal into the Bitterroot Ecosystem. Servheen (2003) predicted linkages that would allow dispersal. These linkages will be evaluated for effects to dispersing grizzly bears.

The most significant barriers to connectivity include the I-90 corridor, Montana Highway 200, Montana Highway 93, and associated human development. Servheen (2003) predicted several linkage areas through these developed areas into the Bitterroot Ecosystem. Passage of bears through these linkage areas may dictate where bears enter the Nez Perce-Clearwater and the Bitterroot Ecosystem to some extent.

Most fragmentation between the Northern Continental Divide and Bitterroot Ecosystems occurs along the I-90 corridor between Missoula, Montana and Superior, Montana and along U.S. Highway 93 north of Missoula from Evaro Hill to Ravalli Hill. Missoula is a rapidly growing city and suburban development has been rapidly spreading west and north along these major highway corridors. Some connectivity areas were available between Alberton, Montana and Superior, Montana; between Superior, Montana and St. Regis, Montana; and northwest of St. Regis (Servheen, Waller, and Sandstrom 2003). Bears traveling through these linkage areas would most likely enter the Nez Perce-Clearwater through the Hoodoo or Mallard Larkin areas. The area between Lolo, Montana and Lolo Hot Springs, Montana along U.S. Highway 12 is well connected. Bears traveling through this area would have little trouble passing into the plan area and would do so near Lolo Pass.

Servheen (2003) did not evaluate connectivity south of Lolo, Montana. The spread of the Northern Continental Divide Ecosystem population southward may enable this area to serve as a path through which bears may disperse. Bears dispersing through this area would also face significant barriers through Highway 93 and associated development into the Bitterroot Ecosystem area. However, if they made it through these areas, bears would have an easy time reaching the Bitterroot Ecosystem because they would enter the Bitterroot National Forest and be a short distance away from the Bitterroot Ecosystem boundary.

State Management of Grizzly Bears

The Montana Department of Fish, Wildlife, and Parks completed a grizzly bear management plan for western Montana in 2006 (Dood et al. 2006) and a grizzly bear management plan for southwestern Montana in 2013 (Montana Fish Wildlife and Parks 2013). Grizzly bear management plans establish goals and strategies to manage and enhance grizzly bear populations and to minimize the potential for grizzly bear-human conflicts. A long-term goal is to allow the populations in western and southwestern Montana to reconnect through intervening currently unoccupied habitats.

The Montana Department of Fish, Wildlife, and Parks is very active in providing public information and education about conserving grizzly bears and their habitat. Several bear management specialists, including one stationed nearby in Missoula, work with landowners and educate the public to avoid or resolve grizzly bear-human conflicts and to reduce grizzly bear mortalities. Bear specialists provide information and assistance to landowners on appropriate ways to secure food and bear attractants and respond to reports of conflicts with black bears and grizzly bears. These programs have a proven track record of success in informing the public, reducing the availability of attractants to bears on private and public lands, and reducing human-caused mortalities of grizzly bears.

Montana and Idaho regulate hunting for black bears and other wildlife species. Hunting of grizzly bears has not been allowed in Montana since 1991. There is a potential for grizzly bear mortality by hunters to occur as a result of mistaken bear identification or self-defense, especially in proximity to the carcasses of harvested animals. The Montana Department of Fish, Wildlife, and Parks provides a variety of public information and education programs, including a mandatory black bear hunter testing and certification program, to help educate hunters in distinguishing the two species. Black bear hunting seasons have been shortened in recent years, reducing the potential for mistaken identity. These efforts have helped to decrease legal and illegal shooting mortalities. No adverse cumulative effects are anticipated due to management actions of the Montana Department of Fish, Wildlife, and Parks.

The State of Idaho cooperates with the U. S. Fish and Wildlife Service and the Forest Service for the proper management of grizzly bears. The state supports grizzly bear recovery in the Bitterroot Ecosystem through participation in the Interagency Grizzly Bear Bitterroot Ecosystem subcommittee and supports the recovery of grizzly bears in the ecosystem but desire grizzly bears to migrate to the recovery zone on their own. While the State of Idaho does not have a grizzly bear plan for the Bitterroot Ecosystem, they do have plans that support efforts to recover grizzly bears in other ecosystems in the state like the Greater Yellowstone Ecosystem, Selkirk Ecosystem, and Cabinet-Yaak Ecosystem. The state also participates in outreach and education efforts and provide hunters with information on grizzly bear identification and safety information to help reduce or avoid accidental grizzly bear deaths. The State of Idaho also participates in efforts to reduce grizzly bear human conflicts. The Statewide Wildlife Action Plan addresses grizzly bear management and habitat and provides goals, objectives, and strategies related to grizzly bears.

Idaho's strategy for grizzly bears, outlined in their Statewide Wildlife Action Plan, includes continuing conservation partnerships, reducing or preventing illegal and accidental mortalities, reducing anthropogenic attractants and other potential for human-bear conflicts, and managing access to limit conflict and disturbance. The Idaho Department of Fish and Game allows liberal black bear hunting, including over bait. They engage the public in education about the difference between black and grizzly bears and notify the public about the potential to encounter a grizzly bear in the Clearwater region.

Climate Change

The rate of change and the impacts from climate change are accelerating. The U.S. Fish and Wildlife Service examined climate change and potential future effects on the grizzly bear in its five-year status review (U.S. Department of the Interior 2011c). The most likely ways in which climate change may potentially affect grizzly bears are reduction in snowpack levels, shifts in the denning season, shifts in the abundance and distribution of some natural food sources, and changes in fire regimes due to summer drought.

Reduced snowpack or a shorter winter season could improve over-winter survival of bears, assuming that sufficient bear foods are available later in the fall and earlier in the spring. However, a shorter denning period could increase the potential for spring and fall encounters between grizzly bears and hunters and recreationists, which in turn would increase the risk of mortality to grizzly bears (Servheen and Cross 2010). The extent and rate to which individual plant species or plant communities will be impacted by climate change is not possible to foresee with any level of confidence (Fagre et al. 2003, Walther et al. 2002). However, there is general consensus that grizzly bears are flexible enough in their diet that they will not be impacted directly by plant community changes in response to climate change (Servheen and Cross 2010). Fire frequency and severity are predicted to increase in the western United States as a result of climate change. Large, severe wildfires that convert mature forest to early successional condition alter the availability of grizzly bear foods and cover, potentially changing how bears use the landscape. Decreases in forest cover could benefit grizzly bears by increasing the production of shrubs, berries, and root crops in the years following large fires. The potential positive and negative effects of climate change would likely be variable and are difficult to predict. Grizzly bears are habitat generalists and opportunistic omnivores, which may make them less susceptible to changes in plant communities than some other species of wildlife. There is a high degree of uncertainty, but the continuing effects of climate change are unlikely to reduce the ability of the Nez Perce-Clearwater to support occasional bears moving into or through the action area.

Conclusions

Once grizzly bears establish a population, and perhaps as they move into the plan area, they will inevitably encounter existing conditions that could lead to conflict. The plan does not, nor could it, prohibit all actions that could lead to effects on grizzly bears, human-bear conflicts, and mortality as they move into the national forest. Some actions conducted under the plan or in the existing condition will increase the probability of human-bear conflicts that most likely will leads to either bear relocation or deaths after they become established. The most impactful factors for grizzly bear persistence across their range has been those that influence survival. Other than natural mortality, grizzly bear mortality is most affected by human-bear conflicts that result from grizzly bear and human behavior when they are in proximity and often result in bear deaths. Conflicts arise from bears being attracted to human foods, surprise encounters, livestock depredation, hunting related contact, and recreation related contact. All of these conflicts are correlated with the travel access system, and multiple studies have found that bear survival is related to motorized access.

The plan area and alternatives would contribute to the recovery of grizzly bears because the Bitterroot Recovery zone currently provides the ecological conditions for a grizzly bear population, which is maintained through wilderness management under law and the plan direction across all alternatives would contribute to recovery, provided they can disperse there. Direction for the Bitterroot Recovery Zone in the Land Management Plan would prohibit any new motorized uses in the recovery zone because it identifies these lands as unsuitable for motorized uses so no motorized roads and trails would be allowed. This would maintain the ecological conditions within the recovery zone as nearly 100 percent secure habitat.

The salient question then becomes, does the plan area outside the recovery zone provide the ecological conditions to provide connectivity to the Bitterroot Recovery Zone? Areas outside of the Bitterroot Recovery Zone, excluding Management Area 3, also could currently contribute to grizzly bear recovery because they currently have the sufficient secure habitat for female dispersal and reproduction required for allowing grizzly bears to spread into the Bitterroot Recovery Zone. Together with the designated wilderness, the plan area provides 2,698,716 acres of protected lands, of which 84 percent or 2,268,274 is secure habitat, an area larger than Yellowstone National Park. The 84 percent are secure habitat conditions in Management Area 1 and 2 lands are comparable to the percent in the North Continental Divide and Greater Yellowstone ecosystems. Consider that the Idaho Roadless Rule Areas in the Nez Perce-Clearwater Alone include 1,481,636 acres, of which 76.6 percent is secure habitat, which is an area comparable to the Selkirk and Cabinet-Yaak ecosystems, with a total amount of secure habitat that exceeds the amount of secure habitat in both those ecosystems combined. These measures would provide for grizzly bear recovery within the recovery zone and would largely maintain the conditions in the Idaho Roadless Rule Areas that would overall provide for grizzly bear connectivity and occupancy. Clearly, the plan area provides conditions capable of supporting grizzly bear populations and connectivity.

Grizzly bears are most likely to enter the Nez Perce-Clearwater from the north or northeast from potentially three other grizzly bear ecosystems. Based on female dispersal patterns, female dispersal could require females living on the Nez Perce-Clearwater outside of the Recovery Zone before they reach the Bitterroot Recovery Zone. However, the recovery zone is within the dispersal capabilities of female grizzly bears. The plan area currently has these ecological conditions as a result of a combination of management direction in the 1987 plans for elk security, restrictions on road construction in the Idaho Roadless Rule, designated wilderness management, and recommended wilderness management, which all constrained travel access.

Forest plans provide integrated plan components for the management of resources and allocate lands for a variety of uses. Various direction in the Land Management Plan has the potential to affect grizzly bears. This is expected as the plan balances human uses with measures for the sustainability of natural resources including wildlife habitat. Many areas of the plan have direction that would be beneficial to grizzly bear habitats. Other direction would have negative consequences for grizzly bear habitat, which includes Forestlands related to timber, energy and minerals, sustainable recreation, ecosystem services, suitability, and timber (related to roads), and have the potential to modify potential grizzly bear habitat. The plan does not authorize these activities but instead provides the broad programmatic direction under which actions would be guided. This plan used the new suitability plan components authorized by the 2012 Planning Rule to identify lands suitable for various uses. As such, this analysis evaluated the effects of the programmatic direction, the land allocations, and the uses suitable within those lands. Under the alternatives, the potential for effects stem from suitability determinations for timber production, temporary roads, livestock grazing, minerals, and motorized travel, each of which have environmental consequences. Many of these activities are constrained in Management Areas 1 and 2 because they are identified as unsuitable or conditionally suitable. The integrated plan components do not vary much by alternative. The land allocations on the other hand vary their distribution and the alternatives provide a gradient of land allocations that provide different levels of protection for grizzly bear habitats.

The most impactful factor influencing the future potential maintenance of secure habitat under the alternatives are the variations in motorized access explored to strike a balance of ecological conditions with social and economic considerations. Access was one of the issue statements for the development of the plan, with some wanting more access while others wanting less. The most impactful potential change under the alternatives are variations in the recreation opportunity spectrum, which dictates suitability for motorized uses. In terms of grizzly bear conservation, alternatives that provide the most secure habitat not suitable for motorized use ,better provide future conditions for grizzly bear occupancy. Other alternatives have lower amounts of secure habitat not suitable for motorized uses, with the Preferred Alternative having the second lowest amount at 66 percent.

However, some roadless rule areas are suitable for motorized uses in some areas. In these areas, since roads are prohibited, the key consideration would be the future creation and use of motorized trails within Management Area 2, which is mostly composed of Idaho Roadless Rule areas. Even with increased areas suitable for motorized uses, the plan area would follow Idaho Roadless Rule restrictions that would restrict roads, manage designated and recommended wilderness to maintain wilderness character, and authorize motorized access only after a site-specific analysis. There are a total of 1,681,779 acres of secure habitat completely protected as either designated wilderness or Idaho Roadless Rule areas where motorized uses are not suitable. About 565,519 acres of secure habitat in Idaho Roadless Rule Areas are suitable for motorized uses, with only limited possibilities of new roads due to the Idaho Roadless Rule constraints, but plan component MA2-GDL-WL-05 would apply to constrain the development of motorized trails.

In these cases, plan direction in the wildlife section limit motorized trails so that they would have to maintain areas 5,000 acres or larger without motorized access on either side of the new trail. While this mechanism would allow incremental reductions in secure habitat, it establishes a limit on both the overall amount of secure which could be impacted by motorized trails, a limit on the conditions that would allow motorized trails, and which would in turn limit the local distribution of motorized trails in Management Area 2. This plan component would restrict where and how much new motorized access there would be in Management Area 2 and still maintain many areas as secure habitats. This plan component was based on conditions preferred by elk but exceeds the sizes of secure habitat preferred by grizzly bears. Thus, the plan area would maintain the ecological conditions for connectivity into the Bitterroot Recovery Zone and even potential occupancy by grizzly bears. Still, a total of 542,720 acres of secure habitats in Idaho Roadless Rule Areas are not suitable for motorized uses within Idaho Roadless Rule Areas. This plan component would restrict where and how much new motorized access there could be in Management Area 2 and still maintain many areas as secure habitats because most of the secure habitats in Idaho Roadless Rule Areas are larger than 10,000 acres and could only be divided a limited number of times.

The context for this constraint is important to consider. In other grizzly bear ecosystems, constraints on motorized access were typically limited to areas within the recovery zones and were not applied or were applied at lower levels outside of recovery zones. MA2-GDL-WL-05 applied to Idaho Roadless Rule Areas that are completely outside the Bitterroot Recovery Zone and with the recovery zone fully protected from motorized uses. These are appropriate constraints given that the Nez Perce-Clearwater is currently considered unoccupied, and that these measures apply outside the recovery zone.

The alternatives provide varying amounts of recommended wilderness, which would slightly enhance connectivity for grizzly bears over Idaho Roadless Rule area management. The proposed Mallard-Larkin, Meadow Creek North-Upper North Fork, Rawhide, Hoodoo, Sneakfoot, and Northfork Spruces White Sand recommended wilderness areas would provide the most benefits to connectivity for dispersing bears to enter the Bitterroot Ecosystem. These are found in various combinations under the alternatives and would be best for grizzly bear connectivity in the following order: Alternative W, Alternative Z, the No Action Alternative, Alternative Y, and Alternative X. The Preferred Alternative selected the Hoodoo, Mallard Larkin, and Meadow Creek areas as recommended wilderness, which is more than in the No Action Alternative.

Alternatives for wild and scenic river suitability would provide some limited connectivity for bears because they would provide linear corridors for travel in various amounts that could be followed by dispersing bears. The benefits of these alternatives for grizzly bear connectivity from highest to lowest are in the following order: Alternative W, Alternative Z, Alternative Y, and Alternative X. The Preferred Alternative selected only a few rivers as suitable.

The key determination is whether the plan would provide connectivity from the Northern Continental Divide, Cabinet-Yaak, or Selkirk ecosystems into the Bitterroot Recovery Zone. Bears would most likely have to pass through the northern portion of the Nez Perce-Clearwater to enter this ecosystem. The northern portion of the Nez Perce-Clearwater provides the ecological conditions to provide connectivity because it has low road densities and management areas, such as Idaho Roadless Rule areas that restrict motorized development. Forest management may affect connectivity for grizzly bears, but mechanisms are in place to constrain those activities to maintain conditions for connectivity. Cumulative effects outside of Forest Service control may make it difficult for bears to enter into the Nez Perce-Clearwater and the Bitterroot Ecosystem from the other ecosystems to the north of the Nez Perce-Clearwater. The most significant barrier is highways, such as I-90, Montana Highway 200, and Montana Highway 93, and the associated human development around these highways that pose the most significant challenges for dispersing grizzly bears to make it into the Bitterroot Ecosystem. Based upon the linkage areas identified in Servheen and others (2003), the most likely places for bears to enter the Nez Perce-Clearwater are between the Mallard-Larkin area and the Hoodoo area. Once bears cross the highways and associated development in and around Missoula, Montana, they should be able to be connected to the Bitterroot Ecosystem.

The plan establishes three species specific desired conditions and a species-specific guideline for grizzly bears that will guide management of all future projects under the plan. These include FW-DC-WL-06, FW-DC-WL-07, FW-DC-WL-08, and MA2-GDL-WL-01. Additional plan desired conditions would guide the Nez Perce-Clearwater to provide for connectivity in for FW-DC-WL-09 for species like grizzly bears and others. Many other coarse filter ecosystem plan components also contribute to ecological conditions for grizzly bear dispersal and occupancy. Collectively, all these aspects of the plan combine to establish measures that will continue to maintain ecological conditions for grizzly bears to disperse into the Bitterroot Recovery Zone and establish a grizzly bear population.

The plan includes a potential management approaches section specific to grizzly bear management and which takes an adaptive approach to manage grizzly bears as they move into the area. While these are optional plan content and are not required to be followed the same as plan components, provide agency intent on management of grizzly bears in the future as bears move into the area. Topics include participation by the Nez Perce-Clearwater National Forest as a member of the Bitterroot Ecosystem subcommittee to understand best available science and best practices regarding grizzly bears in the Bitterroot Ecosystem and support recovery in the Bitterroot Recovery Zone. Potential management approaches also describe the use of minimization measures and conservation recommendations by the Bitterroot Ecosystem Subcommittee including sanitation plans, infrastructure, and reducing attractants. It describes incorporating consideration of connectivity for grizzly bear at a site-specific scale, and follow direction of the U.S. Fish and Wildlife Service regarding management, project level analysis, and consultation for grizzly bear on projects to reduce human-bear conflict and reduce impacts to current bear secure habitat.

The effects of the plan must be viewed as an integrated whole rather than focusing on individual plan components because it is the integrated and interacting parts of the plan that provide the overall guidance for forest management. The plan does not have many species-specific plan components for grizzly bears because of the direction in the 2012 Planning Rule to provide the ecosystem integrity and coarse filter ecosystem plan components to provide the ecological conditions for recovery. In whole, the plan provides a variety of plan desired conditions, guidelines, standards, and suitability of uses that indirectly benefit grizzly bears. Examples include plan components noted in the "Plan Direction that Contributes to Grizzly Bear Recover" section above.

These measures meet the requirements of the 2012 Planning Rule to provide the ecological conditions to contribute to recovery. These measures are also sufficient to provide the ecological conditions within the Bitterroot Recovery Zone for the achievement of recovery goals as outlined in the 1993 Grizzly Bear Recovery plan including the Bitterroot Ecosystem Chapter of the Recovery Plan (1996).

Multiple Uses Wildlife

The following analysis addresses the effects to socially and economically important wildlife and their habitat from the suite of plan components and range of alternatives considered in the Land Management Plan. The 2012 Planning Rule directs that plans must provide for ecosystem services and multiple uses within Forest Service authority and the inherent capability of the plan area. Plans must include plan components for multiple uses and for integrated resource management to provide for ecosystem services and multiple uses in the plan area. The responsible official must consider habitat conditions for wildlife, fish, and plants commonly enjoyed and used by the public and for hunting, fishing, trapping, gathering, observing, subsistence, and other activities in collaboration with federally recognized tribes, other federal agencies, and state and local governments. This must be done while meeting requirements for providing for the diversity and abundance of wildlife under Section 219.9 of the planning rule.

The spatial scale of this analysis includes the lands administered by the Nez Perce-Clearwater for effects. This area was chosen because the Nez Perce-Clearwater only has control of habitat conditions within the plan area. For cumulative effects, the spatial scale is the Clearwater Region of the Idaho Department of Fish and Game. The cumulative effects analysis area was chosen because the Idaho Department of Fish and Game typically has the basic role in fish and resident wildlife management and has primary authority and responsibility as trustee over wildlife populations. Therefore, this analysis tiers to the state's game management units, which are bounded by their regional boundaries.

Wildlife data from the Idaho Department of Fish and Game was obtained to inform the analysis, which contains data of game species found within the plan area. Idaho Department of Fish and Game data represents the best scientific information available for wildlife populations of species commonly used for multiple uses. The Nez Perce Tribe was also engaged for their expertise in wildlife species important to them to exercise their treaty reserved rights. Additional data sources included the Forest Service's Natural Resource Information System database of wildlife observations, migratory bird monitoring data from the Intermountain Bird Observatory, and other sources of data held internally. When available and relevant, the state provides habitat models for game species, count data, trend data, and other sources of information. The literature cited throughout this section is also identified as the best scientific information.

The Nez Perce-Clearwater engaged the Nez Perce Tribe, the Idaho Department of Fish and Game, and the Clearwater Basin Collaborative, as well as members of the public, in the development of plan components for multiple use wildlife species. Among these government agencies, groups, and individuals, there was an almost universal desire to have healthy populations of wildlife species typically used by the public, even though they may disagree in how to achieve or maintain this goal. The Nez Perce-Clearwater leveraged the expertise of these entities and brought in experts from the Pacific Northwest Research Station's Forestry and Range Sciences Laboratory in La Grande, Oregon, to help draft plan components to provide the ecological conditions needed for these species. These plan components were integrated with other resource areas to allow the Forest Service to balance the Nez Perce-Clearwater's ability to provide other multiple uses. The plan components underwent multiple iterations and changes during this process.

The effects of the plan components and alternatives on multiple use wildlife were evaluated under the context of 1) how the plan will maintain or improve habitat conditions for commonly used species and 2) how the plan might affect the ability of the public to continue to use this resource. The ability of the plan area to do this depends upon the size of the populations of these wildlife species. The Forest Service does not control all the factors that control wildlife populations. The primary factors the Forest Service has responsibility and control over is to provide the ecological conditions for these species within Forest Service authority and the capability of the plan area. These responsibilities must be balanced with other multiple uses while providing for the diversity and abundance of wildlife.

Changes between Draft and Final Environmental Impact Statements

During public meetings and in comments on the Draft Environmental Impact Statement, there was concern that plan components FW-STD-WL-02 and FW-GDL-WL-05 would inappropriately restrict pack goat use within the plan area. The response was to clarify FW-STD-WL-02 to not include pack goats. It now states:

In order to prevent disease transmission between wild sheep and domestic sheep and goats, domestic sheep and goat grazing (excluding pack goats) shall not be authorized in or within 16 miles of bighorn sheep occupied core herd home ranges.

Originally, FW-GDL-WL-05 was intended to prevent "permitting" or, in other words, issuing a special use permit for pack goat use within bighorn sheep core herd home ranges. A special-use authorization is a legal document, such as a permit, term permit, lease, or easement, which allows occupancy, use, rights, or privileges of agency land. The authorization is granted for a specific use of the land for a specific period.

An organization or individual requires a special use permit to occupy, use, or build on Forest Service land for personal or business purposes, whether the duration is temporary or long term. Similarly, if there is a fee being charged or if income is derived from the use, or if an activity on those lands involves individuals or organizations with 75 or more participants or spectators, then a special use permit is required. Guideline FW-GDL-WL-05 was not intended to restrict the public from personal use of pack goats within bighorn sheep core herd home ranges. After consideration of the comments, and the low probability of contact that pack goat use may present to the bighorn sheep herd, it was thought that measures to reduce the probability of contact could be included in special use permits that would safely allow pack goat use under a special use permit. As in the Draft Environmental Impact Statement, the guideline allows use of pack goats by the public when a special use permit is not required. FW-GDL-WL-05 was edited to clarify the guideline which now states:

New authorizations and permit reauthorizations for domestic goat packing should include provisions to prevent disease transmission between domestic goats and bighorn sheep.

Affected Environment

Existing Condition

The plan area supports 62 species commonly used by the public for hunting, trapping, gathering, subsistence, and other uses. These species use a variety of habitats or key ecological features provided by ecosystem plan components. Table 287 lists the species commonly used as big game, upland game, furbearers, and waterfowl. Tribes may use other species in addition to these species for clothing, subsistence, ceremonial purposes, religious purposes, or to exercise treaty reserved rights.

Table 287. Wildlife typically used by the public, how they are used, and a brief habitat description.

Common Name	Use	Habitat Description
Bighorn sheep	big game	Rocky steep break lands.
Gray wolf	big game	Ranges in all northern habitats where there is suitable food with densities being highest where prey biomass is highest (Fuller 1989). Food is extremely variable but mainly large ungulates, such as moose, caribou, deer, elk, and wild boar. Wolves will also eat smaller prey items, livestock, carrion, and garbage.
Moose	big game	Found in woodland habitats, both coniferous and broad-leaved. This species prefers a mosaic of second-growth boreal forest, openings, swamps, lakes, and wetlands. Forages on broadleaf trees, preferring birch, ashes, and willow, in the spring and summer and the twigs of these species, as well as of fir, alpine, and juniper, in the autumn and winter. It also eats shrubs, such as blueberry and heather, dwarf shrubs, herbs, and aquatic plants.
Mountain goat	big game	Most occur in high altitude habitats up to the limit of vegetation. Although they sometimes descend to sea level in coastal areas, they are primarily an alpine and sub-alpine species. Their diet includes grasses, herbs, sedges, ferns, moss, lichen, twigs, and leaves from low-growing shrubs and conifers in their high-altitude habitat. The most common range feature is steep, rocky terrain.
Mountain lion or cougar	big game	Cougars are found in a broad range of habitats in all forest types, as well as lowland and montane desert. Several studies have shown that habitat with dense understory vegetation is preferred; however, cougars can live in very open habitats with only a minimum of vegetative cover. In North America, deer make up 60-80 percent of the diet. In the plan area, cougars are an important predator of elk.

Common Name	Use	Habitat Description
Mule deer	big game	Adapted to a variety of habitats including temperate forest, desert and semi desert, open range, grassland, field, and scrub habitats, as well as mountainous areas. Feeds mostly on browse.
Rocky Mountain elk	big game	Mainly coniferous forests interspersed with natural or man-made openings, such as mountain meadows, grasslands, burns, and logged areas. Forages on grasses, forbs, or browse, depending upon availability.
Whitetail deer	big game	Whitetail deer inhabit a wide range of habitats from temperate to subtropical and semi-arid environments in North America and include rainforests and other equatorial associations, such as deciduous forests and savannas of Central America and northern South America. Requirements are met in practically every ecological type, including grasslands, prairies, plains, mountains, hardwoods, coniferous and tropical forests, deserts, and even woodlots associated with farmland.
American badger	furbearer	Grasslands, meadows, open forest, brush, and deserts. Prefers grasslands or shrub lands, which can include parklands, farms, and treeless areas with friable soil and a supply of rodent prey. They may also be found in forest glades and meadows, marshes, brushy areas, hot deserts, and mountain meadows.
American beaver	furbearer	Rivers, springs, and lakes with adjacent woody broad-leaved foods, such as willow, aspen, and hardwoods.
American mink	furbearer	Species is found along streams and lakes, as well as in swamps and marshes. It prefers densely vegetated areas. It dens under stones or the roots of trees, in expropriated beaver castor or muskrat houses, or in self-excavated burrows. Forages on a variety of prey.
Common muskrat	furbearer	Found in brackish and fresh-water lakes, ponds, streams, rivers, and marshes.
Coyote	furbearer	Coyotes utilize almost all available habitats, including prairie, forest, desert, mountain, and tropical ecosystems. Prey populations are a key feature of these habitats. Foods include small mammals, birds, and deer sized ungulates.
Ermine or short-tailed weasel	furbearer	Often found in successional or forest-edge habitats, scrub, alpine meadows, marshes, riparian woodlands, hedgerows, and riverbanks that have high densities of small mammals, especially Microtus and Arvicola voles. Coniferous and mixed woodlands are preferred.
Long-tailed weasel	furbearer	Found in a wide variety of habitats, usually near water. Associated with non-forested habitats within forested landscapes. Favored habitats include brushland, open woodlands, field edges, riparian grasslands, swamps, and marshes. Dens are in abandoned burrows made by other mammals, rock crevices, brush piles, stump hollows, or space among tree roots. These weasels are usually most abundant in late seral stages or ecotones where prey diversity is greatest. Waterways provide access to suitable habitat and are a natural avenue for dispersal, particularly in areas that otherwise are unsuitable. Feeds primarily on small mammals, occasionally birds, other small vertebrates, and insects. They are not found in deserts or thick, dense forests.
Northern river otter	furbearer	Found anywhere there is a permanent food supply, such as fish, crustaceans, and amphibians, and easy access to water. In Idaho, river otters prefer valleys over mountain habitats, and they select valley streams over valley lakes, reservoirs, and ponds. Woody vegetation and log jams are important habitat features. In plan area, most observations are in larger rivers.
Red fox	furbearer	Utilizes a wide range of habitats, including forest, tundra, prairie, desert, mountains, farmlands, and urban areas.
Western spotted skunk	furbearer	Widespread in many habitats. In Idaho, western spotted skunks occur most commonly along streams, especially in the vicinity of basaltic outcroppings and rock piles. In southeastern Washington, uses rocky places and riparian thickets of willow and cottonwood. Commonly uses canyons, cliffs, rimrocks, lava fields,

Common Name	Use	Habitat Description
		and arid valleys, whereas, in coastal regions it is common in alder, salmonberry, riparian alder, riparian hardwood, and tanoak habitats. Known to use dens of other animals, such as beavers and woodrats, or under buildings. Dens in rock outcrops, road cuts, under shrubs, in crevices, and tree cavities.
California quail	upland game	Found in chaparral, sagebrush scrub, grassland oak, and riparian and foothill woodlands.
Chukar	upland game	Steep, rocky, mountainous terrain and a mixture of brush, grasses, and forbs. In the plan area, found in dry break lands.
Dusky grouse	upland game	Summer—shrub step, grassland, aspen, or non-forested alpine adjacent to conifer forest or open conifer forest, also forest mosaic. Abundant arthropods for broods and lush vegetation for adult food. Winter—high elevation conifer forest, Douglas-fir, and lodgepole important in winter diet.
Gray partridge	upland game	Agricultural fields and grasslands; in summer, especially with broods, mainly fields with cereal grains and row crops but also roadsides and shelterbelts.
Mountain cottontail	upland game	Occurs in a variety of habitats throughout its range. In the north, it primarily occupies sagebrush habitat while it occurs more frequently in forested areas in the south. Feeds on sagebrush and juniper all year where this vegetation occurs but grasses are preferred when available in spring and summer.
Mourning dove	upland game	Nests in a wide array of ecological types, usually open woodlands and edges between forest and prairie. Foods are seeds of herbaceous plants found in early successional habitats.
Ring-necked pheasant	upland game	Open habitats, often associated with agriculture lands.
Rock pigeon	upland game	Nest in crevices and caves in rocky seaside cliffs or interior uplands, especially near open scrub vegetation or human agriculture. Also, around human infrastructure.
Ruffed grouse	upland game	Closely associated with aspen. Most abundant in early-successional forests dominated by aspens and poplars. Present in riparian habitat and early-seral-stage deciduous forest in mountainous regions of Pacific Northwest. Although associated with aspen, heavy seasonal use of conifers in Idaho.
Snowshoe hare	upland game	Associated with conifer and mixed deciduous forest of North America. It requires dense understory vegetation, which it uses as cover. Diet consists mostly of grasses, forbs, sedges, and ferns.
Spruce grouse	upland game	Strongly associated with conifer forest. Fire seres are the typical habitat of this bird that prefer relatively young stands over more mature conifer forests.
Wild turkey	upland game	Found in Ponderosa pine, aspen/fir, spruce/fir, and oak. Brood rearing habitat consists of grassy openings in mixed conifer forests, stands of aspen, and open meadows.
American coot	waterfowl	Wetland species with heavy emergent vegetation along the shoreline in combination with deeper water.
American wigeon	waterfowl	Shallow, freshwater wetlands: sloughs, ponds, small lakes, marshes, and rivers.
Blue-winged teal	waterfowl	Shallow ponds with abundant invertebrates
Canada goose	waterfowl	A broad range of habitats near lakes, ponds, larger streams, marshes, muskegs, and wet hummocky areas.
Canvasback	waterfowl	Uncommon visitor in the plan area, only during migration. Uses a wide variety of aquatic features during migration, such as ponds, lakes, and slow rivers.
Cinnamon teal	waterfowl	Wetlands, ponds, and lakes with emergent vegetation.
Eurasian wigeon	waterfowl	Wetland or aquatic habitat.

Common Name	Use	Habitat Description
Gadwall	waterfowl	Breeding habitat—seasonal and semi-permanent wetlands, mixed prairie, parkland, shortgrass prairie, and tallgrass prairie. Migration habitat—lakes, reservoirs, beaver ponds, and farm ponds.
Green-winged teal	waterfowl	Forest wetlands. Breeds in wetlands in boreal forest and deciduous parklands and wetlands adjacent to grasslands or sedge meadows with brush thickets or woodlands.
Harlequin duck	waterfowl	Clear, fast-flowing rivers and streams with boulder substrates, low acidity, wide riparian vegetative zones, abundant aquatic insect larvae, midges, caddis flies, stone flies, mayflies, and salmonid roe.
Lesser scaup	waterfowl	Large seasonal and small, semi-permanent wetlands and lakes with emergent vegetation.
Mallard	waterfowl	Wide variety of wetlands, lakes, ponds, and other aquatic environments.
Northern pintail	waterfowl	Open country with shallow, seasonal, or intermittent wetlands and low vegetation.
Northern shoveler	waterfowl	Found in a variety of wetland habitats with nearby grasslands or rangelands for nesting.
Redhead	waterfowl	Habitat generalist. Uses wide variety of wetlands.
Ring-necked duck	waterfowl	Only a migrant in plan area. Migration habitat includes shallow lakes and impoundments with dense stands of flooded emergent or submergent vegetation. Mostly documented on large rivers in plan area.
Ruddy duck	waterfowl	Prairie pothole region where it nests in wetlands and marshes. No nesting habitat in plan area. Only a visitor to large rivers or wetlands in the plan area.
Sandhill crane	waterfowl	Open grasslands, meadow, wet meadows, marshes, and shallow wetlands. Nests near or in water on floating nests.
Snow goose	waterfowl	Migrant only in the plan area. Classification based upon migratory habitats. Frequents protected freshwater and brackish marshes, slow-moving rivers, large and small lakes, impoundments, farm fields, and sand bars; avoids forested areas.
Tundra swan	waterfowl	Migrant only in plan area - Migration habitat shallow ponds, lakes, and riverine marshes; also harvested agricultural fields and fields growing winter cereal grain. Sego pondweed important.
Wilson's snipe	waterfowl	Edges of bogs, fens, willow and alder swamps, and marshy edges of ponds, rivers, and brooks.
American black bear	big game	Reported from a broad variety of forested habitats from deciduous forests in eastern North America to coniferous forests in the west. Dense forests, riparian areas, open slopes, or avalanche chutes during spring green-up. Uses snow slides, stream bottoms, and wet meadows in early and mid-summer. May concentrate in berry and whitebark pine areas in fall. Hibernates in natural cavities, such as in trees or rocks, under logs, and brush piles. Studies in north central Idaho show bears select mature grand fir and Douglas-fir with greater than 60 percent canopy cover and select riparian areas. They also select fruiting shrub fields for foraging.
American marten and Pacific marten	furbearer	Associated with late-seral coniferous forests characterized by closed canopies, large trees, and abundant standing and fallen woody material. It dens in hollow trees or logs, in rocky crevices, or in burrows. Diet consists of rodents, hares, birds, and seasonal fruit. Voles, squirrels, and hares are the most important prey seasonally.
Bobcat	furbearer	A wide variety of habitats, including boreal coniferous and mixed forests in the north, bottomland hardwood forest and coastal swamp in the southeast, and desert and scrubland in the southwest. High rabbit and small mammal populations are requisite. They seem to prefer shrub, open, or early seral habitats over forested habitats. Only large, intensively cultivated areas appear

Common Name	Use	Habitat Description
		to be unsuitable habitat. Areas with dense understory vegetation and high prey density are most intensively selected. They sleep in hidden dens, often in hollow trees, thickets, or rocky crevices.
Northern raccoon	furbearer	Found almost anywhere water is available along streams and shorelines. Dens under logs or rock, in tree cavities, ground burrows, or banks. Most abundant in hardwood swamps, mangroves, flood forests, and marshes. Opportunistic omnivore, eating fruits, nuts, insects, small mammals, bird eggs and nestlings, reptile eggs, frogs, fish, aquatic invertebrates, worms, and garbage.
Barrow's goldeneye	waterfowl	Barrow's goldeneye is a cavity-nesting duck that depends heavily on the availability of large cavities. Winters mostly in marine habitats (salt water) and a few inland open rivers. Uses open rivers in the plan area during winter only. Most observations were during migration or wintertime. Prefers alkaline to freshwater lakes in parkland areas and, to a lesser extent, subalpine and alpine lakes, beaver ponds, and small sloughs for breeding. In British Columbia, breeding habitat includes aspen parkland, open Ponderosa pine forests, rangeland, alpine meadows, and subalpine lakes in closed coniferous forest at 300–1,850 meters elevation.
Bufflehead	waterfowl	Ponds, small lakes, and cavities for nesting during breeding season. Uses lakes or major river systems during migration.
Common goldeneye	waterfowl	Winter habitat only in the plan area. Winter habitat is usually marine environments but inland they use larger lakes and rivers as far north as open water is available. Most observations in the plan area are in larger rivers during fall, winter, and early spring. Migrates north for the summer.
Common merganser	waterfowl	Oligotrophic lakes and rivers bordered by mature tree cavities and abundant fish. Uses large rivers extensively in plan area during the breeding season.
Hooded merganser	waterfowl	Forested wetland habitats, including emergent marshes, small lakes, ponds, beaver wetlands, forested creeks and rivers, and swamps. Only a migrant in plan area.
Wood duck	waterfowl	Wide variety of habitats: creeks, rivers, overflow, bottomlands, swamps, marshes, and beaver and farm ponds. Abundant plant and invertebrate food bases close to suitable nest sites are essential components of breeding habitat. Herbaceous emergent plants, flooded shrubs, and downed timber are important. Mature forests are needed for development of trees with suitable cavities for nesting. Trees producing suitable nest sites are greater than 11 inches DBH but are commonly 23 inches.

Table 288. Wildlife species commonly used by the public and their assigned habitat grouping and subgrouping, as analyzed in the Abundance and Diversity of Wildlife Report

Species Name	Habitat Grouping	Habitat Subgroups
Sandhill Crane	Aquatic, wetland, water, and riparian habitats	Aquatic non-forested interface or non-forested wetlands
Bufflehead	Aquatic, wetland, water, and riparian habitats	Aquatic and forested habitats or forested wetlands
Common Merganser	Aquatic, wetland, water, and riparian habitats	Aquatic and forested habitats or forested wetlands
Hooded Merganser	Aquatic, wetland, water, and riparian habitats	Aquatic and forested habitats or forested wetlands
Wood Duck	Aquatic, wetland, water, and riparian habitats	Aquatic and forested habitats or forested wetlands
Common Muskrat	Aquatic, wetland, water, and riparian habitats	Aquatic generalist

Species Name	Habitat Grouping	Habitat Subgroups
Canada Goose	Aquatic, wetland, water, and riparian habitats	Aquatic generalist
Mallard	Aquatic, wetland, water, and riparian habitats	Aquatic generalist
American Mink	Aquatic, wetland, water, and riparian habitats	Aquatic generalist
American Coot	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
American Wigeon	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Blue-winged Teal	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Cinnamon Teal	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Eurasian Wigeon	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Gadwall	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Green-winged Teal	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Northern Pintail	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Northern Shoveler	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Redhead	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Ring-necked Duck	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Wilson's Snipe	Aquatic, wetland, water, and riparian habitats	Depressional wetlands, ponds, wetlands, marsh, emergent vegetation
Canvasback	Aquatic, wetland, water, and riparian habitats	Open water-Lakes, large rivers, open water within wetlands
Lesser Scaup	Aquatic, wetland, water, and riparian habitats	Open water-Lakes, large rivers, open water within wetlands
Ruddy Duck	Aquatic, wetland, water, and riparian habitats	Open water-Lakes, large rivers, open water within wetlands
Snow Goose	Aquatic, wetland, water, and riparian habitats	Open water-Lakes, large rivers, open water within wetlands
Tundra Swan	Aquatic, wetland, water, and riparian habitats	Open water-Lakes, large rivers, open water within wetlands
American Beaver	Aquatic, wetland, water, and riparian habitats	Riparian habitats
Northern Raccoon	Aquatic, wetland, water, and riparian habitats	Riparian habitats
Northern River Otter	Aquatic, wetland, water, and riparian habitats	Riverine
Harlequin Duck	Aquatic, wetland, water, and riparian habitats	Riverine
Barrow's Goldeneye	Aquatic, wetland, water, and riparian habitats	Riverine

Species Name	Habitat Grouping	Habitat Subgroups
Common Goldeneye	Aquatic, wetland, water, and riparian habitats	Riverine
Western Spotted Skunk	Substrate habitats—Rock outcrop; soil, downed wood; cliff, talus, or cave habitats	Habitats under rocks, logs, downed wood, or leaf litter
Rocky Mountain Elk	Ecotone, forest edge, or habitat combinations	Forested and non-forested habitats interface, forest edges, open habitats with scattered trees, or open woodland
White-tailed deer	Ecotone, forest edge, or habitat combinations	Forested and non-forested habitats interface, forest edges, open habitats with scattered trees, or open woodland
Dusky Grouse	Ecotone, forest edge, or habitat combinations	Forested and non-forested habitats interface, forest edges, open habitats with scattered trees, or open woodland
Mourning Dove	Ecotone, forest edge, or habitat combinations	Forested and non-forested habitats interface, forest edges, open habitats with scattered trees, or open woodland
Wild Turkey	Ecotone, forest edge, or habitat combinations	Forested and non-forested habitats interface, forest edges, open habitats with scattered trees, or open woodland
Ermine or Short-tailed Weasel	Ecotone, forest edge, or habitat combinations	Forested and non-forested habitats interface, forest edges, open habitats with scattered trees, or open woodland
Moose	Ecotone, forest edge, or habitat combinations	Forested and non-forested habitats interface, forest edges, open habitats with scattered trees, or open woodland
Mule deer	Non-forested or early seral habitats	Shrubland, thickets, woodlands, and early seral forest. Forested and non-forested habitats interface, forest edges, open habitats with scattered trees, or open woodland
American Marten and Pacific Marten	Forested habitats	Closed Forest- higher density late seral or old forest or large tree habitat, with closed canopy
Ruffed Grouse	Forested habitats	Early seral forest
American Black Bear	Forested habitats	Closed Forest—higher density late seral or old forest or large tree habitat with closed canopy
Snowshoe Hare	Forested habitats	Forest understory
Chukar	Non-forested or early seral habitats	Meadow, grassland, forbland, or scrubland
American Badger	Non-forested or early seral habitats	Meadow, grassland, forbland, or shrubland
Gray Partridge	Non-forested or early seral habitats	Meadow, grassland, forbland, or shrubland
Mountain Cottontail	Non-forested or early seral habitats	Meadow, grassland, forbland, or shrubland
Ring-necked Pheasant	Non-forested or early seral habitats	Meadow, grassland, forbland, or shrubland
California Quail	Non-forested or early seral habitats	Shrubland, thickets, woodlands, and early seral forest
Spruce Grouse	Non-forested or early seral habitats	Shrubland, thickets, woodlands, and early seral forest
Gray wolf	Resource habitats—nectar, fruit, seeds, plant forage, or prey	Carrion or prey populations
Mountain Lion or Cougar	Resource habitats—nectar, fruit, seeds, plant forage, or prey	Carrion or prey populations

Species Name	Habitat Grouping	Habitat Subgroups
Red Fox	Resource habitats—nectar, fruit, seeds, plant forage, or prey	Carrion or prey populations
Long-tailed Weasel	Resource habitats—nectar, fruit, seeds, plant forage, or prey	Carrion or prey populations
Bobcat	Resource habitats—nectar, fruit, seeds, plant forage, or prey	Carrion or prey populations
Coyote	Resource habitats—nectar, fruit, seeds, plant forage, or prey	Carrion or prey populations
Mountain Goat	Substrate habitats—rock outcrop, soil, downed wood, cliff, talus, or cave habitats	Cliff or steep terrain
Bighorn Sheep	Substrate habitats—rock outcrop, soil, downed wood, cliff, talus, or cave habitats	Cliff or steep terrain

A total of 17, or about 27 percent of these species, use snags or downed trees as important habitat characteristics. Ten species use snags while eleven species use downed wood. Four species use both downed wood and snags. Those that use these features are composed mostly of furbearers and waterfowl species. The only big game species that uses snags or downed trees is the black bear. See Table 289 for the species associated with snags and downed trees.

Table 289. Commonly used wildlife that are known to use snags, downed trees, or both

Common name	Uses Snags or Decayed Live Trees	Uses Downed Trees
American Mink	N	Y
Coyote	N	Y
Ermine or Short-tailed Weasel	N	Y
Long-tailed Weasel	N	Y
Northern River Otter	N	Y
Western Spotted Skunk	N	Y
Harlequin Duck	N	Y
Barrow's Goldeneye	Y	N
Bufflehead	Y	N
Common Goldeneye	Y	N
Common Merganser	Y	N
Hooded Merganser	Y	N

Northern Raccoon	Y	Y

Most of the animals identified in Table 289, with a few exceptions, are common without concern for their conservation status. Therefore, management of habitats for and on behalf of these species is primarily for social and economic purposes, and management considerations must be balanced with other resource uses. While management emphasis occurs because of social and economic reasons, their use is often contingent upon factors such as population size, growth, and distribution that are driven by their ecology. Big game populations attract the attention of the public and provide some of the largest economic and social benefits. The Nez Perce-Clearwater developed appropriate species-specific plan components for these species, which are discussed in more detail below.

Economic Contribution of Hunting, Fishing, and Wildlife Watching

The U.S. Fish and Wildlife Service periodically publishes the economic impact of wildlife related recreation in the United States. The most recent assessment was published in 2011 and was revised in 2014. The assessment is called *The 2011 National Survey of Fishing, Hunting, and Wildlife-Associated Recreation* (U.S. Department of the Interior and U.S. Department of Commerce 2014). The following information originates from this publication. The document estimates the economic contribution of wildlife related recreation both nationally and by state. The total nationwide wildlife related recreation included 90.1 million participants and an estimated 144.7 billion dollars of expenditures. These included hunting, fishing, and wildlife watching. Because this analysis focuses on wildlife, it does not detail the economic impact of fishing, but that data is available in the 2011 report.

Nationally, in 2011, 13.7 million people 16 years old and older enjoyed hunting a variety of animals within the United States. They hunted 282 million days and took 257 million trips. Hunting expenditures totaled $33.7 billion. Big game hunting was the most popular type of hunting. Almost 11.6 million hunters pursued big game, such as deer and elk, on 212 million days. Big game-related expenditures for trips and equipment totaled $16.9 billion. There were 4.5 million hunters of small game, including squirrels and rabbits. They hunted small game on 51 million days and spent $2.6 billion on small game hunting trips and equipment. Migratory bird hunters numbered 2.6 million. They spent 23 million days hunting birds, such as waterfowl and doves. Migratory bird-related trip and equipment expenditures totaled $1.8 billion. Of the $33.7 billion spent by hunters in 2011, 31 percent was spent on trip-related expenses, equaling $10.4 billion. Food and lodging totaled $3.9 billion, or 37 percent of all trip-related expenses. Transportation spending was $4.8 billion, 46 percent of trip expenditures. Other trip expenses, such as guide fees, land use fees, and equipment rental, totaled $1.8 billion or 17 percent of all trip-related expenses. Expenditures for auxiliary equipment, including camping equipment, binoculars, and special hunting clothing, accounted for $1.8 billion or 13 percent of all equipment expenses. Special equipment, such as campers or all-terrain vehicles, amounted to $4.4 billion or 31 percent of all equipment expenditures. A large majority of participants, 94 percent or 12.9 million, hunted within their resident state in 2011.

Observing, feeding, or photographing wildlife was enjoyed by 71.8 million people 16 years old and older in 2011. Of this group, 22.5 million people took trips away from home for the purpose of enjoying wildlife, while 68.6 million stayed within a mile of home to participate in wildlife-watching activities. In 2011, wildlife watchers spent $54.9 billion. Trip-related expenses, including food, lodging, and transportation, totaled $17.3 billion, totaling 31 percent of all expenditures. A total of $27.2 billion was spent on equipment, equating to 49 percent of all wildlife-watching expenses. The remaining $10.5 billion, or 19 percent of the total, was spent on magazines, membership dues, contributions to conservation or wildlife-related organizations, land leasing and owning, and plantings.

Of all the wildlife in the United States, birds attracted the biggest following. Approximately 46.7 million people observed birds. Wildlife watchers spent $17.3 billion on trips pursuing their activities. Food and lodging accounted for $9.3 billion (54 percent of all trip-related expenditures), transportation expenses totaled $6.0 billion (35 percent), and other trip costs, such as land use fees and equipment rental, amounted to $1.9 billion (11 percent) for the year. These recreationists purchased $27.2 billion worth of equipment for wildlife watching and photography. The most-watched birds were waterfowl, primarily ducks and geese, which were watched by 13.3 million people. Next on the list of most-watched were birds of prey, which drew 12.9 million trip-takers, followed by songbirds with 12.1 million watchers. Herons, shore birds, and other water birds attracted 10.6 million recreationists. Land mammals, such as deer, bears, and coyotes, were observed, fed, or photographed by 13.7 million people, totaling 61 percent of all away-from-home participants. In 2011, the most visited areas for Americans to observe, feed, or photograph wildlife were publicly owned lands. Approximately 82 percent of all trip-taking wildlife watchers used public areas, while just 34 percent used private areas.

In 2016, the Rockville Institute for State Fish and Wildlife Agencies conducted a study using similar methods as those for the 2011 study identified above in preparation for the nationwide U.S. Fish and Wildlife Service survey in 2021. In 2016, 1,796,227 people age 16 and older fished, hunted, or watched wildlife in Idaho, including both residents and nonresidents. Of the total number of participants, 838,888 (47 percent) were sportspersons (hunted or fished) and 1,545,113 (86 percent) participated in wildlife-watching activities in Idaho. Of the sportspersons, 690,657 fished and 293,059 hunted in Idaho. The sum of anglers, hunters, and wildlife watchers is greater than the overall number of participants in wildlife-related recreation because many of the individuals engaged in more than one wildlife-related activity. Among the residents of Idaho age 6 to 15 who participated in the activity in their home state or elsewhere in the United States, there were 168,668 sportspersons, of whom 167,672 fished and 31,526 hunted. There were also 192,538 wildlife watchers, some of whom also hunted or fished.

In 2016, state residents and nonresidents spent a total of $4,704,808,660 on wildlife recreation in Idaho. Of that total, trip-related expenditures were $1,538,031,253 (33 percent), equipment expenditures were $2,898,210,584 (62 percent), and other expenditures were $268,566,823 (6 percent). Other expenditures include items such as licenses, contributions, land ownership and leasing. A total of 403,776 state residents and nonresidents hunted in Idaho in 2016, for a total of 5,000,897 days of hunting. That is an average of 12 days per hunter. Of these hunters, 229,928 (57 percent) were state residents. State residents hunted 2,980,307 days in Idaho (60 percent of all hunting days in the state). Among the 403,776 state residents and nonresidents who hunted in Idaho in 2016, a total of 389,230 (96 percent) hunted big game, 80,133 (20 percent) hunted small game, 41,132 (10 percent) hunted migratory birds, and 24,304 (6 percent) hunted other animals. A total of 4,397,881 days were spent hunting big game, 609,170 days hunting small game, 396,202 days hunting migratory birds, and 238,845 days hunting other animals. In 2016, hunting-related expenditures in Idaho totaled $1,051,222,570. The portion of expenditures related to taking trips for hunting in Idaho, such as food, lodging, transportation, and other expenditures, was $299,249,971 (28 percent of all hunting expenditures). Each hunter in Idaho spent, on average, $741 on trip-related costs during 2016. The portion of hunting-related expenditures spent on equipment in Idaho in 2016 was $694,731,062 (66 percent of all hunting expenditures). Expenditures on the subset of equipment specifically for hunting totaled $268,339,165, while expenditures on the subset of auxiliary equipment, such as tents and special hunting clothing, totaled $79,769,895. Expenditures on other items, such as magazines, membership dues, licenses, permits, and land leasing and ownership totaled $57,241,537 (5 percent of all hunting expenditures).

The Idaho Department of Fish and Game estimated the total amount spent locally in their Clearwater Region. They used their mandatory hunter survey data for hunter effort and the estimated expenditures per day from the Rockville Institute for State Fish and Wildlife Agencies study (2016, Idaho specific report Table 18 page 28 and Table 2 page 16), which includes trip related expenses and equipment for resident and non-resident hunters, to estimate the amount of expenditures by hunters in the Clearwater Region. Combining data of hunter effort from Game Units 8a, 10, 10a, 12, 14, 15, 16, 16a, 17, 18, 19, and 20, they estimated 52,378 hunters spent 335,035 days hunting and spent approximately $59,880,806 in the Region on deer and elk hunting in 2019. They estimated 13,594 hunters spent 61,920 days hunting upland game and wild turkeys for $3,559,781 of expenditures in the Clearwater Region in 2019. They only had data on waterfowl hunting efforts from 2009 but they estimated that 902 hunters spent 6,307 days hunting waterfowl, resulting in $1,093,192 spent on waterfowl hunting in the Region. These numbers were generated by wildlife biologists rather than by economists, but this is the best recent estimate of expenditures locally.

In 2016 in Idaho, 1,532,543 state residents and nonresidents participated in wildlife watching, which includes feeding, observing, or photographing wildlife. Of these wildlife watchers, 1,054,111 (69 percent) participated in away-from-home wildlife watching in Idaho, with activities occurring at least one mile away from home. Of these away-from-home wildlife watchers, 417,603 (40 percent) were state residents and 636,508 (60 percent) were nonresidents. State residents participated in away-from-home wildlife watching for 5,881,561 days in Idaho (71 percent of all away-from home wildlife watching days in the state) and nonresidents participated in away-from-home wildlife watching for 2,348,448 days in Idaho (29 percent of all away-from-home wildlife watching days in the state). In 2016, wildlife watching-related expenditures in Idaho were a total of $2,521,763,223. The portion of expenditures related to taking trips for wildlife watching in Idaho, such as food, lodging, transportation, and other expenditures during a trip, was $516,930,272 (20 percent of all wildlife watching expenditures). Each away-from-home wildlife watcher in Idaho spent, on average, $490 on trip-related costs during 2016. The portion of wildlife watching-related expenditures spent on equipment in Idaho in 2016 was $1,842,486,359 (73 percent of all wildlife watching expenditures). Expenditures on the subset of equipment specifically for wildlife watching, such as binoculars, totaled $255,585,794, while expenditures on the subset of auxiliary equipment, including tents and backpacking equipment, totaled $101,675,146, and expenditures on the subset of special equipment like campers and trucks totaled $1,485,225,420. Special and auxiliary equipment are items that were purchased for wildlife watching but could also be used in activities other than wildlife watching. Expenditures on other items, such as magazines, membership dues, plantings, and land leasing and ownership, totaled $162,346,592 (6 percent of all wildlife- watching expenditures).

In summary, wildlife related recreation is a multi-billion-dollar contribution in Idaho with millions of participants. Most expenditures are made by residents of the state, with additional revenues brought into the state from non-residents. These expenditures bring money into local communities that support businesses, such as sporting goods stores, grocery chains, restaurants, hospitality services, outfitters and guides, artists, photographers, transportation services, and manufacturing. Many of these people conduct their activities on public lands. Participation in big game hunting, the largest contributor to hunting related wildlife recreation, is inextricably tied to big game numbers and big game numbers in the plan area are related to habitat conditions. Habitat conditions also support populations of upland game and waterfowl for hunting and wildlife watching.

Bighorn sheep

Four bighorn sheep population management units contain a total of approximately 400 bighorn sheep on lands managed by the Nez Perce-Clearwater and the Wallowa-Whitman National Forests. The population management units include the Lower Salmon, Lower Panther-Main Salmon, Selway, and Hells Canyon. Bighorn sheep are managed as a trophy big game species by the Idaho Department of Fish and Game and efforts to increase population numbers include translocations. A limited number of bighorn sheep tags are offered to the public through a random drawing as a once in a lifetime opportunity. The highly sought after tags provide an opportunity for a backcountry bighorn sheep hunt in rugged terrain. Bighorn sheep are also popular for wildlife viewing and photography, and people seek out opportunities to do these as a primary activity or incidental to other recreational activities like river rafting.

The species also has importance to the Native American tribes, who since time immemorial have used bighorn sheep as a first food, clothing, shelter, tools, utensils and used the horns to fashion bows. Bighorn sheep have high ceremonial, cultural and spiritual value to tribes. As such they are considered sacred by tribes. Bighorn sheep are predominantly shown on petroglyphs throughout the western United States. Bighorn sheep hunters either hunt on their own or use a guide. Based on archeological evidence and verbal histories of tribal elders, prior to European settlement bighorn sheep were the primary game animal that sustained the Nez Perce way of life .

As bighorn sheep occupy remote, steep, and rugged habitats, especially within large river canyons like the Salmon River, habitat conditions have not been altered much by development. Herds in the Salmon River canyon are shared by the Payette National Forest, while herds along Hells Canyon are shared with the Wallowa-Whitmen National Forest. Non-native plants, especially non-native grasses, have invaded some of the dry river canyons occupied by bighorns. Forest succession as a result of fire exclusion has also reduced bighorn sheep in some areas. Hunting opportunities depend on the size of bighorn sheep populations, and bighorn sheep herd numbers are thought to be disease limited.

Black Bear

Black bears are found throughout the planning area. Black bears are important as both a target species for hunters and as a predator that may influence populations of large ungulates, like elk and deer, which are also popular hunted species. Black bear distribution in Idaho corresponds closely to the distribution of coniferous forests. Black bear populations respond to low berry production and hunting pressure. Black bears prey upon deer and elk fawns but rarely adults. Black bear populations are related to changes in birth rates associated with the availability of nutritious foods, especially late summer and fall berry production. Long-term trends are directly related to changes in habitat quantity and quality. Forest management practices, wildland fire, and plant succession influence black bear habitat quality.

Black bear populations are thought to be stable, but the Idaho Department of Fish and Game has been using long hunting seasons and liberal harvest to try to reduce black bear predation on elk, particularly in the Selway and Lolo Game Management Zones. Hunting of black bears includes baiting, hound hunting, and stalking. Most bears taken are over bait in the spring, followed by hound hunting, and the least effective method is stalking or still hunting. Some bears are taken opportunistically as people are hunting other species. Black bear hunting opportunities provides a recreational opportunity and a source of sustenance for those who participate. Many outfitter and guide operations have promoted and hosted black bear hunting opportunities to supplement income lost because of low elk numbers.

Elk

North American elk are among the most popular and iconic of wildlife species in North America. A broad spectrum of public land users places strong cultural, social, economic, and ecological importance on the species (Rowland et al. 2018). Native American tribes in the western United States focus much of their cultural and first foods traditions on elk, and tribal hunting depends on abundant elk populations on public lands for tribal uses. The 2014 Assessment estimated that, in Idaho, elk hunting generates more than $70 million annually in direct hunter expenditures like fuel, meals, and lodging. The combined economic impact of elk hunting in Clearwater County and Idaho County alone was in excess of $27.6 million in 2007 (U.S. Department of the Interior and U.S. Department of Commerce 2014). Elk hunting is more than just a recreational opportunity. Elk provide a source of sustenance for hunters. Many hunters from local communities, as well as those that come from across the state, rely on hunting big game, like elk, as a source of meat. Native American tribes use elk as a source of sustenance and other uses when exercising treaty reserved rights. Bull elk can weigh in around 700 pounds while cow elk weigh in around 500 pounds, so successful harvest can provide a substantial amount of meat. These benefits are sourced largely from public lands where recreational uses of elk compose a major land use. Rural communities throughout the western United States not only benefit economically from hunting and viewing but have social and cultural networks built on elk as part of rural lifestyles. Conversely, elk use of private lands is increasing, is often undesired, and can have substantial economic costs from crop depredation, competition with livestock forage, and damage to reforestation efforts. Maximizing elk use on public lands while minimizing use on private lands meets the desires of land use stakeholders because the vast majority of recreational uses of elk occur on public lands and many private landowners are intolerant of resident populations (Rowland et al. 2018).

Elk herd numbers are influenced by a combination of forage availability, habitat quality, predation, and hunter harvest. Their distribution is influenced by disturbance from roads and hunting pressure. The Assessment (U.S. Department of the Interior and U.S. Department of Commerce 2014) for the Nez Perce-Clearwater described the condition and trend of elk populations in the plan area, the economic impacts that elk have in Idaho, threats and stressors to elk, factors that influence vulnerability to hunting, and detailed information about the effects of roads on elk. Identified threats and stressors included invasive weeds, departed fire return intervals and forest succession, timber management and associated roads, loss of hiding cover, livestock grazing, human development, energy development and mining, reduced winter forage, disturbance, roads and motorized trails, and vulnerability to hunters. Within the last few years, several publications using large datasets from multiple study areas have been analyzed together and been published. This existing condition section focuses on new publications since the 2014 Assessment was produced. This section recaps the population trends and describes the effects and need for change from management direction in the 1987 Plans.

Prehistoric numbers of elk are not known, though archeological evidence shows that elk were consistently found at archeology sites throughout the region (Peek et al. 2020). Historically, elk herds on the Nez Perce-Clearwater were much lower than today. In 1805, Lewis and Clark reported that their indigenous guides noted the presence of elk in parts of the plan area. During the late 1800s and early 1900s, elk were rarely reported on the Nez Perce-Clearwater. The causes of these low numbers could be a combination of use by people, predators, and lack of forage. Beginning after the 1910, 1919, and 1934 fires, which burned vast areas of the Nez Perce-Clearwater, elk herds began to increase rapidly until in the 1930s when herds developed that were large enough to raise concern that they were damaging the winter ranges (Space 1981). This increase in numbers was presumably because of a combination of high amounts of forage created by the fires, intensive predator control of bears and lions, the institution and enforcement of hunting regulations between 1897 to 1903, and the establishment of a game preserve where hunting was not permitted (Space 1981, Parsell 1990, Cochrell 1970). Between 1954 and 1957, the first helicopter flights to count elk were conducted on the Clearwater National Forest. A total of 8,577 elk were counted on winter range by helicopter. Estimating that 80 percent were counted, the total population in the

Clearwater National Forest alone was estimated at 10,700 (Space 1981). On the Nez Perce National Forest, the elk herd in the Selway-Bitterroot was considered the largest in the United States at one time.

Following a decline in early seral habitats, elk populations declined through the 1970s. Increased timber management in the 1970s and 1980s, along with changes in game regulations, once again led to an increase in elk populations during the 1980s through early 1990s. Decreases in timber harvest beginning in the late 1980s and early 1990s correspond to a decrease in elk populations since that time when herds again began to decline in response to increasing loss of early seral habitat. These declines started before wolves were introduced into the plan area in the 1990s. Elk herds have continued to decline or have remained lower since.

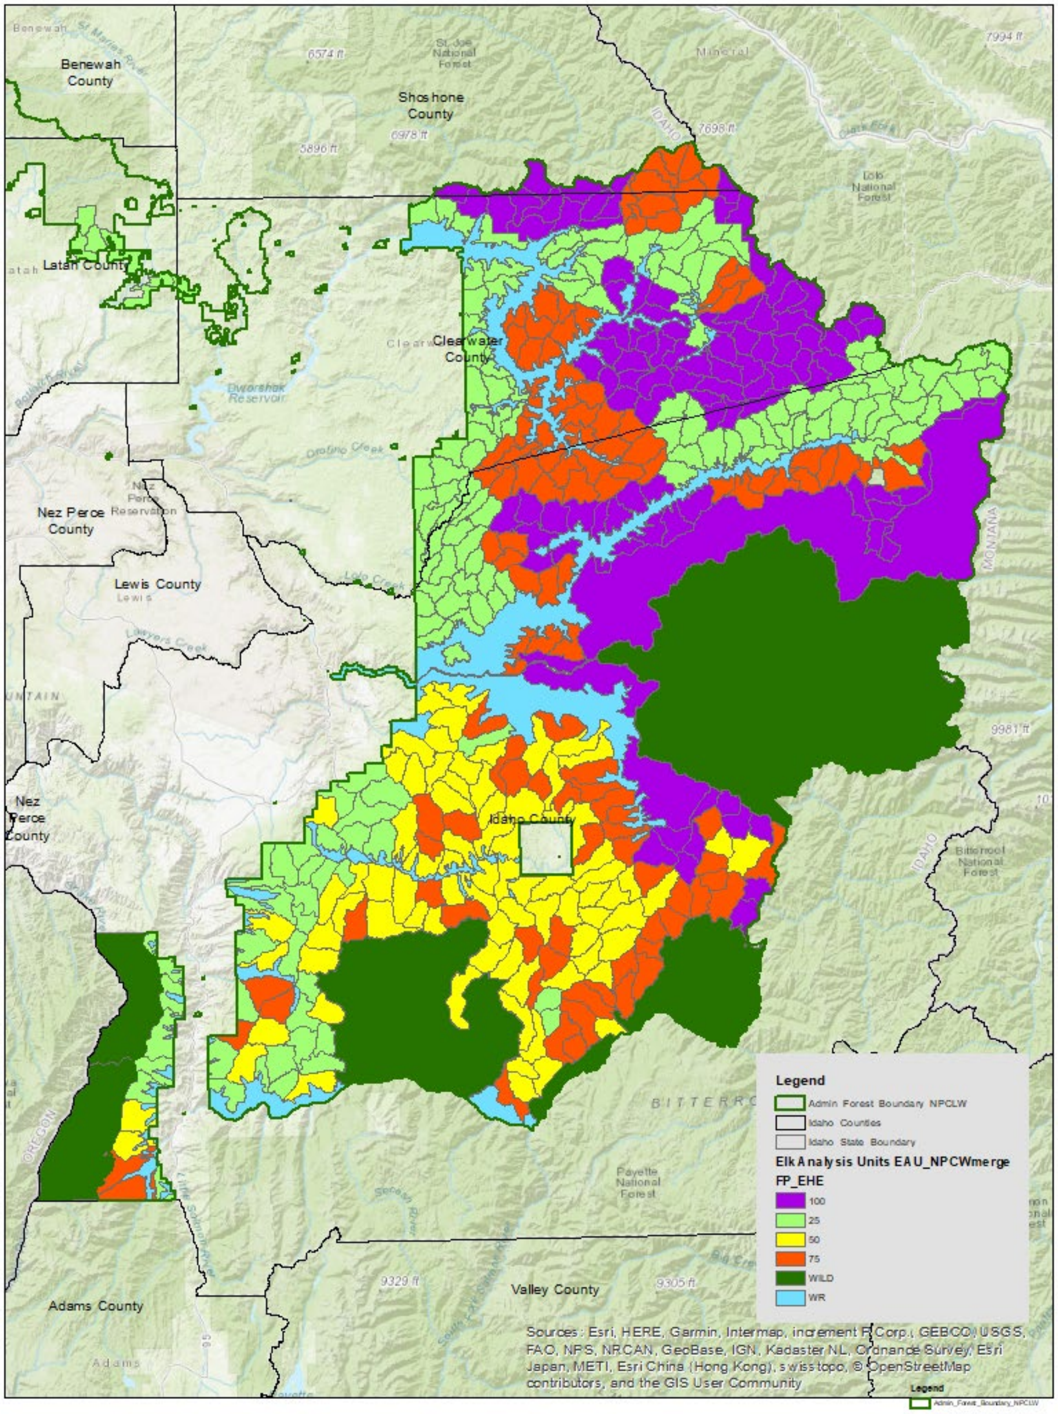

Figure 110. Elk analysis units used in the 1987 Nez Perce and Clearwater Forest Plans

Light green = elk analysis units that require maintaining a minimum of 25 percent habitat security
Yellow = elk analysis units that require maintaining a minimum of 50 percent habitat security
Orange = elk analysis units that require maintaining a minimum of 75 percent habitat security
Purple = elk analysis units that require maintaining a minimum of 100 percent habitat security
Dark green = wilderness
Light blue = elk winter ranges

Elk habitats under the 1987 Forest Plans consisted of an emphasis on enhancing winter habitats though active management and managing elk habitat effectiveness and elk vulnerability through road density management. The plans required analysis of factors such as road building, livestock grazing, elk habitat preferences, cover, forage, road density and security areas. The Clearwater Plan was later amended and emphasized elk habitat effectiveness and reducing elk vulnerability. The 1987 Plans used elk analysis units as the scale for which effects were analyzed. The plans also required that elk analysis units maintain a minimum amount of elk habitat effectiveness of 25 percent, 50 percent, 75 percent, or 100 percent. These correspond to roughly 4.2 miles per square mile for 25 percent, 1.8 miles per square mile for 50 percent, and 0.8 miles per square mile for 75 percent habitat effectiveness. An elk habitat effectiveness (EHE) model computed habitat effectiveness using the density of open roads; quantity and distribution of cover; availability of forage; access to security areas; and livestock use. The number and acres of elk habitat effectiveness objectives in the 1987 Plans are shown in Table 290. Elk analysis units are not delineated within wilderness nor within elk winter range. Elk habitat effectiveness is calculated using open motorized roads and trails but not closed motorized routes The elk vulnerability (EV) model estimated the effects of access and hunter effort activities during fall hunting seasons on elk at the game management unit scale. It considers both open and closed roads. The amount of winter habitat manipulation proposed as objectives in the 1987 Plans were achieved generally as projected (FACTS data, accessed August 2019).

Table 290. Number and acres of elk analysis unit habitat effectiveness objectives under the 1987 plans

% Objectives	Number	Acres
25%	155	748,273
50%	81	496,186
75%	117	614,401
100%	103	10,300
Total	456	1,869,160

The total number of roads on the Nez Perce-Clearwater have been steadily decreasing since 1999 (Table 291Table 292). A total of about 1,625 miles of National Forest System roads and non-National Forest System roads have been decommissioned during this time. Most of this decommissioning took place on the non-system roads from former timber harvest practices, which were no longer needed because of new harvest techniques, or roads in unstable terrain or with failing drainage structures. However, there have been additions to National Forest System roads during this time as well. These additions include the construction of approximately 46 miles of new roads for vegetation, special uses, recreation management, and watershed improvements by relocating roads away from stream habitats. Many of the increases were to roads that were better located roads to provide a more stable, less impacting road system. The cost of decommissioning was estimated at $5,491 per mile in 2010. Yet, despite these measures, the trend in elk populations has continued downward sharply since 1987.

Table 291. Miles of roads decommissioned from 1999 to 2018 on the Clearwater National Forest

Year	Miles	Year	Miles

Elk populations in the Clearwater Basin have declined substantially across large areas of the eastern portion of the basin during the past three decades. These declines have coincided with a loss of early-seral habitat, increased human pressures, and increasing predator population (Cook et al. 2018). The outcomes of management strategies in the 1987 Plans for elk have not maintained or increased elk herds. Since 1987, when the plans were signed, elk populations in game management zones with low quality or declining forage, high amounts of hiding cover, and low road densities, such as the Lolo Zone, the Selway Zone, and some game management units in the Elk City Zone, have declined. Meanwhile, those with high quality and quantity of forage, such as in the Palouse, Dworshak, some portions of the Elk City, and Hells Canyon zones, have increased or remained at the Idaho Department of Fish and Game objective, despite having high road densities and high vulnerability (Cook et al. 2018)). In these units, elk can often find refuge from hunting pressure on private lands, or extremely rugged terrain, which allows these areas to support elk despite higher road densities.

The importance of high-quality nutritional resources is increasingly thought to be important to elk population performance. Higher amounts of high quality dietary digestible energy during the summer has been correlated to faster calf growth, better winter survival, increased calf production, earlier breeding phenology, and better calf survival. Lukacs et al. (2018) studied elk population trends in 101 elk management units from 7 states in the western United States. They tested the effects of predator richness, forage productivity, and precipitation on elk population performance. Forage productivity on summer and winter ranges had the strongest effect on elk recruitment relative to other factors.

Spring, summer, and fall encompass the life stages of calf birth (spring, early summer) and calf growth and survival (summer, fall) to weaning (Cook 2014). These life stages include the critical phase of summer and fall calf growth, when nutritional limitations can be severe for lactating females (Cook 2014). Without adequate summer and fall nutrition, females cannot successfully produce a healthy calf to weaning and a calf cannot enter the winter period in adequate condition to withstand prolonged periods of severe weather. A substantial number of elk use the forest year-round within the Nez Perce-Clearwater.

Nutrition influences productivity of ungulates by affecting many aspects of animal performance, including nutritional condition, ovulation, timing of breeding and subsequent parturition, juvenile growth, primiparity, and susceptibility to a variety of causes of mortality (Cook et al. 2013). Nutritional condition is defined as the state of body components, principally fat and lean mass, controlled by nutrition, which influences an animal's future fitness. Studies have highlighted the importance of summer nutrition in influencing ungulate recruitment through changes in maternal and calf body condition (Middleton et al. 2013a, Bonenfant et al. 2002, Parker et al. 2009, Cook, Cook, and Mech 2004).

Increased precipitation, especially in late summer, improves forage productivity, which increases nutritional condition and pregnancy rates of females (Cook, Johnson, et al. 2004). Site productivity may also affect nutrition abundance and quality (Cook et al. 2018). The effects of spring and summer habitat conditions on maternal body condition may carry forward for greater than or equal to one-year and influence calf recruitment the following spring (Wilmers and Levi 2013). Following birth, the summer conditions juveniles experience will influence growth and the ability to survive the following winter (Portier et al. 1998). Elk recruitment is affected by factors influencing maternal body condition and the probability of females becoming pregnant (Cook et al. 2013, Bonenfant et al. 2002, Proffitt et al. 2014, Cook, Johnson, et al. 2004), the birth mass of elk calves, and additional factors, such as forage availability, weather conditions, and predators, affecting the probability of calf survival in their first year (Griffin et al. 2011). There is increasing evidence from detailed studies of maternal nutrition that summer forage conditions may be more important than winter conditions in some settings (Middleton et al. 2013b, Cook et al. 2013, Rowland et al. 2018, Cook, Johnson, et al. 2004). A relatively small difference in the forage quality consumed by elk in the summer and autumn can have strong effects on fat accretion, timing of conception, and the probability of pregnancy for lactating cows, calf growth, yearling growth, and yearling pregnancy rates.

The Clearwater Basin Collaborative's elk project initiated a long-term monitoring and habitat restoration project for elk in the Clearwater basin. This project aims to understand elk population dynamics by assessing animal fitness, nutritional status, and habitat use across the Clearwater basin. To date, approximately 250 cow elk have been captured and radio collared. Radio-collars allow collaborators to evaluate explicit habitat use and connections to winter and summer ranges, facilitate cause-specific mortality, and promote recapture to compare seasonal body condition assessments. Upon capture, other information collected includes age, pregnancy rate, body fat measurements, genetic information, internal parasite loads, and trace elements and selenium. Body condition and pregnancy rates of elk in the Clearwater basin indicate that limitations in animal condition are primarily associated with summer nutrition, as opposed to winter. Variation in body fat levels of female elk followed a northeast-to-southwest geographic gradient of study areas, with body fat highest on the North Fork Clearwater, lowest on Craig Mountain and the South Fork Clearwater, and intermediate in the Dworshak Reservoir area. Elk populations and their distribution in the Clearwater basin are highly variable. The populations and productivity of herds have declined during the past 20 to 30 years in eastern wildlife zones, which are largely associated with roadless and wilderness areas. Examples of these eastern areas of decline include the Lolo and Selway Zones (Cook et al. 2018). Elk populations and their productivity in the central and western parts of the basin have increased during the past two decades, sometimes substantially. Examples of these western areas of growth include the Palouse and Hells Canyon Zones, where elk numbers were low or nonexistent a few decades ago (Cook et al. 2018).

The Clearwater Basin Collaborative's study modeled nutritional resources within the Clearwater basin and tested six model versions to predict dietary digestible energy of elk, a key currency of nutritional status of elk habitats during summer (Cook, Cook, et al. 2016, Cook et al. 2018). Models were tested by evaluating selection by radio collared elk, wherein the best model was determined by increased selection through increased elk dietary digestible energy. While there were differences among the performance of models among elk herds, the best model overall was Model 6, which was a modified expert opinion model of dietary digestible energy.

In general, the predictions of body fat of lactating elk during the month of December from the four Idaho herds increased, with increasing estimates of the percentage of area providing levels of dietary digestible energy greater than 2.75 and 2.90 kilocalories per gram. The data also indicates that the herds in the Clearwater basin have relatively low levels of autumn body fat, body size, and pregnancy rates. The autumn body fat level and the pregnancy rate of lactating females are measures of summer nutrition, and low values for these two measures generally are indicative of reduced performance of other measures of productivity, such as calf and yearling growth rates, age at first breeding, and timing of breeding in autumn (Cook et al. 2018, Cook, Johnson, et al. 2004).

The Clearwater Basin Collaborative's study also produced a forage potential spatial layer that predicts the dietary digestible energy expected in the event of disturbance. Generally, high-quality nutrition on the Nez Perce-Clearwater exists mostly in disturbed forested habitats and shrub fields. The plan area has very few areas of non-forested habitats and few natural meadows. Nutritional response is greater on the Clearwater portion of the national forest and lower on the Nez Perce side. Areas with ash cap and more moisture produce the best nutritional responses at low-to-mid-elevations. Higher elevation sites tended to have lower nutritional potential than lower elevation sites. Many winter ranges tend to have lower nutrition potential, especially along the Salmon River. Some winter ranges along the Lochsa have high nutrition potential. The plan does not emphasize treatments within winter ranges, but it should be within the best nutrition potential sites when doing so. While still important, treating winter ranges does not appear to provide conditions that would improve reproduction based upon nutrition. The elk nutrition model was run through the SIMPPLLE model to predict the changes in the amount of area that has high nutrition forage under the plan components and alternatives. This allowed the national forest to understand the relationship between the desired conditions and elk vital rates and will become a valuable tool when managing elk habitats.

Good summer nutrition is important for the survival of cow and calf elk over winter (Cook, Johnson, et al. 2004). When nutrition during the summer and autumn is poor, cow elk are likely to breed later than cows with good body condition, or not at all (Cook et al. 2001). Recent research by Rowland et al. (2018) suggests that the percentage of elk ranges providing higher levels of dietary digestible energy was highly correlated with the pregnancy rates of lactating females and that autumn body fat levels were highly correlated with the percentage of elk ranges providing higher dietary digestible energy levels. The results further illustrated the importance of managing for nutrition in combination with other covariates, such as roads, slope, and cover-forage edges, which affect elk use of nutritional resources to achieve desired distributions of elk. Cook et al. (Cook et al. 2018) suggests substantial emphasis on summer range management is probably warranted. The results from other studies on elk in forested communities (Cook, Cook, et al. 2016, Cook 2014) also identified a key role of active habitat management for improving nutritional conditions across landscapes.

Calf mortality during winter most often reflects prior summer and fall nutritional limitations. Cook et al. (2014) found that 18 of 21 elk populations sampled across the western United States showed strong summer and fall nutritional limitations rather than winter limitations. Of the additional seven elk populations monitored in the Clearwater basin, all showed summer and fall nutritional limitations (Rowland et al. 2018). By inference, most landscapes in the western United States appear inadequate to fully meet the maintenance needs of lactating female elk during summer and fall (Cook 2014), including those landscapes associated with the seven elk populations monitored in the Clearwater basin (Cook et al. 2018).

Cook et al. (2013) showed winter range conditions had little influence on body fat conditions of elk. Similarly, they found that winter severity has little influence on the body fat dynamics of female elk (Cook et al. 2013). Instead, the body fat levels in spring were strongly correlated to the body fat levels the previous autumn, a relationship that was generally the same across all winter ranges included in Cook et al. (2013). In the Clearwater basin, the pattern of body fat loss over winter relative to autumn body fat was similar to the herds sampled in Cook et al. (2013), and autumn body fat accounts for greater than 70 percent of the variation in spring body fat found in the Clearwater herds (Cook et al. 2018).

In western Oregon and Washington, pregnancy rates and body fat of lactating female elk were positively correlated with the landscape composition (percent area) of dietary digestible energy that met or exceeded summer and fall lactation needs (Rowland et al. 2018). Proffitt et al. (2016) also found a positive correlation of landscape composition of digestible forage biomass and performance of female elk in Montana. In the Clearwater basin, preliminary results show that the body fat of lactating females is related positively to increasing the landscape composition of higher levels of late-summer dietary digestible energy predicted by the nutrition models evaluated thus far (Cook et al. 2018). Results from the spatially explicit nutrition model can then be used to predict the pregnancy rates and body fat of lactating female elk in a given summer range based on the percentage of the analysis area occurring in the higher nutritional classes of dietary digestible energy (Rowland et al. 2018).

In western Oregon and Washington, female elk showed strong selection for and higher habitat use of those areas within landscapes that met or exceeded their nutritional lactation maintenance needs (Rowland et al. 2018, Cook et al. 2018). The habitat use models built from the nutrition models evaluated for the Clearwater basin also showed an increasing selection by elk for increasing levels of dietary digestible energy by lactating females during late summer (Cook et al. 2018). Clearly, management of summer-fall nutrition on public lands is an essential foundation for sustaining productive, abundant elk populations to address the currently unmet but highly desired opportunities for tribal and public uses of elk.

Management of summer-fall nutrition to meet the maintenance needs of lactating females, however, may not ensure that elk use areas of higher nutrition. A variety of non-nutrition factors, including physical topography, vegetation, and roads, combined with available nutrition to account for elk use of landscapes. Non-nutrition factors can have a strong effect on habitat use, particularly roads and trails open to any type of public motorized use. Motorized uses could render many areas of high-quality nutrition unusable by elk because of displacement.

Vales et al. (2017) describes elk habitat management on a 93,000-acre forest managed by the Muckleshoot Indian Tribe. This area is managed intensively for both forestry and elk production. An Elk Foraging Index used to develop management plans is derived from forage abundance, forage quality, and forage intake. Their system uses a nutrition-derived index based on the annual number of lactating and nonlactating cow elk the forage could support founded on sound biological relationships. Management of this area has resulted in a high adult survival of cow elk less than or equal to 16 years old, few malnutrition mortalities, pregnancy rates of 85 percent, and high spring calf-to-cow ratios of 35 calves per 100 cows. In contrast, habitat limitations on adjacent federal lands have reduced the carrying capacity due to the Northwest Forest Plan, which restricts timber harvest to promote late successional stands. The Tribe’s Tomanamus Forest, however, is managed intensively and has numerous clearcuts with stands of varying age that support elk. Access on the Tomanamus Forest is limited. This study is evidence that nutrition-based management of elk can successfully support higher elk populations.

Over 30 studies conducted during the past 40 years on public lands have shown consistently strong avoidance by elk of roads and motorized trails open to the public (Wisdom and Rowland 2018, Wisdom et al. 2018). It is perhaps the most studied aspect of elk habitat selection and use. These studies have universally and consistently shown avoidance of motorized use by elk. Example studies include Lyon (1979), Lyon (1983), Leege (1984), Wisdom (1986), Thomas et al. (1988), Hillis et al. (1991), Lyons and Christenson (1992), Unsworth et al. (1993), Unsworth et al. (1998), Rowland et al. (2000), Rowland et al. (2005), Rumble et al. (2005), Proffit et al. (2014), Bergen (2016), Ranglack et al. (2017), Wisdom (2018), and DeVoe et al. (2019). Rowland et al. (2000) showed that elk habitat selection response related to the distance from open motorized access is a strongly linear relationship. Avoidance behavior occurs at distances between 0.5 to 2.4 miles from open roads, meaning that landscape use by an elk population can be substantially diminished within these distances from open roads and trails (Rowland et al. 2018). In some cases, areas without sufficient space away from roads exclude elk altogether. Elk avoidance of all-terrain vehicles and dirt bikes on motorized trails has been shown to be similar to or greater than the avoidance of forest roads open to public motorized access (Wisdom et al. 2004), with flight responses reported at a distance of 0.93 miles away. Rowland et al. (2005) concluded that the reduction in effective habitat for elk is the ultimate effect of elk displacement; however, substantial reductions in elk habitat use are typically confined to less than one-half miles from an open road.

Many studies are described and referenced in the Assessment (U.S. Department of the Interior and U.S. Department of Commerce 2014) in relation to the effects of roads so a discussion about the effects of roads is not detailed extensively here. Rowland et al. (2005) evaluated the published literature on the effects of roads on elk and summarized the following: 1) Elk avoid areas near open roads, 2) Elk vulnerability to mortality from hunter harvest, both legal and illegal, increases as open roads increase, and 3) In areas of higher road levels, elk exhibit higher levels of stress and increased movement rates. Elk may be displaced from otherwise usable habitats and may be displaced from public lands onto private lands where they are not accessible to public uses. Intuitively, loss of usable area due to displacement would reduce the total capacity of the landscape to provide for elk perhaps lowering overall carrying capacity. Travel management inevitably involves tradeoffs between the benefits that increased road and motorized trail access provides versus their ecological and economic costs.

The effectiveness of Forest Service practices, such as elk habitat effectiveness measures, has been tested empirically. Rowland et al. (2000) tested the hypothesis that elk selected habitats farther away from roads and then compared whether relative elk habitat selection versus elk habitat effectiveness corresponded with the observed values of varying levels of road density. Rowland et al. (2000) also evaluated the effects of different spatial patterns of roads on elk habitat selection. While selection increased with the distance to open roads, habitat effectiveness corresponded only weakly to elk habitat use (Rowland et al. 2000). Instead, Rowland et al. (2000) suggested that elk are responding to the spatial distribution patterns of roads as an important factor, which is not necessarily measured by road density or habitat effectiveness. Simulations of road spatial patterns suggested that evenly spaced roads had the greatest negative effect on habitat, while randomly spaced roads and clumped patterns of roads allowed for less influence on habitat selection (Rowland et al. 2000). Thus, distance from roads, or the spatial distribution of roads, is a more important measure for elk habitat selection than road density per se. The management direction for elk in the 1987 plans, especially within Management Area 3, resulted in a current road system that is relatively evenly spaced with few gaps large enough to provide for elk use, even though many elk analysis units meet the elk habitat effectiveness requirements.

Ranglack et al. (2017) studied elk habitat selection during the fall in Montana. They demonstrated elk avoid hunting pressure. The response of elk was similar for rifle and archery season but differed in which variables were more important. During both hunting seasons, elk selected areas that restrict public hunting access and had higher values on the normalized difference vegetation index, an index of photosynthetic activity which could indicate higher forage quality. Elk also selected for higher canopy cover, areas with greater distance from open motorize routes, but avoided areas of high hunter effort. Selection differed when they were on lands not accessible to hunters. While on public lands, the mean distance to motorized routes for elk locations was 1.61 miles and 1.28 miles during the archery and rifle seasons, respectively. These distances are largely within the ranges of elk responses from studies across the west. For publicly accessible lands, elk responses to distance to motorized routes, canopy cover, and hunter effort quickly reached pseudo thresholds at greater than or equal to 0.95 miles from motorized routes, greater than or equal to 9 percent canopy cover, and greater than or equal to 3.44 hunter days per mile with respect to hunter effort, after which further increases in distance to motorized routes, canopy cover, and hunter effort resulted in only small increases in elk resource selection. The mean canopy cover of the elk locations was

27.7 percent and 19.6 percent for the archery and rifle seasons, respectively. These canopy cover amounts are far below those in on the Clearwater National Forest.

Ranglack et al. (2017) analyzed telemetry data from nine elk populations that ranged from Yellowstone National Park along the Idaho-Montana border north to near Missoula, Montana. Some of these populations are adjacent to or border parts of the plan area and, in some cases, have vegetation conditions similar to those here. Ranglack et al. (2017) found an interaction of road distance and forage availability. At high normalized difference vegetation index values, there was little difference in elk selection for areas near versus far from motorized routes, but at low normalized difference vegetation index values (NDVI), elk were more likely to use areas far from motorized routes. High normalized difference vegetation index values indicate potentially higher nutrition, while lower values indicate lower nutrition, suggesting that elk were selecting areas of potentially higher nutrition even when those nutrition sources were closer to roads. Ranglack et al. (2017) did not find support for traditional elk security measures. Rather, they found that less canopy cover and more distance from roads were better fitted to their data and suggested that the influence of motorized routes is more important than canopy cover to female elk resource selection. They recommended retaining 5000-acre sized blocks without motorized access. The distances at which Ranglack et al. (2017) showed avoidance behaviors to roads are similar to those reported in other studies. For example, their recommended distance from motorized use was 0.953 miles. Declines in elk habitat use have been reported within 0.25–1.8 miles of open roads (Lyon and Christensen 2002). Rowland et al. (2018) reported that avoidance behavior at which elk no longer responded to motorized disturbances was up to 2.4 miles. Given that the distances of avoidance behavior reported by Ranglack et al. (2017) are comparable to those in multiple other studies, the fact that Ranglack used data from nine elk populations from a variety of habitat conditions, and that some of the areas these populations use are adjacent to the plan area, the Land Management Plan adopted Ranglack's recommendations for 5,000-acre block sizes in Management Area 2's guidelines. Ranglack's results suggest that during hunting seasons, female elk still seek out areas of high nutritional value even when they are closer to motorized routes. Ranglack et al. (2017) cautioned that extrapolation of their results beyond the study area may or may not be appropriate, as results generated in one area may perform extremely poorly when applied in areas that are geographically distant or dissimilar ecologically.

The Idaho Department of Fish and Game modeled elk habitat selection from several datasets of radio collared elk across the state (Bergen et al. 2016). Habitat selection using the statewide dataset results differed from those of regional populations. Two regional populations in this study occurred within the Nez Perce-Clearwater. The northern portion of the national forest fell within the Bitterroot Mountain regional population area and the southern portion of the national forest fell within the Idaho Batholith population. Elk habitat selection differed in the two areas but also had some similarities.

Habitat in the Bitterroot area had the following variables as important: the average amount of canopy cover within two kilometers, the sum of non-forested normalized difference vegetation index values within two kilometers, the amount of deciduous shrub within two kilometers, terrain position index, the amount of fire occurrence within two kilometers between 2005 to 2015, and land-use types deemed to be excluded from elk use in developed areas, as well as talus, cliffs, and open water. In the Idaho Batholith selection, variables include the following, in order of importance: maximum non-forested normalized difference vegetation index recorded value within two kilometers, the amount of evergreen forest within two kilometers, the amount of mesic sage and shrub within two kilometers, the amount of fire occurrence within two kilometers between 2005 to 2015, and land-use types deemed to be excluded from elk use in developed areas, as well as talus, cliffs, and open water. In both areas, factors that influenced habitat selection were variables that suggest nutrition is important. For example, both areas included the sum of non-forested normalized difference vegetation index within two kilometers, which is thought to be an indicator for higher nutrition. Similarly, the number of deciduous shrubs and mesic sage and shrubs within two kilometers would suggest elk are seeking forage resources in both areas. Both areas also contain selection for fire occurrence within two kilometers. Once again, this metric suggests selection for conditions that promote nutrition but the amount and distribution at a landscape scale were also important. In both areas, elk avoided land-use types deemed to be excluded from elk use, which were defined as developed areas including roads, talus, cliffs, and open water.

The findings of Bergen et al. (2016) suggest that landscape scale characteristics influence habitat selection by elk. For example, elk in the Bitterroot population area select for deciduous shrub composition within two kilometers at the landscape scale in a power function shape to where deciduous shrubs compose slightly less than half of the surrounding landscape, after which elk selection decreases rapidly. Elk have a quadratic selection for increased canopy cover averaged within two kilometers where selection increases dramatically at 33 to 42 percent, then plateaus and decreases beyond 65 percent. In the Idaho Batholith population area, elk select for deciduous shrub composition where selection increases logarithmically to approximately where deciduous shrubs compose 50 percent of the surrounding land use within two kilometers, after which selection decreases with higher compositions but still maintains a positive selection. Elk were less likely to select for land uses that are considered to be excluded, such as open water, road, developed areas, talus, and cliffs. Elk selected for areas that are not developed, talus, cliffs, or open water (excluded class) ten times more than these habitat types (Bergen et al. 2016).

Elk selection increases quadratically for areas that have greater amounts of evergreen forest to where 60 percent of the surrounding area is evergreen forest, afterwards elk selection drops as the percent of evergreen forest increases in the landscape within two kilometers. Mesic sage and shrub communities are increasingly selected for until they comprise approximately 28 percent of the vegetative composition within two kilometers, after which there is a logarithm decline in this selection with increasing composition (Bergen et al. 2016). These findings suggest the interspersion of habitat patches at the landscape scale are an important consideration when managing elk habitats. These selection patterns suggest landscape characteristics, as well as their habit of using edges between forage and cover.

It has long been recognized that elk seek ecotones or habitat edges. Rowland et al. (2018) found that elk select for areas close to cover-forage edges, reporting an 8.1 percent decrease in use for each 100-meter increase in distance to edge within an opening because of their preference for foraging sites with secure patches of cover nearby. Several elk habitat models reflect elk selection for sites close to cover-forage edges, presumably for security (Wisdom et al. 1986, Thomas et al. 1988, Benkobi et al. 2004). As forage and cover areas become larger than optimum, less of the total area is used by elk (Wisdom et al. 1986). Wisdom (1986) suggested that most elk use of forage occurs within 100 yards of forested edges and the use of cover is within 300 yards of the edge of open foraging areas. Management to benefit elk should arrange the shape and size of forage and cover patches to increase edges by creating irregularly shaped forage areas with high edge to interior ratios that are interspersed at a landscape scale. Patches of forest retained within openings can facilitate use more than larger openings. The term habitat interspersion used in MA3-GDL-ELK-01 is meant to capture the concept of the spatial arrangement of patches at a landscape scale and cover to forage edges.

Several studies suggest elk select habitat based on slope, with milder slopes selected more than steeper slopes. Preference by elk for gentle to moderate slopes has been documented previously in Wisdom et al. (1986), Edge et al. (1987), and Sawyer et al. (2007). Rowland et al. (2018) used telemetry datasets from across the west to identify habitat use by elk. They found that elk selected mild slopes and that slope was one of the most important factors predicting habitat use, finding a 5.3 percent decrease in use for each percent increase in slope. Predicted use decreased sharply in all areas as slope increased between 0 and 40 percent, with a very low probability of use predicted for slopes greater than 60 percent. They recommended that slope remains an important consideration in planning habitat improvements for elk. For example, road closures on mild terrain may improve habitat use more than a closure of a road on a steep slope. Similarly, a silviculture prescription to enhance elk forage habitat positioned on mild slopes would have higher use than those positioned on steep slopes.

Rowland et al. (2018) provided an example of habitat management for elk on forested lands. This study evaluated the effects of elk habitat use on a National Forest landscape from the combination of nutrition and open roads management. The study demonstrated how habitat use can be improved through silviculture and how areas of enhanced nutrition may not be used by elk are displaced by effects of open roads that encompass the areas of higher nutrition. They recommended addressing four variables that determine elk habitat use: distance from roads, the amount of higher quality nutrition, forage to cover edges, and slope. These principles were incorporated into management approaches to form the basis and framework for elk habitat management.

Moose

Moose are an important big game animal in the planning area. Moose populations are in serious decline in some parts of the plan area, particularly from the Lochsa River south and especially in the Selway River and South Fork Clearwater River drainages. Moose were evaluated in the 2014 Assessment (U.S. Department of the Interior and U.S. Department of Commerce 2014), which speculated on causes of moose decline. Even as some moose populations in the plan area are suffering drastic declines, the population in other parts of the plan area appear to be increasing, apparently in response to extensive habitat alteration by silvicultural and agricultural practices that increase early seral browse favored by moose. Forage is increasingly thought to be important to moose.

Moose are hunted in the plan area and permits are issued through a drawing as a controlled hunt, which limits participation. Moose hunting is considered a once in a lifetime hunt. Hunters who draw moose tags and successfully harvest may not apply for these tags again. Moose are of high interest and importance to Native American tribes. Moose are also of interest to wildlife watchers.

Schrempp et al. (2019) evaluated moose population trends and forage condition trends across Idaho. They found that the quantity of forage shrubs was estimated to have declined over the past 30 years in about half of the population management units, with the greatest declines predicted for high-energy forage species. The population trend index was correlated with the percent change in availability of moderate-energy forage shrubs, indicating that the availability of forage shrubs and change in availability over time might be affecting population dynamics for moose in northern Idaho. The role of summer nutrition in regulating reproduction and survival has been documented for moose via twinning rates, recruitment, and survival (Franzmann and Schwartz 1985, Monteith et al. 2015, Sand et al. 2012). Results from Schrempp et al. (2019) indicate that variation in the quantity of forage for moose across northern Idaho is likely correlated with moose population trends statewide. This suggests that fire suppression, lack of disturbance, and forage quality and quantity are likely important threats to moose populations.

Factors identified by the Assessment (U.S. Department of the Interior and U.S. Department of Commerce 2014) as causing declines in moose populations include roads, predators, climate change, parasites, and the loss of Pacific yew. Multiple-use wildlife plan components were designed to provide for many big game species, including moose. For example, FW-DC-WLMU-03 and FW-DC-WLMU-04 pertain to moose habitat conditions, including the desire to maintain Pacific yew as a winter food. Winter habitat selection favors subalpine fir and Pacific yew plant communities. The vegetation desired conditions for riparian areas and forested and non-forested habitats would contribute to moose habitats.

Moose migration or seasonal movement patterns are not well understood in the plan area. It is suspected that there is movement from higher elevations to lower elevations during winter. However, moose have been observed during winter flights wintering in fairly high elevations in deep snow. They tend to stay in relatively small areas when doing this.

Mountain Goat

Unlike many areas in the west, mountain goat populations in the plan area are native. Lewis and Clark noted that their guides indicated that there were mountain goats in the Blacklead area while passing through. Mountain goats are hunted in the plan area but on a very limited basis. A hunter is allowed only one opportunity to hunt for mountain goats in his lifetime. Demand for a mountain goat hunting opportunity is high, with 400 to 500 applications submitted for the 40 to 50 mountain goat permits available annually statewide. Many of the historic mountain goat hunting areas in the Clearwater region are currently closed to hunting because of low population levels or the loss of mountain goats entirely from previously occupied ranges. The mountain goat is recognized as a Species of Greatest Conservation Need (SGCN), priority Tier 3, in the Idaho State Wildlife Action Plan (Idaho Department of Fish and Game 2017b). It is not identified as a species of conservation concern for the plan area because most populations occur in wilderness, recommended wilderness, or Idaho Roadless Rule areas, which results in a lack of threats.

The Nez Perce-Clearwater Assessment (U.S. Department of Agriculture 2014f) evaluated the status and threats to mountain goats in the plan area and described their biology, population dynamics, mortality factors, diseases and parasites, response to human disturbance, roads in goat habitat, and population status in the plan area. Recently, the Idaho Department of Fish and Game published their Mountain Goat Management Plan (Idaho Department of Fish and Game 2019b). It identifies climate change as a threat to mountain goats.

Historically, in Idaho, there were many more mountain goats than there are today. Open seasons with unlimited tags through the 1950s reduced mountain goat populations in many areas. Mountain goats are now lost from previously occupied ranges (Wakkinen, Wolf, et al. 2017). Increasingly, conservative hunting season structure with controlled hunts has helped stabilize some populations but others continue to decline (Wakkinen, Wolf, et al. 2017).

Mountain goats inhabit rugged landscapes characterized by steep rocky cliffs, talus slopes, grassy ledges, and alpine meadows. Such inaccessible terrain offers unexploited food resources and protection from predators. Mountain goats are generalists with a diet that includes grasses, sedges, rushes, forbs, low growing shrubs, woody shrubs, conifers, mosses, and lichens, depending on the season. Migration to wintering areas occurs along well-traveled corridors with the first heavy snowfall. Winter ranges are typically at lower-elevation cliff complexes with south and west aspects where snow is less abundant and persistent. However, some populations in the plan area winter and summer in the same areas.

In areas where grasses are covered by snow, mountain goats readily switch to a diet of browse, including mountain mahogany and conifers. Mosses and lichens may also be eaten where available (Côté and Festa-Bianchet 2003). Smith (1976) reported a correlation between female nutrition and kid-nanny ratios and Bailey (1991) reported that the availability of summer forage was related to pregnancy rate. Winter forage is critical to adult over-winter survival and fetal development (Fox et al. 1989).

Populations of mountain goats have declined in the plan area and are absent in many areas of the Nez Perce-Clearwater that historically had populations. Causes of the decline are not fully understood but overharvest caused some of the goats in areas historically occupied to be eliminated and some have not yet been repopulated. It is possible that currently occupied mountain goat habitat is not well connected to areas historically occupied. In Idaho, many mountain goat populations are on isolated mountain ranges with limited dispersal opportunities across intervening valleys resulting in isolation and reduced gene flow between herds (Shafer et al. 2011). Because mountain goats in Idaho occur on the periphery of their range and in isolated areas with small population sizes, they have lower levels of genetic diversity compared to their counterparts in the core of their range (Idaho Department of Fish and Game 2019b, Shafer et al. 2011). Maintaining migration corridors and landscapes that are permeable to individual movements increases effective population size, genetic diversity, and adaptive potential while providing movement routes for mountain goats to respond to climate change (Sexton et al. 2011).

Threats identified in the Draft Idaho Mountain Goat Plan include road building, timber harvest, mining, power or infrastructure, oil and gas extraction, wildfire and fire suppression, or changing climate, which may reduce the limited habitat that currently exists (Idaho Department of Fish and Game 2019b). Fire suppression could negatively affect mountain goat habitat by preventing late successional forests from being converted to early successional stages, reducing forage. Mountain goats are susceptible to disturbance by recreational activities, both motorized and non-motorized, and may abandon preferred high-quality areas because of disturbance. Several modes of backcountry recreation, including snowmobiling and heli-skiing, have the potential to disturb goats. Helicopters generate the disturbance of greatest concern. Repeated disturbance by helicopters, snowmobiles, logging, or road building can cause displacement from habitat, group dissolution, nanny-kid separations, and injury. The extent to which these disturbance threats are in effect in the plan area depends upon whether these activities are allowed where the herds are currently located. Nearly all existing herds are observed within either Idaho Roadless Rule areas or designated wilderness. Within the plan area, most mountain goat herds do not experience threats from road building, timber harvest, mining, power infrastructure, nor oil and gas extraction because of where they are located. There is local concern for impacts of winter motorized recreation on mountain goat populations in the plan area. Winter motorized recreational use is currently not allowed where it is occurring.

Climate change modeling in both coastal Alaska and the Washington Cascades suggest that mountain goat ranges will shrink up to 86 percent under some projected scenarios, becoming more fragmented and isolated by the end of the century (Johnston et al. 2012, White et al. 2018). A similar pattern could be expected for mountain goats in Idaho given that they already occur at the highest elevations available across most of the state, particularly in the Panhandle, Clearwater, and Southwest regions (Idaho Department of Fish and Game 2019b). As temperatures rise, mountain goats can adapt behaviorally, altering daily elevational movements and foraging times to select microsites, providing cooler or warmer conditions as necessary (DeVoe et al. 2015, Frederick 2015).

Flesch et al. (2016) argued that they possess sufficient physiological and ecological plasticity to deal with projected changes in climate. The Draft Idaho Mountain Goat Plan predicted a 0.9 to 1.6-meter decline in winter snow accumulation and about a 4.2 to 4.3 degree increase in temperatures in mountain goat habitat in the Black Snow, Lochsa-Selway, and Lower Salmon population management units, which are the Idaho Department of Fish and Game mountain goat units in the plan area (Idaho Department of Fish and Game 2019b).

Winter is a time of profound nutritional deprivation for mountain goats (Fox et al. 1989). Deep snow reduces food availability and increases energy expenditure (Dailey and Hobbs 1989). Mountain goats often constrain their movements and occupy small home ranges during winter (Keim 2004, Schoen and Kirchoff 1982, Smith 1982). Winter range is important to the long-term survival of mountain goats and should be identified and managed to reduce disturbance to mountain goats.

Mountain goat populations are distributed in many areas of the Nez Perce-Clearwater as metapopulations. A metapopulation structure is one composed of many disjointed populations that are maintained by immigration and emigration between populations. In the plan area, none of the subpopulations are large compared to other big game numbers. Some of the larger herds reach close to 200, while other herds occur in the number of 20 to 50 individuals. Larger subpopulations are found along the Salmon River breaks in the Frank-Church and Gospel-Hump wilderness areas, the Mallard-Larkins area, and the Hoodoo area. Smaller subpopulations are scattered in the Selway-Bitterroot Wilderness, along the Lochsa corridor, and in the South Fork Clearwater area. The status of some of these smaller populations was recently in question but actual flight counts are lacking. The most acute decline based on limited survey effort is within the Blacklead subpopulation within the Hoodoo Recommended Wilderness Area, where the Idaho Department of Fish and Game has documented sharp declines in mountain goat numbers.

A winter habitat model was produced by the Idaho Department of Fish and Game that was analyzed by for the Land Management Plan (Figure 111). While well distributed, many of the suitable habitats in the Nez Perce-Clearwater are unoccupied because of over harvest in the past. The observation data provides a relative distribution of occupied areas. The mountain goat observation records provided line up well with the modeled habitats, but it should be noted that the mountain goat observations are over a time spanning from 1956 to 2018 and do not reflect current population numbers or status. Idaho flight efforts have only been conducted sporadically in the plan area in the last decade because of low numbers, the size of the Nez Perce-Clearwater, and the expense and danger associated with flight counts. Most observations are those incidentally observed during elk surveys. The population number and winter habitat model was used in delineating recommended wilderness for the Preferred Alternative, which include mountain goat habitat in the Hoodoo recommended wilderness even though the boundaries were altered to accommodate recreation.

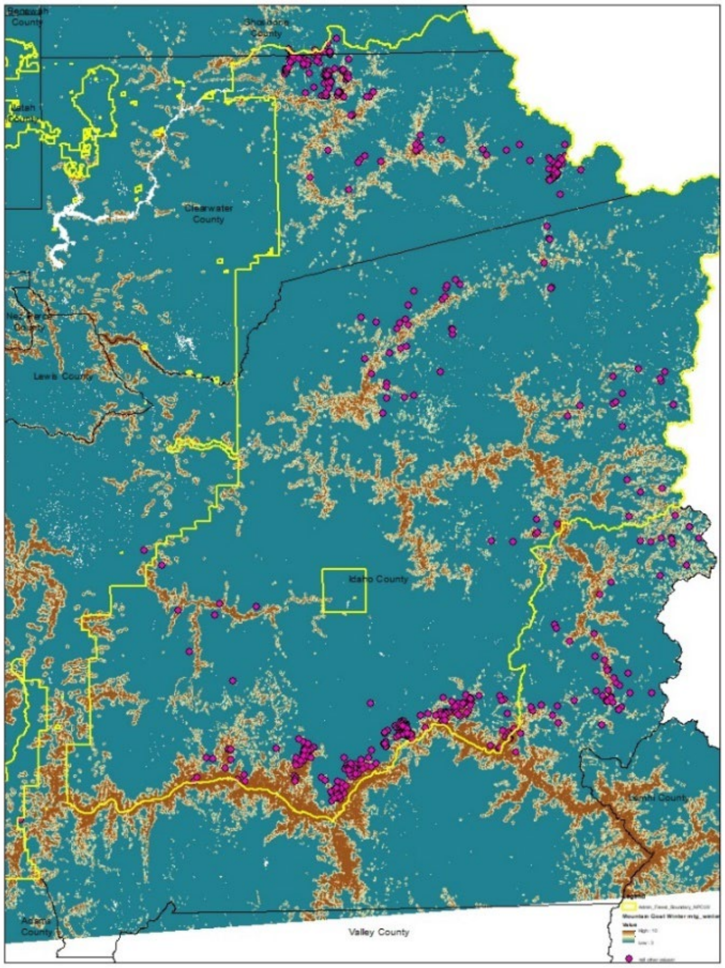

Figure 111. Modeled mountain goat winter habitat. Mountain goat locations in are shown as purple dots, and winter habitat is shown in brown. Green represents non-winter habitat for mountain goats.

Mountain goat migration in the plan area is not well understood. While mountain goats may move to slightly lower elevations in winter, in general, the Idaho Department of Fish and Game has witnessed them staying at higher elevations, above alpine, with movement restricted to areas with rocky escape cover perhaps close to wind swept ridges.

In July of 2017, during an in-person conversation, Clay Hickey stated recent flight counts by the Idaho Department of Fish and Game in areas occupied by goats in the Great Burn area, also known as the Hoodoo recommended wilderness area, documented snowmobile tracks near historic mountain goat areas and counted less than twenty individuals where past winter counts were in the low one-hundreds. The alternatives for recommended wilderness and whether snow mobiles are suitable in recommended wilderness could affect some populations of mountain goats in the plan area.

Black Snow Population Management Unit

Mountain goat habitat in the Black Snow Population Management Unit is located on the Idaho Panhandle and Nez Perce-Clearwater National Forest (Figure 112). Most of the currently occupied mountain goat habitat is covered under the Idaho Roadless Rule. Mountain goats are arranged in a metapopulation system with mountain goats living on isolated rocky areas among a sea of heavily forested areas. The mountain goats between Snow Peak and Black Mountain reside in the Mallard-Larkins primitive area. The most recent survey, in 2017, counted 128 mountain goats in the Black Snow Population Management Unit; however, the eastern portion of the population management unit showed a substantial decline from the previous survey. There are concerns with increasing snowmobile and snow bike access to mountain goat habitat in both the western part of Game Management Unit 9 and the eastern portion of Game Management Unit 10 in the Black Snow Population Management Unit.

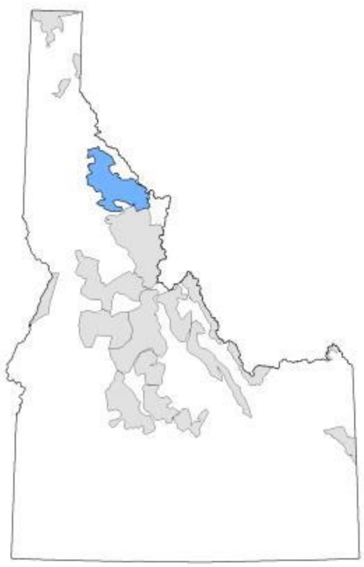

Figure 112. Black Snow mountain goat population management unit

Lochsa-Selway Population Management Unit

The mountain goats in the Lochsa-Selway Population Management Unit are found primarily on the Idaho-Montana border and in rocky cliffs on the Lochsa and Selway River drainages in Game Management Units 12 and 17 (Figure 113). Nearly all these lands are managed by the Forest Service and much of the mountain goat habitat is located within wilderness. Areas in Game Management Units 16 and 16A would have been included in this population management unit, but forest encroachment has eliminated much of the habitat and mountain goats have not been observed there in decades. Mountain goats in this population management unit are accessible within Game Management Unit 12 but largely inaccessible to hunters in Game Management Units 17, 16, and 16A. The Lochsa population varied from a high of 85 mountain goats in 1987 to 48 in 1996, the last year surveyed. Mountain goats are still observed through much of the area at low numbers and may still have similar population levels. The Selway population last had a complete survey in 1994, where 151 mountain goats were observed. A smaller survey of high grading mountain goat habitat in the same area in 2014 only observed 19 mountain goats. There has not been a hunt in the Lochsa-Selway Population Management Unit since the 1980s, and mountain goats have continued to decline in the Selway. Timber encroachment on small islands of habitat due to fire suppression has likely impacted mountain goat distribution over the last 60 years.

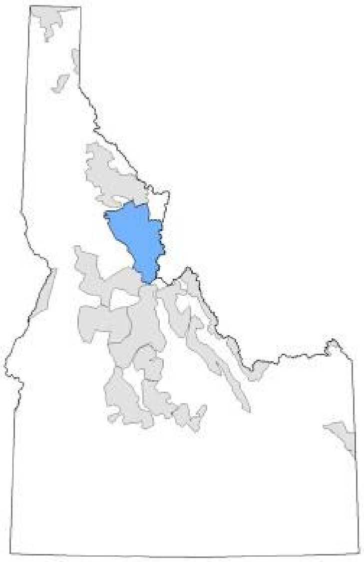

Figure 113. Lochsa-Selway mountain goat population management unit

Lower Salmon Population Management Unit

The Lower Salmon Population Management Unit includes mountain goats along the South Fork Clearwater River in Game Management Unit 15 from Mill Creek to Tenmile Creek, drops south to include both sides of the Salmon River from the mouth of Wind River in Game Management Units 19 and 19A, and east to the mouth of Disappointment Creek in Game Management Units 20 and 20A (Figure 114). It also contains the east side of the South Fork Salmon River up to Elk Creek. This population management unit falls within parts of the Nez Perce-Clearwater, Bitterroot, and Payette National Forests and much of this unit is located within the Gospel-Hump and Frank-Church River of No Return wilderness areas. Mountain goat habitat in the Lower Salmon Population Management Unit consists largely of broken river canyon cliffs but also includes several subalpine basins. Mountain goats in this unit are very sparsely distributed in small groups and connectivity is very low. It is estimated that there were around 160 mountain goats in this unit in the mid-1950s (Brandborg 1955). The first Idaho Department of Fish and Game flight records began in 1961. Much of this data comes from partial, intermittent mountain goat surveys or from incidental observations during elk surveys. The first full mountain goat survey in the Lower Salmon Population Management Unit was conducted in 1982. Forty-two mountain goats were observed on the lower South Fork Salmon River (South Fork) and the south side of the main Salmon River (South Main) and 92 goats were counted on the north side of the Main Salmon River (North Main) in Game Management Unit 15. In 1990, another full mountain goat survey was conducted on the South Fork and South Main Salmon where 36 mountain goats were observed. In 1993, a full survey of the North Main Salmon yielded 49 mountain goats. No mountain goat specific surveys have occurred along the North Main Salmon since that time. The last full survey of the South Fork and South Main Salmon occurred in 2003, where observers counted only three mountain goats. Most of the habitat in this unit is remote and unroaded. The potential impacts of motorized and non-motorized recreation are minimal.

Figure 114. Lower Salmon mountain goat population management unit

Across the Nez Perce-Clearwater

Observations of mountain goats from 1956 to 2018 show that 49 percent of the observations of mountain goats in the plan area have been documented in Idaho Roadless Rule areas, 46 percent have been observed in designated wilderness, and about 4.2 percent have been observed within the general forest portion, or Management Area 3, of the Nez Perce-Clearwater.

Mountain Lion

Historically, mountain lions were viewed as a predator to be eliminated as a threat to livestock herds. Mountain lions were reclassified as a game animal in 1972, which gave the Idaho Department of Fish and Game management authority over the species. Mountain lions are important as both a target species for hunters and as a predator that may influence populations of large ungulates, like elk and deer, which are also popular hunted species. The energetic needs of female lions with kittens limit viable populations to areas with enough deer and elk. Thus, land use or habitat management practices that impact ungulate prey will also impact mountain lions. The Assessment (U.S. Department of Agriculture 2014f) outlines mountain lion biology, factors leading to vulnerability, and population trends. Mountain lion hunting is offered in over-the-counter license sales in and around the plan area to reduce numbers and increase other big game animals. Populations appear stable in the Palouse Zone, Hells Canyon Zone, Elk City Zone, and Selway Zone. Mountain lion populations in the Lolo Zone are thought to be declining due to low elk populations.

Mule Deer

The plan area is on the northern edge of good mule deer habitat, but mule deer can be found throughout the plan area in suitable habitats. Mule deer populations on the Nez Perce-Clearwater are located in the Snake, Salmon, and Selway River drainages. They are found in steeper habitat that contains browse for food and a mix of chaparral or forest for cover mixed with open areas. They can also be found in open habitats with few or no trees. Mule deer mostly eat browse, but a smaller portion of their diet contains grasses and forbs. The proportion of these foods varies seasonally, with the proportion of grasses and forbs increasing during the spring and summer. In winter, they travel to lower elevations on western or southern facing aspects to avoid deep snow. Winter is thought to be the most challenging season for them, and protection of winter habitat has been a mainstay of mule deer habitat management across the west.

Agents of change in mule deer habitat include fire exclusion and the reduction in habitat quality because of invasion by exotic weeds and grasses. Restoration of fire regimes can benefit mule deer by increasing forage quality and quantity. The coarse filter plan components in the Forestlands; Meadows, Grasslands, and Shrublands; and Invasive Species sections of the plan can contribute to mule deer habitat. Their populations are controlled by hunting, predators, and habitat conditions.

Mule deer are economically important to the Idaho Department of Fish and Game and many small rural economies in Idaho. Cooper and Unsworth (Idaho Department of Fish and Game 2000) estimated mule deer hunting resulted in a direct expenditure of $42 million in trip-related expenses, not including equipment purchases. Many of these expenditures were for fuel, meals, and lodging in rural towns. Using a typical economic multiplier of 2.5, the Idaho Mule Deer Plan estimated that the total estimated economic impact of mule deer hunting in Idaho exceeded $100 million. Additionally, more than 1,000 jobs in Idaho are directly supported by mule deer hunting-related expenditures (Idaho Department of Fish and Game 2000). In 2006, direct revenues to the Idaho Department of Fish and Game from mule deer license and tag sales were nearly $6.3 million, representing nearly 20 percent of the total license and tag revenues used to implement important wildlife conservation programs, including enforcement, population monitoring and research, and habitat conservation. Guide services in backcountry areas, including within designated wilderness areas, offer highly valued mule deer hunting opportunities where clients will pay upwards of $5,000 for the services. Additionally, parts of the Nez Perce-Clearwater above the Salmon River canyon offer trophy mule deer hunting opportunities. Mule deer could be considered the third most pursued big game species in the plan area behind whitetail deer and elk.

Mule deer are more common in the southern portion of the Nez Perce-Clearwater than they are in the northern part. Mule deer are primarily browsers and shrub fields are an important component of their habitat. While whitetail deer are ubiquitous, mule deer in most areas of the Nez Perce-Clearwater occur in limited pockets of suitable habitats, which includes grasslands and shrublands, often on steeper slopes. Mule deer populations in the plan area are generally stable compared to those in other parts of the state, which exhibit a wide range of variability. Mule deer populations across the region, including in the plan area, appear to be increasing, partly in response to very conservative harvest management. Populations probably did not change much until the large fires of the early 1900s that converted vast expanses of unbroken forest into a mosaic of successional vegetation types and large numbers of domestic livestock altered grass-dominated habitats into shrub cover. They make up less than 10 percent of the deer harvest over most of the Nez Perce-Clearwater. Weather, fire, and plant succession have ultimately played a much larger role in mule deer populations than efforts of wildlife managers.

Mule deer movements or migration are not well understood in the plan area. It is thought that they migrate down drainages from higher to lower elevations in the winter, though they show higher fidelity to river breaks. Habitats where they occur face few threats to migration or movement routes from forest management because of where they occur.

Whitetail Deer

White-tail deer are one of the most sought-after big game animals in the Clearwater region and in the state. Whitetails are abundant north of the Salmon River. The highest densities of white-tailed deer in the state are thought to occur in the lower Clearwater and Salmon River drainages. Whitetail deer movements or migration patterns are not well understood in the plan area. Harvest records from the Idaho Department of Fish and Game confirm that, from 1994 through 2003, Clearwater region white-tailed deer have averaged 43 percent of the total statewide deer harvest (Idaho Department of Fish and Game 2019b). The percentage is likely to be much higher in the planning area due to the high number of whitetails compared to mule deer.

Whitetail deer are an important source of subsistence for tribal members exercising their treaty reserved rights. White-tailed deer hunting is also economically important in Idaho. Deer hunting, including both white-tailed and mule deer, provided 840,000 hunter days and generated $109 million in retail sales in 2001 (International Association of Fish and Wildlife Agencies 2002). Approximately 2,000 jobs were tied directly to deer hunting in 2001 and resulted in $1.3 million in state income tax. Forest Service lands in the plan area that are popular for deer hunting comprise substantial portions of Clearwater, Latah, and Idaho Counties. Based on Cooper et al. (2002), the combined economic impact of deer hunting in those three counties alone was in excess of $31 million in 2007. Whitetail deer are a source of meat for many living within the local communities and others who travel into the area for whitetail deer hunting.

The Assessment (U.S. Department of Agriculture 2014f) describes winter and summer habitats, predation, disease, and biology. Essentially, whitetail deer seek out forested areas in winter for thermal cover and seek out open areas for forage quality in the summer. The Assessment outlines the population trends and threats to whitetail deer. Summer range quality has also been linked to productivity, recruitment, and growth rates in deer (Cheatum and Morton 1946, Julander et al. 1961). Consequently, deer select spring, summer, and fall habitats with the most nutritious forages available. As summer progresses, deer initially follow spring green-up to higher elevations and make extensive use of clear-cuts, burns, and open forest areas but eventually shift to more mesic northerly aspects and forested habitats in late summer and fall. Whitetail deer would benefit from a variety of stand size classes and a mosaic pattern of disturbance offering hiding and foraging cover. Whitetail deer populations are generally healthy in most of the Nez Perce-Clearwater but may have declined in Game Management Units 16A, 17, 19, and 20 due to forest succession.

Gray Wolf

Wolves are managed as a big game species in Idaho and are actively hunted and trapped in the plan area. They were introduced in the mid-1990s to recover their populations after federal listing. They can exert a large response on other big game populations. Wolf population size and productivity is determined by the abundance of their prey, which in Idaho is primarily elk, though they will also take deer, moose, mountain goats, and bighorn sheep. Wolf populations are distributed throughout the plan area. Wolves are a factor in the declines of elk herds in some parts of the planning area, particularly in the Lolo and Selway Elk Management Zones. Wolves are a charismatic wildlife species that are popular to watch. Wolves are very mobile and are now expanding their range outside of what has been considered optimal habitat. Most mortality of wolves in Idaho is human caused. The Assessment (U.S. Department of Agriculture 2014f) outlines causes of wolf mortality, impact on big game populations, the ecological effect of wolves, and the Idaho Department of Fish and Game wolf management, status, and trends. Wolf populations have likely decreased in some parts of the plan area. The Idaho Department of Fish and Game controls wolf populations through the availability of hunting tags.

Furbearers

Thirteen species that occur on the Nez Perce-Clearwater are considered furbearers. Furbearers include the long-tailed weasel, short-tailed weasel, mink, red fox, bobcat, river otter, beaver, muskrat, coyote, northern raccoon, American marten, badger, and spotted skunk. The Nez Perce-Clearwater has an extensive history of fur trapping, both before and after European settlement. Furbearers provide recreation and economic contributions for people in the plan area. Lynx, fisher, and wolverine were also considered furbearers but hunting and trapping for those species is currently prohibited in Idaho. Bobcat and marten (both Pacific and American combined) are, by far, the most valuable furbearers in the plan area as they consistently bring high dollar value for their pelts. Species such as badgers, skunks, weasels, and sometimes otters are often trapped incidentally while targeting other species. The Idaho Department of

Fish and Game tracks furbearer populations of many species through an index of catch per unit effort. They estimate that the species trend is up if the catch per unit effort is higher and estimate it is declining if there is a decline in catch per unit effort for that species. Bobcats and river otters require mandatory reporting and tagging of trapped individuals.

Furbearers use a variety of habitats in the plan area, and plan components that provide for ecosystem integrity provide for most furbearing species. Furbearers that use aquatic and riparian habitats include beavers, river otters, muskrats, mink, skunks, and raccoons. Badgers tend to use non-forested habitats like shrublands, grasslands, and meadows. Long-tailed and short-tailed weasels use the interface between forested and non-forested habitats. There are two species of marten present—the Pacific marten and the American marten—and both would be considered mature forest species. Coyotes, red foxes, and bobcats are generalists that use a variety of habitats so long as prey populations are abundant.

Fur trapping is an activity that produces economic benefits to individuals and industry because the primary motivation for trapping is to sell furs for money, which are then used in the manufacturing of clothing. Fur prices fluctuate because of market demand and vary by species. The State of Idaho produces an annual fur bearer report with economic values of fur trapping (Idaho Department of Fish and Game 2018). The 2018 report identified that the state sold 1830 trapping licenses for the 2017-2018 season, an increase of four percent over the previous year. Idaho trapping licenses sell for $29.75 per resident adult and $8.25 for youth trappers. Trappers reported harvesting (trapping and hunting) 20,452 animals, up from 15,969 for 2016-2017. A total of 10,853 pelts were reported sold for a value estimated at $372,572.26. The number of pelts sold, and their estimated value, increased to 7,545 pelts reported sold for a value estimated at $195,250.77 during 2016-2017.

The statewide rank by dollar value per species pelt was wolf, bobcat, coyote, otter, marten, red fox, beaver, badger, skunk, spotted skunk, raccoon, mink, weasel, and muskrat. The price per pelt for all harvested species ranged from an average of $299.35 for wolves to $2.98 for muskrat. The top five furbearers based upon total dollar value of pelts sold were coyote, bobcat, marten, muskrat, and red fox. Bobcat trappers and hunters checked 1,360 animals, up from 921 animals the previous season. Based on an average pelt price of $34.33 and 14 pelts sold per trapper, trappers earned an average income of $480.62, up from $284.68 the previous season. Using an approximation of 65 percent reporting, the Idaho Department of Fish and Game estimated harvest for all trappers, including those who did not submit a report, was 31,465 animals taken and 16,697 pelts sold. The estimated statewide value of pelts sold is $1,041,696, up from $657,501 the previous season. Furbearer pelt revenue by county was calculated using the Idaho Department of Fish and Game furbearer report. The dollar value was estimated by using the average price per pelt and multiplying that by the number of animals harvested in each county for each type of fur bearer. During the 2017-2018 season, pelts from Idaho County generated approximately $38,348.09, and Clearwater County generated $14,270.88. The 2012–2013 total market value of all furbearers harvested in the Idaho Department of Fish and Game's Region 2 was $115,096; however, most of the plan area harvest would have occurred in Clearwater and Idaho County. The total market value of furbearers in Clearwater and Idaho County for the 2012–2013 season was $94,746. Bobcat and marten were, by far, the most valuable furbearers in the plan area in 2012–2013, having combined market values from Idaho and Clearwater Counties of $53,793 and $34,391, respectively (Idaho Department of Fish and Game, unpublished data, see project record file).

Different fur bearers each use unique habitats and they are represented in habitat groups like the aquatic and riparian habitats, open or non-forested habitats, ecotone or forest edge habitats, and forested habitats. Many of these species do not face significant threats to their habitats. These species are secure in the plan area. Perhaps the most significant threat to most of these species includes over trapping, which occurred in the past but has not typically been a challenge in Idaho since trapping regulations were established. While over trapping can be a threat, the state monitors furbearer populations and regulates trapping of these species to ensure their persistence. Furbearers are primarily provided for through ecosystem plan components. Furbearers are provided for through aquatics plan components, forestlands plan components, and the plan components in the Meadows, Grassland, and Shrubland section of the plan.

Martens (Pacific martens were considered subspecies of American martens previously) have been a species of conservation interest overtime and marten habitat was modeled in SIMPPPLLE to ensure that the plan will provide for long term peristence. Camera trap surveys, as well as fur harvest trends, suggest martens are common and abundant (Krohner 2020). Krohner (2020) conducted a camera trap study evaluating fisher occupancy but also detected martens in many fisher cells. Marten were detected on camera in 31 of the 54 cells, which were distributed across the plan area excluding wilderness areas. Genetic samples from this study detected both American and Pacific martens, and both species occur across most of the plan area. Overall marten occupancy was estimated at 0.63, and it was estimated that marten occupied 97 of 154 (approximately 63 percent) total grid cells. Habitats for martens are typically mature, old coniferous forests with complex structural features. Preferred conifer types have included subalpine fir and Engelmann spruce stands, lodgepole pine, and sometimes Douglas-fir, but martens have been observed in other forest types as well. Baker (1992) reported martens using younger age classes but denning was reported in residual old structures from previous forests, suggesting that legacy trees and retained large diameter snags can provide for martens even when age classes are changed through management.

Upland Game

The Nez Perce-Clearwater has an abundant population of upland game species. Upland game are distributed in many areas of the Nez Perce-Clearwater. Upland game includes species like California quail, cottontail rabbits, snowshoe hares, chukars, wild turkeys, mourning doves, ring-necked pheasants, gray partridges, and three grouse species. Of these, wild turkey, chukars, and grouse are the most popular species to hunt within the plan area. Upland game species are dependent upon early seral or non-forested habitats, ecotone habitats, and forest habitats. Some species, such as California quail, chukar, and pheasants, are distributed at lower elevations in the non-forested habitats. Snowshoe hares, spruce grouse, dusky grouse, and ruffed grouse are found forestwide. Populations of most of these species are thought to be secure and abundant. Primary threats include invasive weeds, fire suppression or succession, and grazing. The state monitors and regulates harvest of these species to help ensure their continued availability for use. Upland game species are primarily provided for through the ecosystem plan components. In particular, those that facilitate increased early seral habitats and healthy non-forested habitats and a mosaic pattern of forest and non-forested habitats. Plan direction that provides for these species can be found in the Forestlands and the Meadows, Grassland, and Shrubland sections.

Waterfowl

Waterfowl occur in the plan area but probably receive limited hunting pressure. These include a variety of duck and geese. They are all grouped into aquatic habitats, with some occurring in wetland habitats, others in open water, and others in riverine habitats. The most abundant aquatic habitats are the large rivers in the plan area, though there are some small lakes, reservoirs, and wetlands in limited quantities. Waterfowl have value as viewable wildlife or for photography. Species like the harlequin duck can draw bird watchers from afar, seeking to check that species off their life list. Feathers from waterfowl can be used in tribal clothing. Plan direction in the in the Aquatic Ecosystem section would provide well for these species.

Environmental Consequences of Plan Direction

Ecosystem Plan Components

The ecosystem plan components would help provide the ecological conditions to provide for species that are commonly used by the public for hunting, fishing, gathering, viewing, subsistence, and other uses. The way these plan components provide for the species depends on the specific ecology of each species. Most of these species are common and abundant in the plan area. Plan components that seek to restore the natural range of variability should provide for many species, even though some species may decline in numbers while other species increase. Plan components for terrestrial wildlife habitats are integrated with the vegetation plan components. Vegetation plan components are specified for potential vegetation types, which are groupings of individual habitat types (Pfister et al. 1977). Habitat types are an aggregation of ecological sites of like biophysical environments, such as climate, aspect, and soil characteristics, that produce plant communities with similar composition, structure, and function. Potential vegetation types serve as a basis for describing certain ecological conditions across the Nez Perce-Clearwater and are useful in understanding potential productivity, natural biodiversity and the processes that sustain these ecosystem conditions. The potential vegetation types are the warm-dry, warm-moist, cool-moist, and cold coniferous forest types. Because wildfire, insects, and disease have historically created a mosaic of habitats that range from young, open forest with shade-intolerant conifer species to dense, old forest with shade-tolerant species, most of the associated wildlife species are adapted to a complex of successional stages and species compositions that are based on the natural range of variation. This complex of successional stages meets their needs for nesting or denning, foraging, resting, cover, and connectivity. Fire and regeneration harvest in coniferous forest create early-successional habitat on a temporary basis. The plan components do not vary by alternative and were designed to provide the ecological conditions to provide for all the plan's wildlife. So in most cases for the species below, the plan effects do not vary by alternative. Where they do, the different effects are specified.

Several game species are dependent upon early seral or non-forested habitats. Non-forested habitats can be persistent but may be encroached by forest growth and some of them are susceptible to invasion by exotic vegetation. Mountain meadows and parklands, persistent shrublands, and lower elevation grasslands are examples of these types of habitats. The important features of these habitats are native vegetation in good condition and a distribution that reflects the natural disturbance regimes. Plan direction in Forestlands section for early seral habitats and those in the Meadows, Grasslands, and Shrublands section provide for these species.

Several game species use the interface between non-forested or early seral habitats and forested habitats. The plan direction in the Forestlands section contains direction on how to arrange these features on the landscape and should provide for the mix of forested and non-forested habitats needed by many big game and upland game species.

Many waterfowl species and some fur bearers depend upon aquatic and riparian habitats. Plan direction for aquatic and riparian habitats are extensive in the plan and would provide for these species by protecting these systems. The plan also contains direction to restore succession for some aquatic habitats to restore hardwood and deciduous vegetation in riparian habitats encroached and shaded out by coniferous forests as a result of fire suppression. Species such as beavers would benefit from restoration of hardwood or deciduous vegetation in riparian areas because they serve as a food source.

Plan components for forest dwelling species must consider the needs of a variety of wildlife species. Some species, like American and Pacific martens, prefer mature and old forest in cold and cool moist potential vegetation types, while black bears use a variety of habitats for their subsistence. Black bears, for example, select mature forest with high canopy cover and riparian areas but are highly dependent upon fruit bearing shrubs as an important source of nutrition at certain times of the year. Shrubs, such as huckleberries, grow best in open forests that provide some shade but let ample light into the understory. Black bears also use riparian habitats and avalanche paths for habitats. Thus, a variety in ages benefits bears. Similarly, ruffed grouse are forest dwelling birds that are most often found in early seral habitats. Thus, ecosystem plan components that provide for a variety of age classes are necessary for providing for a variety of forest species. Plan components that contribute to black bear habitat include those that speak to desired size classes in each broad potential vegetation type and retain legacy trees snags and downed wood, which would provide for denning and hibernation habitat.

The wildlife section includes plan components that provide for a variety of multiple use wildlife. Desired condition FW-DC-TE-05 states habitat conditions in the plan area provide ecological conditions that support the diversity of plant and animal communities and provide ecosystem integrity. FW-DC-TE-06 addresses the desire to provide for a diversity of habitats that would meet the needs of multiple use species by providing a mix of habitat patches of various size classes that would meet the needs of species that use edges and ecotones, species that use forested habitats, and species that use early seral or non-forested habitats. These will be effective because most of the ungulates depend upon ecotones or forest edges for their preferred habitats.

A goal of the plan is that the Nez Perce-Clearwater provides habitat conditions to meet Idaho Department of Fish and Game management plan objectives. Similarly, it is a desired condition that habitat supports opportunities for hunting, fishing, trapping, gathering, observing, photography, subsistence, cultural interactions, and the exercise of treaty reserved rights, as in FW-DC-WLMU-01. Language in FW-DC-WLMU-01 indicating a desire that “wildlife is distributed in habitats within their respective seasonal ranges” suggests desired conditions have a wide distribution of these species in the plan area but is not to be construed to mean that all wildlife occurs forestwide at all seasons of the year. Since wildlife species use a variety of habitats, FW-DC-WLMU-02 is a desired condition that habitats in each potential vegetation type function within a desired range of variation to contribute to multiple use wildlife needs. FW-DC-WLMU-03 provides an emphasis that the habitats in the plan area provide for ungulate species that meet their life history requirements year-round, including both summer and winter. This desired condition is adequate for the management of winter ranges to promote winter range restoration as needed.

As noxious weeds are a challenge throughout the west and in the plan area, FW-DC-WLMU-03 has language desiring that big game habitats are composed of native vegetation. This language applies to all the ungulates in the plan area, including elk, mule deer, whitetail deer, bighorn sheep, and mountain goats. FW-DC-WLMU-04 is a plan component emphasizing Pacific yew as an important feature of moose habitat. FW-DC-WLMU-05 is a desired condition emphasizing the role natural processes have in maintaining or improving the mosaic habitats needed for many game species. FW-DC-WLMU-06 was added in response to comments addressing the desired emphasis on social, cultural, and economic contributions of big game in the plan area.

There are three guidelines included in plan direction for the management of multiple use wildlife species. FW-GDL-WLMU-01 recognizes the impact that unauthorized routes have on game species and seeks to minimize these impacts and emphasizes that closures of these features should be effective. FW-GDL-WLMU-02 is a guideline that requires new fence installation be designed to reduce impacts on wildlife movements unless the intent is to exclude wildlife. Situations where this exception would be needed occur where wildlife would hinder efforts to restore habitat and need to be fenced out for that purpose. Another example would be in the event that fencing might be needed to prevent vehicle-wildlife strikes. These and other situations where wildlife fencing are appropriate would not be restricted; however, these situations are not expected to be common.

FW-GDL-WLMU-03 is a guideline designed to reduce disturbance during critical time periods of the lifecycle of big game species. Winter range restoration is not discouraged within the plan and FW-DC-WLMU-03 would encourage consideration of winter habitat management for ungulates. Additional emphasis on winter range was added to FW-DC-MLMU-02 to suggest added protection of disturbance to wintering big game. When treating winter range, it is encouraged to target areas that would provide the best nutritional response as with summer range.

Elk

Elk are identified as a focal species in the plan and are a management emphasis. As elk received much interest from both government agencies and the public, they are emphasized in the plan as a key focus for improving their habitat conditions and populations in the plan area. While the focus was on elk, many of the other multiple use species will also benefit from habitat management for elk. The Nez Perce-Clearwater collaborated extensively on plan components for elk based upon the best available scientific information.

Conceptual Basis for Management of Elk on the Nez Perce-Clearwater National Forest

In a collaborative effort, plan components were drafted to improve the condition of elk habitats in the plan area base upon increased awareness about the factors that most importantly influence elk populations. Participants included representatives from the Idaho Department Fish and Game and the Nez Perce Tribe, researchers from the Pacific Northwest Research Station, and members of the Land Management Plan interdisciplinary team. The framework for elk habitat management is described in detail within the management approaches section of the plan. Management approaches outlines agency intent related to elk habitat management.

Two concepts, nutrition and habitat use, provide the foundation for managing elk populations, encompassing both hunting and non-hunting periods on the Nez Perce-Clearwater under the proposed plan. Forest plan direction is most logically built on these two concepts incorporating best available science to ensure that elk populations are productive and abundant to meet land use desires from a wide spectrum of stakeholders who place high cultural, social, economic, and ecological importance on the species on public lands.

The desired condition FW-DC-MLMU-06 emphasizes these two concepts as a management framework for elk. Nutrition is defined as the dietary nutrients needed by a lactating female elk to meet its maintenance needs during summer and fall, a period of nutritional stress in response to demands of a calf at heel. Adequate summer-fall nutrition of a lactating female ensures survival of her calf through winter and allows the female to be in sufficient condition after weaning to again produce and recruit a calf the following year, avoiding alternate-year calf production by a female.

Habitat use is defined as the relative probability of elk use of a specified landscape and areas within the landscape. The size of the specified landscape is assumed to be an area large enough to encompass that used by a summer-fall population of elk. Sub-watersheds typically meet this definition, but other boundaries and spatial extents can also be used. Compatibility with the size of area occupied by an elk population or another ecologically meaningful management unit is key. The Nez Perce-Clearwater selected HUC12 for the scale at which to apply these measures in the proposed plan because HUC12s are commonly used as an unbiased sized area delineated by landscape features and are used by a variety of resource specialists in managing the Nez Perce-Clearwater and would be compatible for integration.

HUC12s also meet or exceed the size criteria to meet summer fall use. In comparison, HUC12s are about twice the size of the elk analysis units used in the 1987 Plans. Rowland et al. (2018) provided example applications of nutrition and habitat use evaluations for regional and local landscapes for elk management.

An additional consideration is the desired harvest and hunter opportunity during fall hunting seasons and associated effects on elk distribution and population performance. Past management has addressed this issue through the concept of elk security or habitat security, which has been defined and used in a wide variety of ways, many of which are contradictory and confusing. Importantly, past definitions do not recognize the important role of nutrition and habitat use as foundational to management of elk hunter harvest and hunter opportunity. See Christensen et al. (1993) for an example of this misunderstanding where security is appropriately identified as a measure of conservation in relation to harvest but without recognition that elk must be present on a landscape via appropriate management of nutrition and habitat use to have something to hunt or conserve.

This view largely reflects landscape conditions of the 1980s and early 1990s when concepts of elk security were developed at a time when early seral habitat was abundant from a legacy of intensive timber harvest and nutritional conditions were vastly better than current conditions on public lands. Current conditions in the plan area suggest the limiting factor is a lack of adequate nutrition and high predation rates, rather than hiding cover, as cover is abundant in the plan area.

This is not intended to disparage the concept of elk security, but its use needs to be updated to reflect contemporary concepts of producing and sustaining a productive and abundant elk population based on nutrition and habitat use. Furthermore, the research cited above suggests these concepts require updating to consider the spatial arrangement of roads, rather than a simplified density estimate without considering the interaction of nutrition and roads. Without sufficient summer-fall nutrition and high habitat use, there will be few elk that can be hunted and conserved via the traditional concepts of elk security.

The framework emphasizes the distance from roads rather than road density and integrates nutrition and other factors widely known to influence elk habitat use, such as slope and arrangement of seral conditions at a landscape scale. The framework is flexible enough to provide what elk need within watersheds. For example, a given watersheds may have ample distance from roads but lack nutritional resources, another might have a road distribution that precludes use, and other watersheds might lack the spatial arrangement of seral conditions to provide for forage to edge cover and meet the needs of elk selection at landscape scales and might benefit from a diversity of seral patches of appropriate size or shape to provide edges spatially arranged across the watershed.

Elk select habitats on milder slopes compared to steeper slopes, so features that affect habitat use, such as nutrition, are more effective for elk when they occur on milder slopes. Similarly, factors that increase disturbance to elk, like open motorized roads and trails, are more detrimental if located on milder slopes preferred by elk. Some watersheds might benefit more from these factors if forage resources are created on mild slopes or disturbance factors were removed from mild slopes. Adjusting one or more of these four factors to increase or maintain predicted female elk body fat at a landscape scale could have direct positive effects on elk vital rates. Rowland et al. (2018) showed that it is possible to predict female fat based upon the proportion of a landscape that has high quality nutritional forage usable by elk. The amount of predicted female fat can be dramatically increased by small percent changes in the amount of area that contains greater than 2.6 kcal/g dietary digestible energy. Female reproductive output is correlated with higher levels of percent body fat.

Goals that underlie management of elk habitat use and nutrition include a public land manger’s desire to:

- Minimize distributional shifts to private lands.
- Meet Tribal First Food objectives.
- Meet hunter harvest objectives or avoid overharvest.
- Meet hunter opportunity desires.
- Minimize non-consumptive effects.
- Meet fall nutritional needs of lactating females and associated habitat use objectives.

Management for elk habitat use will vary substantially according to which of the above objectives are specified by public land managers in a given watershed in collaboration with state wildlife agencies, tribes, and other public lands stakeholders. These factors could be manipulated to positively improve conditions or reduce impacts through evaluation of alternatives during projects. Importantly, all these goals relate to achieving desired levels of habitat use as a basis for managing ecological conditions for elk. Habitat use includes nutrition to ensure that there is an elk population to manage for hunting.

During the collaborative effort, it was recognized that elk in the different management areas of the Nez Perce-Clearwater have different needs related to nutrition and habitat use and the ability to manage habitats differ as well. Elk within Idaho Roadless Rule areas have ample security or distance from roads but may lack abundant high-quality nutrition. Idaho Roadless Rule areas are composed of large blocks of land without motorized access. These areas may lack nutritional resources due to fire suppression. Thus, in the plan components for Roadless Rule areas, emphasis is on higher nutrition at a landscape scale under MA2-DC-ELK-01 and objective MA2-OBJ-ELK-01 while maintaining the large areas without motorized access that could be impacted by development of new motorized trails. MA2-DC-ELK-02 and FW-GDL-WL-05 emphasize retaining areas of 5000 acres or larger without motorized access consistent with Ranglack et al. (2017).

Watersheds within Management Area 3 might lack nutritional resources or have areas not used by elk because the distribution of open motorized routes, which may not provide enough distance from roads to be usable. Similarly, they may have abundant nutritional resources but lack habitat uses because they do not provide enough distance from open roads. Management Area 3 is the least restrictive management area for habitat alteration to improve elk habitats from a nutritional standpoint. Therefore, the ability to provide abundant nutritional resources is enabled in this management area. Watersheds in Management Area 3 could benefit from increasing high quality nutrition to help alleviate the effects of roads. A manager might select to keep roads created during timber harvest from being open to the public after project completion or choose to strategically close a road segment to increase the distance elk have to use habitats between roads, especially if roads impact areas of mild slopes with high nutrition. Alternatively, a decision maker might choose to locate roads in areas so that habitats farther from roads are not impacted or where roads will have less disturbance on areas with milder slopes. This framework gives flexibility to decision makers for a variety of measures that can be used to measurably change conditions for female elk, which will improve predicted body fat. Percent body fat is tied directly to known factors that most influence elk population growth, such as calf survival, winter survival, pregnancy rates, and calf to cow ratios. FW-DC-MLMU-06 and MA3-GDL-WLMU-01 are intended to help managers move ecological conditions towards higher habitat use and increasing nutritional resources for elk. Additional detail and agency intent on implementing this elk plan direction can be found in the Management Approaches section of the Forest Plan which lays out the intended framework for elk habitat management and project analysis.

All these plan components are designed to be used in consideration with the best available science on an elk forage response spatial layer. The nutritional response layer is a geographic information system map layer derived from a combination of physical and biological conditions across the Nez Perce-Clearwater that predict the nutritional response that would occur following disturbance (Cook et al. 2018). This spatial data was created based upon science and verified through measurement of nutritional resources on the ground and evaluated through telemetry-based elk habitat selection (Cook et al. 2018). A total of six potential nutritional models were evaluated and one was identified as best representing nutritional responses across the region, though some of the other models performed better in individual herd areas. Model 6 performed better overall across all study areas than all the other models, showing a positive relationship of increasing elk use with increasing dietary digestible energy, and is the recommended model (Cook et al. 2018). Management designed to increase nutritional resources for elk should be targeted in areas expected to provide higher quality nutritional resources, which are mapped in the nutritional response spatial layer. High quality nutritional resources are defined as areas that produce vegetation with greater than or 2.6 kilocalories per gram of dietary digestible energy.

Dietary digestible energy levels near or above 2.6 kilocalories per gram meet the basic nutritional requirements of elk and were highly correlated with pregnancy rates of lactating females (Rowland et al. 2018). Autumn body fat levels were highly correlated with the percentage of elk ranges or landscapes providing dietary digestible energy levels above this basic requirement (Rowland et al. 2018). It is not likely sufficient to create early seral conditions in areas with a poor nutritional response if the expected outcome is to provide elk forage. Small percentage changes in the amount of high-quality nutritional resources at a landscape scale can have dramatic effects on predicted elk fat (Rowland et al. 2018). Thus, language in the desired condition plan components and in the objectives direct the location of management to achieve desired vegetation conditions towards areas predicted to have higher nutritional response. Objectives MA2-OBJ-ELK-01 and MA2-OBJ-ELK-02 and direct treatments to restore vegetation. These would be targeted towards areas with the highest nutritional responses to increase the area within the landscape that provides higher quality nutrition. These locational considerations line up well with departures from the natural range of variation that should be restored through the vegetation desired conditions found in the Forestlands section of the plan.

The Nez Perce-Clearwater contracted with Ecosystem Research Group to run the elk nutrition model through SIMPPLLE to predict the response of disturbance, including wildland fire, timber harvest, and insects and diseases to estimate how the amount of high-quality forage would fluctuate through time under the alternatives. The model evaluated the benefits to elk pregnancy and elk body fat within the three management areas by combining simulated vegetation treatments with predicted nutritional potential data layers. The model evaluated only the response of the treatments without consideration of the travel system.

Results suggest that nutrition sufficient to benefit pregnancy and body fat would occur within Management Area 3 under all alternatives over the next 50 years (Figure 120 and Figure 123). These increases, while they appear modest, represent a significant increase in the landscape that provides high quality nutrition for elk. These modest gains in high quality nutrition represents large increases in potential body fat and to support higher pregnancy rates. Nutrition sufficient to benefit body fat and pregnancy was static or only had modest changes within Management Areas 1 and 2 (Figure 118, Figure 119, Figure 121, Figure 122, Figure 123). This was likely because of a few factors. First, much of Management Areas 1 and 2 has limited areas that have productive site potential to provide a high nutritional response. Second, the ability of the agency to treat these areas are limited because of restrictions imposed by wilderness and the Idaho Roadless Rule. Third, natural disturbances such as fire have been operating within Management Area 1 and has already created a lot of early seral conditions within that area.

Within Management Area 3, results are very favorable and show that the amount of high-quality forage increases throughout the 50-year timeframe modeled under all alternatives. The results suggest about a 17 percent increase in the area of nutrition that produces greater than 2.58 kilocalories per gram of dietary digestible energy over the 50-year timeframe compared to current conditions. This is the amount that contributes to pregnancy. There is about a 100 percent increase in the area that produces greater than 2.75 kilocalories per gram of dietary digestible energy in the excellent category. This is the amount of nutrition that supports higher body fat. As these areas are highly selected by elk, these areas should increase elk habitat use. Studies on elk from the Clearwater Basin Collaborative Elk Project suggest that an increase from 5 to 20 percent of the landscape having more than 2.75 kilocalories per gram of dietary digestible energy can increase percent body fat from about 8 up to 12 percent and increase pregnancy rates for female elk from approximately 40 percent to nearly 100 percent. With approximately a 6 percent change in areas with greater than 2.9 percent of dietary digestible energy, the predicted percent body fat can change from 6 to 8 percent up to above 12 percent. These changes in body fat should improve both calf and female elk survival during winter. The largest jump in elk nutritional resources is in Management Area 3, with Management Area 2, and Management Area 1 remaining relatively static.

Within Management Area 3, alternatives that provide a quicker pace to achieve desired vegetation conditions provides more high quality nutrition than alternatives that achieve desired vegetation conditions at a slower pace. The Preferred Alternative provides a seventeen percent increase in nutrition that would provide for increased pregnancy rate in Management Area 3. The Preferred Alternative also would provide a thirty six percent increase in nutrition that would contribute to higher body fat. This alternative is intermediate compared to the fastest and slowest pace for achieving desired conditions in other alternatives. The six figures below compare the alternatives by how much habitat is projected in SIMPPLLE to produce sufficient dietary digestible energy sufficient to provide for elk body fat and pregnancy. Habitat that provides for greater than or equal to 2.75 kilocalories per gram dietary digestible energy provides for body fat while habitat that provides greater than 2.58 kilocalories per gram dietary digestible energy provides for higher elk pregnancy rates.

The best nutritional response is projected to occur within Management Area 3 (see Figure 115 through Figure 123). Whether habitats with high quality nutrition are usable by elk would depend upon whether they would be located within about a half mile or more from motorized routes open to the public. If located closer than about a half mile from open motorized routes, they would receive less use by elk and have lower benefits to elk pregnancy, body fat and elk habitat use. There is currently about 29 percent of Management Area 3 located more than one half mile away from open motorized routes, therefore areas that can provide both high quality nutrition and that are farther than a half mile from open motorized routes are limited. The road system likely also limits the carrying capacity of Management Area 3 to provide for elk population growth. Intuitively, when less area supports elk habitat use, the result is lower elk population potential. The desired conditions for increase nutrition that is usable by elk should help encourage conditions that will better provide for elk in forestwide including Management Area 3.

The integrated approach to evaluating nutrition and open motorized uses outlined within Management Approaches could result in improvements in the capacity of the landscape to provide for elk populations, especially within Management Area 3 because it would provide a mechanism to strategically locate high quality nutrition away from open motorized routes. This can happen through a combination of increasing nutrition while also increasing distances from open motorized roads and trails through strategic travel decisions. Plan direction and the framework within management approaches would encourage this integrated framework to provide for elk habitat use and nutrition. The specific process is spelled out in the management approaches section of the plan. The spatial layers for nutrition potential used in conjunction with the travel management system will allow strategic placement of elk habitat treatments.

The integrated framework outlined within management approaches provides an analytical framework through which to base decisions to evaluate tradeoffs of the combined effects of nutrition and motorized access for the benefit of elk. The framework would provide alternatives within projects to evaluate the road system concurrently with the production of nutritional resources to maximize elk use of nutrition. The steps to the management approach framework for elk essentially takes the following steps: 1) calculate all nutritional resources within a HUC 12 watershed or watersheds where the project is located, 2) use the nutrition potential map to identify the areas for treatment, 3) calculate the change in area of high quality nutritional that would result from the project, 4) subtract out any nutritional resources not usable by elk because of proximity to open motorized roads or trails, and also evaluate how slope, nutrition and the arrangement of nutrition across the watershed would provide habitat use 5) provide alternatives and outcomes for motorized use, nutrition, slope, and the arrangement of nutrition on the landscape to evaluate how much additional usable nutrition is created by the project by alternatives. More specifically, the project would evaluate how existing open roads impact use of high quality nutrition; evaluate how new road segments might affect the use of high quality nutrition if they remain open to the public; and identify which roads, new or existing, might have the most impact to nutrition use and high quality nutrition and offer decision makers the opportunity to consider alternatives that strategically closing new or existing roads to the public where appropriate to increase elk habitat use especially of high quality nutritional resources. The deciding official could then weigh the alternatives and potentially select those that would maximize elk habitat use and nutrition production to the benefit of elk fat accretion and pregnancy. Guideline MA3-GDL-ELK-01 would require decision makers to improve predicted cow elk body fat when conducting treatments to benefit elk habitat. Specifically, the term predicted body means to change habitat conditions to improve predicted body fat and support higher pregnancy rates using four covariates that have been found to influence habitat use and sufficient nutrition (Rowland et al 2018). These include the amount of high-quality nutrition, distance to nearest road open to motorized use by the public, distance to cover-forage edge, and slope.

Management Areas 1 and 2 provide more areas without open motorized roads and trails but are projected to have areas of high nutrition remain static in the model. However, the nutritional response layer and objective MA2-OBJ-ELK-01 would provide the ability to target the best nutritional resources. New roads are restricted by the Idaho Roadless Rule. However, two plan components constrain motorized use to the benefit of elk in Management Area 2. FW-DC-MLMU-07 is a desired condition that motorized access does not preclude use of high-quality nutritional resources or winter ranges. FW-GDL-WL-05 constrains the establishment of new motorized roads and trails unless areas 5000 acres or larger can be maintained without motorized access. The guideline includes a few exceptions, from which it does not apply. The guideline does not apply to Community Protection Zones as defined by the Idaho Roadless Rule: Areas with existing motorized access that are currently less than 5,000 acres; and existing trails that are relocated or reconstructed to mitigate negative impacts to ecological resources.

These plan components would maintain both large areas without motorized uses and prevent motorized trails from impacting habitat use of nutritional resources.

It is important item to note that the SIMPPLLE model simulations were not programed to prioritize the areas of highest nutritional response; rather, we projected treatments randomly within constraints of Management Areas to achieve desired vegetation conditions. Therefore, it only shows the response of achieving desired vegetation conditions.; In reality, projects could be strategically directed to areas that have higher potential nutritional response to result in greater benefits to elk nutrition than SIMPPLLE model results suggest.

A forestwide analysis was conducted to evaluate whether the desired conditions for elk could be achieved and how much treatment would be needed to achieve higher body fat levels in elk within each HUC 12 watershed. All HUC 12 watersheds within the plan area have the nutrition potential to produce at least 20 percent of their area in nutrition categories of 2.6 kilocalories per gram or higher (Figure 115). Some watersheds, despite having sufficient total nutrition potential, do not have enough potential nutrition outside of the influence of open motorized routes (farther than one-half mile) to allow the watershed to achieve 10 percent area with high quality nutrition to enable elk use (Figure 115). For example, 38 out of 238 watersheds in the plan area do not have enough high-quality nutrition potential outside one-half mile from a road to reach 10 percent usable nutrition. Most of these watersheds are those within Management Area 3. Treatments within these watersheds would not be the most effective for elk enhancements.

Watersheds where roads preclude use of high-quality nutrition could be improved by strategic and surgical changes to the travel system in conjunction with improvements in existing nutrition in high potential areas. The treatments could include relocation of existing motorized routes to areas with low nutrition potential or surgical closures of open motorized routes in areas with high quality potential nutritional resources. The total area that would need to be increased to enable potential nutrition outside of one-half mile from an open road to reach at least 10 percent amounts to about 40,283 acres within the 38 watersheds identified above. Assuming, that 1 mile of road closure is approximately 640 acres of habitat per mile of road closed, then it would take about 63 miles of open motorized route closures or relocation to allow each watershed to achieve a minimum of 10 percent usable nutrition potential. However, this number of closures or any closures for that matter may not be feasible given the road system is a minimum needed for forest management. In these cases, nutrition could be improved as far from open motorized routes as possible as identified by site specific analysis. Additional nutrition could potentially offset some effects of motorized routes as suggested by Ranglack (2016, 2022).

The travel system of open motorized routes (roads or motorized trails open to the public) complicates whether the nutrition currently available is useable by elk (Figure 116). Seemingly, the road system would reduce use of high-quality nutrition below 10 percent of the landscape even when the total area with this level of nutrition is present. When the system of motorized routes is considered, 78 watersheds currently do not provide at least 10 percent of the area of watersheds outside of one-half mile from an open motorized route. A total of 53 watersheds has between 10 and 20 percent of their area producing at least 2.6 kilocalories per gram dietary digestible energy (DDE), and about 107 HUC12 watersheds provide more than 20 percent of their area with at least 2.6 kilocalories per gram DDE (Table 295). These conditions leave many areas of the Nez Perce-Clearwater without adequate available nutrition to support good body condition and pregnancy from a habitat use perspective. A total of 95,195 acres of treatment would be required outside of one-half mile from a road to allow the 78 watersheds to reach a minimum of 10 percent area with adequate nutrition. The treatments would likely need to be either treatments outside one-half mile of open motorized routes, or an increase in the space outside one-half mile of the motorized route system with high nutrition or both concurrently in some watersheds.

A total of 33 watersheds has high amounts of nutrition total (≥20 percent) but not more than 10 percent of the nutrition exists outside of one-half mile. An additional 27 have between 10 and 20 percent but not enough outside of one-half mile from a road to provide 10 percent available nutrition (compare Figure 116 with Figure 117). Twenty-seven watersheds have enough nutrition total to exceed 20 percent but have only 10 percent of it outside one-half mile from a road. Twenty-six watersheds have between 10 and 20 percent currently with between 10 to 20 percent outside of one-half mile from a road. A total of 107 watersheds has a total amount higher than 20 percent and also have more than 20 percent outside of one-half mile from a road.

Table 295. The number of HUC 12 watersheds with various percent ranges of areas with nutrition equal to or higher than 2.69 kcal/g of dietary digestible energy (DDE)

Percent of area that has 2.6 kcal/g DDE	Number of Watersheds	Status
Watersheds that have 0-10%	18	Insufficient to support elk
Watersheds that have 10-20%	53	Supports pregnancy
Watersheds 20-40%	81	Supports high levels of pregnancy
Watersheds with ≥40%	86	Supports High Levels of pregnancy

In the Nez Perce-Clearwater landscape treatments produce high quality nutrition for about 20 years post disturbance (Rowland 2018). In terms of total treatments needed to maintain adequate nutrition on the landscape as a basis for a forestwide objective, approximately 10 percent of the total forest would need to be treated every 10 years or approximately 20 percent every 20 years to achieve 10 percent nutrition at the landscape scale. That would equate to about 393,906 acres of treatment every decade, which is well within the amount needed to achieve desired vegetation conditions (recall the plan objectives for total disturbance was 530,000 to 645,000 acres of treatment per decade). These treatments could occur as part of treatments to meet desired conditions for vegetation, via wildfire, or through treatments specifically to benefit elk, but would not exceed the total disturbance amounts per decade specified in description of the alternatives in the Final Environmental Impact Statement. To have the greatest effect, these treatments would have to occur within areas with high nutrition potential. Thus, under the plan the main consideration is whether those treatments occur within areas with high nutrition potential and particularly whether that nutrition will be usable by being located outside of one-half mile from an open motorized route. SIMPPLLE modeling suggests that the greatest change in nutritional response under the plan would occur within Management Area 3 and these are also the areas with the highest nutrition capacity. Treatments within Management Area 3 accounted for nearly all the increase in total nutrition within the plan area. This information formed the basis of objectives for elk habitat treatments. A technical guide was developed by Pacific Northwest Research Station to enable practitioners to better recognize areas that would support high nutrition potential and select areas for treatments. This technical guide is due out in 2023.

A few brief observations are in order. First, some watersheds are not capable of producing a minimum of at least 10 percent nutrition. These watersheds would not be a priority for treatments towards elk habitat improvements but it would be appropriate to provide as much high quality nutrition as the landscape allows or provide more areas of moderate or lower quality nutrition to compensate. Some watersheds might have a travel system which makes it possible to achieve at least 10 percent away from open motorized uses. In these watersheds, it may not be possible to close roads because the travel system in some of these watersheds support main access points into the Nez Perce-Clearwater and could not be closed. These watersheds would be lower priority for treatments to enhance elk habitat, and the strategy might be to provide more high-quality nutrition, even if it cannot be located away from open motorized routes. In watersheds that have adequate total nutrition, but not enough away from open motorized routes, the strategy could include a careful evaluation of the travel system to determine if improvements could be made, or by increasing high quality nutrition in places located away from open motorized routes. These watersheds would be a higher priority for treatments. The highest priority watersheds for treatments to improve elk body fat at the landscape scale, are those with inadequate nutrition and a motorized travel system with secure habitats sufficient to allow the creation of high-quality nutrition located away from open motorized routes. This could be accomplished by nutrition enhancements alone and measures to maintain the road system at current levels would be appropriate. The watersheds that have adequate nutrition away from roads would benefit from a strategy to periodically maintain or renew nutrition.

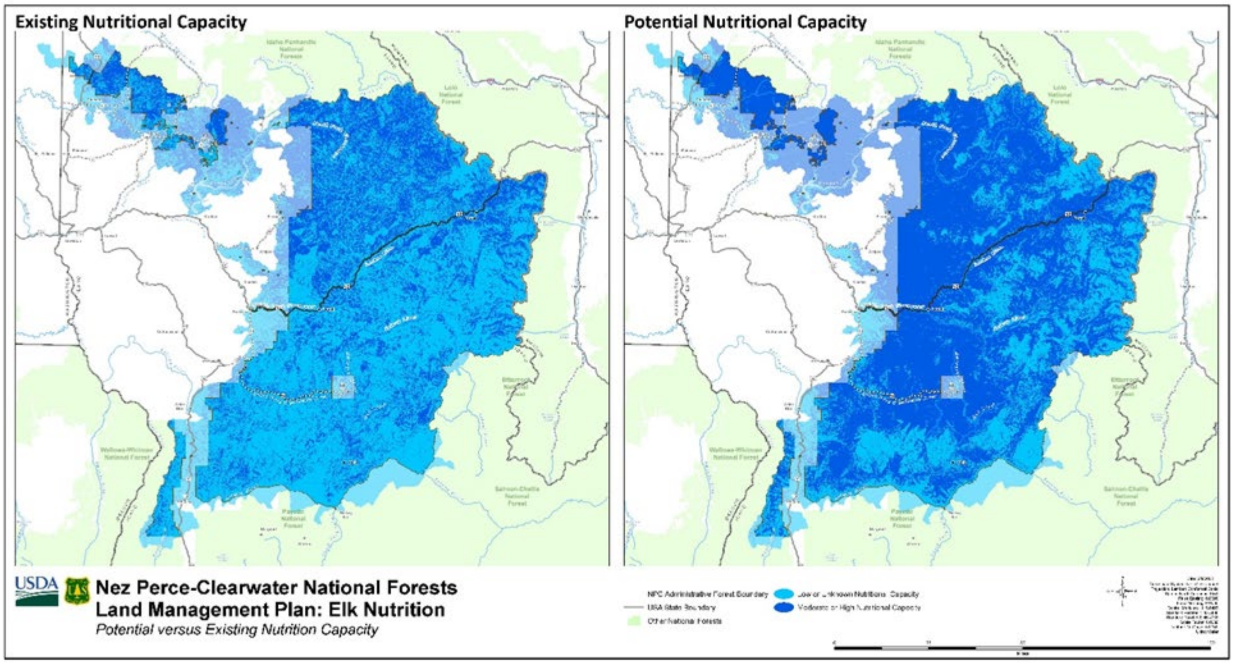

Figure 115. The existing (map A on the left) and potential nutrition (map B on the right). The map on the right shows the areas in dark blue that would produce a ≥ 2.6 kcal/g of dietary digestible energy if the canopy was reduced. The map on the right shows the estimated areas that currently have ≥2.6kcal/g dietary digestible energy shown in dark blue based on National Land Cover Canopy Data as of 2016. Light blue colors represent areas that produce less than 2.6 kcal/g of dietary digestible energy.

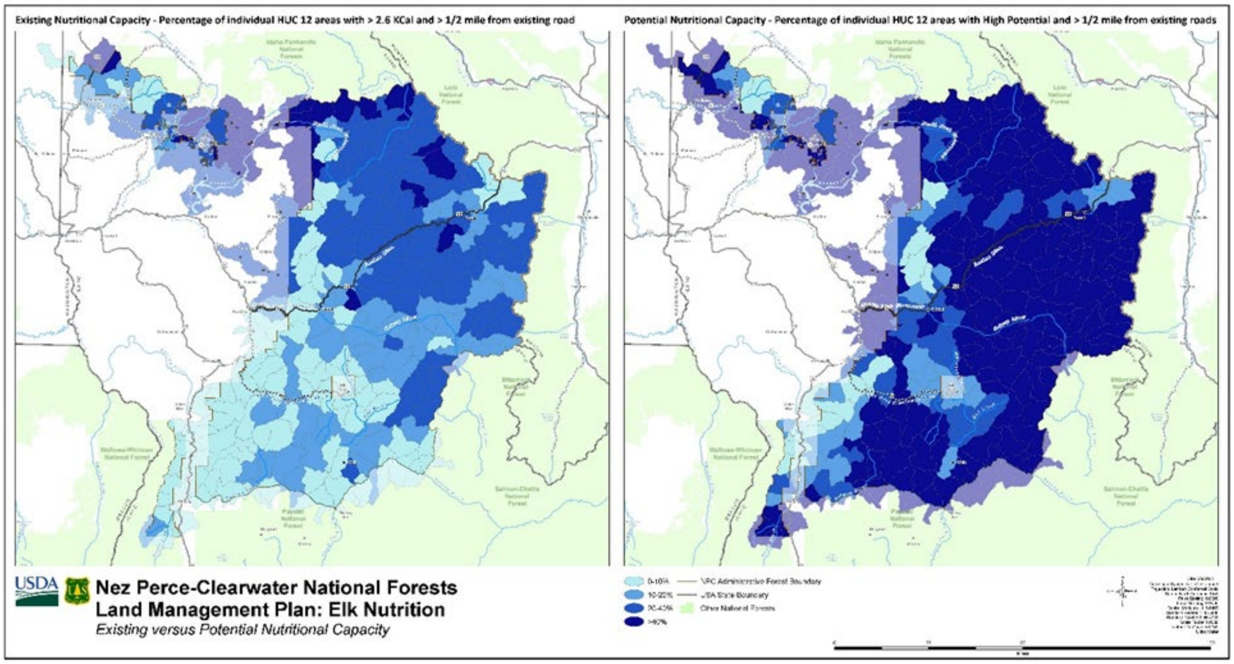

Figure 116. The existing (Map A on the left) and potential nutrition (Map B on the right) outside 1/2 mile from an open motorized route. The colors represent the amount as a percent of the watershed that contains one of four ranges ≥40 percent, 20 to 40 percent, 10 to 20 percent, 0 to 10 percent located outside one-half mile from an open motorized route. The darkest blue represents watersheds with ≥40 percent of their area having 2.6kcal/g located outside of one-half mile from an open motorized route, whereas the lightest blue represents watersheds that have less than 10 percent of their area with ≥2.6kcal dietary digestible energy outside of one-half mile from an open motorized route.

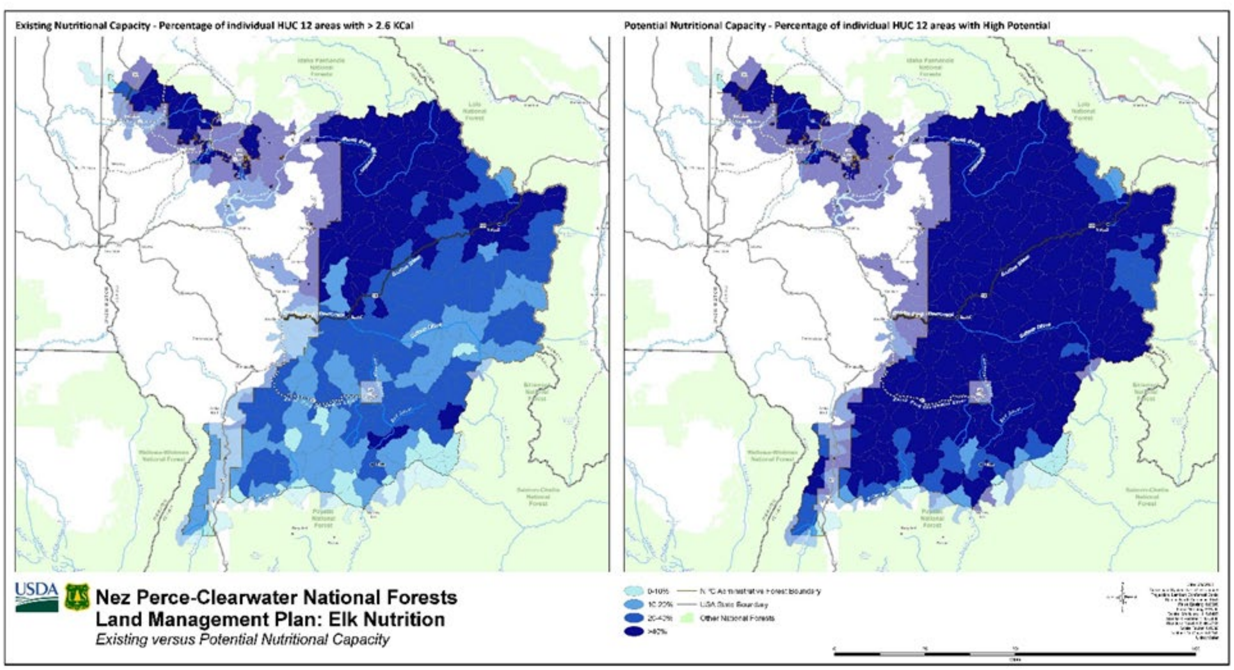

Figure 117. The amount of existing (Map A on the left) and potential nutrition (Map B on the right) within HUC 12 watersheds. The watersheds are colored to represent amount as a percent of the watershed that contains one of four ranges ≥40 percent, 20 percent to 40 percent, 10 to 20 percent, 0 percent to 10 percent. The

darkest blue indicates potential to produce 40 percent or more, lighter blue indicates areas that have the potential to produce between 20 and 40 percent, lighter blue indicates the potential to produce between 10-20 percent while the lightest blue watersheds indicate the potential to only produce less than 10 percent high quality nutrition.

Current estimates of body fat measured on captured female elk suggest they are currently below 8 percent on herds in the South Fork Clearwater samples, just below 10 percent on North Fork Clearwater elk herd, just above 9 percent on the Lochsa elk samples, and about 8 percent on the Riggins population samples. Pregnancy rates are between 70 to 95 percent in these herds. Increasing body fat, which should lead to improved pregnancy rates among female elk would directly increase reproductive performance of elk populations.

Figure 118 through Figure 123 show the change in the acres of various levels of dietary digestible energy by management areas as modeled in SIMPPLLE. These predictions suggest a positive change in nutritional quality, body condition, and reproduction across most alternatives, with alternatives that have a quicker schedule for restoring vegetation desired conditions having more benefits to elk.

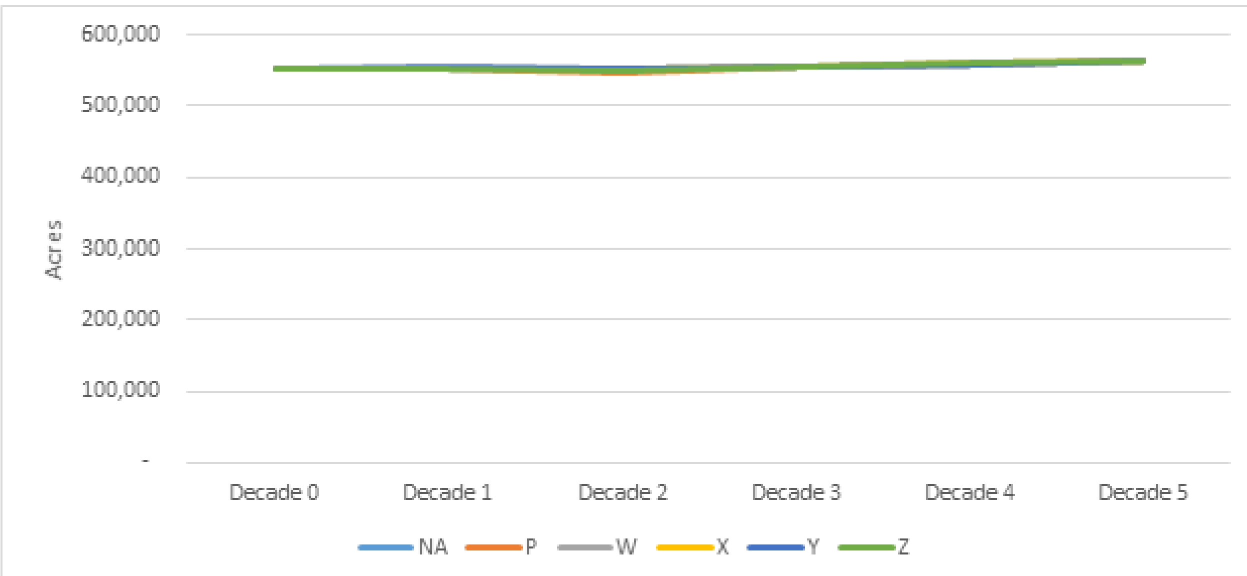

Figure 118. Acres of elk habitat projected to provide 2.58+ kcal/g dietary digestible energy (sufficient for higher elk pregnancy rates) by alternative and decade within Management Area 1, which is composed of protected areas such as wilderness, wild and scenic rivers, and the National Historic Landmark

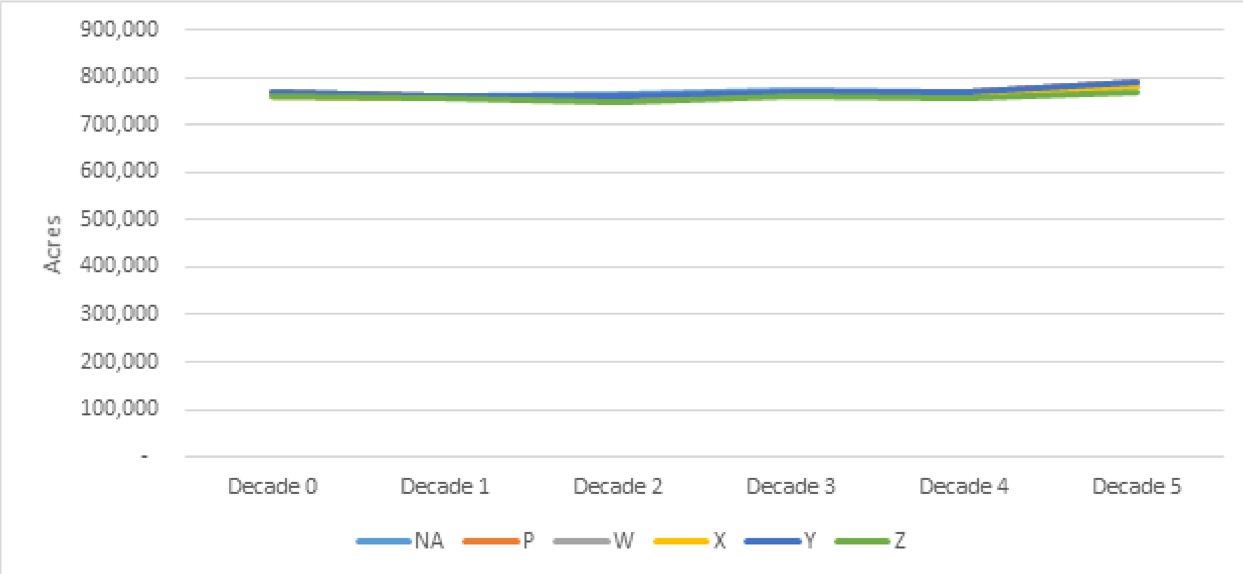

Figure 119. Acres of elk habitat project to provide 2.58+ kcal/g dietary digestible energy (sufficient for higher elk pregnancy rates) by alternative and decade in Management Area 2, which is composed primarily of Idaho Roadless Rule areas and recommended wilderness area

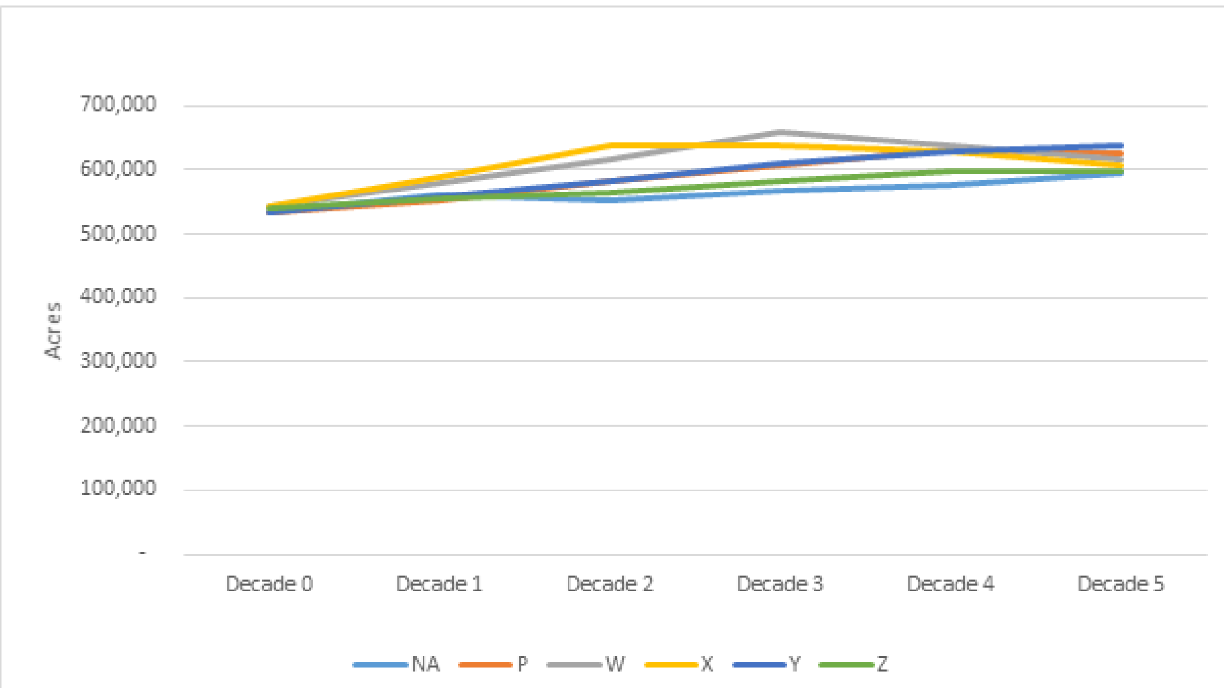

Figure 120. The trend in projected elk habitat acres predicted to provide ≥2.58 kcal/g dietary digestible energy (sufficient for higher elk pregnancy rates) by alternative and decade in Management Area 3, which is composed primarily of non-designated areas

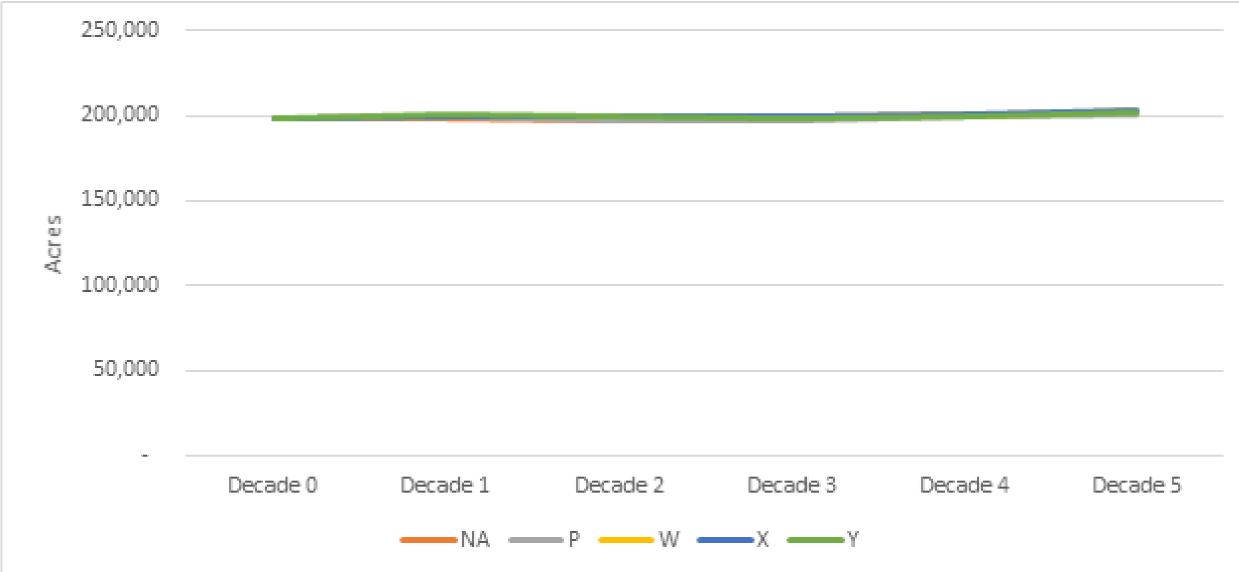

Figure 121. Projected elk habitat acres needed to provide 2.75+ kcal/g dietary digestible energy (sufficient to promote elk body fat) by alternative and decade for Management Area 1, which is composed of protected areas such as wilderness, wild and scenic rivers, and the National Historic Landmark

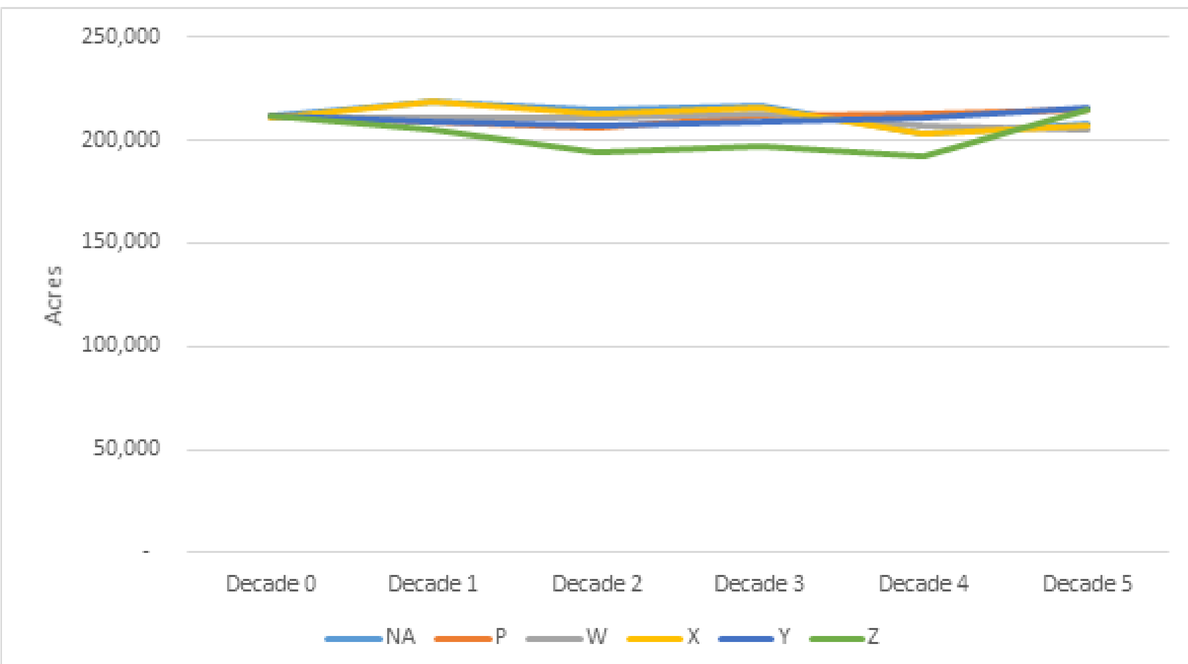

Figure 122. Projected elk habitat acres needed to provide 2.75+ kcal/g dietary digestible energy (sufficient to promote elk body fat) by alternative and decade for Management Area 2, which is composed largely of Idaho Roadless Rule areas and recommended wilderness

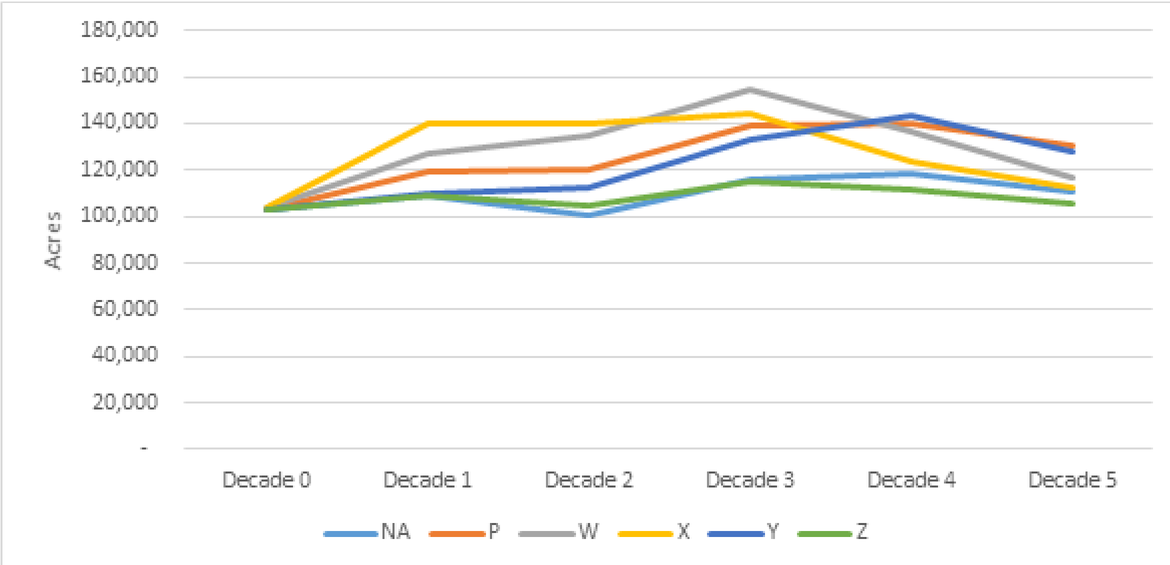

Figure 123. Projected elk habitat acres needed to provide 2.75+ kcal/g dietary digestible energy (sufficient to contribute to elk body fat) within Management Area 3, which is composed primarily of non-designated areas

Calf survival is influenced by size at parturition, which is influenced by nutrition. Thorne (1976) studied the relationship between adult nutrition, calf weight, and survival in captive elk. This study showed weight loss during pregnancy was significant and directly correlated to calf weight at birth and at four weeks of age. Thorne (1976) found that calves that weighed 35 pounds at birth survived better than calves that weighed 25 pounds at birth. The data indicated that cow elk that lost three percent of their body weight during pregnancy did not produce calves that weighed 35 pounds at birth. Thus, better elk nutrition can provide for better calf survival.

Some commenters were concerned about the shift from an emphasis on winter habitat to an emphasis on summer nutrition. According to the nutritional response spatial layer, some of the poorest areas for predicted nutritional response are on winter ranges because of thinner soils and drier conditions. Therefore, while winter habitats are important to big game, these areas often do not produce the desired nutritional response. The plan emphasizes reducing disturbance in desired conditions FW-DC-WLMU-01 and FW-DC-WLMU-07, which expresses a desire to provide for big game habitats in their respective seasonal ranges and reduce disturbances in winter range. The intent of these guidelines is meant to reduce disturbance during winter. FW-GDL-WLMU-03 is intended to prevent disturbance to wintering big game to achieve the desired conditions for winter habitat.

FW-DC-WLMU-06 is a desired condition that desires maintain or improve elk habitat use and provide nutritional resources sufficient to support productive elk populations. In some areas, treatments could produce both high quality summer and winter nutrition concurrently. The collaborative elk group voiced concern to prevent habitat management for elk from extending beyond the vegetation desired conditions in the terrestrial ecology plan components, which are based on the natural range of variation. Therefore, desired condition FW-DC-WLMU-06 contains language that would direct management to operate within the framework of the terrestrial vegetation components. Similarly, there is a recognition that noxious weeds adversely impact some important wintering areas, so the plan also included a desired condition that elk habitat are composed of native vegetation for early seral states.

MA3-GDL-WLMU-01 is a constraint that requires improvement in predicted cow elk body fat. The requirement is meant to improve predicted cow elk body fat which would require improving one or more of four factors that either provide nutritional resources or improve habitat use, or both. These factors include increasing distance from roads to improve habitat use, increasing high quality nutritional resources, increasing habitat interspersion, or either increasing habitat use or nutritional resources on slopes less than 40 percent. It is anticipated that this framework will tie habitat conditions directly to increased elk vital rates over time. MA3-GDL-ELK-01 only applies to Management Area 3. This guideline would provide a long-term improvement in elk habitat conditions in Management Area 3. It was selected to apply to Management Area 3 only because areas in Management Areas 1 and 2 have fewer factors that affect habitat use, so the focus in those areas is on improving nutrition.

Guidelines FW-GDL-WLMU-01 is intended to ensure motorized route closures remain closed. FW-GDL-WLMU-02 is designed to reduce or prevent fencing from creating a barrier to wildlife movements for game animals. Perhaps the change that would affect elk the most are plan components that identify where some types of uses are suitable to occur. Suitability is a new type of plan component allowed within the 2012 Planning Rule. Identifying lands as suitable for specific uses is a way to identify if lands are suitable for that use. For example, the plan must determine where motorized uses would be suitable. A suitability determination does not authorize anything specific on the ground but identifies where those uses are suitable in future decisions. It should be noted that, even though an area is identified as suitable, does not necessarily mean that the use would occur there, only that it could after a site-specific analysis and decision.

The alternatives vary the types and amounts of areas that are suitable for a variety of uses, including motorized and non-motorized uses, which are determined by the recreation opportunity spectrum settings. Three settings, the rural, roaded natural, and semi-primitive motorized settings, are suitable for motorized uses, while the primitive and semi-primitive non-motorized settings are not suitable. Under the existing condition, approximately 45 percent is suitable for summer motorized use, while 55 percent of the Nez Perce-Clearwater is not suitable for motorized uses. Similarly, about 39 percent of the Nez Perce-Clearwater is suitable for winter motorized travel, whereas 61 percent is unsuitable.

The components for elk do not vary by alternative as they were designed to increase elk herds, a goal common to most parties and desired by most elk comments. Elk habitat management has been a focus and priority in the plan. Several commenters requested constraints in the plan to protect elk calving areas. The Nez Perce-Clearwater evaluated elk calving models provide by the Idaho Department of Fish and Game and determined that calving areas and needs are similar to those used for female elk nutrition. The models are not specific enough to use in Forest Plan guidance.

Whitetail and Mule Deer

The plan components address habitats for deer by addressing the needs for ungulates, as noted above. Other than those plan components, the plan does not specifically address whitetail or mule deer. It is anticipated that plan components to increase high-quality forage for elk will also benefit deer. Similarly, plan components that restore forest habitats are also expected to benefit deer because they emphasize increasing the amount of early seral habitat conditions. Whitetail deer use forested habitats in the winter while mule deer use non-forested habitats in winter. In the summer, deer seek areas with good forage, such as meadows, shrub lands, and early seral habitats. Plan components for forest size class provided diversity of age in size classes to provide hiding cover, forage, and winter habitat for deer. Guideline FW-GDL-WLMU-03 restricts disturbing activities on winter ranges, which will serve to reduce disturbance to these species during this challenging time. FW-GDL-WLMU-02 restricts creating barriers through fencing. FW-GDL-WLMU-01 also addresses impacting deer through motorized use outside of the national forest's designated road system. Plan components in the fire section seek to restore natural fire disturbance and reduce uncharacteristic wildfire. Plan direction in the Forestlands section of the document suggests an increase in early seral forests across the broad potential vegetation types. These increases would benefit both mule deer and whitetail deer. Modeling results indicate that wildfire is the biggest driver of forest condition in the plan area. Fire plan components help facilitate the increased use of wildland fire to restore vegetation conditions. Plan components found in the meadows, grassland, and shrubland section should contribute to habitats for deer. The effects of the plan direction are generally beneficial to deer populations.

Moose

Moose populations are increasingly thought to be responsive to the amount of forage available to them. Like deer, moose will benefit from increases in high quality nutrition provided by both ecosystem plan components and elk plan components. Plan components will help provide conditions to improve habitat conditions for moose and restore forest habitats, benefiting moose because they emphasize increasing the amount of early seral habitat conditions. Moose use forested habitats in the winter and particularly rely upon Pacific yew as winter forage. FW-DC-WLMU-04 emphasizes Pacific yew as a winter food for moose. In the summer, moose seek areas with good forage, such as early seral forest habitats, meadows, shrublands, and aquatic vegetation. Plan components for forest size class provide diversity of age in size classes to provide hiding cover, forage, and winter habitat for moose. FW-GDL-WLMU-03 restricts disturbing activities on winter ranges and will protect these species during this challenging time. Plan components in the multiple use wildlife section restrict creating barriers through fencing, which are known to affect calves. Fire plan components seek to restore natural fire disturbance and reduce uncharacteristic wildfire, which should benefit moose through increased early seral conditions and nutrition. Modeling results indicate that wildfire is the most influential driver of forest conditions. Plan components can help facilitate the increase of wildland fire to restore vegetation conditions, benefiting moose. Meadows, grassland, and shrubland plan components should contribute to habitats for moose.

Mountain Goats

Few plan components are directed towards mountain goats, as most habitats are inaccessible to anthropogenic threats and are protected in many ways by restrictions in wilderness, recommended wilderness, or roadless areas. FW-DC-WLMU-05 and FW-DC-WL-03 would help to increase connectivity for mountain goats. Lack of connectivity from current populations to unoccupied suitable habitats is suspected to have caused mountain goat habitats to remain unoccupied and is thought to be caused by fire suppression, which creates conditions unfavorable to mountain goat travel at high elevations. Connectivity between mountain goat populations and suitable habitats potentially prevents mountain goat distribution from increasing in areas formally occupied by mountain goats. FW-DC-GS-05 describes desired vegetation conditions in subalpine areas, including mountain goat habitat, and would direct management towards improved forage conditions for mountain goats. While there are few plan components specific to mountain goats, alternatives for recommended wilderness and motorized over-snow travel suitability within recommended wilderness has potential impacts to mountain goats. Mountain goats are sensitive to disturbance and tend to leave suitable habitats if disturbed. The effects are particularly acute during the winter when mountain goats may not be able to travel through deep snow. Alternatives for recommended wilderness in the Hoodoo area, the Mallard-Larkin area, Moose Mountain, and Bighorn Weitas would include several mountain goat herds, including some of the largest herds in the plan area. Allowing these areas to be open to motorized over-snow travel could potentially expose mountain goats to this disturbance.

In the Preferred Alternative, the Mallard Larkin and Hoodoo areas were identified as recommended wilderness with modified boundaries as compared to the No Action Alternative. These modified boundaries were a compromise between the desires of motorized winter recreationalists and providing protections for mountain goats. They excluded areas popular with recreational users from recommended wilderness so that use could be suitable for motorized winter recreation. However, areas of concentrated use by mountain goats were included in recommended wilderness and would not be suitable for summer nor winter motorized uses. This strikes a balance in providing for both the desires of winter recreational users and the protection of mountain goat populations. These recommended wilderness areas contain two of the three largest herds in the plan area. The other large herd is located in designated wilderness areas and is also protected from winter recreation disturbances. The Preferred Alternative does not include the Bighorn Weitas area nor the Moose Mountain wilderness area, which contains small herds of mountain goats. Additionally, winter motorized recreation in recommended areas were found not suitable so these measures would protect mountain goats in the plan area from disturbance.

To understand snowmobile use in the plan area, landscape characteristics selected by snowmobilers were modeled spatially to evaluate the overlap of mountain goat habitats and other wildlife habitats with modeled snowmobile preferences (Olson et al. 2017). Modeling was conducted by Lucretia Olson and used parameters similar to those she used in Olson et al. (2017). The model was validated by user data and Forest Service recreation staff who have expert knowledge of the use in the plan area. The snowmobile model is a function of terrain, access, canopy cover, and snow depth, which are features that may contribute to the ease of which snowmobilers can use an area. It creates a probability surface, at which values closer to one would be preferred for snowmobiling while those closest to zero would not be preferred. It does not necessarily predict where snowmobile use is occurring or the number of snowmobilers using an area because use also depends upon whether the areas are open administratively, have available access, or other factors. Rather, it predicts where snowmobiling might be desirable or easier to the average snowmobile user. The model appeared to represent well where most snowmobile use is occurring and performed better in the Clearwater side of the national forest than on the Nez Perce side.

Model results suggest low amounts of overlap between snowmobile use and known mountain goat population areas. This makes sense because most mountain goat habitat is too steep for comfortable snowmobile use. However, some areas predicted to have high probability values in the snowmobile model are in proximity and adjacent to known mountain goat herds, particularly the herd on Blacklead Mountain, which may leave them susceptible to access by highly skilled snowmobilers. Highly skilled snowmobilers can access steeper terrain and more rugged conditions that average snowmobilers. The model did not perform well at predicting use by highly skilled snowmobilers because it shows areas known to be used by advanced snowmobile users as not preferred by typical snowmobilers. The model only predicts snowmobiler preferences and does not predict snow bike use, which may have different use patterns than snowmobiles.

Bighorn Sheep

This section evaluates the effects to bighorn sheep as a species used by the public for multiple uses. Bighorn sheep in the plan area are provided for through plan components for ungulates. FW-DC-WLMU-03 emphasizes that the habitats in the plan area provide for ungulate species that meets their life history requirements in both summer and winter. As noxious weeds are a challenge throughout the west and in the plan area, FW-DC-WLMU-03 has language desiring that big game habitats are composed of native vegetation. Plan components in the invasive section of the document also serve to provide for bighorn sheep habitats. Fire plan components and those for forested vegetation would also help increase disturbance that would decrease encroachment of forested habitats into bighorn sheep habitats. FW-GDL-WLMU-03 restricts disturbing activities on winter ranges, which will serve to protect these species during this challenging time. Plan components in the Multiple Uses Wildlife section of the the plan would help provide for continued opportunities for hunting at harvestable and huntable populations of bighorn sheep.

Wolves, Cougars, and Black Bears

Wolves, cougars, and black bears are not emphasized in the plan specifically. The populations of wolves and cougars are dependent upon healthy ungulate populations, which are provided for in the plan. Black bears are dependent upon ungulate populations and resources such as berries, seeds, and vegetation for forage. A variety of forested successional stages and coarse filter ecosystem plan components for size class provide the vegetative forage for bears, as well as cover conditions. The primary factors influencing populations of these species is hunting pressure and ungulate populations. Plan alternatives provide some additional protection for these species though differing amounts of recommended wilderness, which can influence hunter access. Recommended wilderness would protect these species slightly better than Idaho Roadless Rule areas, but the differences are minor. Suitability of motorized uses also vary by alternative. The alternatives that find more area suitable could allow more motorized access in the future that could increase the area used for bear baiting. This would increase the opportunity for bear hunting but would also facilitate increased bear harvest. The primary benefit the plan provides for these species is that large remote areas provide refuge from hunter harvest. These characteristics are provided in Idaho Roadless Rule areas, recommended wilderness, and designated wilderness under all alternatives. The Idaho Department of Fish and Game regulates harvest of these species for their continued availability as a hunted resource. The Idaho Department of Fish and Game monitors population trend indicators and can apply appropriate measures to manage hunting to increase or decrease populations according to their management plans. Population objectives and hunting tag numbers, which are the primary drivers of hunter harvest, are not within the authority of the Forest Service. Current Idaho Department of Fish and Game objectives for populations of these species are lower than current population numbers and the Idaho Department of Fish and Game is managing for reduced numbers but persistent populations of these species.

Furbearers

Modeling results in SIMPPLLE suggest that both Pacific and American marten habitat remains within the the natural range of variation under all action alternatives and, while marten habitats decline slightly under the plan components over the next 50 years, martens should continue to persist in sufficient numbers to allow trapping (Figure 124) (Ecosystem Research Group 2021)(Ecosystem Research Group, LLC 2021). Marten habitat remains above the natural range of variability low and only declined slightly suggesting that martens will remain long term. Ecosystem plan components that can contribute to habitat for martens includes those in the cold and cool moist broad potential vegetation type group that speak to desired size classes, particularly those that pertain to larger size classes, large legacy trees and snags, downed wood and snags, multistory habitat for lynx, and the compositions of dominance types that will continue to provide for martens. Downed wood requirements in the plan provide for retention of downed wood for martens though the minimum size of three inches in these plan components would be too small. Still the desired conditions For forest size class and dominance type, requirements for live tree retention, and snag retention would still provide for marten habitat after disturbance. Timber production would only occur in Management Area 3, and a limited amount of timber harvest would occur outside Management Area 3.

Because the majority of marten habitat is within the Idaho Roadless Rule and designated wilderness areas, habitats should continue to function to provide for this species. Plan component MA1 and MA2-DC-FOR-05 would provide the patch and pattern at the landscape scale to continue to provide for marten. Guideline MA2 and MA3-GDL-FOR-01 would provide coarse woody debris for marten denning. MA3-DC-FOR-11 would generally provide for martens but some preferred forest types are not the old growth types emphasized in the plan (Ruggiero et al. 1994a). FW-DC-FIRE-01 seeks to allow wildfire to restore the structural characteristics of vegetation under a natural fire regime, and FW-OBJ-FIRE-03 is an objective to reduce uncharacteristic wildfire that potentially threatens marten habitats. FW-DC-WL-03 and FW-GDL-WL-01 would provide the arrangement of habitats on the landscape to provide connectivity for martens. Plan components for Canada lynx would also benefit martens. Marten prefer coniferous forest cover, but prey on a wide variety of small mammals, including those that have high densities in forest openings. Modeling results from PRISM and SIMMPPLE suggest that marten habitat will be relatively stable to slightly declining under the alternatives.

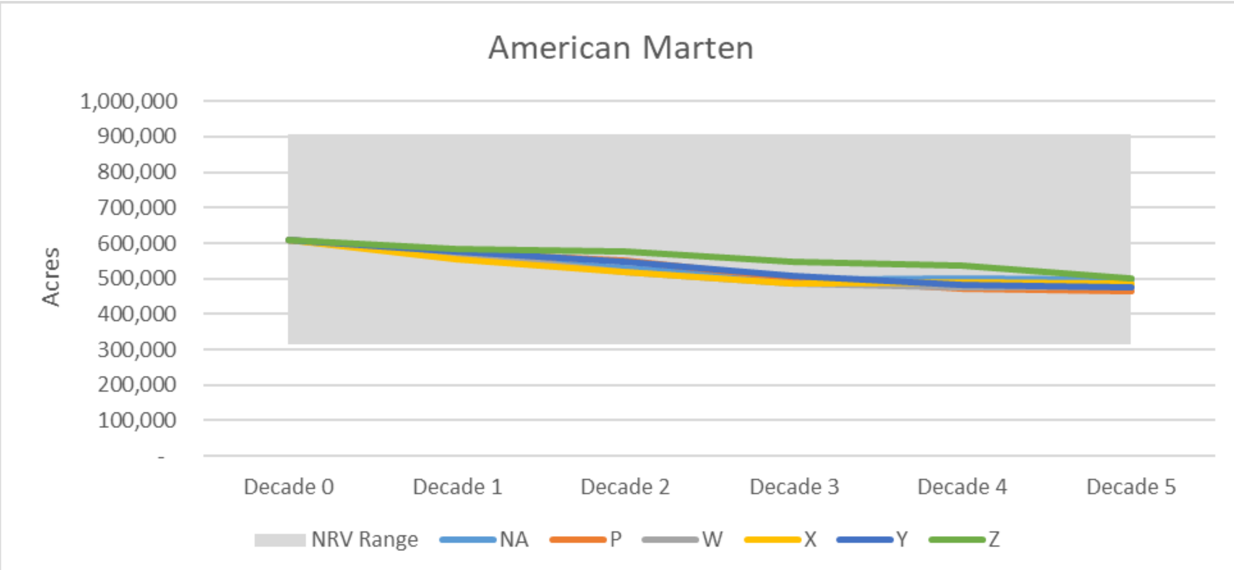

Figure 124. The trends in American marten habitat as modeled by SIMPPLLE and PRISM

The plans coarse filter ecosystem plan components would provide for species like coyotes and bobcats or other small to medium size carnivores. Plan components that would provide habitats are included in the forestlands, Meadow grassland and shrubland and aquatic plant components. The plan should continue to provide harvestable populations of furbearers.

Aquatics plan components in several sections of the plan would provide for species that use aquatic or riparian habitats, including rivers, open water, wetlands, and riparian habitats. They prevent many actions known to degrade aquatic habitats. Riparian areas evolved under disturbance regimes that promoted a variety of age classes in some riparian areas and naturally have more deciduous vegetation. Forest succession can allow conifer encroachment into riparian areas that crowd out deciduous woody plants. Disturbances, such as fire, kills encroaching conifers and allows for deciduous or hardwood species to become established again. Modeling in SIMPPLLE suggests that riparian areas have less hardwood dominated conditions than would occur under natural disturbance. Riparian habitats were modeled in SIMPPLLE and PRISM and the results suggested that disturbance within riparian habitat would increase over time, mostly as result of natural disturbance, to support increases in hardwood and deciduous vegetation in the riparian zones.

The plan has limited allowances but still has allowances in the aquatic ecosystem section that would allow restoration of these conditions to benefit a number of riparian and aquatic wildlife species. Beavers, for example, typically rely on deciduous trees and shrubs as a food source and do not tend to occupy stream reaches that are conifer dominated. A combination of natural disturbance and active restoration would increase or improve the amount of deciduous vegetation in the riparian area. These plan components provide a robust framework for managing aquatic and riparian habitats for waterfowl and furbearers that use aquatic habitats. They minimize or eliminate threats to these resources and provide ample protection against factors that alter these habitats. They include objectives that restore degraded conditions in the plan area. These plan components protect the vegetation surrounding water and reduce impacts that would affect flow, sediment, water quality, and geomorphology. These plan components are adequate to provide for the species that are grouped into the aquatic, wetland, water, and riparian habitat group, including the 32 species that are commonly used by people that use these habitats. These include all the waterfowl and several of the furbearers. American and Pacific martens have been reported to use riparian areas, and riparian management zone plan components will contribute to marten habitats. These areas should continue to provide the preferred forest types and structure that would provide for martens. Overall, the coarse filter ecosystem plan components would provide for furbearers.

No Action Alternative

Several species of wildlife used by the public would continue to experience declining habitat conditions due to forest succession and fire suppression. Emphasis for elk would continue to be on treating winter range and providing elk security addressing road density while not directly responding to the best available scientific information indicating that providing adequate summer nutrition usable by elk would increase elk vital rates. Elk security would remain high throughout Idaho Roadless Rule areas, wilderness areas, and recommended wilderness but elk populations would continue to be down in these areas. Management would continue with Elk Analysis Units as the scale and framework at which elk management is applied. These measures would continue to maintain the amount and intensity of elk security measures.

Modeling results suggest that, under all alternatives, the amount of high-quality forage greater than about 2.58 kcal/g of dietary digestible energy would increase. Forest conditions would trend towards increased nutrition and meet the needs of many multiple use species, especially upland game and ungulates. These changes are mostly driven by projections for increased wildfire under a changing climate, given our current fuels conditions. However, an emphasis on fire suppression in the 1987 Plans would continue and these results may not be realized. Management of natural fires would still be possible at similar rates as they have been. It was not possible for the model to account for the ability to target the areas that would produce the highest nutritional response; therefore, modeling only reflects the response to restoring vegetation back to the desired vegetation conditions. It may be possible through targeted restoration for elk to increase the amount of high-quality forage through strategic treatments.

This alternative did not use the recreation opportunity spectrum settings to identify suitability for motorized uses. Instead, motorized access was open unless closed by site specific projects or decisions. The 1987 plans impose other constraints on motorized uses that included constraints on roads imposed by fish conservation measures, elk habitat effectiveness measures, the identification of designated wilderness and more. The introduction of the Recreation Opportunity Spectrum to identify lands suitable for motorized uses is a new mechanism in the action alternatives that provides some constraints on motorized uses. These constraints cause a long-term decline in motorized access resulting in benefits to species that are sensitive to roads. Species like elk, black bear, and moose would benefit from motorized restrictions. However, the lack of motorized access has reduced the ability of the Idaho Department of Fish and Game and hunters to reduce predator populations. Alternatives that increase motorized access are better for predator reduction to help big game.

Waterfowl and furbearers that use aquatic habitats would be provided for in a similar manner as in the proposed plan components and alternatives because PACFISH and INFISH provide similar levels of protection for aquatic habitats as those in the Aquatic Ecosystems section of the Land Management Plan. Several rivers would remain eligible for wild and scenic status and management of these eligible rivers would continue to provide habitats for aquatic species. Eligible acres of wild and scenic river corridors would be 172,710 acres. These rivers would continue to be managed to protect the outstandingly remarkable values that make them eligible. This direction may help some multiple use wildlife species and may hinder active restoration for them in other areas. There would be no change in the amount of designated wild and scenic rivers.

Furbearers that use terrestrial habitats would be only affected by the amount of recommended wilderness and the amount of area suitable for motorized uses under the recreation opportunity spectrum under the alternatives and whether motorized over-snow travel was allowed. This is because trapping itself is the biggest factor in population changes for most of these species outside of prey abundance. The amount of recommended wilderness would directly influence accessibility during winter, which is when trapping is most effective and usually conducted. All Idaho Roadless Rule areas are suitable for winter motorized travel and these areas are not protected from the influence of trapping. Therefore, the amount of recommended wilderness and whether winter over-snow travel is allowed is the primary indicator for population trends of furbearers. In the No Action Alternative, over-snow motorized travel is not allowed in recommended wilderness and furbearers are less accessible to trappers than they are in other parts of the Nez Perce-Clearwater. The No Action Alternative is intermediate compared to the other alternatives in the amount of recommended wilderness. In all alternatives, furbearers would be provided for trapping and other uses and the Idaho Department of Fish and Game regulations, monitoring, and management would continue to sustain these species. For American and Pacific martens, the amount of habitat is estimated on the high end of the natural range of variation and preliminary modeling results suggest a decline in preferred mature subalpine fir and Engelmann spruce forests. However, these declines do not drop below those on the low end of the natural range of variation for marten habitat.

The amount of recommended wilderness would remain the same with the Hoodoo, Mallard-Larkin, and Selway additions remaining recommended wilderness. The Hoodoo area would stay intact in its current form and not be reduced, as in other alternatives. The amount of recommended wilderness would be intermediate compared to the other alternatives. Mountain goat populations in the Hoodoo recommended wilderness area would not be subject to motorized over-snow travel, as it is currently not allowed. In other alternatives, over-snow travel would be allowed. The amount proposed under the No Action Alternative is intermediate to other alternatives for recommended wilderness.

Within recommended wilderness, activities to restore vegetation would continue to be restricted. This would continue to inhibit most restoration activities in the current recommended wilderness. This would impact the national forest's ability to proactively restore these habitats and provide forage for ungulates or connect mountain goat habitat through disturbance. However, restoration activities in many other Idaho Roadless Rule areas that are currently in the backcountry restoration theme would remain in this theme, which allows restoration and improvements in big game habitat. Restoration would only be achieved in recommended wilderness through wildfire, which may not produce the best nutritional response. Under the 1987 Plans, the management direction for wildfire is to confine, contain, and control wildfire. Under the new plan direction, wildland fire would be more permissive in many areas of the Nez Perce-Clearwater.

Effects do not vary by alternative because the plan components were designed to provide for all species by providing ecosystem integrity. The plan does vary by alternative for species that require or use early seral habitats because the plan varies the pace at which desired conditions are achieved. For species that use early seral habitats, the No Action Alternative implements treatments to meet desired conditions at among the slowest paces among the alternatives. Species that use early seral conditions include ungulates and some furbearers. These species would not have habitat created for them at a faster pace compared to the other alternatives.

Both current recommended wilderness and Idaho Roadless Rule areas would continue to provide for wolf, black bear, and cougar populations. If the decline in high quality forage lead to low big game populations or continued downward trends, predator populations would also decline. Use of game carts, chainsaws, mechanized travel such as bicycles, and aircraft would continue to be prohibited in recommended wilderness.

Alternative W

Alternative W reaches desired vegetation conditions faster than the No Action Alternative and slightly slower than Alternative X. Thus, it has a relatively more aggressive schedule for restoring the system back to the desired conditions, which are based upon the natural range of variation. For ungulates, this quicker paced schedule would improve forage resources quicker than the No Action Alternative. While the pace may be quicker, the total amount of high-quality forage does not differ much overall among the alternatives.

Modeling results suggest that, under all alternatives, the amount of high-quality forage greater than about 2.58 kilocalories per gram of dietary digestible energy would increase, especially within Management Area 3. This makes sense because the desired conditions for vegetation do not vary by alternative, rather the pace or the methods of achieving those desired conditions vary. However, vegetation management would contribute substantially to forage as well, especially within Management Areas 2 and 3. Under Alternative W, forest conditions would trend towards increased nutrition to meet the needs of many multiple use species. The more proactive schedule in Alternative W would allow more areas to be targeted to increase the amount of the highest quality forage while restoring forests to towards their natural range of variation. Proactive management through wildland fire would occur more proactively under Alternative W in Idaho Roadless Rule areas, especially within backcountry restoration themed areas. Management of natural fires in designated wilderness would still be possible at similar rates as they have been under the No Action Alternative. The ability of the Nez Perce-Clearwater to achieve desired amounts of elk forage would be hindered within recommended wilderness as explained below.

In Alternative W, slightly more areas were identified as suitable for motorized uses compared to the No Action Alternative. This could reduce elk habitat use in some areas, especially those that would be suitable for motorized uses. The percentage of the planning area that is suitable for summer motorized uses would be 47 percent, an increase of about 2 percent suitable for motorized use from the No Action Alternative. Forty-eight percent of the plan area would be suitable for winter motorized travel, while 52 percent would be unsuitable. Maps of the alternatives for the summer and winter recreation opportunity spectrum can be found in the Appendix A. Areas suitable for motorized uses could displace elk, and winter motorized uses would allow about 10 percent more access to winter trapping of furbearers. Limited access to some areas has resulted in the inability of the State to manage wolf and other predator populations resulting in significant reductions in big game. Alternatives with more motorized uses could help hunters and wildlife managers access areas to reduce predator populations. This alternative is a slight improvement over the no action in this regard, but is worse than the Preferred Alternative in how it allows for predator control purposes.

Waterfowl and furbearers that use aquatic habitats would be provided for in a similar manner in all alternatives as measures in PACFISH and INFISH are similar to those in the aquatic ecosystem plan components. However, under a more aggressive schedule of treatments, more potential impacts could occur under this alternative. Alternative W proposes the most rivers as suitable wild and scenic rivers. The proposed area of suitable wild and scenic river corridor is more than those eligible under the No Action Alternative. Eligible acres of wild and scenic river corridors would be 172,710 acres under the No Action Alternative versus 65,650 acres under Alternative W. This direction may help some multiple use wildlife species and may hinder active restoration for them in other areas under this alternative than in the No Action Alternative. There would be no change in the amount of designated wild and scenic rivers.

The amount of recommended wilderness would increase the most under Alternative W. In addition to the Hoodoo, the Mallard-Larkin, and the Selway additions, this alternative would add Bighorn-Weitas, North Lochsa Slope, East Meadow Creek, Moose Mountain, Rapid River, North Fork Spruce-White Sands, Sneakfoot Meadows, Meadow Creek-Upper North Fork, and West Meadow Creek. This amount of recommended wilderness would be the most compared to the other alternatives. The amount of recommended wilderness would have environmental consequences on mountain goats, furbearers, elk, and other ungulates and predatory big game, as described below. As such, many species that do well away from humans would do better when more recommended wilderness is identified.

Under Alternative W, more mountain goat populations would be included in recommended wilderness than other alternatives with the addition of herds in Moose Mountain, the southern portion of the Mallard-Larkin Idaho Roadless Rule areas, and the North Lochsa Slope Idaho Roadless Rule area. These mountain goat populations would benefit from the additional recommended wilderness area because they would not be subject to motorized over-snow travel under Alternative W. Access to mountain goats by hunters would be more difficult. On the other hand, the ability to connect mountain goat habitats within the plan area or the ability to improve mountain goat habitat conditions through active management would be constrained within recommended wilderness under this alternative. Comparatively, in Alternatives X and Y, over-snow travel would be allowed.

Furbearers that use terrestrial habitats would mainly be affected by the amount of recommended wilderness and whether motorized over-snow travel was allowed. This is because trapping itself is the biggest factor for effects for most of these species outside of prey abundance. The amount of recommended wilderness and motorized over-snow travel would directly influence accessibility during winter, which is when trapping is most effective and usually conducted. Idaho Roadless Rule areas, except those identified as recommended wilderness, are suitable for winter motorized travel and these areas are currently accessible for trapping facilitated by this increased access. Therefore, the amount of recommended wilderness and whether winter over-snow travel is allowed is the primary indicator for effects to furbearers. In Alternative W, the amount of recommended wilderness dramatically increases, and furbearers would be much less accessible to trappers than they are currently. While this would serve furbearers well, it would also adversely impact the ability for people to use this resource effectively. In all alternatives, furbearers would continue to be available for trapping, but access and availability decreases under Alternative W. The Idaho Department of Fish and Game regulates, monitors, and manages furbearers and this management would continue to sustain these species.

The ability of the Nez Perce-Clearwater to pursue active management to achieve desired conditions would be most constrained in this alternative compared to the others because of the high amount of recommended wilderness, which would make many areas that are currently in the backcountry restoration theme be managed more like the backcountry recreation theme. Active management for restoration purposes is strongly restricted in this theme. Therefore, the ability of the national forest to increase forage for elk and other ungulates in Management Area 2, as a result of restoring the natural range of variation, would be highly restricted under this alternative because so many of the Idaho Roadless Rule areas would be recommended wilderness. This would impact the national forest's ability to proactively restore these habitats for ungulates. Restoration would mostly be achieved in recommended wilderness through wildland fire, which may not occur in areas expected to produce the best nutritional response or would occur in areas with low nutrition potential. The limiting factor for elk in the plan area, particularly within the Roadless Rule areas, is the lack of forage because of lack of disturbance.

Both current recommended wilderness and Idaho Roadless Rule areas would continue to provide for wolf, black bear, and cougar populations. Under Alternative W, these species would be less accessible to the public in the recommended wilderness. Hunting is used by the Idaho Department of Fish and Game to reduce populations of predators and this alternative would provide for these species the most compared to other alternatives. However, if the decline in high quality forage leads to depressed or declining big game populations or continued downward trends, predator populations would also decline.

Under this alternative mechanized travel is prohibited in recommended wilderness, as well as game carts. The prohibition of mechanized travel, such as bicycles, would have slight benefits to big game because mountain bikes have been documented to displace elk (Wisdom et al. 2018). Bikes or other mechanized travel may have disturbance effects. Under this alternative, this activity would be prohibited in the largest amount of area. However, mechanized travel is not intensive in the plan area at the present time. The prohibition on the use of game carts might make some areas more difficult for people to remove game animal carcasses from recommended wilderness. The utility of game carts depends upon the terrain and vegetation conditions. In the plan area, game carts are not very useful unless there is a road or trail nearby or unless the terrain is fairly level. On the other hand, game carts allow some hunters to take animals farther away from roads or trails and transport game carcasses more effectively. Whether to allow or disallow game carts would have little effect on the wildlife, as most hunters have additional options that can allow removal of game carcasses.

Alternative X

Alternative X reaches desired vegetation conditions the fastest out of all the alternatives and slightly faster than Alternative W. Thus, it has the most aggressive schedule for restoring the system back to the desired conditions, which are based upon the natural range of variation. For ungulates, this quicker paced schedule would improve forage resources quicker than any other alternative. While the pace may be quicker, all alternatives seek to achieve the same desired forest conditions.

SIMPPLLE modeling results suggest that, under this alternative, the amount of high-quality forage greater than about 2.58 kilocalories per gram of dietary digestible energy would increase the fastest rate, mostly within Management Area 3. Vegetation management would contribute substantially to forage. Under Alternative X, forest conditions would trend towards increased nutrition to meet the needs of many multiple use species. The more proactive schedule in Alternative X would allow more areas to be targeted to increase the amount of high-quality forage while restoring forests to towards desired conditions. Proactive management through wildland fire would occur more under Alternative X in Idaho Roadless Rule areas, especially within backcountry restoration themed areas. As no areas would be identified as recommended wilderness, this alternative has the least constraints on improving habitat for big game. Management of natural fires in designated wilderness would still be possible at similar rates as they have been under the No Action Alternative.

In Alternative X, more areas were identified as suitable for motorized uses compared to the No Action Alternative. This could displace elk habitat use in some areas, especially those that would be suitable for motorized uses. The percentage of the planning area that is suitable for summer motorized uses would be 58 percent, an increase of about 13 percent suitable for motorized use compared to the No Action Alternative. Seventy percent of the plan area would be suitable for winter motorized travel, while 30 percent would be unsuitable. Maps of the alternatives for summer and winter recreation opportunity spectrum can be found in Appendix A. Areas suitable for motorized uses could displace elk, and more winter motorized uses would allow more access to winter trapping of furbearers. This would be good for trappers, but furbearers would be exposed to more trapping pressure. Species that are sensitive to motorized uses would not do as well under this alternative. Limited access to some areas has resulted in the inability of the State to manage wolf and other predator populations resulting in significant reductions in big game. Alternatives with more motorized uses could help hunters and wildlife managers access areas to reduce predator populations.

Waterfowl and furbearers that use aquatic habitats would be provided for in a similar manner in all alternatives as measures in PACFISH and INFISH are similar to those in the aquatics plan components. However, under a more aggressive schedule of treatments, more potential impacts could occur under this alternative. Alternative X proposes no rivers as suitable for wild and scenic rivers. The proposed area of suitable wild and scenic river corridor is more than those eligible under the No Action Alternative. Eligible acres of wild and scenic river corridors would be 172,710 acres under the No Action Alternative versus 0 acres under Alternative X. There would be no change in the amount of designated wild and scenic rivers.

The amount of recommended wilderness would be none under Alternative X, which would reduce the amount of recommended wilderness compared to the No Action Alternative. The Hoodoo, the Mallard-Larkin, and the Selway additions would no longer be recommended wilderness. The amount of recommended wilderness would be the least compared to the other alternatives. The amount of recommended wilderness would have environmental consequences on mountain goats, furbearers, elk, and other ungulates and predatory big game, as described below. The amount of designated wilderness would not change under this alternative.

Under Alternative X, no mountain goat populations would be included in recommended wilderness. All mountain goat populations currently in recommended wilderness would be subject to motorized over-snow travel, except for those in designated wilderness. This would be detrimental to some herds that are not in designated wilderness. On the other hand, the ability to connect mountain goat habitats or improve mountain goat habitat conditions through active management would be the most permissible in this alternative.

Furbearers that use terrestrial habitats would mainly be affected by the amount of recommended wilderness and whether motorized over-snow travel was allowed. This is because trapping itself is the biggest factor for effects for most of these species outside of prey abundance. Therefore, the amount of recommended wilderness and whether winter over-snow travel is allowed is the primary indicator for effects to furbearers. The amount of recommended wilderness and motorized over-snow travel would directly influence accessibility during winter, which is when trapping is most effective and usually conducted. Idaho Roadless Rule areas, except those identified as recommended wilderness, are suitable for winter motorized travel and these areas would be accessible for trapping facilitated by this increased access. In Alternative X, the amount of recommended wilderness dramatically decreases, and furbearers would be more accessible to trappers than they are currently. While this would serve to increase the ability for people to use this resource effectively, it could allow over trapping in some areas.

Preliminary spatial modeling of snowmobile probability of use suggests many areas of the Nez Perce-Clearwater will continue to be inaccessible during the winter, even if there is no recommended wilderness, because much of the national forest is too steep, has too much canopy cover, or is too far from access to be used by most trappers. In all alternatives, furbearers would continue to be available for trapping. The Idaho Department of Fish and Game regulates, monitors, and manages furbearers and this management would continue to sustain these species under this alternative.

The ability of the Nez Perce-Clearwater to pursue active management to achieve desired conditions would be most proactive under this alternative. Therefore, the ability of the national forest to increase forage for elk and other ungulates as a result of achieving vegetation desired conditions would be the easiest. All big game species would benefit from higher amounts of nutrition, with ungulates benefiting from more nutrition and predatory big game benefiting from higher ungulate populations. Idaho Roadless Rule themes would remain the same and the ability to restore would be allowed to the extent allowed under the roadless rule. The limiting factor for elk in the plan area, particularly within the Roadless Rule areas, is the lack forage because of lack of disturbance. Both current designated wilderness and Idaho Roadless Rule areas would continue to provide for wolf, black bear, and cougar populations. However, under Alternative X, these species would be slightly more accessible to the public for hunting. Hunting is used by the Idaho Department of Fish and Game to reduce populations of predators and this alternative would allow greater access compared to other alternatives. The Idaho Department of Fish and Game manages and monitors the amount of harvest of predatory big game animals so that they persist on the landscape. This would continue under all alternatives.

Under this alternative all areas are open to mechanized travel, as well as game carts. Allowing mechanized travel, such as bicycles, would have slight detrimental consequences to big game because mountain bikes have been documented to displace elk (Wisdom et al. 2018). Under this alternative, this activity would be allowed in the largest amount of area. However, mechanized travel is not intensive in the plan area at the present time. The use of game carts in what is currently recommended wilderness might make game retrieval easier for people to remove game animal carcasses from these areas. The utility of game carts depends upon the terrain and vegetation conditions. In the plan area, game carts are not very useful unless there is a road or trail nearby or unless the terrain is fairly level. Game carts would allow some hunters to take animals farther away from roads or trails and transport game carcasses more effectively. Game cart use has little effect on wildlife, or habitat, whether they are allowed or not.

Alternative Y

Alternative Y would reach desired vegetation conditions faster than Alternative Z and the No Action Alternative but slower than Alternatives W and X. Thus, it has a relatively more relaxed schedule for restoring the system back to the desired conditions, which are based upon the natural range of variation. For ungulates, this more moderate paced schedule would improve nutritional resources quicker than the No Action Alternative but slower than Alternatives W and X. While the pace may be quicker, at the end of five decades, the amount of high-quality nutrition is slightly less than in other alternatives. This is because desired conditions for vegetation do not vary by alternative, so management is directed towards similar outcomes. However, since the rate is slower, the elk herd would take more time to rebound towards higher levels desired by many of the public and partner agencies.

SIMPPLLE modeling results suggest that, under all alternatives, the amount of high-quality forage greater than about 2.6kcal/g of dietary digestible energy would increase throughout the plan area. This makes sense because the desired conditions for vegetation do not vary by alternative. Vegetation management would contribute substantially to forage, especially within Management Areas 2 and 3. Under Alternative Y, forest conditions would trend towards increased nutrition to meet the needs of many game species. The less proactive schedule in Alternative Y would allow fewer areas to be targeted to increase the amount of the highest quality forage while restoring forests to towards their natural range of variation. Proactive management through wildland fire would be moderate under Alternative Y in Idaho Roadless Rule areas compared to Alternatives W and X. Management of natural fires in designated wilderness would still be possible at similar rates as they have been under the No Action Alternative.

In Alternative Y, slightly less areas were identified as suitable for motorized uses compared to the No Action Alternative. This could benefit elk habitat use in some areas, especially those that would not be suitable for motorized uses. Other species that are displaced or impacted by motorized uses would do better with this alternative. The percentage of the planning area that is suitable for summer motorized uses would be 44 percent, a decrease by about 1 percent suitable for motorized use from the No Action Alternative. Sixty-two percent of the plan area would be suitable for winter motorized travel, while 39 percent would be unsuitable. Maps of the alternatives for summer and winter recreation opportunity spectrum can be found in Appendix A. Areas suitable for motorized uses could displace elk, and more winter motorized uses would allow more access to winter trapping of furbearers. This would be good for trappers, but furbearers would be exposed to more trapping pressure. Limited access to some areas has resulted in the inability of the State to manage wolf and other predator populations resulting in significant reductions in big game. Alternatives with less motorized uses reduce the ability of hunters and wildlife managers to access areas to reduce predator populations as in this alternative.

Waterfowl and furbearers that use aquatic habitats would be provided for in a similar manner in all alternatives as measures in PACFISH and INFISH are similar to those in the aquatics plan components. Under a less proactive schedule of treatments, fewer potential impacts could occur under this alternative. Alternative Y proposes intermediate amounts of rivers as suitable as wild and scenic. The proposed area of suitable wild and scenic river corridor is more than those eligible under the No Action Alternative. Suitable acres of wild and scenic river corridors would be 100,623 acres under Alternative Y. These acres would help some game species be neutral to others and hinder habitat enhancement efforts for others. There would be no change in the amount of designated wild and scenic rivers.

The amount of recommended wilderness would decrease under Alternative Y versus the No Action Alternative because the Hoodoo area would decrease from a boundary change. The change in the amount of recommended wilderness would have environmental consequences on mountain goats, furbearers, elk, and other ungulates and predatory big game, as described below. Species that do better in unpopulated areas or without human presence would do slightly better in this alternative.

Under Alternative Y, one of the larger mountain goat meta-populations in the Nez Perce-Clearwater and one of two core mountain goat areas within the Black Snow Population Management Unit would be excluded from recommended wilderness. Mountain goat populations in the Black Snow Population Management Unit were used as a source of goats to transplant into other portions of the state for 40 years (Idaho Department of Fish and Game 2019b). This population appeared stable to increasing during times when the transplants were occurring. The Idaho Department of Fish and Game counted these populations in 2017 and found the mountain goat population in the eastern portion of the unit, which would be those in the Blacklead areas of the Hoodoo recommended wilderness area, showed a substantial decline from the previous survey (Idaho Department of Fish and Game 2019b). In the past, Idaho Department of Fish and Game surveys in this area occurred in the late winter or spring (Idaho Department of Fish and Game 2019b). There are concerns with increasing snowmobile and snow bike access to mountain goat habitat in the east portion of Game Management Unit 10 in the Black Snow Population Management Unit (Idaho Department of Fish and Game 2019b). Changing the boundary for these mountain goats could have adverse environmental consequences for this metapopulation of mountain goats.

Furbearers that use terrestrial habitats would mainly be affected by the amount of recommended wilderness and whether motorized over-snow travel is allowed. This is because trapping itself is the biggest factor for effects for most of these species outside of prey abundance. The amount of recommended wilderness and motorized over-snow travel would directly influence accessibility during winter, which is when trapping is most effective and usually conducted. Idaho Roadless Rule areas, except those identified as recommended wilderness, are suitable for winter motorized travel. Therefore, the amount of recommended wilderness and whether winter over-snow travel is allowed is the primary indicator for effects to furbearers. In Alternative Y, the amount of recommended wilderness decreases, and furbearers would be slightly more accessible to trappers than they are under the No Action Alternative. In all alternatives, furbearers would continue to be available for trapping, but access and availability increases slightly under Alternative Y. The Idaho Department of Fish and Game regulates, monitors, and manages furbearers and this management would continue to sustain these species.

The ability of the Nez Perce-Clearwater to pursue active management to achieve desired conditions would be similar to the No Action Alternative, more than Alternative W, and less than in Alternative X. The ability of the national forest to increase nutrition for elk and other ungulates in Management Area 2, as a result of achieving desired vegetation conditions, would be allowed under this alternative. Restoration would be achieved in recommended wilderness through wildland fire, which may not occur in areas expected to produce the best nutritional response. While prescribed fire is suitable within these areas, there is limited nutrition potential to elicit a nutritional response. The limiting factor for elk in the plan area, particularly within the Roadless Rule areas, is insufficient nutrition.

Current recommended wilderness, designated wilderness, and Idaho Roadless Rule areas would continue to provide for wolf, black bear, and cougar populations. Under Alternative Y, these species would be slightly more accessible to the public than in the No Action Alternative. These populations would forage upon the population of ungulates and big game populations would continue downward trends.

Under this alternative, mechanized travel is prohibited in recommended wilderness, as well as game carts. The prohibition of mechanized travel, such as bicycles, would have slight benefits to big game because mountain bikes have been documented to displace elk (Wisdom et al. 2018). Under this alternative, this activity would be prohibited. However, mechanized travel is not intensive in the plan area at the present time. The prohibition on the use of game carts might make some areas more difficult for people to remove game animal carcasses from recommended wilderness. The utility of game carts depends upon the terrain and vegetation conditions. In the plan area, game carts are not very useful unless there is a road or trail nearby or unless the terrain is fairly level or sparsely vegetated. On the other hand, game carts allow some hunters to take animals farther away from roads or trails and transport game carcasses more effectively. Whether to allow or disallow game carts would have little effect on the wildlife as most hunters have additional options that can allow removal of game carcasses. Game cart use would have minor to no effect on game species.

Alternative Z

Alternative Z would reach desired vegetation conditions at a similar rate to the No Action Alternative but slower than Alternatives W and X. Thus, it has a relatively more relaxed schedule for restoring the system back to the desired conditions, which are based upon the natural range of variation. For ungulates, this more moderate paced schedule would continue to impair forage resources and cause continued declines in elk, deer, and moose populations due to forest succession and lack of forage. At the end of five decades, modeling results suggest that the amount of high-quality forage is less than in other alternatives. Since the rate is slower, the elk herd would take more time to rebound towards higher levels desired by many of the public and state agencies and tribal entities. As for big game nutritional improvements are often the result of efforts to achieve desired vegetation conditions, the alternatives that favor a faster pace favor big game to a greater extent than alternatives that rely on a slower pace.

Preliminary modeling results suggest that under all alternatives, the amount of high-quality forage greater than about 2.6 kilocalories per gram of dietary digestible energy would increase, especially within

Management Area 3, but do so more slowly in this alternative than in other alternatives. This makes sense because the desired conditions for vegetation do not vary by alternative. Vegetation management would contribute to nutrition within Management Areas 3 but does so more slowly than other alternatives. The less proactive schedule in Alternative Z would allow fewer areas to be targeted to increase the amount of the highest quality forage while achieving desired vegetation conditions. Proactive management through wildland fire would be similar to the No Action Alternative under Alternative Z but slower in Idaho Roadless Rule areas compared to Alternatives W and X. Management of natural fires in designated wilderness would still be possible at similar rates as they have been under the No Action Alternative.

In Alternative Z, slightly less areas were identified as suitable for motorized uses compared to the No Action Alternative. This could benefit elk habitat use in some areas, especially those that would not be suitable for motorized uses. The percentage of the planning area that is suitable for summer motorized uses would be 43 percent, a decrease of about 2 percent suitable for motorized use from the No Action Alternative. Seventy percent of the plan area would be suitable for winter motorized travel, while 30 percent would be unsuitable. Maps of the alternatives for summer and winter recreation opportunity spectrum can be found in Appendix A. Limited access to some areas has resulted in the inability of the State to manage wolf and other predator populations resulting in significant reductions in big game. Alternatives with less motorized uses reduce the ability of hunters and wildlife managers to access areas to reduce predator populations.

Waterfowl and furbearers that use aquatic habitats would be provided for in a similar manner in all alternatives as measures in PACFISH and INFISH are similar to those in the aquatics plan components. Under a less proactive schedule of treatments, fewer potential impacts could occur under this alternative. Alternative Z proposes the most amounts of rivers as suitable as wild and scenic. The proposed area of suitable wild and scenic river corridor is more than those eligible under the No Action Alternative. Suitable acres of wild and scenic river corridors would be 149,691 acres under Alternative Z. These acres would help some aquatic species be neutral to other upland game and terrestrial fur bearers and habitat enhancement efforts for big game within the corridors would be more difficult. There would be no change in the amount of designated wild and scenic rivers.

Alternative Z is the second highest alternative for the amount of recommended wilderness compared to the other alternatives. The alternative would include the Hoodoo, Mallard-Larkins, East Meadow Creek, Rapid River, Meadow Creek-Upper North Fork, North Fork Spruce-White Sands, Sneakfoot Meadows, Rawhide, and Pot Mountain Idaho Roadless Rule areas. This is the only alternative that would include Pot Mountain. The change in the amount of recommended wilderness would have environmental consequences on mountain goats, furbearers, elk, and other ungulates and predatory big game as described below.

Under Alternative Z, more mountain goat populations would be included in recommended wilderness than in all but Alternative W. However, the mountain goats in recommended wilderness under this alternative would still be subject to disturbance from motorized over-snow travel. Access to mountain goats by hunters would be more difficult in these recommended wilderness areas. The ability to connect mountain goat habitats within the plan area or the ability to improve mountain goat habitat conditions through active management would be constrained within recommended wilderness under Alternative Z. Thus, this alternative restricts hunter access but does not provide protections against over-snow travel.

Furbearers that use terrestrial habitats would mainly be affected by the amount of recommended wilderness and whether motorized over-snow travel is allowed. This is because trapping itself is the biggest factor for effects for most of these species outside of prey abundance. The amount of recommended wilderness and motorized over-snow travel would directly influence accessibility during winter, which is when trapping is most effective and usually conducted. Idaho Roadless Rule areas, except those identified as recommended wilderness, are suitable for winter motorized travel. Therefore, the amount of recommended wilderness and whether winter over-snow travel is allowed is the primary indicator for effects to furbearers. In Alternative Z, the amount of recommended wilderness is the second most among alternatives and furbearers would be accessible to trappers because winter motorized travel would be allowed. In all alternatives, furbearers would continue to be available for trapping, but access and availability increases a lot under Alternative Z. The Idaho Department of Fish and Game regulates, monitors, and manages furbearers and this management would continue to sustain these species.

The ability of the Nez Perce-Clearwater to pursue active management to achieve desired conditions would be constrained in this alternative more than all but Alternative W because of the high amount of recommended wilderness, which would change many areas that are currently in the backcountry restoration theme to the backcountry recreation theme. Active management for restoration purposes is strongly restricted in this theme. Therefore, the ability of the national forest to increase forage for elk and other ungulates in 474,288 acres of recommended wilderness would be highly restricted under this alternative. This would not be an insignificant amount. This would impact the Nez Perce-Clearwater's ability to proactively restore these habitats for ungulates. Restoration would only be achieved in recommended wilderness through wildfire, which may not occur in areas expected to produce the best nutritional response. The limiting factor for elk in the plan area, particularly within the Roadless Rule areas, is the lack forage because of lack of disturbance. Modeling results from the elk forage potential spatial layer shows that Pot Mountain contains many areas of high and moderate forage potential. Similarly, East Meadow Creek has some of the higher amounts of forage potential for elk on the Nez Perce side of the national forest.

Current recommended wilderness, designated wilderness, and Idaho Roadless Rule areas would continue to provide for wolf, black bear, and cougar populations. Under Alternative Z, the higher amounts of recommended wilderness would be better for these species because of the limited access it would provide. These populations forage upon the population of ungulates and these species would decline as well if big game populations continue downward trends.

Under this alternative, mechanized travel is allowed in recommended wilderness, as well as game carts. Allowing mechanized travel, such as bicycles, would have slight detrimental effects to big game because mountain bikes have been documented to displace elk (Wisdom et al. 2018). Under this alternative, this activity would be allowed. However, mechanized travel is not intensive in the plan area at the present time. The allowance of game carts in recommended wilderness might make some areas more accessible for some people to remove game animal carcasses. The utility of game carts depends upon the terrain and vegetation conditions. In the plan area, game carts are not very useful unless there is a road or trail nearby or unless the terrain is fairly level or sparsely vegetated. On the other hand, game carts allow some hunters to take animals farther away from roads or trails and transport game carcasses more effectively. Whether to allow or disallow game carts would have little effect on the wildlife as most hunters have additional options that can allow removal of game carcasses. These two uses would have minor to no effect on game species.

Preferred Alternative

The Preferred Alternative adopts a quicker schedule to achieve desired vegetation conditions and would reach desired vegetation conditions faster than all alternatives but Alternative X. Thus, it has a relatively more aggressive schedule for restoring the system back to the desired conditions, which are based upon the natural range of variation. For ungulates, this more aggressive paced schedule would improve nutrition resources quicker than most other alternatives and would produce a higher amount of high-quality forage. Since the rate is faster, the elk herd would take less time to rebound towards the higher levels desired by many of the public and partner agencies. As objectives for big game forage improvements are nested within the efforts to restore the vegetation back to its natural range of variability, the alternatives that favor faster restoration activities favor big game to a greater extent than the alternatives that rely on a slower paced towards restoration.

Preliminary modeling results suggest that, under all alternatives, the amount of high-quality forage greater than about 2.6kcal/g of dietary digestible energy would increase throughout the plan area. This makes sense because the desired conditions for vegetation do not vary by alternative. Vegetation management would contribute substantially to forage, especially within Management Areas 2 and 3. While the increase in amount looks modest, it is sufficient to realize substantial gains in elk body condition likely leading to higher pregnancy rates, higher calf survival, better winter survival and overall better vital rates. Under the Preferred Alternative, forest conditions would trend towards increased nutrition to meet the needs of many game species. The more proactive schedule in the Preferred Alternative would allow more areas to be targeted to increase the amount of the highest quality forage while achieving desired vegetation conditions. Proactive management through wildland fire would be higher under the Preferred Alternative in Idaho Roadless Rule areas compared to all alternatives but Alternative W. Management of natural fires in designated wilderness areas would still be possible at similar rates as they have been under the No Action Alternative.

In the Preferred Alternative, more areas were identified as suitable for motorized uses which could affect elk habitat use in some areas, especially those that were not suitable for motorized uses in the 1987 Plans but would be found suitable in the Preferred Alternative. The percentage of the planning area that is suitable for summer motorized uses is 55 percent, a change of about 10 percent from the No Action Alternative. Sixty percent of the plan area would be suitable for winter motorized travel, while 40 percent would be unsuitable. Maps of the alternatives for summer and winter recreation opportunity spectrum can be found in Appendix A. Some areas were found not suitable for winter motorized recreation in this alternative to protect wintering big game animals. Limited access to some areas has resulted in the inability of the State to manage wolf and other predator populations resulting in significant reductions in big game. Alternatives with more motorized uses could help hunters and wildlife managers access areas to reduce predator populations.

Waterfowl and furbearers that use aquatic habitats would be provided for in a similar manner in all alternatives as measures in the Aquatic Ecosystem sections of the plan would provide adequate protections for these habitats. Under a more proactive schedule of vegetation treatments, more potential impacts could occur under this alternative; however, the aquatic plan components should prevent many impacts from sedimentation. The vegetation desired conditions should provide the coarse filter ecosystem plan components to sustain most furbearers that us upland environments. As many are carnivores, these conditions could provide for more prey that use early seral conditions. The Preferred Alternative proposes fewer rivers as suitable wild and scenic rivers. It includes Cayuse Creek, Fish Creek, Hungery Creek, Weitas Creek, Kelly Creek, North Fork Kelly Creek, Middle Fork Kelly Creek, South Fork Kelly Creek, Colt Killed Creek, and Meadow Creek. It also contains two eligible rivers—the Little North Fork and the Salmon River. Only the harlequin duck was identified as an outstandingly remarkable value for any of the rivers and is the only species sometimes hunted. Several of these rivers have had past observations of harlequin ducks. The proposed area of suitable wild and scenic river corridor is less than those eligible under the No Action Alternative. These acres would help some game species, be neutral to others, and hinder habitat enhancement efforts for others that need early seral conditions. There would be no change in the amount of designated wild and scenic rivers. It should be noted that the existing designated rivers also provide for the harlequin duck.

The amount of recommended wilderness would increase under the Preferred Alternative versus the No Action Alternative because the Meadow Creek area was identified as recommended wilderness. It is most similar to Alternative Y but with boundary changes. The Preferred Alternative would decrease the Hoodoo area through a boundary change, but protection of mountain goat use areas was retained and would not be open to winter motorized uses. Similarly, the Mallard Larkin area was retained as recommended wilderness and also protects mountain goats from winter motorized uses. The Preferred Alternative would change the boundaries of two recommended wilderness areas important to mountain goats. Those include the Hoodoo and Mallard Larkin recommended wilderness areas. Areas within these recommended wilderness areas will be suitable for summer motorized only in limited circumstances consistent with the Idaho Roadless Rule, and unsuitable for winter motorized uses. Therefore, the associated motorized suitability would help protect mountain goat habitat. The change in the boundary might facilitate or make enforcement of illegal winter motorized restrictions more challenging, however, illegal motorized use is enforced by law enforcement, and the Forest Service provides users with information about where winter motorized uses are allowed or prohibited. Note that the plan does not authorize motorized uses, and a subsequent decision with associated environmental analysis is required to authorize such uses. The increase in the amount of recommended wilderness would have beneficial environmental consequences on mountain goats, furbearers, elk, and other ungulates and predatory big game, as described below.

Under the Preferred Alternative, one of the larger mountain goat meta-populations in the Nez Perce-Clearwater and one of two core mountain goat areas within the Black Snow Population Management Unit would be included in recommended wilderness. Mountain goat populations in the Black Snow Population Management Unit were used as a source of goats to transplant into other portions of the state for 40 years (Idaho Department of Fish and Game 2019b). This population appeared stable to increasing during times when the transplants were occurring. The Idaho Department of Fish and Game counted these populations in 2017 and found the mountain goat population in the eastern portion of the unit, which would be those in the Blacklead areas of the Hoodoo recommended wilderness area, showed a substantial decline from the previous survey (Idaho Department of Fish and Game 2019b). In the past, the Idaho Department of Fish and Game surveys in this area occurred in the late winter or spring (Idaho Department of Fish and Game 2019b). There are concerns with increasing snowmobile and snow bike access to mountain goat habitat in the east portion of Game Management Unit 10 in the Black Snow Population Management Unit (Idaho Department of Fish and Game 2019b). Including the mountain goat population areas in recommended wilderness in the Preferred Alternative would help ensure that protections for mountain goats are adequate to provide for habitat conditions for healthy populations of these species because winter motorized uses there would be unsuitable and thus not allowed. The recommended wilderness areas would still allow administrative use of the area, including use by the Idaho Department of Fish and Game, to manage wildlife populations. The ability to actively manage vegetation for the benefit of big game would be less in recommended wilderness areas. This alternative strikes a balance between the protection of mountain goat populations and winter recreational use.

Furbearers that use terrestrial habitats would mainly be affected by the amount of recommended wilderness and whether motorized over-snow travel is allowed. This is because trapping itself is the biggest factor for effects for most of these species outside of prey abundance. The amount of recommended wilderness and motorized over-snow travel would directly influence accessibility during winter, which is when trapping is most effective and usually conducted. Therefore, the amount of recommended wilderness and whether winter over-snow travel is allowed is the primary indicator for effects to furbearers. In the Preferred Alternative, the amount of recommended wilderness increases, but motorized over-snow travel suitability increases from 39 to 60 percent so furbearers would be more accessible to trappers in some areas than they are under the No Action Alternative. Recommended wilderness would not be suitable for over-snow travel in the Preferred Alternative. The Idaho Department of Fish and Game regulates, monitors, and manages furbearers, and this management would continue to sustain these species.

The ability of the Nez Perce-Clearwater to pursue active management to achieve desired conditions would be higher in the Preferred Alternative than all alternatives but Alternative W. The ability of the Nez Perce-Clearwater to increase forage for elk and other ungulates in Management Area 2, as a result of restoring the natural range of variation, would be allowed under this alternative. Restoration would be achieved in recommended wilderness through wildland fire and target the best nutrition there., However, this may not be easy because these areas naturally have lower nutrition potential. The limiting factor for elk in the plan area, particularly within the roadless rule areas, is the lack forage because of lack of disturbance.

Current recommended wilderness, designated wilderness, and Idaho Roadless Rule areas would continue to provide for wolf, black bear, and cougar populations. Under the Preferred Alternative, these species would have more protection through recommended wilderness than in the No Action Alternative. These populations would forage upon the population of ungulates and big game populations.

Under this alternative, mechanized travel is prohibited in recommended wilderness. The prohibition of mechanized travel, such as bicycles, would have slight benefits to big game because mountain bikes have been documented to displace elk (Wisdom et al. 2018). Bikes and other mechanized travel have the potential to displace wildlife like elk. That this activity is not suitable in the Preferred Alternative in recommended wilderness prevents this type of disturbance in those areas. Under this alternative, this activity would be prohibited. However, mechanized travel is not intensive in the plan area at the present time. The prohibition on the use of game carts might make some areas more difficult for people to remove game animal carcasses from recommended wilderness areas. The utility of game carts depends upon the terrain and vegetation conditions. In the plan area, game carts are not very useful unless there is a road or trail nearby or unless the terrain is fairly level or sparsely vegetated. On the other hand, game carts allow some hunters to take animals farther away from roads or trails and transport game carcasses more effectively. Whether to allow or disallow game carts would have little or no effect on the wildlife as most hunters have additional options that can allow removal of game carcasses.

Effects to Multiple Use Wildlife from other Resource Areas and Common to All Alternatives

Air Quality

Air quality plan components will have little to no environmental consequences on wildlife resources. However, airshed management regulations under the Clean Air Act and the National Ambient Air Quality Standards often hinder the ability of the Nez Perce-Clearwater to manage vegetation for wildlife through prescribed fire from a smoke management perspective.

Carbon Storage

Plan components for carbon storage have little to no environmental consequences for multiple use wildlife.

Climate Change

The plan does not specifically address climate change. However, the plan has components that address a desire to have the Nez Perce-Clearwater resilience to future climates. These plan components would have little to no environmental consequences to multiple use wildlife. However, plan direction in the Forestlands section provide for habitats that are more resilient to the effects of climate change.

Cultural or Heritage

Plan components for cultural resources would have little to no environmental consequences to multiple use wildlife.

Suitable Wild and Scenic River Management

The amount of river miles suitable as wild and scenic rivers varies by alternative. The rivers considered are preliminarily classified as either wild, scenic, or recreational based upon their existing condition. Depending upon the selected alternative, their management will be consistent with these classifications. Some management activities are not suitable in these areas depending upon the classification and whether those uses are consistent with the Wild and Scenic Rivers Act. Suitability within these classifications can be found in Appendix F of the Land Management Plan.

In general, these uses are often beneficial to wildlife and many wildlife species would benefit from this management. MA2-GDL-SWSR-03 is a guideline that allows wildlife habitat enhancement within suitable wild and scenic rivers and corridors with the caveat that they should be designed to protect the outstandingly remarkable values for which they were found suitable. In some cases, this direction could alter or prevent active management of wildlife habitat for the enhancement of multiple use wildlife. Management of suitable wild and scenic rivers would benefit aquatic multiple use wildlife, such as waterfowl and aquatic furbearers.

Research Natural Areas

Research natural areas are areas identified for their unique natural ecosystems for the purposes of scientific study and education and for maintenance of biological diversity. Management of research natural areas is to maintain a representation of natural systems. Plan components for research natural areas would have either beneficial or little to no environmental consequences to multiple use wildlife.

Lolo Trail National Historic Landmark

Management of the Lolo Trail National Historic Landmark would have beneficial consequences or little to no environmental consequences to multiple use wildlife.

Physical and Biological Ecosystem Management

The plan components in the physical and biological ecosystem management section form the basis of wildlife habitat and provide the primary guidance for the management of wildlife habitats. These ecosystem plan components are based on the current understanding of the natural range of variability under a naturally functioning disturbance regime. Plan components for terrestrial, biophysical, forested lands, fire, and invasive species are the most influential. Many of these plan components and direction were evaluated in the environmental consequences section of the document.

Ecosystem Services

An Ecosystems Services section was added to the Land Management Plan. These components outline desired conditions for ecosystem services, including hunting and fishing. It also contains guideline FW-GDL-ES-01, which requires that routes open for summer and areas open for winter recreation should not be reduced in net. This plan component would maintain the existing amount of these features and would need to be considered when increasing space between the roads for elk. The plan has several sections that address economic and social sustainability. For example, plan components found in the livestock grazing, forest products, energy and mining, infrastructure, timber, recreation, tribal treaty rights, and multiple use wildlife are designed to provide ecosystem services. The plan integrates many of these resource uses with ecosystem plan components. This is because, in many cases, the use and sustainability of these resources for economic benefits are dependent upon the sustainability and conditions of the ecosystem. This is especially true for elk because the availability of elk hunting permits is based on the elk population. Nevertheless, this plan component would help ensure access for opportunities to harvest wildlife used for multiple uses.

Fire Management

Fire was one of the predominant disturbance factors on the Nez Perce-Clearwater in pre-Columbian times. The ecosystem is adapted to fire and functions properly when fires are at play at amounts and intensities as they were during those times. The system is currently departed from its natural range of variability as a result of primarily fire suppression and past extractive uses. This change has led to the departures found currently. Plan components for fire are designed to address these departures while protecting the communities and infrastructure in and around the plan area. Wildland fire is an essential ecological function in Nez Perce-Clearwater fire-adapted ecosystems. Balancing the safe and effective management of wildland fire to maintain and restore ecological integrity with the protection of communities, valued resources, and assets within and around the National Forest forms the core challenge of wildland fire management. This can be accomplished by implementing a coordinated risk management approach to build landscapes that are resilient to fire-related disturbances and preparing for and executing a safe, effective, and efficient response to fire. Fire plan components guide management to use fire within a risk-based framework to restore and enhance ecosystem integrity on the Nez Perce-Clearwater.

FW-STD-FIRE-01 states all wildfires shall have a management response that considers risk to life and safety, considering the costs and effects to resources and values at risk. FW-GDL-FIRE-01 guides wildfire management strategy and tactics to take an opportunistic approach integrating wildland fires to existing fuels treatments, past wildfires, forest health, and wildlife habitat improvement projects on the landscape. This would directly result in some benefits to multiple use wildlife species. FW-GDL-FIRE-02 addresses noxious weeds when considering planned ignitions. These plan components would contribute to the restoration of ecosystems, which would enhance habitat for many multiple use species, and improve habitat conditions for them.

Aquatic Ecosystems and Fisheries

Aquatics plan components manage aquatic, riparian, and wetland ecological conditions in the plan area. The plan contains a number of fish species listed under the Endangered Species Act and plan components were designed to contribute to the recovery of these fish. Plan components for aquatic ecosystems and are designed to prevent many threats to these habitats. All multiple use wildlife must drink water for their survival and all of them use aquatic or riparian habitats at times. Riparian habitats contribute disproportionately to biodiversity and are important to many wildlife species, including those commonly used by people. For commonly used wildlife, some species are more dependent upon the condition of these systems than others. Waterfowl are directly dependent upon aquatic ecosystems and the quality and quantity of these habitats directly affects their populations. On the other hand, ungulates may use these habitats for foraging and drinking but they depend only upon a source of water within a couple of miles for their needs. Their populations are not often limited by the available water.

About 32 species commonly used by the public are dependent upon aquatic habitats and were grouped into the aquatic, wetland, water, and riparian habitat group. These habitats were analyzed in the Aquatics Ecosystems and Fisheries section as a coarse filter analysis for these species. The analysis found in the aquatic wildlife section of the Abundance and Diversity of Wildlife section analyzes effects to these species from the coarse filter components in detail. The conclusions in that report found that the plan provides well for aquatic and riparian habitats, providing ecosystem integrity to these systems, and should provide well for aquatic wildlife species. The plan components provide either protection or mitigation for most major threats. Plan components in this section are generally beneficial to other commonly used wildlife.

The major exception is that some evidence from modeling the natural range of variation suggests that vegetation around aquatic and riparian habitats could be outside of the natural range of variability and may depend upon infrequent disturbance, such as fire, for maintenance. However, the effects these departures may have on wildlife commonly used by the public are unclear. The most likely effect is that some broad-leaved plants may be suppressed from lack of disturbance. Broad-leaved habitats are important to a wide variety of migratory birds, which contribute to bird watching. Broad-leaved shrubs and trees also contribute to foods for ungulates, beavers, and black bears. Beavers are perhaps the most impacted species when broad-leaved vegetation is lost through succession in riparian habitats. They can be absent from areas previously occupied when succession by coniferous vegetation causes a loss of broadleaved riparian vegetation. Beavers have sometimes been called ecosystem engineers because they manipulate aquatic systems to the benefit of dozens of other wildlife species. The aquatics plan components restrict the active management of these systems to provide this disturbance through planned ignitions or vegetation manipulation. This may prohibit some important needed restoration activities.

Forest Products (Other Than Timber)

Forest products are resources available to the public for their use and benefit. Forest products include firewood, mushrooms, Christmas trees, berries, and other resources. Plan components for these activities include FW-DC-SFP-01 and FW-DC-SFP-02 help provide these resources to the public in a sustainable manner. These activities can have some environmental consequences that can impact multiple use wildlife. Specifically, firewood harvest can adversely affect species that use snags and downed wood, and berry picking can affect forage resources for black bears and migratory birds. Firewood gathering is usually conducted near roadways, in upland areas, mostly on the uphill side of roadways, and is rarely collected on the downhill side of a road. Because most riparian areas are on the downhill side of roads, firewood is gathered less often in riparian areas. Desirable species are those with the highest British thermal units, which, in descending order, include western larch, Douglas-fir, lodgepole pine, Ponderosa pine, and Engelmann spruce. Other species, such as grand fir and subalpine fir, are not desirable. Firewood is not collected very far away from roads. Current management restricts users to harvest only dead and downed trees and restricts the harvest of red cedar from firewood gathering. Within Management Area 3, the harvest of firewood can influence the abundance of snags close to roads (Wisdom and Bate 2008).

Ten multiple use wildlife species use snags for reproducing or denning as crucial structures and eleven species use downed wood. Four species use both downed wood and snags. These include both terrestrial and aquatic multiple use species. Species that use downed wood include the mink, coyote, short-tailed weasel, long tailed weasel, northern river otter, western spotted skunk, harlequin duck, black bear, American marten, bobcat, and northern Raccoon. Species that use snags or dead portions of live trees include Barrow's goldeneye, bufflehead, common goldeneye, common merganser, hooded merganser, wood duck, American black bear, American marten, bobcat, and northern raccoon. Therefore, most of these species are either waterfowl or furbearers, with only one big game species included. Most firewood gathering probably occurs in upland habitat and not riparian areas. Therefore, those species most likely affected include the short and long-tailed weasel, American black bear, and bobcat. These other species are likely to use snags or downed wood within riparian areas, which have lower chances of use by firewood collectors.

Plan components in forested habitats have desired conditions to provide snags for several wildlife species and guidelines to retain snags during management to help provide for these species. The Forest Service

Northern Region used Forest Inventory Analysis data to evaluate snag abundance trends in northern Idaho (Bollenbacher et al. 2009b). They found that snag numbers in wilderness were similar in numbers to those in the managed front where firewood collection is currently occurring. These numbers suggest snags are still abundant and available for these species in the plan area.

Infrastructure

Infrastructure is primarily associated with road systems, buildings, and backcountry airstrips. Plan components for infrastructure include desired conditions to maintain infrastructure to meet their purpose and for maintenance. Facilities, such as ranger stations, fire towers, and guard stations, can affect wildlife habitats locally but their footprint and distribution in the plan area are so small comparative to the land base that they have only minor effects. There are seven airstrips in the plan area, and they have been established for a long period of time. Airstrips have comparatively little effect on multiple use wildlife habitats other than their footprint and the disturbances they pose. They do allow access into areas that would otherwise be accessible except on horseback or foot. A portion of their use is conducted by licensed and permitted outfitter and guides that take clients into the backcountry areas for hunting and fishing. Thus, they provide social and economic benefits and uses of wildlife resources for appropriate human uses. There are some multiple use wildlife species that are hunted more around these airstrips as a result of the access airstrips provide. The amount of hunting pressure from outfitters and guides is small compared to that of the general public. Outfitter and guide numbers for hunting are limited by the Idaho Department of Fish and Game, which only issues permit for these activities to a limited number of guides. The number of permits for outfitter and guides and hunting permits are regulated by the Idaho Department of Fish and Game to maintain a huntable population. So, while some individuals are taken, the population is managed to sustain and support the use of this resource. The number of permits issued for hunting is not within Forest Service control.

The road system has influenced some multiple use species. Species that have shown response to roads include black bears, mule deer, elk, and moose. Several of these species show avoidance behavior or response to disturbance from motorized vehicles.

The installation, maintenance, and use of recreation facilities, including trails, has the potential to affect big game through the removal or fragmentation of habitat and displacement through avoidance of human use. The revised plan alternatives include several forestwide components that address the addition of new roads, including those specific to elk.

Invasive Species

Invasive species poses a risk to habitat for many wildlife species. Invasive species can affect habitat conditions because they can dominate areas to the exclusion of native plants. The effects are most pronounced in non-forested habitats. Species affected by invasive plants include big game, upland game, and waterfowl. The plan and alternatives have plan components addressing invasive plants. See Section 2.1.7 for invasive species plan components. Plan components in the wildlife section of the document are meant to promote native species, as in FW-DC-WLMU-03 and FW-DC-MLMU-06.

Lands and Lands Special Uses

This section concerns the acquisition or disposition of forest lands, rights of way, and easements. These activities can have effects on the amount and location of lands that serve as wildlife habitats. The plan does not contain plan components for the prioritization of these activities related to multiple use wildlife. However, it does have desired conditions that consider habitats for Species of Conservation Concern and federally listed species. While not specified, nothing in the plan precludes acquisition of lands that could serve as habitats for game species. Nothing in the plan would prevent disposal of important habitats for multiple use species. The plan does have language that desires to maintain access to the public through easements. Maintaining access to public lands for hunting is an important issue for sportsmen in the northern Rockies.

FW-GDL-WL-02 gives direction on actions that might affect wildlife movements. It applies to some habitat features for multiple use animals, such as migration areas or winter range.

Livestock Grazing

Direct interaction between livestock and game species are likely to occur. The extent of the effects depends upon the overlap of wildlife habitat and livestock allotments. Allotments are limited in the plan area. Only about 14.8 percent of the Nez Perce-Clearwater is grazed. Allotments occur in the Palouse district and along the western portion of the plan area from near Musselshell Meadows southward. Nearly all the allotment areas are habitat for a variety of multiple use species. For example, elk and whitetail deer occur almost forestwide, except in cliff areas. In contrast, mountain goats rarely occur within allotments. Most of the allotments are grazed by cattle and the plan only has one sheep allotment, which is vacant. Big game species are among those affected the most by grazing. Grazing can also affect migratory birds that are popular for wildlife watching.

The effects of livestock grazing on big game species can include direct competition for resources and degradation of habitat conditions. Grazing can influence vegetation communities through reduced productivity, changing plant composition, and herbaceous structure. Coe et al. (2001) suggests competition for resources has the potential to occur between cattle and elk to a higher degree than between mule deer and cattle. Elk demonstrated a higher degree of displacement and avoidance from cattle compared to mule deer, which is likely due to resource partitioning and associated spatial displacement (Coe et al. 2001, Stewart et al. 2002). This highlights the importance of maintaining a balance and diversity of forage species on the landscape to benefit big game as they transition between seasonal ranges. Increased vegetative vigor and production could retain a greater proportion of digestible biomass for big game species to utilize. Indirect effects include those associated with grazing infrastructure, including mortalities associated with fence entanglements. These effects may occur within grazed allotments.

Predatory big game, such as wolves, cougars, and black bears, are affected by grazing because they sometimes prey upon livestock. In response, people often seek to kill the depredating predator. This can result in impacts to individuals at the local scale and can reduce the population of predatory big game species when grazing is widespread. At the same time, this reduction can benefit ungulate species. The plan does not have plan components to reduce these effects.

The revised plan alternatives contain a desired condition that grazing allotments supply livestock forage and contribute to local ranching operations while staying within or moving toward desired ecological conditions. When stocking rates are high, range resources are degraded. FW-DC-GRZ-01 is a plan component that expresses a desire to have the planning area provide for livestock use and provide economic and cultural benefits to local communities and produce forage for multiple uses in a sustainable manner. FW-GDL-GRZ-03 is a guideline that requires allotment plans to maintain plant vigor, root development, soil cover, and places a cap of 35 to 55 percent utilization on allotments. After evaluating many grazing studies, Holechek et al. (1999) defined moderate grazing between 40 to 45 percent. These guidelines should be sufficient to maintain plant vigor and rangelands for both livestock and wild ungulates. This guideline should also provide for range conditions that would support upland game. Effects to migratory birds would be lower due to this plan component.

Livestock grazing may impact riparian areas, which are important habitats for waterfowl and aquatic forebears. Livestock tend to forage within riparian areas and cause degradation of riparian vegetation, soil compaction, erosion, and sedimentation into streams in some cases. Grazing-specific guidelines found in the aquatics plan components contain measures to maintain or improve riparian habitat, including specific, quantifiable forage utilization measures within riparian areas.

Infrastructure, such as fences and water developments, should be designed and located to prevent barriers and reduce the probability for injury or mortality to wildlife. FW-GDL-WLMU-02 addresses this concern by requiring that new fencing be designed to reduce barriers to big game.

Management Area Allocations

The allocation of management areas was evaluated in detail under the alternatives. The framework of the proposed Forest Plan and alternatives is that the Nez Perce-Clearwater is managed within three management areas. Management Area 1 is designated areas, such as designated wilderness or designated wild and scenic rivers. Management Area 2 is largely composed of Idaho Roadless Rule areas and will also include research natural areas and suitable wild and scenic rivers. Management Area 3 is the front country and is meant to be managed as general forest. It emphasizes timber extraction, motorized uses, vegetation restoration, and developed recreation. This type of management has benefits and drawbacks for multiple use wildlife. Increased human presence and motorized uses can displace these species, while increased vegetation treatments provide more high-quality forage.

The Forest Plan and alternatives will not change the amount of designated wilderness and designated wild and scenic rivers. Under the plan alternatives, various amounts of recommended wilderness and suitable wild and scenic rivers are proposed. All recommended wilderness areas being considered originate from existing Idaho Roadless Rule areas. Suitable wild and scenic rivers proposed under the alternatives were identified for their outstandingly remarkable values through a process consistent with the directives for the 2012 Planning Rule. The amount of wild and scenic rivers suitable under the alternatives include some lands that were formerly considered front country or general forest management under the 1987 Plans. All other management areas are nested within these management areas. Some examples include research natural areas and the Lolo Trail National Historic Landmark.

Management is most restricted within Management Area 1 and the least restrictive under Management Area 3. Management Area 2 is intermediate between these two. Management areas regulate the reason why projects may be proposed and the types of activities that are allowed. Management area direction has important ramifications for the management of habitats for multiple use wildlife. The vegetation within the Nez Perce-Clearwater is largely composed of conifer forest of high canopy cover. As canopy closure increases, forage quality for ungulates declines. In much of the Nez Perce-Clearwater, the only practical forage resources are those created by disturbance, such as wildland fire, or timber harvest. Management Area 1 restricts disturbance to only natural wildfire. Management Area 2 allows active management to restore ecological conditions but does not allow timber production to achieve it. Idaho Roadless Rule areas also include stipulations as to the purpose and need for which restoration activities may be conducted. Management Area 3 may be managed for a variety of reasons to meet multiple use objectives including for wildlife. Timber management is emphasized in Management Area 3 and will help create forage for ungulates and early seral conditions for a variety of wildlife. The ability to actively manage wildlife habitats for the benefit of game species is directly impacted by management area direction. For further discussion on how management area allocation effects big game species refer to the alternative evaluation section above.

Energy and Minerals

Impacts to multiple use wildlife from minerals and energy activities could include the potential alteration or removal of habitat, increased fragmentation, and the potential for human-caused mortality from high-speed traffic or high traffic levels on roads. Plan components in the energy and minerals section of the document are desired conditions for these uses to be available and contribute to the social and economic contribution of the Nez Perce-Clearwater to the communities within the extent of the law. Energy development is negligible to non-existent on the Nez Perce-Clearwater. Mineral extraction on the Nez Perce-Clearwater occurs in many places but most typically occurs within waterways or through hard rock mining. These activities could impact habitats for aquatic furbearers and waterfowl locally. Aquatics plan components for mineral extraction addresses some of these impacts. Otherwise, consequences to wildlife habitats from plan components in the mineral extraction and energy section would have a minor footprint within the plan area. The overall threat impact is low for the Nez Perce-Clearwater for multiple use wildlife.

At-Risk Plants

Plan components for at-risk plants include FW-GDL-TE-01. This plan component has no environmental consequences or beneficial consequences for multiple use wildlife. In some cases, projects under the plan to enhance habitat for multiple use wildlife may need to be altered to protect at-risk plants. These are minor consequences that should not adversely affect this resource.

Recommended Wilderness

The discussion in the evaluation of alternatives explores the environmental consequences of recommended wilderness. This section evaluates the consequences of plan components within recommended wilderness areas. Plan components for recommended wilderness are generally beneficial for wildlife. MA2-DC-RWILD-01 is a desired condition to maintain wilderness character. Most wildlife species benefit from this type of management. As all recommended wilderness areas being considered fall within Idaho Roadless Rule areas, many of the activities allowed and disallowed or dictated by the Idaho Roadless Rule. Idaho Roadless Rule direction applies, even though the plan components do not specify this. Recommended wilderness would be managed as if they were within the backcountry recreation theme under the Idaho Roadless Rule. A variety of activities are not suitable in recommended wilderness. Examples include road construction, timber production, and construction of new buildings or facilities. Some activities are suitable in some alternatives but not in others. Effects of these activities are evaluated in alternatives section above. MA2-DC-RWILD-02 is a desired condition that indicates natural disturbance as the primary disturbance force affecting the composition, structure, and patterns of vegetation. Recommended wilderness management from this desired condition would restrict active management to enhance habitat for multiple use species. MA2-DC-RWILD-03 is a desired condition for these areas to contribute to connectivity and facilitate animal movements. Restrictions on road construction will benefit species such as elk, cougars, black bears, and gray wolves. Several furbearer species will also benefit from recommended wilderness areas because these areas are less accessible to some extent.

In some areas of the Nez Perce-Clearwater, noxious weeds have become established and may spread if not treated. Weeds have impacted important winter range for ungulates species. MA2-SUIT-RWILD-20 would allow herbicide use to control noxious weeds and recommended wilderness areas.

Hunting and fishing guides provide important social and economic functions that benefit society to facilitate use of wildlife commonly used by the public. MA2-SUIT-RWILD-19 finds outfitter and guides activities suitable in recommended wilderness areas.

There was concern from the state agency that management direction within recommended wilderness would hinder their ability to manage wildlife populations through activities, such as scientific studies, wildlife census, wildlife translocations, and other wildlife management activities, related to their responsibility to manage wildlife. MA2-SUIT-RWILD-21 is a plan component identifying these activities as suitable in recommended wilderness in coordination with the Nez Perce-Clearwater. Finding this activity suitable would allow state agencies, such as that of the Idaho Department of Fish and Game, to continue management activities they deem necessary to continue to manage multiple use wildlife in these areas.

Except for MA2-DC-RWILD-02, the plan components identified above changed conditions only slightly over Idaho Roadless Rule area management. MA2-DC-RWILD-02 would constitute the biggest change from roadless rule area management to recommended wilderness management terms with respect to its effect on wildlife habitat management, which would hinder active management to promote multiple use wildlife.

Idaho Roadless Rule Areas

Management of Idaho Roadless Rule areas are largely directed by the Idaho Roadless Rule. Many activities allowed and disallowed by the roadless rule are identified as suitability plan components in the plan. Timber production is not suitable, but timber harvest is allowed in some themes and for some reasons. Permanent road construction is not suitable in many themes but is suitable in community protection zones. The Idaho Roadless Rule imposes constraints and exceptions to the construction of roads in Idaho Roadless Rule Areas. Temporary road construction is not suitable in many themes, except community protection zones and backcountry restoration area themes. Prescribed fire is suitable, which would allow restoration of ecological conditions and would enhance habitat for ungulates. MA2-DC-IRA-02 is a desired condition that disturbance reflects natural disturbance. Mineral leasing is not suitable in some themes, which have beneficial consequences for wildlife. Motorized and mechanized travel in both summer and winter are suitable uses. Allowing these activities may have environmental consequences to the ecological conditions for species like elk, black bears, wolves, and other multiple use species that display avoidance behavior of motorized activities.

The plan contains specific desired conditions for wildlife and Idaho Roadless Rule areas. MA2-DC-IRA-05 is an ecological condition that expresses a desire for these areas to provide for elk herds. MA2-DC-IRA-03 is a desire that these areas provide a variety of wildlife habitat conditions including connectivity, foraging, and denning. The multiple use section of the plan also contains desired condition MA2-DC-WLMU-01that seeks to increase high quality elk nutrition in Idaho Roadless Rule areas. Furthermore, to address concerns that motorized use within Idaho Roadless Rule areas would decrease the size of areas without motorized access in some areas, MA2-DC-WLMU-02 is a desired condition that areas of 5,000 acres or larger remain without motorized access. This desired condition has an associated guideline, MA2-GDL-WL-05, that restricts the addition of new motorized trails unless areas 5,000 acres or larger without motorized access are available adjacent to that area and should avoid areas of high nutrition potential when possible. These plan components will help ensure that uses allowed within Idaho Roadless Rule areas continue to provide for multiple use species, such as elk.

Scenery

Plan direction for viewshed management or scenery would have negligible to beneficial environmental consequences for multiple use wildlife.

Soils

Plan direction for soils have beneficial environmental consequences for wildlife species commonly used by the public. It would be expected that no adverse environmental consequences would result from soil plan components.

Suitable Wild and Scenic Rivers

Management of suitable wild and scenic rivers is generally beneficial to most wildlife species. It would be beneficial to most commonly used wildlife as well. Those most benefiting from suitable wild and scenic river management are waterfowl and aquatic furbearers. Management of suitable wild and scenic rivers can also affect ungulate habitat. Winter range for ungulate species in the plan area occurs on south and west facing aspects along many rivers in the plan area. The various ungulates stratify themselves by elevation and terrain features. For example, moose winter at higher elevation and deeper snow than elk, while elk winter higher than deer generally. Bighorn sheep use the rugged terrain of the Salmon River year-round and require rugged escape cover as an important feature of habitat. Some mountain goat populations winter on steep cliffs above the North Fork Clearwater, Salmon River, Selway River, and Lochsa River. Other mountain goat herds winter in rugged cliff habitat far from rivers. River corridors can also contribute to high quality forage ungulates. All these species require forage resources as a required habitat feature.

Management of habitat to benefit ungulates is best performed when disturbance occurs creating new or improved forage resources for both winter and summer habitat. This disturbance can come from both natural and man created sources. However, these activities are not prohibited within suitable wild and scenic rivers. In fact, guideline MA2-GDL-SWSR-03 allows projects to protect and enhance wildlife and fish habitat so long as the projects protect the outstandingly remarkable values.

Management of suitable wild and scenic rivers for outstandingly remarkable values can reduce the ability to actively manage these habitats for the benefit of ungulates in some cases if the activity would conflict with the management of the outstandingly remarkable value. Suitability of some uses can take away some tools used to implement these types of projects. So, projects would have to use tactics that are suitable within river corridors, which varies by whether the river is wild scenic or recreational.

MA2-DC-SWSR-01 is a desired condition directing management to protect the outstandingly remarkable values and free flowing characteristics. These have beneficial consequences to waterfowl and aquatic furbearers. In general, these are beneficial to neutral for other commonly used species.

MA2-STD-SWSR-02 prohibits construction of roads within suitable wild and scenic rivers in the wild category. This has beneficial consequences on a broad variety of wildlife. Elk are known to exhibit avoidance behavior of roads and this restriction would allow the continued use of elk along these rivers.MA2-GDL-SWSR-01 requires a high scenic integrity objective within corridors of scenic class on suitable wild and scenic rivers. This guideline would help reduce impacts of projects conducted under the plan for some species but hinder active management for ungulates in some cases. In most cases, this guideline would alter projects to maintain scenic objectives.

MA2-GDL-SWSR-02 requires that trails, airfields, and roads protect the outstandingly remarkable values. MA2-GDL-SWSR-04 is a requirement to make stabilization or protection of heritage resources. While the allowance of these features can have some impacts, this plan direction would have little or no consequences for commonly used wildlife. Projects to construct these features would be analyzed individually for their effects.

The identification of wild and scenic suitability has the potential to attract greater use of these rivers by the public. People could be attracted to features that may qualify a river as having outstandingly remarkable values. The potential for increased human uses could affect some wildlife species by disturbing habitats and displacing species. The harlequin duck is suspected to respond to recreational disturbances. While this is a hunted species, populations are also an outstandingly remarkable value for some of these rivers because of their rarity and because some of these rivers host regionally important populations of this species.

Sustainable Recreation (Including Developed and Dispersed Recreation)

Sustainable recreation plan components guide and establish the Nez Perce-Clearwater's recreation program. Recreation is an important use of the National Forest and is highly valued by the public. The recreation program seeks to provide a range of recreational user experiences. Included in those uses are opportunities for camping in developed campgrounds and camping outside of developed sites, hiking and backpacking on and off trails, riding on mechanized transportation such as bicycling, recreational driving of motorized vehicle recreation, floating rivers, swimming, rock climbing, wildlife watching, fishing, trapping, hunting, and other uses. These activities can affect commonly used wildlife and their habitats by displacement because of avoidance behavior. Many species benefit from motorized access controls including furbearers, and herbivorous big game. However, motorized routes can facilitate predator control by the Idaho Department of Fish and Game and hunters. The effects vary by the species, habitat, and the activities.

Recreation and Access Management

The recreation opportunity spectrum is developed with guidance from the final directives and varies by alternative. The recreation opportunity spectrum establishes the settings under which various recreational activities are permitted or disallowed, especially those that allow or disallow motorized recreation. The classes of recreation opportunity spectrum determine the combination of activities allowed. Primitive and semi-primitive non-motorized are the settings that disallow motorized use. The intention in some of our plan is to connect trails and provide more loop opportunities for motorize trail use in both Management Area 3 and Management Area 2. Some of the alternatives for recreation opportunity spectrum settings reflect this. Hunting and trapping are a form of recreation that is supported by the recreation opportunity spectrum setting. Various levels of motorized access and recreation opportunity spectrum settings provide different opportunities for user experience hunting in various settings. The plan components for elk habitat and access have struck a balance to allow for these opportunities while conserving the wildlife resources.

Winter recreation opportunity spectrum settings differ from those in summer. The rational being that the effects of motorized use over the snow differ from those in the summer because winter recreation does not physically alter the land in the form of a road or trail. While this is the case, many wildlife species are displaced by both types of recreation and the effects differ because winter is a more stressful time for many wildlife species. The winter recreation opportunity spectrum allows much more liberal use of snowmobiling than summer motorized travel. While the recreation opportunity spectrum technically allows snowmobile use, users tend to gravitate towards areas with fewer trees, smoother ground, less steep slopes, and are influenced by the placement of access points and roads. Motorized over-snow travel within winter range for big game could be detrimental to winter survival. While in the summer, elk might move in response to motorized use, in winter they often do not have other places to go because of deep snows. In the Preferred Alternative, some areas used by big game were identified as not suitable for winter recreation to help protect wintering big game. Fortunately, most snowmobiling is not desirable in the same areas as those providing for big game winter range. Winter range occurs along the Lochsa, Selway, Middle Fork Clearwater, North Fork Clearwater, Southfork Clearwater, and Salmon Rivers and some in the Island area of the Nez Perce-Clearwater. These are not near the groomed snowmobile trail systems. The four groomed snowmobile trail systems include the Fish Creek Recreation Area, Lolo Pass/Powell, Elk City/Dixie Area, and Elk River Snowmobile Trail System. Grooming is accomplished in partnership with Idaho Parks and Recreation, Montana Fish Wildlife and Parks, Timberliners, Missoula Snowgoers, Snodrifters, and Valley Cats Snowmobile Club. Outfitted operations provide snowmobile trips for visitors.

An area may be suitable for motorized use but that does not mean motorized use is allowable everywhere in that setting. Motorized use by wheeled or over-snow vehicles is restricted to designated trails, roads, and areas, as shown on the motor vehicle use maps for the Nez Perce-Clearwater. Travel management decisions are separate, project-level decisions that determine the specific areas and routes for motorized recreation consistent with the desired recreation opportunity spectrum, as mapped.

Hiking, mechanized, and motorized recreation has been shown to displace elk from important habitats, sometimes to great distances (Wisdom et al. 2018). Some of these disturbances are more impactful than other. For example, motorized use by ATVs evoked the largest distances while cycling was intermediate, and hiking and horseback riding had the smallest distances of displacement. It is well established that elk are displaced from habitats by motorized traffic as dozens of studies have shown avoidance behavior and displacement. Other studies have pointed out that elk vulnerability to hunting increases with increased road miles. The installation, maintenance, and use of recreation facilities, including trails has the potential to affect big game through the removal or fragmentation of habitat and displacement through avoidance of human use. The development of motorize trails and roads can facilitate increased access for trapping on some species. Vehicle strikes can increase on roads of higher speed. Plan components that facilitate these types of developments would likely have some detrimental consequences to elk and other commonly used wildlife.

The road system can be a source of habitat degradation in aquatic systems. The release of sediment from road systems into aquatic systems can affect habitat conditions for many aquatic species. Aquatics plan components address sedimentation from the road system into aquatic systems by a combination of desired conditions, objectives for restoration, and standards and guidelines that prevent the road system from degrading aquatic habitats. These plan components should be adequate for sustaining the habitats for waterfowl and aquatic furbearers and continue to provide benefits to ungulates and black bears.

For waterfowl and aquatic furbearers, aquatic recreation such as floating and swimming can cause disturbance and displacement from these habitats. These effects are usually sub lethal but may affect breeding success and use of an area. Harlequin ducks have been suspected of being affected by recreation on rivers, but this has not been tested empirically in the science.

FW-DC-REC-07 is a desired condition that recreation would be designed to minimize environmental impacts. Plan components in the elk section of the plan have measures to address motorized routes and are specific to in the management areas. They to apply appropriately to projects that seek to create new motorized trails in Management Area 2 and new motorized roads or trails in Management Area 3.

All revised plan alternatives include the desired condition that the transportation system provides for safe and efficient travel and access to the National Forest with minimal impacts on natural resources, including wildlife.

Timber

Plan components for timber harvest include a suite of desired conditions, objectives, and restrictions to provide a sustainable level of use and apply the appropriate measures to ensuring that the timber production on the Nez Perce-Clearwater addresses many of the concerns of this use on other resources. Many species of commonly used wildlife benefit from early seral habitat conditions and would do well in areas of timber production. For example, many species in the ecotone, forest edge, or habitat combinations and the non-forested or early seral habitats groupings both benefit from timber harvest because it can create these conditions. In total, ten species of commonly used wildlife use ecotones between forested and non-forested habitats and seven species use early seral or non-forested habitats. These two groups make up about 27 percent of the species commonly used by the public and most of these species are among the most economically or socially important commonly used species. These include whitetail deer, elk, moose, and forest grouse.

Plan components within the revised plan alternatives address composition, structure, and function of vegetation communities, which provide a coarse filter strategy designed to support disturbance regimes that will maintain and reinforce ecological integrity and biodiversity. Revised plan alternatives include plan components to maintain vegetation within the natural range of variation when possible. All revised plan alternatives contain desired conditions for grassland and shrubland habitats with native plant communities that are self-sustaining and support biodiversity with few non-native species present. These plan components would provide for a wide diversity of foraging options for big game species. Forested habitats provide cover and shelter for big game from both environmental conditions and human use, such as hunting. Forage can also be found within forested areas characterized by more open canopies. Coniferous forests provide hiding cover for big game animals to escape from predators, contribute to thermoregulatory needs, and provide access to winter forage. Desired conditions to maintain forest structure within the natural range of variation for tree density as measured by canopy cover would provide a range of forest cover conditions to meet these needs of big game. All revised plan alternatives identify areas that are suitable for timber production, which includes areas where growing, tending, harvesting, and regenerating crops of trees for commercial purposes may be emphasized. Regeneration harvest would create openings that would provide greater volume of forage.

Size and shape of openings created through regeneration harvest in the revised plan alternatives would be designed to mimic openings created by natural processes. All revised plan alternatives specify that clearcutting and other methods of regeneration harvest are to be used only were deemed appropriate for multiple resource needs, including wildlife habitat.

While some species benefit from timber harvest, others can be adversely affected by timber harvest. Commonly used wildlife species that may have habitat reduced by timber harvest includes the American marten, which depends upon mature forest conditions. Species like black bears benefit in some ways from early seral conditions created by timber harvest and are adversely affected in other ways, such as loosing cover. Similarly, several aquatic species use forested habitats near wetlands. Under the aquatics plan components, timber production is not suitable in riparian areas and appropriate measures are included to reduce impacts to these important habitats. Therefore, timber harvest should not have adverse effects on waterfowl and aquatic furbearers.

Since the ecosystem is adapted to disturbance, this temporary loss of habitat recovers over time. A level of timber harvest can be sustained as long as the amount and distribution does not exceed the rates or change the patterns at which natural disturbance changed these habitats. When it does, it can cause departures from the natural range of variability. Because timber harvest is based upon the desired conditions in the vegetation section, it should not result in conditions outside of the natural range of variation and continued departures. This type of management should provide the ecological conditions and ecosystem integrity for many commonly used species.

FW-DC-TBR-01 includes a desire to use timber production and harvest to restore vegetation conditions and reflects the scale of natural disturbances and is designed to reach forest vegetation desired conditions. This addresses an important departure characteristic present on the Nez Perce-Clearwater created by artificial 40-acre limits on harvest that do not replicate landscape patterns found under natural disturbance (Hessburg et al. 2015). These landscape changes have had some detrimental effects on habitat configuration for many wildlife species, including those commonly used by the public. Elk are known to use edges more than interiors of openings and these measures would provide for that use. See Section 5.1 for specific timber plan components that can benefit elk habitat.

Timber production is often associated with increases in roads to access the timber and transport it. Timber operations often improve existing roads to be suitable for logging trucks. Timber operations can create new permanent roads or use temporary roads that are then closed or restored after harvest. These roads can affect a variety of wildlife species, but perhaps the most affected would be elk. Elk are displaced from otherwise useable habitats because of motorized uses on roads. Elk plan components provide a strategic and flexible system for evaluating and making decisions on roads developed during timber harvest activities. Roads associated with timber harvest and recreational uses in some areas of the Nez Perce-Clearwater, especially Management Area 3, might not be used by elk in areas with little space between roads for them to use.

Watershed Management

Watershed management is largely beneficial to species commonly used by the public. This is especially true for waterfowl and aquatic furbearers. These systems probably are outside of their natural range of variability because of fire suppression and past harvest practices. However, the current condition is not adversely impacting many species. In some cases, lack of disturbance has probably caused some forest types to transition from broadleaved vegetation into conifers. This change may have reduced the ability of some areas to support beavers. Aquatics plan components are comprehensive to provide for these aquatic ecosystems but may lack disturbance to provide for broadleaved vegetation. Some aquatics measures may complicate restoration of upland wildlife habitats, such as early seral conditions for ungulates.

Tribal Treaty Rights

Tribal treaty rights are generally favorable for wildlife. Plan direction in the tribal trust treat rights section would generally benefit wildlife. Many commonly used wildlife species are also commonly used by tribes for clothing, spiritual purposes, subsistence, hunting, fishing, gathering, trapping, and other uses. As mentioned previously, wildlife are sacred to tribes and are not divulged as to their use and location, nor can all the ways that tribes value wildlife be described. Plan components within tribal treaty rights section consists of desired conditions that provide a sustainable diversity of habitats necessary to provide plant and animal species that are of tribal importance. They desire to support wildlife populations at huntable and harvestable levels for the exercise of treaty reserved rights. Standards and guidelines restrict activities that are detrimental to the exercise of treaty reserved rights. These plan components would help support wildlife at huntable and harvestable populations and for treaty reserved rights.

Vegetation

The premise of the 2012 Planning Rule is that ecosystems maintain ecosystem integrity. Ecosystem integrity is achieved when ecological conditions operate within their natural range of variability in terms of their structure, function, composition, and connectivity. The ecological conditions described in the

Forestlands section seek to ensure that the lands within the Nez Perce-Clearwater achieve and maintain ecological integrity. The structure, function, composition, and connectivity of terrestrial ecosystems were considered in developing the plan components for vegetation, including those for forested habitats, non-forested habitats, and aquatic habitats. These ecological conditions are designed to provide for all wildlife, including those commonly used by the public. Achieving desired conditions for vegetation may result in short-term effects to some species while other species will benefit from these activities. In general, it can be expected that species that use non-forested and early seral habitats will increase on the landscape while those species that use late seral forests may decrease in some areas. However, the percentages and proportions of a variety of size classes were designed into the vegetation section to replicate the natural range of variation. Hessberg et al. (2015) described seven principles to restoring forests in the Pacific Northwest. They suggested that mature forests were much less abundant historically than it is today. Similarly, forests were less dense than they are today. Many young stands commonly contained large and very large trees that survived the last disturbance event. While stands were younger, these relics provided some of the same habitat components used by species in mature and old stands. Plan components describing and requiring a desire to retain these elements are an important feature of maintaining the natural range of variability. Periodic disturbances, such as fire, shifted species dominance types of trees to those that are more fire resistant. Fire suppression and past vegetation management have shifted dominance types from fire tolerant species to fire intolerant species. The effect of these changes on wildlife are not well understood but they likely shifted species distribution and abundance and the proportion of species that use a variety of habitat types.

These changes may also have affected species commonly used by the public. It is suspected, for example, that mountain goat habitat may shrink due to encroachment and may not be as connected as it once was. Similarly, bighorn sheep habitats have probably been reduced through increased forest succession. While historically common, black bear populations may be higher than they were in the past due to the amount of mature forest. Several of the species that are early seral or ecotone dependent have been affected by fire suppression and lack of disturbance, which has caused advancing forest succession. Restoring the structure, function, composition, and connectivity of habitats in the plan area to ensure that they have ecosystem integrity will generally be to the benefit of most species commonly used by the public. Vegetation management will be neutral to beneficial in most cases for predatory big game, such as bears, cougars, and wolves.

Wildlife

This section evaluates the effects on wildlife plan components on wildlife used for multiple uses. Plan components for wildlife are generally beneficial to species commonly used by the public. Some management direction for species like fisher might seem on the surface to be diametrically opposed to habitat management for elk. It must be kept in mind that small increases in the amount of forage for elk can result in large benefits in fat accumulation, reproductive rates, calf survival, and winter survival. Modeling results from SIMPPLLE suggest fisher habitats are very departed in extent of disturbance, and composition compared to historical conditions because of fire exclusion and past timber practices. Without intervention, and under a warmer climate, modeling results suggest that fisher habitat will dramatically decline regardless of management. Modeling results suggest that these changes will come largely through natural disturbance, such as fire, insects, disease, and other disturbance agents. These changes will naturally benefit several ungulates and other species that use early seral habitats commonly used by the public. Additional early seral conditions should benefit ungulate populations and benefit predatory big game as well.

Plan components under the Northern Rockies Lynx Direction could slow or prevent some restoration activities in in cold and cool moist broad potential vegetation type groups, which could benefit species commonly used by the public. Over the short-term, this will benefit species like American martens and snowshoe hares. Over longer time frames, stand conditions could extend above their natural range of variation, leaving them susceptible to uncharacteristic wildfire as a result of this direction. The Nez Perce-Clearwater should take advantage of opportunities in lynx habitat allowable under the Northern Rockies Lynx Direction to increase stand diversity and function to a larger extent than it has in the past to benefit both lynx and species commonly used by the public.

Plan components that direct the Nez Perce-Clearwater to increase patch diversity and connectivity should benefit many wildlife species, including those commonly used by the public. Some management for species, such as elk, could temporarily affect species that depend on mature forest. For example, treatments for elk might affect American marten habitat. Modeling results using SIMPPLLE suggest that American marten habitat will decline slightly under the plan alternatives; however, this habitat is above its natural range of variability, so some decline is expected as a result of management towards this end. Management directed towards improving elk populations should have beneficial effects on predatory big game.

Summary of Consequences

By and large the plan will provide for the majority of species that are used for hunting, fishing, gathering, trapping, viewing, traditional or ceremonial uses or other uses. The plan favors some and perhaps decrease habitat for others depending on life history. Elk and other big game were a focus of the development of the plan and plan components were designed to benefit these species. The extent to which management is directed to benefit multiple use wildlife was balanced with competing resources including recreation, timber management, motorized access and more.

Generally, the plan will managed towards vegetation conditions that were at the warm-dry range of variability, and because of increased disturbances during those times, habitats were more likely to be in an early seral condition. For large herbivores, additional early seral conditions are generally favorable for nutritional resources and herds of most big game are expected to benefit. These include elk, moose, white-tailed deer, mule deer, bighorn sheep, and mountain goats. Most upland game species as well as many furbearers would benefit from early seral conditions. Species like some furbearers, like American and Pacific martens that depend on mature or older forests will likely decline to some extent.

The plan and Preferred Alternative favor more access for recreational and economic purposes. The wildlife species that are sensitive to motorized uses or are accessed more easily by motorized access will not do as well relatively speaking than if the motorized system favored fewer roads and less human access. Several species are at least somewhat sensitive to roads and motorized uses, which include elk, black bears, large predators like wolves and cougars. Several species are not influenced greatly by motorized access, and this would have a neutral effect on them. The land allocations in the Preferred Alternative for recommended wilderness encompass some important mountain goat areas and the Preferred Alternative would be better for them than other alternatives. Bighorn sheep populations are relatively unaffected by much in the plan, but measures to reduce exposure to pathogens would prevent losses, but there is small risk with potentially large consequences from pack goats uses.

Land allocations that favor more recommended wilderness would benefit most wildlife species, but some depend on these types of areas more than others. For example, most furbearers are less accessible for trapping in recommended wilderness areas, while black bears are less likely to be baited in recommended wilderness areas. Wolves, cougars, mountain goats, black bears, bighorn sheep thrive in areas with less human disturbances. The allocation of recommended wilderness in the Preferred Alternative, which represents an increase over the No Action Alternative, would benefit these species.

A summary of potential consequences from the Land Management Plan to wildlife is presented in Table 296. These are the relative benefits of the items that vary by alternative based on the species biology, responses to different disturbance factors, whether they benefit from early seral conditions or late seral conditions, or other factors that vary by alternative. Larger numbers represent whether the species is perceived to be more affected by some aspect of the alternatives for vegetation conditions, motorized route management, land allocations, or plan direction. Lower numbers reflect a lower intensity or slight response to the factors in the alternatives. These are meant to give a broad index or general sense of the relative benefits to the species of the suite of alternatives and factors. The factors above, along with the relative importance of those factors to the species, were considered in assigning the relative score to each species for each alternative. However, again, all multiple uses species should be provided for as a result of the plan.

Table 296. Summary of consequences to wildlife by alternative (Alt), using relative benefit to people scale, from high (5) to low (1)

Game type	Animal name	No Action Alt	Alt W	Alt X	Alt Y	Alt X	Preferred Alt
Big Game	Elk	2	4	5	3	2	4
Big Game	Mule Deer	2	4	5	3	2	4
Big Game	White-Tailed Deer	2	4	5	3	2	4
Big Game	Moose	2	4	5	3	2	4
Big Game	Bighorn Sheep	5	5	5	5	5	5
Big Game	Mountain Goat	3	5	1	1	2	5
Big Game	Black Bear	4	3	3	5	4	3
Big Game	Cougar	2	4	5	3	2	4
Big Game	Wolves	2	4	5	3	2	4
Upland Game	Spruce Grouse	2	4	5	3	2	4
Upland Game	Ruffed Grouse	2	4	5	3	2	4
Upland Game	Dusky Grouse	2	4	5	3	2	4
Upland Game	Snowshoe hare	5	5	5	5	5	5
Upland Game	Turkey	2	4	5	3	2	4
Upland Game	Chukar	5	5	5	5	5	5
Furbearer	American Marten	4	4	2	3	4	3
Furbearer	American Beaver	4	4	4	4	4	4
Furbearer	River otter	5	5	5	5	5	5
Furbearer	Bobcat	3	4	5	3	3	4
Furbearer	Long tailed weasel	2	4	5	3	2	4
Furbearer	Short-tailed weasel or Ermine	2	4	5	3	2	4
Furbearer	Red fox	5	5	5	5	5	5
Furbearer	Badger	2	4	5	3	2	4
Furbearer	Mink	5	5	5	5	5	5
Furbearer	Skunk	5	5	5	5	5	5
Furbearer	Raccoon	5	5	5	5	5	5

3.2.10 Air Quality

Air quality is one of the many resources the Forest Service is required to monitor and protect on public lands. Air quality is dependent on the type and amount of pollutants emitted into the atmosphere, the location and topography of an airshed and the prevailing meteorological and weather conditions. Both external and internal sources of air pollution affect the Nez Perce-Clearwater. Sources of air pollution within the Nez Perce-Clearwater include particulates and chemicals single space generated from timber and mining operations, prescribed fire, wildfire, road dust, and transportation and other combustion engines sources. Air pollution sources outside of the Nez Perce-Clearwater that affect the forest include agricultural sources, such as crop burning, municipal emissions, and other sources, including long distance source emissions transmitted via continental air flow patterns.

There is a need to alter management activities in compliance with the 2012 Planning Rule, which will have effects on air as a resource. The focus of this discussion will be on how the various Nez Perce-Clearwater Forest Plan alternatives could affect air quality through management activities, specifically focusing on the use of prescribed fire. Leasing of land for mining operations also occurs on the Nez Perce-Clearwater and air quality impacts from mining are addressed in the Energy and Minerals section. All management activities described can exacerbate public health issues, as well as obscure visibility. Of all potential sources of air pollution from management activities that occur on the Nez Perce-Clearwater, smoke is the most substantial contributor to air quality and visibility. However, there is a need to use fire to maintain and restore the fire-adapted ecosystems on the Nez Perce-Clearwater and to reduce hazardous fuels in the wildland-urban interface. In addition, there is a desire to continue to use timber and mineral extraction as part of cultural, economic, and recreation activities.

Relevant Laws, Regulations, and Policy

Federal Laws

Clean Air Act of 1955, as amended in 1967, 1970, 1977, and 1990 (42 U.S.C. 85 § 7401 et seq.): This federal act is a legal mandate designed to protect the public and the environment from air pollution. Although this policy created the foundation for air quality regulation, states and counties are often responsible for implementation of the air quality standards. The Clean Air Act assigns the task of setting the national ambient air quality standards (NAAQS) to the Environmental Protection Agency (EPA). The EPA evaluates and updates these standards every five years. The 1977 Clean Air Act amendments, strengthened by the 1990 amendments, gave federal land managers an “affirmative responsibility” to protect the air quality related values of Class I areas from adverse air pollution impacts. Mandatory Class I areas were designed under the Clean Air Act and are usually pristine areas of the country which receive the highest degree of regulatory protection from air pollution impacts. Air quality related values are the features or properties of a Class I area which can be changed by air pollution.

Clean Air Act Conformity: This provision of the Clean Air Act requires federal agencies to ensure that the actions they undertake in nonattainment and maintenance areas are consistent with federally enforceable air quality management plans for those areas.

Prevention of Significant Deterioration: This provision of the Clean Air Act requires federal land managers “to preserve, protect, and enhance the air quality in national parks, national wilderness areas, national monuments, ... and other areas of special national or regional natural, recreational, scenic, or historic value.” This section addresses resource protection through the establishment of ceilings on additional amounts of air pollution over baseline levels in “clean air” areas, protection of the air quality-related values of certain special areas, and additional protection for the visibility values of certain special areas.

Wilderness Act: This federal act requires the Forest Service to minimize the effects of human use or influence on natural ecological processes and preserve natural conditions within wilderness.

Consequently, this includes minimizing the effects of human caused air pollution to the wilderness and its air quality related values.

Regional Haze Rule (40 CFR Part 51): This rule, issued by the Environmental Protection Agency, mandates that states address control of human-caused air pollution that impacts visibility in designated Class I airsheds. Class I airsheds are congressionally appointed wilderness areas greater than 5,000 acres in existence before 1977. The goal of the Regional Haze Rule is to return visibility conditions in Class I areas to natural background conditions by the year 2064.

National Ambient Air Quality Standards (40 CFR part 50): This standard establishes health-based levels of certain air pollutants considered healthy for all persons in all areas. Levels have been established nationally, and states can choose to adopt and enforce the national standards or create and abide by their own stricter standards. Secondary standards are established for public welfare protection, including protecting against decreased visibility and damage to animals, crops and vegetation, and buildings.

The Interim Air Quality Policy on Wildland and Prescribed Fires (U.S. EPA 1998): On May 15, 1998, the Environmental Protection Agency (EPA) issued the Interim Air Quality Policy of Wildland and Prescribed Fires to address impacts to public health and welfare (U.S. Environmental Protection Agency 1998). The goal of the policy is to allow fire to function in an ecological role to help maintain healthy ecosystems. In doing so, it must also balance the need to protect public health and welfare from the impacts of fire-related air pollution emissions. The policy is interim because it does not yet address agricultural burning or regional haze (U.S. Environmental Protection Agency 1998). The Interim Air Quality Policy of Wildland and Prescribed Fires suggests air quality and visibility impact evaluations of fire activities on federal lands should consider several different items during planning (U.S. Environmental Protection Agency 1998). In a project-level environmental analysis document, it is appropriate to consider and address, to an extent practical, a description of applicable regulations, plans, or policies; identification of sensitive areas (receptors); and the potential for smoke intrusions in those sensitive areas. Other important disclosure items include applicable smoke management techniques, participation in a basic smoke management program, and the potential for emission reductions. Ambient air quality and visibility monitoring for Class I areas are typically done collaboratively with the states. Impacts to regional and sub-regional air are addressed operationally through coordinated smoke management programs. The EPA urges the states to develop, implement, and certify smoke management programs that meet the recommended requirements of the Interim Air Quality Policy of Wildland and Prescribed Fires. The Forest Service is a member burner of the Montana and Idaho Airshed Group.[21] Member burners submit burn requests to the Smoke Monitoring Unit, which coordinates and approves prescribed burning activities in a manner designed to meet ambient air quality standards.

National Environmental Policy Act Guidance on Consideration of the Effects of Climate Change and Greenhouse Gas Emissions (revised draft of 2014): This guidance explains that agencies should consider both the potential effects of a proposed action on climate change, as indicated by its estimated greenhouse gas emissions, and the implications of climate change for the environmental effects of a proposed action. The revised draft guidance supersedes the draft greenhouse gas and climate change guidance released by the Council on Environmental Quality in February 2010 and, unlike the 2010 draft guidance, the revised draft guidance applies to all proposed federal agency actions, including land and resource management actions (Climate Change and Forest Carbon).

[21] Montana Idaho Airshed Group: https://mi.airshedgroup.org/

State and Local Laws

Idaho State Implementation Plan: Each state is required, under the Clean Air Act, to have an Environmental Protection Agency (EPA) approved state implementation plan (section 110(a)(2)) to identify a strategy to maintain or attain national ambient air quality standards (section 110(h)(1)). The Idaho State Implementation Plan is the collection of EPA-approved programs, policies, and rules that the State of Idaho uses to attain and maintain the primary and secondary national ambient air quality standards.

Idaho Smoke Management Plan: Idaho does not have an EPA-approved smoke management plan, so the state follows federal and interagency basic smoke management guidelines. Idaho is in the process of developing a state smoke management plan through its negotiated rulemaking process. It is unknown when this process will be completed.

Methodology

Spatial Scale

The analysis area or region of influence for air quality depends on the specific pollutant(s) and emissions source(s) involved, as well as weather patterns, terrain, and prevailing winds. Primary pollutants are emitted directly; secondary pollutants are formed through chemical reactions in the atmosphere from precursor pollutants. The region of influence for a primary pollutant depends on the rate of emissions from a source, the elevation of the source, the type of pollutant, and the meteorological conditions that limit its dispersion and dilution during transport away from the emissions source. The region of influence for primary pollutants is an area potentially subject to measurable air quality impacts under unfavorable dispersion conditions and is generally a relatively small area, ranging from one mile to less than a few miles from the source. The region of influence for a secondary pollutant, such as ozone, is much larger because secondary pollutants can impact air quality for hundreds of miles.

The analysis area for the evaluation of effects to air quality from forest plan alternatives is the airshed in which the Nez Perce-Clearwater lies. An airshed is a geographical area in which atmospheric characteristics, such as wind patterns, are similar. Airshed boundary descriptions are detailed in the Montana and Idaho Airshed Group Operations Guide (Montana Department of Environmental Quality 2010). The Nez Perce-Clearwater lies within Airsheds 12B and 13, which are shown in Figure 125. There are no impact zones directly within Airsheds 12B and 13. Impact zones are areas identified in the Montana and Idaho Airshed Group Operations Guide as smoke sensitive or that have an existing air quality problem. Impact zones near the Nez Perce-Clearwater include Pinehurst in Airshed 11, McCall in Airshed 15, Salmon in Airshed 17, and Missoula in Airshed 3a (not pictured, in western Montana).

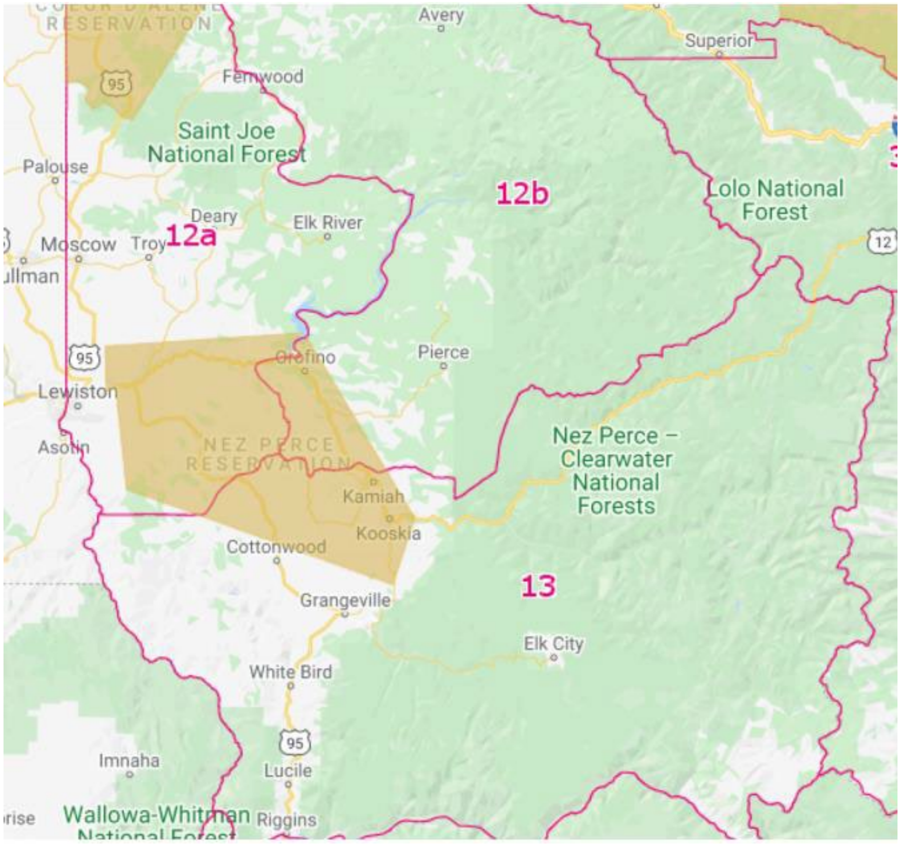

Figure 125. Airsheds (outlined), impact zones (shaded areas) and Nez Perce Reservation boundary.

Data Source: (Montana Department of Environmental Quality 2010)

Temporal Scale

The planning timeframe for this Land Management Plan is 15 years, but the impacts of fire will be analyzed in this report for the short-term (present to 10 years) and the long-term (10 to 30 years). Because of the interplay of effects between prescribed burning and wildfire, it is important to analyze smoke impacts to ambient air and visibility in both the short- and long-term. Prescribed fire activities generally occur under favorable atmospheric conditions for smoke dispersion to limit human health impacts. Wildfires managed to meet Land Management Plan objectives offer long-term benefits by reducing future wildfire emissions. Research indicates that prescribed burning results in an 18 to 25 percent reduction in carbon dioxide from smoke emissions, with examples as high as 60 percent (Wiedinmyer and Hurteau 2010).

Past, Present, and Future Activities used in the Analysis

No additional actions beyond those proposed under each alternative will be included in the effects analysis. Of all potential sources of air pollution from management activities that occur on the Nez Perce-Clearwater, smoke is the most substantial contributor to air quality and visibility.

Methods and Assumptions

This analysis examines the potential air quality impacts from implementation of the proposed forest plan and alternatives. The proposed action is programmatic covering the broad pattern of potential projects and wildfires that can influence air quality. Project-level emissions analysis will take place prior to conducting any smoke-producing management activities.

The assessment of air quality impacts is qualitative in nature. Quantitative values for smoke and other emissions are difficult to predict because they rely on site-specific information, including vegetation and meteorology. The primary approach compares the tradeoffs between potential smoke emissions from the restoration treatments that reduce the potential wildfire emissions and the wildfire emissions that would occur without the restoration. This section focuses on regulated air pollutants.

Assumptions

There are many uncertainties about when or where wildfires occur and what potential other sources of smoke may be and how great the emissions. Several assumptions were made for this analysis to address these uncertainties.

- Wildfire—It is unknown exactly when, where, or how much wildfire will occur, but the trend of increasing large wildfires and associated high smoke emissions is expected to continue (Hurteau et al. 2014). In addition, research indicates that wildfire emissions are widely underestimated (Liu et al. 2017).
- Smoke emissions—The amount of emissions released from combustion of vegetation depends on the type of vegetation, density of vegetation, and the completeness of combustion.
- Smoke management—Smoke management would be practiced actively with all prescribed fires and wildfires managed to meet land management plan objectives. This would include smoke prediction modeling, smoke monitoring, and close coordination with the local air districts.

Measurement Indicators

The key indicators are ambient air quality and visibility, as follows:

- An alternative would be considered to have potentially significant impacts if its implementation would result in a national ambient air quality standard's non-compliance violation, as determined by the Idaho Department of Environmental Quality.
- An alternative would be considered to have potentially significant impacts to visibility if its implementation would result in changes to or degradation of visual quality, views, and the aesthetic landscape.

The units of measure for both indicators are acres of wildfire and acres of prescribed fire per alternative. These indicator measurements were chosen because fire is the greatest producer of smoke that can have effects on ambient air quality and visibility.

Affected Environment

Existing Condition

Air quality on the Nez Perce-Clearwater is generally good, with limited upwind industrial sources and periodic robust wind dispersion. The Nez Perce-Clearwater is subject to long-distance transport emissions from sources to the west in Oregon and Washington. Existing sources of emissions include dust from trails during dry conditions and smoke emissions from wildfires and prescribed burns. Local emission levels are low due to the sparse population and vast areas for dispersion.

Air quality is highly influenced by climate. All of the affected environment lies west of the Continental Divide where the climate can be described as a modified North Pacific Coast type in which winters are milder, precipitation is more evenly distributed throughout the year, summers are generally cooler, and winds are lighter. Prevailing wind patterns are shown for the Nez Perce-Clearwater in Figure 126; hourly observed wind data from the Lowell, Idaho, Three Rivers station (pictured lower left) indicate predominant light northern winds, while hourly observed wind data from the Missoula International Airport station (pictured upper right) in Montana indicate predominant moderate westerly winds.

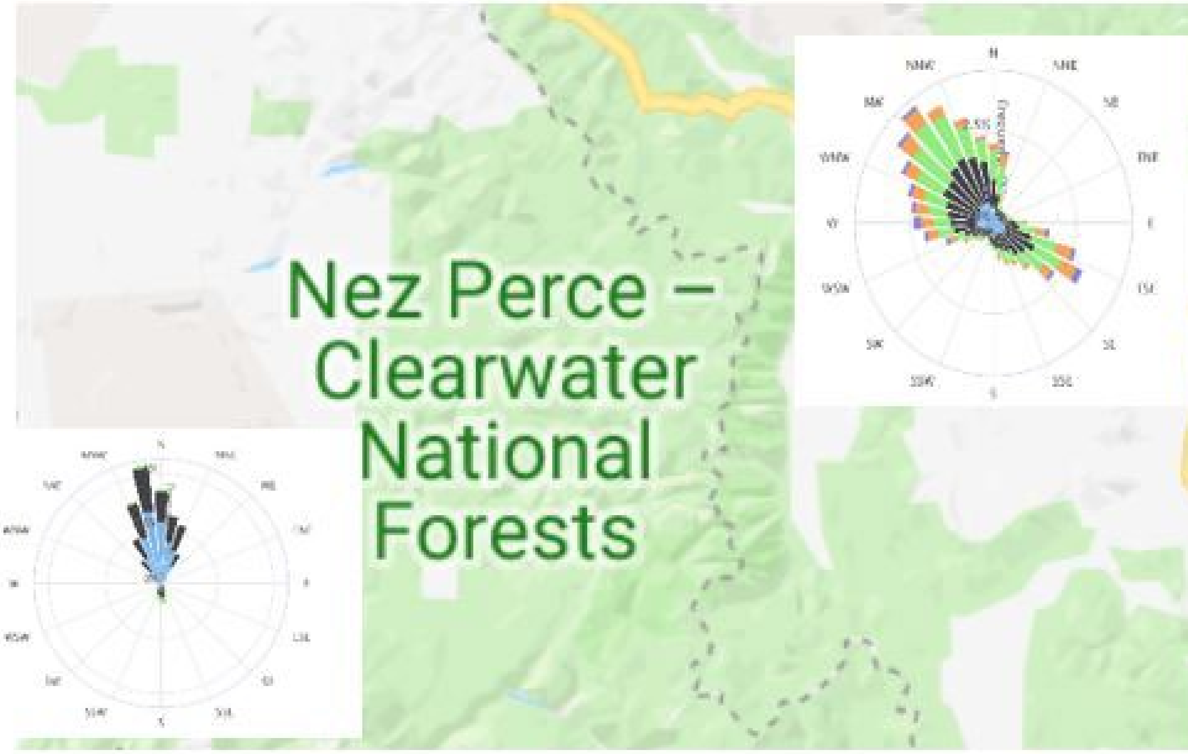

Figure 126. Illustration of predominant wind directions in the Nez Perce-Clearwater National Forests.

Data Source: Midwestern Regional Climate Center Cli-MATE tool

Wind rose information indicates magnitude (miles per hour) and direction (degrees) of wind sources over a 20-year period from January 2000 to January 2019 of hourly monitoring. Wind rose information was obtained for the Lowell, Idaho, Three Rivers station and Missoula International Airport station in Montana from the Midwestern Regional Climate Center Cli-MATE tool.[22]

Ambient Air Quality

The Environmental Protection Agency (EPA) defines six known air pollutants as criteria pollutants for which national ambient air quality standards (NAAQS) are set. Table 297 displays the national ambient air quality standards for the six criteria pollutants defined by the EPA. States are allowed to define their own ambient air quality standards as long as they are at least as strict as the national standards. Idaho's ambient air quality standards are as stringent as the national ambient air quality standards. Because Idaho standards equal national standards, only national standards are shown in Table 297. The most common violation of a national ambient air quality standard from smoke is that of the PM2.5 standard, which refers to atmospheric particulate matter with a diameter less than 2.5 micrometers. Wildfires are considered naturally occurring events; wildfire smoke impacts may not be prevented. State departments of environmental quality are required to have natural emergency action plans that identify procedures to follow when natural events violate air quality standards, such as notifying the public of the health impacts

[22] cli-MATE: MRCC Application Tools Environment (purdue.edu)

of smoke and how to decrease and minimize exposure. Prescribed fires that are ignited by land managers are human-caused and are, therefore, subject to regulation.

Table 297. The Environmental Protection Agency's national ambient air quality standards

Pollutant	Averaging Period	Federal (EPA) standards (2016)[1]	EPA Standard Type
Carbon Monoxide	1 hour	35 ppm	primary
Carbon Monoxide	8 hours	9 ppm	primary
Lead	3 months	1.5 $\mu g/m^3$	NA
Lead	rolling 3 months	0.15 $\mu g/m^3$	primary & secondary
Nitrogen Dioxide	1 hour	100 ppb	primary
Nitrogen Dioxide	1 year	53 ppb	primary & secondary
Ozone	1 hour	NA	primary & secondary
Ozone	8 hours	0.070 ppm (2015 standard)	primary & secondary
Particulate Matter ≤ 10 µm (PM10)	24 hours	150 µg/m	primary & secondary
Particulate Matter ≤ 10 µm (PM10)	1 year	NA	primary & secondary
Particulate Matter ≤ 2.5 µm (PM2.5)	24 hours	35 µg/m	primary & secondary
Particulate Matter ≤ 2.5 µm (PM2.5)	1 year	12.0 µg/m	primary
Particulate Matter ≤ 2.5 µm (PM2.5)	1 year	15.0 µg/m	secondary
Sulfur Dioxide	1 hour	75 ppb	primary
Sulfur Dioxide	3 hours	0.5 ppm	secondary
Sulfur Dioxide	24 hours	0.14 ppm	primary
Sulfur Dioxide	1 year	0.030 ppm	primary
Visibility	1 year	NA	NA

Note. µg/m3 = micrograms per cubic meter, µm = micrometer, NA = not applicable, PM10 = atmospheric particulate matter with a diameter less than 10 micrometers, PM2.5 = atmospheric particulate matter with a diameter less than 2.5 micrometers, ppb = parts per billion, ppm = parts per million, m = meter.

1.For additional information about the federal (EPA) standards, go to https://www.epa.gov/criteria-air-pollutants/naaqs-table.

Data Source: Environmental Protection Agency, National ambient air quality standards, epa.gov/criteria-air-pollutants/naaqs-table, accessed September 2019.

The Clean Air Act requires each state to identify areas that have ambient air quality in violation of the national ambient air quality standards. The status of areas with respect to national ambient air quality standards is categorized as follows:

- Nonattainment – any area that does not meet an ambient air quality standard or that is contributing to ambient air quality in a nearby area that does not meet the standard
- Attainment – meets or is cleaner than the national standard
- Unclassifiable – cannot be classified based on available information

The unclassified designation includes attainment areas that comply with federal standards, as well as areas that lack monitoring data. Unclassified areas are treated as attainment areas for most regulatory purposes. Areas that have been reclassified from nonattainment to attainment are considered maintenance areas. States are required to develop, adopt, and implement a state implementation plan to achieve, maintain, and enforce the national ambient air quality standards in nonattainment areas. The plans are submitted to, and must be approved by, the Environmental Protection Agency (EPA). Deadlines for achieving the national ambient air quality standards vary according to the air pollutant at issue and the severity of existing air quality problems. The State of Idaho is required to notify the public whenever the national ambient air quality standards are exceeded.

The Nez Perce-Clearwater boundary resides within three counties—Clearwater, Idaho, and Shoshone. To understand the current air quality in the Nez Perce-Clearwater, one approach is to examine current emissions estimates. The EPA's National Emissions Inventory (NEI) is a comprehensive and detailed annual estimate of air emissions of air pollutants from many sources, including point, nonpoint, and "event" sources. Table 298 shows estimates of air pollution per county from all potential sources. For more information, see the Environmental Protection Agency's National Emissions Inventory at https://www.epa.gov/air-emissions-inventories/national-emissions-inventory-nei.

Table 298. Tons per year of criteria air pollutants by county

County	Idaho	Clearwater	Shoshone
Population (2010 census)	16,267	8,695	12,765
Carbon Monoxide	343,314	42,128	32,669
Lead	0	0	0
Nitrogen Oxides	5,818	942	1,270
PM10	40,857	5,529	6,033
PM2.5	28,293	2,905	2,228
Sulfur Dioxide	2,220	213	144
Volatile Organic Compounds[1]	180,861	49,150	41,481
Ammonia[1]	6,805	827	360
Total	**623,550**	**103,288**	**85,287**

[1]Volatile Organic Compounds and Ammonia are not listed Criteria Air Pollutants (CAPs) subject to national ambient air quality standards but are regarded as precursors to Ozone and PM2.5, respectively, and may be regulated similarly to the listed Criteria Air Pollutants.

Data Source: Environmental Protection Agency, National emissions inventory 2014, https://www.epa.gov/air-emissions-inventories/national-emissions-inventory-nei, accessed September, 2019.

All areas in the Nez Perce-Clearwater boundary have been designated as in attainment or maintenance with the national ambient air quality standards. However, West Silver Valley, an area north of the Nez Perce-Clearwater in adjacent Shoshone County, has been in moderate nonattainment of the 2012 PM2.5 standard since January 2015 (Figure 127). This area is monitored by the Idaho Department of Environmental Quality, which is working closely with local partners to reach attainment status and comply with federal air quality standards. The emission sources that are being addressed in the Idaho Statement Implementation Plan are open backyard burning, prescribed or slash fires, and woodstoves.[23]

[23] https://mrcc.purdue.edu/CLIMATE/welcome.js

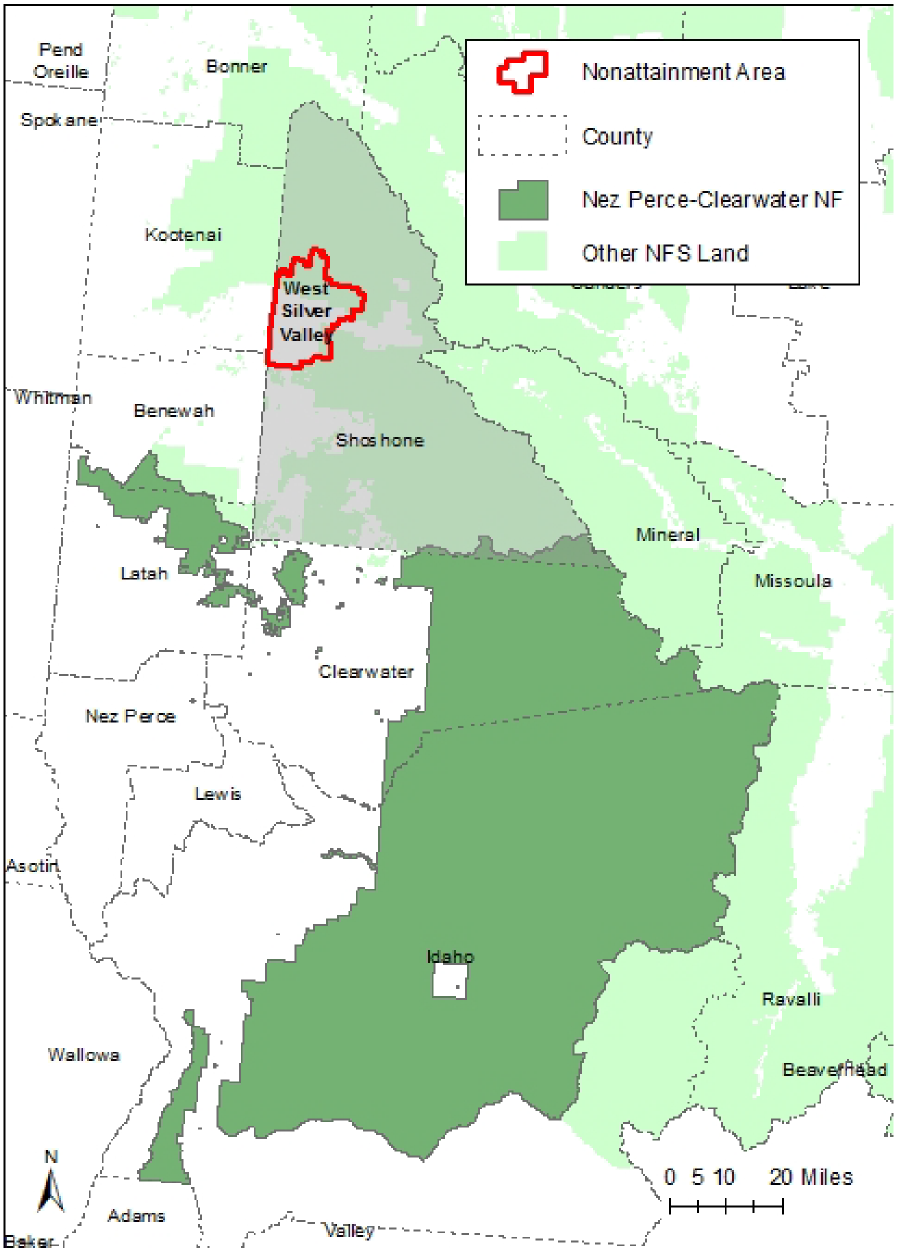

Figure 127. Shoshone County West Silver Valley Nonattainment Area (in red).

Data Source: The Nonattainment Area layer came from Environmental Protection Agency, Nonattainment areas for criteria pollutants (Green Book), https://www.epa.gov/green-book, accessed September, 2019.

The Nez Perce-Clearwater's forest plan is not expected to generate conditions that would significantly affect the West Silver Valley attainment status in the future. Given the proximity, prescribed burning done directly in the forest boundary may have effects on air quality in Shoshone County, but generally northerly winds would be transporting air from Shoshone County to the Nez Perce-Clearwater, not the other way around. Implementing smoke management and coordination, which is present in all forest plan alternatives, will negate smoke effects to the greatest extent possible.

Smoke

In the United States, wildfire smoke is recognized as a significant contributor to exceedances of the national ambient air quality standards established by the Environmental Protection Agency to protect public health and welfare (U.S. Environmental Protection Agency 2016). This is a recent criteria, in part, because the national ambient air quality standards have become more stringent over time based on periodic review, as required by the Clean Air Act, and now allow only small increases in pollutants from background air pollution levels. The duration, areal extant, and concentration of wildfire smoke in the United States has been increasing.

The Environmental Protection Agency's (EPA's) National Emissions Inventory (NEI) details emissions of air pollutants by source category, including point, nonpoint, and "event" sources, as well as finer categories known as "sectors." National Emissions Inventory sector data was aggregated into functional categories to determine the largest sources of criteria air pollutants emissions. Specific methodology for aggregating sector data into functional categories is detailed in Appendix L. Table 299 displays all criteria air pollutants emissions in tons per functional category. A total of 95 percent of emissions in the three Nez Perce-Clearwater counties can be captured by the fire and natural functional groups, with fire releasing over two times the emissions. Table 299 shows how fire is the largest source of criteria air pollutants emissions in the area; thus, smoke is the primary air quality concern. Fire includes emissions from wildfires, prescribed fires, agricultural burning, and pile burning. Natural emissions include biogenic emissions from vegetation and soils.

Table 299. CAP emissions by functional category in Idaho, Clearwater, and Shoshone counties.

Source	Criteria Air Pollutants Emissions (tons)
Fire	550,930
Natural	220,295
All other sources	40,891

Data Source: Environmental Protection Agency, National emissions inventory 2014, https://www.epa.gov/air-emissions-inventories/national-emissions-inventory-nei, accessed September, 2019.

The Forest Service is a member of an organization known as the Montana and Idaho Airshed Group, which coordinates prescribed burns within the State of Idaho. Group members submit prescribed burns to the smoke management unit for daily, site-specific approval. The smoke management unit, located at the Aerial Fire Depot and Regional Office in Missoula, Montana, coordinates efforts to manage smoke during both the wildfire season and prescribed burning season. They are responsible for making sound and timely decisions that consider both the importance of implementing prescribed burns and the minimization of potentially adverse air quality impacts on individual airsheds throughout Montana and Idaho. Adherence to the Montana and Idaho Airshed Group Operating Guide is the current accepted smoke management plan for the State of Idaho. The Montana and Idaho Airshed Group defines impact zones as areas identified as smoke sensitive or as having existing air quality problems (Montana Department of Environmental Quality 2010). The Idaho Department of Environmental Quality expects the Nez Perce-Clearwater to implement basic smoke management practices described in National Wildfire Coordinating Group Smoke Management Guide for Prescribed Fire (PMS 420-2 2018) (National Wildfire Coordinating Group 2001).

The Idaho Department of Environmental Quality does not currently require burners to obtain permits for air quality purposes; however, members of the Montana and Idaho Airshed Group are required by the operations guide to comply with notification and reporting procedures pre- and post-ignition and must seek daily ignition approval from the smoke management unit as described above. The Idaho Department of Environmental Quality is in the process of writing a state Smoke Management Plan through "Negotiated Rulemaking," which will likely include regulatory changes and further oversite of how prescribed fire is managed by the state agency. These changes will likely affect how Nez Perce-Clearwater receives authorization to ignite prescribed fire activities and formalize reporting requirements. A final draft of these regulatory changes has not been issued by the Idaho Department of Environmental Quality as of the publication of this proposed revision; however, a draft of the regulations is available and implementation is expected by 2022.

Air quality is addressed in the individual prescribed fire plan for each prescribed burn. Forest Service Manual 5140 requires a documented burn plan that contains all of the elements outlined in the 2014 Interagency Prescribed Fire Planning and Implementation Procedures Guide (National Wildfire Coordinating Group 2017b). This guide prompts the burn plan author to address all laws and regulations concerning smoke management, as well as the potential for localized nuisance smoke impacts.

In 1998, the Environmental Protection Agency (EPA) released the Interim Air Quality Policy on Wildland and Prescribed Fires (U.S. Environmental Protection Agency 1998). The document was published with the intent of integrating two public policy goals: "(1) to allow fire to function, as nearly as possible, in its natural role in maintaining healthy wildland ecosystems, and (2) to protect public health and welfare by mitigating the impacts of air pollutant emissions on air quality and visibility" (U.S. Environmental Protection Agency 1998). These goals underlie the management approach for fire and vegetation on the Nez Perce-Clearwater as well.

Wildfire smoke can produce three of the six criteria pollutants the EPA has set as maximum standards for protection of human and environmental health. These are carbon monoxide, particulate matter, and volatile organic compounds that can produce ground-level ozone (U.S. Environmental Protection Agency 2016). Smoke is a complex mixture of carbon dioxide, water vapor, carbon monoxide, particulate matter, hydrocarbons, and other organic chemicals. The number of compounds present in smoke number into the thousands (U.S. Environmental Protection Agency 2016). Seventy percent of smoke emissions are made up of small particulate matter, also referred to as PM2.5 or particulate matter smaller than 2.5 micrometers, which has been proven to cause adverse health effects in humans (U.S. Environmental Protection Agency 2016). Because of this, wildfire smoke from naturally ignited fire and prescribed fire poses a potential health threat to the public.

Another smoke emission that poses health risks to humans is carbon monoxide, which can cause short-term health-related problems for firefighters. Carbon monoxide rapidly mixes with surrounding air at short distances from a burn area and it poses little to no risk to the general public. Ground-level ozone, although not a direct product of smoke emissions, is also a concern due to its effects on lung function and plant growth.

The forest plan components are expected to reduce future impacts by distributing some of the locally generated smoke to years that have average to below average fire conditions but still have better dispersion during the wildfire season compared to the prescribed burn season. This will also potentially reduce fuel loading during extreme wildfire seasons, which will also reduce smoke production during those events.

Visibility

As part of the Clean Air Act Amendments of 1977, Congress designated all wilderness areas greater than 5,000 acres and all national parks greater than 6,000 acres as subject to visibility protection requirements. These areas are referred to as "Mandatory Federal Class I Areas." Mandatory Class I Areas within the Nez

Perce-Clearwater are the Selway-Bitterroot Wilderness and Hells Canyon Wilderness. However, the Hells Canyon Wilderness falls within another Forest Service jurisdiction and is not administered by the Nez Perce-Clearwater. The Regional Haze Rule requires states to improve visibility in these Class I areas.

The small size of the PM2.5 makes it highly efficient at scattering light, causing visibility issues and contributing to regional haze. Visibility impairment in the form of regional haze obscures the clarity, color, texture, and form of what can be seen. Emissions from manmade and natural sources can spread across long distances and result in haze, even in remote pristine wilderness areas.

The Regional Haze Rule addresses improving visibility in Class I areas and the Wilderness Act of 1964 mandates that the Forest Service preserve and protect the natural condition of designated wilderness areas, including the intrinsic wilderness values of air quality and visibility, regardless of Class I designation. Regardless of whether smoke violates air quality standards, localized impacts of burning can cause visibility issues. Smoke management practices from the forest industry and state and federal partners, as well as participation in the coordinated efforts of the Montana and Idaho Airshed group, have helped prevent national ambient air quality standards violations and reduced nuisance smoke in the Nez Perce-Clearwater area.

A program known as the Interagency Monitoring of Protected Visual Environments (IMPROVE) was established to monitor visibility in Class I areas and provide information on achieving progress with the Regional Haze Rule. The IMPROVE monitor, located at Sula Peak, monitors pollutant contributions and visibility impairment on the Selway-Bitterroot Wilderness (Figure 128 and Figure 129) indicates no significant trend in visibility on the worst or the best haze values monitored in the Selway-Bitterroot Wilderness. The largest contributor to visibility impairment at the Selway-Bitterroot is organic carbon and is attributed primarily to smoke.

Wildfires will continue to impact visibility in the Class I area. The impacts would be similar under all alternatives. Smoke management opportunities are limited during large wildfires, especially those that are to the upwind of the Nez Perce-Clearwater and affect the Nez Perce-Clearwater's airshed.

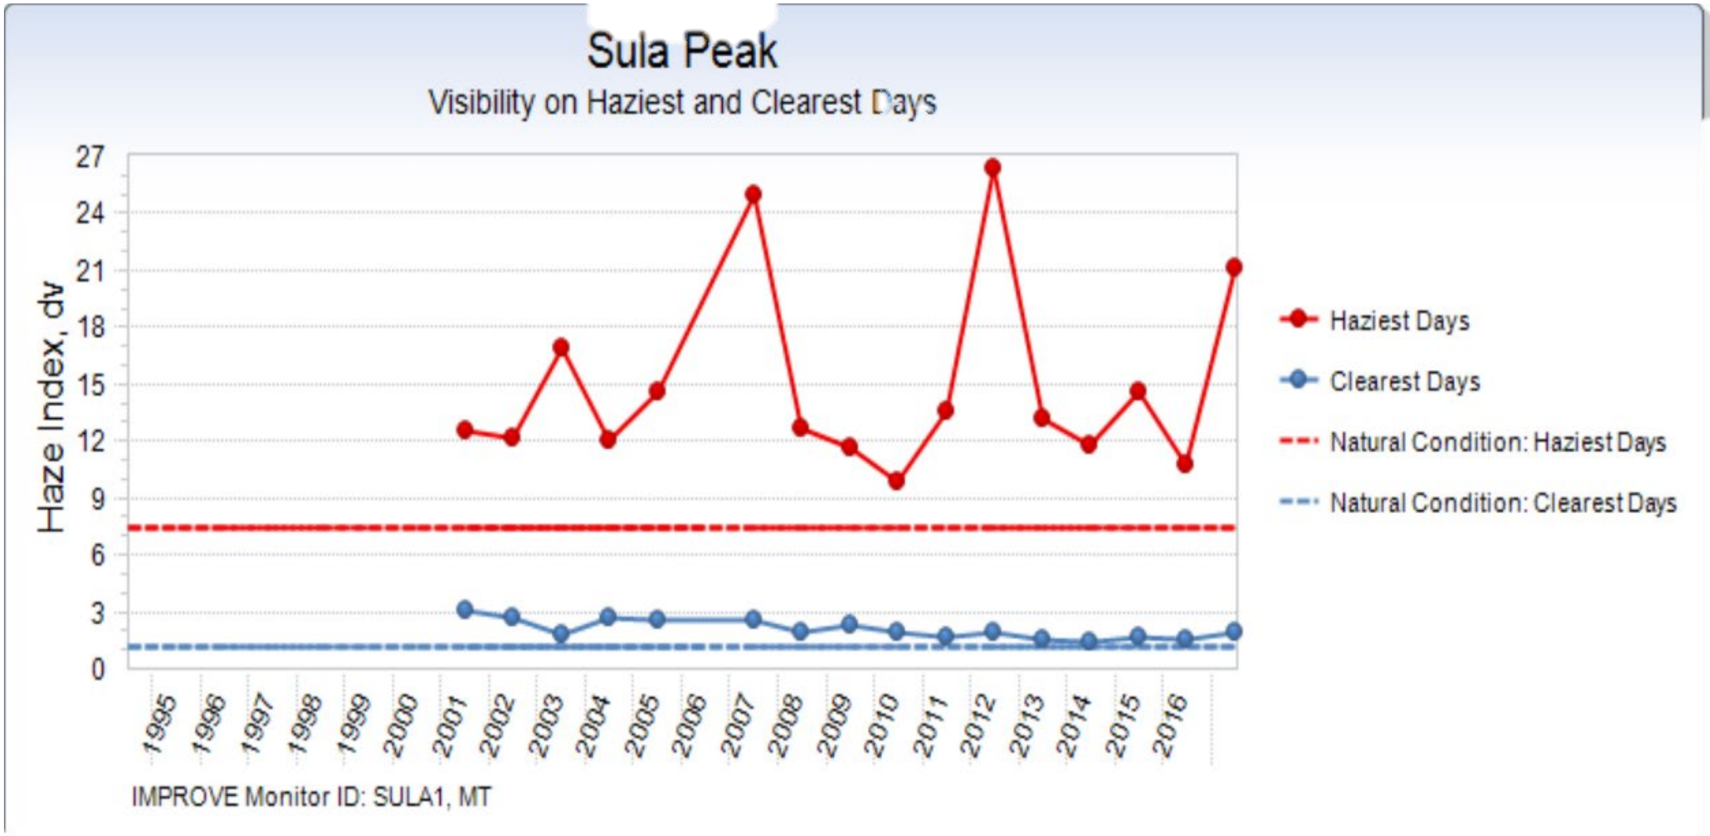

Figure 128. Trends in visibility on haziest and clearest days on Sula Peak (2001-2017)

Environmental Consequences

Table 300 provides the projected average acres per decade of wildfire, and future treatment by alternative.

Table 300. Projected average acres per decade of wildfire and future fuels treatment by alternative

Component and Indicator	No Action Alternative	Alternative W	Alternative X	Alternative Y	Alternative Z	Preferred Alternative
All Wildfire Acres Burned	357,000	358,284	348,245	437,535	438,443	360,258
Future Fuels Treatment Acres	99,050[1]	229,225	239,255	230,075	149,057	227,242
Fire Management Flexibility Acres[2]	349,832	921,519	0	408,452	715,739	320,059

[1]Based on the average annual acres of fuels treatment over the past 10 years under the current plans.

[2]Denotes acres of special management considerations, such as recommended wilderness and suitable wild and scenic river designation.

Effects Common to All Alternatives

Smoke from wildfire is anticipated to be the primary contributor to air quality impacts in the Nez Perce-Clearwater, as it has been historically. The Nez Perce-Clearwater has a limited ability to alter or control the location or extent of this effect due to the unpredictable nature of wildfire and changes in climate. Wildfires have the greatest potential to influence short- and long-term air quality and visibility in the Nez-Perce Clearwater.

The Nez Perce-Clearwater will continue to participate in the Montana and Idaho Airshed Group and will conduct prescribed burning and fuels operations in accordance with operating guidance set forth by the Group. These controls provide the best possible protection of public health and welfare by mitigating the impacts of air pollution while still allowing fire to assume its natural role in maintaining healthy wildland ecosystems.

Effects to No Action Alternative

Current plan direction is to coordinate all Forest Service management activities to meet the requirements of the State Implementation Plan, State Smoke Management Plan (Montana/Idaho Airshed Group Operating Guide), and federal air quality standards.

Under the fire management program, prescribed fire and fuels treatments are conducted within the constraints established by the Montana and Idaho Airshed Group to meet local, state, and federal levels. Continued use of fuels treatments, such as prescribed burning, will affect local air quality and visibility in the short-term. The Nez Perce-Clearwater must meet established air quality standards when conducting fuels treatment activities. In addition, use of prescribed fire and fuels treatments under all of these alternatives will be limited by how much vegetation, when and where burns can occur, and budget constraints. These constraints, as well as adherence to air quality standards, will in turn limit impacts to human health and visibility.

Effects Common to Action Alternatives

Each action alternative reflects a mix of increased fuels treatments by prescribed burning and mechanical treatments. Continued fuels treatment activities will have the potential to affect local air quality in the short-term under each action alternative. Wildfire is expected to have the greatest effect on air quality in the Nez Perce-Clearwater for each alternative.

Effects that Vary by Action Alternative

Each alternative increases the use of fuels treatments and the potential for local, short-term air quality impacts. However, each alternative varies greater in fire management flexibility. Recommended wilderness and suitable wild and scenic river designations will limit the flexibility for fuels treatments. It is likely that natural ignitions will be managed for resource objectives to reduce fuels and move these landscapes toward desired conditions. Alternatives identifying the most acres for recommended wilderness and suitable wild and scenic river designation will have a higher potential for wildfire smoke emissions.

Alternatives W and Z include increased fuels treatments and increased acreage identified as recommended wilderness and suitable wild and scenic river designation. These alternatives will likely have the highest potential for long- and short-term air quality impacts. Alternative X includes increased fuels treatment but does not identify additional recommended wilderness and suitable Wild and Scenic River designation. Alternative X would offer managers the most flexibility in managing fuels treatments. Alternative Y increases the fuels treatments acres and slightly increases wilderness and suitable wild and scenic river designation. The Preferred Alternative increases fuels treatments and slightly decreases wilderness and suitable wild and scenic river designation, marginally increasing fire management flexibility from the current status.

Cumulative Effects

Most impacts to air quality and visibility in the Nez Perce-Clearwater are expected to remain contributable to smoke, primarily from wildfires. Wildfires in upwind areas, including other Western states and Canada, can also contribute to decreased air quality on the Nez Perce-Clearwater. In addition to emissions from wildfire and prescribed burning on the Nez Perce-Clearwater, other sources of emissions could include timber and mining operations, road dust, and transportation and other combustion engine sources. Upwind air pollution sources could also include crop burning, municipal emissions, and emissions attributed to long range transport.

Effects to Resource from Other Resources

As discussed in the affected environment sections, smoke from wildfire and prescribed fire is the largest contributor to air quality and visibility on the Nez Perce-Clearwater.

Summary of Consequences

A summary of consequences of the plan on air quality is included in **Error! Reference source not found.**by alternative.

Table 301. Air quality summary of consequences by alternative

Measurement Indicator	No Action	Alt. W	Alt. X	Alt. Y	Alt. Z	Preferred Alternative
Nez Perce-Clearwater meets all applicable air quality standards	No effect	No effect	No effect	No effect	No effect	No effect

Note: Summary based on fuels treatments, including prescribed burning, not on unplanned ignitions such as wildfire.

Conclusion

The air quality in and around Nez Perce-Clearwater is generally good, with limited influence from industrial, residential, and transportation sources. The primary influence to air quality and visibility in the Nez Perce-Clearwater is smoke from wildfire and prescribed fire activity. Wildfire is expected to remain the primary source of smoke and negative impact to air quality and visibility in and around the Nez Perce-Clearwater.

Prescribed fire and fuels treatments will become an increasingly important tool for managing the Nez Perce-Clearwater and achieving desired ecosystem conditions. The action alternatives vary slightly in the number of acres used for fuels treatments and prescribed burning but do reflect an increase in these activities from the current plan. Continued adherence to the Montana and Idaho Airshed Group management practices and all federal, state, and local regulations is expected to minimize degradation to air quality and visibility from these activities for all alternatives. Increased recommended wilderness and wild and scenic river designated acres could limit fire management flexibility and potentially increase smoke attributed to wildfire. The Preferred Alternative increases acres for fuels treatments and prescribed burning and decreases acres for recommended wilderness and wild and scenic river designation, thus slightly increasing fire management flexibility.

3.2.11 Ecological Sustainability

The mission of the U.S. Forest Service is to sustain the health, diversity, and productivity of the Nation's forests and grasslands to meet the needs of present and future generations. The 2012 Planning Rule specifies that land management plans must include forestwide plan components to provide for integrated social, economic, and ecological sustainability, while providing for ecosystem services and multiple uses. Ecological sustainability refers to the capability of ecosystems to maintain ecological integrity and meet the needs of the present generation without compromising the ability of future generations to meet their needs. Specifically, the land management plan must include plan components to guide the Nez Perce-Clearwater's contribution to ecological sustainability and be designed to 1) maintain, restore, or promote the ecological integrity of terrestrial, riparian, and aquatic ecosystems; 2) maintain the diversity of plant and animal communities; and 3) support the persistence of native species within the plan area, subject to the extent of Forest Service authority and the inherent capability of the plan area (FSH 1909.12, 23.1).

As described in Section 23.11 of Forest Service Handbook 1909.12, ecosystems in the plan area should have ecological integrity and adaptive capacity and support a diversity of species and habitat types. Ecosystems have integrity when their composition, structure, function, and connectivity are operating normally over multiple spatial and temporal scales. Adaptive capacity is the ability of ecosystems to respond, cope, or adapt to disturbances and stressors, including environmental change, to maintain options for future generations. The diversity of terrestrial, riparian, and aquatic ecosystems and habitats is fundamental to providing ecological conditions that support the abundance, distribution, and long-term persistence of native species and diversity of plant and animal communities.

Various aspects of a resilient ecosystem require both new and updated individual and integrated direction regarding habitat conservation and restoration, species conservation, management of vegetative fuels, management of wildfire and ecological responses to it, management of invasive species, and dealing with the effects of climate change. The land management planning revision process identified a need for specific integrated direction regarding ecosystem restoration and resiliency. In 1987, forest plan components were established to manage ecosystems toward achieving desired conditions that maintain and improve species composition, habitat, and function. Direction reflected the best scientific data and information available at that time. Since then, certain aspects of this direction have been updated by forest plan amendments. However, much of the direction in the 1987 Nez Perce and Clearwater Forest Plans was developed to manage specific elements of specific ecosystems that have evolved markedly over the past 26 years. Today, because of changes in ecosystem conditions and the newly arisen issues that affect them, 1987 Forest Plan direction does not ensure future ecosystem restoration and sustainability. For example, it has no components that address how to manage resources to ensure ecosystem resilience and adaptation to climate change.

This section describes some key ecological elements on the Nez Perce-Clearwater and provides a summary detailing how the Land Management Plan will provide for ecological sustainability (36 CFR 219.8) and support the diversity of plant and animal communities and persistence of native species (36 CFR 219.9). Land Management Plan desired condition, standards, guidelines, and suitability determines are common across all Action Alternatives. Land Management Plan objectives vary between on alternatives, depending on the pace of implementing objectives.

Relevant Laws, Regulations, and Policy

The Nez Perce-Clearwater will follow all laws, regulations, and policies that relate to managing National Forest System land. The Land Management Plan is designed to supplement, not replace, direction from these sources. Other Forest Service direction, including laws, regulations, policies, executive orders, and Forest Service directives via manuals and handbooks are not repeated in the Land Management Plan.

Federal Laws

Multiple-Use Sustained-Yield Act of 1960: Congress has affirmed the application of sustainability to the broad range of resources over which the Forest Service has responsibility. The Multiple-Use Sustained-Yield Act confirms the Forest Service's authority to manage the national forests and grasslands "for outdoor recreation, range, timber, watershed, and wildlife and fish purposes" (16 U.S.C. § 528) and does so without limiting the Forest Service's broad discretion in determining the appropriate resource emphasis or levels of use of the lands of each national forest and grassland.

Forest and Rangeland Renewable Resources Planning Act (RPA) of 1974, as amended by National Forest Management Act (NFMA) of 1976 (16 U.S.C. 1600-1614, 472a): This Act states that the development and administration of the renewable resources of the National Forest System are to be in full accord with the concepts for multiple use and sustained yield of products and services as set forth in the Multiple-Use Sustained-Yield Act of 1960. It sets forth the requirements for land and resource management plans for units of the National Forest System, including requiring guidelines to provide for the diversity of plant and animal communities based on the suitability and capability of the specific land area and within multiple use objectives.

Agency Regulations

36 CFR 219.8: Requires land management plans to provide for social, economic, and ecological sustainability within Forest Service authority and consistent with the inherent capability of the plan area.

36 CFR 219.9: Requires land management plans to provide for the diversity of plant and animal communities and the persistence of native species in the plan area, within Forest Service authority and consistent with the inherent capability of the plan area.

Policy

Forest Service Manual 2020 provides policy for reestablishing and retaining ecological resilience of National Forest System lands and resources to achieve sustainable multiple use management and provide a broad range of ecosystem services. Resilient ecosystems have a greater capacity to survive disturbances and large-scale threats, especially under changing and uncertain future environmental conditions, such as those driven by climate change and human uses.

The Forest Service Manual objective is that ecosystems ecologically or functionally are restored so that, over the long term, they are resilient and can be managed for multiple use and provide ecosystem services, including but not limited to carbon storage and sequestration.

Forest Service Manual 2020 policy directs the Forest Service to emphasize ecosystem restoration across the National Forest System and within its multiple use mandate (FSM 2020.3(1)). Additionally, the Forest Service may reestablish, maintain, or modify the composition, structure, function, and connectivity of aquatic and terrestrial ecosystems to sustain their resilience and adaptive capacity (FSM 2020.3(3)).

Ecoregions

An ecological type is a category of land with a distinctive combination of landscape elements, differing from other types in the kind and amount of vegetation it can produce and in its ability to respond to management actions and natural disturbances (Winthers et al. 2005). Ecoregions denote areas of general similarity in ecosystems and in the type, quality, and quantity of environmental resources. Ecoregions are identified through the analysis of the spatial patterns and the composition of biotic and abiotic elements, including geology, physiography, vegetation, climate, soils, land use, wildlife, and hydrology. By recognizing the spatial differences in the capacities and potentials of ecosystems, ecoregions stratify the environment by its probable response to disturbance (Bryce et al. 2017). The use of ecoregions is beneficial when planning and implementing management actions using an all-lands approach, as ecoregions cross ownership boundaries.

There are four levels within the ecoregion hierarchy as delineated by the United States Environmental Protection Agency. The Nez Perce-Clearwater is located within the Northwestern Forested Mountains Level I ecoregion and the Cold Deserts and Western Cordillera Level II ecoregions. There are 10 Level III ecoregions and 71 Level IV ecoregions in Idaho (McGrath et al. 2002). The Nez Perce-Clearwater is comprised of 4 Level III ecoregions and 19 Level IV subregions, as shown in Figure 130.

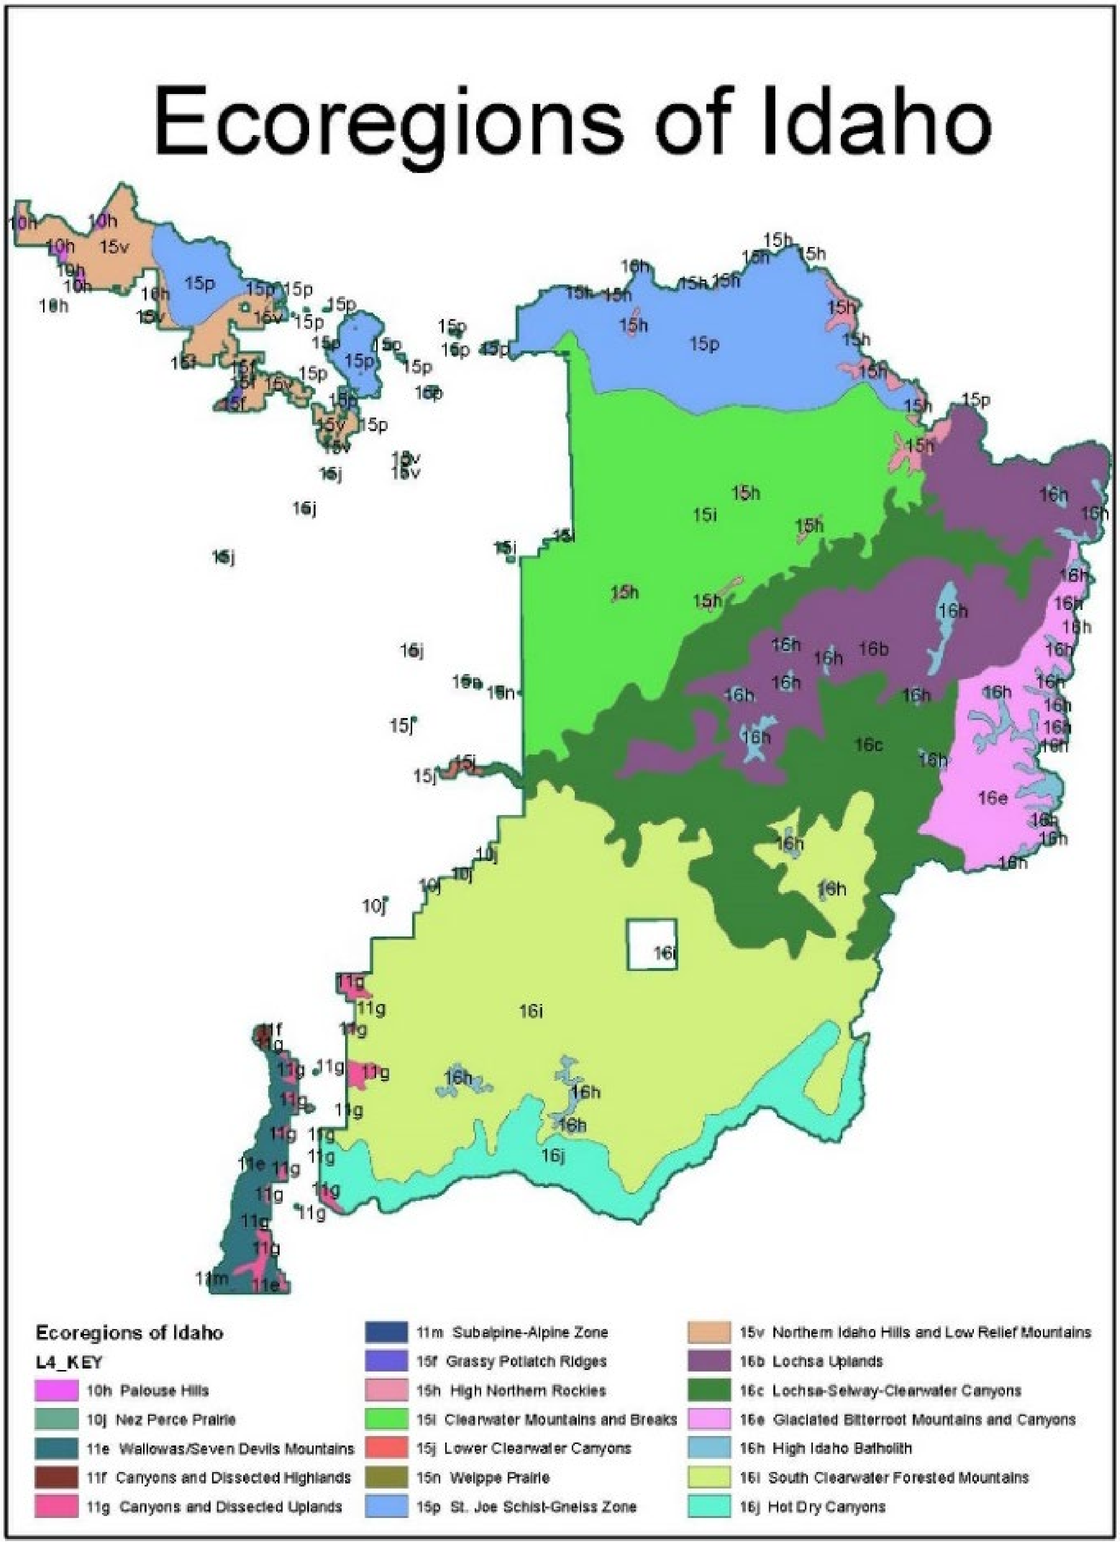

Figure 130. Level III ecoregions and Level IV subregions within the plan area

Source: http://www.ecologicalregions.info/data/id/id_eco_lg.pdf and https://www.nrc.gov/docs/ML1018/ML101800248.pdf.

The Columbia Plateau ecoregion occurs on less than one percent of the Nez Perce-Clearwater, totaling about 91,000 acres. It is an arid grassland and sagebrush steppe that is surrounded by moister, predominantly forested mountainous ecoregions. The Columbia Plateau ecoregion is underlain by thick basalt. It includes Level IV ecoregions 10h Palouse Hills and 10j Nez Perce Prairie.

The Blue Mountains ecoregion occurs on two percent of the Nez Perce-Clearwater. It is mountainous and mostly volcanic in origin. Douglas-fir, subalpine fir, grand fir, Engelmann spruce, western larch, lodgepole pine, and Ponderosa pine occur within this ecoregion. The Blue Mountains ecoregion includes Level IV ecoregions 11e Wallowa/Seven Devils Mountains, 11f Canyons and Dissected Highlands, 11g Canyons and Dissected Uplands, and 11m Subalpine-Alpine Zone.

The Northern Rockies ecoregion occurs on 31 percent of the Nez Perce-Clearwater. It is mountainous and rugged. Climate, trees, and understory species are characteristically maritime influenced. Douglas-fir, subalpine fir, Engelmann spruce, western larch, lodgepole pine, and Ponderosa pine, as well as Pacific indicators such as western redcedar, western hemlock, mountain hemlock, and grand fir, occur within this ecoregion. Western white pine was once common but has been decimated by blister rust, early to mid-twentieth century logging, and fire suppression. Whitebark pine is also undergoing a considerable population decline because of white pine blister rust, mountain pine beetle, and uncharacteristic wildfire resulting from altered fire regimes. Thick volcanic ash deposits occur over much of the ecoregion. The Northern Rockies ecoregion includes Level IV ecoregions 15f Grassy Potlatch Ridges, 15h High Northern Rockies, 15i Clearwater Mountains and Breaks, 15j Lower Clearwater Canyons, 15n Weippe Prairie, 15p St. Joe Schist-Gneiss Zone, and 15v Northern Idaho Hills and Low Relief Mountains.

The Idaho Batholith ecoregion occurs on 66 percent of the Nez Perce-Clearwater. It is mountainous, deeply dissected, partially glaciated, and characteristically underlain by granitic rocks. Soils derived from granitics are droughty and have limited fertility and, therefore, provide only limited amounts of nutrients to aquatic ecosystems. They are highly erodible when vegetation is removed. Maritime influence is slight and lessens toward the south. Grand fir, Douglas-fir, western larch, and, at higher elevations, Engelmann spruce and subalpine fir occur within this ecoregion; Ponderosa pine, shrubs, and grasses grow in deep canyons. The Idaho Batholith ecoregion includes Level IV ecoregions 16b Lochsa Uplands, 16c Lochsa-Selway-Clearwater Canyons, 16e Glaciated Bitterroot Mountains and Canyons, 16h High Idaho Batholith, 16i South Clearwater Forested Mountains, and 16j Hot Dry Canyons.

The Level III and IV ecoregion delineations and descriptions incorporate information from Bailey's ecoregions (Bailey 1995). The Forest Service uses Bailey's ecoregions to evaluate and compare biophysical conditions across large landscapes. The Nez Perce-Clearwater is located almost entirely within the M333 Northern Rocky Mountain Forest Steppe and M332 Middle Rocky Mountain Steppe ecological provinces as delineated by Baily (1995). Nested within the ecological provinces are ecological sections. The Nez Perce-Clearwater is primarily located in the M332A Idaho Batholith and M333D Bitterroot Mountain sections, with small amounts occurring in the M332G Blue Mountains and 331A Palouse Prairie sections (McNab et al. 2007). These sections are further broken down into Land Type Associations (LTA), which are landscape scale biophysical stratifications using landform and geologic material information. The Nez Perce-Clearwater contains 92 land type associations.

System Drivers

Ecological Processes

Ecological processes are the interactions among the physical, chemical, and biological elements of an ecosystem and occur at multiple spatial and temporal scales. These processes are crucial for maintaining healthy ecosystems and supporting the long-term persistence of biodiversity.

Examples of ecological processes include:

- Types, frequencies, severities, patch sizes, extent, and spatial pattern of disturbances, such as fires, grazing, timber harvest, landslides, floods, and insect or disease outbreaks
- Ability of native species to move throughout the plan area and cross into adjacent areas to use habitat that fulfills their life cycle needs
- Successional pathways and stand development of major vegetation types, longevity, and turnover of habitats
- Pollination
- Predation and herbivory at multiple trophic levels
- Hydrologic flow regimes, including time, duration, and magnitude
- Sediment transport, including timing and duration
- Soil development and retention
- Energy flow
- Nutrient cycling and retention

Natural Disturbance Regimes

Natural disturbance regimes are the primary influences on forested and non-forested ecosystems across much of the Nez Perce-Clearwater due primarily to the extent of areas where little active management occurs, such as wilderness and Idaho roadless areas. Fire is a primary natural disturbance process that changes vegetation conditions and is a necessary and critical ecological function across the Nez Perce-Clearwater, playing a central role in providing quality habitat for terrestrial and aquatic species.

Other natural disturbance, including insects, disease, landslides, flooding, drought, and weather events such as windstorms, are continually cycling through the landscape. These natural processes create a patchwork of vegetative openings across the Nez Perce-Clearwater and a variety of ecological conditions. See sections for Forestlands, At-Risk Plant Species, Fire Management, Soils, Water Resources, Aquatic Ecosystems and Fisheries, Wildlife, Abundance and Diversity of Wildlife, and Threatened, Endangered, Candidate, and Proposed Wildlife Species for more information related to natural disturbance processes.

Stressors

Ecosystems that are healthy and have ecological integrity are better able to adapt to changes imposed by stressors. Stressors are natural or human-influenced factors that may directly or indirectly degrade or impair ecosystem composition, structure, or ecological process in a manner that may impair its ecological integrity. Examples of stressors include invasive species impacts, loss of spatial connectivity, disruption of natural disturbance regimes, influence of climate change, and uncharacteristic wildland fire. Climate change has the potential to bring about uncharacteristic natural disturbances and could likely exacerbate natural and human-influenced stressors. Direct human influences, such as roads, infrastructure, pollutants, mineral extraction, and fire exclusion, can disrupt ecological processes and cause further stress to the system. Stressors could intensify as increasing demands and pressures from the public for a variety of multiple uses and ecosystem services that national forest lands provide.

Natural Range of Variation

Natural range of variation is the variation of ecological characteristics and processes over scales of time and space that are appropriate for a given management application. The natural range of variation is a tool for assessing the ecological integrity of an ecosystem and does not necessarily constitute a management target or desired condition. Utilizing the natural range of variation can help identify key structural, functional, compositional, and connectivity characteristics for which plan components may be important for either maintenance or restoration of such ecological conditions. Although the intent is to promote ecosystem integrity in the plan area, it may not be possible or appropriate to strive for returning key characteristics to past conditions throughout the plan area.

Discerning the natural range of variation is fundamental in strategic thinking and planning, even if restoration to historical conditions is not the management goal or possible on parts of the plan area. The natural range of variation is useful for understanding each specific ecosystem, for understanding its existing ecological conditions, and for understanding its likely future character based on projections of climate regimes. The natural range of variation also provides a frame of reference for understanding the dynamic nature of ecosystems and how they change over time and acts as a guide to understanding how to restore a resilient ecosystem with structural and functional properties that will enable it to persist into the future. Understanding the natural range of variation provided context and insights and helped with the development of specific plan components that promote the maintenance or restoration of ecological integrity and diversity of terrestrial, riparian, and aquatic ecosystems and habitat types throughout the plan area. These plan components provide an ecosystem (coarse filter) approach to maintaining the persistence of native species.

Although understanding the natural range of variation is important, the future will not be the same as the past. Therefore, in addition to the natural range of variation, additional factors were considered in the development of desired conditions. These included maintaining conditions that contribute to long-term resilience given uncertainties in future climate and disturbances; sustaining stand structures or species compositions that provide habitat for at-risk wildlife or plant species; conserving rare structures or components; mitigating existing or anticipated human use patterns; considering the effects changing climate may have; and acknowledging the ecosystem services expected from forest lands.

Ecological Conditions on the Nez Perce-Clearwater

Ecological conditions on the Nez Perce-Clearwater vary across the landscape. A variety of information can be used to assess terrestrial and aquatic conditions at differing temporal and spatial scales. Two primary tools the Forest Service uses include the Watershed Condition Framework and the Terrestrial Condition Assessment. These assessments cover all national forests across the United States.

Terrestrial Condition Assessment

The U.S. Forest Service has conducted restoration related activities for decades; however, the need for reestablishing and retaining resilience of National Forest System lands to achieve sustainable management has never been greater (Cleland et al. 2017). Deleterious effects of elevated temperature and reduced precipitation, particularly in the west; uncharacteristically severe or frequent wildfire; fragmentation of habitat due to roads; and the effects of air pollution or invasive species are adversely impacting National Forest System lands (Cleland et al. 2017).

The terrestrial condition assessment framework (Cleland et al. 2017) was used to complete a national level assessment of ecological integrity based on uncharacteristic stressors, conditions, and disturbance agents for National Forest System lands in the United States. The terrestrial condition assessment is a mid-scale evaluation utilizing the land type association tier of the national hierarchical framework of ecological units as analysis units (Cleland et al. 1997). Land type associations represent the landscape-level units in the hierarchy, averaging about 20,000 acres in size.

The terrestrial condition assessment was designed to complement the watershed condition framework, a national effort to evaluate the status of watersheds across all National Forest System lands (U.S. Department of Agriculture 2011d, Potyondy and Geier 2011). The Watershed Condition Framework is discussed in further detail in the Water Resources section.

The terrestrial condition assessment evaluates effects of uncharacteristic stressors and disturbance agents on land-type associations to identify restoration opportunities on National Forest System lands in the United States at both the national and regional scales. The terrestrial condition assessment used the ecosystem management decision support system, a spatial decision support system for landscape analysis and planning. Primary national data sources included observed insect and pathogen-induced mortality; key critical loads for soil and the atmosphere; long-term seasonal departures in temperature and precipitation; road densities; uncharacteristic wildfires; historical fire regime departure; wildfire potential; insect and pathogen risk; and vegetation departure from the natural range of variability.

Results from the analysis displayed that about 74 percent of National Forest System lands across the United States had moderate or better overall ecological integrity; whereas 26 percent are in poor or very poor condition (Cleland et al. 2017). As shown in Figure 131, the Nez Perce-Clearwater falls into the poor or very poor condition for overall terrestrial condition.

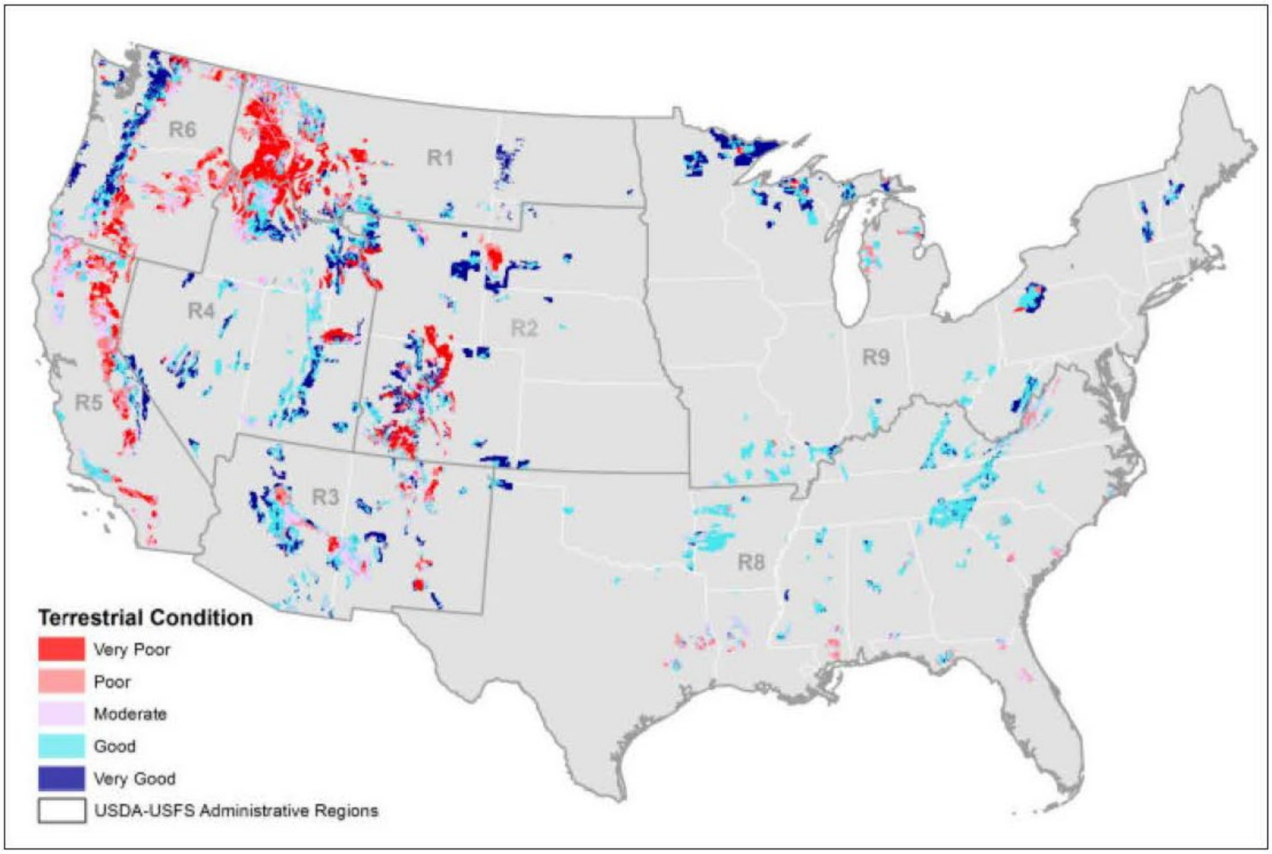

Figure 131. Overall ratings of land type associations from the Terrestrial Condition Assessment on Forest Service administrative lands

Data Source: (Cleland et al. 2017).

The U.S. Forest Service Northern Region has extensive areas with high insect and disease risk, 37 percent of the Region; high and very high wildfire potential, 34 percent of the Region; and high mortality occurring within the past five years, 16 percent of the Region. All western regions are experiencing stress due to elevated temperatures and, to a lesser degree, reduced precipitation. Of greatest concern are increases in winter temperature and decreases in winter precipitation (Cleland et al. 2017). As stated in Cleland and others (2017):

The western United States has been subject to uncharacteristically severe wildfire in past decades largely due to a century of fire suppression, past logging, and climate exposure (Collins et al. 2011). Fire suppression has resulted in increased tree densities and associated moisture demand, and increased fuel loads relative to historical or pre-European settlement forest conditions (Naficy et al. 2010). Increased winter temperatures reduce snowpack and water storage (Margulis et al. 2016) and also reduce cold-induced mortality of damaging insects and diseases (Bentz et al. 2010). Increased temperatures during the growing season reduces fuel moisture, aggravating conditions promoting uncharacteristic wildfire (Abatzoglou and Williams 2016, Westerling 2016) and increases the extent to which trees are stressed and less able to resist adverse effects of insect and disease.

Figure 132 displays the overall terrestrial condition rating of the land type associations from the terrestrial condition assessment for the Nez Perce-Clearwater. Most of the Nez Perce-Clearwater is rated as having poor or very poor terrestrial condition ecological integrity.

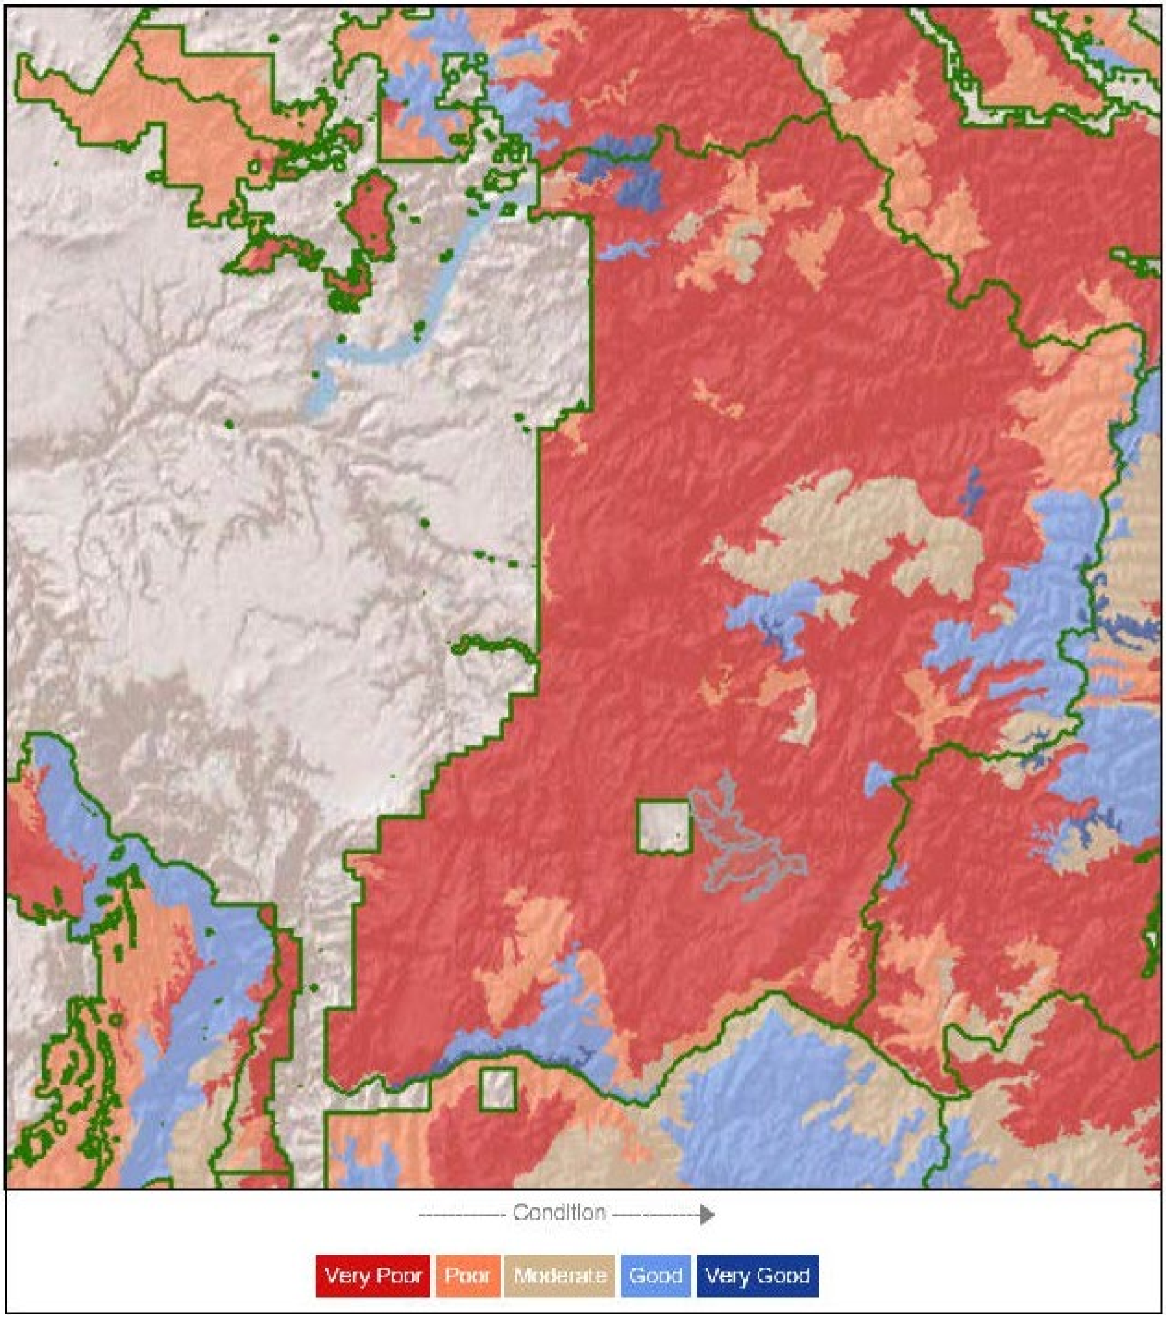

Figure 132. Overall terrestrial condition rating of the land type associations for the Terrestrial Condition Assessment

Data Source: Terrestrial Condition Assessment webmap, accessed 5/20/2019.

The terrestrial condition rating is based on disturbance agents and vegetation condition. Disturbance agents include Biotic and Abiotic agents. Biotic agents include insects and pathogen incidences.

Abiotic agents include road density, climate exposure, air pollution, and uncharacteristic disturbances such as wildfire. Figure 133 displays the disturbance agents' ratings, which show a mix of good, moderate, and poor ratings.

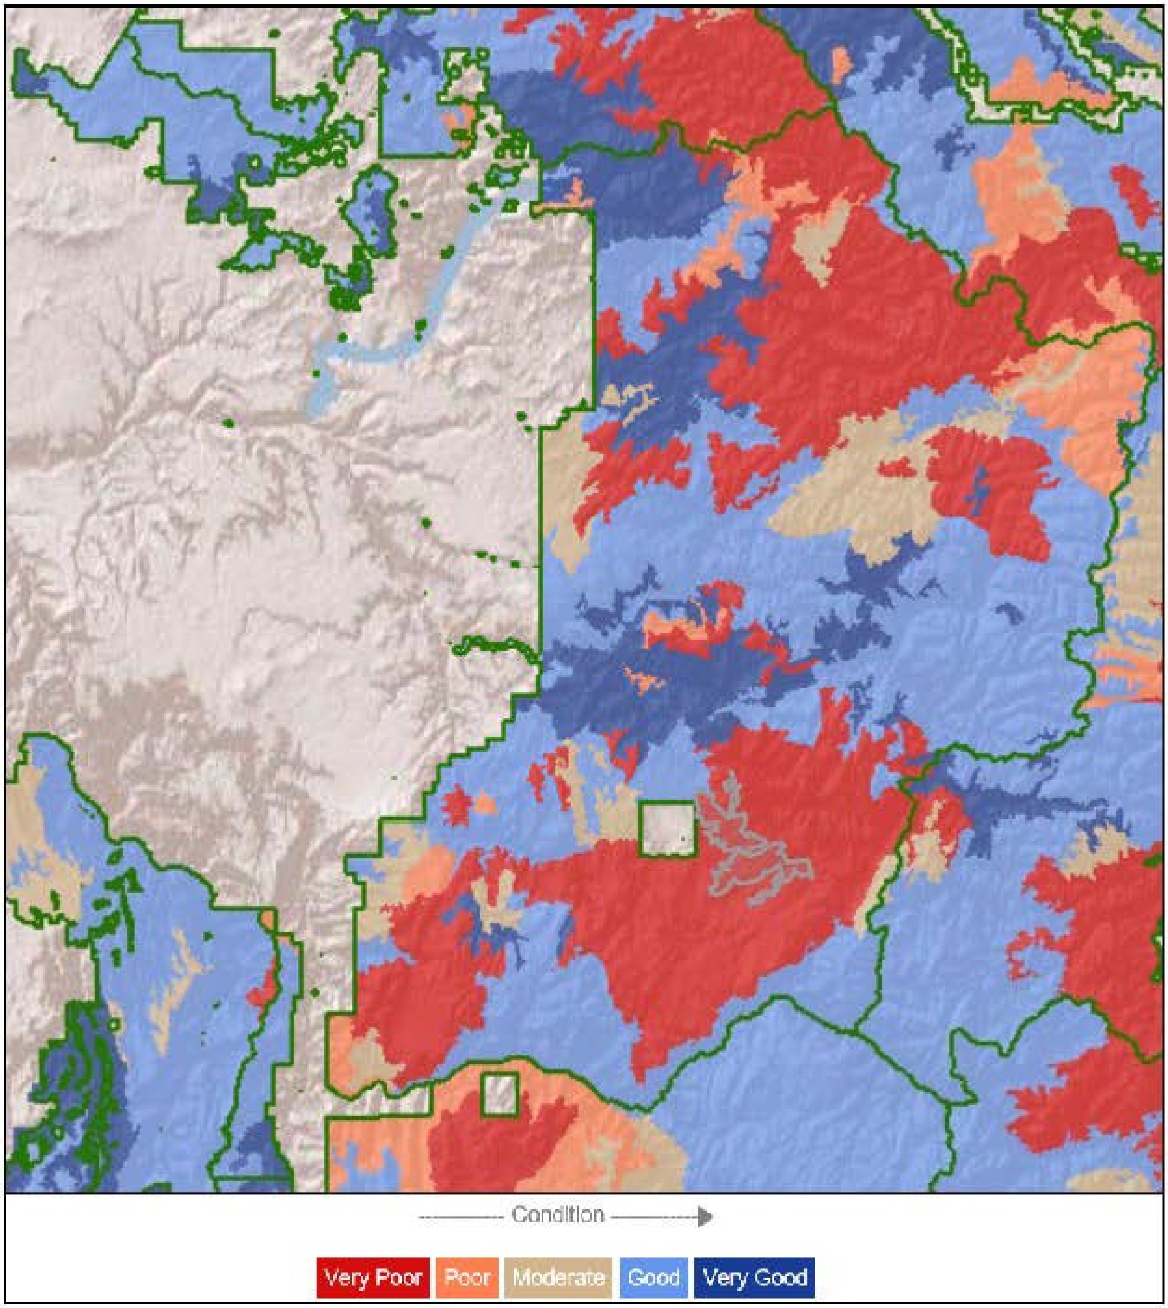

Figure 133. Disturbance agents rating of the land type associations from the Terrestrial Condition Assessment

Data Source: Terrestrial Condition Assessment webmap, accessed 5/20/2019.

The vegetation condition rating consists of wildfire potential, insects and pathogens risk, vegetation departure, and fire regime departure. Figure 134 displays the vegetation condition rating. Most of the

Nez Perce-Clearwater is rated as having poor or very poor vegetation condition. A high wildfire potential occurs across 84 percent of the Nez Perce-Clearwater and insects and pathogens risk occurs across 80 percent of the area.

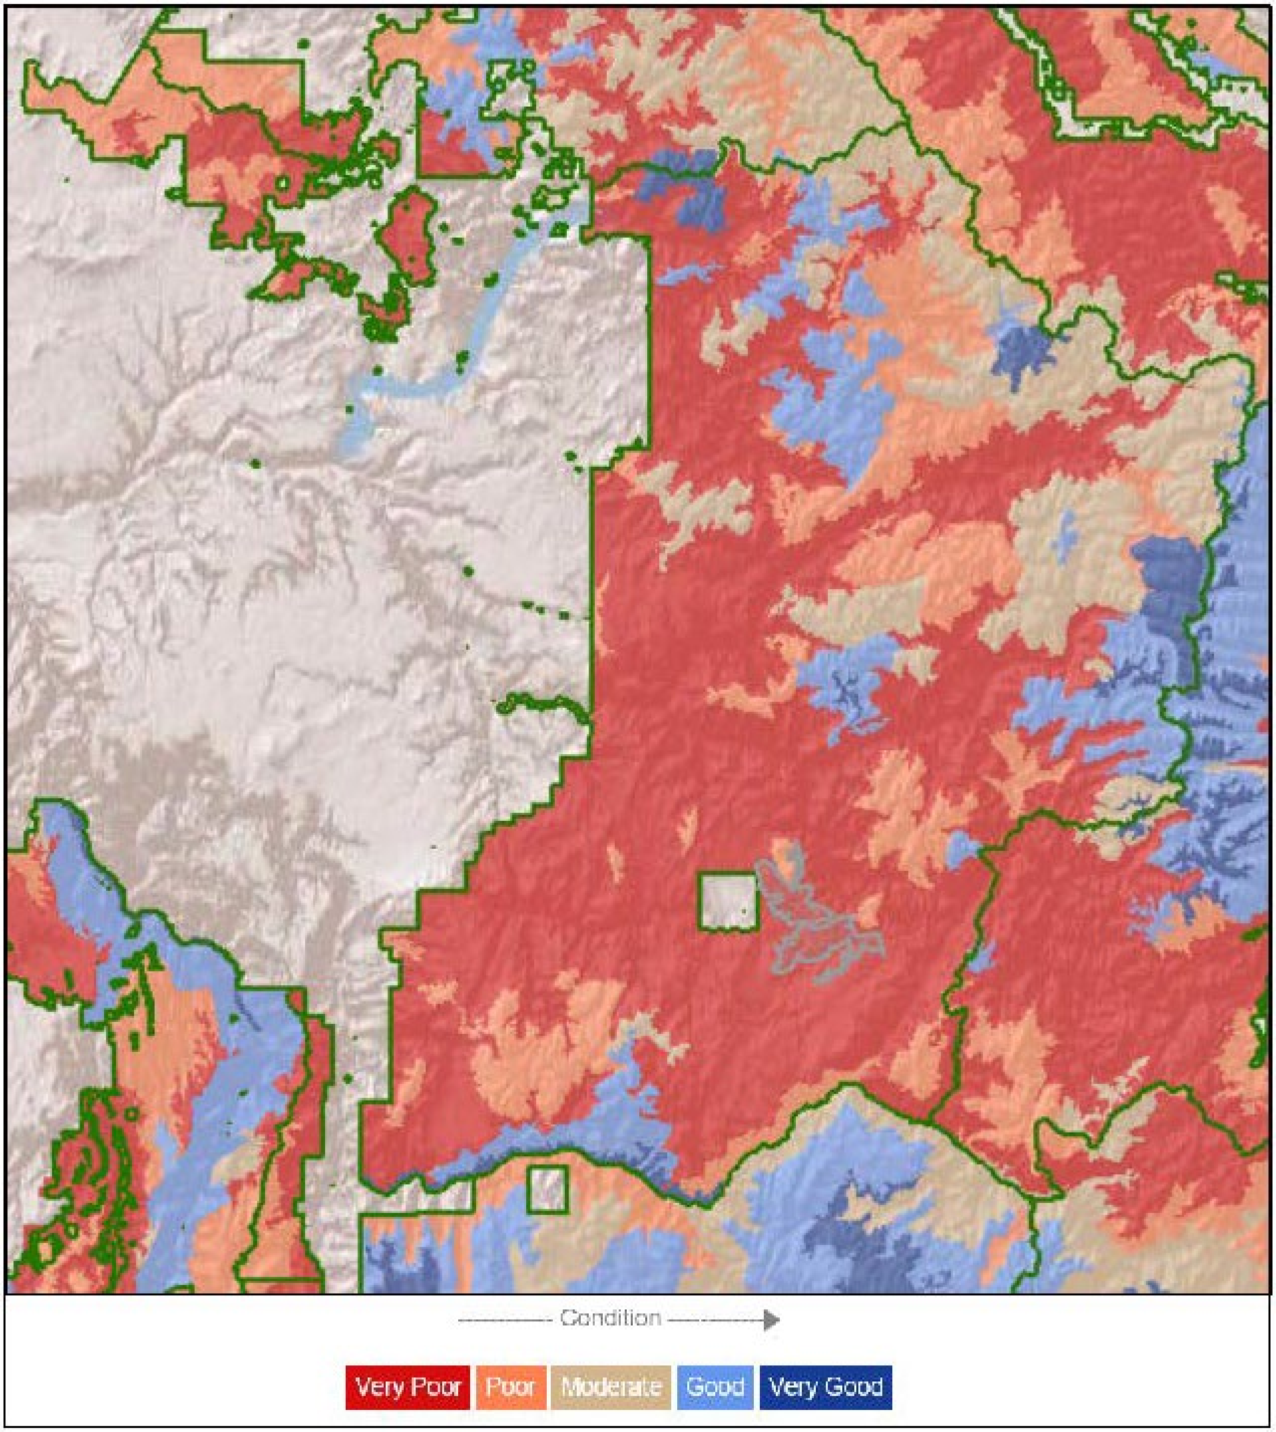

Figure 134. Vegetation condition rating of land type associations from the Terrestrial Condition Assessment

Data Source: Terrestrial Condition Assessment Webmap, accessed 5/20/2019.

Overall, based on the terrestrial condition assessment (Cleland et al. 2017), the Nez Perce-Clearwater has a poor to very poor terrestrial condition rating or low ecological integrity.

The Nez Perce-Clearwater can apply the terrestrial condition assessment as a management tool to assist with identifying and prioritizing project areas for treatment. Utilizing the terrestrial condition assessment in conjunction with the watershed condition framework would facilitate the development of well-integrated projects conducted at the appropriate scale to move towards Land Management Plan desired conditions.

Watershed Condition Framework

The corresponding Watershed Condition Framework (U.S. Department of Agriculture 2011d) is a consistent, nationwide approach to classify watershed condition and to prioritize watershed restoration at the subwatershed (HUC12) scale. Watershed condition classification ultimately categorizes watersheds in one of three discrete classes that reflect the level of watershed health or integrity. The watershed condition analysis completed on the Nez Perce-Clearwater in 2011 resulted in 64 percent of subwatersheds rated as functioning properly, 33 percent rated as functioning at risk, and 3 percent rated as impaired. The Watershed Condition Framework is discussed in further detail in the Water Resources section and Appendix K.

Other Assessments and Data Sources

The Nez Perce-Clearwater National Forest' Wildland Fire Risk Assessment (U.S. Department of Agriculture 2017c) characterizes wildland fire likelihood and intensity, as well as potential effects across the national forests. The assessment provides information to support strategic forest planning and prioritization, support strategic fire management decisions, and categorize potential impacts of wildland fire on highly valued resources. The assessment estimated burn probability, which is the likelihood that a specific geographic location will experience a wildland fire during a specified time (annually). Over 60 percent of the Nez Perce-Clearwater was estimated to have a moderate to high burn probability. The Nature Conservancy (2014) completed a local assessment called Forest Composition and Structure Restoration Needs within the Clearwater Basin, Idaho, to describe the extent of vegetation departure occurring on the Nez Perce-Clearwater. The assessment concluded 35 percent of all forested acres on the Nez Perce-Clearwater and adjacent ownerships, equaling over 1.8 million acres, are currently in need of disturbance to place forest landscapes on a trajectory to their natural range of variability.

The Idaho State Forest Action Plan Resource Assessment (Idaho Department of Lands 2020) was developed by the Idaho Department of Lands in partnership with many other agencies and organizations. Its purpose is to ensure that federal and state resources are focused on landscape areas with the greatest opportunity to address shared priorities and achieve measurable outcomes. The Forest Resource Assessment provides a geospatial analysis of conditions and trends for all forested lands in Idaho. Threats to and benefits from forest resources were identified and form the foundation of the analysis.

The Idaho State Wildlife Action Plan (Idaho Department of Fish and Game 2017b) includes information on the ecological conditions of Nez Perce-Clearwater lands; describes key conservation targets for fish and wildlife species and their habitats; identifies threats to those targets, such as invasive weeds and wildfire; and provides recommended actions to address the threats. The ecological conditions assessment based on a landscape integrity model ranked Nez Perce-Clearwater lands as primarily very good and good. Very good conditions are described as having an absence of, or minimal, human disturbance; zero to some stressors and threats present; on-the-ground condition can be negatively impacted by localized stressors, such as invasive species or site-specific land uses like livestock grazing; and ecosystem processes and functions are typically within natural ranges of variation. Good ecological conditions are defined as having a landscape that deviates from the minimally disturbed class due to existing impacts, common in the wildland-urban interface; some stressors and threats present; often the best attainable condition where human impacts are present; and ecosystem processes and functions are usually within natural range of variation.

As noted in the Idaho State Wildlife Action Plan (Idaho Department of Fish and Game 2017b), portions of the Nez Perce-Clearwater, primarily along the national forest boundary or in areas of mixed ownership, were ranked as having fair ecological conditions. Fair ecological conditions are described as having several to many stressors present; land use roughly split between human-altered and minimally disturbed; ecosystem processes and functions are impaired and somewhat outside the range of variation found in the reference condition but are usually still intact; ecosystem processes are restorable; and sometimes the best remaining condition in watersheds with many human impacts.

There is also a variety of subbasin and watershed assessments completed by the Northwest Power and Conservation Council, Idaho Department of Water Resources, Idaho Department of Environmental Quality, Nez Perce Tribe, county soil and water conservation districts, and the Nez Perce-Clearwater that describe watershed and stream conditions.

There are numerous other sources that provide data on ecological conditions, such as Forest Inventory and Analysis (FIA), PACFISH and INFISH Biological Opinion Effectiveness Monitoring (PIBO), NatureServe, Soil Survey Geographic Database (SSURGO), and Landfire.

Management Strategies to Support Ecological Integrity

The 2012 Planning Rule adopts the definition of ecological integrity advanced by Parrish et al (2003) as the quality or condition of an ecological system when its dominant ecological characteristics, such as elements of species composition and diversity, structure, function, and ecological processes, occur within the natural range of variation and can withstand and recover from most perturbations imposed by natural environmental dynamics or human influence (36 CFR 219.19). The outcomes of improved ecological integrity include enhanced resistance, resilience, and adaptive capacity.

Three management strategies commonly published in the literature that support ecological integrity include promoting resilience to change, creating resistance to change, and enabling forests to respond or adapt to change (Holling 1973, Janowiak et al. 2014, Millar et al. 2007, Keane et al. 2018).

Resilience is defined as the degree to which forests and ecosystems can recover from one or more disturbances, either natural or human influenced, without a major shift in composition or function and is the most commonly suggested adaptation option discussed in the context of climate change (Millar et al. 2007). Resilient forests and grasslands accommodate gradual changes related to climate and can cope with disturbances. Resiliency depends on the extent and severity of the disturbance and the rate at which systems recover from disturbances. However, recovery rates are very difficult to define (MacDonald 2000). In most cases, the effect of a given disturbance will diminish over time.

Resistance is the ability of the forest, grassland, or ecosystem to withstand disturbances without significant loss of structure or function. From a management perspective, resistance includes both the degree to which communities are able to resist change, such as from a warming climate, and the manipulation of the physical environment to counteract and resist physical or biological change, such as through burning or harvest treatments (Keane et al. 2018).

The response or adaptive approach intentionally accommodates change rather than resists it, with the goal of enabling or facilitating forested and non-forested ecosystems to respond adaptively as environmental changes accrue. Treatments would mimic, assist, or enable ongoing natural adaptive processes, anticipating events outside the historical conditions, such as extended fire seasons or summer water deficits. Response tactics may include such practices as shifting desired species to new, potentially more favorable sites through planting; managing early-successional forests to "re-set" normal successional trajectories to create desired future patterns and structures; and promoting connected landscapes (Millar et al. 2007).

Although it is important to understand the concepts and purpose behind these three management strategies, it is more important to understand that they all have the same goal of helping the forest and ecosystem adapt to inevitable future changes related to climate while maintaining ecological integrity and continuing to provide desired ecosystem services. No single approach will fit all situations and the integration of various adaptive approaches and management practices is the best strategy (Millar et al. 2007, Spittlehouse and Stewart 2003).

Most of the natural resource desired conditions included in the Land Management Plan incorporate these management strategies with the aim of maintaining or restoring healthy ecosystems that provide ecosystem services and support ecological sustainability in the short and long term.

Ecological Sustainability, 36 CFR 219.8

The 2012 Planning Rule specifies that land management plans must include forestwide plan components to provide for integrated social, economic, and ecological sustainability within Forest Service authority and consistent with the inherent capability of the plan area (36 CFR 219.8). Inherent capability of the plan area is defined as the ecological capacity or ecological potential of an area characterized by the interrelationship of its physical elements, its climatic regime, and natural disturbances (36 CFR 219.19). The following information outlines how the Nez Perce-Clearwater Land Management Plan provides for ecological sustainability.

Sustainability is defined as the capability to meet the needs of the present generation without compromising the ability of future generations to meet their needs (36 CFR 219.19). Ecological sustainability refers to the capability of ecosystems to maintain ecological integrity. The 2012 Planning Rule provides direction for ecological sustainability (36 CFR 219.8) by addressing: 1) ecosystem integrity; 2) air, soil, and water; 3) riparian areas; and 4) best management practices.

Ecosystem Integrity, 36 CFR 219.8(a)(1)

Ecosystems have integrity when their composition, structure, function, and connectivity are operating normally over multiple spatial and temporal scales. However, not every desired condition or acre has to meet the definition of ecosystem or ecological integrity because some specific areas may not have the capability or because another concern, such as public safety, is more important in a specific area.

Ecological integrity is defined as the quality or condition of an ecosystem when its dominant ecological characteristics; for example, composition, structure, function, connectivity, and species composition and diversity occur within the natural range of variation and can withstand and recover from most perturbations caused by natural environmental dynamics or human influence (36 CFR 219.19).

36 CFR 219.8 specifies that a land management plan must include plan components, including standards or guidelines, to maintain or restore the ecological integrity of terrestrial and aquatic ecosystems and watersheds in the plan area, including plan components to maintain or restore structure, function, composition, and connectivity, while considering the following:

- Interdependence of terrestrial and aquatic ecosystems in the plan area.
- Contributions of the plan area to ecological conditions within the broader landscape influenced by the plan area.
- Conditions in the broader landscape that may influence the sustainability of resources and ecosystems within the plan area.
- System drivers, including dominant ecological processes, disturbance regimes, and stressors such as natural succession, wildland fire, invasive species, and climate change and the ability of terrestrial and aquatic ecosystems on the plan area to adapt to change.
- Wildland fire and opportunities to restore fire adapted ecosystems.
- Opportunities for landscape scale restoration.

Each of these items is discussed in further detail to better demonstrate how the Nez Perce-Clearwater Land Management Plan meets the direction for ecosystem integrity outlined in 36 CFR 219.8.

Interdependence of terrestrial and aquatic ecosystems in the plan area, 36 CFR 219.8(a)(1)(i)

Integrated resource management is defined as multiple-use management that recognizes the interdependence of ecological resources and is based on the need for integrated consideration of ecological, social, and economic factors (36 CFR 219.19). In the context of forest planning, the term "integration" means that the plan components work together but does not mean that all uses must be provided for on all lands (FSH 1909.12, Section 22). The Multiple-Use Sustained-Yield Act makes that principle clear by explaining that "multiple use" means management to make "judicious use of the land for some or all" of the renewable resources thereon, with some land "used for less than all of the resources" (16 USC 531).

The plan components in the Land Management Plan were developed in an integrated manner and reflect the interaction and interdependence of terrestrial, aquatic, and riparian ecosystems in the plan area. The integrated plan components work together toward maintaining or achieving ecological integrity, while also considering social and economic factors. The following are examples of integrated plan components included in the Land Management Plan:

FW-DC-FIRE-01. Restore and maintain landscapes: Landscapes across the Nez Perce-Clearwater are resilient to fire-related disturbances in accordance with management objectives. Natural fuel conditions emulate the structure, species mix, spatial pattern, extent, and resiliency of the historic fire regime of the area. Wildland fires burn with a range of intensity, severity, and frequency that allows ecosystems to function in a healthy and sustainable manner and meet desired conditions for other resources.

FW-DC-WTR-02. Spatial connectivity exists within or between watersheds. Lateral, longitudinal, and drainage network connections include floodplains, wetlands, upslope areas, headwater tributaries, and intact habitat refugia. These network connections provide chemically and physically unobstructed routes to areas critical for fulfilling life history requirements of aquatic, riparian-associated, and many upland species of plants and animals.

FW-DC-RMZ-01. Riparian Management Zones reflect a natural composition of native flora and fauna and a distribution of physical, chemical, and biological conditions as compared to reference conditions. The species composition and structural diversity of native plant communities in riparian management zones provide adequate summer and winter thermal regulation, nutrient filtering, appropriate rates of surface erosion, bank erosion, and channel migration. Nutrients, large woody debris, and fine particulate organic matter are supplied in amounts and distributions sufficient to sustain physical complexity and stability.

FW-DC-WL-03. The arrangement and distribution of vegetation patches is consistent with the natural range of variation and varies widely in size, shape, and structure to provide connectivity for native wildlife.

MA3-DC-FOR-11. Snags are present across Nez Perce-Clearwater lands, contributing to diversity of structure and habitat. Snags are unevenly distributed and dynamic over time with highest densities occurring in burned areas and those infested by insects. The lowest densities of snags occur along roads and in developed sites or other areas where the concern for human safety is elevated. A range of decay classes is represented.

Contributions of the plan area to ecological conditions within the broader landscape influenced by the plan area, 36 CFR 219.8(a)(1)(ii)

Ecological conditions within the broader landscape and ecological connectivity

The Nez Perce-Clearwater encompasses approximately four million acres. Although the Land Management Plan would directly guide management of the extensive acreage of the Nez Perce-Clearwater, it also has the potential to influence the broader landscape outside the plan area.

The Nez Perce-Clearwater contains some of the largest tracts of roadless and designated wilderness in the lower 48 states. Approximately 28 percent of the Nez Perce-Clearwater is Idaho roadless and 26 percent is designated wilderness. The Nez Perce-Clearwater contains portions of the Selway-Bitterroot Wilderness, Gospel-Hump Wilderness, and Frank Church-River of No Return Wilderness areas.

Five national forests are adjacent to the Nez Perce-Clearwater. The Idaho Panhandle and Lolo National Forests edge the northern section, the Bitterroot National Forest follows the eastern portion, and the Payette and Wallowa-Whitman National Forests border the southern end of the Nez Perce-Clearwater. The west and northwest portions of the national forest are bordered by mixed ownership lands, including private, state, industrial forestry, and other federal land. There are also scattered parcels of mixed ownership contained within the administrative boundary of the Nez Perce-Clearwater, totaling approximately 136,000 acres.

Nez Perce-Clearwater contains many free-flowing rivers that flow from, through, and into adjacent national forests and lands of mixed ownership. Water is a key ecosystem service that is provided by the Nez Perce-Clearwater and is important in the broader landscape and outside the plan area. Water that originates from Nez Perce-Clearwater eventually flows into the larger Snake and Columbia River systems, which support many communities in Idaho, Washington, and Oregon. Additionally, these aquatic ecosystems provide habitat for unique and diverse populations of fish and wildlife, enabling native species to move throughout the plan area, and cross into adjacent areas to use habitat that fulfills their life cycle needs.

The Nez Perce-Clearwater supports a number of at-risk plant, fish, invertebrate, and wildlife species. In some cases, national forest system lands may provide all, or a high percentage, of the habitat for a given species; however, in most instances, wildlife generally move from area to area without regard for boundaries. The extensive acreage of undeveloped lands on the Nez Perce-Clearwater interconnected with neighboring public lands provide important habitat security and connectivity for wide-ranging species, such as anadromous fish, lynx, wolverine, and other carnivores. Connectivity is described as ecological conditions that exist at several spatial and temporal scales that provide landscape linkages that permit the exchange of flow, sediments, and nutrients; the daily and seasonal movements of animals within home ranges; the dispersal and genetic interchange between populations; and the long-distance range shifts of species, such as in response to climate change (36 CFR 219.19).

The Nez Perce-Clearwater is located within several broader recovery areas for at-risk species. The Nez Perce-Clearwater contains major rivers and tributaries that are important for federally listed fish species and species of conservation concern. These rivers are considered key habitats in the Snake River recovery plans for Chinook salmon, steelhead, bull trout, lamprey, and sockeye salmon. The Nez Perce-Clearwater also contains lands within the Bitterroot Grizzly Bear Recovery Zone. Although the Nez Perce-Clearwater does not currently support a grizzly bear population, it does provide suitable bear habitat. Additionally, the Nez Perce-Clearwater occurs within the area guided by the Northern Rockies Lynx Management Direction (U.S. Department of Agriculture 2007f), which covers national forests in Idaho, Montana, Utah, and Wyoming.

The Nez Perce-Clearwater is situated within the Yellowstone to Yukon Conservation Initiative region, which stretches 2,000 miles from the Greater Yellowstone Ecosystem to Canada’s Yukon Territory. This region provides much of the best remaining habitat for North America’s threatened or sensitive species, including grizzly bears, wolves, wolverines, lynx, and native fish populations. The Yellowstone to Yukon Conservation Initiative is a non-profit organization that works with partners across varying land ownerships to protect core habitats and keep those habitats connected. The Nez Perce-Clearwater sits within two priority areas of the region. The Salmon-Selway-Bitterroot Ecosystem priority area includes one of the largest continuous roadless areas in the lower 48 States. The Cabinet-Purcell Mountain Corridor priority area is one of the most important linkages in the entire Yellowstone to Yukon region that allows wildlife to move from one key area to another and includes the headwaters of many important salmon and trout rivers.

The Land Management Plan contains plan components that provide for ecological connectivity at multiple temporal and spatial scales that would provide landscape linkages facilitating the exchange of resources and the movements of species across the broader landscape. The following are examples of plan components related to ecological connectivity:

FW-GL-TE-01. The Nez Perce-Clearwater works with federal, state, tribal, and private land managers towards an all-lands approach to management and cooperation, including efforts to mitigate threats or stressors, provide for wildlife and fish habitat connectivity, and to provide social, economic, and ecological conditions that contribute to mutual objectives.

FW-DC-TE-04. Vegetation reflects natural disturbance regimes. The composition, structure, function, and connectivity of native plant communities are appropriate for a given landscape and climatic setting.

FW-DC-WTR-02. Spatial connectivity exists within or between watersheds. Lateral, longitudinal, and drainage network connections include floodplains, wetlands, upslope areas, headwater tributaries, and intact habitat refugia. These network connections provide chemically and physically unobstructed routes to areas critical for fulfilling life history requirements of aquatic, riparian-associated, and many upland species of plants and animals.

FW-GL-WL-02. The Nez Perce-Clearwater cooperates with highway managers, state agencies, tribes, and landowners to implement wildlife and aquatic organism crossings that reduce encounters and contribute to public safety.

FW-DC-WL-03. The arrangement and distribution of vegetation patches is consistent with the natural range of variation and varies widely in size, shape, and structure to provide connectivity for native wildlife.

FW-DC-WL-06. The grizzly bear Bitterroot Recovery Zone provides the ecological conditions to support recolonization of grizzly bears. Land Management Plan land use allocations provide connectivity to allow secure passage from occupied habitat to the Bitterroot Recovery Zone.

FW-DC-WL-09. Wide-ranging species are free to move across and between habitats, allowing for dispersal, migration, genetic interaction, and species recruitment.

MA2-GDL-WL-05. To maintain large areas of unfragmented habitat for wide-ranging species, such as elk and grizzly bear, new motorized trails open to the public should not be authorized in Idaho Roadless Areas unless there are adjacent areas of 5,000 acres without open motorized system routes. This guideline does not apply to Community Protection Zones (CPZs) as defined by the Idaho Roadless Rule, areas with existing motorized access that are currently less than 5,000 acres, and existing trails that are relocated or reconstructed to mitigate negative impacts to ecological resources.

MA2-DC-IRA-03. Roadless areas contribute habitats for wide ranging species and connectivity for movement of wildlife. These areas also provide foraging, security, denning, and nesting habitat for wildlife.

MA2-DC-RWILD-03. Recommended wilderness areas facilitate the connectivity and movement of wildlife species across the Nez Perce-Clearwater by remaining large areas with little human activity.

Ecological conditions, habitats, or key ecosystem characteristics in the plan area that are unique, under-represented, or rare across the broader landscape

The Nez Perce-Clearwater possesses a tremendous range and unusual diversity of habitats, from boreal and coastal elements in the north to extensive grasslands and pine forests in the south. The maritime influence of the Pacific Ocean also contributes to a unique coastal disjunct ecosystem with associated species uncommon to the northern Rockies, such as the Coeur d'Alene and Idaho giant salamanders, deer fern, and Pacific dogwood.

The Nez Perce-Clearwater lies at the heart of the Rocky Mountain Refugium, containing high endemism and biodiversity of land snails, salamanders, and plants. This area is essentially comprised of areas spared from glaciation nor paved by volcanic flows, which allowed some species to survive the last glacial maxima until today (Stagliano et al. 2007). Examples of species or groups that persist today include the extensive land snail biodiversity, the Idaho Giant Salamander, the Coeur d'Alene salamander, and coastal disjunct plant communities. This assemblage of endemics represents a distinctive role and contribution to biodiversity.

The Nez Perce-Clearwater contains various significant biophysical features, such as caves, karst, and rock cavities. Biophysical features provide specialized seasonal and year-round habitats for a variety of wildlife species, including bats, cliff-nesting birds, terrestrial snails, invertebrates, reptiles, and amphibians. Karst features create unique microhabitats and are important areas for rapid subsurface drainage and aquifer recharge.

The Nez Perce-Clearwater is located directly in the path of ash dispersal from three major Pacific Rim volcanic eruptions—Glacier Peak, Mount Mazama, and Mount Saint Helens—depositing an ash cap as deep as 36 inches in some depressions. The resulting soil fertility and water-holding capacity supports the Nez Perce-Clearwater's highly productive ecosystems.

In Idaho, low and mid-elevation peatlands have been recognized as important habitats characterized by a unique suite of environmental conditions and hosting more than forty rare plant and animal species (Bursik and Moseley 1995). Peatlands are generally defined as wetlands with waterlogged substrates and at least 30 centimeters of peat accumulation. They develop in sites that are saturated throughout the growing season and where the rate of biomass accumulation exceeds decomposition. The Nez Perce-Clearwater contains a few small peatland ecosystems that contain habitat for plant and wildlife species that are uniquely adapted to the distinctive suite of conditions associated with these habitats. The health and stability of unique habitats, such as peatlands, can often reflect the overall health of the greater ecosystem of which they are a part.

The Land Management Plan includes plan components that support the conservation of ecological conditions, habitats, or key ecosystem characteristics in the plan area that are unique, under-represented, or rare across the broader landscape, specifically:

FW-DC-TE-01. Uncommon habitat elements (mineral licks, talus slopes, fractured wet bedrock, rocky outcrops, scree slopes, waterfalls, and geologic inclusions) support long-term persistence of endemic species with narrow or vary narrow habitat specificity and limited distribution associated with these habitats.

FW-GDL-TE-01. To conserve at-risk plants, terrestrial invertebrate animals, and Coeur d'Alene salamanders that are found only near the uncommon habitat elements described in FW-DC-TE-01, activities should not remove or alter the habitat when terrestrial plant or invertebrate animal communities that have been assigned a NatureServe ranking of G1 globally critically imperiled or G2 globally imperiled are present unless designed specifically to improve conditions for these species.

FW-DC-TE-02. Peatlands, including fens and bogs, have the necessary soil, hydrologic, water chemistry, and vegetative conditions to provide for continued development and resilience to changes in climate and other stressors. Peatlands support unique plant and animal species.

FW-DC-CAVE-02. Cave formations, relief features, and karst landscapes continue to develop or erode under natural conditions.

FW-DC-SOIL-03. Volcanic ash-influenced soils are intact and retain unique properties, including high soil porosity and high water and nutrient holding capacity.

GA-DC-SR-03. Habitat for endemic terrestrial snails is available.

FW-DC-GS-07. Dasynotus and Pacific dogwood persist in transitional shrubland and forested habitats throughout their ranges on the Middle Fork Clearwater River and its major tributaries.

FW-DC-GS-08. Douglas clover and sticky goldenweed persist in seasonally moist meadows over basalt on the Palouse Ranger District, particularly in the headwaters of the Potlatch River.

Pollinators, 36 CFR 219.8(a)(1)(ii)

Pollinators are crucial components of functioning ecosystems. The Nez Perce-Clearwater contains the habitat conditions to support pollinators providing benefits to the broader landscape. Pollinators, such as most bees and some birds, bats, and other insects, play a crucial role in flowering plant reproduction and in the production of most fruits and vegetables. Without the assistance of pollinators, most plants cannot produce fruits and seeds. There is evidence that many species may be in decline due to a variety of factors. The Land Management Plan includes plan components that promote the maintenance or restoration of ecological conditions for pollinators and improve pollinator health.

Broadly, the desired conditions in the Land Management Plan increase habitat quality for invertebrate pollinator species. Plan components provide habitat for pollinator species in the plan area by promoting the maintenance and restoration of native plant species, encouraging a variety of habitats, and conserving large areas without the habitat fragmentation that has become characteristic of agricultural and developed land. Plan components included in the forestwide terrestrial ecosystem, forestlands, and meadows, grasslands, and shrublands sections are particularly important for restoring and maintaining habitats and successional stages that will support general floral diversity and benefit pollinators.

Specifically, the Land Management Plan emphasizes the importance of pollinators by including a desired condition that promotes plant communities that are comprised of a diverse mix of native grass, forb, shrub and tree species which provide forage for pollinator species (FW-DC-TE-03).

Conditions in the broader landscape that may influence the sustainability of resources and ecosystems within the plan area, 36 CFR 219.8(a)(1)(iii)

Existing conditions of the broader landscape outside National Forest System boundaries may influence the Nez Perce-Clearwater's ability to maintain or restore the ecological integrity of ecosystems. Such conditions may include habitat fragmentation, land use patterns, resource management, or urbanization.

External factors also affect the ability of the Nez Perce-Clearwater to facilitate or mimic dominant ecological processes and system drivers of the broader landscape, especially those related to fire-adapted ecosystems. More human development is occurring near the boundary of lands administered by the Nez Perce-Clearwater. This trend is expected to continue in the future and the need for vegetation treatments being implemented within wildland urban interface areas will increase. The ability to use fire to maintain and restore the fire-adapted ecosystems on the Nez Perce-Clearwater or to reduce hazardous fuels in the wildland urban interface is dependent upon air quality regulations. As air quality regulations become stricter, the ability to use fire as a management tool becomes limited. If past trends of increasing regulations and decreasing burn opportunities continue, the effects would likely result in not being able to use fire at the level needed to make meaningful improvements to forest and fuel conditions.

For the Forest Service, external factors can hinder the success in achieving progress outlined in the strategic plan (U.S. Department of the Interior 2015c). These factors include extreme weather, climate fluctuations, and environmental change beyond the natural range of forest and grassland variability, which may alter ecological productivity and resilience, and legal and regulatory constraints and changes that affect management activities, reduce management options, and diminish program resources. As outlined in the strategic plan, potential challenges to Forest Service success include:

- Actions by external groups and individuals that affect forest and grassland management and make it more difficult to achieve our objectives.
- Demographic shifts or changes in stakeholders' perceptions or values that result in unanticipated shifts in expectations from our forests and grasslands.
- Economic fluctuations which change market conditions and human behavior.
- International crises or homeland security issues that transform public needs affecting our program accomplishments.

The relative stability of the Nation's forests and grasslands can obscure the environmental and land use changes that have occurred over time. Impacts from severe wildfires, insects and diseases, invasive species, human influences, climate change, extreme weather, and other visible disturbances have raised public awareness about the environment. These impacts, along with changing human demands, perpetually challenge the Forest Service's ability to ensure that ecosystems are healthy, resilient, and, thus, more adaptable to changing conditions or that they can be restored to a healthy state (U.S. Department of Agriculture 2015d).

Many management issues related to resources, such as fire, vegetation, invasive plants, water, fisheries, and wildlife, require an understanding of conditions both on and off National Forest System lands. The emphasis of an all-lands approach that focuses on working across boundaries with adjacent landowners can increase efficiency, lower costs, and improve cooperation. The following programs are examples of initiatives the Nez Perce-Clearwater currently uses and would continue to use under the Land Management Plan.

State Forest Action Plan

The Idaho State Forest Action Plan (FAP) is a long-term, comprehensive, coordinated strategy for investing state, federal, and leveraged partner resources. It addresses the issues and priority landscape areas identified in the Resource Assessment. The Forest Action Plan contains large-scale strategies to identify opportunities for willing partners to align their plans, leverage resources, and work together within the public land's areas and per the strategies as a way to gain the greatest value from limited resources in areas that contain multiple high-priority issues of statewide importance. The Forest Action Plan is statewide in scope but is not a site-specific plan. It helps provide focus to landowners, agencies, and collaborative groups during partnership efforts to identify projects and activities to reduce threats to and increase the benefits from Idaho's forestlands. Focusing work in the highest priority areas allows leveraging of funds and coordination across ownerships as a highly effective way to address the most critical forest resource issues in Idaho at a scale where significant, positive changes can be realized.

The State Forest Action Plan identified the Craig-Camas Priority Landscape Area, which overlaps with the Nez Perce-Clearwater. Threats identified are risks from insects and disease to forest health and the potential for uncharacteristic wildfire.

Shared Stewardship

Through shared stewardship, the Forest Service, State of Idaho, and other partners have unprecedented opportunities to co-manage fire risk for desired outcomes at the most appropriate scales. Our concept for an outcome-based investment strategy has three core elements:

- Determining management needs on a state level—Prioritize stewardship decisions directly with the states, setting priorities together and combining mutual skills and assets to achieve cross-boundary outcomes desired by all.
- Doing the right work in the right places at the right scale—Utilize new mapping and decision tools to locate treatments where they can do the most good, thereby protecting communities, watersheds, and economies where the risks are greatest.
- Using all available tools for active management—Utilize every authority and tool to do more work on the ground, including timber sales, mechanical treatments, and carefully managed wildland fire, working with partners and stakeholders to choose the right tools.

National Cohesive Wildland Fire Management Strategy

The National Cohesive Wildland Fire Management Strategy (U.S. Department of Agriculture and U.S. Department of the Interior 2014b) is a strategic push to work collaboratively among all stakeholders and across all landscapes, using best science, to make meaningful progress towards three goals: resilient landscapes, fire adapted communities, and safe and effective wildfire response.

National Wildfire Crisis Strategy

In January 2022, the Forest Service launched a robust, 10-year strategy to address the wildfire crisis in places where wildfire poses the most immediate threats to communities. The strategy, called "Confronting the Wildfire Crisis: A Strategy for Protecting Communities and Improving Resilience in America's Forests," (U.S. Department of Agriculture 2022c) combines a historic investment of congressional funding with years of scientific research and planning into a national effort that will dramatically increase the scale and pace of forest health treatments over the next decade. Through the strategy, the agency will work with states, Tribes and other partners to address wildfire risks to critical infrastructure, protect communities, and make forests more resilient. The initial Wildfire Crisis Landscape Investments assessment (U.S. Department of Agriculture 2022d) identified high-risk firesheds on the Nez Perce-Clearwater, but the firesheds were not selected as a priority landscape. In early 2023, the USDA Forest Service added 11 additional landscapes. As outlined in Wildfire Crisis Landscape Investments (U.S. Department of Agriculture 2023b), high-risk firesheds on the Nez Perce-Clearwater were selected as a priority landscape. The Nez Perce-Clearwater-Lower Salmon priority landscape is 1.5 million acres in size. Work on this landscape will reduce fuels in and near high-risk firesheds, treat acres identified in the "Idaho Forest Action Plan," and restore watersheds critical to communities and habitat for threatened and endangered fish.

Good Neighbor Authority

The Good Neighbor Authority allows the U.S. Forest Service to enter into agreements with the Nez Perce Tribe, Idaho Department of Lands, and Idaho Department of Fish and Game to do the critical management work to keep forests healthy and productive. The Nez Perce-Clearwater has been very successful working with Idaho Department of Lands to improve the planning process and implementation of forest integrated projects.

Collaboration Across the Broader Landscape

The Nez Perce-Clearwater Land Management Plan proposes to collaborate with other land managers across the broader landscape, emphasizing an all-lands approach, working across boundaries and fostering partnerships as demonstrated by the inclusion of the following proposed goals:

FW-GL-TE-01. The Nez Perce-Clearwater works with federal, state, tribal, and private land managers towards an all-lands approach through management and cooperation, including efforts to mitigate threats or stressors, provide for wildlife and fish habitat connectivity, and to provide social, economic, and ecological conditions that contribute to mutual objectives.

FW-GL-TE-02. The Nez Perce-Clearwater cooperates with state agencies, federal agencies, and tribes to develop actions that lead to progress towards meeting other agencies' objectives for native and desired non-native fish and wildlife species.

FW-GL-FIRE-01. Fire adapted communities: The Nez Perce-Clearwater works with adjacent communities to manage vegetation within and adjacent to the national forests to withstand a wildfire without loss of life and property.

FW-GL-FIRE-02. Wildfire response: The Nez Perce-Clearwater and local, state, tribal, and other federal agencies support one another with wildfire response, including engagement in collaborative planning and the decision-making processes that consider all lands and recognize the interdependence and statutory responsibilities among jurisdictions. All jurisdictions that are impacted by wildfire participate in making and implementing safe, effective, efficient risk-based wildfire management decisions.

FW-GL-FIRE-03. The Nez Perce-Clearwater works with adjacent communities, landowners, permittees, and state, local, and other federal agencies to promote a collective understanding about wildfire risk and that wildland fire is an ecological process.

FW-GL-FIRE-04. Fire hazards in wildland urban interface areas are continually monitored. Project development, planning, and treatments are coordinated with local and tribal governments, agencies, and landowners to reduce the risk from wildland fire.

FW-GL-INV-01. The Nez Perce-Clearwater actively participates in Cooperative Weed Management Areas, which are used to determine weed treatment priorities, projects, budgets, and annual programs. Public awareness is promoted using various forms of outreach through the Cooperative Weed Management Areas.

FW-GL-INV-02. The Nez Perce-Clearwater works with federal, state, and county agencies, tribes, non-government organizations, permittees, and adjacent landowners to support integrated pest management, including invasive species prevention, early detection, and rapid response, control and containment, restoration and rehabilitation, and inventory and monitoring activities.

FW-GL-WTR-01. The Nez Perce-Clearwater works with appropriate agencies to control the expansion of aquatic invasive species.

FW-GL-WTR-02. The Nez Perce-Clearwater builds and maintains partnerships to fund and implement projects that result in improved water quality and watershed and stream conditions.

FW-GL-WTR-03. The Nez Perce-Clearwater works with partners to improve aquatic habitat, increase resiliency, and enhance by improving habitat for beaver where appropriate.

FW-GL-CWN-01. The Nez Perce-Clearwater works with the Nez Perce Tribe, State of Idaho, National Marine Fisheries Service, U. S. Fish and Wildlife Service, and other governmental organizations to plan and implement projects that contribute to recovery goals for aquatic species listed under the Endangered Species Act and their designated critical habitat, such that protective measures under the Act are no longer necessary.

FW-GL-CWN-02. The Nez Perce-Clearwater partners with federal agencies, including Section 7 consultation, as required; state agencies; tribes; counties; interested groups; and interested private landowners to recover threatened and endangered species.

FW-GL-WL-01. The Nez Perce-Clearwater cooperates and collaborates with the U. S. Fish and Wildlife Service, other federal agencies, state agencies, and tribes on conservation strategies, recovery plans, habitat management, and ecological conditions on National Forest System lands.

FW-GL-WLMU-01. The national forest cooperates with the Idaho Department of Fish and Game to provide habitat conditions that contribute to wildlife populations at levels meeting Idaho Department of Fish and Game species management plan objectives.

FW-GL-AIR-02. The Nez Perce-Clearwater works with federal, state, and tribal partners to meet applicable air quality requirements.

FW-GL-TT-02. Proposed practices and management activities recognize the role the Nez Perce have had on the ecology of the area and integrate traditional ecological knowledge into future projects.

FW-GL-TT-07. Consultation with the Nez Perce Tribe, traditional cultural practitioners, consulting parties, adjacent landowners, and project designers aid the FS in protecting and enhancing traditional cultural properties, cultural landscapes, sacred sites, and other culturally significant areas that provide tangible links to historically rooted beliefs, customs, and practices.

System drivers, including dominant ecological processes, disturbance regimes, and stressors, and the ability of terrestrial and aquatic ecosystems on the plan area to adapt to change, 36 CFR 219.8(a)(1)(iv)

Resilient ecosystems have a greater capacity to survive disturbances and large-scale threats, especially under changing and uncertain future environmental conditions, such as those driven by climate change and human uses. Ecosystems that are healthy and have ecological integrity are better able to adapt to changes imposed by stressors while retaining their composition, structure, and function. Many of the desired conditions in the terrestrial ecosystems, aquatic ecosystems, and wildlife sections of the Land Management Plan incorporated these concepts, emphasizing the role that dominant ecological processes, including disturbance, have on the landscape. These and other plan components facilitate ecosystem adaptation to the effects of stressors, as well as limiting the ability of natural and human-influenced stressors to impact ecosystem integrity. Numerous standards and guidelines in the Land Management Plan were developed to mitigate stressors associated with forest and grassland management. These plan components provide guidance on how to avoid, minimize, rectify, reduce, or compensate the adverse environmental impacts associated with an action.

The Land Management Plan takes into account the effects of a changing climate (36 CFR 219.8(a)(1)(iv)). During the development process of the Land Management Plan, the Nez Perce-Clearwater participated in a collaborative process through the Northern Rockies Adaptation Partnership. Resulting information was used to develop plan components that would facilitate adaptation to the effects of climate change. The Northern Rockies Adaptation Partnership is a science-management partnership consisting of 15 national forests in the Northern Region of the U.S. Department of Agriculture Forest Service; 3 national parks; the U.S. Forest Service Pacific Northwest and Rocky Mountain Research Stations; the University of Washington; and numerous other organizations and stakeholders. These organizations worked together over a period of two years to identify climate change issues relevant to resource management in the Northern Rocky

Mountains to find solutions that can minimize negative effects of climate change and facilitate transition of diverse ecosystems to a warmer climate. The Northern Rockies Adaptation Partnership provided education, conducted a climate change vulnerability assessment, and developed adaptation options for national forests and national parks that manage more than 28 million acres in northern Idaho, Montana, northwestern Wyoming, North Dakota, and northern South Dakota.

The Northern Rockies Adaptation Partnership publication—*Climate Change Vulnerability and Adaptation in the Northern Rocky Mountains, Part 1 and 2*—is the main source of information for identifying resource vulnerabilities and providing possible strategies and approaches to address vulnerabilities specific to the northern Rockies (Halofsky, Peterson, et al. 2018a, b). Appendix G provides further information on climate change adaptation strategies and identifies plan components that support them.

The Land Management Plan also incorporated other best available scientific information related to climate change and the management strategies of promoting resilience to change, creating resistance to change, and enabling forests to respond to change during plan component development.

Adaptive capacity is the ability of ecosystems to respond, cope, or adapt to disturbances and stressors, including environmental change, to maintain options for future generations (FSH 1909.12). The Land Management Plan provides direction to restore, establish, and maintain functioning ecosystems that would have greater ability to withstand stressors and recover from disturbances, especially with changing and uncertain environmental conditions and extreme weather events. By including plan components that focus on maintaining and restoring healthy ecosystems, promoting resilience, and incorporating climate change adaptation strategies, the Land Management Plan provides the mechanisms to improve the Nez Perce-Clearwater's adaptive capacity.

Although not specifically mentioned, most of the physical and biological ecosystem desired conditions in the Land Management Plan were developed to facilitate natural ecological processes and create healthy ecosystems. The following are examples of plan components that speak to climate change and promote resilience and adaption to environmental change:

FW-DC-CARB-01. Carbon storage and sequestration potential are sustained through maintenance or enhancement of ecosystem biodiversity and function, and forests are resilient to natural disturbance processes and changing climates.

FW-DC-TE-02. Peatlands, including fens and bogs, have the necessary soil, hydrologic, water chemistry, and vegetative conditions to provide for continued development and resilience to changes in climate and other stressors. Peatlands support unique plant and animal species.

Forestlands Desired Conditions. The forestlands desired conditions were developed to promote and increase the resiliency of forest landscapes, approximate natural succession and disturbance processes, and incorporate adaptation to changing climates.

FW-DC-FIRE-01. Restore and maintain landscapes: Landscapes across the Nez Perce-Clearwater are resilient to fire-related disturbances in accordance with management objectives. Natural fuel conditions emulate the structure, species mix, spatial pattern, extent, and resiliency of the historic fire regime of the area. Wildland fires burn with a range of intensity, severity, and frequency that allows ecosystems to function in a healthy and sustainable manner and meet desired conditions for other resources.

FW-DC-SOIL-01. Soil productivity and function contributes to the long-term resilience of ecosystems.

FW-DC-INV-01. Invasive species either are not present or occur at low levels to allow watersheds, vegetation communities, and aquatic ecosystems to retain their inherent resilience and resistance to respond and adjust to disturbances. Plant communities retain their historic diversity and provision of values to fauna.

FW-DC-WTR-01. National Forest System lands provide the distribution, diversity, and complexity of watershed and landscape-scale features including natural disturbance regimes and the aquatic and riparian ecosystems to which species, populations, and communities are uniquely adapted. Watersheds and associated aquatic ecosystems retain their inherent resilience to respond and adjust to disturbances, including climate change, without long-term, adverse changes to their physical or biological integrity.

FW-DC-WL-02. Ecological conditions on the Nez Perce-Clearwater contribute sustainable habitat to maintain species of conservation concern. Habitat is resilient and adaptable to stressors and likely future environments.

GA-DC-SR-02. Habitat for Ponderosa pine associated species, including legacy trees and snags, are within desired conditions within Ponderosa pine systems (See FW-DC-FOR-02, FW-DC-FOR-03, FW-DC-FOR-04, and FW-DC-FOR-05). Understory characteristics do not facilitate stand replacing fires and are composed of native plants that provide insect populations as forage for Ponderosa pine associated species. These habitats are resilient to changes due to climate change.

Wildland fire and opportunities to restore fire adapted ecosystems, 36 CFR 219.8(a)(1)(v)

One of the U.S. Forest Service's 2015-2020 Strategic Plan goals is to foster resilient, adaptive ecosystems to mitigate climate change to sustain the Nation's forests and grasslands (U.S. Department of Agriculture 2015d). Mitigating wildfire risk is one of the strategic objectives identified to meet this goal, as well as restoring ecosystems that are naturally adapted to wildland fire. The intent is that the Nation's forests, grasslands, and adjacent communities and property are resilient to the impacts from wildfire.

Wildland fire refers to both wildfire (unplanned ignitions) and prescribed fire (planned ignitions). Wildland fire plays a natural and beneficial role in many forest types. Fire can also be a tool to help meet desirable outcomes for healthy forest and grassland ecosystems and to help restore, maintain, and protect healthy forests and grasslands. Wildfires, however, can also threaten public safety, property, and natural resources, especially in areas where developed lands intermix with rural forests, known as the wildland-urban interface. See the Fire Management section of the Final Environmental Impact Statement and Appendix 4 of the Land Management Plan for more information regarding fire and fuels management.

Fire is a necessary and critical ecological function across the Nez Perce-Clearwater. The Land Management Plan includes plan components related to wildland fire, fuels management, and restoration of fire-adapted ecosystems (36 CFR 219.8(a)(1)(v)). The integrated fire management plan components were developed using information such as the National Cohesive Wildland Fire Management Strategy, community assessment and mitigation plans, fire's historic role in the plan area, local community wildfire protection plans, local risk assessments, trends in fire behavior, and location of wildland-urban interface (WUI) areas.

In addition to the four fire management goals that emphasize working across boundaries and fostering partnerships (FW-GL-FIRE-01 to FW-GL-FIRE-04, listed above), four desired conditions were developed to emphasize fire's role in the ecosystem and the importance of utilizing fire to achieve ecosystem sustainability, while also providing for public and firefighter safety.

FW-DC-FIRE-01. Restore and maintain landscapes: Landscapes across the Nez Perce-Clearwater are resilient to fire-related disturbances in accordance with management objectives. Natural fuel conditions emulate the structure, species mix, spatial pattern, extent, and resiliency of the historic fire regime of the area. Wildland fires burn with a range of intensity, severity, and frequency that allows ecosystems to function in a healthy and sustainable manner and meet desired conditions for other resources.

FW-DC-FIRE-02. The full range of fire management activities, including both prescribed fire and natural wildfire, are recognized and used by Nez Perce-Clearwater administrators as an integral part of achieving ecosystem sustainability, including interrelated ecological, economic, and social components, such as improved ecosystem resilience and wildlife habitat, protection of property, other values at risk, and public safety.

FW-DC-FIRE-03. Fuels conditions adjacent to private property, administrative sites, and infrastructure promote lessened fire behavior that facilitates safe, effective fire management opportunities. Wildfire occurs at smaller scales and lesser severities in areas where resource objectives and infrastructure limit the desirability of a wildland fire event.

FW-DC-FIRE-04. The role of wildland fire is recognized as an important component of fire adapted ecosystems of the Nez Perce-Clearwater and is increasingly accepted and understood by the public, partners, and within the agency.

To maintain or move toward desired conditions, the Land Management Plan includes three objectives to use wildland fire and other vegetation treatments to improve or maintain desired forest vegetation conditions, based on the natural range of variation and historical disturbance regimes (FW-OBJ-FIRE-01); mitigate hazardous fuels (FW-OBJ-FIRE-02); and allow fire to play its natural role, where appropriate and desirable, to reduce the risk of uncharacteristic and undesirable wildland fires by managing natural, unplanned ignitions to meet desired conditions and objectives as defined in the Land Management Plan on a set number of acres per decade over the life of the plan. (FW-OBJ-FIRE-03).

Additionally, the Land Management Plan specifies that planned ignitions in areas highly susceptible to weed invasion should be planned and implemented with design features to address the spread of invasive species (FW-GDL-FIRE-02) and to restore fire as an ecological process, wildfire management strategy and tactics should utilize the opportunity to integrate wildland fire into other disturbances on the landscape (FW-GDL-FIRE-01). Opportunities for landscape scale restoration, 36 CFR 219.8(a)(1)(vi)

As noted above, the Nez Perce-Clearwater encompasses approximately four million acres and is adjacent to five other national forests. There are countless opportunities for landscape scale restoration given the size of the land base. The Nez Perce-Clearwater is also bordered by mixed ownership lands, including private, state, industrial forestry, and other federal lands. Conducting landscape scale restoration adjacent to or across mixed ownership lands requires coordination between entities, as well as an understanding of key ecosystem process and disturbance regimes.

The landscape is characterized as a defined area irrespective of ownership or other artificial boundaries, such as a spatial mosaic of terrestrial and aquatic ecosystems, landforms, and plant communities, repeated in similar form throughout such a defined area (36 CFR 219.19).

Landscape patterns that reflect natural disturbance regimes promote long-term ecological integrity and ecosystem diversity. Landscape pattern is defined as the arrangement, connectivity, composition, size, and relative abundance of ecosystem patches that occur within an area of land at a given time. Patches can be characterized by vegetation type, seral stage, habitat type, or other relevant features.

Land management in the Inland Pacific United States is facing extraordinary challenges, including increased risk of wildfires, declining plant and animal populations, increased demands for ecosystem services by a growing human population, and great uncertainty regarding the effects of future climate change. Management practices focused on stand level characteristics have created and continue to create landscapes that are less resilient to disturbance and are, in most cases, altering the physical processes by which these landscapes were developed (Northwest Fire Science Consortium 2016). To help guide landscape planning efforts, researchers have created a framework of seven core principles and their implications for management of fire-prone interior forest landscapes. As outlined in *Restoring Fire-Prone Inland Pacific Landscapes: Seven Core Principles* (Hessburg et al. 2015), the seven core principles are:

- **Broad regional landscapes are really landscapes nested within landscapes**. For example, tree neighborhoods nest within successional patches, which nest within local landscapes, eco-subregions, and ecoregions. Implementation of this principle could include planning and managing at appropriate scales to effectively restore connectivity, multi-level landscape patterns, processes, and dynamics.
- **Topography provides a natural template for restoring vegetation patterns**. Implementation of this principle could include the use of topography to guide restoration of successional and habitat patchworks. For example, partition the landscape into basic topographic settings, such as valley-bottoms, ridgetops, and south and north-facing slopes, rather than proximity to roads.
- **Major disturbances like fire and succession drive ecosystem change**. Implementation of this principle could include restoring natural fire regimes and the variation in successional patterns that supported them so that other processes may follow. This principle utilizes both the historical range of variability of regional successional patterns and a future range of variability to inform management targets.
- **Predictable patch size distributions historically emerged from linked climate-disturbance-topography-vegetation interactions**. Implementation of this principle could include restoring size distributions of historical successional patches and allow changing climate and disturbance regimes to modify them. Landscape prescriptions should focus on increasing the occurrence of different sized openings and successional patches.
- **Successional patches are "landscapes within landscapes."** Implementation of this principle could include restoring characteristic tree clump and gap variation in Ponderosa pine and mixed conifer patches. Patch level prescriptions should aim to restore variable patterns within stands and begin to break up uniformity.
- **Widely distributed large, old trees provide a critical backbone to dry pine and dry to moist mixed conifer landscapes.** Implementation of this principle could include retaining and increasing existing large, old trees, old forests, and large snags and down logs in these forest types. Land ownership, allocation, management and access patterns disrupt landscape and

ecosystem patterns. Implementation of this principle could include working collaboratively across ownerships to develop restoration projects.

In addition, researchers suggest that landscape prescriptions are fundamental to restoration, providing a strategy for the implementation of the seven principles, while moving away from stand-level management as a primary focus (Hessburg et al. 2015). Stand level management takes on new meaning within landscape prescriptions. They are the “plug and plays” that accomplish creation of vastly revised spatial patterns of forest conditions and their associated functionality. It is suggested that landscape prescriptions occur at three levels as described in Principle 1 above:

- **Large-scale eco-regional (100,000s to 1,000,000s of acres):** These are strategic prescriptions that identify priority areas for reconnecting habitats and conditions, identify where silviculture or burning may be appropriate, and recognize managed wildfires can contribute greatly to restoration efforts.
- **Local landscape (10,000s to 100,000s of acres; Principles 2, 3, 4 and 6):** These are tactical prescriptions that include the restoration of successional patch size distributions; the retention of old, legacy trees; and the restoration of wildfire and climate resilient landscapes through the use of a broad toolkit.
- **Patch-level (1s to 1,000s of acres; Principle 5):** These prescriptions provide targets for the heterogeneity of the structure, including numbers and sizes of individual trees, tree clumps, and openings.

Wildland fire, insect outbreaks, disease, invasive species, and changes in climate are expected to continue to be a part of the landscape into the foreseeable future. Landscape prescriptions can aim to restore more resilient vegetation patterns that will help adjust the severity and sizes of these disturbances, promote natural post-disturbance recovery, reduce the need for expensive active management, and drastically reduce the role and need of fire suppression.

Many of the wildlife, fire management, water, forestlands, and terrestrial ecosystems plan components included in the Land Management Plan were created using the above core principles. Since these principles form the foundation for many of the natural resource plan components, the Land Management Plan provides an integrated approach to facilitating landscape scale restoration to promote ecological sustainability at multiple spatial and temporal scales.

To achieve landscape scale restoration and work across boundaries, coordination with other adjacent land managers or interested parties is important. As discussed above, there are a variety of initiatives, such as the State Forest Action Plan, shared stewardship, The National Cohesive Wildland Fire Management Strategy, and good neighbor authority, that can facilitate landscape scale restoration. Also, as listed above, the Land Management Plan contains numerous goals that emphasize an all-lands approach, working across boundaries, and fostering partnerships. To better facilitate and align vison, plan components were developed with the consideration of state and county land management plans, as well as including recovery plans for federally listed species that occur at multi-state levels.

The Land Management Plan contains plan components that emphasize the creation of landscape patterns that promote long-term ecological integrity and ecosystem diversity at multiple spatial and temporal scales, as exemplified by:

FW-DC-TE-04. Vegetation reflects natural disturbance regimes. The composition, structure, function, and connectivity of native plant communities are appropriate for a given landscape and climatic setting.

FW-DC-WL-03. The arrangement and distribution of vegetation patches is consistent with the natural range of variation and varies widely in size, shape, and structure to provide connectivity for native wildlife.

FW-DC-WTR-01. National Forest System lands provide the distribution, diversity, and complexity of watershed and landscape-scale features including natural disturbance regimes and the aquatic and riparian ecosystems to which species, populations, and communities are uniquely adapted. Watersheds and associated aquatic ecosystems retain their inherent resilience to respond and adjust to disturbances, including climate change, without long-term, adverse changes to their physical or biological integrity.

FW-DC-TBR-04. Harvests, including regeneration harvests, reflect the scale and pattern of natural disturbances.

MA1-DC-WILD-01. Natural ecological processes and disturbances (for example, succession, wildfire, avalanches, insects, and disease) are the primary forces affecting the composition, structure, and pattern of vegetation.

The forestlands (FOR) and fire management (FIRE) desired conditions focus on creating landscape patterns of forests, meadows, grasslands, shrublands, and riparian areas that were created under ecological processes and landscape disturbance regimes that occurred before extensive human alteration. The forestlands (FOR) and fire management (FIRE) desired conditions and objectives were developed using a variety of data and modeling strategies that incorporated the natural range of variation conditions, including the scale, frequency, and intensity of system drivers of ecosystem change over time. These plan components facilitate the creation of a representative range of successional states for all ecosystems and in patch configurations similar to those that occurred under historical conditions, at a scale resilient to natural disturbances. The forestlands (FOR) plan components were designed to move vegetation toward desired conditions for dominance type, size class, density, structure, forest pattern, and patch size while maintaining connectivity and minimizing fragmentation of vegetation landscapes. The fire management (FIRE) desired conditions emphasize fire's role in the ecosystem and the importance of utilizing fire to achieve ecosystem sustainability, while also providing for public and firefighter safety.

In conjunction with facilitating management activities at the landscape scale, accounting for smaller scales is also important. The Land Management Plan includes desired conditions that focus on maintaining the integrity of scarce or unique smaller areas, as well as standards or guidelines that constrain the levels of disturbance for areas around them, such as the plan components associated with research natural areas (RNA), special areas (SA), and the Lower Salmon River geographic area (SR).

Air, Soil, and Water, 36 CFR 219.8(a)(2)

Air Quality

Air quality is one of the many resources the Forest Service is required to monitor and protect on public lands. Air quality is dependent on the type and amount of pollutants emitted into the atmosphere, the location and topography of an airshed, and the prevailing meteorological and weather conditions. Coordinating with partners and meeting applicable air quality standards are the primary mechanisms for managing air quality. Refer to the Air Quality section in the Final Environmental Impact Statement and Appendix 4 of the Land Management Plan for more information regarding air quality.

The Land Management Plan includes the following plan components that support the maintenance or improvement of air quality (36 CFR 219.8(a)(2)(i)):

FW-GL-AIR-01. Coordinate with local and regional partners to reduce cumulative air quality impacts prior to planned ignition activities.

FW-GL-AIR-02. The Nez Perce-Clearwater works with federal, state, and tribal partners to meet applicable air quality requirements.

FW-DC-AIR-01. Good air quality supports human and ecosystem health and quality of life over the long-term. It enhances visibility and the visual aesthetics of the planning area over the long-term.

FW-DC-AIR-02. The Nez Perce-Clearwater meets applicable federal, state, and tribal air quality standards.

Soils

Soils are an integral part of ecosystems, their function, and the above and below ground interaction of organisms. Soil functions, such as soil biology, soil hydrology, nutrient cycling, carbon storage, soil stability and support, and filtering and buffering, contribute to ecological resilience. Soils that are productive and functioning properly are resilient to natural disturbance and human caused stressors and provide for long-term ecological sustainability. Refer to Section 3.2.1.6 Soils Resource in the Final Environmental Impact Statement for more information regarding soil productivity and function and Appendix 4 of the Land Management Plan for potential management approaches to protect, maintain, or restore soil resources.

The Land Management Plan includes plan components that support the maintenance or restoration of soils and soil productivity, including guidance to reduce soil erosion and sedimentation (36 CFR 219.8(a)(2)(ii)). The following desired conditions emphasize the important role soils have in promoting a resilient and diverse ecosystem that supports ecological integrity:

FW-DC-SOIL-01. Soil productivity and function contributes to the long-term resilience of ecosystems.

FW-DC-SOIL-02. Soil organic matter and down woody material support healthy microbial populations, protect soil from surface erosion, facilitate soil moisture retention, provide nutrients, and maintain soil development and biochemical processes.

FW-DC-SOIL-03. Volcanic ash-influenced soils are intact and retain unique properties, including high soil porosity and high water and nutrient holding capacity.

GA-DC-SR-01. Forest vegetation grows on soils that support and developed under forested ecosystem. Grassland soils, including mollisol soils, support healthy grassland and shrubland communities with few trees.

As outlined in Table 302, the Land Management Plan also includes objectives, standards, and guidelines to protect sensitive soils, maintain or restore soil productivity and function, and reduce soil erosion.

Table 302. Soils Resource Plan Components

Plan Component	Subject
FW-OBJ-SOIL-01	Objective to restore impaired soils
FW-OBJ-WTR-05	Objective to improve soil and watershed conditions
FW-STD-SOIL-01	Maintenance of soil function and productivity
FW-STD-SOIL-02	Rehabilitation of newly created soil impairment
FW-STD-SOIL-03	Incorporation of best management practices
FW-GDL-SOIL-01	Limitation of activities in mass movement areas
FW-GDL-SOIL-02	Post activity ground cover requirements
MA2 and MA3-GDL-SOIL-01	Slope limitations for ground-based equipment
MA2 and MA3-GDL-SOIL-02	Reuse of existing disturbed areas to limit new disturbance
MA2 and MA3-GDL-SOIL-03	Rehabilitation of previously created soil impairment
MA2 and MA3-GDL-SOIL-04	Protection of high soil burn severity soils
MA2 and MA3-GDL-SOIL-05	Decommissioning of FS system and temporary roads
MA2 and MA3-GDL-FOR-01	Retention of coarse wood material

Water Quality

The goal of the Clean Water Act is "to restore and maintain the chemical, physical, and biological integrity of the nation's water." The Idaho Department of Environmental Quality is responsible for ensuring that Idaho's surface, ground, and drinking water resources meet state water quality standards. A water quality standard defines the goals that have been set for a water body by designating uses for the water, sets criteria necessary to protect those uses, and prevents degradation of water quality. Refer to the Water Resources section and Appendix K in the Final Environmental Impact Statement and Appendix 4 and Appendix 6 of the Land Management Plan for more information regarding water quality.

The Land Management Plan includes plan components that emphasize the maintenance or improvement of water quality (36 CFR 219.8(a)(2)(iii)). The following three plan components specifically address water quality standards and control of non-point source pollution:

FW-DC-WTR-05. Water quality, including groundwater, meets or exceeds applicable state water quality standards, fully supports designated beneficial uses, and is of sufficient quality to support surrounding communities, municipal water supplies, and natural resources. The national forest has no documented lands or areas that are delivering water, sediment, nutrients, or chemical pollutants that would result in conditions that violate the State of Idaho's water quality standards.

FW-STD-WTR-02. Project-specific best management practices (BMPs), including both federal and state BMPs, shall be incorporated into project planning as a principal mechanism for controlling non-point pollution sources, to meet water quality desired conditions, and to protect beneficial uses.

FW-STD-WTR-06. To restore watersheds, management activities in watersheds with approved total maximum daily loads shall be designed to comply with the total maximum daily load allocations following project implementation.

The Land Management Plan also includes several objectives to maintain or improve water quality. These objectives focus on maintenance or restoration actions that eliminate or minimize non-point source pollutants or improve conditions so that ecosystems are better able to process pollutants, such as sediment. The objectives also promote functioning riparian areas that have vegetation that filters pollutants, provides shade to streams, and delivers stream nutrients. Other objectives aim at restoring groundwater dependent ecosystems that can provide cold water to streams during summer low flows. Additionally, the standards and guidelines included in the aquatic resources section set requirements or limitations of management actions to maintain water quality and minimize the input of pollutants, such as sediment or chemicals.

Water Resources

The watersheds, rivers, and streams of the Nez Perce-Clearwater provide many ecological, economic, and social benefits. Clean water is a critical resource with over 9,500 miles of perennial streams and 3,800 acres of lakes and ponds supporting high value recreation, municipal water, and habitat for unique and diverse populations of fish and wildlife.

Water draining off the Clearwater National Forest is often used for drinking water supplies. Source water protection areas include watershed areas not specifically designated as municipal watersheds that provide untreated water from streams, rivers, or lakes that are used to supply public drinking water. Refer to the Water Resources section and Appendix K in the Final Environmental Impact Statement and Appendix 4 and Appendix 6 of the Land Management Plan for more information regarding water resources.

The Land Management Plan includes plan components that promote the maintenance or restoration of water resources in the plan area, including lakes, streams, and wetlands; ground water; public water supplies; source water protection areas; and other sources of drinking water, including guidance to prevent or mitigate detrimental changes in water quantity, quality, and availability (36 CFR 219.8(a)(2)(iv)).

There are 34 plan components in the water and aquatic resources (WTR) and municipal watershed (MWTR) sections of the Land Management Plan, including goals, desired conditions, objectives, standards, and guidelines. There are an additional 31 plan components in two other sections of the Aquatic Resources category: riparian management zones (RMZ) and conservation watershed networks (CWN). The Aquatic Resources category also includes 43 additional plan components in sections that provide special guidance for other resource areas that have the potential to affect water, riparian areas, and stream habitat: infrastructure (ARINF), energy and minerals (AREM), livestock grazing (ARGRZ), lands and special Uses (ARLND), and recreation (ARREC). Restoration is emphasized in the Land Management Plan through objectives. Objectives related to water resources focus on reducing sediment from roads, trails, and dispersed camp sites, restoring floodplain function, restoring hydrologic connectivity in meadows, and improving overall watershed conditions.

The following are examples of plan components that support water resources:

FW-DC-WTR-06. Sediment delivery to streams is of the types, quantities, and rates that support the natural instream sediment transport and storage rates and instream sediment substrate composition. The sediment regime in water bodies is not chronically affected by management activities to the extent that the availability of functioning spawning areas and interstitial spaces are reduced.

FW-DC-WTR-07. Instream flows are sufficient to create and sustain riparian, aquatic, and wetland habitats and to retain patterns of sediment, nutrient, and wood routing. The timing, magnitude, duration, and spatial distribution of peak, high, and low flows are retained. Stream flow regimes maintain riparian ecosystems and natural channel and floodplain dimensions. Stream channels transport sediment and woody material over time while maintaining reference dimensions (for example, bankfull width, depth, entrenchment ratio, slope, and sinuosity).

FW-DC-WTR-08. Groundwater dependent ecosystems, including peatlands, bogs, fens, wetlands, seeps, springs, riparian areas, groundwater-fed streams and lakes, and groundwater aquifers, persist in size and seasonal and annual timing and exhibit water table elevations within the natural range of variability. Surface and groundwater flows provide late-season stream flows, cold water temperatures, and sustain the function of surface and subsurface aquatic ecosystems.

FW-DC-WTR-09. Beavers are present in watersheds where their activities benefit ground water, surface water, and aquatic habitat complexity, and where their activities support conservation and recovery of imperiled aquatic species.

FW-DC-MWTR-01. Lands that contribute to municipal watersheds and source water protection areas are in a condition that contributes to consistent delivery of clean water and meets or exceeds State of Idaho water quality standards.

Riparian Areas, 36 CFR 219.8(a)(3)

Riparian areas are important elements of watersheds that provide critical transition zones linking terrestrial and aquatic ecosystems. To maintain the ecological integrity of riparian areas, the Land Management Plan includes plan components that promote riparian areas and are designed to maintain or restore structure, function, composition, and connectivity.

Riparian management zones (RMZs) are portions of a watershed where riparian-dependent resources receive primary emphasis. The Land Management Plan established default widths for riparian management zones around all lakes, perennial and intermittent streams, and open water wetlands (36 CFR 219.8(a)(3)(ii)). Riparian management zone widths are delineated into four categories based on the type of water body and duration of stream flow. All plan components in the riparian management zones section apply to the established zones.

Although 36 CFR 219.8(a)(3)(ii)) requires special attention to land and vegetation for approximately 100 feet from the edges of all perennial streams and lakes, the Land Management Plan defines default widths of 150 to 300 feet from the edges of perennial waterbodies and wetlands greater than one acre and 100 feet from the edges of intermittent streams and wetlands less than one acre.

Additionally, the Land Management Plan contains several standards and guidelines that constrain projects and activities to comply with requirements of the Planning Rule not to cause detrimental changes to water resources that "seriously and adversely affect water conditions or fish habitat" (36 CFR 219.8(a)(3)(ii)(B)). The establishment of riparian management zones does not prohibit projects that may have short-term adverse effects to water conditions and fish habitat, if the actions maintain or restore structure, function, composition, and connectivity of riparian areas over the long term.

Riparian management zones are not intended as exclusion areas or reserves. Instead, management activities designed to benefit aquatic and riparian-dependent resources and move the landscape towards desired conditions are allowed and encouraged within them. Although the default riparian management areas widths are uniform, the management of them is not intended to be.

For further information on riparian areas, see sections Forestlands, At-Risk Plant Species, Water Resources, Aquatic Ecosystems and Fisheries, and Abundance and Diversity of Wildlife in the Final Environmental Impact Statement.

Restoration of riparian areas may be accomplished through passive management or may require active management particularly in areas where natural disturbances, such as fire or flooding, have been prevented from occurring, or if past projects and activities have altered riparian functions, such as where roads are located within riparian areas. Restoration is emphasized in the Land Management Plan through objectives. Objectives related to improvement of riparian areas focus on improving riparian habitat, floodplain function, and hydrologic connectivity.

The Land Management Plan includes the plan components outlined in Table 303 and the following desired conditions to support the ecological integrity of riparian areas:

FW-DC-RMZ-01. Riparian Management Zones reflect a natural composition of native flora and fauna and a distribution of physical, chemical, and biological conditions as compared to reference conditions. The species composition and structural diversity of native plant communities in riparian management zones provide adequate summer and winter thermal regulation, nutrient filtering, appropriate rates of surface erosion, bank erosion, and channel migration. Nutrients, large woody debris, and fine particulate organic matter are supplied in amounts and distributions sufficient to sustain physical complexity and stability.

FW-DC-RMZ-02. Riparian Management Zones feature key riparian processes and conditions that function consistent with local disturbance regimes, including slope stability and associated vegetative root strength, wood delivery to streams and within the riparian management zones, input of leaf and organic matter to aquatic and terrestrial systems, solar shading, microclimate, and water quality.

FW-DC-TE-05. Riparian vegetation includes native assemblages of hardwood trees, deciduous shrubs, conifers and where appropriate, unique coastal disjunct species.

FW-DC-GS-04. Wetland graminoid and riparian shrub habitat type groups are comprised of a mosaic of communities dominated by native species which tolerate and are adapted to periodic flooding and an associated seasonally high-water table. These communities may be dominated by native graminoids, such as water sedge (*Carex aquatilis*) and tufted hairgrass (*Deschampsia cespitosa*), and a variety of native forbs. Native shrubs include willo*w (Salix* spp.), dogwood *(Cornus* spp*.)*, birch (*Betula occidentalis*), cottonwood (*Populus* spp.), alder (*Alnus* spp.) and other native mesic species. Invasive plant species either are not present or occur with low cover.

Best Management Practices for Water Quality, 36 CFR 219.8(a)(4)

Best management practices for water quality, often referred to as “BMPs”, are methods, measures, or practices used to meet nonpoint source control needs as directed by the Clean Water Act. Best management practices can be applied before, during, and after pollution-producing activities to reduce or eliminate the introduction of pollutants into receiving waters (36 CFR 219.19).

The National Best Management Practices Program is guided by the land management planning regulation 36 CFR 219.8 (a)(4), which requires the Chief of the Forest Service to establish requirements for National best management practices for water quality in the Forest Service Directive System. These requirements, and associated program direction, are outlined in Forest Service Handbook 2509.19, Chapter 10 National Core Best Management Practices and Forest Service Manual 2500, Chapter 30, Section 2532 Water Quality Management.

The National Core Best Management Practices (BMP) Technical Guide (U.S. Department of Agriculture 2012b) provides a standard set of core best management practices and a consistent means to track and document the use and effectiveness of best management practices on National Forest System lands. Appendix 4 outlines the management approaches of the Nez Perce-Clearwater Land Management Plan; Section 2.2.1 further describes federal and State of Idaho best management practices direction.

Plan component FW-STD-WTR-02 ensures implementation of national best management practices for water quality: Project-specific best management practices (BMPs), including both federal and state BMPs, shall be incorporated into project planning as a principal mechanism for controlling non-point pollution sources, to meet soil and watershed desired conditions, and to protect beneficial uses.

Diversity of Plant and Animal Communities 36 CFR 219.9

The diversity of terrestrial, riparian, and aquatic ecosystems and habitats is fundamental to providing ecological conditions that support the abundance, distribution, and long-term persistence of native species and diversity of plant and animal communities. The 2012 Planning Rule outlines a complementary ecosystem and species-specific approach to maintaining the diversity of plant and animal communities and the persistence of native species in the plan area that is within Forest Service authority and consistent with the inherent capability of the plan area (36 CFR 219.9). The 2012 Planning Rule provides direction for diversity of plant and animal communities by addressing: 1) ecosystem plan components; 2) additional species-specific plan components; and 3) species of conservation concern.

Ecosystem Plan Components, 36 CFR 219.9(a)

Ecosystem plan components are broken out into two categories: ecosystem integrity and ecosystem diversity. As outlined above, the Land Management Plan includes many plan components that propose to maintain or restore ecological integrity of terrestrial and aquatic ecosystems and watersheds in the plan area, including the maintenance or restoration of their structure, function, composition, and connectivity.

Ecosystem diversity is defined as the variety and relative extent of ecosystems (36 CFR 219.19). Diverse ecosystems provide the ecological conditions necessary to maintain the persistence or contribute to the recovery of native species within the plan area, including at-risk species. At-risk species are federally recognized threatened, endangered, proposed, and candidate species and species of conservation concern. The Land Management Plan includes plan components that propose to maintain or restore the diversity of ecosystems and habitat types throughout the plan area. In doing so, the Land Management Plan includes plan components to maintain or restore 1) key characteristics associated with terrestrial and aquatic ecosystem types; 2) rare aquatic and terrestrial plant and animal communities; and 3) the diversity of native tree species similar to that existing in the plan area.

Key Characteristics Associated with Terrestrial and Aquatic Ecosystems

The Nez Perce-Clearwater spans four Idaho ecoregions, ranging from the arid grassland and sagebrush steppe of the Columbia Plateau ecoregion to the mountainous Blue Mountains, Northern Rockies, and Idaho Batholith ecoregions.

The Nez Perce-Clearwater has a wide diversity of terrestrial vegetation communities due to its geographic location, geology, topography, range in elevation, and climate. Vegetation ranges from dense coniferous forests in warm, moist or dry valley bottoms to sparsely forested types on cold, steep, high-elevation sites. Forested vegetation is categorized into four broad potential vegetation type groups: warm dry, warm moist, cool moist, and cold. There are 14 native conifer tree species found on the Nez Perce-Clearwater, as well as a variety of hardwood species. Plan components in the terrestrial ecosystems (TE) and forestlands (FOR) sections promote the maintenance or restoration of terrestrial vegetation communities within the plan area.

Meadows, grasslands, and shrublands support native plant communities and forage for animals. The Nez Perce-Clearwater contains a mosaic of grassland, meadows, and shrubland vegetation and are generally categorized into five groups: xeric grasslands dominated by bluebunch wheatgrass habitat type groups, mesic grasslands dominated by fescue habitat type groups, xeric shrublands, wetland graminoid and riparian shrub, and subalpine herbaceous and shrub. Plan components in the terrestrial ecosystems (TE); meadows, grasslands, shrublands (GS); and riparian management zones (RMZ) sections promote the maintenance or restoration of native plant communities within the plan area.

Rare plant species occur throughout the Nez Perce-Clearwater, but sites of high representation and general floral diversity occur in areas of coastal disjunction in the low elevations of the larger Clearwater Basin tributaries, larger grassland complexes, and arid non-forest habitats that form islands in the general mesic forest types. There are an identified 52 at-risk plant species located within or near the boundaries of the Nez Perce-Clearwater. Habitats for at-risk plants are broken out into seven different guilds: grasslands, meadows, mesic forests, rocky habitats, subalpine forests, transitional habitats, and wetlands.

Rocky habitats are often associated with the alpine habitats, including rock outcrops and scree. Vegetation is sparse or largely lacking. Bryophytes and lichens often occur in crevices and flourish on open rock surfaces where the competition from vascular plants is absent. Rock outcrop and scree habitats may also be found at lower elevations. Rocky habitats are often fragile systems. Plan components in the terrestrial ecosystems (TE) section provide protections for rocky habitats.

Wildlife habitat conditions vary widely from the dry, rugged canyons of the Salmon River to the moist cedar forests of the Selway River drainage, the rolling uplands of the Palouse, and the high-elevation mountains across the Nez Perce-Clearwater. The diversity in habitat and topography contributes to the biodiversity of wildlife communities. There have been recorded observations of approximately 364 species of wildlife within the Nez Perce-Clearwater, including 201 birds, 67 mammals, 9 reptiles, 11 amphibians, 67 gastropods, 3 mussels, and 6 invertebrates. Key habitat groupings important for wildlife species include aquatic, wetland, water and riparian habitats; forested habitats, non-forested, or early seral habitats; substrate habitats, such as rock outcrops, soils, downed wood, cliffs, talus, or caves; ecotone, forest edge, or habitat grouping combinations; and alpine, boreal, or high elevation habitats. A number of species are reliant on available resources, such as nectar, fruit, seeds, plant forage, or prey, rather than specific habitat types or structure. Plan components in the terrestrial ecosystems (TE); cave and karst features (CAVE); forestlands (FOR); meadows, grasslands, shrublands (GS); fire management (FIRE); riparian management zones (RMZ); wildlife (WL); multiple uses wildlife (WLMU); elk (ELK); and Lower Salmon River area (SR) sections promote the maintenance or restoration of wildlife habitats within the plan area.

The Nez Perce-Clearwater contains diverse landscape conditions spanning five different fire regimes. A fire regime describes the frequency, predictability, and severity of fire in an ecosystem. Natural fire regime groups are broken out by fire return intervals and fire severity types. Approximately 54 percent of the Nez Perce-Clearwater occurs in Fire Regime III, characterized by a fire return interval or frequency of 35 to 200 years and a low to mixed fire severity. Approximately 33 percent of the national forest occurs in Fire Regime IV, characterized by a fire return interval or frequency of 35 to 200 years and a high fire severity. Plan components in the fire management (FIRE) section promote the maintenance or improvement of desired forest and grassland vegetation conditions to create resilient ecosystems and provide quality habitat for plant and animal species.

The three major river systems—Salmon, Clearwater, and Snake—and their accompanying tributaries provide important aquatic and riparian habitat for many species. The Nez Perce-Clearwater supports approximately 18 native fish species, three non-native fish, and many native aquatic invertebrates, macroinvertebrates, amphibians, and mussels. Aquatic ecosystems are varied, ranging from high gradient, steep canyon tributaries to lower gradient rivers with wide flood plains. Streams provide important spawning and rearing habitat for anadromous fish species. Other aquatic ecosystems include high mountain lakes and groundwater dependent ecosystems, such as meadows, seeps/springs, and peatlands. Plan components in the terrestrial ecosystems (TE); cave and karst features (CAVE); and aquatic ecosystems (WTR, RMZ, CWN, ARINF, AREM, ARGRZ, ARLND, ARREC) sections promote the maintenance or restoration of aquatic and riparian habitats.

Rare Aquatic and Terrestrial Plant and Animal Communities

The Nez Perce-Clearwater possesses a tremendous range and unusual diversity of habitats, from boreal and coastal elements in the north to extensive grasslands and pine forests in the south. The maritime influence of the Pacific Ocean also contributes to a unique coastal disjunct ecosystem with associated species uncommon to the northern Rockies, such as the Coeur d’Alene and Idaho giant salamanders, deer fern, and Pacific dogwood. The local climatic transition caused by extreme terrain differences result in high floral diversity, including endemic species like the evergreen kittentail, Dasynotus, Idaho barren strawberry, spacious monkeyflower, the federally listed Spalding's catchfly, and four species of pine.

Persistent hardwood-dominated plant communities are rare on the Nez Perce-Clearwater but are important components of diversity, providing habitat for a variety of birds and other wildlife species. Aspen may occur as a persistent community in riparian areas or as a transitional community in upland areas. These communities often dominate in the early stages of forest succession immediately after disturbance. Aspen is more common than cottonwood on the Nez Perce-Clearwater, which is confined to riparian areas with fluctuating water tables and is more common on the private lands outside of the national forest boundary.

In addition, the diverse vegetative communities on the Nez Perce-Clearwater provide terrestrial habitats that host several regionally unique native wildlife populations. This includes native lineages of fisher and bighorn sheep, as well as mountain quail, the white-headed woodpecker, and the harlequin duck.

The Salmon, Clearwater, and Snake Rivers and their accompanying tributaries offer important aquatic and riparian habitat for many species, including lamprey, bull trout, steelhead trout, westslope cutthroat trout, and Chinook salmon. The Nez Perce-Clearwater's substantial spawning and rearing habitat for steelhead trout and Chinook salmon provides a large portion of the total returns of adult anadromous salmonids in the Snake and Columbia River basins.

Additionally, a large number of endemic gastropods are found in the major river systems, particularly in the Salmon River. The sheer number and diversity of endemic aquatic species within the planning area is notable and exemplary within the western United States. Many species of gastropods in the plan area are regional endemic species limited to northern Idaho, western Montana, southern British Columbia, and eastern Washington. Others are Idaho endemics limited in many cases to Idaho, while some are local endemics with distributions limited to parts of the Nez Perce-Clearwater and some lands just outside the plan area. The Selway forestsnail, the Mission Creek Oregonian, and the nimapuna disc are some examples of local endemic gastropods.

The lower Salmon River canyon has exceptional landsnail diversity, and several landsnail species are local endemics limited to the lower Salmon River canyon. Most of these species occur outside of the plan area boundaries at lower elevations but some taxa have been observed on the Nez Perce-Clearwater. The Land Management Plan establishes the Lower Salmon River Geographic Area to emphasize and better protect endemic gastropod habitats and other unique ecological conditions.

Endangered Species Act, Federally Listed Threatened and Endangered Species, and Candidate Species

As shown in Table 304, the Nez Perce-Clearwater currently supports one species federally listed as endangered under the Endangered Species Act, eight listed as threatened, and one candidate species.

Table 304. Species listed by the Endangered Species Act (ESA) as federally listed threatened, endangered, candidate, and proposed species in the plan area

Species[1]	ESA Status
Snake River spring and summer Chinook salmon (*Oncorhynchus tshawytscha*), Salmon River Basin	Threatened

Species[1]	ESA Status
Snake River fall Chinook salmon (*Oncorhynchus tshawytscha*), Clearwater and Salmon River Basins	Threatened
Snake River sockeye salmon[2] (*Oncorhynchus nerka*), Salmon River Basin	Endangered
Snake River steelhead trout (*Oncorhynchus mykiss*), Clearwater and Salmon River Basins	Threatened
Columbia River bull trout (*Salvelinus confluentus*), Clearwater and Salmon River Basins	Threatened
Spalding's catchfly (*Silene spaldingii*)	Threatened
Canada Lynx (*Lynx canadensis*)	Threatened
Grizzly Bear (*Ursus arctos horribilis*)	Threatened
Whitebark pine (*Pinus albicaulis*)	Threatened
Monarch Butterfly (*Danaus* plexippus)	Candidate
Wolverine (*Gulo gulo*)	Candidate

1 - Water howellia (*Howellia aquatilis*) was included in early analysis but has been delisted. Macfarlane's four-o'clock (*Mirabilis macfarlanei*) is listed as threatened, but there is not known occurrence on lands administered by the Nez Perce-Clearwater, although it is known to occur very close to the Nez Perce-Clearwater boundary.

2 - Although species are present, sockeye salmon spawning or rearing does not occur on the Nez Perce-Clearwater.

As discussed in previous sections above, the Land Management Plan includes plan components to maintain or restore rare aquatic and terrestrial plant and animal communities. The Land Management Plan also includes plan components that emphasize the protection, preservation, management, or restoration of natural environments and ecological communities to recover federally listed endangered and threatened species and potentially avoid federally listing of proposed and candidate species, for example:

FW-GL-WL-01. Through cooperation and collaboration with the U. S. Fish and Wildlife Service, other federal agencies, state agencies, and tribes on conservation strategies, recovery plans, and habitat management, ecological conditions on National Forest System lands contribute towards recovery of federally listed threatened or endangered species, candidate, and proposed species are conserved and future listings are prevented.

FW-DC-WL-01. The Nez Perce-Clearwater provides habitat conditions for federally listed threatened, endangered, and candidate plant and animal species that contribute to their recovery to the point at which listing is no longer appropriate. Habitat used by federally listed species provide conditions to meet their life history needs.

Canada Lynx

The Canada lynx is federally listed as threatened under the Endangered Species Act. Lynx and snowshoe hares, the lynx's primary winter prey, are strongly associated with moist, cool, boreal spruce-fir forests. Lynx habitat may be affected by changes in climate, as snowpack is projected to decline.

The U.S. Fish and Wildlife Service prepared a recovery outline for the Canada lynx (U.S. Department of the Interior 2005a) that was to provide interim guidance until a formal recovery plan had been approved. No recovery plan has yet been developed for the lynx.

The Northern Rockies Lynx Management Direction (NRLMD) amended 18 forest plans for the national forests in Idaho, Montana, Utah, and Wyoming, including the Nez Perce-Clearwater (U.S. Department of Agriculture 2007c). Under the Northern Rockies Lynx Management Direction, the

Nez Perce National Forest is considered unoccupied, and the Clearwater National Forest is considered occupied. The U.S. Fish and Wildlife Service has determined that lynx “may be present” on both Forests, and both Forests are considered to be secondary areas. No critical habitat on the Nez Perce-Clearwater has been designated by the U.S. Fish and Wildlife Service.

Coarse filter plan components provide for habitat diversity that benefit lynx, and plan components FW-GL-WL-01 and FW-DC-WL-01 support federally listed threatened or endangered species. Lynx are the only federally listed species with a species specific plan component: Canada lynx habitat shall be managed in accordance with the Northern Rockies Lynx Management Direction (U.S. Department of Agriculture 2007f) and Record of Decision (U.S. Department of Agriculture 2007e) and any amendments, updates, or new direction forthcoming (FW-STD-WL-01).

This standard incorporates all the components included in the Northern Rockies Lynx Management Direction (U.S. Department of Agriculture 2007f) and Record of Decision (U.S. Department of Agriculture 2007e), which is included in Appendix 5 of the Land Management Plan. Table 305 summarizes the number and type of components for general management actions, vegetation management, livestock grazing, human uses, and linkage areas. The components were developed to conserve and promote the recovery of lynx by reducing or eliminating adverse effects from land management activities on National Forest System lands while preserving the overall multiple-use direction.

Table 305. Summary of components in the northern Rockies lynx management direction

Category	Objectives/Desired Conditions	Standards	Guidelines
General Management Actions	1	2	1
Vegetation Management	4	4	5
Livestock Grazing	1	0	4
Human Uses	6	0	12
Linkage Areas	1	1	2

Data Source: Northern Rockies Lynx Management Direction

Grizzly Bear

Grizzly bears may be present within the Nez Perce-Clearwater. See the section Threatened, Endangered, Candidate, and Proposed Wildlife Species for more information on grizzly bear and records of occurrence. The Nez Perce-Clearwater contains a large proportion of the Bitterroot grizzly bear recovery zone. The Selway-Bitterroot Wilderness and the Frank Church-River of No Return Wilderness make up the core of the Bitterroot ecosystem recovery zone for the federally listed threatened grizzly bear. Reestablishment of the grizzly bear in this recovery zone is currently through natural dispersal. This zone is in relatively proximity to other grizzly bear recovery zones and encompasses areas where grizzly bears could come from the north and east into the Bitterroot Recovery Zone. The Grizzly Bear Recovery Plan (U.S. Department of the Interior 1993) and Supplement: Bitterroot Ecosystem Recovery Plan Chapter (Servheen 1996) outline the criteria needed for recovery.

The Nez Perce-Clearwater Land Management Plan would maintain the ecological conditions for grizzly bears to recolonize the Bitterroot recovery zone, allow for migration, dispersal, and genetic interchange between grizzly bear recovery zones, and reduce grizzly bear and human conflict through the following plan components.

FW-DC-WL-06. The grizzly bear Bitterroot Recovery Zone provides the ecological conditions to support recolonization of grizzly bears. Land Management Plan land use allocations provide connectivity to allow secure passage from occupied habitat to the Bitterroot Recovery Zone.

FW-DC-WL-07. The risk of grizzly bear-human conflict is reduced through awareness. The public, Forest Service employees, contractors, volunteers, and permittees are knowledgeable of conflict prevention strategies through education and interpretation.

FW-DC-WL-08. Within occupied grizzly bear habitat, developed recreation sites, administrative sites, and dispersed recreation sites where garbage disposal services are provided, facilities are equipped with necessary infrastructure so that food, garbage, and other attractants can be made inaccessible to grizzly bears to reduce the potential of human-bear conflict.

FW-DC-WL-09. Wide-ranging species are free to move across and between habitats, allowing for dispersal, migration, genetic interaction, and species recruitment.

FW-GDL-WL-05. To maintain large areas of unfragmented habitat for wide-ranging species, such as elk and grizzly bear, new motorized trails open to the public should not be authorized in unroaded areas unless there are adjacent areas of 5,000 acres without open motorized system routes. This guideline does not apply to Community Protection Zones (CPZs) as defined by the Idaho Roadless Rule.

Fish Species

The Nez Perce-Clearwater supports five fish species currently listed as threatened or endangered under the Endangered Species Act (Table 304) and contains designated critical habitat for these species. Critical habitat is the specific areas within the geographic area, occupied by the species at the time it was listed, that contain the physical or biological features that are essential to the conservation of endangered and threatened species and that may need special management or protection. Critical habitat may also include areas that were not occupied by the species at the time of listing but are essential to its conservation.

Recovery plans identify actions needed to restore threatened and endangered species to the point that they are again self-sustaining elements of their ecosystems and no longer need protection under the Endangered Species Act. Although recovery plans are not regulatory documents, they serve as a central organizing tool for guiding and coordinating recovery efforts across a wide spectrum of federal, state, tribal, local, and private entities. The following recovery plans include portions of the Nez Perce-Clearwater. In 2015, the U.S. Fish and Wildlife Service completed the Columbia River bull trout recovery plan (U.S. Department of the Interior 2015c) and recovery unit implementation plans for the Mid-Columbia and Upper Snake recovery areas (U.S. Department of the Interior 2015a, d). The National Marine Fisheries Service published the recovery plan for Snake River sockeye salmon in 2015 (National Oceanic and Atmospheric Administration 2015); the recovery plan for Snake River spring/summer Chinook salmon and steelhead in 2017 (National Oceanographic and Atmospheric Agency 2017); and the Snake River recovery plan for fall Chinook salmon, also in 2017 (National Oceanic and Atmospheric Administration 2017).

Of special note, coho salmon (*Oncorhynchus kisutch*) were historically believed to be native to the Clearwater basin but were officially declared extirpated, or non-existent, in 1985. Efforts to re-introduce the species are ongoing, and returning adults have been documented in several areas, including the Clear Creek tributary to the Middle Fork Clearwater River.

The Land Management Plan direction related to aquatic ecosystems is designed to move towards recovery of fish listed under the Endangered Species Act through restoration and conservation of designated critical habitat and streams across the planning area. Direction is also intended to conserve and restore habitat for aquatic species of conservation concern and to prevent future listings. One of the mechanisms for achieving these goals is the establishment of a conservation watershed network.

A conservation watershed network is a designated collection of watersheds where management emphasizes habitat conservation and restoration to support federally listed fish and species of conservation concern. Using specific criteria, 81 HUC12 watersheds were identified, forming a network of existing or historic population strongholds and habitats with high potential for productivity and fish abundance. These areas support freshwater life stages and demographic processes that are crucial for maintaining viable populations of wide-ranging fish. Selected conservation watershed network watersheds are expected to provide a pattern of protection across the landscape where the habitat of migratory salmonids receives special attention and treatment.

The desired conditions for Conservation Watershed Networks are intended to be used in conjunction with desired conditions for Water and Aquatic Resources and Riparian Management Zones. Conservation Watersheds are intended to sustain the integrity of key aquatic habitats and maintain multi-scale connectivity for at-risk fish and aquatic species, identifying important areas needed for conservation or restoration, and ensuring ecosystem components needed to sustain long-term persistence of species.

Conservation Watershed Networks are the highest priority for restoration actions for the aquatic environment. Restoration would be achieved through the collective objectives within the Aquatic Ecosystem plan components. Aquatic restoration is also encouraged in HUC12 subwatersheds outside of the conservation watershed network that are important for native fish species.

Coarse filter plan components in the aquatic ecosystems (WTR, RMZ, CWN) section provide for ecological conditions and habitat diversity that benefit fish species and FW-GL-WL-01 and FW-DC-WL-01 support federally listed threatened or endangered species. The Land Management Plan also includes other plan components specific to the recovery of threatened and endangered fish species, for example:

FW-DC-WTR-03. Aquatic habitats contribute to ecological conditions capable of supporting self-sustaining populations of native species and diverse plant, invertebrate, and vertebrate aquatic and riparian-dependent species. Aquatic habitats are key contributors to for the recovery of threatened and endangered fish species and provide important habitat components for all native aquatic species.

FW-DC-WTR-10. Critical habitat components (primary biological features) provide the ecological conditions necessary to achieve species recovery. Spawning, rearing, and migratory habitats are widely available and inhabited. Listed aquatic species have access to historic habitat and appropriate life history strategies (for example, bull trout resident, fluvial, adfluvial, and anadromy) are supported.

FW-GL-CWN-01. The Nez Perce-Clearwater works with the Nez Perce Tribe, State of Idaho, National Marine Fisheries Service, U. S. Fish and Wildlife Service, and other governmental organizations to plan and implement projects that contribute to recovery goals for aquatic species listed under the Endangered Species Act and their designated critical habitat, such that protective measures under the Act are no longer necessary.

FW-GL-CWN-02. The Nez Perce-Clearwater partners with federal agencies, including Section 7 consultation, as required; state agencies; tribes; counties; interested groups; and interested private landowners to recover threatened and endangered species.

FW-DC-CWN-01. Conservation Watershed Networks have functionally intact ecosystems that provide high-quality water and contribute to and enhance the conservation of aquatic species of conservation concern and recovery of threatened or endangered fish species.

FW-DC-CWN-02. Streams within the Conservation Watershed Network provide habitat that supports robust native fish populations, which can expand to and recolonize adjacent unoccupied habitats. These areas conserve key demographic processes likely to influence the sustainability of aquatic species.

FW-DC-CWN-03. Roads in the Conservation Watershed Network present minimal risk to aquatic resources.

FW-STD-CWN-01. In Conservation Network Watersheds not meeting aquatic and riparian desired conditions, activities shall be designed and implemented in a manner that supports or contributes towards the recovery of federally listed species and the achievement of these desired conditions and does not retard them when evaluated at the HUC12 subwatershed scale. Short-term adverse effects from project activities may occur when they support the long-term recovery of aquatic and riparian desired conditions and federally listed species.

FW-STD-ARINF-07. In the Conservation Watershed Network and HUC12 subwatersheds with Endangered Species Act critical habitat or listed aquatic species, when constructing or reconstructing roads, projects shall result in a net decrease in the hydrologic connectivity of the road system and stream channel network unless no further decreases are needed to meet desired conditions for Water and Aquatic Resources or Conservation Watershed Network. Treatment priority shall be given to roads or road segments that pose the greatest relative ecological risk to riparian and aquatic ecosystems. The net decrease is measured by project area.

Spaulding's Catchfly

Spalding's catchfly, federally listed as threatened, is naturally found infrequently on the Nez Perce-Clearwater. It is a perennial herb located in grassland habitats dominated by Idaho fescue and prairie June grass that generally support a diverse array of forbs on well-developed soils. While the U.S. Fish and Wildlife Service intends to identify critical habitat for this species, critical habitat designation was precluded at the time of listing due to a lack of funding. The recovery plan for Spalding's catchfly was completed in 2007 (U.S. Department of the Interior 2007) and outlines the recovery strategy, recovery goals, objectives, and delisting criteria.

Although there is no species-specific plan component for Spalding's catchfly, desired condition FW-DC-GS-02 promotes Spalding's catchfly habitat and FW-GL-WL-01, FW-DC-WL-01 and FW-GDL-GRZ-02 support federally listed threatened or endangered plant species.

Whitebark Pine

The U.S. Fish and Wildlife Service published a final rule (87 FR 76882) on December 15, 2022 to list the whitebark pine as a threatened species under the Endangered Species Act. Included in the rule is a special rule pursuant to section 4(d) of the act that identifies actions necessary to conserve and recover the whitebark pine, as well as a limited number of prohibited acts (87 FR76882). The Service has concluded that the whitebark pine is likely to become endangered in the foreseeable future throughout its range. Regulation and policy governing whitebark pine and associated habitats provide measures that are necessary and advisable to provide for the conservation of the species. The U.S. Fish and Wildlife Service determined that designation of critical habitat for the whitebark pine was not prudent at the time of the notice.

Whitebark pine is associated with high elevation and its distribution has been primarily influenced by the cold continental air masses in higher elevations in northern Idaho. On the Nez Perce-Clearwater, whitebark pine is typically found above 6,500 feet elevation. Whitebark pine is considered a “keystone” and “foundation” species because of its significant role in subalpine ecosystems (Keane and Parsons 2010, Jenkins 2011). As a keystone species, this five-needled pine influences the health and life cycle of other native plants and animals. White pine blister rust remains the primary threat to whitebark pine. This blister rust is a non-native fungal disease that harms whitebark pine trees across the West. Additional threats impacting the health of the species include mountain pine beetles, altered fire regimes, and climate change.

Whitebark pine is included in several plan components in the Forestlands section that are designed to maintain or improve composition, structure, function, and connectivity of cool moist and cold potential vegetation type groups (FW-DC-FOR-09, FW-DC-FOR-10, MA1 and MA2-DC-FOR-09, MA3-DC-FOR-07, MA3-DC-FOR-08, MA3-OBJ-FOR-03, MA3-OBJ-FOR-04, MA2-OBJ-FOR-01, MA2-OBJ-FOR-04, MA2-OBJ-FOR-05). The Land Management Plan also includes plan components MA2 and MA3-DC-FOR-10, MA3-STD-FOR-01, MA2 and MA3-GDL-FOR-02, MA2 and MA3-GDL-FOR-03, and MA2 and MA3-GDL-FOR-04, which are designed to maintain or increase old growth conditions, including those for whitebark pine. Although not specifically mentioned, all the plan components in the Forestlands section associated with cool moist and cold potential vegetation type groups benefit whitebark pine species.

Monarch Butterfly

On December 15, 2020, the U.S. Fish and Wildlife Service announced that listing the monarch butterfly under the Endangered Species Act is warranted but precluded. This makes monarch butterflies a “candidate species” that are re-evaluated annually for potential listing. The monarch will remain a candidate species until it is determined that listing is warranted, or that current conservation actions have recovered the population enough that listing is not warranted.

Although there is no species-specific plan component for monarch butterfly, FW-GL-WL-01 and FW-DC-WL-01 support federally listed threatened, endangered, or candidate species. Desired condition FW-DC-TE-03 promotes monarch butterfly habitat, emphasizing that plant communities are comprised of a diverse mix of native grass, forb, shrub, and tree species, which provide forage for pollinator species.

Wolverine

The wolverine is listed as an Endangered Species Act candidate species. Wolverine live at low densities and occupy remote areas with persistent snowpack, which they use for denning. Winter food resources influence habitat selection. They rely on small mammals and ungulates as food sources, both scavenging and hunting their prey. Wolverine habitat may be affected by changes in climate, as snowpack is projected to decline. More than 80 percent of modeled wolverine habitat occurs in designated or recommended wilderness areas and Idaho Roadless areas.

Although there is no species-specific plan component for wolverines, coarse-filter plan components provide for habitat diversity that benefits wolverines and FW-DC-TE-05, FW-GL-WL-01, and FW-DC-WL-01 support federally listed threatened or endangered species. Also, plan components associated with wilderness and roadless area also benefit wolverines. See the lands with distinctive classifications below.

For further information on federally listed threatened, endangered, candidate, and proposed species, see Sections Forestlands, At-Risk Plant Species, Aquatic Ecosystems and Fisheries, and Threatened, Endangered, Candidate, and Proposed Wildlife Species in the Final Environmental Impact Statement. Species of Conservation Concern, 36 CFR 219.9(c)

A species of conservation concern is a species, other than federally recognized threatened, endangered, proposed, or candidate species, that is known to occur in the plan area and for which the regional forester has determined that the best available scientific information indicates substantial concern about the species' capability to persist over the long-term in the plan area.

The regional forester's species of conservation concern list (Marten 2019) identifies six animal species: bighorn sheep, fisher, mountain quail, white-headed woodpecker, harlequin duck, and pacific lamprey. The regional forester's list of species of conservation concern also identifies 30 plant species. See the At-Risk Plant Species section for a full list of plant species and associated habitats.

The species identified in the list meet the criteria for species of conservation concern as defined by the 20I2 Planning Rule and its implementing directives. The 20I2 Planning Rule requires forest plans to include plan components that provide the ecological conditions necessary to maintain a viable population of each species of conservation concern within the plan area (36 CFR 219.9(b)(1)).

For further information on species of conservation concern see Final Environmental Impact Statement Sections At-Risk Plant Species, Aquatic Ecosystems and Fisheries, and Abundancy and Diversity of Wildlife.

The Land Management Plan emphasizes species of conservation concern by emphasizing that ecological conditions on the Nez Perce-Clearwater contribute sustainable habitat to maintain species of conservation concern. Habitat is resilient and adaptable to stressors and likely future environments (FW-DC-WL-02).

Coarse filter plan components in the terrestrial ecosystems (TE); cave and karst features (CAVE); forestlands (FOR); meadows, grasslands, shrublands (GS); fire management (FIRE); aquatic ecosystems (WTR, RMZ, CWN); wildlife (WL, WLMU, and ELK); and Lower Salmon River area (SR) sections provide for the maintenance and improvement for habitats supporting species of conservation concern. The Land Management Plan also includes other plan components specific to species of conservation concern, as shown in Table 306, to provide for ecological conditions that promote the diversity of plant and animal communities.

Table 306. Summary of plan components for species of conservation concern

Plan Component	Subject
FW-DC-GS-07	Desire for persistence of Daubenmire's dasynotus (*Dasynotus daubenmirei*) and Pacific dogwood (*Cornus nuttallii*)
FW-DC-GS-08	Desire for persistence of Douglas' clover (*Trifolium douglasii*) and sticky goldenweed (*Pyrrocoma hirta* var. *sonchifolia*)
FW-GDL-RMZ-10	Requirement to relocate pacific lamprey prior to channel dewatering

Plan Component	Subject
FW-DC-CWN-01	Desire for conservation watershed networks to have functionally intact ecosystems that contribute to and enhance the conservation of aquatic species of conservation concern
FW-DC-CWN-02	Desire for streams in the conservation watershed network to provide habitat that supports robust native fish populations
FW-DC-CWN-03	Desire for roads in the conservation watershed network present minimal risk to aquatic resources
FW-OBJ-CWN-02	Objective to stormproof road in conservation watershed networks
FW-DC-WL-04	Description of desired fisher habitat
FW-DC-WL-05	Description of desired bighorn sheep habitat
FW-GL-WL-03	Goal for public education to help reduce disease transmission to bighorn sheep from pack goats
FW-STD-WL-02	Limits domestic sheep and goat grazing authorization within 16 miles of bighorn sheep ranges
FW-GDL-WL-04	Requirement to include provisions in permit authorizations for domestic goat packing to prevent disease transmission to bighorn sheep
FW-STD-ARGRZ-03	Requires measures be included in annual operating instructions to prevent trampling of fish redds of species of conservation concern
FW-DC-ARREC-01	Recreation facilities and their use have minimal impacts on aquatic resources, including species of conservation concern
GA-DC-SR-02	Desire for maintenance or improvement of Ponderosa pine ecosystems and habitat for Ponderosa pine associated species, which include white-headed woodpecker and mountain quail
GA-OBJ-SR-01	Objective to improve mountain quail habitat

For further information on species of conservation concern, see the sections At-Risk Plant Species, Aquatic Ecosystems and Fisheries, and Abundance and Diversity of Wildlife in the Final Environmental Impact Statement.

Monitoring Plan and Focal Species

Appendix 3 of the Land Management Plan includes monitoring questions to track the status of a select set of the ecological conditions required under 36 CFR 219.9 to contribute to the recovery of federally listed threatened and endangered species, conserve proposed and candidate species, and maintain a viable population of each species of conservation concern.

The monitoring plan also includes monitoring questions to evaluate the status of focal species as a means to assess the ecological conditions required under 36 CFR 219.9. Focal species are a small subset of species whose status permits inference to the integrity of the larger ecological system to which it belongs. Monitoring focal species provides meaningful information regarding the effectiveness of the plan in maintaining or restoring the ecological conditions to maintain the diversity of plant and animal communities in the plan area.

Focal species are commonly selected on the basis of their functional role in ecosystems. The monitoring program must include one or more monitoring questions addressing the status of focal species as a means to assess the ecological conditions required under 36 CFR 219.9. Focal species for the Nez Perce-Clearwater are Western Pearlshell Mussel, Ponderosa Pine Xeric Habitat Ecotone, and Elk.

Western Pearlshell Mussel

The western pearlshell is long-lived, sedentary, and sensitive to environmental change, so it is considered an excellent indicator of water quality and overall watershed integrity. This species appears to be intolerant of sedimentation and increases in stream temperature. The desired condition for streams that support mussels is for aquatic habitats to contribute to ecological conditions capable of supporting self-sustaining populations of native species and diverse plant, invertebrate, and vertebrate aquatic and riparian-dependent species (FW-DC-WTR-03). The most effective means to improve western pearlshell mussel habitat is to minimize impacts by following Land Management Plan standards and guidelines and to utilize best management practices. Implementing water and aquatic resource objectives can restore habitat and improve riparian and stream functions.

Ponderosa Pine Xeric Habitat Ecotone

The Ponderosa Pine Xeric Habitat Ecotone is a transitional area of vegetation between low elevation, dry site Ponderosa pine and xeric grasslands and shrublands. This ecotone is threatened by a variety of stressors, including invasive species expansion, altered fire regimes, risk of severe wildfire, and changing climate. Decades of fire exclusion have resulted in an increase in understory ladder fuels, shifts in species composition toward shade tolerant species less resistant to fire, increases in crown fires, higher canopy densities, and forest succession. This habitat would otherwise have been maintained at more open densities by frequent low intensity fire. The change in disturbances shifts these forests away from the natural range of variability in terms of age structure, patch size, and species composition. Non-native, invasive, and noxious plants are an additional threat and are a pervasive problem in these dry habitats.

The ecotone supports wildlife species associated with Ponderosa pine dominated habitats, including two species of conservation concern, including the White-headed woodpecker, and the Mountain quail. Additionally, other Ponderosa pine associated species have drawn conservation interest or attention over time. The long-term persistence of these species can be achieved by restoring and conserving these important habitats and monitoring these habitats as a focal species will track the status and progress of conserving and restoring Ponderosa pine habitats.

Desired conditions (FW-DC-FOR-02) for the hot dry and warm dry Ponderosa pine habitat types in the warm dry broad potential vegetation type group[24] include stand densities that reflects the historic fire regime, which typically included frequent underburns, so stands are open and many-aged with younger trees occurring as small even-aged groups or individuals interspersed among the larger, long-lived trees. The overstory is dominated by large Ponderosa pine and the understory is composed of native grasses, forbs, and low shrubs.

The desired condition (FW-DC-GS-01) of xeric grassland communities, such as the bluebunch wheatgrass habitat type groups, is to have vegetation dominated by native bunchgrasses while conifers are absent or occur as scattered individuals. Xeric shrubland plant communities occur infrequently on drier sites, and the desired condition (FW-DC-GS-03) is to support shrub species, such as mountain mahogany and sumac. The understory should typically be dominated by native grass species. Canopy cover varies depending on the site and growing conditions but should typically be low to moderate.

[24] This is meant to include only the warmest and driest Ponderosa pine and Douglas-fir habitat types that historically experienced low severity underburns almost exclusively. This includes the Hot Dry and Warm Dry Northern Region (Region 1) Habitat Type Groups as described in (Milburn et al. 2015)

Management of these ecotones requires increasing the resiliency of hot/warm-dry Ponderosa pine habitat types as well as maintaining the non-forested xeric plant communities along this gradient. Managed wildland fire and associated pre-fire vegetation treatments are critical tools needed to maintain these sites and associated habitat characteristics.

Elk

Elk are one of Idaho's most iconic wildlife species and are one of the most highly sought-after big game animals in the state. Population declines have impacted this herd previously renowned for its abundance and trophy opportunity, which used to draw hunters from all over the country. The elk herds in the plan area play a distinctive role in the local communities and contribute to social and economic sustainability. There is a strong desire by the public, local and state governments, tribes, outfitter and guides, sportsman's groups, and other interest groups to improve habitat conditions for elk and recover and grow elk populations.

Elk herd numbers are influenced by both ecological and anthropogenic factors, such as forage availability, habitat quality, predation, and hunter harvest. Threats and stressors that can affect elk or their habitat include invasive weeds, departed fire return intervals and forest succession, timber harvest activities and associated road use, livestock grazing, human development adjacent to National Forest System lands, and motorized use on roads and trails.

The plan contains several desired condition that direct the management of elk habitats and include an emphasis on providing moderate or high quality nutrition and in particular to provide that nutrition in areas that are usable by elk. The amount and distribution of early seral nutritional resources are consistent with the desired conditions in the Forestlands and Meadows, Grasslands, and Shrublands sections of the Land Management Plan. The desired condition for Management Area 1 is that forage is created and maintained through natural disturbance processes and elk habitat quality is not degraded by invasive plant species. Additionally, it is desired that motorized access does not preclude use of high-quality nutritional resources or winter ranges.

On the Nez Perce-Clearwater, the most effective means to increase moderate or high-quality nutritional forage is through disturbance to forested habitats to create more early seral stage openings, particularly in those areas with higher nutritional capacity as modeled. Disturbance may include timber harvest, natural fire, prescribed fire, or other activities that reduce canopy cover.

Lands with distinctive classifications

Lands with distinctive classifications contain habitats that provide for rare aquatic and terrestrial plant and animal communities. These lands include the Lower Salmon River geographic area; research natural areas; special areas; recommended and designated wilderness areas; Idaho roadless areas; and eligible, suitable and designated wild and scenic rivers. Although these specially classified lands sometimes overlap with more than one designation, these areas still cover over 60 percent of the Nez Perce-Clearwater.

Lower Salmon River Geographic Area

The Lower Salmon River Geographic Area contains rich geological complexity, contributing to a biological community that is unique within the plan area. This geographic area contains a large portion of the driest of the warm dry potential vegetation group dominated by Ponderosa pine under a frequent low intensity fire system. These habitats support species associated with Ponderosa pine dominated habitats, including several species of conservation concern. The Lower Salmon River Geographic Area is host to most observations of Ponderosa pine species of conservation concern. For example, the Idaho Department of Fish and Game's Species Diversity Database (accessed January

2017) shows most observations of white-headed woodpecker, Lewis's woodpecker, fringed myotis, Townsend's big eared bats, and mountain quail occur within this geographic area. Similarly, the area contains substantial amounts of habitat for the flammulated owl and pygmy nuthatch.

The area is home to remarkable biodiversity and high endemism of land and aquatic snails. The lower Salmon River canyon has long been known as a hot spot of biodiversity for land snails, where more than 60 species have been identified to date, which represents more than half of the land snail biodiversity within the State of Idaho. Many of the land snail species are thought to be restricted to the lower Salmon River corridor, with some occupying this area and portions of the nearby Snake River while others are only known to inhabit a few rock outcrops. This area also provides habitat for wintering elk and important habitat for mule deer and contributions towards habitat for bighorn sheep. The Lower Salmon River geographic area totals approximately 210,695 acres.

The Land Management Plan includes the following plan components to support ecological intergrity in the Lower Salmon River Geographic Area:

GA-DC-SR-01. Forest vegetation grows on soils that support and developed under forested ecosystem. Grassland soils, including mollisol soils, support healthy grassland and shrubland communities with few trees.

GA-DC-SR-02. Habitat for Ponderosa pine associated species, including legacy trees and snags, are within desired conditions within Ponderosa pine systems (See FW-DC-FOR-02, FW-DC-FOR-03, FW-DC-FOR-04, and FW-DC-FOR-05). Understory characteristics do not facilitate stand replacing fires and are composed of native plants that provide insect populations as forage for Ponderosa pine associated species. These habitats are resilient to changes due to climate change.

GA-DC-SR-03. Habitat for endemic terrestrial snails is available.

GA-OBJ-SR-01. 100 acres of mountain quail habitat are restored in each five-year period.

Research Natural Areas

Research natural areas are permanently established to maintain areas of natural ecosystems and areas of special ecological significance. Research natural areas provide protection for biological diversity, affording some degree of assurance that a wide array of plant and animal species will be afforded a high degree of protection in the future. This protection may be most important for soil microorganisms, fungi, insects, and other forms of biological diversity on which ecosystems often depend the most, but which are the least understood. Research natural areas also can be selected to help protect specific populations of threatened, endangered, or sensitive species.

The Nez Perce-Clearwater has 18 designated research natural areas, totaling approximately 29,500 acres. The established research natural areas on the Nez Perce-Clearwater are permanently designated for the purpose of conserving biodiversity, conducting non-manipulative research and monitoring and fostering education. They serve as high-quality representative areas of the major forms of vegetative variability found in the Nez Perce-Clearwater, and they present reference areas for the study of natural ecological processes, including disturbances and climate change. They are also useful as controls, providing reference conditions when evaluating the impact of management on an area. In addition, the Land Management Plan includes four proposed research natural areas and the expansion of an existing research natural area under all action alternatives, totaling approximately 2,946 acres. The proposed research natural areas would be established through a separate decision by the regional forester. Forest Service Manual 4063 provides direction in the management of these areas and would be followed to conserve the plant associations or other features for which they were established. See Section 3.6.3 Research Natural Areas for more information.

The Land Management Plan includes a desired condition for research natural areas emphasizing designated and proposed research natural areas maintain a representation of natural systems found on the Nez Perce-Clearwater as a baseline for research, monitoring, and education by the agency, academia, and public interests. Wildfire, insects, and pathogens, along with other processes and disturbances, continue to affect vegetation, reflecting the dynamic nature of the systems they represent. Research natural areas contribute to ecological sustainability and biological diversity (MA2-DC-RNA-01).

Special Areas

Special areas are a category of administratively designated areas defined as an area or feature managed to maintain its unique special character or purpose (36 CFR 219.19), including those that may be botanical, geological, recreational, scenic, zoological, paleontological, or historical in nature. Such areas are protected and managed for public use and enjoyment and are identified due to their unique or special characteristics. Special areas are not congressionally designated but are administratively designated by the Chief of the Forest Service, regional forester, or forest supervisor (FSM 2372). The Nez Perce-Clearwater has eight designated areas covering 602 acres that would maintain their designations under all Action Alternatives. The Land Management Plan also includes six proposed special areas under all Action Alternatives, totaling 1,403 acres. Forest Service Manual 2372 provides direction in the management of these areas and would be followed to conserve the features for which they were established. See Section 3.6.4 Special Areas for further information.

The Land Management Plan includes a desired condition emphasizing that pecial Areas provide for public use and enjoyment and protect areas with scenic, geological, botanical, zoological, paleontological, archaeological, or other special characteristics or unique values on the Nez Perce-Clearwater. Education and interpretation of these areas promote public awareness of these special features (GA-DC-SA-01).

Recommended and Designated Wilderness Areas

Wilderness areas allow natural ecological processes and disturbances to dominate and are important for maintaining species diversity and conserving threatened and endangered species. The Nez Perce-Clearwater contains the entire Gospel-Hump Wilderness and portions of the Selway-Bitterroot and Frank Church-River of No Return Wilderness areas, totaling approximately 1,139,000 acres within the national forest boundary. The combination of these three wilderness areas comprise an expansive block of nearly four million acres of wilderness in central Idaho and western Montana. Additionally, the Preferred Alternative proposes to recommend portions of four Idaho Roadless areas as recommended wilderness: East Meadow Creek, Hoodoo, Mallard-Larkins, and West Meadow Creek. Recommended wilderness areas are lands that have wilderness characteristics and may be suitable for inclusion in the National Wilderness Preservation System.

The Land Management Plan includes the following plan components to support ecological integrity in Recommended and Designated Wilderness Areas:

MA1-DC-WILD-01. Natural ecological processes and disturbances (for example, succession, wildfire, avalanches, insects, and disease) are the primary forces affecting the composition, structure, and pattern of vegetation.

MA2-DC-RWILD-01. Recommended wilderness areas maintain their existing wilderness characteristics to preserve opportunities for inclusion in the National Wilderness Preservation System.

MA2-DC-RWILD-02. Recommended wilderness areas are characterized by a natural environment where ecological processes and disturbances, such as natural succession, fire, avalanches, insects, and diseases, are the primary forces affecting the composition, structure, and patterns of vegetation.

MA2-DC-RWILD-03. Recommended wilderness areas facilitate the connectivity and movement of wildlife species across the Nez Perce-Clearwater by remaining large areas with little human activity.

Idaho Roadless Areas

The Nez Perce-Clearwater contains 34 separate Idaho roadless areas, totaling approximately 1,482,000 acres. Each area is assigned one or more management theme as outlined in the Idaho Roadless Rule—wild land recreation; primitive; backcountry/restoration; general forest, rangeland, and grassland; special areas of historic and tribal significance; and forest plan special areas. Each theme has established prohibitions with exceptions or conditioned permissions governing road construction, timber cutting, and discretionary mineral development. There are no open roads within the roadless areas.

The Land Management Plan includes the following plan components to support ecological integrity in Idaho Roadless Areas:

MA2-DC-IRA-01. Roadless Areas maintain the roadless characteristics and themes assigned to them in the Idaho Roadless Rule.

MA2-DC-IRA-02. The composition, structure, and pattern of vegetation reflect natural disturbances and follow Idaho Roadless Rule themes, as assigned.

MA2-DC-IRA-03. Roadless areas contribute habitats for wide ranging species and connectivity for movement of wildlife. These areas also provide foraging, security, denning, and nesting habitat for wildlife.

MA2-DC-IRA-05. Habitat configuration, distribution, and composition provide ecological conditions that increase elk herds.

Eligible, Suitable and Designated Wild and Scenic Rivers

Congress passed the National Wild and Scenic Rivers System Act in 1968 for the purpose of preserving rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. Natural values include water quality, geology, botany, fish, and wildlife. The act is recognized for safeguarding the special character of these rivers while also allowing for their appropriate use and development. The Nez Perce-Clearwater has three designated Wild and Scenic Rivers: Middle Fork Clearwater River, Salmon River, and Rapid River. The Middle Fork Clearwater includes the Lochsa and Selway Rivers. Designated Wild and Scenic River acres within the Nez Perce-Clearwater's administrative boundary total approximately 57,890 acres.

Additionally, the Preferred Alternative identified twelve river segments as eligible or suitable for inclusion as part of the Wild and Scenic Rivers System. Eleven rivers were identified as suitable: Salmon River, Weitas Creek, Kelly Creek, North Fork Kelly Creek, Middle Fork Kelly Creek, South Fork Kelly Creek, Cayuse Creek, Colt Killed Creek, Fish Creek, Hungery Creek, and Meadow Creek

(Selway). The Little North Fork Clearwater River is to remain eligible with no suitability decision made as part of the Land Management Plan. Interim protection measures would still apply. The Land Management Plan includes the following plan components to support ecological integrity in Designated and Eligible and Suitable Wild and Scenic Rivers:

MA1-DC-DWSR-01. Designated wild, scenic, and recreational rivers retain their free-flowing condition, water quality, and the outstandingly remarkable values for which the river was designated.

MA2-DC-E&SWSR-01. Eligible and suitable wild, scenic, and recreational rivers retain their free-flowing condition, preliminary classification, and the outstandingly remarkable values that provide the basis for their eligibility or suitability for inclusion in the system.

Diversity of Native Tree Species

The Nez Perce-Clearwater has a wide diversity of terrestrial vegetation communities due to its geographic location, geology, topography, range in elevation, and climate. Vegetation ranges from dense coniferous forests in warm, moist or dry valley bottoms to sparsely forested types on cold, steep, high-elevation sites. Forested vegetation is categorized into four broad potential vegetation type groups – warm dry, warm moist, cool moist, and cold.

The Nez Perce-Clearwater supports 14 native conifer tree species found on the Nez Perce-Clearwater: Ponderosa pine, Douglas-fir, grand fir, lodgepole pine, western larch, western white pine, western red cedar, western hemlock, mountain hemlock, Pacific yew, Engelmann spruce, subalpine fir, alpine larch, and whitebark pine. Several hardwood tree species are present and may be intermixed with conifer species or may occur as single species patches on suitable landscapes. Hardwood species include quaking aspen, paper birch, water birch, cottonwood spp., mountain ash, mountain mahogany, and Rocky Mountain maple.

An important feature to note about the forests of the northern Rocky Mountain ecosystem is the influence of long-lived, fire tolerant, early successional species in the successional process and in the composition and structure of forests at all stages of development and on all sites. Species, such as western larch, Ponderosa pine, western white pine, whitebark pine, and Douglas-fir, are able to survive for several centuries. In many areas, the fully developed "true" climax forest conditions may be relatively uncommon due to the long-term persistence of these early successional species. These species tolerance of low or even moderate severity fire allows some to survive through the less severe fire events. Though they may or may not be numerous, they grow to large stature and become prominent features of the overstory tree canopy, providing important structural components of late successional and old growth forests. When severe stand replacing fire occurs, they are well adapted to take advantage of the open burned forest conditions and reforest the site.

The ecosystem elements, such as species composition, structural stage, stand age, canopy closure, and fuel loadings, are representative of the potential vegetation types' resilience to current and future disturbance. Fire is a primary ecological process that has created, maintained, and renewed vegetation on the Nez Perce-Clearwater. With fire exclusion, dense understories and thickets of conifers have produced stands that are highly susceptible to a variety of insect and disease epidemics and uncharacteristic wildfire effects. The fire regimes within the warm dry and warm moist potential vegetation type have moderate to high departures, indicating that many of these areas have missed one or more fire return intervals and have the potential for higher severity fire as a result. The cool and cool moist potential vegetation types have low to moderate departure but could move toward a higher departure without disturbance.

Old growth forests are ecosystems distinguished by old trees and related structural attributes. Old growth encompasses the later stages of stand development that typically differ from earlier stages in a variety of characteristics, which may include tree size, accumulations of large dead woody material, number of canopy layers, species composition, and ecosystem function. The Land Management Plan provides direction for managing old growth that is consistent with natural patterns and ecological processes and includes plan components MA2 and MA3-DC-FOR-10 and MA3-STD-FOR-01, which are designed to maintain or increase old growth conditions.

MA2 and MA3-DC-FOR-10. Amounts of Ponderosa pine, western larch, western white pine, and whitebark pine dominant old growth cover types are maintained or increased from existing amounts. Amounts of western redcedar, Pacific yew, and western hemlock dominant old growth cover types are maintained through time.

MA3-STD-FOR-01. Within Ponderosa pine, western larch, western white pine, Pacific yew, western redcedar, western hemlock, and whitebark pine old growth stands, vegetation management activities shall not be authorized if the activities would likely modify the characteristics of the stand to the extent that the stand would no longer meet the definition of old growth ten years post activity. See glossary for old growth definition.

Plan components MA2 and MA3-GDL-FOR-02, MA2 and MA3-GDL-FOR-03, and MA2 and MA3-GDL-FOR-04 also provide guidance for maintaining old growth cover types.

For further information on terrestrial ecosystem integrity and diversity, see the section Forestlands in the Final Environmental Impact Statement.

The Land Management Plan includes numerous plan components to maintain or restore the persistence and diversity of native tree species within the plan area, as shown in Table 307. The plan components in the forestlands section were developed to maintain or restore the composition, structure, function, and connectivity of terrestrial ecosystems, considering multiple spatial and temporal scales.

Table 307. Summary of plan components that maintain or restore the persistence and diversity of native tree species

Plan Component	Subject
FW-DC-TE-04	Desired condition for native plant communities
FW-DC-TE-05	Desired condition for riparian vegetation, including conifers and hardwoods
FW-DC-FOR-01	Aspen persists as vigorous; multi-age stands over time across its range
FW-DC-FOR-02, FW-DC-FOR-04, FW-DC-FOR-07, FW-DC-FOR-10, MA1 and MA2-DC-FOR-09, MA3-DC-FOR-07	Desired condition for within-stand characteristics for each potential vegetation type
FW-DC-FOR-03, FW-DC-FOR-06, FW-DC-FOR-09, FW-DC-FOR-13	Desired condition for vegetation composition for each potential vegetation type
MA1-DC-FOR-01, MA2-DC-FOR-01, MA3-DC-FOR-01, MA1-DC-FOR-02, MA2-DC-FOR-02, MA3-DC-FOR-03, MA1-DC-FOR-03, MA2-DC-FOR-03, MA3-DC-FOR-05, MA1-DC-FOR-04, MA2-DC-FOR-04, MA3-DC-FOR-08	Desired condition for stand density for each potential vegetation type
FW-DC-FOR-05, FW-DC-FOR-08, FW-DC-FOR-11, FW-DC-FOR-12	Desired condition for size class distribution for each potential vegetation type

Plan Component	Subject
MA1 and MA2-DC-FOR-05, MA1 and MA2-DC-FOR-06, MA3-DC-FOR-02, MA1 and MA2-DC-FOR-07, MA3-DC-FOR-04, MA1 and MA2-DC-FOR-08, MA3-DC-FOR-06, MA3-DC-FOR-09	Desired condition for landscape pattern and patch size for each potential vegetation type
MA3-DC-FOR-11	Description of snag densities and distribution to contribute to diversity of structure and habitat
MA3-DC-FOR-12	Description of the role of timber harvest to affect composition, structure, and pattern of vegetation
FW-OBJ-FOR-01	Objective to restore aspen
FW-OBJ-TE-01	Objective to restore hardwood species in riparian areas
MA3-OBJ-FOR-01, MA3-OBJ-FOR-02, MA3-OBJ-FOR-03, MA3-OBJ-FOR-04	Objective to restore vegetation acreage in Management Area 3 through timber harvest for each potential vegetation type
MA2-OBJ-FOR-01	Objective to restore vegetation acreage in Management Area 2 through timber harvest and prescribed fire for all potential vegetation types
MA2-OBJ-FOR-02, MA2-OBJ-FOR-03, MA2-OBJ-FOR-04, MA2-OBJ-FOR-05	Objective to increase seral species through artificial regeneration following wildfire for each potential vegetation type
MA3-GDL-FOR-06	Guidance for live tree retention
MA3-GDL-FOR-07, MA2 and MA3-GDL-FOR-05	Guidance for snag retention
MA2 and MA3-GDL-FOR-01	Guidance for Coarse Woody Material retention by potential vegetation type group

Additional, Species-specific Plan Components, 36 CFR 219.9(b)

The Land Management Plan also includes species specific plan components for species not federally listed or identified as species of conservation concern, as shown in Table 308, to further provide for ecological conditions that promote the diversity of plant and animal communities.

Table 308. Summary of general species-specific plan components

Plan Component	Subject
FW-GDL-TE-01	Limits the removal or alteration of habitat of at-risk plants, terrestrial invertebrate animals, and Coeur d'Alene salamanders assigned a particular NatureServe ranking
FW-DC-CAVE-04	Provision for maintenance of bat habitat and limitation of bat diseases
FW-STD-CAVE-02	Requires decontamination procedures to prevent the introduction or spread of disease to bats
FW-GDL-CAVE-02	Provision for bat population enhancement and protection measures
FW-DC-FOR-01	Desire for persistence of aspen
FW-GL-WTR-03	Goal of improving habitat for beaver where appropriate
FW-DC-WTR-09	Desire for beaver presence in suitable areas to improve aquatic conditions
FW-GDL-WTR-07	Requirement to relocate western pearlshell mussel prior to channel dewatering
FW-GDL-WL-02	Requires avoidance of impacts to bats when closing mines
FW-DC-WLMU-03	Desire for the persistence of pacific yew, which provides moose winter habitat
MA1-DC-WLMU-01, MA2-DC-WLMU-01, MA3-DC-WLMU-01	Desire for habitat conditions to maintain or improve elk habitat use and provide high-quality nutritional resources sufficient to support productive elk populations

Plan Component	Subject
FW-DC-WLMU-07	Elk habitat is provided though the planning area to contribute to elk populations
MA2-DC-WLMU-02	Desire for areas at least 5000 acres in size to exist without motorized access
MA1-OBJ-WLMU-01, MA2-OBJ-WLMU-01, MA3-OBJ-WLMU-01	Objectives to improve elk habitat and produce high-quality nutritional resource areas
MA3-GDL-WLMU-01	Guidance to improve elk habitat to improve predicted cow elk body fat condition
MA2-GDL-WLMU-01, MA2-GDL-WLMU-02	Guides the increase of available summer forage for elk
FW-OBJ-TT-01	Restore forested stands to promote huckleberry abundance
FW-OBJ-TT-02	Increase camas production

Conclusions

The Land Management Plan provides for ecological integrity in an integrated manner. The Land Management Plan, under all Action Alternatives, includes plan components that:

- provide for ecological sustainability (36 CFR 219.8) and the diversity of plant and animal communities and persistence of native species (36 CFR 219.9);
- specify direction to restore, establish, and maintain functioning ecosystems that would have greater adaptive capacity to withstand stressors and recover from disturbances, especially changing and uncertain environmental conditions and extreme weather events; and
- give direction to retain or restore ecological conditions to sustain ecosystems that maintain the diversity of plant, fish, and animal communities and the persistence of native species in the plan area.

The Land Management Plan also includes plan components that address the effects of a changing climate and provide climate change adaptation strategies. See Appendix G for examples of climate change adaptation strategies and the plan components that support the strategies.

3.3 Tribal Trust and Responsibilities

Trust responsibilities arise from the United States' unique legal relationship with Indian tribes. It derives from the Federal Government's consistent promise in the treaties that it signed to protect the safety and well-being of the Indian tribes and tribal members. Federal Indian Trust responsibility is now defined as a legally enforceable fiduciary obligation, on the part of the United States, to protect tribal lands, assets, resources, and reserved rights, as well as a duty to carry out the mandates of federal law with respect to American Indians and Alaska Native tribes. This responsibility requires that the Federal Government consider the best interests of the Indian tribes in its dealings with them and when taking actions that may affect them. The trust responsibility includes protection of the sovereignty of each tribal government. The United States recognized tribes by treaty, executive order, or statute; each method reserved rights in different ways. The Nez Perce-Clearwater National Forest is responsible for the government’s trust responsibility by ensuring actions do not diminish rights of Indian tribes and tribal members and by treating National Forest System resources as trust resources where fiduciary rights exist.

The intent of this report is to analyze the extent to which each alternative protects tribal resources and reserved rights on the Nez Perce-Clearwater.

The Nez Perce-Clearwater is considered part of the aboriginal homeland of the Nez Perce Tribe, herein referred to as Tribe, and the Nez Perce-Clearwater's boundaries lie within the territories ceded to the United States by the Nez Perce Tribe in the Treaty of 1855. At that time, Nez Perce leaders reserved hunting, fishing, gathering, and pasturing rights on "open and unclaimed land," which the courts later determined included lands now managed by the Nez Perce-Clearwater. Although subsequent treaties in 1863 and 1868 diminished the size of the original reservation from 7.5 million acres to its current 750,000 acres, all off-reservation rights were preserved. The Nez Perce Tribe is extremely interested in nearly all activities proposed on the Nez Perce-Clearwater and is actively engaged in implementing many projects on the Nez Perce-Clearwater.

Following the Nez Perce War of 1877, many Nez Perce were exiled in Oklahoma. Most survivors later returned to the Nez Perce Tribe in Idaho, the Confederated Tribes of the Umatilla Indian Reservation in Oregon, and the Colville Confederated Tribes in Washington. Therefore, those tribes occasionally indicate an interest in the Nez Perce-Clearwater projects, especially projects in the vicinity of the Nez Perce (Nee-Me-Poo) National Historic Trail, which was designated by Congress to commemorate the flight of about 750 Nez Perce men, women, and children during that war.

Currently, there are about 3,500 enrolled Nez Perce citizens and roughly 60 percent of those live on the Nez Perce Reservation, adjacent to the Nez Perce-Clearwater's boundary. The Dawes Act opened about 500,000 acres of the Nez Perce Reservation to non-Indian settlement, leaving only 250,000 acres for the Nez Perce people. This increases the importance of the Nez Perce-Clearwater for subsistence. Modern Nez Perce people hunt, fish, and gather traditional foods and medicines on the Nez Perce-Clearwater. Many Nez Perce people continue to access traditional sites for religious and spiritual purposes.

The Nez Perce-Clearwater and Nez Perce Tribe actively cooperate in areas of treaty interest, rights, traditional and cultural resources, and ecosystem integrity by maintaining opportunities for traditional land and resource use. The presence of healthy habitats is fundamental to the achievement of both usable and harvestable levels of resources significant to American Indians, as well as to ecosystem integrity.

Since the 1990s, the Nez Perce Tribe has continued to increase internal capacity to engage with the Forest Service in a variety of ways. The Nez Perce Tribe began leveraging Bonneville Power Association funds to invest in habitat improvements to mitigate the effects of hydropower dams in the Snake River Basin. In 1998, the Tribe and the Clearwater National Forest jointly completed aquatic habitat improvement work in the Lochsa drainage. The project's success quickly led to a dynamic aquatic restoration partnership that exists to this day and extends across the entire Nez Perce-Clearwater, south into the Payette and Boise National Forests, and west into the Wallowa-Whitman and Umatilla National Forests. In addition to the aquatic restoration partnership, the Nez Perce Tribe and the Nez Perce-Clearwater also have robust relationships around invasive weeds, fire management, youth engagement, and a growing relationship in climate change adaptation.

With the Nez Perce Tribe's cultural connection to salmon and their contributions to habitat improvement, the Tribe tends to be very cautious of soil disturbance from vegetation-related activities and their comments typically favor minimal harvest and road construction.

Nez Perce-Clearwater leadership seeks to learn from both tribal leaders and tribal citizens to improve understanding of how Nez Perce-Clearwater actions can impact treaty-protected resources, access to exercise treaty rights, and the tribal economy. The federal government has trust responsibilities to tribes under a government-to-government relationship to ensure that the Tribe's reserved rights are protected. Consultation with tribes in the early phases of project planning helps the Nez Perce-Clearwater meet trust responsibilities. The Nez Perce-Clearwater strives to protect treaty rights and adhere to trust responsibilities in a variety of ways, including the following:

- Employ a full-time tribal liaison to be a single point of contact and track issues and identify emerging opportunities.
- Meet at least quarterly with Nez Perce Tribe professional staff to provide early and frequent opportunities to communicate about proposed projects and to inform both Nez Perce-Clearwater and tribal decision makers.
- Consult with the Nez Perce Tribal Executive Committee, as needed, when staff identify possible project impacts or when Nez Perce-Clearwater or Nez Perce Tribe leadership deems it necessary.
- Provide annual opportunities for Nez Perce Tribal Executive Committee field visits to build and maintain interpersonal relationships with the Nez Perce-Clearwater leadership team and to gain shared understanding around land management issues and opportunities.
- Participate in the Nez Perce Tribe's bi-annual General Council meetings with tribal members to interact with and learn from Nez Perce citizens.
- Train Nez Perce-Clearwater employees on treaty rights, trust responsibilities, and Nez Perce culture to raise awareness and sensitivity.
- Reach out to neighboring tribes on projects in areas of known interest.

Tribal consultation on the current revision of the Land Management Plan began in 2012 when the Nez Perce-Clearwater was initially identified as an "early adopter." The Nez Perce-Clearwater and Nez Perce Tribe cooperated to provide a liaison to the revision efforts to help coordinate internal staff meetings and external tribal public meetings. A Nez Perce Tribal Executive Committee representative and the Land Management Plan liaison participated in several public collaboration events. Dozens of staff meetings and conversations with Nez Perce Tribe specialists helped to inform the team of the Nez Perce Tribe's unique perspectives. The Land Management Plan team accepted invitations from the Nez Perce Tribe to speak with tribal citizens at community meetings on the Nez Perce Reservation and at the General Council.

The Nez Perce Tribe accepted an invitation to be a cooperating agency in July of 2014.

The team invited the Coeur d'Alene Tribe, Confederated Salish-Kootenai Tribes, and the Confederated Tribes of the Colville Reservation to consult. Traditionally the Coeur d'Alene and Confederated Salish-Kootenai tribes have deferred to the Nez Perce Tribe on management recommendations for the Nez Perce-Clearwater.

The Coeur d'Alene Tribe was established by Executive Order in 1873. A small portion of the Palouse Ranger District abuts the Coeur d'Alene Reservation. To date, the Coeur d'Alene Tribe has been most interested in Palouse District projects nearest their reservation.

The Idaho-Montana border is a natural geographic division between the Nez Perce and Confederated Salish-Kootenai Tribes. The Confederated Salish-Kootenai tend to be most interested in activities proposed adjacent to the Montana border and along the Lolo Trail, which was a traditional travel corridor for them.

3.3.1 Relevant Laws, Regulations, and Policy

Federal Laws

Treaty with the Nez Perce of 1855, Article 3: Secured for the Nez Perce, “"...the right, in common with citizens of the United States, to travel upon all public highways...the exclusive right of taking fish in all the streams where running through or bordering said reservation...also the right of taking fish at all usual and accustomed places in common with citizens of the Territory; and of erecting temporary buildings for curing, together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land.” National Forest System lands have been determined to be “opened and unclaimed” and are subject to these treaty-reserved rights.

Treaty with the Nez Perce of 1863, Article 8: “The United States also agrees to reserve all springs or fountains not adjacent to, or directly connected with, the streams or rivers within the lands hereby relinquished...and further, to preserve a perpetual right of way to and from the same, as watering places, for the use in common of both whites and Indians.”

The Hellgate Treaty of 1855: The Flathead, Kootenai, and Upper Pend d'Oreilles Indian Tribes reserved rights under the Hellgate Treaty of 1855 (July 16, 1855). These rights include the "right of taking fish at all usual and accustomed places, in common with citizens of the Territory, and of erecting temporary buildings for curing; together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land.”

National Historic Preservation Act of 1966 (P.L. 89-665, as amended, P.L. 91- 423, P.L. 94-422, P.L.94-458 and P.L. 96-515) – Regulations 36 CFR Part 800 and 36 CFR 36 CFR Part 7: This act pertains only to tangible properties, such as buildings, structures, sites, or objects, which are important in history and prehistory. It requires agencies to consider the effects of undertakings on properties eligible to or listed in the National Register of Historic Places by following the regulatory process specified in 36 CFR 800. The portions of that act that relate specifically to coordination with Indian Tribes were added in the 1992 amendments. These additions reflect the increased importance placed on tribal relations. A section of the act directs state and federal governments to assist in the establishment of preservation programs on Indian lands.

The portions of Section 2 pertaining to tribal relations state the following:

It shall be the policy of the federal government, in cooperation with other nations and in partnership with the state, local governments, Indian Tribes, and private organizations and individuals to:
(2) Provide leadership in the preservation of the prehistoric and historic resources of the United States and of the international community of nations and in the administration of the national preservation program.
(6) Assist state and local governments, Indian Tribes and Native Hawaiian organizations and the National Trust for Historic Preservation in the United States to expand and accelerate their historic preservation programs and activities.

National Environmental Policy Act of 1969 (P.L .91-190) and Regulations 40 CFR 1500-1508: With this act, federal agencies began to invite Indian Tribes to participate in forest management projects and activities that may affect them.

National Forest Management Act of 1976 (P.L. 4-588): This act directs consultation and coordination of National Forest System planning with Indian Tribes.

American Indian Religious Freedom Act of 1978 (P.L.95-341 as amended, P.L. 103-344): This act states that "...it shall be the policy of the United States to protect and preserve for American Indians their inherent right for freedom to believe, express, and exercise the traditional religions of the American Indian, Eskimo, Aleut, and Native Hawaiians, including but not limited to access to site, use and possession of sacred objects, and the freedom to worship through ceremonies and traditional rites."

Agencies must make a good faith effort to understand how Indian religious practices may come into conflict with other forest uses and consider any adverse impacts on these practices in their decision-making practices. The consideration of intangible, religious, ceremonial, or traditional cultural values and concerns which cannot be tied to specific cultural sites and properties could be considered under this act.

Archaeological Resources Protection Act of 1979 (P.L. 96-95) and Regulations 43 CFR Part 7: This act establishes a permit process for the management of cultural sites on federal lands, which provides for consultation with affected tribal governments.

Native American Graves Protection and Repatriation Act of 1990 (P.L. 101- 601, 25 U.S.C. 3001-3013) and Regulations 43 CFR Part 10: This act addresses the rights of lineal descendants and members of Indian Tribes, Alaska Native, and native Hawaiian organizations to certain human remains and precisely defined cultural items. It covers items currently in federal repositories, as well as future discoveries. The law requires federal agencies and museums to provide an inventory and summary of human remains and associated funerary objects. The law also provides for criminal penalties in the illegal trafficking in Native American human remains and cultural items.

Healthy Forest Restoration Act of 2003 (P.L. 108-148): This act directs the Forest Service to include tribes in collaboration efforts for planning and multi-party monitoring of hazardous fuels reduction projects.

Tribal Forest Protection Act of 2004 (P.L. 108-278): This act directs the Forest Service to accept and analyze proposals for restoration activities on National Forest System lands that pose a fire, disease, or other threat to Indian forest land. The act also authorizes the Forest Service to enter into agreements or contracts with tribes to implement those projects.

Food, Conservation, and Energy Act of 2008 (P.L. 110-234, "The Farm Bill"): This act authorizes reburial of human remains on National Forest System lands, prevents unauthorized disclosure of cultural information, ensures access for traditional cultural purposes, and authorizes forest products for traditional cultural purposes.

Federal Lands Recreation Enhancement Act of 2004 (16 U.S. Code Chapter 87): §6802.d.1.(I) and (J) of U.S. Code Chapter 87 prohibits the Forest Service from collecting fees from:

- Any person who has a right of access for hunting or fishing privileges under a specific provision of law or treaty.
- Any person who is engaged in the conduct of official federal, state, tribal, or local government business.

Executive Orders

Executive Order 12866 of 1993 – Regulatory Planning and Review: This order enhances planning and coordination with respect to both new and existing regulations and makes the process more accessible and open to the public. Agencies shall seek views of tribal officials before imposing regulatory requirements that might affect them.

Executive Order 12898 of 1994 – Environmental Justice in Minority Populations and Low-Income Populations: This order directs federal agencies to focus on the human health and environmental conditions in minority and low-income communities, especially in instances where decisions may adversely impact these populations.

Executive Order 13007 of 1996 – Indian Sacred Sites: This order acknowledges the role of federal agencies to protect and preserve the religious practices and places of federally-recognized tribes and enrolled tribal members. It also requires agencies to consult with federally recognized tribes to address tribal concerns for sacred sites on public land and to ensure access to religious places and avoidance of adverse effects to sacred sites in accordance with existing legislation.

Executive Order 13084 of 1998 – Consultation and Coordination with Indian Tribes Governments: This order calls upon agencies to use flexible policy approaches at the Indian tribal level in cases when a proposed waiver is consistent with applicable federal policy objectives. The order calls upon agencies to grant waivers in areas where the agency has discretion to do so. This should be done when a tribal government makes a request and, for those instances where the agency may decline such a request, a reason must be supplied to the tribe.

Executive Order 13175 of 2000 – Consultation and Coordination with Indian Tribal Governments: This order provides direction for consultation with tribal governments for formulating or implementing policies that have tribal implications. The order also provides direction regarding consultation and coordination with Indian Tribes relative to fee waivers and calls upon agencies to use a flexible policy with tribes in cases where proposed waivers are consistent with applicable federal policy objectives. It directs agencies to grant waivers in areas where the agency has the discretion to do so when a tribal government makes a request. When a request is denied, the agency must respond to the tribe in writing with the rationale for denial.

Executive Order 14008 of 2021, Tackling the Climate Crisis at Home and Abroad: This order provides direction for a government-wide approach to combat the climate crisis. The order requires a coordinated approach from planning to implementation coupled with substantive engagement by stakeholders, including state, local, and tribal governments. This order also created the Justice40 Initiative that sets the goal that 40% of covered investments will benefit disadvantaged communities and required the development of an online assessment tool to identify disadvantaged communities. Finally, the order also established the Environmental Justice Scorecard.

Executive Order 13985 - Advancing Racial Equity and Support for Underserved Communities Through the Federal Government: This order recognizes the unbearable human costs of systemic racism that arise from entrenched disparities in our laws and public policies, and in our public and private institutions that have often denied equal opportunity to individuals and communities. Consequently, this order 1) provides a definition of equity and underserved communities; 2) direct the Domestic Policy Council to coordinate efforts to embed equity principles, policies, and approaches across the Federal Government; 3) direct OMB to study methods and identify best practices for equity assessments then conduct equity assessment of agency policies, programs, and actions; 4) **establish an Equitable Data Working Group; and 5) require equity action plans for each agency.**

Executive Order 14072 of 2022 – Strengthening the Nation's Forests, Communities, and Local Economies: This order established a policy to, among other things, pursue science-based, sustainable forest and land management; conserve America's mature and old-growth forests on Federal lands; invest in forest health and restoration; support indigenous traditional ecological knowledge and cultural and subsistence practices in our Nation's forests; and honor Tribal treaty rights. A November 2022 letter (Guidance for Federal Departments and Agencies on Indigenous Knowledge) issued guidance and promising practices that Agencies should consider when working with Tribal Nations and Indigenous Peoples to include Indigenous Knowledge in Federal policy, research, or other decision making. It reaffirms that Agencies should recognize and, as appropriate, apply Indigenous Knowledge in decision making, research, and policies across the Federal Government.

Executive Order 14096 of 2023 - Revitalize Our Nation's Commitment to Environmental Justice for All: This order revitalizes and builds on the federal government's commitment to environmental justice. It adds achieving environmental justice to the mission of each agency and recognizes communities with environmental justice concerns experience disproportionate and adverse human health or environmental burdens. This order also updates the definition of environmental justice; 2) create environmental justice strategic plans and subsequent environmental justice assessments; 3) establish an Environmental Justice Subcommittee of the National Science and Technology Council, the White House Environmental Justice Interagency Council, and the White House Office of Environmental Justice is hereby established within the Council of Environmental Quality.

Agency Regulations

36 CFR 261 – Prohibitions in Areas Designated by Order (2011): This regulation enforces the closure of National Forest System lands to protect privacy of tribal activities and "provides regulations regarding special closures to provide for closure of National Forest System lands to protect the privacy of tribal activities for traditional and cultural purposes…to ensure access to National Forest System land, to the maximum extent practicable, by Indian and Indian Tribes for traditional and cultural purposes."

36 CFR 223.239 and 36 CFR 223.240 – Sale and Disposal of National Forest System Timber, Special Forest Products, and Forest Botanical Products: Section 223.239 provides regulations for free-use without a permit for members of tribes with treaty or other reserved rights related to special forest products. It also provides regulations for free-use without a permit upon the request of the governing body of a Tribe. Section 223.240 provides regulations regarding harvest of special forest products by tribes with treaty or other reserved rights.

Policy

Forest Service Manual 1500: External Relations – Chapter 1560: State, Tribal, County, and Local Agencies; Public and Private Organizations – Interim Directive No. 1560-2010-1: This policy provides an interim directive for implementing Sections 8103 and 8106 of the "2008 Farm Bill" regarding reburial sites on National Forest System land, reburial, and prohibition on disclosure.

Forest Service Handbook 2409.18: Timber Sale Preparation Handbook – Chapter 80: Uses of Timber Other than Commercial Timber Sales, Special Forest Products–Forest Botanical Products – Section 82.5: Forest Products for Traditional and Cultural Purposes – Amendment No. 2409.18-2017-1: This policy provides directive for granting trees, portions of trees, or forest products to federally recognized Indian Tribes free-of-charge for non-commercial traditional and cultural purposes, per Section 8105 of the "2008 Farm Bill."

#30-MOU-98-001 – "Campground MOU": Local policy between the Nez Perce Tribe and six National Forests within their ceded territories exempting enrolled Nez Perce tribal members from campground fees and camping stay limits.

Nez Perce Tribe Firewood Policy Letter (May 28, 2006): Letter from six Forest Supervisors in the Nez Perce Tribe's ceded territories exempting enrolled tribal members from fees to collect firewood. Letter describes ways to obtain firewood while complying with public health and safety restrictions and good stewardship practices.

Joint Secretarial Order 3403 on Fulfilling the Trust Responsibility to Indian Tribes in the Stewardship of Federal Lands and Waters of 2021: This order establishes how the Departments of Agriculture and Interior will fulfill their obligations to Federally recognized Indian Tribes by directing Agencies to, among other things, 1) ensure that all decisions relating to Federal stewardship of Federal lands, waters, and wildlife under their jurisdiction include consideration of how to safeguard the interests of any Indian Tribes such decisions may affect, 2) make agreements with Indian Tribes to collaborate in the co-stewardship of Federal lands and waters, and 3), identify and support Tribal opportunities to consolidate Tribal homelands and empower Tribal stewardship of those resources.

Memorandum of Understanding Regarding Interagency Coordination and Collaboration for the Protection of Tribal Treaty Rights of 2021: This memo affirms the protection of tribal treaty rights, reserved rights and similar tribal rights to natural and cultural resources when federal action is taken. More specifically, it emphasizes that Treaty-protected rights to use of and access to natural and cultural resources are an intrinsic part of tribal life and are of deep cultural, economic, and subsistence importance to tribes. It underscores that treaties protect not only the right to access natural resources, such as fisheries, but also protect the resource itself from significant degradation.

Presidential Memo on Indigenous Traditional Ecological Knowledge and Federal Decision Making of 2021: This memo recognizes Indigenous Traditional Ecological Knowledge (ITEK)—a form of Indigenous Knowledge—as one of the many important bodies of knowledge that contributes to the scientific, technical, social, and economic advancements of the United States and to our collective understanding of the natural world. Furthermore, it emphasizes the rights of Indigenous knowledge holders to control access to their knowledge, to grant or withhold permission, and to dictate the terms of its application. It created the Interagency Working Group on Indigenous Traditional Ecological Knowledge to enhance interagency collaboration and coordination and create guidance for including ITEK into Federal scientific and policy decisions.

Presidential Memo on Guidance for Federal Departments and Agencies on Indigenous Knowledge of 2022: This document directs Agencies to include Indigenous Knowledge as an aspect of best available science. More specifically, to assist Agencies in (1) understanding Indigenous Knowledge, (2) growing and maintaining the mutually beneficial relationships with Tribal Nations and Indigenous Peoples needed to appropriately include Indigenous Knowledge, and (3) considering, including, and applying Indigenous Knowledge in Federal research, policies, and decision making. It also identifies promising practices—based on agency experience and Tribal and Indigenous input—for collaborating with Tribal Nations and Indigenous Peoples, considering and applying Indigenous Knowledge in implementing statutory and regulatory requirements, and respecting the decisions of

Tribal Nations and Indigenous Peoples to engage or decline to participate in Federal processes, on their terms.

Strengthening Tribal Consultations and Nation-to-Nation Relationships: A USDA Forest Service Action Plan (February 2023): This Action Plan provides agency guidance and assistance to fulfill the Federal trust responsibility, honor treaty obligations, and support Tribal self-determination. It is divided into four focus areas and is designed to address barriers identified during consultation with Tribes and Alaska Native Corporations and by staff in the Tribal Relations Program. The Action Plan includes tables of action items and responsible staff and program areas across the Forest Service with an intended completion date. The action items are centered on the agency, but may require upward coordination with U.S. Department of Agriculture (USDA). The Action Plan provides a framework for advancing existing laws, regulations, and policies in the Forest Service and is not intended to amend or establish new policy or directive.

USDA Forest Service Equity Action Plan of 2023: Required under Executive Order 13985 - Advancing Racial Equity and Support for Underserved Communities Through the Federal Government, this plan outlines the USDA Forest Service's commitment and supports the U.S. Department of Agriculture's and Administration's leadership in advancing racial equity and support for underserved communities. It describes 10 high-impact Agency-wide actions that will benefit Tribes, partners, the public, and employees.

Memorandum on Restoring Healthy and Abundant Salmon, Steelhead, and Other Native Fish Populations in the Columbia River Basin (Sep 7, 2023): This memorandum sets forth the following language as the policy:

Section1. Policy. It is a priority of my Administration to honor Federal trust and treaty responsibilities to Tribal Nations — including to those Tribal Nations harmed by the construction and operation of Federal dams that are part of the Columbia River System (CRS) — and to carry out the requirement of the Pacific Northwest Electric Power Planning and Conservation Act (Public Law 96-501) to operate, manage, and regulate the CRS to adequately protect, mitigate, and enhance fish and wildlife affected by the Federal dams in the Basin in a manner that provides equitable treatment for fish and wildlife with the other purposes for which the Federal dams are managed and operated.

In recognition of these priorities, it is the policy of my Administration to work with the Congress and with Tribal Nations, States, local governments, and stakeholders to pursue effective, creative, and durable solutions, informed by Indigenous Knowledge, to restore healthy and abundant salmon, steelhead, and other native fish populations in the Basin; to secure a clean and resilient energy future for the region; to support local agriculture and its role in food security domestically and globally; and to invest in the communities that depend on the services provided by the Basin's Federal dams to enhance resilience to changes to the operation of the CRS, including those necessary to address changing hydrological conditions due to climate change.

It also includes instructions to federal agencies regarding implementation, and directs federal agencies to use their authorities and available resources to further the policy found in Section 1.

State and Local Plans

Nez Perce Tribe Department of Fisheries Resource Management Plan (2013–2028): The Nez Perce Tribe's fisheries resource management plan includes a set of management goals and management objectives to achieve those goals. Management objectives include those related to achievement of escapement goals for anadromous fish, including habitat management of key populations within the Nez Perce-Clearwater, such as Lolo Creek, the Potlatch River, the Upper South Fork Clearwater River, the Lochsa River, Meadow Creek, Moose Creek, and the Upper Selway River. Habitat management objectives include emphasis on watershed restoration within a "ridge-to-ridge" management philosophy where stream habitat is degraded. The government-to-government relationship with the U.S. Forest Service, including the Nez Perce-Clearwater, is also described. Co-management of federal lands and cooperation on an extensive body of work, including restoration projects, fish and habitat monitoring, operation of acclimation sites, facility use, harvest access, and effects of forest management actions, transpires on the 11 National Forests with which the Nez Perce Tribe shares a working relationship.

Nez Perce Tribe's Draft Integrated Resource Management Plan: The Nez Nez Perce Tribe is currently in the process of developing an integrated resource management plan. This plan seeks to "establish programmatic resource management direction and balance the Tribe's economic development and resource stewardship goals within the boundaries of the Nez Perce Reservation" (Nez Perce Tribe 2023). The plan is in draft form at present, and the tribe is soliciting comments and holding public meetings. However, it is expected that a final version will be produced that articulates the Tribe's values and objectives with regard to natural resources on their lands. Because this plan is an ongoing planning effort subject to future revision, the following is quoted from the current version of the plan:

"This Integrated Resource Management Plan describes the Nez Perce Tribe's vision and strategy for the management of our natural and cultural resources. It has been developed to express the cultural values of the Nimiipuu; sustain and promote the welfare and opportunities of current and future generations; protect, perpetuate, and enhance the ecological diversity and long-term sustainability of our homeland; and enhance our sovereignty. It specifically describes our overall natural and cultural resource management vision, our desired future condition of our Reservation and its resources, and our strategy to make that vision a reality for our descendants. It is the first such plan developed by and for the Nimiipuu" (Nez Perce Tribe 2023).

The Nez Perce Tribe Integrated Resource Management Plan is similar to the revised forest plan in that it identifies long term desired conditions, however its scope is broader in that it describes desired conditions for not only environmental resources, but also social and cultural conditions as well.

Nez Perce Tribe Forestry and Fire Management Plan: The Nez Perce Tribe manages some 770,000 acres of tribal trust lands in North and Central Idaho; a portion of which is adjacent to the Nez Perce-Clearwater. The Nez Perce Forest Management Plan provides for economically, socially, and environmentally sustainable forest management of tribal lands.

3.3.2 Methodology

Spatial Scale

Nearly all the plan area is within the ceded territory of the Nez Perce Tribe and the entire Nez Perce-Clearwater is subject to the Treaty of 1855. There are about 3,500 enrolled citizens and roughly 60 percent of those live on the Nez Perce Reservation. The Dawes Act opened about 500,000 acres of the Nez Perce Reservation to non-Indian settlement, leaving only 250,000 acres for the Nez Perce people. This increases the importance of the Nez Perce-Clearwater for subsistence. Modern Nez Perce people hunt, fish, and gather traditional foods and medicines on the Nez Perce-Clearwater. Many Nez Perce people continue to access traditional sites for religious and spiritual purposes.

The spatial scale for analyzing both indirect and cumulative effects is the administrative boundary of the Nez Perce-Clearwater.

Temporal Scale

It is important to understand the past context of the Nez Perce separation from their traditional homelands in considering effects. 1855, when the *Treaty with the Nez Perce's* was signed outlining the rights of the Nez Perce Tribe, was chosen as a starting point. Many subsequent activities have happened since that time. The Forest Service mission charges management to "meet the needs of current and future generations." Nez Perce and neighboring tribes typically look seven generations, or roughly 140 years, to the future when making decisions. However, to account for emerging technologies and changes in social norms, the standard planning time frame of 15 years is what will be considered here.

Past, Present, and Future Activities used in the Analysis

The following past actions seem to have influenced the existing condition of tribal resources on the Nez Perce-Clearwater:

Roads: Primitive harvest systems of the past required an extensive road system. Benefits of these road systems to tribal members include motorized access to areas once only accessible by foot or horse. As lifeways changed for many Nez Perce families who were expected to adopt the European lifestyle of living in one place and finding work for pay, they no longer had time to travel by foot or horse to the forests. Roaded access allowed for evening and weekend trips to hunt, gather, or travel to religious sites.

On the flip side, roads also created access for all citizens, resulting in increased competition for resources. Another unintended impact of primitive roads was not fully understood until much later. Roads have the potential to degrade fish and aquatic organism habitat where culverts block passage, surfaces erode, or failures trigger mass wasting. Roads can interfere with habitat security for some wildlife species. Today the Nez Perce Tribe voices concerns about impacts of roads to habitat quality and some tribal leaders and citizens are concerned about competition for resources, especially big game, huckleberries, and firewood.

In the 2000s, the Nez Perce and Clearwater Forests and the Nez Perce Tribe jointly increased efforts to reduce road-related impacts on aquatic and terrestrial habitats. Road densities and some motorized accesses were reduced. Some tribal members have voiced concern over loss of motorized access to hunt, gather, and cut firewood.

Fire Suppression and Timber Harvest: Prior to the westward expansion and European settlement, fire was the primary disturbance mechanism in the forests. Lightning was not the only source of fire. According to Nez Perce Tribe Cultural Resource Director Nakia Williamson, the Nez Perce have managed the landscape with fire for countless generations. Fire rejuvenated botanical foods and medicines and provided forage for livestock and big game. Fire kept conifers and brush from encroaching on meadows and camp areas.

Williamson further described the symbiotic relationship between the Nez Perce people and the botanical resources. In addition to the Nez Perce use of fire, disturbances like digging roots and pruning limbs from shrubs aerated soils and invigorated new growth. Williamson noted that the declining interaction between the Nez Perce people, and the botanical resources led to declining numbers and quality of those resources.

Following the 1910 fires, land managers took a very aggressive fire suppression approach. Timber harvest became the predominant disturbance mechanism. The Forest Service met the post-World War II wood product needs of the growing country with an active timber program. Later, broad social support, especially at the national level, for aggressive timber harvest from National Forests faltered. By the late 1980s, timber harvest on the Nez Perce and Clearwater Forests was greatly reduced while aggressive fire suppression continued. With reduced fire and harvest on the landscape, the general trend has been denser forests dominated by species less resilient to insects, disease, and fire (See the Forestlands section for additional information). Many plant and animal species important to tribes rely on some level of disturbance. The Nez Perce Tribe has voiced concern about appropriately balancing vegetation and fuels treatment needs with the potential impacts those treatments might have on aquatic habitat and big game security.

Recreation: The Nez Perce people, and neighboring tribes, have moved across these forests for thousands of years, camping in flat areas near water and accessing the highest points for exceptional views and spiritual purposes. Today, those same flat areas near water and high mountain vistas are popular with Nez Perce-Clearwater visitors. Areas near water became recreation campsites and high points were used for lookout towers. Travel routes carved out by Native American use over thousands of years later became Forest Service trails or roads. Improved access to special places; improved motorized technology, such as motorcycles, all-terrain vehicles, and snowmobiles; and increased visitor numbers amplify challenges associated with protecting special places, culturally important flora and fauna, and cultural sites.

Most Nez Perce people do not view hunting, fishing, camping, berry picking, or cutting firewood as “recreation.” These activities are integral to the Nez Perce culture, religion, health, and economy. Furthermore, they are legally protected rights. Care is taken to protect archaeological resources associated with camp sites, trails, and other recreation facilities when managing for recreational use. It is important to consider that actions designed to benefit recreational users can also have negative impacts on the ability of tribal members to exercise treaty-protected rights.

Aquatic Restoration: Salmon are a cornerstone of the Nez Perce culture. Declining salmon runs from a combination of the Columbia River hydroelectric system, ocean conditions, commercial harvest, and fragmented habitat greatly impacted the Nez Perce and other salmon-dependent tribes. Improving anadromous fish habitat to aid in the recovery of threatened and endangered and listed species has been a priority for the Nez Perce Tribe since the mid-1990s. The Tribe has committed considerable time and energy to leveraging hydropower mitigation funds to invest in habitat improvements on the Nez Perce-Clearwater. Reducing road densities, eliminating aquatic barriers, and reducing road-related sediment to streams have been primary focus areas for two decades. More recently there has been an emphasis on in-stream channel and meadow habitat restoration. Occasionally, these projects run counter to tribal members’ desire for access.

Mining: Discovery of gold on the original 1855 Nez Perce Reservation triggered two treaties that effectively reduced the original reservation from 7.5 million to 750,000 acres, creating an understandable disdain for mining that continues to this day. Currently, there are dozens of active claims and recreational mining activities across the Nez Perce-Clearwater. Level of activity rises and falls with the market price of gold and other locatable minerals. The Tribe is very concerned about the impacts of mining on cultural sites and aquatic habitat and water quality.

Grazing: One of the many rights reserved by the Nez Perce in the 1855 Treaty was “the privilege of…pasturing their horses and cattle upon open and unclaimed land.” Currently, no enrolled Nez Perce people are exercising the right to graze on lands managed by the Nez Perce-Clearwater. One person is pasturing cattle in an area managed by the Wallowa-Whitman within the administrative boundaries of the Nez Perce-Clearwater. Some tribal members have indicated possible interest in exercising this right on the Nez Perce-Clearwater. As a legal right, tribal grazing would not require a permit and would likely be regulated and enforced by the Tribe. The Tribe acknowledges the potential for grazing impacts on other resources and Nez Perce Tribal Executive Committee has requested the Nez Perce-Clearwater work with the Tribe to identify suitable grazing allotments and monitoring plans for tribal grazing.

Methods and Assumptions

Desired future conditions were carefully drafted to protect tribal rights and resources. It is assumed all alternatives for achieving those desired future conditions protect tribal rights and resources.

Measurement Indicators

Three indicators were used to assess the extent that each alternative responds to particular tribal rights and interests.

- Access
- Places
- Resource Usability

"Access" was measured using the theme of each alternative combined with road and trail management objectives and standards. "Places" were measured by relatively ranking alternative objectives and standards for access and management of significant locations for the tribe. "Resource usability" was measured by a relative ranking of each alternative based on biophysical trends and tribal interest species habitat trends. Together, these measurement indicators give an overview of the major concerns and relative means of ranking alternatives.

3.3.3 Affected Environment

Tribal Rights and Interests

Each tribe has slightly different rights according to treaties, executive orders, and various laws, regulations, and court orders. The Nez Perce Tribe clearly retained off-reservation treaty rights across the entire Nez Perce-Clearwater. While the Confederated Salish-Kootenai Tribes have similar off-reservation rights, the Nez Perce-Clearwater is entirely within the Nez Perce Tribe's ceded territories. For this reason, the Salish-Kootenai have typically deferred to the Nez Perce Tribe on management recommendations and consultation.

This analysis will mostly focus on the Nez Perce Tribe because the Nez Perce-Clearwater lies within the Nez Perce Tribe's aboriginal homeland, is subject to their treaty, and because of the level of cooperation and involvement between the Nez Perce Tribe and the Nez Perce-Clearwater. Even though other tribes are not mentioned in detail, analysis of effects should be relatively similar for all tribes.

Nearly all of the Nez Perce-Clearwater is within the ceded territory of the Nez Perce Tribe, and the entire Nez Perce-Clearwater is subject to the Treaty of 1855. In this treaty, the Nez Perce Tribe reserved the right of "taking fish at all usual and accustomed places in common with citizens of the Territory; and of erecting temporary buildings for curing, together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land."

Roughly 60 percent of the 3,500 enrolled Nez Perce citizens with treaty-reserved rights live on the reservation, a relatively short distance from the Nez Perce-Clearwater. The Nez Perce-Clearwater provides essential locations for traditional foods, including game, salmon, roots, berries, and mushrooms; wood for firewood and tipi poles; and for traditional botanical medicines. The Nez Perce-Clearwater is also home to countless culturally and spiritually significant areas.

The Nez Perce-Clearwater plays an important role in the Nez Perce Tribe's economy. Nez Perce-Clearwater resources provide a healthy, affordable source of foods and medicines, as well as firewood. These resources are also part of a direct production economy where trading of goods is part of an ongoing barter and gifting system of trade. Additionally, many family-wage jobs on the reservation are directly and indirectly related to resource-related activities.

To date, no tribal members have exercised the right to graze on lands directly managed by the Nez Perce-Clearwater; some are, however, exercising that right on adjacent forests. The Nez Perce Tribe Executive Committee has informed the Nez Perce-Clearwater that they may be reducing grazing on tribal lands and that tribal members would likely seek to exercise grazing rights on the Nez Perce-Clearwater. Thus, it is reasonable to expect an increase in tribal grazing on the Nez Perce-Clearwater.

The Nez Perce do not see themselves as separate from the lands they inhabit. They have always lived here and interacted with the plants and animals in an interdependent relationship. It was this relationship Nez Perce leaders sought to preserve when they signed the 1855 Treaty. For the modern Nez Perce, protecting and exercising those rights remains core to maintaining who they are as a people. In recent years, there has been a broad scale effort by the Nez Perce to rebuild and strengthen that relationship and interdependence with the land. As such, they actively engage the Forest Service at all levels: locally, regionally, and nationally.

When the original Nez Perce and Clearwater Forest Plans were written, tribal treaty rights and the federal trust responsibility were not broadly understood. Several executive orders, statutes, and subsequent directives have helped clarify and define agency roles and tribal trust responsibilities. Subsequently, awareness, understanding, and incorporation of those rights into management has steadily improved.

In 1998, five National Forests in the Nez Perce Tribe's ceded territories acknowledged the need for improved communication between the Forest Service and tribal leadership and created a full-time tribal liaison position. Around that same time, the Clearwater Forest and Nez Perce Tribe began collaborating on three activities: aquatic restoration to improve salmon habitat; an inter-tribal natural resource youth camp; and protection and interpretation of resources within the Lolo Trail National Historic Landmark during the Lewis and Clark bicentennial commemoration. These partnerships led to a robust and dynamic Forest Service-Nez Perce Tribe relationship and have informed and shaped how projects are developed and implemented on the Nez Perce-Clearwater today.

The Nez Perce and Clearwater National Forests administratively combined in 2013; yet, the Nez Perce-Clearwater is still managed under two separate plans. Furthermore, there are prescriptive elements in each that dictate the use of specific models and methods that are no longer relevant. This has been the source of frustration and confusion for Nez Perce-Clearwater and Nez Perce Tribe staff and leadership seeking to understand and comply with the Land Management Plans. Additionally, the Tribe's ceded territories and off-reservation rights span at least 13 National Forests in 3 different Forest Service Regions, resulting in considerable variation and complexity for the Tribe to navigate.

With all of the above in mind, to protect tribal rights and interests in the Land Management Plan, the Nez Perce Tribe generally advocates for enforceable standards and plan components, protection of population strongholds of fish and wildlife and riparian management zones, improvement of watershed conditions, and improved methods of identifying traditional cultural properties and sacred sites.

Access

There is a challenging balance between protecting treaty-reserved resources and providing sufficient access to allow Nez Perce tribal members to exercise treaty rights. Tribal resource specialists, as well as written comments from the Nez Perce Tribal Executive Committee, tend to advocate for reduced road densities and motorized access. This largely stems from a legacy of primitive logging systems that required substantially more roads than modern systems. Many of those roads were abandoned and left to revegetate naturally but were later determined to be the sources of slope stability and sediment issues. The Nez Perce Tribe has been a proponent for decommissioning roads and has leveraged significant funding and resources to decommission and obliterate hundreds of miles of both system and non-system forest roads to improve both fish and wildlife habitat.

Conversely, several tribal citizens have voiced concerns over reduced access to favorite hunting sites, botanical and firewood gathering spots, and spiritual places. Hunting and gathering food and firewood are not lifestyle choices nor recreation for most Nez Perce. For many, these activities are economically necessary means by which they feed their families and heat their homes. An abundance of resources means little to them without access to those resources.

Prior to the 1990s, motorized access across the Nez Perce-Clearwater was fairly unrestricted. As road-related impacts to aquatic health and wildlife security were identified, limits on motorized access and removal of roads deemed unnecessary for management needs became increasingly common. Since 1998, the Nez Perce-Clearwater has decommissioned over 900 miles of system and non-system roads in partnership with the Nez Perce Tribe. It is important to acknowledge many of these roads were not easily accessible, even by foot. It is equally important to acknowledge that tribal members say some access important to them has been eliminated. The increased popularity of all-terrain vehicle, utility terrain vehicle, and over-snow motorized use by many forest visitors has not extended to the Nez Perce people. While some choose to hunt or gather on foot or by horseback, the preferred method of access is by full-sized motor vehicles. Many note they simply cannot afford the expensive trail machines or describe the trail vehicles as undesirable as they are incapable of transporting entire families, including infants and elders who cannot access areas by other means.

Access to traditional campsites is a concern. Places popular to camp hundreds of years ago are still favored today. Many traditional camp and village sites are now developed or dispersed recreation sites. In 1998, five National Forests in the Nez Perce Tribe’s ceded territory established a policy eliminating fee and stay limits for enrolled Nez Perce. Initially, some user conflict was anticipated but did not seem to materialize. For the most part, the favored time for tribal members to use river campsites is during the early spring and late fall salmon and steelhead seasons. In the heat of the summer, when visitor recreation use is highest on the rivers, many Nez Perce prefer to be in the mountains gathering huckleberries, camas, and other foods and medicines.

Places

It is difficult to convey the depth of importance many places on the Nez Perce-Clearwater hold for the Nez Perce. The Nez Perce trace their origins to a specific site near the Nez Perce-Clearwater boundary, and thousands of years’ worth of deeply rooted interaction with the resources define them as a people. The Nez Perce named each place for its significance. Unlike Europeans who later settled the area, local bands did not name places after people. Instead place names described a significant event, a special resource, or a meaningful activity. As a result, generations of people would know the unique value of each place by its descriptive name.

In the years following relocation to the reservation, speaking their native language, and practicing their native religion was discouraged. A new life emphasizing the English language, school education, agricultural practices, and jobs for pay was expected. Not only were they geographically separated from many important places, but most Nez Perce also no longer had time to travel as the new job-based economy would not allow free time. Places were renamed by incoming settlers and many original names and significances faded from memory. The Nez Perce describe a challenging time in which they were in danger of losing their native language and knowledge of important places altogether.

For the past three decades, the Tribe has prioritized preserving their language. Through robust youth and language programs they are reestablishing connections to well-known significant places and are working with elders to identify lesser-known areas. There have been cooperative efforts between the Nez Perce-Clearwater and tribal elders to identify and re-name offensive place names. As these efforts continue, it can be expected that new places of importance will emerge.

While some tribally significant places have been identified, place identification and, therefore, protection remains a challenge. There is some reluctance on the part of any tribe to share locations for fear of disclosure and potential threat of vandalism and looting. There are other sites that are known only to, and held closely by, certain family circles. Neither tribal leaders nor tribal cultural program managers know these family locations.

Many commonly known sites occur on high ridgetops or on flats near water. Places that were popular thousands of years ago are likely popular today, posing unique management challenges. Important sites near water can be at risk from recreation-related resource damage. Higher elevation sites are more remote, making monitoring and protection against vandalism more difficult.

One particularly challenging site is Pilot Knob. Pilot Knob is geographically situated with a nearly unobstructed 360 view for miles, making it not only a place for spiritual renewal for countless generations of Nez Perce but also a desirable location for non-tribal recreationists and a strategically important location for emergency communication equipment. Many entities, including interagency emergency service providers, rely on communication towers on Pilot Knob for critical communications across a landscape otherwise unreachable by radio or cell service. In order to remove the communication equipment and still provide for public safety, new equipment would need to be installed at multiple sites across the Nez Perce-Clearwater; all with their own unique access, resource, and economic challenges that have, to date, been determined unfeasible.

Resource Usability

In addition to the availability of and access to resources, usability of those resources is also very important. The biophysical environment and habitat for species of interest to tribal trends can have significant effects to tribal resource use. Considering the effects of each alternative on these resources can help determine which alternatives have the least impact. Items of special interest mentioned during Land Management Plan and project consultation include fish, big game, camas, berries, and firewood gathering. Many of the big game, upland and migratory birds, and aquatic species of concern to tribes are the same ones in which the Land Management Plan provides direction for protection. Specific management activities are analyzed during NEPA analysis of the effects; effects are generally mitigated through best management practices in other highly managed areas.

It should be noted that the quantity of a specific resource is different than quality. For instance, a particular root species commonly gathered by Nez Perce is prolific across the Nez Perce-Clearwater. However, there are a few key areas in which the quality and potency of the root is known to exceed all others. Protecting and managing for the "usability" of resources such as these is challenging. Like sacred places, particular botanicals and favorite gathering locations are rarely disclosed for fear of exploitation. If known, managers could propose beneficial treatments and avoid actions that could negatively impact these resources.

Camas has long been known by Nez Perce-Clearwater managers to be important to tribes. While camas plants themselves may be plentiful in some areas, gatherers note a decline in the size and quality of camas bulbs over the past decades. Other than fencing known camas meadows to exclude livestock, a "hands-off" approach has been taken where camas occurs; harvest and fuels treatments have been excluded in these areas. Recent conversations with elders and gatherers indicate that the Nez Perce traditionally actively managed for camas. In addition to aerating the soil during camas harvest with *tú·kes,* or digging sticks, gatherers often set fire to the meadows as they left, both stimulating next year's soil productivity and preventing encroachment from surrounding conifers.

Usability can be applied to the land in general, as well. Not all acres of land are equal. This is important to note when analyzing impacts for proposals like land exchanges. For instance, exchanging 50 acres of easily accessible land with meadow ecosystems that produce important traditional foods for 100 acres of valuable timber might not be favorable or beneficial to a tribe, even if the Forest Service stands to gain 50 acres. First, land under historic Forest Service management is subject to tribal treaty rights; lands acquired might not be. Second, unless the acquired acres have similar usable and equally accessible resources to those being exchanged, there might be no benefit to the tribe.

3.3.4 Environmental Consequences

The land management plan provides a programmatic framework that guides site-specific actions but does not authorize, fund, or carryout any project or activity. Because the land management plan does not authorize or mandate any site-specific projects or activities, including ground-disturbing actions, there can be no direct effects. However, there may be implications, or longer-term environmental consequences, of managing the Nez Perce-Clearwater under this programmatic framework.

The previous sections generally described the American Indian Affected Environment within the Nez Perce-Clearwater. More specifically, the Affected Environment section provides a baseline understanding of the relationship between the lands managed by the Nez Perce-Clearwater and the Nez Perce people who have always occupied these lands. The following section considers the potential impacts of alternative management scenarios on this relationship. This section provides a brief summary of the expected impacts to the key benefits the Nez Perce-Clearwater provides and explores how those impacts may affect tribal trust responsibilities. For more details and the complete analysis of effects to specific Nez Perce-Clearwater resources, please see the relevant resource analysis.

Effects Common to All Alternatives

Under all alternatives, the Nez Perce-Clearwater will continue to provide the full suite of treaty-protected resource benefits as described in the Affected Environment section. Over the life of the plan, no consequential adverse impacts are expected to tribal rights in the primary analysis area or to any of the key treaty-reserved resources that the Nez Perce-Clearwater currently provides. For more details on each benefit, please see the relevant resource analysis.

Effects Common to Action Alternatives

Contributions to treaty-reserved resources are expected to be different under the action alternatives than under the No Action Alternative. This is due in part to tribal-specific plan components and desired future conditions carefully designed to acknowledge and incorporate the unique cultural and ecological perspectives and rights of native peoples and to new management direction across resource areas focused, to varying degrees, on increasing vegetation management through fuels treatments and harvest, increasing opportunities for motorized and mechanized access, and specifically identifying geographic areas of tribal interest for added protection. The relative contributions vary by alternative.

To recap, access, places, and resource usability were used to evaluate alternatives.

Access

The alternatives primarily affect access to important hunting, fishing, gathering, and spiritually significant places by increasing or decreasing the percentage of available full-sized motorized and non-motorized routes, particularly in the summer. As noted earlier, the most common method for tribal members accessing areas for culturally and economically important activities is by full-sized motorized vehicles and typically occurs during snow-free months. Alternatives that provide for more off-highway vehicle use can also help alleviate congestion and user-conflict on full-sized routes.

The No Action Alternative offers 45 percent of the Nez Perce-Clearwater as suitable for summer motorized use. The Preferred Alternative and Alternative X propose the greatest departure from the No Action Alternative, with an increase to 55 and 58 percent, respectively. Alternative W proposes a slight increase to 47 percent. The motorized access proposed in Alternative Z decreases summer use to 43 percent, increases winter use from 39 to 70 percent. Alternative Z is not expected to provide a broad benefit to tribal access unless there is a dramatic change in tribal members' methods of travel.

Tribal communities, like any community, are incredibly diverse. Whether increased access is perceived positively or negatively largely depends upon how individuals or family units relate to the landscape and the resources. Those who actively subsist or seek spiritual opportunities on the Nez Perce-Clearwater may prefer increased access opportunities and argue that it is essential to their ability to exercise their rights. Others who are content in knowing those special place and resources exist without a need to obtain those resources or personally visit those areas may feel differently.

Places

As described earlier, the importance of "place" to the Tribe collectively, to tribal families, or to individuals is difficult to describe and evaluate; this is compounded by a general reluctance to share details of specific places for fear of exploitation. Years' worth of coordination with tribal staffs and conversations with tribal members yielded information that helped to identify and delineate geographic areas of importance, as well as identify desirable habitat conditions that make a "place" desirable.

Pilot Knob Geographic Area

Pilot Knob has long been known as a significant spiritual site for the Nez Perce Tribe. Its location and geographic formation also made it the best-known location for communication equipment, a use that continues today. The Nez Perce-Clearwater and Nez Perce Tribe have grappled with the conflicting needs for decades.

The plan identifies the Pilot Knob Geographic Area for its significance to the Nez Perce Tribe. All action alternatives include the goal of co-managing Pilot Knob with the Nez Perce Tribe to develop, analyze, implement, and monitor activities. Desired conditions describe the area from the Tribe's perspective and look to reduce the communication facility footprint.

The Preferred Alternative includes an objective to initiate a study of suitable replacements for communication sites within five years and a guideline to seek approval from the Nez Perce Tribe Executive Committee prior to authorizing activities within the geographic area. Alternative Y proposes not renewing communication leases and not approving new authorizations.

Alternative Y provides the most immediate protection of the prehistoric and historic integrity of the geographic area and provides for the least disturbance to tribal members seeking spiritual solace. It does not resolve the need for a communication site(s) to adequately provide emergency and non-emergency communications for several entities, including the Nez Perce Tribe. While the Preferred Alternative does not immediately satisfy the desire to rid Pilot Knob of the communication equipment and protect the solitude of tribal members, it does establish a time frame for the Forest Service to initiate a study in which the Tribe and the Nez Perce-Clearwater would cooperatively explore options. The Preferred Alternative also provides for flexibility to propose management activities within the geographic area with the Tribe's support.

Lochsa Corridor

An increase in proposed commercial traffic use along U.S. Highway 12 elevated awareness of the significance of the Lochsa Corridor to the Nez Perce Tribe. The Lochsa Corridor is much closer to communities on the Nez Perce Reservation and is frequently used by tribal and non-tribal locals, as well as forest visitors from afar. The corridor is popular for hunting, fishing, and gathering.

Special Areas

In all action alternatives, the Land Management Plan proposes to designate over 1,000 acres as special areas due to unique botanical, historical, or recreational values. Inclusion of these special areas would enhance and protect the places of importance to the Nez Perce Tribe.

The effects from fuels treatments and timber harvest can be perceived as positive or negative depending upon the relationship to a place. For instance, if a place derives its significance as a family location to gather huckleberries or to hunt big game, timber harvest and fire might be beneficial, as habitats for both big game and huckleberry can be stimulated by these activities. Conversely, if significance is derived because the place is a traditional gathering spot for a shade-tolerant plant that thrives under thick overstory, the effects could be negative. The intent of the tribal trust and resource-specific goals, desired conditions, objectives, standards, and guidelines is to provide appropriate direction for achieving mutually desirable and beneficial outcomes on the ground.

Tribal-specific plan components and desired future conditions can also drive proposed activities on the ground, using timber harvest and wildland fire as tools to enhance important places by promoting their vigor and resilience, or by reducing fuels to protect them.

Recognizing that forests are dynamic ecosystems and that no single place will remain unchanged, it can be helpful to look at the overall desired conditions for forested vegetation and how quickly the desired outcome could be achieved to evaluate effects. Tribal and other resource-specific components describe desired future conditions that provide guidance during project development and are designed to identify and consider tribal uses and minimize impacts to those uses.

Desired forest conditions are predicted to be met in 20 years under Alternative X. Under Alternative W, desired conditions would be achieved in 30 years. A combination of natural processes and timber harvest would take about 50 years to attain under Alternative Y. Alternative Z would rely largely on natural processes to meet desired conditions in 100 or more years.

Resource Usability

Many Nez Perce members describe how some areas produce more “potent” medicines. Some share concerns that, despite availability, the quality of some resources is declining. Both are examples of usability. The mere presence of a resource does not necessarily make it useful as a food or medicine. Conversations during the development of the Land Management Plan raised awareness of optimal habitat conditions and beneficial management activities used for generations to stimulate growth of culturally important species. These conversations, and the information shared on climate change and the potential impacts to terrestrial and aquatic habitats and species of tribal significance, resulted in several plan components to promote collaborating with the Nez Perce Tribe and tribal members to actively manage for increased usability of important species. For example, desired conditions call for sustainable diversity of habitats to provide habitat for tribally important species and objectives were added to promote huckleberry and camas health. Similar to above, the alternatives can be compared by how quickly desired forest conditions are met.

Effects to Resource from Other Resources

Fire Management

Fire and fuels management may lead to the loss of some species of interest while benefitting others. Likewise, access to sacred and archaeological sites of importance to tribes can be affected. The effects of fire on major species are well known; however, there has been little study of more obscure resources. Therefore, the only way to analyze the effects is to look at major habitats. It is also important, when planning for the potential use of natural, unplanned ignitions, to meet land management plan objectives that take into account the timing in relation to tribal resource use and sacred traditions.

Again, depending on the resource or sacred use, it is difficult to analyze the effects numerically, and a relative ranking based on qualitative factors is the only practical analysis to determine the effects from fire and fuels management. With the move toward managing natural, unplanned ignitions to meet land management plan objectives, management areas will be analyzed for specific effects. However, if considered in the larger context of the Land Management Plan, a return to a more natural fire regime could be considered preferable to the tribes, depending on resources, tribal use, and timing.

Timing and location of wildland fire management activities should consider necessary access for tribal resources and sacred site uses through appropriate consultation.

Fisheries

As mentioned in multiple sections of this report, fisheries are of extreme cultural and economic importance to the Nez Perce Tribe. For this reason, the Nez Perce-Clearwater actively involved Nez Perce Tribe specialists in the development of a Nez Perce-Clearwater Aquatic and Riparian Conservation Strategy. Because of the forestwide direction in the Aquatic and Riparian Conservation Strategy, it is expected that the action alternatives would have the same or similar outcomes as the No Action Alternative. See the Aquatic Ecosystems and Fisheries section for more detailed information.

Forest Products (other than timber)

Special forest products are treaty-protected resources and adequate access to such resources is important. Certain mushrooms, berries, and firewood tend to be more prevalent in areas of disturbance. Alternative X provides for the greatest level of vegetation manipulation to potentially benefit tribally significant special forest products and access to them. For resources, such as fir or cedar boughs or shade-tolerant shrubs that may be more sensitive to disturbance, it can be generally assumed the greater the disturbance, the slower the rate of recovery.

Invasive Species

Invasive species are of grave concern to the Nez Perce Tribe. Invasive species impact habitat for tribally significant wildlife and botanicals. The Nez Perce Tribe has been an important partner in controlling invasive species on National Forest System lands, including back-country and wilderness areas, as well as on adjacent ownerships. They operate a Biocontrol Center in which insects that prey on invasive plant species are incubated. They have trained staff certified to use a wide variety of chemical controls.

Lands and Lands Special Uses

The Nez Perce Tribe objects to the loss of aboriginal lands through exchange or sale. Only Congress can abrogate treaty rights. Since lands managed by the Nez Perce-Clearwater are subject to the 1855 Treaty, it seems likely that Congressional involvement could be necessary. Some consideration may be given where access, opportunities, or resources equivalent or greater than those lost are provided.

None of the alternatives propose a change in land ownership.

There is an assumption that increased special use requests will come with population increases and increased uses of lands adjacent to National Forest System lands.

Alternative Y proposes that no new communication site authorizations will be renewed, and no new authorizations will be approved on Pilot Knob throughout the life of the Land Management Plan. These proposed changes address the cultural concerns raised by the Nez Perce Tribe but do not acknowledge a shared interest in ensuring emergency communications across the area. The Preferred Alternative directs a study to be initiated in five years to explore alternative sites, which both addresses the need for change and establishes a timeframe in which to work on the solution.

Livestock Grazing

The Nez Perce people historically grazed horses and cattle within the area now known as the Nez Perce-Clearwater. The right to continuing grazing livestock was reserved in the 1855 Treaty. The Nez Perce-Clearwater acknowledges the Nez Perce primacy to graze. Therefore, none of the alternatives are expected to change or affect this right. No tribal members currently graze on the Nez Perce-Clearwater.

Many Nez Perce Tribe resource specialists, especially in the fields of fisheries, exotic weeds, and wildlife, raise concerns about the impacts of grazing on aquatic and wildlife habitat. Additional information and analysis may be found in the respective sections of this environmental impact statement.

Sustainable Recreation (including developed and dispersed recreation)

It is assumed that recreation will likely increase over time. Recreation and road access are significant issues to tribes. Recreation sites, both developed and dispersed, often overlay archaeological and resource use sites. High-density recreation especially tends to indirectly reduce Tribal use, given the conflicts between traditional uses and modern recreation activities. Tribal members use some Nez Perce-Clearwater recreation facilities and need access to certain areas to exercise their treaty rights.

Existing developed recreation sites are retained in all alternatives. Direction in the Land Management Plan for developed recreation does not change across alternatives and does not include discussion of increasing the number nor size of sites. Therefore, there is not expected to be any impact to the tribal trust resource under any of the Land Management Plan alternatives. Site specific planning for developed recreation might have impacts in the future to the tribal trust resource; those developments would be proposed and impacts disclosed and considered in future site-specific NEPA analyses.

Dispersed use, especially camping and motorized open use areas, overlapping traditional gathering or resource use areas may have significant impacts on the ability of traditional practitioners to access and gather resources.

Motorized and road access is a significant issue to the Tribe. While younger tribal members may be able to reach resource and religious areas on foot or by horseback, elderly practitioners may require motorized access to effectively reach these same areas. While this is an issue to the Tribe, access is guaranteed under treaty, law, regulation, and policy, to some extent. Increased motorized suitable access could be a benefit to the Tribe by increasing their ability to exercise their treaty rights. Conversely, it is possible for increased motorized suitable access and overall increased recreational use to affect tribal uses by increasing the overlapping areas and quantity of tribal uses and non-tribal recreational use.

The amount of motorized access varies by alternative. Since not all locations, times, and uses are disclosed by tribal practitioners, it is difficult to analyze alternative trade-offs regarding the differences in recreation opportunity spectrum classes. Specific authorities do allow line officers to temporarily close areas for cultural purposes, which may mitigate some of the possible effects of increasing overall recreation and increased motorized suitable access acres. Alternative X finds the most acres of the Nez Perce-Clearwater suitable for motorized use. This does not ensure that motorized use will actually occur nor that the Nez Perce-Clearwater will develop more opportunities for this use, just that it is suitable. Site specific analysis regarding development of expanded motorized access would need to be conducted and a tribal trust analysis would be conducted at that time and would influence the design of these types of projects. On the opposite end of the spectrum is Alternative Z, which finds the least number of acres suitable for motorized use.

Timber

Depending on the habitat type and management action, vegetation management may cause both beneficial and harmful effects to resources, traditional uses, sacred sites, and cultural properties of interest to the tribes.

For use of traditional resources, the differences between alternatives are so complex that they can only be discussed in relative terms, while the use and management of sacred sites and cultural properties may be discussed in more specific terms if their location and description are known to the Nez Perce-Clearwater.

Identifying the better alternative would depend on the types of traditional resource and whether mechanical treatment or natural succession is the better route. Alternative X would be favored where mechanical treatment would yield best benefits; Alternative Z favors resources that do not respond well to disturbance.

Cultural Resources

The locations of so few sacred sites are known that it is difficult to argue for differences in the effect between alternatives. The Tribe must evaluate the impacts from the alternatives where information is not shared with the Nez Perce-Clearwater.

For cultural properties, there is not a significant amount of difference between the alternatives because, depending on where treatable acres are in each alternative, the difference may be irrelevant. See the Cultural Resources section for more detail.

Water Resources

High quality water is essential for the aquatic resources used by tribes for many thousands of years and is central to the circle of life. Fish species, particularly salmon and steelhead, have been a cornerstone of Nez Perce survival and core to their culture for countless generations. While the Forest Service does not manage "fisheries" (fish populations), it does manage the access and biological habitats and disturbances that effect water quality, and the longer-term viability of aquatic species and overall management of the water quality and aquatic habitat management is of concern to tribes.

For use of traditional resources, the differences between alternatives are so complex that they should be discussed in relative terms, while use and management of water quality and aquatic habitat may be discussed in more specific terms. Additional information and analysis may be found in the respective sections of this environmental impact statement.

Watershed Restoration Program

The watershed restoration program and Forest Service-Nez Perce Tribe partnership is of great interest and concern to the Nez Perce Tribe. Habitat improvement and species recovery are among the Nez Perce Tribe's highest priorities. Furthermore, the Tribe has noted the partnership work performed on the Nez Perce-Clearwater provides many jobs within the Tribe and in the surrounding communities. Alternative X provides the highest potential for aquatic restoration activities. Alternative Z provides the least.

Wildlife

For countless generations, tribes used, and continue to use, wildlife for sustenance, clothing, and tools, and for religious articles and purposes. While the Forest Service does not manage wildlife populations, it does manage the access and biological habitats that effect wildlife numbers and longer-term viability. As such, overall management objectives of the habitat are of concern to tribes.

For use of traditional resources, the differences between alternatives are so complex that they should be discussed in relative terms, while the effects of each alternative on wildlife habitats may be discussed in more specific terms.

Alternatives X and W allow for the greatest ability to restore ecosystems that are out of desired conditions with respect to wildlife. The No Action Alternative does not provide adequate direction and breaks up habitats more than other alternatives. While Alternative Z provides more undisturbed land for protection of wildlife, it does not allow active restoration to the extent found in Alternative X and W, leaving natural processes on their own to bring habitats back to a desired condition. While Alternative X provides more potential for active restoration, it has the most disturbances and least emphasis on security habitat essential for some species. Additional information and analysis may be found in the respective sections of this environmental impact statement.

3.4 Human Uses

The human uses section includes subsections on cultural resources, sustainable recreation, scenery, and infrastructure, as well as land ownership and land uses.

3.4.1 Cultural Resources

Cultural resources are considered in a manner in the proposed Land Management Plan that is a notable departure from the framework presented in the current forest plans. The 1987 plans reflect a distant point in time on the ever-evolving continuum of federal cultural resource management business practices. Those plans captured the administrative reality of the time whereby the agency was learning to embrace the regulatory compliance procedures set forth in the multitude of laws emerging from the 1960s and 1970s. As such, many standards of the day were a quasi-reiteration of then extant laws meant to locate and protect historic properties but did little to advocate the actual enhancement of those properties. The proposed Land Management Plan makes little attempt to repackage federal mandates meant to locate and protect historic properties as compliance with those laws is mandatory. Instead, the proposed plan attempts to move cultural resource management constructs more firmly into the enhancement arena by crafting desired conditions and indicators meant to improve the condition classification of the Nez Perce-Clearwater's historic properties that have been, or otherwise will be, located and protected from project activities through the commonplace adherence to existing federal laws. The assumption (explained below in the Analysis Methods and Assumptions section) is that these federal laws and executive orders will continue to exist during the life of the Land Management Plan.

An exception to the above statement concerns plan components related to the management of the Lolo Trail National Historic Landmark. Those components are more prescriptive than other cultural resource plan components as they reflect a need for change in how the Landmark is managed that has only recently been recognized.

Relevant Laws, Regulations, and Policy

Federal Laws

Organic Act of 1897 (Title 16, United States Code (U.S.C.), section 473-478, 479-482, 551) is the original organic act governing the administration of National Forest System lands. It is one of several federal laws under which the Forest Service operates. Under this act, the Secretary of Agriculture may make regulations and establish services necessary to regulate the occupancy and use of National Forest System lands and preserve them from destruction. Persons violating the act or regulations adopted under it are subject to fines or imprisonment. The Organic Act is one authority used to issue permits for Archaeological Investigations.

Antiquities Act of 1906 (16 U.S.C. 431) provides for permits, for misdemeanor-level penalties for unauthorized use, and for presidential designation of national monuments for long-term preservation. The Archaeological Resources Protection Act has replaced the Antiquities Act as the authority for special use permits if the resource involved is 100 years old or greater. Uniform regulations at 43 Code of Federal Regulations (CFR) part 3 implement the act.

Historic Sites Act of 1935 (16 U.S.C. 461) declares national policy to "preserve for public use historic sites, buildings, and objects of national significance for the inspiration and benefit of the people of the United States." The act authorizes the National Park Service's National Historic Landmarks Program. The National Historic Landmarks Program is implemented by regulations at 36 CFR part 65.

National Historic Preservation Act of 1966 (NHPA) (16 U.S.C. 470), as amended, extends the policy in the Historic Sites Act to state and local historical sites as well as those of national significance, expands the National Register of Historic Places, establishes the Advisory Council on Historic Preservation and the State Historic Preservation Officers, and requires agencies to designate Federal Preservation Officers.

National Historic Preservation Act Section 101(d)(2) establishes criteria for designating Tribal Historic Preservation Officers to assume the functions of a State Historic Preservation Officer on Tribal lands.

National Historic Preservation Act Section 106 directs all federal agencies to take into account the effects of their undertakings, including actions, financial support, and authorizations, on properties included in or eligible for the National Register. Advisory Council on Historic Preservation regulations at 36 CFR part 800 implement National Historic Preservation Act Section 106.

National Historic Preservation Act Section 110 establishes inventory, nomination, protection, and preservation responsibilities for federally owned historic properties.

National Environmental Policy Act of 1969 (NEPA) (42 U.S.C. 4321-4346) establishes national policy for the protection and enhancement of the environment. Part of the function of the federal government in protecting the environment is to "preserve important historic, cultural, and natural aspects of our national heritage." The act is implemented by the Council on Environmental Quality regulations at 40 CFR 1500-1508.

The Archeological and Historic Preservation Act of 1974 (AHPA) (16 U.S.C. 469) is also known as the Archeological Recovery Act and the Moss-Bennett Bill. The Archeological and Historic Preservation Act amended and expanded the Reservoir Salvage Act of 1960 and was enacted to complement the Historic Sites Act of 1935 by providing for the preservation of historical and archaeological data which might be lost or destroyed as the result of the construction of a federally authorized dam or other construction activity. This greatly expanded the number and range of federal agencies that had to take archeological resources into account when executing, funding, or licensing projects. The Archeological and Historic Preservation Act also allows for any federal agency responsible for a construction project to appropriate a portion of project funds for archaeological survey, recovery, analysis, and publication of results.

Federal Land Policy and Management Act of 1976 (FLPMA), (43 U.S.C. 1701), directs the Forest Service to manage National Forest System lands on the basis of multiple use, in a manner that "recognizes the Nation's need for domestic sources of minerals, food, timber, and fiber from the public lands" and that will "protect the quality of…historical…resources, and archeological values." The act provides for the periodic inventory of public lands and resources; for long-range, comprehensive land use planning; for permits to regulate the use of public lands; and for the enforcement of public land laws and regulations. The Federal Land Policy and Management Act compels agencies to manage all cultural resources on public lands through the land management planning process.

National Forest Management Act of 1976 (NFMA) (16 U.S.C. 1600) directs the Forest Service to develop renewable resource plans through an interdisciplinary process with public involvement and consultation with other interested governmental departments and agencies.

Archaeological Resources Protection Act of 1979 (ARPA) (16 U.S.C. 47Oaa *et seq.*), as amended, provides civil penalties and felony and misdemeanor criminal penalties for the unauthorized excavation, removal, damage, alteration, defacement, or the attempted unauthorized removal, damage, alteration, or defacement of any archaeological resource, more than 100 years of age, found on public lands or Indian lands. The act includes National Forest System lands in its definition of public lands. The act also prohibits the sale, purchase, exchange, transportation, receipt, or offering of any archaeological resource obtained from public lands or Indian lands in violation of any provision, rule, regulation, ordinance, or permit under the act, or under any federal, state, or local law. No distinction is made regarding National Register of Historic Places eligibility. The act establishes permit requirements for removal or excavation of archaeological resources from federal and Indian lands. The act further directs federal land managers to survey land under their control for archaeological resources and create public awareness programs concerning archaeological resources. Uniform regulations and departmental regulations at 36 CFR part 296 implement Archaeological Resources Protection Act.

Native American Graves Protection and Repatriation Act of 1990 (NAGPRA) (25 U.S.C. 3001) provides a process for museums and federal agencies to return certain Native American cultural items — human remains, funerary objects, sacred objects, or objects of cultural patrimony — to lineal descendants, and culturally affiliated Indian tribes and Native Hawaiian organizations. The Native American Graves Protection and Repatriation Act includes provisions for unclaimed and culturally unidentifiable Native American cultural items, intentional excavation and unanticipated discovery of Native American cultural items on federal and Tribal lands, and penalties for noncompliance and illegal trafficking. The act requires agencies and museums to identify holdings of such remains and objects and to work with appropriate Native American groups toward their repatriation. Permits for the excavation or removal of "cultural items" protected by the act require Tribal consultation, as do discoveries of "cultural items" made during activities on federal or Tribal lands. The Secretary of the Interior's implementing regulations are at 43 CFR part 10.

Federal Lands Recreation Enhancement Act of December 8, 2004, (REA) (16 U.S.C. 6801-6814) permits federal land management agencies to charge modest fees at recreation facilities that provide a certain level of visitor services. The Recreation Enhancement Act also permits fees for specialized recreation permits necessary when recreation activities require exceptional visitor safety measures, extraordinary natural and cultural resource protection, or dispersal of visitors to ensure that good experiences are sustainable. The Recreation Enhancement Act includes provisions that require the use of Recreation Resource Advisory Committees to provide the public with information about fees and how fee revenues will be used. The primary goal of the Recreation Enhancement Act is to enhance visitor facilities and services to provide a quality recreation program.

Other Acts such as Multiple-Use Sustained-Yield Act of 1960 (16 U.S.C. 528-531) and the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA) (17 U.S.C. 1600-1674)) include authorities that establish national forest management direction and thereby may affect Heritage Program activities.

Executive Orders

Executive Order 11593 - Protection and Enhancement of the Cultural Environment, issued May 13, 1971, directs federal agencies to inventory cultural resources under their jurisdiction, nominate all federally owned properties that meet the criteria to the National Register of Historic Places, use due caution until the inventory and nomination processes are completed, and assure that federal plans and programs contribute to preservation and enhancement of non-federally owned properties.

Executive Order 13007 - Indian Sacred Sites, issued May 24, 1996, directs federal land management agencies, to the extent permitted by law, and not clearly inconsistent with essential agency functions, to accommodate access to and use of Indian sacred sites, to avoid affecting the physical integrity of such sites wherever possible, and, where appropriate, to maintain the confidentiality of sacred sites. Federal agencies are required to establish a process to assure that affected Indian tribes are provided reasonable notice of proposed federal actions or policies that may affect Indian sacred sites.

Executive Order 13175 – Consultation and Coordination with Indian Tribal Governments, issued November 6, 2000, directs federal agencies to establish regular and meaningful consultation and collaboration with Tribal officials in the development of federal policies that have Tribal implications, to strengthen the United States government-to-government relationships with Indian tribes and to reduce the imposition of unfunded mandates upon Indian tribes. Public Law (P.L.) 108-199 and 108-477 added language that directed the Office of Management and Budget and all federal agencies to consult with Alaska Natives and Alaska Native Corporations on the same basis as Indian tribes under E.O. 13175.

Executive Order 13287 – Preserve America, issued March 3, 2003, establishes federal policy to provide leadership in preserving America's heritage by actively advancing the protection, enhancement, and contemporary use of the historic properties owned by the federal government. The order encourages agencies to seek partnerships with state, tribal, and local governments, and the private sector to make more efficient and informed use of historic properties for economic development and other recognized public benefits. The order requires federal agencies to review and report on their policies and procedures for compliance with National Historic Preservation Act, Section 110 and 111, improve federal stewardship of historic properties, and promote long-term preservation and use of those properties as federal assets contributing to local community economies.

The order requires the head of each agency to designate a Senior Policy Official. In addition, it directs the Secretary of Commerce, working with other agencies, to use existing authorities and resources to assist in the development of local and regional heritage tourism programs.

Executive Order 13327 – Federal Real Property Asset Management, issued February 4, 2004, establishes the Federal Real Property Council to develop guidance for each agency's asset management plan. The Senior Real Property Officer of each agency is required to develop and implement an agency asset management planning process that meets the form, content, and other requirements established by the Federal Real Property Council. In relation to cultural resources, the Senior Real Property Officer shall incorporate planning and management requirements for historic properties under E.O. 13287 – Preserve America. E.O. 13327, para. 2(a) defines "federal real property" as any real property owned, leased, or otherwise managed by the federal Government, both within and outside the United States, and improvements on federal lands.

Agency Regulations

The principal regulations for the administration of the Forest Service Heritage Program are:

Protection of Historic Properties (36 CFR part 800). These regulations implement Section 106 of the National Historic Preservation Act and define how federal agencies meet the statutory responsibility to take into account the effects of their undertakings on historic properties. The regulations identify consulting parties as State Historic Preservation Officers, Indian tribes, and Native Hawaiian organizations, including Tribal Historic Preservation Officers; representatives of local governments; applicants for Federal assistance; and additional consulting parties. The Advisory Council on Historic Preservation issues these regulations and oversees the operation of the National Historic Preservation Act Section 106 process. The regulations identify the goal of consultation, which is "to identify historic properties potentially affected by the undertaking, assess its effects, and seek ways to avoid, minimize or mitigate any adverse effects on historic properties" (36 CFR 800.1).

National Register of Historic Places (36 CFR part 60). These regulations establish the National Register of Historic Places, referred to as the National Register for the remainder of this section, as a planning tool to help federal agencies evaluate cultural resources in consultation with State Historic Preservation Officer (SHPO) and the Advisory Council on Historic Preservation (Advisory Council). 36 CFR 60.4 provides the criteria for determining whether cultural resources are eligible for listing on the National Register.

Protection of Archaeological Resources Uniform Regulations (36 CFR part 296). These regulations implement the Archaeological Resources Protection Act by establishing the uniform definitions, standards, and procedures for federal land managers to follow in providing protection for archaeological resources located on public lands and Indian lands. The regulations define the prohibited acts, which include excavating, removing, damaging, or otherwise altering or defacing archaeological remains; and selling, purchasing, exchanging, transporting, or receiving any archaeological resource that was removed from federal land in violation of Archaeological Resources Protection Act or any other federal law. The regulations also provide requirements for issuing permits under the authority of the Archaeological Resources Protection Act to any person proposing to excavate or remove archaeological resources from public lands or Indian lands.

Native American Graves Protection and Repatriation Regulations (43 CFR part 10, Subpart B – Human Remains, Funerary Objects, Sacred Objects, or objects of Cultural Patrimony from Federal or Tribal Lands). These regulations carry out provisions of the Native American Graves Protection and Repatriation Act of 1990. The regulations establish a systematic process for determining the rights of lineal descendants and Indian tribes and Native Hawaiian organizations to certain Native American human remains, funerary objects, sacred objects, or objects of cultural patrimony with which they are affiliated. The regulations pertain to the identification and appropriate disposition of human remains, funerary objects, sacred objects, or objects of cultural patrimony that are in federal possession or control or in the possession or control of any institution of state or local government receiving federal funds. The regulations pertain to these objects whether they are inadvertently discovered or excavated intentionally under a permit issued under the authority of the Antiquities Act or Archaeological Resources Protection Act.

Curation of Federally-owned and Administered Archaeological Collections (36 CFR part 79). These regulations establish definitions, standards, procedures, and guidelines for federal agencies to preserve collections of pre-Contact and historic material remains, and associated records recovered under the authority of the Antiquities Act, Reservoir Salvage Act, National Historic Preservation Act, and Archaeological Resources Protection Act.

Planning (36 CFR part 219). These regulations set forth a process for developing, adopting, and revising land and resource management plans for the National Forest System and prescribe how land and resource management planning is to be conducted on National Forest System lands.

Statement of Federal Financial Accounting Standards 29, Heritage Assets and Stewardship Land, July 7, 2005, (SFFAS 29). The Federal Accounting Standards Advisory Board issued this statement, which changes the classification of information reported for heritage assets and stewardship land provided by SFFAS 8. SFFAS 29 reclassifies all heritage assets and stewardship land information as basic except for condition information, which is reclassified as required supplementary information. This standard requires additional reporting disclosures about stewardship policies and an explanation of how heritage assets and stewardship land relate to the mission of the agency.

Policy

It is the policy of the Forest Service to:

- Establish and maintain effective relationships with federal, state, tribal, and local governments and historic preservation organizations at all levels of the agency to ensure protection of cultural resources and to promote Heritage Program efficiencies.
- Fully integrate opportunities for preservation, protection, and utilization of cultural resources into land use planning and decisions.
- Manage cultural resources through a process of identification, evaluation, and allocation to appropriate management categories that protect cultural resource values and benefit the public.
- Recognize cultural resources through National Register of Historic Places nomination, National Historic Landmark recommendation, and other special designations.
- Provide opportunities for public use and enjoyment of cultural resources through education and outreach programs that promote resource stewardship.
- Facilitate scientific research of cultural resources to increase understanding of past human cultures and environments.
- Use cultural resource data to increase scientific understanding of the evolution and condition of ecosystems and to benefit Forest Service land management practices.
- Protect cultural resources from the effects of Forest Service or Forest Service-authorized undertakings, unauthorized use, and environmental damage.

State and Local Law

Protection of Graves - 2005 Idaho Code, Title 27, Chapter 5. Prohibits the willful removal, mutilation, defacement, injury, or destruction of a grave or a cairn used as a memorial to the dead.

The law also prohibits the possession of artifacts or human remains taken from a cairn or grave on or after January 1, 1984, publicly displaying or exhibiting human remains, or selling any human artifacts or human remains taken from a cairn or grave.

State and Local Plans

The Idaho Historic Preservation Plan. The plan establishes the priorities and goals for the historic preservation community throughout the State of Idaho and attempts to take purposeful steps and actions to create a state-culture in which Idaho's historic, archaeological, and cultural resources are recognized as important in the lives of Idahoans. The plan encourages the active engagement in preserving, sharing, and using cultural resources to inform and positively influence the future of the State of Idaho.

The plan has four goals consisting of:

- Ensure that decision makers, at all levels, and the public are informed and knowledgeable about historic preservation issues, practices, opportunities, and its value, and take an active role in historic preservation efforts.
- Take the appropriate steps to help historic preservation efforts transition into the 21st century using current and future best practices and the development and adoption of new and emerging technologies.
- Ensure that historic preservation efforts throughout the state are aware of and have access to sufficient and sustainable sources of financial support.
- Continue to ensure that archaeological resources and documents are accorded permanent curation in accredited facilities in the State of Idaho.

Methodology

Spatial Scale

36 CFR 800.16 (d) defines the area of potential effects concerning cultural resource management as "the geographic area or areas within which an undertaking may directly or indirectly cause alterations in the character or use of historic properties, if any such properties exist. The area of potential effects is influenced by the scale and nature of an undertaking and may be different for different kinds of effects caused by the undertaking."

Accordingly, the spatial scale for both indirect and cumulative effects associated with programmatic decisions made within the Land Management Plan is the administrative boundary of the Nez Perce-Clearwater — excepting potential effects to the Lolo Trail National Historic Landmark. Because the Landmark extends into Montana on the Lolo National Forest, effects to the integrity of the Landmark occurring on the Nez Perce-Clearwater could foreseeably affect the integrity of the Landmark in Montana. The reverse is also true.

Temporal Scale

The length of time used for considering effects to cultural resources is the life of the plan. The year 1861 was chosen as a starting date to coincide with the discovery of gold in north Idaho and the notable landscape disturbance resulting from that activity. A multitude of other disturbance activities followed and continue to the present. Fifteen years into the future is the expected duration of the Land Management Plan.

Past, Present, and Future Activities used in the Analysis

Beginning with the 1861 placer mining boom, a succession of events and technologies began in use on what is now the Nez Perce-Clearwater that affected or destroyed untold numbers of cultural resource sites. An example of other activities that have impacted cultural resources consist of, but are not limited to, the following:

- Mining
- Road construction
- Logging activities
- Aquatic restoration
- Recreation development
- Railroad construction
- Grazing activities
- Prescribed fires
- Forest Service facility management

Wildfire has also adversely affected cultural resources.

Slowly, the value and recognition of cultural resources resulted in laws and regulations promoting the protection of this disappearing resource. Nonetheless, the sites remaining today are indicative of fractured, non-renewable data sets which must be considered in conducting cumulative effects analyses.

Analysis Methods and Assumptions

A notable assumption made in the formulation of cultural resource plan components and associated effects analysis is that federal cultural resource laws listed above in the Relevant Laws, Regulations, and Policy section will continue to exist throughout the entirety of the new planning cycle. It is these laws that provide the necessary protection to cultural resources such that the Land Management Plan can move beyond protection requirements and focus on resource enhancement including, but not limited to, preservation, rehabilitation, restoration, and interpretation activities. If these federal laws were to change during the life of the Land Management Plan, the effects analysis included herein would likely cease to have the necessary relevancy to aid resource management decisions.

Measurement Indicators

To facilitate the protection and enhancement of historic properties throughout the duration of the new planning cycle, the concept of integrity is being used as an indicator. Integrity is the means in which a cultural resource eligible for, potentially eligible for, or listed in the National Register of Historic Places conveys its significance. Without integrity a cultural resource cannot qualify for the National Register. If a significant cultural resource loses important aspects of its integrity, it will no longer qualify for the National Register.

Integrity has seven elements as described in 36 CFR 60.4 consisting of:

- Location
- Design

- Setting
- Materials
- Workmanship
- Feeling
- Association

Each of the seven elements of integrity are described below following definitions offered by the Advisory Council on Historic Preservation.

Location. Location is the place where the historic property was constructed or the place where the historic event occurred. The relationship between the property and its location is often important to understanding why the property was created or why something happened. The actual location of a historic property, complemented by its setting, is particularly important in recapturing the sense of historic events and persons. Except in rare cases, the relationship between a property and its historic associations is destroyed if the property is moved.

Design. Design is the combination of elements that create the form, plan, space, structure, and style of a property. It results from conscious decisions made during the original conception and planning of a property, or its significant alteration, and applies to activities as diverse as community planning, engineering, architecture, and landscape architecture. Design includes such elements as organization of space, proportion, scale, technology, ornamentation, and materials.

A property's design reflects historic functions and technologies as well as aesthetics. It includes such considerations as the structural system; massing; arrangement of spaces; pattern of fenestration; textures and colors of surface materials; type, amount, and style of ornamental detailing; and arrangement and type of plantings in a designed landscape.

Design can also apply to national register districts, whether they are important primarily for historic association, architectural value, information potential, or a combination thereof. For districts primarily significant for historic association or architectural value, design concerns more than just the individual buildings or structures located within the boundaries. It also applies to the way in which buildings, sites, or structures are related. For example, the spatial relationships between major features, the visual rhythms in a cultural landscape, the layout and materials of walkways and roads, and the relationship of other features and any extent archeological component or site.

Setting. Setting is the physical environment of a historic property. Whereas location refers to the specific place where a property was built or an event occurred, setting refers to the *character* of the place in which the property played its historical role. It involves *how*, not just where, the property is situated and its relationship to surrounding features and open space.

Setting often reflects the basic physical conditions under which a property was built and the functions it was intended to serve. In addition, the way in which a property is positioned in its environment can reflect the designer's concept of nature and aesthetic preferences.

The physical features that constitute the setting of a historic property can be either natural or manmade, including such elements as:

- Topographic features such as a gorge or the crest of a hill
- Vegetation

- Simple manmade features including paths or fences
- Relationships between buildings and other features or open space

These features and their relationships should be examined not only within the exact boundaries of the property but also between the property and its *surroundings*. This is particularly important for national register districts.

Materials. Materials are the physical elements that were combined or deposited during a particular period of time and in a particular pattern or configuration to form a historic property. The choice and combination of materials reveal the preferences of those who created the property and indicate the availability of particular types of materials and technologies. Indigenous materials are often the focus of regional building traditions and thereby help define an area's sense of time and place.

A property must retain the key exterior materials dating from the period of its historic significance. If the property has been rehabilitated, the historic materials and significant features must have been preserved. The property must also be an actual historic resource, not a re-creation; a recent structure fabricated to look historic is not eligible. Likewise, a property whose historic features and materials have been lost and then reconstructed is usually not eligible.

Workmanship. Workmanship is the physical evidence of the crafts of a particular culture or people during any given period in history or prehistory. It is the evidence of artisans' labor and skill in constructing or altering a building, structure, object, or site. Workmanship can apply to the property as a whole or to its individual components. It can be expressed in vernacular methods of construction and plain finishes or in highly sophisticated configurations and ornamental detailing. It can be based on common traditions or innovative period techniques.

Workmanship is important because it can furnish evidence of the technology of a craft, illustrate the aesthetic principles of a historic or prehistoric period, and reveal individual, local, regional, or national applications of both technological practices and aesthetic principles.

Feeling. Feeling is a property's expression of the aesthetic or historic sense of a particular period of time. It results from the presence of physical features that, taken together, convey the property's historic character. For example, a rural historic district retaining original design, materials, workmanship, and setting will relate the feeling of agricultural life in the nineteenth century. A grouping of prehistoric petroglyphs, unmarred by graffiti and intrusions and located on its original isolated bluff, can evoke a sense of tribal spiritual life.

Association. Association is the direct link between an important historic event or person and historic property. A property retains association if it is the place where the event or activity occurred and is sufficiently intact to convey that relationship to an observer. Like feeling, association requires the presence of physical features that convey a property's historic character. For example, the Lolo Trail whose natural and manmade elements have remained intact since the nineteenth century will retain its quality of association with the historic travel route.

Because feeling and association depend on individual perceptions, their retention alone is insufficient to support investment in the property.

Affected Environment

Existing Condition - General Historic Properties

In the centuries preceding Lewis and Clark and the Corps of Discovery's arrival in 1805, the Inland Northwest was a kaleidoscope of cultures. A span of time exceeding 10,000 years gave rise to a complex array of aboriginal cultures finely honed to the resources and seasonal rhythm of their respective areas. Historically, the Nez Perce-Clearwater's area was primarily the homeland to hunting, fishing, and gathering bands collectively referred to as the Nez Perce Indians. While the primacy of the Nez Perce use and presence across the Nez Perce-Clearwater is unquestionable, other peripheral groups also used the area. Most prominent among these proximally situated groups were those historically known as the Pend d' Oreille and Flathead Bitterroot Salish, Coeur d' Alene, and Northern Shoshone Indians. Today all these groups retain an ongoing vibrant culture with an unbroken tie to the Nez Perce-Clearwater.

Historically situated at the edge of the Columbia Plateau and Great Basin aboriginal cultural areas, the Nez Perce-Clearwater's locality existed at a crossroad of cultures. While the nature of the region's resources necessitated a similar economy among these groups, each nonetheless brought with them a differing language and orientation. Cultural interaction such as trade and marriage served to weave this diverse cultural landscape together, but the culture of each group retained a core identity.

As noted above, the Nez Perce-Clearwater's landscape is largely characterized by deep canyons possessing elevation-dependent ecosystems within. The vertical compression of these ecotones within the canyons resulted in a multitude of resources being available within a limited area throughout the seasons. This allowed small, extended family groups to largely orient themselves to a given watershed area and obtain the necessary resources to live throughout the year. The seasonal timing of resource availability within a watershed largely predicated the movement of groups as well as the type of resource collection activity. Ethnographically, winter was a more sedentary time generally spent at villages along the lower stream courses subsisting largely on stored foods. This successful approach to resource utilization allowed a given band to live for generations within a greater watershed area and develop sophisticated knowledge of the landscape. The acquisition of the horse at the dawn of the 18th century notably transformed this subsistence cycle. This equestrian use increased mobility, expanded use areas, altered relationships amongst Tribes, and transformed their economies and way of life.

American Indian use of the Nez Perce-Clearwater over the centuries is thus manifest in hundreds of archaeological sites in addition to ancient trails, areas of traditional importance, sacred sites, and oral traditions. Discrete and ever-disappearing, archaeological sites and the myriad of activities they reflect represent only a very small sample of the complex, rich, and dynamic past lifeways associated with each group.

The arrival of the Corps of Discovery to the Nez Perce-Clearwater's area in 1805 marks the beginning of the historic period for central Idaho. With it came a succession of events that dramatically changed American Indian culture. Although Euro-American trade items, the acquisition of the horse and early waves of communicable diseases had reached the Inland Northwest prior to the Corps' arrival, it was the succeeding 75 years which were to have a profound effect. The Coeur d' Alene War of 1858, the Nez Perce War of 1877, and the Sheepeater War of 1879, along with the reservation system, largely brought an end to the transhumant lifeways which had characterized American Indian culture for centuries.

Following the Corps of Discovery's eastward departure from the Nez Perce-Clearwater in 1806, a slow trickle and then tide of Euro-American fur trappers and explorers entered the Inland Northwest. In 1811 Donald McKenzie of the Pacific Fur Company led a small contingent of "Overland Astorians" to Fort Astoria on the Oregon coast following a route along the western flank of the Nez Perce-Clearwater through Hells Canyon (Cox 1832). The following year the Pacific Fur Company established a small post near present day Lewiston, Idaho, along the Clearwater River (Jones 1993). Later, in 1831, John Work of the Hudson's Bay Company led a fur brigade east across the Lolo Trail corridor into Montana (Lewis and Phillips 1923).

Indeed, transient travels through central Idaho typify the documented Euro-American use of the Nez Perce-Clearwater for the next several decades. Presbyterian minister Samuel Parker traversed the Southern Nez Perce Trail in 1835 as he traveled west on a reconnaissance mission for the American Board of Commissioners for Foreign Missions (Parker 1838). Likewise, Bitterroot Valley resident and prolific traveler John Owen travelled east and west across the Southern trail in 1854. John Owen had two years earlier traversed the Lolo Trail corridor and continued to do so several times as late as 1863 (Baird and Baird 2003). John Mullan also travelled westward on the Lolo Trail corridor in 1854 as part of a railroad survey for the War Department (Stevens and Palmer 1855).

The discovery of gold near present-day Pierce in 1860, and a year later at Elk City and Florence, ushered in a wave of settlement and land use that transformed the Nez Perce-Clearwater's natural and political landscape. Thousands of miners and accompanying tag-along businesses sprang up overnight in makeshift towns along with a nascent transportation network connecting each. Millions of dollars of gold were extracted from the Nez Perce-Clearwater, with the Florence Basin itself producing almost $10 million dollars in the 1860s (Idaho State Historical Society 1960). This locally produced capital provided an important source of hard currency for the Union during the Civil War (Idaho State Historical Society n.d.). Thus, the economic impetus for, and political organization of, the Idaho Territory at the time of its formation in 1863, and later State of Idaho in 1890, had its initial origins squarely within the Nez Perce-Clearwater's area. Today, thousands of historic mining features can be found throughout central Idaho and embody an historic theme replete with ecological, economic, political, and social implications.

Continued mining, small-scale lumbering, hard-scrabble farming and ranching, and homesteading typified the use on and around the Nez Perce-Clearwater during the 1870s and 1880s. This time period also saw the beginning of conservation related concerns expressed over the condition of forested watersheds on public lands in the eastern United States. These initial concerns eventually culminated in the Forest Reserve Act of 1891. The Act allowed the President to set apart and reserve forested public lands as an initial step in their protection from unregulated use (Steen 1976). In 1897, the amount of forested acreage reserved under the Act was doubled by President Grover Cleveland. As a part of this augmentation, 4.1 million acres were set aside in central Idaho and western Montana as the Bitterroot Forest Reserve. In 1905, the Forest Reserves were reformulated into national forests and managed by the newly created U.S. Forest Service within the Department of Agriculture. Shortly thereafter, on July 1, 1908, both the Clearwater and Nez Perce National Forests were created from portions of the Bitterroot, Coeur d' Alene, and Weiser National Forests. In 1934, additional acreage was added to both Forests when the Selway National Forest was dissolved. Nearly eight decades later, the two Forests were administratively combined on February 6, 2013 and are today known as the Nez Perce-Clearwater.

Since 1908 the history of the Nez Perce-Clearwater largely chronicles the administrative growth of both the Clearwater and Nez Perce National Forests. The first several decades of Clearwater and Nez

Perce National Forest's administration saw each Forest following similar trends as other national forests in the interior Northwest. Mapping of the Clearwater and Nez Perce National Forests occurred along with the establishment of initial communication lines, fire lookout locations, and administrative sites. Fire control was perhaps the top priority for early forest rangers. The initial lack of a functional communication network, difficult access to remote areas, limited infrastructure, and a shortage of labor led to unchecked devastating fires in the early 20th century. Destructive fire seasons such as those of 1910, 1919, 1929 and 1934 (Space 1981) left a landscape legacy still extent today. Too, the extraction of millions of board feet of white pine lumber on the Clearwater National Forest notably altered the vegetative landscape. For example, between approximately 1906 and 1930, many miles of temporary logging railroads were constructed across the Nez Perce-Clearwater to extract this resource. The extent of this harvested volume was so great that the largest white pine lumber mill in the world at the time was constructed in Potlach, Idaho, to process the resource, along with one of the most technologically advanced mills of the day built at Elk River (Petersen 1987). Grazing, too, affected forest conditions and use of the Nez Perce-Clearwater. For example, from 1911 through 1942 at least 2,691,139 ewes, lambs, and goats grazed across the Nez Perce-Clearwater (Steadman 2005, U.S. Department of Agriculture 1943). The advent and arrival of the Civilian Conservation Corps in the 1930s also had a profound effect on the cultural landscape of the Nez Perce-Clearwater. Administrative facilities, bridges, roads, and trails were subsequently constructed which increased active management and access to many portions of the Nez Perce-Clearwater. Following World War II, resource extraction increased to support a booming post-war economy. The legacy of this intensive activity is apparent today in not only the condition and management classification of the Nez Perce-Clearwater's landscapes, but also the multitude of policies that regulate forest management activity.

The human story of the Nez Perce-Clearwater is thus a rich narrative reflecting a converging cross-section of cultures, technologies, values, and environments. Table 309 lists the broad historic themes which have transpired across the Nez Perce-Clearwater and the associated cultural resource site types typical of each.

Table 309. Historic themes and general cultural resource site types of the Nez Perce-Clearwater.

Historic Theme	Site and Feature Type(s)
American Indian Use[1]	Artifact scatters, lithic procurement sites, rock-art, rock shelters, camps, villages, fishing sites, rock cairns, areas of traditional importance, peeled tree groves, trails, etc.
Backcountry Aviation	Airstrips and crash sites
Chinese Sojourners	Habitation features, artifact scatters, and mining features
Civilian Conservation Corps	Ranger stations, camps, public campgrounds, bridges, roads, trails, and fire lookouts
Conflict - Western Frontier	Camp sites along the Lolo Trail
Exploration and Fur Trade	Camp sites along the Lolo Trail
Fire Detection	Fire lookout stations
Forest Service Administrative History	Administrative sites and telecommunication lines
Homesteading and Ranching	Buildings, structures, orchards, and artifact scatters
Hydroelectric Development	Small dams
Incarceration	Internee camps and prison camps
Lands	Boundary and survey markers
Logging and Lumbering	Railroad grades, flumes, splash dams, camps, middens, and artifact scatters

Historic Theme	Site and Feature Type(s)
Mining	Townsites, placer mines, load mines, ditches, mills, building, structures, dams, cemeteries, etc.
Missionary Period	Camp sites along the Southern Nez Perce Trail
Outdoor Recreation	Ranches, developed and dispersed camps, motorways, and artifact scatters
Range Management	Cabins, stock driveways, corrals, and watering stations
Settlement - Local	Schools and middens
Transportation	Roads, trails, bridges, and waystations
Trapping	Martin sets, cabins, and line shacks

[1]With assistance from the Nez Perce Tribe this theme might be disassembled into multiple categories as portrayed for non-native use of the Nez Perce-Clearwater.

The cultural resources included in Table 309 are non-renewable properties. Unlike natural and biotic resources, they cannot be replanted, reintroduced, restocked or otherwise grown. Once a given cultural resource, or its integrity, has been destroyed it is generally gone forever.

Existing Condition - Lolo Trail National Historic Landmark

The Lolo Trail National Historic Landmark was determined eligible as a National Historic Landmark by the Department of Interior on October 9, 1960, as an outgrowth of congressional direction found in the 1935 Historic Sites Act. Later, in 1963, it was formally registered as a National Historic Landmark with an official certification ceremony held at the Powell Ranger Station on August 11, 1965. It was subsequently listed on the National Register on October 15, 1966, upon the National Register's creation that year following the passage of the National Historic Preservation Act.

Nationally, the 2,500 properties designated as National Historic Landmarks tell stories that are of importance to the history of the entire nation, not just local communities, or states. They are places where our nation's most significant historic events occurred. The designation of a property as a National Historic Landmark indicates the property "possesses exceptional value or quality in illustrating and interpreting the heritage of the United States," and "represents an outstanding aspect of American history and culture." Accordingly, these properties must possess a high, not simply good, level of historic integrity to retain their status as a National Historic Landmark.

The portion of the greater Lolo Trail National Historic Landmark located in Idaho is approximately 60,000 acres in size and 62 statute miles in length extending from the Nez Perce-Clearwater boundary in the west near Musselshell Meadows to the Nez Perce-Clearwater boundary to the east at Lolo Pass. It encompasses 1 percent of the Nez Perce-Clearwater and varies approximately between a quarter to one and three-quarter miles wide. The Landmark also extends well onto the Lolo National Forest. Thus, the Landmark is essentially a lineal corridor, but also has several lateral extensions giving it a somewhat braided appearance.

Approximately 8 percent of National Historic Landmarks are located on federal land. Therefore, the Lolo Trail National Historic Landmark is a relatively rare entity on the federal landscape. Indeed, the Lolo Trail National Historic Landmark is the largest National Historic Landmark in the Northern Region of the U.S. Forest Service and encompasses the longest intact segments of both the Nez Perce National Historic Trail and the Lewis and Clark National Historic Trail in the United States. The Lolo Trail National Historic Landmark is thus the single most important stronghold for both the Lewis and Clark and Nez Perce National Historic Trail in the United States.

Nationally, in 2000 and 2001, of the more than 2,500 National Historic Landmarks, approximately 90 percent were considered preserved “without damage or imminent threats” by the National Park Service. The remaining 10 percent fell into one of three undesirable condition classifications. Unfortunately, the Lolo Trail National Historic Landmark falls into this latter 10 percent and is specifically listed in the “watch” category. A National Historic Landmark listed in the “watch” category is defined as a property “that faces impending actions or circumstances that likely will cause a loss of integrity.” The rationale for the watch listing was the result of past timber harvesting operations within the Landmark. Numerous plan components have been crafted to ensure the integrity of the Landmark persists. Additionally, the Landmark has been designated as a distinct geographic area.

Environmental Consequences

The land management plan provides a programmatic framework that guides site-specific actions but does not authorize, fund, or carryout any project or activity. Because the land management plan does not authorize or mandate any site-specific projects or activities, including ground-disturbing actions, there can be no direct effects. However, there may be implications, or longer-term environmental consequences, of managing the Nez Perce-Clearwater under this programmatic framework.

Effects to No Action Alternative

The current forest plans generally only propose the active protection of historic properties from agency activities, not proactive measures meant to enhance or improve historic property conditions. Therefore, the indirect effects of the current forest plans would be the slow loss of integrity of non-renewable historic properties due to natural deterioration and the consequences of time.

Effects Common to Action Alternatives

The four action alternatives generally have six main themes that fluctuate between alternatives and address the significant issues identified during scoping. These themes consist of timber harvest; prescribed fire; aquatic restoration, specifically the recovery of listed fish species; recommended wilderness; wild and scenic river suitability; and motorized travel.

For the purposes of this effect’s analysis, these six themes are considered to affect, both indirectly and cumulatively, the general integrity of historic properties in the following manner:

- **Timber Harvest and Prescribed Fire**. Assuming historic properties are protected by extent federal laws during these activities, timber harvest and prescribed fire can benefit historic properties by removing fuel around historic properties making them more defensible during future wildfires. Additionally, these activities will occur around hundreds of previously recorded cultural resources over the life of the plan that, to date, have never been formally evaluated for their eligibility to the National Register. These activities will thus provide the mechanism to visit and formally evaluate these sites such that non-eligible sites can be removed from future management consideration. This will thoughtfully reduce the number of historic properties the Nez Perce-Clearwater manages, considers, and mitigates for during future planning efforts; better help allocate scarce resources to those properties worthy of investment; and reduce risk exposure to fire fighters by not protecting non-eligible properties during wildfires.
- **Riparian Restoration.** This activity generally occurs within the narrow confines of riparian systems. These streamside localities typically have a high number of historic properties given their flat, well-watered landforms attracted historic human activity. Unlike other agency activities that can be designed to avoid historic properties, aquatic restoration activities

necessarily are focused within these specific, narrow corridors and their adjacent terraces. Avoiding historic properties during aquatic restoration projects is often not possible.

- **Recommended Wilderness**. A reasonably foreseeable outgrowth of recommended wilderness is wilderness designation. Wilderness designation has a neutral, trending-positive effect on cultural resources. Fuel reduction is generally not possible around historic properties in wilderness, but wilderness designation may cause the timely evaluation of previously recorded sites for their eligibility to the National Register because of efforts to remove cultural resources that do not contribute to wilderness character. This evaluation process will help allocate scarce resources to those historic properties worthy of investment and reduce risk exposure to fire fighters by not protecting non-eligible properties during wildfires. Designated wilderness also does not have the suite of trammeling activities found in front-country environs. This management context thus provides an environment that, at times, is more conducive to the long-term preservation of historic properties.
- **Wild and Scenic River Suitability**. A reasonably foreseeable outgrowth of wild and scenic river suitability is wild and scenic river designation. Designation of wild and scenic stream courses has a neutral effect on cultural resources. Fuel reduction meant to benefit historic properties can be more difficult around historic properties having an outstanding remarkable value in wild portions of wild and scenic stream corridors. However, designated streams possessing an outstanding remarkable value related to historic and cultural values offer additional protection to historic properties beyond that offered by the National Historic Preservation Act.
- **Motorized Travel**. Motorized traffic introduces certain effects to historic properties. These effects might include, but are not limited to the following:
    - ♦ Initial damage to archaeological properties resulting from the construction of routes through these properties and subsequent motorized use of those routes, which may cause further soil compaction, soil displacement, rutting, erosion, deflation, and artifact breakage.
    - ♦ An increase in access and use to a particular locality having historic properties resulting in potentially higher occurrences of artifact collecting, vandalism, and dispersed recreational impacts to historic properties.

Table 310. Raw ranking of alternatives by relative amount of proposed activity.

Activity	Activity Benefit to Historic Property Integrity	No Action Alternative	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternative
Timber Harvest	a	1	5	6	3	2	4
Prescribed Fire	b	6	3	5	4	1	2
Recommended Wilderness	c	2	6	1	4	5	3
Wild and Scenic River Suitability	d	2	4	2	5	6	3
Riparian Restoration	e	3	3	3	3	3	3
Motorized	f	4	3	1	5	6	2

Ranking: 1=least beneficial to 6 being most beneficial to cultural resources. a=most beneficial to f=least beneficial to cultural resources. Ranking in this table does not reflect additive weighting, as does Table 312.

Cumulative Effects

The cumulative consequences of the indirect effects noted above is that hundreds of historic properties would continue to be protected from project specific activities, but few instances of actual interpretation, maintenance and repair, or compatible use would occur that would sustain or enhance resource integrity. The net result would be the slow loss of historic properties on the Nez Perce-Clearwater as the 1987 plans generally only attempt to "cause no further harm" to the resource.

Effects to Resource from Other Resources

Climate Change

A warmer climate will alter the scale and amplify the effects of wildfires on historic properties by increasing the likelihood of sites being burned or impacted by fire suppression efforts, as well as increasing instances of post fire-flooding.

Prolonged seasonal droughts can also lead to soil deflation and erosion as desiccation diminishes vegetative ground cover. This increases the likelihood of artifact exposure, trampling, and illegal collection activity.

Hydrologic impacts such as higher winter stream-flows resulting from warmer temperatures or precipitation falling in the form of rain may cause flooding, scouring, and debris flows. Canyon mouths and stream bottoms would especially be affected by this activity and are archaeologically sensitive landforms that have attracted human use for millennia (Halofsky, Peterson, et al. 2018b).

Cultural landscapes may also be affected by climate change as alteration of vegetation and related species can affect the National Register integrity categories of feeling and setting. Ethnobotanical plant species important to tribal communities may also be affected in terms of seasonal timing, abundance, and distribution.

Cultural Resource Management

Historic property management is specifically meant to benefit cultural resources. There are occasions, however, when low-level adverse effects to historic properties may occur to achieve a long-term benefit to the resource, such as archaeological disturbance experienced when stabilizing a site.

Fire Management

Assuming historic properties are protected by extent federal laws during these activities, fire can benefit historic properties by removing fuel around historic properties making them more defensible. Specifically, prescribed fire activities occur around hundreds of previously recorded cultural resources over the life of the Land Management Plan that to date have never been formally evaluated for their eligibility to the National Register of Historic Places. These activities will thus provide the mechanism to visit and formally evaluate these sites such that non-eligible sites can be removed from future management consideration. This will thoughtfully reduce the number of historic properties the Nez Perce-Clearwater manages, consider, and mitigate for during future planning efforts, better help allocate scarce resources to those properties worthy of investment, and reduce risk exposure to fire fighters by not protecting non-eligible properties during wildfires.

Infrastructure

Roads are often built along drainages, ridgetops, and through saddles. The continued maintenance and repair of these roads can negatively affect archaeological properties located on these, and other, archaeologically sensitive landforms.

Well maintained historic facilities benefit historic properties. Decommissioning or conveying historic buildings has an adverse effect on historic properties. Plan component FW-GDL-CR-01 is meant to help facilitate the consideration of heritage values when future use determinations concerning historic buildings are proposed.

Lands and Lands Special Uses

Mountain top communication sites can conflict with Tribal use of those same localities for traditional use and religious activities.

Livestock Grazing

Livestock management features, such as fences and water developments, can affect historic properties. Fences built across or down ridgetops serve to concentrate livestock atop landforms having a high potential for archaeological site location. Water developments centered on springs and seeps are located at locations on the landscape that attracted historic human use. Archaeological sites located at these locations can be damaged through trampling, soil mixing, and deflation.

Minerals

Prospecting, exploratory, developmental, and production related activities associated with managing locatable minerals has a notable potential to effect historic properties. Placer mining activities are often more impactive to historic properties than lode mining operations.

Recommended Wilderness

Wilderness has a neutral, trending-positive effect on cultural resources. Fuel reduction is generally not possible around historic properties in wilderness, but wilderness designation may cause the timely evaluation of previously recorded sites for their eligibility to the National Register because of efforts to remove cultural resources that do not contribute to wilderness character. This evaluation process will help allocate scarce resources to those historic properties worthy of investment and reduce risk exposure to fire fighters by not protecting non-eligible properties during wildfires. Designated wilderness also does not have the suite of trammeling activities found in front-country environs. This management context thus provides an environment that, at times, is more conducive to the long-term preservation of historic properties.

Soils

Desired conditions for soil resources are complimentary to historic property management excepting soil restoration activities which can disturb archaeological sites.

Suitable Wild and Scenic Rivers

Suitability of wild and scenic stream courses generally has a positive effect on cultural resources. Fuel reduction around historic properties having an outstanding remarkable value in suitable wild and scenic stream corridors is possible. Additionally, designated streams possessing an outstanding remarkable value related to historic and cultural values offer additional protection to historic properties beyond that offered by the National Historic Preservation Act.

Sustainable Recreation - Including Developed and Dispersed Recreation

Developed and dispersed recreation sites often occur in common with locations on the landscape that also attracted historic human use. The existence of archaeological sites at these locations poses a potential effect to historic properties if unmitigated recreation use continues at these sites. These recreation sites do, however, offer opportunities for interpretation and public education concerning Nez Perce-Clearwater history and other issues associated with historic property management. Plan component FW-GDL-CR-02 is meant to resolve ongoing effects located at both developed and dispersed recreation sites.

Roads and Motorized Trails Management

Motorized traffic introduces certain effects to historic properties. These effects might include, but are not limited to the following:

- Initial damage to archaeological properties resulting from the construction of routes through these properties and subsequent motorized use of those routes, which may cause further soil compaction, soil displacement, rutting, erosion, deflation, and artifact breakage.
- An increase in access and use to a particular locality having historic properties resulting in potentially higher occurrences of artifact collecting, vandalism, and dispersed recreational impacts to historic properties.

Timber

Assuming historic properties are protected by extent federal laws during timber harvest operations, this activity can benefit historic properties by removing fuel around the properties making them more defensible during wildfires. Additionally, these activities will occur around hundreds of previously recorded cultural resources over the life of the plan that to date have never been formally evaluated for their eligibility to the National Register of Historic Places. These activities will thus provide the mechanism to visit and formally evaluate these sites such that non-eligible sites can be removed from future management consideration. This will thoughtfully reduce the number of historic properties the Nez Perce-Clearwater manage, consider, and mitigate for during future planning efforts; better help allocate scarce resources to those properties worthy of investment; and reduce risk exposure to fire fighters by not protecting non-eligible properties during wildfires.

Riparian Restoration

This activity generally occurs within the narrow confines of riparian systems. These streamside localities typically have a high number of historic properties given their flat, well-watered landforms attracted historic human activity. Unlike other agency activities that can be designed to avoid historic properties, aquatic restoration activities necessarily are focused within these specific, narrow corridors and their adjacent terraces. Avoiding historic properties during aquatic restoration projects is often not possible.

Summary of Consequences

The raw rankings shown in Table 310 are predicated on the quantitative amount of each activity by alternative. The rankings in the tables need a qualitative-additive weighting, however, to properly frame the degree to which each of the six activities can benefit historic property integrity. That additive weighting is shown in Table 311 and Table 312.

Table 311. Additive weighting of relative effects to cultural resources from other activities.

Ranking	Activity
3 (most favorable)	Timber Harvest, assuming historic properties are protected during project implementation
2	Prescribed Fire, assuming historic properties are protected during project implementation
1	Recommended Wilderness
0	Wild and Scenic River Suitability
-1	Riparian restoration
-2 (least favorable)	Motorized

Table 312. Numerical weighting added to the raw ranking of alternatives in Table 310.

Activity	No Action Alternative	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternative
Timber Harvest[1]	4	8	9	6	5	7
Prescribed Fire[1]	8	5	7	6	3	4
Recommended Wilderness	3	7	2	5	6	4
Wild and Scenic River Suitability	2	4	2	5	6	3
Riparian Restoration	2	2	2	2	2	2
Motorized	2	1	-1	3	4	0
Totals	21	27	21	27	26	20

Ranking: 1=least beneficial to 6 being most beneficial to cultural resources. Ranking in this table does not reflect additive weighting, as does Table 312.

[1]Assuming historic properties are protected during project implementation

Based on this analysis, Alternatives W and Y will benefit the integrity of historic properties the most, while the Preferred Alternative will have the most potential impacts to cultural resource integrity.

Conclusion

Because historic property management issues were not identified as being specific drivers of alternatives for the Land Management Plan, there are no overt differences between alternatives related to short term uses and long-term productivity of cultural resources that can be weighed in effective terms.

Also, historic properties are non-renewable resources. Unlike natural and biotic resources, they cannot be replanted, reintroduced, restocked, or otherwise grown. Once a given historic property, or its integrity, has been destroyed, it is generally gone forever. A potential exception to this statement relates to historic buildings. Removing or modifying vegetation that contributes to an historic building's integrity through the elements of setting and feeling, as defined above, may have a short-term impact to the integrity of the property. However, given the historic building likely serves as the primary feature or visual anchor on site, impacts to the vegetation may not entirely destroy the significance of the site. In time, vegetation can be purposely reestablished or restored to that appropriate for the period of significance. Thus, the long-term benefits of vegetation manipulation accomplished for the purposes of wildfire protection, or the restoration of the historic setting and feeling, can potentially outweigh the short-term impacts to the site's visual integrity. This management concept does not, however, apply to the Lolo Trail National Historic Landmark. Because the Landmark's primary means of conveying its significance is through setting and feeling, alterations to those elements leaves insufficient integrity remaining to convey its significance.

Additionally, minor impacts to the integrity of an archaeological site may be acceptable if the purpose of that effect is to facilitate on-site historic preservation activities meant to address larger issues affecting the site's integrity.

3.4.2 Sustainable Recreation

Recreation participation is how most Americans have come to know their National Forests and Grasslands. For many Americans then, sustainable recreation is an important portal for understanding the value, meaning, history, and relevance of National Forests and Grasslands (U.S. Department of Agriculture 2010a). The 2012 Planning Rule defines sustainable recreation as the set of recreation settings and opportunities on the National Forest System that is ecologically, economically, and socially sustainable for present and future generations. The focus of forest recreation management is to provide a range of environmentally sustainable opportunities to participate in a variety of recreational activities in forest settings to meet the needs and desires of visitors. Recreation settings are the social, managerial, and physical attributes of a place that, when combined, provide a distinct set of recreation opportunities.

The Forest Service often categorizes recreational activities into two descriptions – developed recreation and dispersed recreation. Both types of recreation are categorized further by the recreation opportunity spectrum. The recreation opportunity spectrum includes a non-motorized and motorized access opportunities discussion, in addition to developed and dispersed opportunities. In some cases, these recreation opportunities are enhanced through the services offered by those in possession of a recreation special use permit for outfitting and guiding services or a recreation event.

Developed recreation occurs in settings that have been created or constructed for specific recreational purposes on the national forest, such as overnight campgrounds, picnic sites, downhill ski areas, rental cabins, boat docks, visitor centers, interpretive trails with display panels, organizational camps, and special use permitted recreation residence tracts. Fees may or may not be charged. These locations are usually given site names, inventoried, and categorized in Nez Perce-Clearwater databases with basic capacity information and design features.

Dispersed recreation occurs across the forest where there is little or no infrastructure or facilities except roads and trails. Activities include hiking, bird watching, driving for pleasure, rock and ice climbing, boating, hunting, fishing, horseback riding, berry picking, backcountry skiing, snowmobiling, camping, and motorized and mechanized trail use. Dispersed camping occurs in the general forest area that has little, or no Forest Service facilities provided, often where there is repeated dispersed use. Recreation special use permits are issued to private businesses, individuals, institutions, other government entities, and nonprofit groups to provide for occupancy and use of the national forests beyond what is normally available to the public.

Changes Between Draft and Final Environmental Impact Statements

Analysis as documented in the Draft Environmental Impact Statement characterized the Forests as having existing recreation opportunity spectrum class designations “based on modeling of travel routes and terrain, as well as the existing forest plan direction.” The Draft Environmental Impact Statement went on to say “This existing condition distribution of classes is not the same as the desired recreation opportunity spectrum distribution from the 1987 plans. The existing condition classifications were based on the 1987 plans, as well as closure orders, the Clearwater travel plan, and other management decisions made since 1987 that have impacted the recreation opportunities across the Nez Perce-Clearwater.”

Subsequent to the release of the Draft Environmental Impact Statement, it was recognized that the 1987 Nez Perce and Clearwater Forest Plans did not make decisions regarding designation of Recreation Opportunity Spectrum (ROS) classes. Rather, the Nez Perce Forest Plan provided direction to “Manage for a full array of recreation opportunities, from primitive to roaded natural, as described by the Recreation Opportunity Spectrum (ROS).” Indicating that ROS direction and protocols were to be used in the planning, analysis, and implementation of project level decisions. Under the No Action Alternative, the development of recreation opportunity spectrum direction would remain part of project level decisions applicable only to those decision areas, remaining inconsistent with 2012 Planning Rule direction to incorporate the recreation opportunity spectrum into the Land Management Plan.

The Clearwater Forest Plan identified five areas as recommended wilderness. The term “semiprimitive recreation” is used to in the descriptions of the recommended wilderness areas. The Plan also allocated five roadless areas to management without roads under three types of management emphasis. One management emphasis description is Management Area A3 – Semiprimitive recreation. A definition of Semiprimitive Recreation Setting is provided in the glossary consistent with the classification definition in the ROS User Guide. Additionally, Appendix F – Travel Planning uses ROS terms such as primitive, semi-primitive, motorized and nonmotorized recreation. However, as with the Nez Perce Plan, ROS was not used as a management tool to determine motorized and nonmotorized suitability across the Forest and there is no designation of ROS classifications in the Forest Plan.

Developing an ROS classification as per the ROS User Guide that did not exist prior to this Land Management Plan revision process is problematic because that ROS classification is not a true representation of the existing condition under the 1987 Forest Plans and subsequent travel management decisions and closure orders. This developed representation is described as the No Action alternative and is used as the baseline in the comparison of alternatives involving suitability of areas for summer and winter motorized use. However, there is a significant difference in the areas and acreage suitable for motorized between the true existing condition and the developed ROS classifications. This discrepancy portrayed an inaccurate change between the No Action alternative and the action alternatives.

To correct this misapplication of ROS classes, the ROS maps for the No Action alternative have been removed and replaced by maps that accurately portray the areas open and closed to summer and winter motorized recreation under the 1987 Plans. The corrected acreages were then used for comparative purposes of the effects of ROS classifications in the action alternatives. Those numbers are presented in the Final Environmental Impact Statement.

Relevant Laws, Regulations, and Policy

Laws

Organic Administration Act of June 4, 1897 (30 Stat. 11, as amended): This act authorizes the establishment of national forests.

Term Permit Act of March 4, 1915 (Pub. L. 63-293, Ch. 144, 38 Stat. 1101, as amended; 16U.S.C. 497): This act provides direction to the National Forest System lands to authorize occupancy for a wide variety of uses through permits not exceeding 30 years.

Multiple-Use Sustained-Yield Act of June 12, 1960 (Pub. L.86-517, 74 Stat. 215): This act provides direction to National Forest System lands to provide access and recreation opportunities. The act states "the policy of Congress is that national forests are established and administered for outdoor recreation..."

National Forest Roads and Trails Act of October 13, 1964 (Pub. L. 88-657, 78 Stat. 1089, as amended): This act declares that an adequate system of roads and trails should be constructed and maintained to meet the increasing demand for recreation and other uses. The act authorizes road and trail systems for the national forests. It authorizes granting of easements across National Forest System lands, construction and financing of maximum-economy roads (Forest Service Manual 7705), and imposition of requirements on road users for maintaining and reconstructing roads, including cooperative deposits for that work.

Land and Water Conservation Fund Act of 1965 (Pub. L. 88-578, 78 Stat. 897 as amended; 16 U.S.C. 460l-4604 (note); 460l-4604 through 6a, 460l-4607 through 460l-4610, 460l-4610a-d, 460l-4611): "The purposes of this act are to assist in preserving, developing, and assuring accessibility to all citizens of the United States of America...[to] such quality and quantity of outdoor recreation resources...[and] providing funds" to states for acquisition, planning, and development of recreation facilities and federal agencies for acquisition and development of certain lands and other areas .

Architectural Barriers Act of August 12, 1968 (Pub. L. 90-480, 82 Stat. 718 51 U.S.C. 4151- 4154, 4154a, 4155-4157): This act establishes additional requirements to ensure that buildings, facilities, rail passenger cars, and vehicles are accessible to individuals with disabilities. It covers architecture and design, transportation, and communication elements of recreational site planning and development.

National Trails System Act of October 2, 1968 (Pub. L. 90-543, 82 Stat. 919, as amended): This act was signed into law by President Lyndon B. Johnson on October 2, 1968. The purpose of the act was "to promote the preservation of public access to, travel within, and enjoyment and appreciation of the open-air, outdoor areas and historic resources of the nation." This act authorized three types of trails: 1) national scenic trails, 2) national recreation trails, and 3) connecting-and-side trails. In 1978, national historic trails were also added to the national trail system. National scenic trails and national historic trails may only be designated by Congress. National recreation trails may be designated by the Secretary of Interior or the Secretary of Agriculture. Through designation, these trails are recognized as part of the American National Trail System.

Trails for America in the 21st Century (Executive Order 13195): This order was signed by President Clinton in 2001 to achieve the common goal of better establishing and operating the American national system of trails. It addresses development and management of national scenic and historic trails by protecting trail corridors.

The Nez Perce (Nimíipuu or Nee-Me-Poo) National Historic Trail Public Law No (99-44510/06/1986): By Congress, this public law added the Nez Perce Trail to the national trails system as a national historic trail.

Rehabilitation Act of September 26, 1973 (Pub. L. 93-112, Title V, 87 Stat. 390, as amended; 29U.S.C. 791, 793-794, 794a, 794b): This act requires that programs and activities conducted by federal agencies and by entities that receive funding from, or operate under a permit from, federal agencies provide an equal opportunity for individuals with disabilities to participate in an integrated setting as independently as possible. The only exception to the requirement is when the program would be fundamentally altered if changes were made solely for the purpose of accessibility.

Forest and Rangeland Renewable Resources Planning Act of August 17, 1974 (Pub. L. 93-378, 88 Stat. 476, as amended): Per Section 10, this act declares that “the installation of a proper system of transportation to service the National Forest System...shall be carried forward in time to meet anticipated needs on an economical and environmentally sound basis.”

Federal Land Policy and Management Act of October 21, 1976 (Pub. L. 94-579, 90 Stat. 2742, as amended): Per Section 102, this act declares that “the public lands be managed in a manner that…will provide for outdoor recreation and human occupancy and use.”

Secure Rural Schools and Community Self-Determination Act of October 30, 2000 (Pub. L. 106-393, 114 Stat. 1607; 16 U.S.C.500 note): This act provides provisions to make additional investments in, and create additional employment opportunities through, projects that improve the maintenance of existing infrastructure; implement stewardship objectives that enhance forest ecosystems; and restore and improve land health and water quality.

Federal Lands Recreation Enhancement Act of December 8, 2004 (Pub. L. 108-447, as amended): This act gives the Secretaries of Agriculture and Interior the authority to establish, modify, charge, and collect recreation fees on federal recreational lands where a certain level of amenities has been developed.

Federal Cave Resources Protection Act of 1988 (Pub. L. 101-691): This act aims to “secure, protect, and preserve significant caves on Federal lands for the perpetual use, enjoyment, and benefit of all people; and to foster increased cooperation and exchange of information between governmental authorities and those who use caves located on Federal lands for scientific, education, or recreational purposes.” Specific effects of the act include prohibiting the disclosure of location of significant caves, the removal of cave resources, and vandalizing or disturbing cave resources.

Executive Orders

Executive Order 12862, Setting Customer Service Standards: This order requires information about the quantity and quality of recreation visits for national forest plans.

Executive Order 11644, as amended: This order establishes policy and procedure “that will ensure that the use of off-road vehicles on public lands will be controlled and directed so as to protect the resources of those lands, to promote the safety of all users of those lands, and to minimize conflicts among the various uses of those lands.”

Executive Order 13443, Facilitation of Hunting Heritage and Wildlife Conservation: This order directs federal agencies to facilitate the expansion and enhancement of hunting opportunities and the management of game species and their habitat.

2012 Planning Rule (36 CFR 219): This rule states that in developing a proposed plan revision, plan components must include sustainable recreation, including recreation settings, opportunities, access, and scenic character. Recreational opportunities could include non-motorized, motorized, developed, and dispersed recreation on land, water, and air.

Methodology

Spatial Scale

The geographic scope of the analysis is the National Forest System lands administered by the Nez Perce-Clearwater. All lands of all ownership within the Nez Perce-Clearwater boundary form the geographic scope for cumulative effects.

Temporal Scale

The temporal scope is the anticipated life of the plan.

Past, Present, and Future Activities used in the Analysis

Recreation has occurred on the Nez Perce-Clearwater in some form since before the designation of the forests and has been influenced throughout this period by the multiple-uses occurring across the forests. Likewise, it is expected that multiple uses will continue to influence recreation in the future. Some of the activities that have influenced, continue to influence, and are expected to influence in the future are:

- Road building, maintenance, and decommissioning
- Trail construction, maintenance, and decommissioning
- Timber Harvest
- Mining
- Grazing
- Fire Management
- Aquatic Restoration
- Fisheries management
- Wildlife management
- Cultural Resources management
- Scenery management

The first six of these activities have often been the basis for creation of recreation access opportunities and recreation settings. They not only influence the ability of recreationists to access the forest but have also altered the characteristics of the forest that provide a variety of recreational activities. The remaining four of these activities are often the attractors for which visitors come to the forest.

Methods and Assumptions

The context for evaluating sustainable recreation on the Nez Perce-Clearwater is the Nez Perce-Clearwater's recreation setting and opportunities, developed through the Recreation Facilities Analysis process (U.S. Department of Agriculture 2014m). In doing so, sustainability is focused on those things the Nez Perce-Clearwater is uniquely poised to provide and framed within the broader landscape of Idaho, Eastern Washington, Eastern Oregon, and Western Montana.

The desired recreation opportunity spectrum for both summer and winter was mapped across the Nez Perce-Clearwater by each alternative to indicate the suitability of recreation related activities. The methodology for mapping the recreation opportunity spectrum for each alternative follows the National Recreation Opportunity Spectrum (ROS) Inventory Mapping Protocol (U.S. Department of Agriculture 2019b). Each alternative was then analyzed for the total number of acres and percentage of the desired recreation opportunity spectrum settings on the Nez Perce-Clearwater. Motorized and non-motorized access were not independently mapped, as they are components of the desired recreation opportunity spectrum and are therefore included in that mapping.

Developed recreation sites were mapped using existing Nez Perce-Clearwater databases as points. The Northern Region undertook an inventory of dispersed sites and added this data to the Nez Perce-Clearwater databases in 2010. This data was also mapped to indicate concentrations of dispersed use in some portions of the Nez Perce-Clearwater. While this data helps indicate where dispersed use occurs, it is assumed that not all dispersed sites were mapped and that new ones are continuing to develop.

Since adoption of the forest plans, recreation activities across the Nez Perce-Clearwater have changed. This analysis assumes that changes to recreational use patterns would occur naturally as a result of factors associated with recreation trends, advances in technology, aging population, aging infrastructure, increase or decrease in local populations, and climatic changes.

The Land Management Plan establishes programmatic level direction. It does not make site-specific travel planning designations, maintenance level determinations, operational choices, or project-level decisions. The Land Management Plan sets broad level context for sustainable recreation and trails management across the vast Nez Perce-Clearwater landscape. If higher-level land management allocations result in inconsistencies with travel planning direction, subsequent travel plan amendments or modification may be necessary. In addition to the laws and executive orders listed above, the Forest Service Manual provides nation-wide and regional direction on recreation management topics. Those policies are not repeated in Land Management Plans.

Information sources

The Nez Perce-Clearwater used the best available data relevant to inform the analysis for the Land Management Plan components for recreation settings, recreation opportunities, recreation special uses, and recreation access. Data for this analysis and the associated Land Management Plan components was pulled from a variety of monitoring and assessment databases. The latest three National Visitor Use Monitoring (NVUM) assessments provide information regarding recreation use and trends across the Nez Perce-Clearwater. Much of the recreation data used in this analysis comes from the Forest Service infrastructure database (INFRA). This forest-level database is a collection of web-based data entry forms, reporting tools, and mapping tools. The database provides a geographic information system that enables the Forest Service to manage and report accurate information about constructed features and land units inventory, as well as visualize, analyze, interpret, and understand data to reveal relationships and patterns. The special-use data system (SUDS) provides information about special-use authorizations, such as outfitter and guide permits and recreation events. The Idaho Statewide Comprehensive Outdoor Recreation Plan (SCORP) also informs the Forest Service about statewide tourism and recreation activities and plans.

Measurement Indicators

For comparison purposes, two indicators were used to determine the effects to sustainable recreation.

First, areas of Recreation Opportunity Spectrum (ROS) classes were allocated across the landscape by alternative in consideration of Management Area land allocations. There are six ROS classes arranged along a continuum that provides a framework for defining recreation opportunity environments. The acreage and percent of desired summer and winter classes were used to indicate the settings a recreating visitor might expect in any given area. This, in turn, would indicate the locations and acres favorable for preferred recreational experiences.

A refinement of these classes was used as a second indicator to assess the differences in recreation access and recreation experience opportunity. This was measured by determining the acres suitable for summer wheeled motor vehicle use, and the acres suitable for motorized over-snow vehicle use. The acres suitable for summer and winter motorized use vary across alternatives, again in consideration of Management Area allocations. Qualitative evaluation of the effects of Land Management Plan direction to how well it supports and benefits people for motorized access further indicates differences across alternatives.

Therefore, the two indicators for determining impacts to sustainable recreation were measured by the following four metrics:

- Settings by acres of desired summer recreation opportunity spectrum classes
- Settings by acres of desired winter recreation opportunity spectrum classes
- Recreation experience opportunity by acres suitable or not suitable for motorized over-snow vehicle use
- Recreation experience opportunity by acres suitable or not suitable for motorized summer vehicle use

Affected Environment

Sustainable recreation management encompasses many aspects of recreational use on the Nez Perce-Clearwater. The recreation settings available on the Nez Perce-Clearwater serve as the basis for providing opportunities for visitors to recreate. Access, whether motorized or non-motorized, and facilities, whether developed or dispersed, allow visitors to achieve and enjoy their desired recreational opportunities. Finally, recreation special uses help facilitate these opportunities by offering assistance to achieve these experiences when visitors might otherwise be unable to realize them. Collectively, these attributes create a sustainable recreation management strategy. All of them are affected by trends in visitor use and activity choices people make based on their objectives and desired experiences.

Visitor Use

National Forest visitor use monitoring report data indicates that from fiscal year 2013 to fiscal year 2017 the volume of recreation use on the national forests was estimated to be about 149 million recreation visits. The nationwide survey further indicates the value of visitors to the economic sustainability of the nation, especially in rural areas. Ten billion dollars is estimated to be spent annually by recreation visitors in areas near national forests and grasslands. Furthermore, approximately 10.3 billion dollars is reflected in the gross domestic product and recreation visitation sustains about 143,000 full-time and part-time jobs (U.S. Department of Agriculture 2017g).

Three national visitor-use monitoring reports and surveys have been completed for the Nez Perce-Clearwater. The latest round of visitation estimates was completed in 2016 for the combined Nez Perce-Clearwater (U.S. Department of Agriculture 2017g). The previous two rounds, in 2006 and 2011, were completed for each of the forests independently since they were not administratively combined at the time those surveys were conducted (U.S. Department of Agriculture 2018c, e, d, f). Estimated annual visitation is around 550,000 visits for the Nez Perce-Clearwater. Table 313 shows the data from the three survey years broken out by the different types of visits users engaged in while visiting the Nez Perce-Clearwater.

Table 313. Estimated site visits for the plan area in 2006, 2011, and 2016

Visit Type	2006	2011	2016
Day Use Developed Site Visits	195,000	155,000	205,000
Overnight Use Developed Site Visits	81,000	69,000	74,000
General Forest Area Visits	385,000	235,000	409,000
Designated Wilderness Visits	30,000	21,000	76,000
Total Estimated Site Visits1	689,000	481,000	763,000
Total Estimated National Forest Visits[1]	440,000	294,000	550,000

Note that a site visit is different than a forest visit since a single visitor may visit multiple site types within a single forest visit.

NVUM surveys are conducted every five years, so numbers apply only to the respective year, not to a five-year interval.

Data Source: National Visitor Use Monitoring Reports for 2006 and 2011 for the Nez Perce and Clearwater National Forests separately and for 2016 a combined Nez Perce-Clearwater Report.

General forest area visits dominate the visit type with almost three-quarters of visitors indicating that their visit included use of an undeveloped or general forest area. Just over one-third of visitors did visit a developed day-use site, while only about one-tenth of visitors indicated using a developed overnight facility. The Nez Perce-Clearwater visitation distribution is slightly different than the National Forest System as whole data. Across the country about two-thirds of visitors indicate a general forest visit, about half visit a day-use developed site visit, and about one-tenth visit a developed overnight visit (U.S. Department of Agriculture 2017g). Therefore, compared to the National Forest System as a whole, the Nez Perce-Clearwater may have slightly higher dispersed use, slightly lower developed day-use, and about the same developed overnight use.

In 2016 National Visitor Use Monitoring data indicated more than half, 57 percent, of the visitors to the Nez Perce-Clearwater were male. This is very similar to the nationwide forest visitation gender breakdown of about 60 percent male (U.S. Department of Agriculture 2017g, 2016c).

About 32 percent of visitors travelled less than 50 miles, which is considered to be a local visitor. This may indicate that the Nez Perce-Clearwater draws visitors from a more regional than local scale. The nationwide survey results indicate that about 50 percent of visitors would be considered local visitors. With that said, almost 60 percent of Nez Perce Clearwater visitors are day visitors, whose visit does not include an overnight stay. This further indicates a more regional than national or international visitation distribution. Income data indicates a concentration of households making between 25,000 and 75,000 dollars a year. Finally, the average amount of money spent per party on a trip to the Nez Perce-Clearwater is estimated to be 583 dollars (U.S. Department of Agriculture 2016c).

Just over half of Nez Perce-Clearwater visitors are ages 20 to 59. Those under age 20 represent about 16 percent of visitors and the remaining about 27 percent of visitors are 60 or older. Again, these age distributions are similar to those for forest visitation nationwide. About 68 percent of forest visitors are 20 to 59 years old, about 15 percent are under age 20, and about 17 percent are 60 or older. However, comparing by decade indicates that the Nez Perce-Clearwater forest visitors' average ages are slightly older than the nationwide forest visitor. The highest single decade of ages for Nez Perce-Clearwater visitors is 60 to 69, while nationwide the highest decade is 50 to 59. This would indicate that the Nez Perce-Clearwater may have a higher representation of retired visitors than nationally (U.S. Department of Agriculture 2017g, 2016c).

Viewing natural features and hiking or walking are the two activities visitors indicated they participated in at the highest rates. 45 percent of visitors indicated participating in hiking or walking and 44 percent in viewing of natural features at some time during their visit. These participation rates closely match the nationwide visitor use survey report as well. The Nez Perce-Clearwater survey indicates slightly higher participation in hunting and fishing, but the difference is less than ten percent for hunting and less than five percent for fishing. The data aligns relatively well with outdoor recreation trend research (Cordell 2012) that asserts that some of the more traditional outdoor activities, such as hunting and fishing, are declining and being replaced by other nature-based recreation, such as wildlife viewing, bird watching, and photography. There are three other activities in the top ten activities that Nez Perce-Clearwater visitors participate in that differ more than five percent from the nationwide survey. Driving for pleasure is participated in by 15 percent more visitors to the Nez Perce-Clearwater; developed camping by 9 percent more; and visiting historic sites by 5 percent more. All of the other top ten activities are within less than five percent of the nationwide survey (U.S. Department of Agriculture 2017g, 2016c). Table 314 displays the full list of activities and participation rates for the Nez Perce-Clearwater in 2016.

Table 314. Activity Participation on the Nez Perce National Forest as surveyed in 2016

Activity	Percent Participation1	Percent Main Activity2	Average Hours Doing Main Activity
Hiking or Walking	44.5	9.8	5.8
Viewing Natural Features	43.4	16.9	4.6
Relaxing	37.9	7.0	27.3
Driving for Pleasure	35.6	7.3	3.2
Viewing Wildlife	29.8	1.7	4.7
Developed Camping	17.6	4.2	32.5
Hunting	13.4	11.6	18.6
Fishing	12.5	5.3	11.0
Nature Center Activities	11.6	2.1	2.4
Visiting Historic Sites	10.0	0.6	4.1
Picnicking	9.0	0.7	17.0
Cross-country Skiing	7.3	6.8	2.0
Motorized Trail Activity	7.2	1.6	8.1
Primitive Camping	7.0	1.1	55.1
Nature Study	6.3	0.2	3.6
Gathering Forest Products	6.2	1.1	3.8
OHV Use	5.2	1.0	19.0
Motorized Water Activities	3.9	2.5	13.6

Activity	Percent Participation1	Percent Main Activity2	Average Hours Doing Main Activity
Other Non-motorized	3.6	0.8	2.3
Non-motorized Water	3.4	2.0	14.2
Bicycling	2.9	0.4	9.1
Backpacking	2.7	0.8	33.3
Snowmobiling	2.6	2.6	4.8
Resort Use	2.2	0.1	25.6
Some Other Activity	1.8	1.0	3.8
No Activity Reported	1.4	15.7	N/A
Other Motorized Activity	0.5	0.2	0.0
Horseback Riding	0.5	0.1	10.5
Downhill Skiing	0.0	0.0	0.0

[1] Survey respondents could select multiple activities, so this column may total more than 100%.

[2] Survey respondents were asked to select just one of their activities as their main reason for the forest visit. Some respondents selected more than one, so this column may total more than 100%.

Data Source: (U.S. Department of Agriculture 2016c)

Other sources of information about outdoor recreation participation nationwide indicate a relatively steady level of participation over the past ten years at about half of the United States population (White et al. 2016, The Outdoor Foundation 2018). In the mountain region, which consists of Idaho, Montana, Wyoming, Nevada, Utah, Colorado, Arizona and New Mexico, about eight percent of the population participates in outdoor recreation (The Outdoor Foundation 2018). Similarly, Idaho Tourism indicates that outdoor recreation including hiking, backpacking, camping, fishing, and visiting parks and historic sites are top activities tourists come to Idaho to experience (Idaho Department of Parks and Recreation 2018).

Activities projected to grow the fastest nationally in number of participants include developed skiing, undeveloped skiing, challenge activities, equestrian activities, viewing or photographing nature, and motorized water activities. Recreation activities expected to show low growth include visiting primitive areas, motorized off-road activities, motorized snow activities, hunting, fishing, and floating (White et al. 2016). In Idaho, utility task vehicle, or UTV use, is the fastest growing trending outdoor activity according to the Idaho State Comprehensive Outdoor Recreation Plan (Idaho Department of Parks and Recreation 2018).

Idaho is ranked third in the nation for number of resident participants in outdoor recreation, behind Alaska and Montana. Regionally, Washington, Utah, and Wyoming also sit in the top ten states for outdoor recreation participation (Outdoor Industry Association 2017b, a). This supports the notion that outdoor recreation in Idaho, and likely on the Nez Perce-Clearwater, is locally and regionally based.

According to 2020 U.S. Census Bureau data, Idaho had the second highest population growth in the country over the past decade. However, where this growth is occurring has changed over the years. In the past, growth was concentrated in urban areas, and rural areas had shrinking populations. Half of Idaho’s counties saw a decline in population between 2010 and 2015, with a concentration of these declines in less populated counties across the state. More recently, growth is occurring in and around smaller communities as well as in the larger urban areas; many of these smaller communities that are experiencing growth are proximate to the Nez Perce-Clearwater.

This growth is expected to lead to a demand for more outdoor recreation in nearby public lands (Idaho Department of Parks and Recreation 2018). 2016 National Visitor Use Monitoring Data for the Nez Perce-Clearwater indicates that a greater percentage of visitors are already visiting from more regional locations rather than local communities (U.S. Department of Agriculture 2016c). This is supported by the Idaho Tourism report indicating that recreational vehicle campers are the most likely overnight trip visitors to Idaho and that the majority of overnight trips originate in Idaho, Washington, California, Utah, and Oregon (Idaho Department of Parks and Recreation 2018). It is likely that this will be further increased by the rising populations in the region, such as from Missoula, Montana; Spokane, Washington; and Coeur d'Alene, Idaho as well as population increases local to the Nez Perce-Clearwater.

The Idaho Statewide Comprehensive Outdoor Recreation Plan (Idaho Department of Parks and Recreation 2018) indicates the age distribution of Nez Perce-Clearwater visitors may also change as a reflection of the changes in the population of Idaho's age distribution. Those over 65 accounted for the largest percent growth in an age group between 2010 and 2015. This age group now represents about 15 percent of the population in Idaho. Furthermore, the age group of 40 to 60 accounts for about 30 percent of the Idaho population. In the future, as this age group retires, there may be an increase in forest recreation visitation and demand for this sector. This may not only influence the amount of forest recreation use but also the activity type. Lastly, the State of Idaho, like the nation, is experiencing Hispanic population growth. The Hispanic population increased by 13 percent in Idaho between 2010 and 2015. A study examining Hispanic participation in outdoor recreation indicates that outdoor opportunities and settings that facilitate family and community gatherings may be more appealing than those that do not facilitate these experiences (Adams et al. 2006). Again, this shift in the population of Idaho and the region may influence changes in future Nez Perce-Clearwater recreation visitation demands.

Recreation Settings and Opportunities

In addition to the goal of providing access to the forest and within the forest, the Forest Service also strives to provide opportunities for recreationists to obtain satisfying recreational experiences by offering choices in types of settings and activities. Recreation activities on the Nez Perce-Clearwater include, but are not limited to, hiking, camping, hunting, fishing, off-highway vehicle driving or riding, picnicking, swimming, boating, cross-country skiing, snowmobiling, backpacking, horseback riding, mountain biking, paddle boarding, wildlife watching, visiting historic sites or scenic driving, and participating in interpretive programs or tours.

The Forest Service uses a framework called the recreation opportunity spectrum (Table 315), which describes different settings across the landscape and the attributes associated with those settings. The recreation opportunity spectrum defines a recreation opportunity setting as the combination of physical, biological, social, and managerial conditions that give value to a place (Clark and Stankey 1979).

Table 315. Recreation opportunity spectrum classes and definitions[1]

Recreation Opportunity Spectrum	Definition
Primitive (P)	This setting supports large, remote, wild, and predominantly unmodified landscapes. There is no motorized activity and little probability of seeing other people. Primitive settings are managed for quiet solitude away from roads, people, and development. There are few, if any, facilities, or developments. Most of the primitive settings coincide with designated wilderness boundaries and recommended wilderness areas.

Recreation Opportunity Spectrum	Definition
Semi-Primitive Non-motorized (SPNM)	The semi-primitive non-motorized settings include areas of the Nez Perce-Clearwater managed for non-motorized use. Mechanized transport such as mountain bikes are often present. Rustic facilities are present for the primary purpose of protecting the natural resources of the area. These settings are not as vast or remote as the primitive settings, but they also offer opportunities for exploration, challenge, and self-reliance.
Semi-Primitive Motorized (SPM)	This setting is managed for backcountry motorized use on designated routes. Routes are designed for off-highway vehicles and other high-clearance vehicles. This setting offers visitors motorized opportunities for exploration, challenge, and self-reliance. Mountain bikes and other mechanized transport are also sometimes present. Rustic facilities are present for the primary purpose of protecting the natural resources of the area or providing portals to adjacent primitive or semi-primitive non-motorized areas.
Roaded Natural (RN)	This setting is managed as natural appearing with nodes and corridors of development that support higher concentrations of use, user comfort, and social interaction. The road system is generally well defined in this setting and can typically accommodate passenger car travel. System roads also provide access to other recreation opportunity spectrum settings of semi-primitive motorized, semi-primitive non-motorized, and primitive areas.
Rurall)	This setting represents the most developed recreation sites and modified natural settings on the Nez Perce-Clearwater. Facilities are designed primarily for user comfort and convenience.

Note: Urban is not described since it is not present on the Nez Perce-Clearwater.

Data Source: Adapted from text in Nez Perce-Clearwater National Forests Forest Plan Assessment Section 9.0 Recreation.

The recreation opportunity spectrum has six distinct classes in a continuum that describe settings ranging from highly modified and developed to primitive and undeveloped (Clark and Stankey 1979, U.S. Department of Agriculture 1982a). Five of the recreation opportunity spectrum classes apply to the Nez Perce-Clearwater: primitive, semi-primitive non-motorized, semi-primitive motorized, roaded natural, and rural. There are no urban recreation opportunity spectrum classes on the Nez Perce-Clearwater.

Table 316. Existing summer and winter motorized recreation access by acres and percent of plan area

Motorized Access	Summer Acres	Summer %	Winter Acres	Winter %
Motorized	2,403,316	61%	2,481,670	63%
Nonmotorized	1,535,850	39%	1,457,496	37%

Access

Visitors select their access based on their preferred setting, experience, and mode of transportation. Roads, motorized trails, non-motorized trails, rivers, and airstrips are present on the Nez Perce-Clearwater for visitors to walk, bike, boat, ride, drive, or fly to their destination. Strategically placed transportation corridors and entry points facilitate safe reliable access to diverse recreation settings and key destinations across the Nez Perce-Clearwater.

In some cases, the travel routes themselves are the destination. These include historic roads such as the Lolo Motorway, Elk City Wagon Road, and the Magruder Corridor Road, which provides a popular primitive route between Elk City, Idaho, and Darby, Montana. This unique road enables visitors to experience the settings of the adjacent Selway-Bitterroot and Frank Church River of No Return wilderness areas and the roadless areas of East and West Meadow Creek while driving. This road is recommended for high clearance vehicles only. Historic trail routes such as the Southern Nez

Perce Trail are also popular trail destinations. Special designations for travel corridors include: National Historic Trails such as the Nez Perce (Nee-Me-Poo) and the Lewis and Clark National Historic Trails; National Recreation Trails; Wild and Scenic Rivers; and Scenic Byways. Historic routes and rivers offer visitors the opportunity to trace the footsteps and voyages of past cultures, inhabitants, and explorers. Much of the transportation network affords visitors the opportunity to view diverse wildlife and spectacular scenery.

Forest access links local communities with forest settings and facilitates nature-based recreation opportunities for residents. Three adjacent Forests provide road and trailhead access to the Nez Perce-Clearwater: the Lolo National Forest on the northeast provides opportunities to access the Great Burn Recommended Wilderness area; the Bitterroot National Forest on the east provides access to the Selway-Bitterroot wilderness via numerous trailheads, including Paradise which provides river access to the wild section of the Selway River; and the Idaho Panhandle National Forest's St. Joe National Forest on the north provides access to the Mallard-Larkins primitive area and the upper North Fork area.

There are about 5,300 miles of system trails on the Nez Perce-Clearwater documented in the national infrastructure database, which is the official database for the Forest Service. There are about 1,300 miles of trails located inside designated wilderness areas.

Table 317 shows the total miles of trail by different types of designed use. Trails designed for one use may have multiple allowable uses on them. For example, a trail designed for bicycle use may have allowable uses for pack and saddle horses and hiking.

Table 317. Miles of trail by designed use managed by ranger district

District	Hike	Pack[1]	Bike	Winter Non-Motorized[2]	Winter Motorized	Motorcycle	Motorized Vehicle < 50 inch[3]	Motorized Vehicle > 50 inch[4]	Total Miles
Salmon	1	454	0	6	88	62	111	0	722
Red River	5	590	0	2	316	20	83	0	1,016
Moose Creek	1	739	0	0	24	19	4	0	787
Palouse	1	51	15	20	0	16	172	0	275
North Fork	3	611	0	14	272	0	426	61	1,387
Lochsa	4	766	0	8	114	4	222	2	1,120
Total	15	3,211	15	50	814	121	1,018	63	5,307

Note: Designed use is the use for which the trail was designed, although other uses maybe allowed; for example, a trail designed for pack use may also be used by hikers.

[1]Pack type trails are designed for pack and saddle users.

[2]Non-motorized winter use includes both Nordic skiing and snowshoeing trails.

[3]Motorized vehicles less than 50 inches wide. The Forest Service classifies e-bikes as motor vehicles.

[4]Motorized vehicles greater than 50 inches wide.

There are four groomed snowmobile trail systems on the Nez Perce-Clearwater, including the Fish Creek Recreation Area; Lolo Pass and the Powell area; Elk City and the Dixie area; and the Elk River Snowmobile Trail system. Five groomed Nordic ski trail systems provide primitive and semi-primitive non-motorized opportunities at Fish Creek Recreation Area, Musselshell Meadows, Lolo Pass, Elk River Nordic Ski Trails, and Palouse Divide Nordic Ski Area.

Developed and Dispersed Recreation

The Nez Perce-Clearwater's developed recreation program provides a wide range of opportunities appropriate to their recreation settings. Developed recreation opportunities provide much of the infrastructure necessary for the enjoyment of a wide variety of recreation activities in the analysis area. Developed recreation opportunities are located at sites and have infrastructure or features designed to protect the resources, reduce conflicts, and provide for safety. Depending upon the location and the facilities available, these developed sites may or may not have fees associated with them. Sustainable recreation sites are generally managed on a continuum based on a development scale ranging from 1 to 5.

Table 318 provides a list of sites whose scale is 1 or 2, dispersed recreation sites, while those of 3, 4, or 5 are developed recreation sites. On the Nez Perce-Clearwater, just under half of designated recreation sites are 1 or 2 on the development scale, indicating that they are dispersed sites with few amenities.

Table 318. Recreation site development scale standards

Scale	ROS[1] Consistency	Type	Typical Facility Features	Emphasis
0	All	Dispersed	User created; no USFS investment or amenities	Monitoring
1	All	Dispersed	User created; informal vehicle circulation and parking; minimal USFS investment and amenities may include signage	Resource protection
2	All	Dispersed	User created; defined vehicle circulation and parking; minimal USFS investment and amenities may include signage, tables and fire rings; occasional a vault toilet	Resource protection
3	Roaded Natural, Rural and Urban only	Developed	Designed site; defined and delineated vehicle circulation and parking; significant USFS investment and amenities may include signage, tables, fire rings, toilets, waste collection, potable water; roads are surfaced and maintenance level 3 or 4	Visitor comfort and resource protection
4	Roaded Natural, Rural and Urban only	Developed	Designed site; defined and delineated vehicle circulation and parking; significant USFS investment and amenities may include signage, tables, fire rings, toilets, waste collection, potable water, interpretive materials, grills, flush toilets; roads, parking and paths are surfaced and maybe paved as well as maintenance level 4 or 5	Visitor comfort and resource protection
5	Rural and Urban only	Developed	Designed site; defined and delineated vehicle circulation and parking; significant USFS investment and amenities may include signage, tables, fire rings, toilets, waste collection, potable water, interpretive displays, grills, flush toilets; may include utility hook-ups, showers and laundry facilities; roads, parking and paths are delineated and often paved as well as maintenance level 4 or 5	Visitor comfort and resource protection

[1]ROS: recreation opportunity spectrum

Data Source: Adapted from Recreation Site Development Scale Direction (FSH 2309.13.10-Recreation Site Development Scale Direction).

The Nez Perce-Clearwater has approximately 212 recreation facilities serving a variety of different recreational opportunities. Most of the recreation facilities on the Nez Perce-Clearwater were developed in the 1960s when highway development expanded access to more of the forest and especially to many of the waterways, where facilities are concentrated across the forest. While most of the facilities are in the lower 2 to 3 development scale categories and well aligned with the US

Forest Service national niche of being rustic, there are some Class 4 and 5 facilities with amenities such as flush toilets and electrical hookups. Developed sites across the forest are generally well maintained, although there is some deferred maintenance especially along the South Fork of the Clearwater and Selway River Corridors where basic improvements are needed. Hazard tree and other vegetation issues due to mature or overly mature growth are common in almost all developed facilities across the Nez Perce-Clearwater.

Table 319 discusses the facilities, as well as associated fees and reservations. Most sites are not fee or reservation sites, with the exceptions being campgrounds. About half of the campgrounds on the Nez Perce-Clearwater are fee campgrounds but less than ten accept reservations. There is no concessionaire operated or maintained facilities on the Nez Perce-Clearwater.

Table 319. Number of recreation facilities, facilities with fees, and on the reservation system, by site type

Type	Facilities	Facilities with Fees	Reservation System
Campground (developed)	55	29	6
Camping Area (dispersed)	53	0	0
Group Campground	3	0	1
Visitor Centers	3	0	0
Picnic Day Use Site	12	0	1
Pavilion	3	0	2
Cabin or Lookout	16	11	12
Boat Launch	3	0	0
River Access or Boating Site[1]	5	3[1]	0
Trailheads	40	0	0
Interpretive Sites	12	0	0
Fishing Sites	3	0	0
Snow Park or Snow Play	4	0	0
Total	212	43	22

1Fee at boating site is for floating permit on main Salmon River.
Data Source: INFRA

Dispersed recreation consists of those activities that take place *outside* of developed recreation areas. Dispersed sites generally do not have fees associated with them and have little or no amenities such as toilets, tables, or garbage collection. They may, however, be designated, such as those that are 0-2 on the development scale. Many minor recreation sites are identified as dispersed sites. These dispersed sites are generally improved for resource protection rather than user convenience. Many of these sites have been improved but much of the maintenance identified has been deferred.

Most recreation use on the Nez Perce-Clearwater occurs in primitive dispersed sites rather than developed facilities. Dispersed recreation sites are typically concentrated in the Nez Perce-Clearwater's roaded natural recreation opportunity spectrum settings. Most of these primitive sites are established over time by reoccurring recreational use and tend to be in areas with desirable characteristics, particularly those with easy access to forest system roads, relatively flat topography, and proximity to water. Dispersed users are often seeking a more secluded camping experience without the rules and regulations typically associated with developed sites and tend to be self-sufficient users. National Visitor Use Monitoring Data from 2016 shows that 29 percent of overnight visitors camped in an undeveloped site and 42 percent stayed at developed campgrounds on the Nez Perce-Clearwater (U.S. Department of Agriculture 2016c).

In 2009, the U.S. Forest Service Northern Region began developing a standardized protocol for inventorying and monitoring resource conditions of dispersed recreation sites. The Nez Perce-Clearwater supports a large, dispersed recreation program and, at this time, the majority of dispersed recreation sites across the Nez Perce-Clearwater have been inventoried and entered into the infrastructure database, also known as INFRA. However, dispersed recreation sites emerge as users choose to visit new locations when others are occupied or otherwise undesirable and at any given time it is likely that not all existing dispersed sites are captured in the database. Areas that show particularly high concentrations of dispersed sites include those along waterways such as the Clearwater River, the Palouse River, the Lochsa River, and Kelly Creek. The bulk of dispersed sites inventoried fall into three categories of use – x overnight use, day-use, and trailhead use. About 80 of the overnight use sites and 20 of the day-use and trailhead sites include access to a toilet and sometimes a fire ring to reduce resource impacts. These areas are highly sought after not only because of presence of these basic amenities but also because there is no cost for occupancy or use of these amenities and fewer agency regulations. Many dispersed sites hold a significant value for families and friends that traditionally return year after year for activities such as hunting, fishing, horse packing, and off-highway vehicle riding based out of these dispersed sites. Table 320 displays the inventoried dispersed recreation sites by site type across each of the ranger districts on the Nez Perce-Clearwater.

Table 320. Number of dispersed recreation sites by site type on Nez Perce-Clearwater ranger districts

District	Overnight[1]	River[2]	Trailhead	Snow[3]	Day[4]	Total
Salmon	225	0	26	0	16	267
Red River	228	1	35	1	11	276
Moose Creek	69	2	6	1	6	84
Palouse	139	0	12	0	8	159
North Fork	249	1	16	0	23	289
Lochsa	331	10	14	1	28	384
Total	1241	14	109	3	92	1459

Note: Dispersed sites are development class 0-2 and were queried this way in the INFRA database.
[1]Overnight includes campgrounds, camping areas, group campgrounds, cabins, and lookouts
[2]River includes boating sites, fishing sites and swimming sites
[3]Snow includes snow parks and snow play areas
[4]Day includes day use areas, interpretive sites and observation sites
Data Source: INFRA.

This work has included embedding boulders to restrict direct access to riparian areas, reducing the useable area within dispersed sites, hardening sites with gravel to clearly identify parking locations for vehicles, and installing fencing. While rare, there have been occasions where dispersed sites were decommissioned and removed from use when riparian impacts were unable to be mitigated.

There are numerous dispersed recreation activities that do not include overnight use. Some of these include backcountry skiing, backcountry snowmobiling and snow-biking, fishing, hunting, and forest product gathering. Trail-based activities include hiking, trail running, horseback riding and pack stock use, motorcycle, all-terrain vehicles, and utility-terrain vehicle riding, and bicycling and e-biking. Water-based activities include kayaking, rafting, tube floating, swimming, and lounging on the Forests' rivers, streams, lakes, and hot springs. These recreational uses span the recreation opportunity spectrum, as some are motorized or adjacent to roads while others are not. A few of these have more specific dispersed activity locations, such as backcountry skiing in the Lolo Pass area and snowmobiling on the Elk River Snowmobile Trail System, or the three most popular undeveloped hot springs – Jerry Johnson, Weir and Stanley.

Recreation Special Uses

Recreation special use permits are issued to private businesses, individuals, institutions, and nonprofit groups to provide for occupancy and use of the national forest beyond what is normally available to the public. Permitted recreation uses provide specific recreational opportunities to the public and deliver economic benefits to rural economics. Examples of commercial enterprises requiring permits include outfitting and guiding services, resorts, recreation events, and organizational camps. Noncommercial recreation uses are those where the use or activity does not include an entry or participation fee and the purpose is not primarily the sale of a good or service. Examples of noncommercial use include family reunions, weddings, or other similar group gatherings. The Forest Service issues these permits under the authority of a variety of specific laws.

About 60 recreational use permits are issued in any given year across the Nez Perce-Clearwater. Table 321 displays recreation special uses by type and district for those issued in 2019. The actual number varies year to year based on public demand.

Table 321. Recreation special uses by type and district

District	Isolated Cabin	Non-Commercial Group	Outfitter and Guide	Private Camp	Recreation Event	Resort
Salmon	0	0	11	0	0	0
Red River	1	0	8	0	0	1
Moose Creek	0	0	11	0	0	0
Palouse	0	1	2	0	0	0
North Fork	0	0	9	0	1	0
Lochsa	0	0	12	2	1	1
Total	1	1	53	2	2	2

Date Source: Special Uses Database queried September 2019.

Outfitter and guide permittees operating on the Nez Perce-Clearwater make up the largest number of commercial recreational use. The three districts with large areas of designated wilderness and designated Wild and Scenic Rivers have the largest number of outfitter and guides, although there is a relatively equal distribution of outfitting and guiding permits across all districts. Hunting outfitting and river related guiding are the dominate types of outfitters and guides.

There are two commercial, privately owned resorts operating on the Nez Perce-Clearwater. One is located on the Lochsa District along the Lochsa River and the second on the Red River District associated with a hot spring. These commercial resorts are permitted under 20-year special use permits. Per the terms on their permits, any changes to the land or the exterior of their buildings must be submitted to the Forest Service for analysis of potential resource impacts.

Climate Change

The effects of climate change projected to occur in the future include changes in temperature, precipitation, and disturbance patterns that drive and stress ecosystems and the benefits they provide, including quality recreation opportunities. Global climate models project that the Earth's current warming trend will continue throughout the 21st century in the Northern Rockies and is projected to increase 4 to 5 degrees by 2050 (Halofsky, Peterson, et al. 2018a, b). Temperature is expected to increase for all seasons.

A warmer climate will generally improve opportunities for warm-weather recreation, such as hiking, camping, and sightseeing, because it will create a longer time during which these activities are possible. Higher temperatures may have both positive and negative effects on wildlife-based activities (hunting, fishing, birding) and gathering of forest products (for example, berries, mushrooms), depending on how target habitats and species are affected. Recreationists may prefer more water-based activities to seek refuge from hotter and longer summer weather. The changes in timing and size of snowmelt may reduce boating and fishing opportunities that could create overcrowding, overuse, user conflict, and resource damage.

These changes are certain to affect the amount and location of snowpack, and timing of snow melt. A warmer climate is expected to reduce snowpack, thereby reducing opportunities for snow-based winter activities, such as cross-country skiing and snowmobiling. These changes will reduce the area, timing and duration for winter recreation activities. This, in turn, may cause over-crowding and user conflict as winter recreationists vie for these reduced opportunities. Shrinking snowpack may also create conflict and adversely affect wildlife species that use these same areas while recreationists want to be there.

Environmental Consequences

In all alternatives, including the No Action Alternative, climatic factors, natural disturbances, recreation trends, use patterns, and emerging technologies would continue to influence the specific type, amount, and location of recreation opportunities across the Nez Perce-Clearwater. Recreational use is expected to increase in the analysis area over time. Dead and dying trees, wildfire, and other natural occurrences may impact the location and availability of some areas for recreation use. The health and safety of the recreating public would continue to influence recreation management.

Travel plans, when completed, would continue to provide site-specific direction where motorized recreational uses could or could not take place. Current travel planning on the Clearwater signed 2017 will continue to provide direction to this portion of the Nez Perce-Clearwater. Nez Perce travel planning will be completed after the Land Management Plan and will provide site-specific direction regarding motorized recreational use on this portion of the Nez Perce-Clearwater. Demand for motorized vehicle access and trails is predicted to increase as technology advances allowing motor vehicles to use terrain that is currently prohibitive. Likewise, an aging population of visitors may also increase demand for motorized access to facilitate this population's visitation to and enjoyment of the Nez Perce-Clearwater. In particular, demand for developed and maintained areas may increase.

Land Management Plan direction for developed and dispersed recreation does not vary across alternatives in the revised plan. Developed recreation components state that recreation opportunity spectrum design criteria would be followed, as well as new and rehabilitated facilities would follow accessibility guidelines and the Built Environment Image Guide. The following management activities are not suitable uses of developed recreation sites: timber production, livestock grazing, and extraction of locatable minerals or saleable mineral materials.

Dispersed recreation management issues are also included with the components for different classifications of the recreation opportunity spectrum. There is a desire to provide a wide variety of settings for public use.

In all alternatives, natural disturbances, recreation use patterns, and emerging technologies would continue to influence the need for recreation special use permits across the Nez Perce-Clearwater. Vegetative conditions can seriously impact the location and infrastructure of recreation special uses. Additionally, the condition of aging infrastructure can have effects to permit holders in both the short- and long-term. Emerging technologies, as well as shifts and changes in recreational interests, can influence the kinds and location of special uses on the landscape.

Effects from the No Action Alternative

The No Action Alternative continues to benefit uses and interests that were benefited by the 1987 forest plans and changes to those plans resulting from the Clearwater travel plan decision and Nez Perce closure orders. Those uses that were curtailed or limited under the 1987 plans, the Clearwater travel plan, or Nez Perce closure orders would remain curtailed or limited.

Recreation Settings, Opportunities, and Access

The settings and opportunities would continue to be managed as defined by the current 1987 plans for each forest independently with changes due to implementation of the Clearwater travel plan and other closure orders. Table 316 in the existing condition discussion, found earlier in the document, shows the acres and percent of motorized and nonmotorized recreational access on the Nez Perce-Clearwater.

Visitor use is expected to continue to increase, especially general use and day use. Motorized activity use such as utility task vehicle, or UTV use, is expected to increase as that demand increases in Idaho and neighboring states. Access for this and other emerging uses, such as mountain bikes, electric bicycles, and over-the-snow motorcycle-snowmobile hybrid devices, also known as snow bikes, would not be supported to a large degree as the current management plans were not written with these uses in mind. These uses continue to find areas on the Nez Perce-Clearwater that support their activity, but no areas were planned or designed for those uses. This may stress existing trails and areas where these would be allowed but not designed for such uses. Trail design mitigates impacts for uses which the trail is designed for but does not necessarily mitigate for other uses.

Developed and Dispersed Recreation

Recreation trends and use patterns would continue to influence the demand for development scale, amount, and distribution of developed and dispersed recreation across the Nez Perce-Clearwater. Recreational use is expected to increase in the analysis area over time. Demand for developed and maintained areas may increase because of changing demographics of Nez Perce-Clearwater visitors. The emphasis on integrating a universal design for accessible recreation facilities and maintaining facilities to full standards for sustainability components will result in more developed recreation facilities having greater accessibility.

Developed campground capacity maxes out during summer weekend peak time periods. The existing 55 developed campgrounds would likely continue to be at or near capacity during the busiest weekends. Use of dispersed recreation overnight sites may increase as these developed sites reach or exceed capacity. The existing 212 developed sites on the Nez Perce-Clearwater would be retained and there would not be limits on future development other than those resulting from budget limitations or as specified in the 1987 plans. Dispersed recreation opportunities would continue to be available across parts of the Nez Perce-Clearwater. The health and safety of the recreating public would continue to influence recreation management at developed sites.

As user numbers likely grow, dispersed recreation use is likely to also increase, especially adjacent to waterways that attract use. Non-overnight dispersed recreation activities are likely to continue to increase in demand as well. Increases in dispersed recreation may, in turn, lead to a need for more developed opportunities especially when development protects natural resources and makes the recreational use and natural resources more sustainable. Protection of natural resources would continue to influence recreation management at dispersed sites.

Recreation Special Uses

Plan components in the current Nez Perce National Forest and Clearwater National Forest Plans provide limited direction specific to recreation special uses. The effects from the No Action Alternative would continue these components to encourage use of special use permits to assist in management of recreation opportunities and to limit issuance of permits in designated wilderness to maintain the wilderness character.

Effects from the Action Alternatives

Recreation Settings, Opportunities, and Access

The desired recreation opportunity spectrum varies by alternative to address the diversity of opinions received from the public, as well as to fully analyze resource impacts from changes in the amount of available motorized versus non-motorized acres. These changes are based on management area allocations by alternative. The recreation opportunity spectrum can be used to show the general effect of alternatives to recreation settings, opportunities, and access across the Nez Perce-Clearwater.

Table 322 displays the allocation of the summer recreation opportunity spectrum and Table 323 shows the winter recreation opportunity spectrum for each alternative (refer to Appendix A). Across all alternatives, in winter compared to summer, there is a larger percentage of semi-primitive motorized and a reduction in the percentage of roaded natural and rural. This is the result of most Forest Service roads not being plowed. In winter, there is also a decrease in the percentage of semi-primitive non-motorized because there are some areas that are not open to summer motorized use but that are open to motorized over-snow vehicle use. These areas also contribute to the increased percentage of winter semi-primitive motorized setting.

Table 322. Percent summer recreation opportunity spectrum (ROS) classes by alternative (Alt)

Summer ROS Class[1, 2]	Alt W	Alt X	Alt Y	Alt Z	Preferred
Primitive	29.6	29.6	30.1	30.1	28.9
Semi-primitive non-motorized	23.5	12.8	26.0	27.3	16.2
Semi-primitive motorized	23.2	32.0	19.1	18.2	24.6
Roaded natural	19.7	21.6	20.8	20.5	27.2
Rural	3.9	3.9	3.9	3.9	3.1

Date Source: Nez Perce-Clearwater GIS data.

[1]Under the No Action Alternative, 39 percent was classified as nonmotorized as per 1987 Plan and closures.

[2]Under the No Action Alternative, 61 percent was classified as motorized as per the 1987 Plan and closures.

Table 323. Percent winter recreation opportunity spectrum (ROS) classes by alternative (Alt)

Winter ROS Class[1, 2]	Alt W	Alt X	Alt Y	Alt Z	Preferred
Primitive	28.9	28.9	28.9	28.9	28.9
Semi-primitive non-motorized	22.8	1.0	8.9	1.0	11.0
Semi-primitive motorized	42.7	63.6	55.9	63.6	54.1
Roaded natural	5.6	6.4	6.3	6.4	6.0
Rural	0.0	0.0	0.0	0.0	0.1

Date Source: Nez Perce-Clearwater GIS data.

[1]Under the No Action Alternative, 37 percent was classified as nonmotorized as per 1987 Plan and closures.

[2]Under the No Action Alternative, 63 percent was classified as motorized as per the 1987 Plan and closures.

Table 324 and Table 325 lump the summer and winter recreation opportunity spectrum classes by the non-motorized or motorized suitability by alternative. An area may be suitable for motorized use based on its recreation opportunity spectrum class but that does not mean motorized use is allowable everywhere in that setting. Motorized use by wheeled and over-snow vehicles is restricted by motor vehicle use maps for the Nez Perce-Clearwater. Travel management decisions are separate, project-level decisions that determine the specific areas and routes for motorized recreation consistent with the desired recreation opportunity spectrum as mapped.

Table 324. Percent suitable summer motorized and non-motorized use, by alternative (Alt)

Suitable Use	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Non-motorized	39.0[1]	53.1	42.5	56.1	57.3	45.1
Motorized	61.0[2]	46.9	57.5	43.9	42.7	54.9

Date Source: Nez Perce-Clearwater GIS data.

[1]Percent nonmotorized as per 1987 Plan and closures.

[2]Percent motorized as per the 1987 Plan and closures.

Table 325. Percent suitable winter motorized and non-motorized use on the Nez Perce-Clearwater by alternative

Suitable Use	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Non-motorized	37.0[1]	51.7	29.9	37.8	29.9	39.9
Motorized	63.0[2]	48.3	70.1	62.2	70.1	60.1

Date Source: Nez Perce-Clearwater GIS data.

[1]Percent nonmotorized as per 1987 Plan and closures.

[2]Percent motorized as per the 1987 Plan and closures.

In summer, the motorized recreation opportunity spectrum classes—semi-primitive motorized, roaded natural, and rural—are third highest in the Preferred Alternative. This is due in part to less recommended wilderness and suitable wild and scenic rivers in this alternative, and those Idaho Roadless Areas with a backcountry restoration theme that are not recommended wilderness being allocated to roaded natural or semi-primitive motorized recreation opportunity spectrum classes. Alternatives W, Y, and Z are very similar in the amount of the forest suitable for motorized use, averaging about 45 percent. These three alternatives also provide the least amount of suitable motorized acres due to higher and similar acres of suitable wild and scenic rivers within these alternatives. Alternative Y provides potential opportunities for motorized loop routes within backcountry restoration Idaho roadless areas that are not allocated as recommended wilderness, while keeping much of those areas non-motorized. As a result, this alternative has a slightly higher percent of suitable motorized acres than Alternative Z. Alternative W, which has the highest acres of recommended wilderness, has the third highest percent of suitable motorized acres after Alternative X, which has no recommended wilderness acres, and the Preferred Alternative which has the second smallest amount of recommended wilderness. This is, in part, due to the suitability of motorized use in those Idaho Roadless areas that are not allocated as recommended wilderness in Alternative W.

In winter, the motorized recreation opportunity spectrum classes—semi-primitive motorized, roaded natural, and rural—are highest in Alternative X and Z. In Alternative Z, during the winter, some of these portions of Management Area 2 would allow motorized use, which is why Alternative X with no recommended wilderness is equal to Alternative Z with almost 500,000 acres of recommended wilderness. These recommended wilderness acres would be classified as suitable for motorized use. The Preferred Alternative has the second least acres suitable for winter motorized use and is a reduction of approximately 4 percent from the No Action alternative.

Alternative W is the only alternative that does not have a substantial difference between summer and winter motorized classes. There is slightly more motorized class in winter than in summer due to those Idaho Roadless Rule areas that are in the backcountry and restoration theme and are not overlapping with any other land allocation being suitable for summer motorized use. The No Action Alternative and Alternative W have more non-motorized winter recreation opportunity spectrum class acres than motorized. This is related to many overlapping land allocation acres in Alternative W with recommended wilderness. In all other action alternatives, approximately half of summer and about two-thirds or more of winter recreation opportunity spectrum class acres fall within a motorized class; basically, most of Management Area 3 and Management Area 2 are suitable for motorized use excluding recommended wilderness areas.

Alternative Y and the Preferred Alternative do not have as many acres of recommended wilderness but the acres that are within this category are not suitable for winter motorized use. As a result, these alternatives have less winter motorized acres suitable than Alternatives X and Z.

Trails

Trail management on the Nez Perce-Clearwater would not vary by alternative other than the suitability of trails to be available for motorized use. The sustainable recreation program on the Nez Perce-Clearwater determines priorities for trail maintenance. No areas would be precluded from new trail construction or reconstruction because of the Land Management Plan. Plan components provide for increasing connectivity of communities to one another and for increased efficiency of moving people along trails from one location to another.

Future trail use, maintenance, and development is primarily a function of increased use, changing demographics, and changing technologies. Changes would need to be consistent with the trails desired conditions, but overall management of the trail system would largely be determined at the project level based on the aforementioned factors and would not vary significantly by alternative.

Conflict between user groups on trails will likely continue and may increase as demand for trails becomes greater. If fewer trails are maintained into the future or groups of users are restricted from some trails, the conflict on remaining trails may increase. User groups continue to coordinate and educate their members to reduce and avoid conflict.

Motorized Over-Snow Vehicle Use

Currently, motorized over-snow vehicle use is suitable on 63 percent of the Nez Perce-Clearwater. The actual area used is substantially less than 63 percent of the Forest. Terrain, vegetation, snow conditions and duration influence where motorized over-snow vehicles can physically go. Vegetation conditions are dynamic over time and change in response to disturbance and succession. Whereas fire may open dense forest areas for over-snow use, succession is closing areas to over-snow use in areas suitable for over-snow use. Non-motorized and non-mechanized transport winter use, such as Nordic skiing, backcountry skiing, and snow shoeing, are allowable on 100 percent of the Nez Perce-Clearwater. Mechanized transport, such as fat-tire bikes that ride over snow, are not allowed in designated wilderness and other specified areas on the Nez Perce-Clearwater that have closure orders prohibiting mechanized transport. Use of fat-tire bikes in the winter in recommended wilderness areas is tied to the suitability of mechanized transport for each alternative. In Alternative Z, the use of fat-tire bikes in the winter would be permitted but not in Alternatives W and Y or the Preferred Alternative. Alternative X has no recommended wilderness.

The differences in suitable acres for winter over-snow vehicle use is due to the selection of the recommended wilderness acres and allocation of winter recreation opportunity spectrum classes. In Alternatives W and Y and the Preferred Alternative, recommended wilderness areas would not be suitable for winter over-snow use. Alternative Z would find over-snow use suitable. The areas being recommended for wilderness vary by alternative, as described in Chapter 2. The boundaries of Alternative Y were specifically developed in response to public input and interest from over-snow motorized user groups to eliminate from recommendation two portions of the Hoodoo Roadless Area, also known as the Great Burn. Likewise, the boundaries in the Preferred Alternative were also established to provide for winter over-snow use outside of recommended wilderness. These exclusions were made to specifically allow for over-snow motorized use in areas where it is currently and historically occurred. This use was curtailed in 2017 through the Clearwater Travel Plan. Alternative Y would permit this use to continue while recommending most of the Hoodoo as wilderness.

Over-snow users have asked the Nez Perce-Clearwater to provide opportunities for a variety of uses. Some users prefer a greater amount of development and accept a lesser amount of risk. These users are most often going to prefer recreating in rural or roaded natural areas. Other users appreciate the convenience of development but also want to get farther into the backcountry and are willing to accept more risk. These users may prefer using the semi-primitive motorized settings as well as the more developed categories. A subset of users who prefer an unconfined experience are willing to accept a much higher level of risk and, generally, have a higher skill level to travel to remote areas. While the recreation opportunity spectrum system as designed does not allow for a primitive motorized experience, these users are looking for just that. The Nez Perce-Clearwater is one of a few remaining areas in the western United States that has the terrain to provide this opportunity. These areas are generally found in the Hoodoo Roadless Area, Bighorn-Weitas Roadless Area, and the West and East Meadow Creek Roadless areas. Alternatives that do not include these areas as recommended wilderness and allow over-snow use in these areas benefit the winter motorized users. Alternatives X and Z best provides for this primitive over-snow motorized use, followed by Alternative Y. Alternative W provides the least area suitable for over-snow motorized vehicle use. The Preferred Alternative has the second least area and represents about a 3 percent decrease from the No Action Alternative. However, this alternative provides specific areas identified as desirable and usable to winter motorized users while addressing other resource and social concerns.

Bicycling

Bicycling, referred to herein as mountain biking, is a use that was in its infancy at the time of development of the current 1987 Forest Plans, also referred to as the No Action Alternative. Mountain bikes generally can travel any trail outside of Wilderness areas on the Nez Perce-Clearwater, and often use a combination of all maintenance level roads and trails to connect desirable areas to ride. In more developed settings, mountain bikers often look for roads that access single-track trails in which they can ride mostly downhill. As the experience level and fitness level of the rider increases, any trail in any direction is a potential trail to ride. Some extreme users may even take self-sufficient multi-day trips. Walking the bicycle for several miles in rough terrain is acceptable in the most primitive areas for the most advanced users.

Mountain biking is prohibited in designated wilderness and in most alternatives of recommended wilderness. Mountain biking is generally suitable in all other areas; however, a closure order may be issued to limit access to mountain bikes, or any other use, following a site-specific NEPA review and decision. Alternative X has zero acres of recommended wilderness. Alternative Z allows for mechanized transport, including bicycles, within the recommended wilderness areas. These two alternatives provide for the greatest amount of access to mountain bikers. Alternatives W and Y and the Preferred Alternative would limit access to mountain bikes in areas recommended as wilderness. The Preferred Alternative has fewer acres of recommended wilderness compared to Alternative W and Y and, therefore, provides more access than Alternatives W and Y for mountain bikes.

Developed and Dispersed Recreation

The effects from the action alternatives are expected to be like those of the No Action Alternative, with a few exceptions based on recreation opportunity spectrum differences by alternative. Demand for dispersed sites may increase or decrease parallel to the amount of motorized access by alternative. As recreation use in general increases, there is likely to be additional demand for dispersed sites. With additional motorized routes, such as in Alternatives W, X, and Y and the Preferred Alternative, much of this demand may be in current non-motorized areas. In Alternatives Y and Z, where less of the Nez Perce-Clearwater is suitable for motorized use, an increased number of dispersed sites would likely be concentrated along currently open roads and trails, as this use would be less accessible elsewhere in the non-motorized areas.

Recreation Special Uses

Plan components across action alternatives do not vary regarding recreation special uses. There are a few plan components regarding recreation special uses. Coordinating with state and partner organizations and boards could better align Nez Perce-Clearwater recreation special use permits with larger state and regional objectives and goals for tourism and outdoor recreational use. This coordination and relationship development could also assist in improving forest land stewardship and resource protection while increasing recreational opportunities for a larger audience. The later may not have individual knowledge, skills, or abilities to pursue recreational opportunities without the assistance of services provided by recreational special use permittees.

Effects from Other Resources

Vegetation Management

Timber harvest has the potential to affect recreation experiences and opportunities in several ways. Short-term effects may include increased noise and dust levels; the sight of landscapes altered by differing types of harvesting; the presence of slash piles and roads reconstructed or constructed for timber sales; additional traffic from logging trucks on roads used by other drivers, off highway vehicles or bicyclists; and the removal of snow for winter log hauling from roads frequented by winter recreational users. Users may be temporarily displaced to other locations because of log truck traffic, helicopter operations, or the noise from chainsaws, for example.

Overall use of the road system for vegetation management activities is directly tied to timber harvest output, acres of forest being managed each year, and, to a lesser degree, the amount of prescribed fire being planned. Alternatives with higher levels of these management activities can expect increased traffic from both commercial and administrative use. New road construction is likely to be limited and temporary road construction is likely to be used as a more common method for short-term access needs. Road development for vegetation management purposes has the potential to increase dispersed use along these now more accessible travel-ways. In the interior of the Nez Perce-Clearwater where access previously has been limited, this has the potential to attract more visitors and increase recreational use there. As use increases, visitors would experience less solitude and remoteness. Primitive and semi-primitive non-motorized settings could change to semi-primitive motorized and roaded natural settings. Recreational benefits from vegetation management improved or new roads can include enhanced opportunities to gather firewood and other forest products for hunting access and dispersed camps or to recreate. While many new roads constructed for vegetation management are temporary or decommissioned post activity, some can be left open to create additional recreation opportunities if those opportunities align with the recreation opportunity spectrum designations for the area. Constraints in the Idaho Roadless Rule on road construction and timber harvest greatly limits the amount of these activities expected to occur. Therefore, these activities are not expected to increase visitors or facilitate recreational use in these areas.

Alternative X has the highest amount of planned vegetation management activities in terms of planned harvest acres and timber output closely followed by Alternative W. Alternative Z and the No Action Alternative have the lowest amount of planned vegetation management. The Preferred Alternative is third highest. It is, therefore, expected that recreational impacts from vegetation management would be higher in Alternatives W and X than in Alternatives Y and Z and the No Action Alternative. With an increase of harvest activities under the Preferred Alternative, forest visitors can expect to incur increased traffic, noise, visual impacts, and possible increased use of recreation facilities and trails by forest workers.

Timber production is not suitable in developed recreation sites. Timber harvest units may overlap with existing dispersed sites, as well as potential new dispersed sites. Dispersed users may choose to move out of areas during harvest activities and may or may not return post-activity. Hazard tree removal in developed recreation sites to provide for visitor safety may occur even where timber production is not suitable. Dispersed recreation areas typically do not have systematic hazard tree removal.

Aquatic, Riparian and Fish Management

Aquatic plan components may limit new developed and dispersed recreation sites in riparian management zones. New recreation sites and facilities would be located 100 feet from a stream or waterway. However, developed recreation facilities may still be constructed outside of the 100-foot distance or within the 100-foot buffer if they are a water-related site such as a boat ramp. Construction of new developed recreation sites, including considerations for outhouse location and water systems, would need to meet more stringent requirements to ensure these developments are disconnected from the waterways.

Additionally, plan components encourage the mitigation, relocation, or removal of recreation facilities that are currently within riparian management zones if they are degrading aquatic or riparian resources. Dispersed recreation sites within the riparian management zone would be moved, mitigated, or relocated outside of riparian management zones at a rate of two sites per five years. Nearly all developed and dispersed recreation sites within riparian management zones on the Nez Perce-Clearwater are located where people enjoy and choose to be, which is commonly a location associated with water. Removing sites from the riparian management zone and placing them outside of this zone reduces their appeal to many recreationists. Over time, this will put more and more pressure on the remaining recreation sites or user created sites near waterbodies and may increase the ecological effects on these sites.

Objectives to maintain and reconstruct trails will benefit recreational users. Decommissioning of roads may impact recreational use if those roads were used for recreational purposes. Many roads that are decommissioned are overgrown and do not receive regular use for recreation purposes and the impact is expected to be negligible. Alternatives W and X have the most reconstruction and maintenance of roads and would benefit recreationalists the most but also have the highest number of roads that would be decommissioned. Alternatives Y and Z and the Preferred Alternative would reconstruct and maintain fewer miles of roads. Trail reconstruction and maintenance is constant across alternatives and the impacts would not vary.

Hazard trees felled for safety of users retained onsite for aquatics benefits are not likely to have an impact on recreationists.

Wildlife Management

Land Management Plan wildlife management direction affects motorized recreation opportunities. Restrictions that limit types of access and impose seasonal closures during sensitive periods, such as calving, and when animals emerge from dens, can temporarily displace recreationists to other areas. The Nez Perce-Clearwater’s motor vehicle use map limits motor vehicle use to designated routes or areas, yearlong or seasonally, often in response to wildlife and fish considerations.

Recreational benefits from wildlife management could include increased hunter and wildlife viewer satisfaction, as well as angler satisfaction. The effect on recreation from wildlife management is similar for all action alternatives. Road management decisions for wildlife may move recreation use to different areas but is not expected to greatly change use levels across the Forest. Areas identified as suitable or not suitable for motorized recreation will provide different hunting and fishing opportunities to meet a variety of hunting and angling experiences. Wildlife management activities commensurate with these suitabilities can enhance user experiences as well as wildlife habitat conditions.

Plan components require provisions to be included for domestic goat packing. This includes goat packing by outfitters and guides and by recreational and subsistence hunters, as well as for general recreation purposes. Goat packing is an activity that occurs on the Nez Perce-Clearwater. Any provisions that limit the ability of goats to be used for packing activities would negatively impact those recreation uses.

A wildlife multiple use plan component requires closures on roads to be more effective when implementing projects to reduce unauthorized use. Authorized use would not be affected by this plan component. However, if many miles of roads were placed into a closed status for wildlife purposes, recreationists would have fewer areas open to motorized use, which could lead to crowding and other undesirable ecological impacts on the remaining open routes in an area or encroachment into nonmotorized areas.

The wildlife plan components with the potential to impact recreation uses the greatest are the elk wildlife plan components. A plan component restricts authorization of new motorized routes in Management Area 2 if they cannot maintain areas without motorized use that are at least 5,000 acres in size. This plan component may directly limit the ability to meet the recreation opportunity spectrum desired condition of Alternatives W, X, and Y and the Preferred Alternative, and may preclude the ability to authorize new motorized roads or trails, especially those that create loop opportunities in some Idaho Roadless Areas. However, given the large size of many of the roadless areas, it would be possible for new motorized routes to bisect the roadless areas and still meet the guideline.

These plan components would affect where and how much motorized access is available within Management Area 2. However, any trails opened to motorized use in Management Area 2 would represent an increase over current conditions, as the vast majority of Management Area 2 is currently void of such trails. Additionally, these elk plan components are put in place to directly benefit the elk resource by improving habitat with the indirect effect of improving elk populations over time. As elk populations increase, hunter success and opportunity for wildlife viewers would also increase.

Fire Management

Fire Management plan components envision vegetation conditions that would support lessened fire intensity adjacent to communities and infrastructure and reduce negative impacts to values at risk. This would include fuels treatments in areas around locations used under special use permits, recreation rentals, and campgrounds. Fuels management effects on recreation are like effects described under vegetation management. An increase in fire extent, creating a long-lasting change to the setting, could cause a shift in recreational use. The degree of these effects is difficult to determine and is based on the size and intensity of a wildfire event. Prescribed fire has some level of predictability of time, location, and intensity, which may decrease the short-term impacts on visitors. These effects are proportional to the amount of fire management activities being implemented in each alternative. The planned fuels management through prescribed burning varies between alternatives from approximately 6,450 acres per year in Alternative Z to 8,332 in Alternative X. The Preferred Alternative anticipates approximately 6,800 acres per year. Fire suppression actions are also likely to continue and could result in the use of gated roads, as described above. In some cases, roads that are impassible to motor vehicle use due to revegetation or other restrictive condition might be opened to facilitate suppression actions. These roads would probably be used for the duration of the suppression efforts and post-fire work and then returned to their previous status.

Minerals Management

Proposals for exploration and development are driven by external parties and market forces and are regulated by existing mining law. Access through long-term and temporary road development are often associated with mineral exploration and development, but a site-specific analysis is required prior to any approval for exploration or development activities.

If any mine reclamation activities occur, they would likely use existing roads. These might be roads that are not currently designated for motor vehicle use. The roads would probably be used for the duration of the reclamation work and then returned to their previous status.

Recreation could be affected by mineral exploration and extraction in all alternatives. Short-term effects might include noise and visual impacts from exploration, open-pit, or underground mining operations. Over the long-term effects might include increase in the amount and regularity of traffic on primary roads, transition from a more naturally appearing landscape to a more developed landscape that may include new permanent underground or open-pit mines and physical structures; and new roads and road corridors constructed for mining or drilling operations that might change the recreation setting. Depending on the size and other factors of the operation, mining activities effectively reduce or remove recreational opportunities in and proximate to the activities. They can affect hunting, fishing, camping and other nonmotorized and motorized activities to varying degrees.

The potential for oil and gas development on the Nez Perce-Clearwater is low. Mineral facilities could affect visitors, depending on the location of development and the setting affected.

Cultural and Heritage Resources

Management of heritage and cultural resources on the Nez Perce-Clearwater generally benefit recreation activities. The continued existence of cultural resources improves the recreation experience. Routes that are maintained to protect their Natural Register integrity would generally keep routes open to the public but would not lead to increased development. This would keep the recreation experience as it is now and the maintenance level of these routes would not likely increase, even with increased use over time. Adaptive-reuse policies of historic buildings could lead to additional recreational use of these buildings. Routes that impact cultural resources may be rerouted, reconstructed, or decommissioned over time. This could reduce the areas available for both motorized and non-motorized use to some extent. However, existing infrastructure generally has been located to avoid impacts and, thus, are less likely to be causing impacts.

Tribal Trust Responsibilities

The Nez Perce-Clearwater provides a range of high-quality, sustainable recreation opportunities, including four-season use, dispersed and developed facilities and sites, day use and overnight use, motorized and non-motorized use, and guided and independent opportunities. A variety of recreation settings are provided through management area allocations and recreation opportunity spectrum classes that offer a range of summer and winter recreation access and opportunities. Allocation of ROS classes provides access and opportunities for hunting, fishing, gathering, solitude, spiritual quest, and pursuing traditional cultural practices via a variety of motorized and non-motorized roads and trails in a variety of settings from undisturbed, natural conditions to areas where management activities are apparent, human encounters with other forest visitors can be expected, and various amenities are provided in developed and dispersed sites. The spectrum of ROS classes provides for traditional access methods such as hiking and horseback in some locations as well as more modern forms of motorized and mechanized methods in other locations. While ROS is discussed in terms of recreation access and settings, these same principles apply to cultural practices as well and supports the opportunity to engage in the rights granted under the Nez Perce Treaty of 1855.

Livestock Grazing Management

Sights, sounds, and smells associated with livestock grazing may or may not be part of a persons preferred recreation experience. Livestock grazing has occurred on the Nez Perce-Clearwater for as long as or longer than Euro-American recreation use of the land. Most traditional recreational activities are accustomed to livestock grazing in the west and are not impacted to a degree that would reduce recreation or detract from the recreationists experience to any large degree. Livestock grazing remains constant across all action alternatives and is like the grazing levels in the No Action Alternative. Impacts would not vary by alternative.

In grazing management, suitable areas are capable areas minus areas chosen to be unacceptable to graze to minimize conflicts with areas such as campgrounds, other developed recreation sites, research natural areas, fenced rights-of-way, or other areas closed by decision. Therefore, when recreation special uses are within a developed setting, livestock grazing would not cause an effect. However, if the special use permit was granted for areas open to grazing, then participants may encounter cattle, fencing, and water developments.

Air Quality, Rare Plant, and Invasive Species Management

There are no anticipated significant effects from the management direction pertaining to air quality, rare plants, and invasive species. Increased recreational activity may provide increased need and opportunity to inform and educate the public to aid in the prevention of the spread of invasive species.

Designated Areas and Roadless Areas

Designated areas do adjust recreation opportunities depending on the designation. Designated areas are designated by Congress outside of the forest planning process. Designated areas do not vary by alternative. Reduced or curtailed motorized access is often a result of designation.

The Idaho Roadless Rule does not impact recreation activities directly. However, new road construction is generally not permitted within roadless areas, which precludes any road-based recreation in Idaho Roadless Areas. Motorized trails are not precluded from being established, opened, or maintained within Idaho Roadless Areas. Increasing motorized trails in roadless areas would create different recreation settings, opportunities, and expectations of forest visitors. Increased motorized use could affect wildlife movement and behavior thereby affecting the hunting experience.

Recommended Wilderness

Management of recommended wilderness generally promotes recreational use. However, protection of the attributes making these locations recommended wilderness areas may impact recreational experiences over time. For example, special use permits for outfitting or guiding associated with motorized travel might not be permitted as a result of this Land Management Plan. Recreation special uses within recommended wildernesses would need to be aligned with the natural setting and recreational purposes of these areas. Likewise, construction of new developed recreation facilities within recommended wilderness would not be authorized and in many cases replacement of existing facilities may not occur either. Depending on the final decision, areas currently open to motorized or mechanized use may be closed if those areas become recommended wilderness. While this would decrease motorized and mechanized opportunities, it would increase opportunity for solitude and primitive recreation.

Suitable Wild and Scenic Rivers

Management of eligible and suitable wild and scenic rivers potentially promotes recreational use. However, protection of outstandingly remarkable values may impact recreational experiences over time. For example, should it be determined in the future that boating negatively affects harlequin duck nesting and populations, actions to limit boating during sensitive periods would be a possible result of this Land Management Plan. If a developed or dispersed recreation facility along a suitable wild and scenic river is causing fisheries populations to be impacted, those impacts would need to be mitigated to protect the fisheries outstandingly remarkable values which might require removal of the facility.

The dominance of dispersed sites adjacent to waterways may also be influenced by the miles of eligible and suitable wild and scenic rivers in each alternative. In Alternative Z, where the highest number of rivers are found suitable, dispersed site management may increase to ensure retention of the outstandingly remarkable values for which the river was found suitable. Development of facilities along those stretches of river is also likely to be reduced since buildings and structures may not be suitable for these river stretches.

Positive impacts of the protection of outstandingly remarkable values may also occur. Trails and boatable waters are outstandingly remarkable values within the recreation category. In eligible and suitable rivers with these outstandingly remarkable values, these uses would be required to be protected and, thus, would be benefited over time.

New roads would not be constructed in eligible and suitable wild rivers. Roads may be constructed in scenic classified rivers if they only cross the suitable river. Motorized use is generally not acceptable in wild river segments. New trails in wild segments would generally be non-motorized. Recreation facilities would be permitted to be constructed in recreational suitable rivers. Wild rivers would preclude development of large facilities as outlined in plan components, while smaller facilities would be appropriate in scenic classifications.

The rivers found eligible or suitable as wild and scenic rivers varies by alternative. Alternative X finds zero river segments suitable and manages according to the Idaho Department of Water Resources Rivers Plan, which would not impact recreation.

Research Natural Areas

Motorized recreation is not permitted in research natural areas. Proposed research natural areas would be established under all action alternatives. This would reduce the overall number of miles of trails open to motorized use. However, most research natural area were selected, in part, because they do not have conflicts with other resources, including recreational activity.

Cumulative Effects

The analysis area for cumulative effects includes the Nez Perce-Clearwater and adjacent public lands, including the Idaho Panhandle, Bitterroot, Lolo, and Payette National Forests; Bureau of Land Management lands; State of Idaho lands; and public lands within municipal cities and towns within a half days drive, or about 250 miles, of the Nez Perce-Clearwater. These public lands provide a wide range of recreation opportunities in addition to those provided by the Nez Perce-Clearwater. Differences in agency’s missions provide a broad variety of recreation experiences.

Adjacent national forests receive recreation visitors like the Nez Perce-Clearwater. To address the impacts associated with increased visitors, all public land agencies have employed additional recreation management actions or have installed additional facilities to prevent damage to natural and cultural resources. It is expected that recreational uses on national forest lands will continue to increase as more people nationwide continue to look for places to recreate. As more people venture onto public lands, differing societal desires and ideas of the recreation opportunities public lands should provide will continue to influence public land management policy. Coordination with other agencies and organizations to provide recreation opportunities would continue to be necessary to meet public demands.

Within the expected life of the Land Management Plan, the human population growth near, around and interested in the Nez Perce-Clearwater is expected to increase. As the population increases, the demand for a variety of recreation settings, experiences, and opportunities in open, natural space will likely grow. Land-management agencies will continue to provide a variety of recreation opportunities but are not likely to be able to meet all the demand for every activity desired. All alternatives accommodate a mix of recreation opportunities and settings for recreationists. Alternative Z would provide the most non-motorized settings for summer, slightly more than Alternative Y, followed by Alternative W. Alternative W would provide the most non-motorized settings in winter followed by the Preferred Alternative. Alternative X and the Preferred Alternative provide the most motorized opportunity in the summer and Alternatives X and Z provide the most motorized opportunity in the winter.

The expected increased use of utility task vehicles, utility-terrain vehicles, and other off highway vehicles across the cumulative effects area may result in increased conflict among motorized and non-motorized user groups. As use increases, compliance with regulations could become a greater challenge as recreational participants increase in number and compete for space and resources. Idaho Roadless Rule Areas, Management Area 2 under the Land Management Plan, could potentially be the most affected areas as demand for motorized use increases. Potentially affecting areas that currently offer semi-primitive nonmotorized recreation settings that provide solitude, quite recreation, and minimal encounters with, or signs of, other users.

Motorized recreation opportunities that are road dependent have decreased over the decades due to road decommissioning and closures that have occurred primarily to benefit anadromous fisheries. The amount of non-motorized recreation opportunities has increased with these changes and the amount of motorized or road-related recreation opportunities has decreased across the Nez Perce-Clearwater. The preferred alternative reduces the area suitable for motorized over-snow vehicle use approximately three percent.

Areas currently available for motorized over-snow vehicle use has decreased primarily because of the Clearwater Travel Plan. Previous areas available to motorized over-snow vehicle use, especially in the Hoodoo (Great Burn) area, are no longer available resulting in a greater concentration of motorized over-snow vehicle use on the remaining areas open to this activity, as well as displacing motorized over-snow vehicle users beyond the Nez Perce-Clearwater. Much of the over-snow motorized use comes from Montana, especially from the counties of Missoula, Ravalli, and Superior. As these populations continue to increase, there will be more and more pressure for these activities on public lands. Other national forests in and available from the recreation region of comparison have closures that limit areas available for winter motorized use. Collectively, this leads to increased demand on those areas open that could lead to overcrowding, changes in the recreation setting, and encroachment into nonmotorized areas. The preferred alternative reduces the area suitable for motorized over-snow vehicle use approximately 3 percent. However, strong consideration was given to areas that provide desirable conditions and are popular with over-snow while delineating suitable and not suitable areas. Therefore, while the total suitable area is reduced, the majority of the suitable motorized over-snow vehicle use area provides appropriate physiological conditions and are currently popular with these recreationists.

Conclusion

Sustainable nature-based recreation is a key component of the resources and values provided by the Nez Perce-Clearwater. However, things are changing. The number of recreationists coming to the Forest is increasing, the types of recreational activities and the technology to pursue them is ever changing, visitor expectations change, and ecological conditions are changing. In light of all of this, understanding and managing the effects from other resource management on recreation settings and opportunities, and the effects on other resources and their management from management of sustainable recreation is a complex management responsibility. Application of Land Management Plan components serves to meet the plethora of resource goals and objectives in the Plan. Thereby moving the Forest toward desired conditions for the full array of resources and values, ensuring that recreation opportunities are ecologically, economically, and socially sustainable for present and future generations.

The allocation of recreation opportunity spectrum classes is primary in this effort. The recreation opportunity spectrum classifications vary by alternative (Table 326) per the intent of the 2012 Planning Rule. All the revised plan alternatives would establish guidance and desired recreation opportunity spectrum classes for both summer and winter recreation settings and set expectations for the recreation settings on the Nez Perce-Clearwater. Desired recreation opportunity spectrum classes would aid in managing both existing and emerging recreation uses. Establishing clear expectations and identifying a spectrum of settings for recreation users is important to the long-term sustainable management of recreation use on the Nez Perce-Clearwater. Travel plans, when implemented, would continue to provide the site-specific direction where motorized uses can and cannot occur.

Table 326. Acres of sustainable recreation and access by indicator and alternative (Alt)

Measurement Indicator	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Motorized Access Suitability	2,403,316	1,846,585	2,270,448	1,729,937	1,660,349	2,161,917
Non-Motorized Access Suitability	1,535,850	2,092,581	1,668,718	2,209,229	2,278,817	1,777,249
Winter Over-Snow Motorized Access Suitability	2,481,670	1,903,114	2,760,060	2,450,733	2,760,053	2,369,176

Data Source: Nez Perce-Clearwater GIS data.

3.4.3 Scenery

Scenery provides an important sense-of-place backdrop, setting, and character-defining element that can be valued and enjoyed by both forest visitors and people in adjacent communities. While many of the benefits of the Nez Perce-Clearwater scenery are intangible, there are very real and quantifiable economic benefits that contribute to local economies and communities. For example, outfitter and guide services associated with the many rivers across the Nez Perce-Clearwater are dependent on the aesthetics of these unique waterways.

The spectacular scenery found on the Nez Perce-Clearwater varies from deep river canyons to high mountain peaks. These scenic backdrops bring local, regional, national, and even a few international visitors to the area to enjoy the Nez Perce-Clearwater. National visitor use monitoring data (U.S. Department of Agriculture 2018g) indicates that the top five most common activities on the Nez Perce-Clearwater are hiking and walking, viewing natural features, relaxing, driving for pleasure, and viewing wildlife. All of these include scenery as an integral part of their appeal; an appeal that would likely be diminished if the scenery were to be dramatically altered.

Relevant Laws, Regulations, and Policy

Federal Laws

National Environmental Policy Act of 1969 (Pub. L. 91-190, 42 U.S.C. 4321-4347, January 1, 1970): This act directs the federal government to "… (2) assure for all Americans…healthful, productive, and aesthetically and culturally pleasing surroundings; … [and] (4) preserve important historic, cultural, and natural aspects" of our environment. It further directs agencies to "ensure the integrated use of the natural and social sciences and the environmental design arts in planning and in decision making which may have an impact on man's environment." The act directs agencies to develop methods and procedures "which will insure that [scenery and other] unqualified environmental amenities and values may be given appropriate consideration in decision making along with economic and technical considerations."

Wild and Scenic Rivers Act of 1968 (Pub. L. 94-588, 16 U.S.C. 1600, October 22, 1976): This act declares that certain selected rivers, with their immediate environments, that possess outstandingly remarkable scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values shall be preserved in free-flowing condition, and that they and their immediate environments shall be protected for the benefit and enjoyment of present and future generations.

National Forest Management Act of 1976 (Pub. L. 94-588, 16 U.S.C. 1600, October 22, 1976): This act states that aesthetics will be considered for all multiuse planning. "Sec. 6 (3) F … (ii) the interdisciplinary review as determined by the Secretary has been completed and the potential environmental, biological, esthetic, engineering, and economic impacts on each advertised sale area have been assessed, as well as the consistency of the sale with the multiple use of the general area; (iii) cut blocks, patches, or strips are shaped and blended to the extent practicable with the natural terrain; … [and] (v) such cuts are carried out in a manner consistent with the protection of soil, watershed, fish, wildlife, recreation, and esthetic resources, and the regeneration of the timber resource."

Regulation

Title 36 of the Code of Federal Regulations (CFR), Part 219 - Planning, Subpart A—National Forest System Land Management Planning (36 CFR part 219, subpart A): This regulation establishes the planning requirements for developing, amending, and revising land management plans for units of the National Forest System as required by the National Forest and Rangeland Renewable Resources Planning Act of 1974. Section 219.8 (b)(2) directs that the Plan must include Plan components to guide the Nez Perce-Clearwater National Forest's contribution to social and economic sustainability, considering sustainable recreation; including recreation settings, opportunities, and access; and scenic character. Section 219.10(a)(1) further requires that the Plan must provide for ecosystem services and multiple uses, including outdoor recreation, range, timber watershed, wildlife, and fish. When developing plan components for integrated resource management, that the responsible official must consider: "Aesthetic values, air quality, cultural and heritage resources, ecosystem services, fish and wildlife species, forage, geologic features, grazing and rangelands, habitat and habitat connectivity, recreation settings and opportunities, riparian areas, scenery, soil, surface and subsurface water quality, timber, trails, vegetation, viewsheds, wilderness, and other relevant resources and uses."

Taken together, these requirements direct the Forest Service to take into account the contribution of National Forest scenic resources to the social and economic sustainability of the National Forest System.

Forest Service Manual 2380: This manual outlines Forest Service policy and direction for the management of scenic resources. Section 2380.3 describes Forest Service policy with regard to scenic resources. The four components of the policy are listed below:

- Inventory, evaluate, manage, and, where necessary, restore scenery as a fully integrated part of the ecosystems of National Forest System lands and of the land and resource management and planning process.
- Employ a systematic, interdisciplinary approach to scenery management to ensure the integrated use of the natural and social sciences and environmental design.
- Ensure scenery is treated equally with other resources.
- Apply scenery management principles routinely in all National Forest System activities.

Forest Service Manual Section 2380.31: This manual requires the use of the basic concepts, elements, principles, and variables defined in the (U.S. Department of Agriculture 1995b)

Direction

Agriculture Handbook 701 – Landscape Aesthetics: A Handbook for Scenery Management (U.S. Department of Agriculture 1995b), referred to as the Scenery Management System: The goal of the scenery management system is to create and maintain landscapes having high scenic diversity, harmony, and unity. The scenery management system provides a systematic approach for inventorying, analyzing, and determining the relative value and importance of National Forest scenery. The system guides establishment of scenic character, originally referred to as landscape character, and scenic integrity goals and objectives for landscape and project planning, implementation, and monitoring. It recognizes that the landscape and scenery are dynamic and the application of scenic integrity objectives does not relate to a static scenic character description but to a description that considers dynamic and changing landscape processes. It recognizes the value of a natural-appearing National Forest landscape, and the relationship of human-introduced visual elements in that landscape.

Forest Service Handbooks: provide guidance for the management of scenic resources. While the associated Volume 1 has been replaced by the Scenery Management System, the resource specific portions associated with U.S. Department of Agriculture, Forest Service, National Forest Landscape Management, Volume 2 (U.S. Department of Agriculture 1974c) are still valuable and applicable in many cases:

- Chapter 2 – Utilities Agriculture Handbook 478
- Chapter 4 – Roads Agriculture Handbook 483
- Chapter 5 – Timber Agriculture Handbook 559
- Chapter 6 – Fire Agriculture Handbook 608 (U.S. Department of Agriculture 1985)
- Chapter 8 – Recreation Agriculture Handbook 666

State and Local Plans: There are no specific state or local plans that pertain to scenery management but the Idaho Statewide Comprehensive Outdoor Recreation Plan (Idaho Department of Parks and Recreation 2018) does recognize the importance of scenery for the recreating public. With more than 33.5 million acres, nearly 65 percent of land in Idaho is federally owned. Therefore, the federal government is an essential provider of outdoor recreation in Idaho and offers opportunities and experiences that are not provided by local or state governments. These lands include some of Idaho's most iconic rivers, mountains, and landscapes. Across Idaho, federal agencies manage forests, deserts, reservoirs, waterways, and wildlife habitats that are critical to the state's outdoor recreation opportunities (Idaho Department of Parks and Recreation 2018).

Methodology

Spatial Scale

The spatial boundary for the indirect and cumulative effects analysis area encompasses lands within the Nez Perce-Clearwater National Forests administrative boundary, as well as areas outside of the Nez Perce-Clearwater boundary that contain critical travelways and use areas from which the Nez Perce-Clearwater is viewed. This extension encompasses ten miles beyond the administrative boundary. Areas outside of the Nez Perce-Clearwater boundary would include selected sections of federal and state highways, communities, and use areas that are considered critical viewing areas for the Nez Perce-Clearwater. Areas were chosen that meet the criteria listed in the Scenery Management System Handbook (U.S. Department of Agriculture 1995b). Maps of the concern level viewing platforms are included in the project record.

Temporal Scale

The duration of effects on scenic quality varies depending on aspect, elevation, soil conditions, and the dominant species of vegetation found in the area where management activities occur. In most cases, management activities within the planning area up to 30 years to return to a point where past harvest activities are no longer dominant. This temporal scale closely matches the anticipated life of the plan.

Past, Present, and Future Activities used in the Analysis

As part of the assessment, past harvest activities were reviewed. Past harvest primarily occurred on approximately one third of the Nez Perce-Clearwater, an area referred to as the managed front. Limited harvest occurred on what is now identified as Idaho Roadless Rule areas. This information was used to inform the existing condition mapping. Activities outside of the Nez Perce-Clearwater boundary include management activities on other federal, state, and private land ownership adjacent to the Nez Perce-Clearwater. These areas are expected to continue to be managed primarily for timber and agricultural resources. This will have the greatest effect in areas where there is intermingled ownership. Critical viewsheds, such as U.S. Highway 12 and U.S. Highway 95, are within areas where intermingled ownership is most prevalent.

Methods and Assumptions

This analysis will focus on three main components of managing the scenery resource. First, determining the existing scenic integrity and scenic character across the Nez Perce-Clearwater. Second, determining the desired condition of scenery in the future, measured by desired scenic character descriptions. Third, determining the potential effects of the proposed alternatives on the desired scenic character. This analysis reviews the alternatives in the context of the desired condition of scenic character and scenic integrity objectives.

Agriculture Handbook 701, the Scenery Management System (U.S. Department of Agriculture 1995b), describes the process and methodology for inventorying, assessing, and describing the scenery resource. This process outlines the steps to establish both the scenery resource measure and the scenery resource indicator; scenic character was set as a scenery resource measure and scenic integrity objectives were created as a scenery resource indicator. Scenic character descriptions for both the existing condition as well as the desired condition were developed for identified zones across the Nez Perce-Clearwater and are outlined in the Land Management Plan's Appendix 7 and spatially displayed within the maps found in Appendix A. Agriculture Handbook 701, the Scenery Management System (U.S. Department of Agriculture 1995b) also describes the process to determine and map scenic integrity objectives. Appendix J outlines the steps taken during the scenery management system inventory process and the scenic integrity objectives are displayed spatially within the maps found in Appendix A.

The scenic integrity objectives proposed for each alternative assume that vegetation would continue to evolve and be affected by various factors, such as fire, insects, drought, and disease. An assumption is also made that the wildland urban interface areas would continue to expand and become more developed. This may increase both the need to address fuel build-up around properties of other ownership, as well as pressure to protect aesthetics associated with landowners' sense of place.

The following figures illustrate examples of each of the scenic integrity objectives found in the plan area. Figure 135 shows an example of a very high scenic integrity level where there are only minute, if any, deviations from the scenic character. This image shows the northside of Gedney Mountain from below the summit of the peak. This location is within the Selway Bitterroot designated wilderness.

Figure 135. Example of location with very high scenic integrity.

Figure 136 shows an example of a location with a high scenic integrity level where deviations are not evident and do not dominate the scenic character. This photo is along U.S. Highway 12 near Syringa, Idaho, where a fuels reduction project occurred adjacent to the travelway, which is a high concern level travelway due to designation as a Scenic Byway and adjacency to a designated wild and scenic river.

Figure 136. Example of a location with high scenic integrity.

Figure 137 provides an example of existing moderate scenic integrity level where the landscape appears slightly altered and deviations remain visually subordinate to the scenic character. This image shows a past timber harvest near Little Boulder Campground on the Palouse Ranger District near Helmer, Idaho. Harvest occurred in both the foreground and middle ground viewshed.

Figure 137. Example of a location with moderate scenic integrity.

Figure 138 shows an example of existing low scenic integrity where the landscape appears altered, and deviations begin to dominate the scenic character. This photo was taken at Dixie Summit near Dixie, Idaho. Multiple timber harvest units are visible in the middle ground.

Figure 138. Example of a location with low scenic integrity.

Measurement Indicators

The key indicator for analyzing alternatives for this land management plan are the scenic integrity objectives, as displayed in the maps and tables for each alternative found in Appendix A. Scenic integrity objectives indicate a minimum threshold of intactness of the desired scenic character. Management activity induced modifications are analyzed in terms of changes in line, form, color, texture, opening pattern, harmony, size, and scale from the existing natural scenic character during project-level analysis.

This indicator is described in the Scenery Management System Handbook (U.S. Department of Agriculture 1995b). The methodology for analyzing this indicator is also described in this handbook and can be applied using the tools described in the handbook.

Affected Environment

Existing Condition

Scenic Character

The affected environment for the scenery resource is partly portrayed by a description of the scenic character. The 2012 Planning Rule defines scenic character as:

a combination of the physical, biological, and cultural images that gives an area its scenic identity and contributes to its sense of place. Scenic character provides a frame of reference from which to determine scenic attractiveness and to measure scenic integrity.

The landscape of the Nez Perce-Clearwater begins in the jagged peaks of the Bitterroot Mountains and flows to the deep canyons of the Salmon, Selway, Lochsa, and Clearwater Rivers. Broad coniferous forests cover the mountains that stretch from the rolling hills of the Palouse Plateau to the Camas Prairie. Across the Nez Perce-Clearwater, nature provides an extraordinary scenic backdrop for recreationists whether they are on foot, on a motorized trail vehicle, or in a car. Visitors can travel extensive scenic byways, follow ancient routes across the mountains, or enjoy recreation opportunities in natural surroundings.

Among the many discrete places that people recreate on the Nez Perce-Clearwater, four broad zones are described in this Land Management Plan to group the diverse scenic settings found on the Nez Perce-Clearwater. They include the: Palouse, North Fork, Middle Fork, and South Fork. A detailed description of scenic character by these zones is found in the Land Management Plan's Appendix 7.

Inherent Scenic Attractiveness

Inherent scenic attractiveness is a classification of visually unique or distinctive scenery. Inherent scenic attractiveness generally does not change over time, even when events, such as stand replacing fires, may change the scenic character in the short-term or roads, mines, or timber harvests lower the scenic integrity. Landscapes with distinctive characteristics of landforms, river features, and vegetation are generally considered more attractive than those with commonly found vegetative patterns, river features, and landforms. The uniqueness; variety, including seasonal variety; and vividness of these landscape features, especially related to their line, form, color, and textures, are measures for determining the scenic attractiveness. Cultural features, such as historic structures, including those associated with management activities like mining, can also be considered part of the scenic attractiveness. Distinctive landscapes include areas of unusual visual attributes of vividness and patterns and unique or outstanding variety of rock, water, topography, and vegetation forms. Common landscapes include areas that provide positive yet typical vividness and patterns of rock, water, topography, and vegetation that are found throughout the Nez Perce-Clearwater. Indistinctive landscapes are areas with little to no visual variety and uniqueness or vividness in rock, water, topographic, or vegetative forms. A summary of acres and percent of area which falls under each scenic attractiveness class is provided in Table 327. Inherent scenic attractiveness is mapped and can be found in Appendix A.

Table 327. Acres and percent of plan area which falls under each scenic attractiveness class

Classification	Acres	Percent
A-Distinctive	194,347	5%
B-Common	3,739,454	95%
C-Indistinctive	352	<1%

Data Source: Nez Perce-Clearwater GIS and Scenery Management System Handbook model inputs.

Existing Visual Quality Objectives and Scenic Integrity

Existing scenic integrity refers to the current condition of the scenery as it has been influenced or changed by human modifications or constructed features, such as roads, mines, or timber harvest, that are generally considered incongruent with the scenic character of the landscape. Existing scenic integrity indicates the degree of intactness and wholeness of the scenic character, or conversely, it measures the degree of visible disruption.

The current condition of the scenic character varies across the Nez Perce-Clearwater. Past harvest completed across the Nez Perce-Clearwater was informed by the Visual Quality Objective standards expressed in the 1987 Clearwater and Nez Perce National Forest Land Management Plans. Each of these plans outlined the travelways of concern and determined appropriate visual quality objectives given that concern. Large portions of the Nez Perce-Clearwater contain naturally evolving landscapes where the scenery reveals the biophysical features and processes that occur in this geographic area with very limited human intervention. These areas include all the designated wilderness areas, research natural areas, and several large expansive roadless areas that were designated and recommended as wilderness. Broad natural landscapes, such as the viewshed of the Lolo Trail National Historic Landmark and Pilot Knob, have been managed to maintain the Visual

Quality Objectives laid out in the 1987 Forest Plans and appear, for the most part, to have a natural appearing character at this time. There are areas of private land intermingled on both the eastern and western termini of the Lolo Trail that do have very apparent man-made activities but most of the central portion of the trail appears natural.

Within the roaded portion of the Nez Perce-Clearwater, there is evidence of human habitation and management. Some of these areas have openings that appear natural, while others have openings that are obviously created by humans. These openings, while obvious, do not generally dominate the natural character of the landscape. They appear in background views or are minor components of the foreground and middleground views from critical travelways or recreation areas.

Some isolated areas have human impacts that dominate the landscape to the point that they do not meet the Visual Quality Objectives listed in the 1987 Forest Plans. These areas should be improved through landscape restoration efforts. These areas are very limited and generally contain activities, such as rock quarries, that will be rehabilitated when they are no longer needed.

The most recent comprehensive assessment of the existing scenic integrity for the Nez Perce-Clearwater was done at a coarse scale for the entire Forest Service Northern Region in 2010. It was an entirely geographic information system generated product with no ground verification and used available data from key observation travel routes and points that have not been verified on the ground. The resulting product rated the existing scenic integrity of the scenery on National Forest System lands into one of five levels: very high, high, moderate, low, and unacceptably low. A review by the Nez Perce-Clearwater landscape architect and other members of the Nez Perce-Clearwater team of specialists familiar with the landscape indicates that the results of this product may not represent the actual existing condition. Many of the obvious disruptions that resulted in low or unacceptably low scenic integrity have now, ten years later, improved through vegetation regrowth over time.

Environmental Consequences

Effects Common to All Alternatives

The distribution of the scenic integrity objectives in the revised plan alternatives reflects a range in the priorities across the Nez Perce-Clearwater. The priorities range from viewsheds where managing and maintaining the scenic integrity is most important to areas where achieving other goals or meeting other resource needs may be a higher priority.

The scenic integrity objectives and the desired scenic character descriptions proposed in the revised plan alternatives, would provide management direction for all new activities that modify the landscape, including installation of roads and facilities and vegetation management activities, such as incorporating fuel reduction burns and timber harvests. Installed facilities might include such items as utility lines, mining facilities, administrative facilities, and recreation facilities.

Assigned scenic integrity objectives and desired scenic character related to scenery management would serve to maintain and manage the scenic resource in a sustainable way that reflects the value, importance, viewing context, and dynamic nature of vegetation over time across the Nez Perce-Clearwater. The scenic integrity objectives and desired scenic character would not directly prohibit any on-the-ground project work but would influence the design and location of projects to meet or exceed the minimum levels of scenic integrity.

Effects to No Action Alternative

Indirect Effects

Under the No Action Alternative, the current forest plans would still apply to management activities occurring on the Nez Perce-Clearwater. Both the Nez Perce and Clearwater National Forest Plans were developed using the processes described in the Forest Service Visual Management System Handbook (U.S. Department of Agriculture 1974c, b). In that planning process, all National Forest System lands within the planning area were assigned visual quality objectives based on those inventory methods. In general, both the Nez Perce and Clearwater National Forest Plans were relatively consistent in how the process was applied. The only difference between the plans with respect to the process was that individual travelways and their associated concern levels were not specifically included in the Nez Perce National Forest Plan. Therefore, if the No Action Alternative is selected, the two Forests' approaches to scenery management would continue to be inconsistent, complicating scenery management on the Nez Perce-Clearwater. The use of outdated terminology would also continue, as the forest plans that would apply date back to 1987 and the Scenery Management System was implemented in 1995. Visual quality objectives for critical travelways, use areas, and administrative sites would continue to be considered during the planning process for any proposed management activity. Newer computer techniques would continue to be used that allow more accurate analysis of seen areas and distance zones so that newer methodology would continue. Table 328 contains the current Nez Perce and Clearwater National Forest Plan visual quality objectives with definitions, acres, and a crosswalk to the scenery management system terminology.

Table 328. Current Nez Perce and Clearwater National Forest Plans visual quality objectives with definitions, acres, and the comparable scenery management system terminology

Visual Quality Objectives	Total Acres for Nez Perce and Clearwater National Forest Lands in 1987	Crosswalk to comparable Scenery Management System Scenic Integrity Objectives
Preservation: Only ecological changes are allowed to alter the natural landscape.	1,135,433 acres—30% of the Nez Perce-Clearwater National Forests in 1987. This applies to designated wilderness.	Very High: Scenic character is intact with only minute if any deviations.
Retention: Human activities are not evident to the casual forest visitor.	440,396 acres—12% of the Nez Perce-Clearwater National Forests in 1987. This applies, in general, to areas with high concern for scenery, such as the Lolo Trail, designated wild and scenic rivers, and developed recreation sites.	High: Deviations are not evident and do not dominate the scenic character.
Partial Retention: Human activities may be evident but must remain subordinate to the characteristic landscape.	406,867 acres—11% of the Nez Perce-Clearwater National Forests in 1987.	Moderate: Appears slightly altered. Deviations must remain visually subordinate to the scenic character.
Modification: Human activity may dominate the characteristic landscape but must, at the same time, utilize naturally established form, line, color, and texture. It should appear as a natural occurrence when viewed in the middleground and background.	902,532 acres—24% of the Nez Perce-Clearwater National Forests in 1987.	Low: Appears altered. Deviations begin to dominate the scenic character.

Visual Quality Objectives	Total Acres for Nez Perce and Clearwater National Forest Lands in 1987	Crosswalk to comparable Scenery Management System Scenic Integrity Objectives
Maximum Modification: Human activity may dominate the characteristic landscape but should appear as natural when viewed as background.	838,157 acres—23% of the Nez Perce-Clearwater National Forests in 1987.	Very Low: Appear heavily altered. Deviations may strongly dominate.

Data Source: Nez Perce-Clearwater GIS data and Scenery Management System Handbook direction.

Effects Common to All Action Alternatives

The scenic integrity objective within Management Area 1—Wilderness, Wild and Scenic Rivers, and National Historic Landmark Areas—remains similar across alternatives; however, there is a four percent reduction in acres with a very high scenic integrity objective within this management area due to the placement of portions of the Middle Fork Clearwater Wild and Scenic River and the Lolo Trail National Historic Landmark in the High scenic integrity objective category due to the presence of associated infrastructure. Under the action alternatives, Management Area 1 acres are assigned scenic integrity objectives of Very High. Similarly, the Preferred Alternative acreages within Management Area 1 are assigned scenic integrity objectives of Very High (94 percent) or High (6 percent).

Scenic integrity objectives within Management Area 2—Backcountry—are based on a combination of the scenic classes and motorized versus non-motorized recreation opportunity spectrum classes. Management Area 2 includes recommended wilderness areas, suitable and eligible wild and scenic rivers, Idaho roadless rule areas, research natural areas, and parts of the Gospel Hump Geographic Area. The range of scenic integrity objectives is from Very High to Low. The land allocations within this management area include restrictions and opportunities for management actions based on the desired conditions, which would be overlain by the scenic integrity objectives minimum levels of intact scenic character. In all of these areas excluding Research Natural Areas, timber harvest and fuels reduction burning would be suitable across the Nez Perce-Clearwater. If designed well, these management actions could meet the assigned scenic integrity objectives of all acres within this management area.

The range of scenic integrity objectives is also Very High to Low in the front country found within Management Area 3, with over 99 percent being in the Moderate and Low categories. Unlike Management Area 2, the motorized versus non-motorized recreation opportunity spectrum classes do not vary as much across the alternatives within Management Area 3. As a result, the overlay of the recreation opportunity spectrum classes with the scenic classes results in a more consistent split of acres into Very High, High, Moderate, and Low. The percentage differences between High, Moderate, and Low scenic integrity objectives across the alternatives is less than one percent. In all action alternatives, there is less than 1 percent Very High and High, 56 to 78 percent Moderate, and 21 to 44 percent Low.

In each of the discussions of the specific alternatives, two tables are used to show the acreage and percentage differences of the scenic integrity objectives across all management areas. The second table also depicts each management area. Combined, these two tables indicate that the scenic integrity objective acreage variations occur primarily within Management Area 2. This management area is where differing acres of recommended wilderness, suitable wild and scenic rivers, and motorized suitability within these land allocations appear within the recreation opportunity spectrum classes.

Effects that Vary by Action Alternative

The Preferred Alternative

The Preferred Alternative proposes more acres as recommended wilderness than the No Action Alternative and Alternative X but less than Alternatives W, Y, and Z, with 258,210 acres. These areas, in addition to the 1,135,433 acres of designated wilderness, would account for about 1.4 million acres where management actions would maintain either the designated wilderness character or, for the recommended areas, characteristics that maintain opportunities for inclusion in the National Wilderness Preservation System. For areas outside of these land allocations, forest vegetation management actions are proposed to focus on increasing the rate of change towards desired conditions within 30 years. These actions would include timber harvest and fuels management activities. The Preferred Alternative also proposes ten suitable wild and scenic rivers and two eligible wild and scenic rivers where management activity opportunities and tools would be based on the specific river segment's classification, but the focus would likely be on natural processes.

Indirect Effects

The Preferred Alternative has fewer acres of recommended wilderness than Alternatives W, Y, and Z and, therefore, this alternative has fewer acres with a High scenic integrity objective. Under this alternative, there is a slight reduction in the number of acres with a Very High scenery integrity objective in Management Area 1 compared to all other alternatives. This is due to portions of the Middle Fork of the Clearwater Wild and Scenic River and the Lolo National Historic Trail having infrastructure, such as U.S. Highway 12 and the Lolo motorway, that precludes it from obtaining a very high scenic integrity objective. The other action alternatives categorize these lands in a very high category with the aim of consistency across Management Area 1 lands. The Preferred Alternative, with 1,763,316 acres with a moderate scenic integrity objective, has the second most acres in this scenic integrity objective category, behind Alternative X. The acres with a low scenic integrity objective in this alternative are very similar to the other action alternatives, varying by no more than one percent.

Scenic integrity objectives (SIO) would be assigned across Nez Perce-Clearwater by overlaying the scenic classes of the Nez Perce-Clearwater with the management area information and recreation opportunity spectrum information to relate the scenery resource to other resources across the Nez Perce-Clearwater. Acres and percent of the plan area which falls under each SIO under this alternative is provided in Table 329. Table 330 includes the percent of each management area falling within each SIO. The locations of the scenic integrity objectives across the Nez Perce-Clearwater are displayed on the Preferred Alternative map in Appendix A.

Table 329. Scenic integrity objectives (SIO) by acre and percent of the plan area, under the Preferred Alternative

SIO	Acres	Percent of Plan Area
Very High	1,179,117	30%
High	472,631	12%
Moderate	1,763,316	45%
Low	523,992	13%

Data Source: Nez Perce-Clearwater GIS data.

Table 330. Scenic integrity objectives (SIO) by percent of management area, under the Preferred Alternative

SIO	Management Area 1	Management Area 2	Management Area 3
Very High	94%	1%	<1%
High	6%	20%	<1%
Moderate	<1%	79%	56%
Low	0%	<1%	44%

Data Source: Nez Perce-Clearwater GIS data.

Alternative W

Alternative W proposes the largest number of acres as recommended wilderness, approximately 856,932 acres. These areas, in addition to the 1,135,433 acres of designated wilderness, would account for about 2 million acres where management actions would maintain either the designated wilderness character or, for the recommended areas, characteristics that maintain opportunities for inclusion in the National Wilderness Preservation System. For areas outside of these land allocations, forest vegetation management actions are proposed to focus on increasing the rate of change towards desired conditions within 30 years. These actions would include timber harvest and fuels management activities. This alternative also proposes 12 suitable wild and scenic rivers where management activity opportunities and tools would be based on the specific river segment's classification, but the focus would likely be on natural processes.

Indirect Effects

The number of acres of recommended wilderness increase the acres of High scenic integrity objective within this alternative compared to the Preferred Alternative and Alternative X and reduce the number of acres of Moderate scenic integrity objective acres. The acres of High and Moderate in this alternative, compared to Alternatives Y and Z, are more similar. The three alternatives are within one percentage of each other for both of these scenic integrity objectives. The difference is related to the suitability of motorized use in those Idaho Roadless Rule backcountry theme areas not proposed as recommended wilderness. In Alternative W, those areas are suitable for motorized use. In Alternative Y, some areas are found suitable to accommodate loop opportunities in some of these backcountry theme areas. In Alternative Z, motorized use is not suitable. As a result, Alternative W's and Y's High and Moderate acres are almost identical, with the High acres being about 14 percent and the Moderate acres being about 41 percent. This High percent is slightly less than that in Alternative Z and the Moderate percent is slightly more than in Alternative Z. The percent of Low scenic integrity objective acres is less than 1 percent difference across all alternatives, at about 13 percent.

Scenic integrity objectives would be assigned across Nez Perce-Clearwater. Acres and percent of the plan area which falls under each SIO under this alternative is provided in Table 331. Table 332 includes the percent of each management area falling within each SIO. The locations of the scenic integrity objectives across the Nez Perce-Clearwater are displayed on the Alternative W map in Appendix A.

Table 331. Scenic integrity objectives (SIO) by acre and percent of the plan area, under Alternative W

SIO	Acres	Percent
Very High	1,253,457	32%
High	548,717	14%

SIO	Acres	Percent
Moderate	1,607,192	41%
Low	529,690	13%

Data Source: Nez Perce-Clearwater GIS data.

Table 332. Scenic integrity objectives (SIO) by percent of each management area, under Alternative W

SIO	Management Area 1	Management Area 2	Management Area 3
Very High	100%	1%	<1%
High	0%	45%	<1%
Moderate	0%	53%	69%
Low	0%	<1%	31%

Data Source: Nez Perce-Clearwater GIS data.

Alternative X

Alternative X has no proposed recommended wilderness areas or suitable wild and scenic rivers. The highest number of acres are suitable for motorized access under this alternative. Timber outputs in this alternative are expected to be the highest of all alternatives. The timeline for meeting desired conditions for forest vegetation is 20 years, indicating likely higher timber harvests, as well as the largest number of acres of planned ignition burning of all alternatives.

Indirect Effects

Across the Nez Perce-Clearwater, this short duration of time before the desired vegetation conditions are met may increase the visibility of management actions due to short periods of regrowth between actions but may also make the scenery more stable because ecological conditions will be within the historic range of variability across the Nez Perce-Clearwater sooner.

Given that Alternative X has no acres of recommended wilderness or suitable or eligible wild and scenic rivers, as well as the highest amount of recreation opportunity spectrum motorized suitable class acres, this alternative would have the lowest percentage of High scenic integrity objective acres of the five alternatives. This leads to the highest percentage of Moderate scenic integrity objective acres of all alternatives. 75 percent of the Management Area 2 lands within this alternative are within the Moderate scenic integrity objective, while the other alternatives have between 53 and 79 percent. The amount of Low scenic integrity objective acres in this alternative is about the same across all the alternatives because this scenic integrity objective is predominantly found within Management Area 3 land allocations and motorized suitable recreation opportunity spectrum classes, which vary less across alternatives.

Scenic integrity objectives would be assigned across Nez Perce-Clearwater. Acres and percent of the plan area which falls under each SIO under this alternative is provided in Table 333. Table 334 includes the percent of each management area falling within each SIO. The locations of the scenic integrity objectives across the Nez Perce-Clearwater are displayed on the Alternative X map in Appendix A.

Table 333. Scenic integrity objectives (SIO) by acre and percentage across the Nez Perce-Clearwater in Alternative X

SIO	Acres	Percent
Very High	1,253,456	32%

SIO	Acres	Percent
High	322,701	8%
Moderate	1,833,200	47%
Low	529,699	13%

Data Source: Nez Perce-Clearwater GIS data.

Table 334. Scenic integrity objectives (SIO) by percentage of each management area across the Nez Perce-Clearwater in Alternative X

SIO	Management Area 1	Management Area 2	Management Area 3
Very High	100%	1%	0%
High	<1%	23%	<1%
Moderate	<1%	75%	78%
Low	0%	<1%	21%

Data Source: Nez Perce-Clearwater GIS data.

Alternative Y

Alternative Y has an intermediate level of eligible wild and scenic rivers and recommended wilderness acres. Management of vegetation outside of wilderness and recommended wilderness would be completed over a longer period than Alternatives W and X and the Preferred Alternative and shorter than Alternative Z. This alternative would move the Nez Perce-Clearwater towards the desired forest vegetation conditions in about 50 years. The amount of timber harvest and planned ignition burning acres under this alternative is also less than that of Alternatives W and X and the Preferred Alternative but more than Alternative Z. Historic areas of snowmobile use in the Great Burn Recommended Wilderness Area will be removed from the recommended wilderness land allocation, but the remainder of this area would be recommended wilderness. Fourteen rivers are found to be suitable wild and scenic rivers under this alternative.

Indirect Effects

Under this alternative, language to not renew the communication site within the Pilot Knob Geographic Area could affect the existing scenic composition of this portion of the Nez Perce-Clearwater by reducing the appearance of contrasting man-made environmental structures at this site.

The moderate number of acres of recommended wilderness and suitable wild and scenic rivers increases the acres of High scenic integrity objective within this alternative compared to Alternative X and the Preferred Alternative and reduce the number of acres of Moderate scenic integrity objective acres. The acres of High and Moderate in this alternative compared to Alternatives W and Z and the Preferred Alternative are more similar. The three alternatives are within three percentage of each other for High and four Moderate scenic integrity objectives. The difference is related to the suitability of motorized use in those Idaho Roadless Rule backcountry theme areas not proposed as recommended wilderness. Under this alternative, some portions of those areas are suitable for motorized use to create loops within the backcountry theme areas, but the remaining portions of the Idaho Roadless Rule areas are not suitable for motorized use. Therefore, there are slightly more High scenic integrity objective acres in this alternative compared to Alternative W, less than one percent, and two percent less than the Preferred Alternative. There is less High scenic integrity objective acreage in this alternative compared to Alternative Z, which finds motorized use not suitable in these Idaho Roadless Rule areas. As a result, Alternative W and Y are very close in High and Moderate acres, with the High being about 14 percent and the Moderate being about 41 percent for both alternatives. This percent of High is slightly less than that in Alternative Z and the Moderate percent is slightly more than in Alternative Z. The percent of Low scenic integrity objective acres is less than 1 percent difference across all alternatives, at about 13 percent.

Scenic integrity objectives would be assigned across Nez Perce-Clearwater. Acres and percent of the plan area which falls under each SIO under this alternative is provided in Table 335. Table 336 includes the percent of each management area falling within each SIO. The locations of the scenic integrity objectives across the Nez Perce-Clearwater are displayed on the Alternative Y map in Appendix A.

Table 335. Scenic integrity objectives (SIO) by acre and percent of the plan area, under Alternative Y

SIO	Acres	Percent
Very High	1,253,461	32%
High	559,817	14%
Moderate	1,596,333	41%
Low	529,446	13%

Data Source: Nez Perce-Clearwater GIS data.

Table 336. Scenic integrity objectives (SIO) by percent of management area, under Alternative Y

SIO	Management Area 1	Management Area 2	Management Area 3
Very High	100%	1%	0%
High	<1%	40%	<1%
Moderate	<1%	59%	77%
Low	0%	<1%	23%

Data Source: Nez Perce-Clearwater GIS data.

Alternative Z

Alternative Z would rely more on natural processes across the plan area to meet vegetative desired conditions. Recommended wilderness designation would be proposed across areas, comprising 475,000 acres. Thirty-six rivers are found to be suitable wild and scenic rivers under this alternative. Management of vegetation outside of wilderness and recommended wilderness would be completed over the longest period of all action alternatives and the timber harvest and planned ignition burning acres would be the smallest. This alternative would move the Nez Perce-Clearwater towards the desired forest vegetation conditions in about 100 years.

Indirect Effects

Under this alternative, additional snag and leave tree requirements could affect the scenic integrity at a project specific scale by increasing the presence of snags and leave trees, which may impact the foreground views from some concern-level travelways and points. Site specific design mitigations to address this desired condition may have to be considered at the project level.

Across the Nez Perce-Clearwater, this longer duration of time before the desired vegetation conditions are met may reduce the visibility of management actions due to longer periods of regrowth between actions but may also make the scenery less stable because ecological conditions will not be within the historic range of variability across the Nez Perce-Clearwater for a longer duration of time.

This alternative has the highest acres of High scenic integrity objective due to the high amount of recommended wilderness, suitable wild and scenic rivers, and reduced motorized suitable acres. This alternative has the smallest number of acres of Moderate scenic integrity objective. The percent of Low scenic integrity objective acres is less than 1 percent difference across all alternatives, at about 13 percent.

Scenic integrity objectives would be assigned across Nez Perce-Clearwater. Acres and percent of the plan area which falls under each SIO under this alternative is provided in Table 337. Table 338 includes the percent of each management area falling within each SIO. The locations of the scenic integrity objectives across the Nez Perce-Clearwater are displayed on the Alternative Z map in Appendix A.

Table 337. Scenic integrity objectives (SIO) by acre and percent of the plan area, under Alternative Z

SIO	Acres	Percent
Very High	1,253,490	32%
High	601,130	15%
Moderate	1,555,135	40%
Low	529,301	13%

Data Source: Nez Perce-Clearwater GIS data.

Table 338. Scenic integrity objectives (SIO) by percent of management area, under Alternative Z.

SIO	Management Area 1	Management Area 2	Management Area 3
Very High	100%	1%	<1%
High	<1%	43%	<1%
Moderate	<1%	55%	76%
Low	0%	<1%	24%

Data Source: Nez Perce-Clearwater GIS data.

Cumulative Effects

Except when viewers are well inside the Nez Perce-Clearwater boundary viewing only Nez Perce-Clearwater land, viewsheds often include land that is under some other ownership. Viewers may not recognize the boundaries of ownership and a person's eyes certainly do not stop viewing scenery at these boundaries. Therefore, a viewer's experience of the scenery of the Nez Perce-Clearwater often encompasses their experience of both Nez Perce-Clearwater lands and lands of other ownership that lie next to, behind, or in front of the Nez Perce-Clearwater. Where views include interspersed ownership, actions on the other land can positively or negatively affect viewers' attitudes towards the scenery of the Nez Perce-Clearwater. Lands around the Nez Perce-Clearwater may be managed by other federal agencies, including other National Forests, as well as state and private landowners. Each of these ownerships has different direction and management for scenery. As a result, viewers may perceive a difference in the scenic quality of the different lands and may perceive boundaries and other indicators of management action changes across the full landscape viewed.

No Action Alternative

Visual quality objective-based analysis would continue for proposed management activities across the Nez Perce-Clearwater and existing scenic condition would still be monitored. Travelways, use areas, and administrative sites created under the current forest plans would not be included in the existing mapping and would have to be updated on a project-by-project basis.

Alternative W

Alternative W would propose large expanses of recommended wilderness that would mirror large expanses of roadless and recommended wilderness on adjacent Forests. Areas of the Nez Perce-Clearwater that are proposed for more intensive management would be intermingled with state and private timberlands in some areas of the Palouse, North Fork, and Lochsa-Powell Ranger Districts. Intensive management by both Forest Service and other landowners would be found near several communities adjacent to the Nez Perce-Clearwater.

Alternative X

Alternative X would not propose any roadless areas as recommended wilderness. Therefore, more large expanses of the Nez Perce-Clearwater may be open for more intensive vegetative management. Some of these would be intermingled with state and private timberlands in some areas of the Palouse, North Fork, and Lochsa-Powell Ranger Districts. Intensive management by both Forest Service and other landowners would be found near several communities adjacent to the Nez Perce-Clearwater. The currently designated Idaho roadless areas would be retained and their themes would maintain large expanses of un-roaded area.

Alternative Y

Within Alternative Y, recommended wilderness areas will again mirror wilderness areas and recommended wilderness areas on adjacent Forests, creating large expanses of the landscape that reflect primarily natural changes to the landscape. Some of these would be intermingled with state and private timberlands in some areas of the Palouse, North Fork, and Lochsa-Powell Ranger Districts. Intensive management by both Forest Service and other landowners would be found near several communities adjacent to the Nez Perce-Clearwater. The pace of change is expected to be slightly slower than that proposed in Alternatives W and X, so management action driven changes to the landscape near rural communities and intermingled private lands would not be as visible.

Alternative Z

Within Alternative Z, designated areas of wilderness and recommended wilderness will again mirror wilderness areas and recommended wilderness areas on adjacent Forests, creating large expanses of the landscape that reflect primarily natural changes to the landscape. Some of these would be intermingled with state and private timberlands in some areas of the Palouse, North Fork, and Lochsa-Powell Ranger Districts. Intensive management by both Forest Service and other landowners would be found near several communities adjacent to the Nez Perce-Clearwater. The pace of change is expected to be significantly slower than that proposed in the other alternatives. This slower pace could allow for more growth of vegetation between harvests, which would likely reduce the visibility of management action driven changes to the landscape near rural communities and intermingled private lands. In contrast, this slower pace of change could also create a less stable long-term scenic character more susceptible to dramatic changes. These changes could result from events outside the historic range of variability for the ecosystem, such as uncharacteristic fires or widespread insect and disease outbreaks. These occurrences could shift the scenic character from naturally appearing to unnatural appearing and sustain that unnatural appearance for a long duration of time.

Preferred Alternative

Within the Preferred Alternative, designated wilderness and recommended wilderness areas will reflect wilderness areas and recommended wilderness areas on adjacent Forests, creating large expanses of the landscape that primarily display natural changes to the landscape. Some of these would be intermingled with state and private timberlands in some areas of the Palouse, North Fork, and Lochsa-Powell Ranger Districts. Intensive management by both Forest Service and other landowners would be found near several communities adjacent to the Nez Perce-Clearwater. The pace of change is expected to be slower than in Alternatives W and X, so management action driven changes to the landscape near rural communities and intermingled private lands would not be as visible compared to those alternatives.

Effects to Resource from Other Resources

Air Quality

While air quality is not a part of the vegetation and landforms that make up the forest setting, it does contribute to the overall recreation setting across the Nez Perce-Clearwater. Maintenance of good air quality contributes to the recreation experience and allows visitors to enjoy the scenery found in the area. Significant incidences of smoke, especially in river corridors where canyon walls can trap the smoke, can reduce the overall recreation experience for visitors.

Climate Change

Evidence of climate change can be seen across the Nez Perce-Clearwater in the form of increased insect and disease, wildfire occurrences, reduction in quantity of water, and poor growth of vegetation. These factors contribute significantly to the scenic appearance of the forest environment and, therefore, affect the overall scenic quality of the Nez Perce-Clearwater.

Cultural Resources

The Nez Perce-Clearwater has a rich pre-historic and historic story. Events of national importance occurred here and are now memorialized in print media and interpretive facilities. Historic facilities, such as cabins and lookouts, enhance this cultural experience by maintaining tangible evidence of the past. These heritage components enrich the visitor experience and enhance the scenic experiences of forest visitors through maintenance of historic structures. Desired conditions for heritage resources encourage retention of historic structures and protection of significant scenic components of several of the most notable cultural sites and travelways. Plan components for these objectives complement scenic quality guidelines for these areas.

Designated Wild and Scenic River Management

Desired conditions for existing designated wild and scenic rivers complement scenic quality desired conditions to maintain these distinctive river corridors in a way that protects the scenic character of the river landscapes in the long-term.

Suitable Wild and Scenic River Management

Desired conditions for suitable wild and scenic rivers also complement scenic quality desired conditions to maintain these distinctive river corridors in a way that protects the scenic character of the river landscapes in the long-term.

Ecology (other than fire ecology)

Land Management Plan direction related to ecosystems and ecology is designed to provide integrity and sustainability within those ecosystems. The desired condition to restore and maintain landscapes to be resilient natural ecosystem processes usually affects the long-term stability and composition of the scenery resource. Overall, the plan components for ecology are expected to complement the scenic integrity objectives and scenic character goals.

Economic Sustainability

Economic sustainability does not directly affect the scenic resource. However, management activities designed to enhance and protect the Nez Perce-Clearwater environment will likely enhance and protect the scenery resource. For them to be successful and implementable, they must also be economically viable.

Fire Management

Fire occurrences across the landscape are a major part of the dynamic nature of the Nez Perce-Clearwater. Historic fires and the suppression of fires have shaped the landscape's appearance, contributing to the current condition of the Nez Perce-Clearwater scenery. Maintenance of natural processes within areas such as designated wilderness and recommended wilderness complements the desired scenic conditions for the landscapes in those management areas. More active fuels reduction activities and prescribed burning is proposed to occur within general forest areas to also maintain a more natural balance of forest vegetation.

Desired conditions for fire management across the Nez Perce-Clearwater would be to maintain the forest vegetation in a condition that emulates natural conditions. This will require active fire and fuels operations over time to manage forest vegetation and limit uncharacteristic fire events. These activities, when applied appropriately, would meet or exceed the Nez Perce-Clearwater scenic integrity objectives.

Aquatic Ecosystems and Fisheries

While management of the fisheries resource itself would have little effect on the scenic resource, fishing is a major component of recreational use on the Nez Perce-Clearwater. Protection of watershed habitats that sustain the fisheries resource does contribute to the scenic quality and overall forest setting within protected watersheds. This would complement scenic quality in these areas. Structural improvements to protect fisheries can have minor short-term effects on scenic quality but generally do not affect the long-term scenic character. In many cases, actions to protect fisheries, such as reducing sediment into streams, restoring wetlands, and decommissioning roads, will positively affect the scenery resource by improving the scenic integrity from a valued viewing platform.

Forest Products (other than timber)

Much of the vegetation that provides forest products also contributes to the visual variety of the forest setting. Protection of these resources from overuse contributes to the overall scenic quality of an area. The desired condition to maintain viable populations of these species complements the scenic integrity objectives for these areas.

Infrastructure

A significant portion of the Nez Perce-Clearwater infrastructure is composed of historic buildings that have been maintained or restored for both administrative and public use. Historic buildings contribute to the scenic character of the Nez Perce-Clearwater by providing a window to past use of the area expanding the opportunity to experience those historic settings in context.

Invasive Species

Proliferation of invasive species, especially along travel corridors, can affect the overall scenic quality of the landscape. Generally found in the foreground viewshed along road and trail corridors, invasive species often out-compete native species creating an unnatural visual appearance that can be significant. Invasive species management over the long-term will complement the scenic integrity objectives to maintain natural appear landscapes, especially in critical travelway corridors.

Lands and Lands Special Uses

Lands and lands special uses authorizations of occupancy of Nez Perce-Clearwater lands by private entities for uses such as roads, utility corridors, and communication sites can create significant changes to the scenic resources of an area. While utility corridors and communication sites are generally isolated or are found generally in the urban interface, approval of the permitted uses should meet or exceed the scenic integrity objectives of the area.

Livestock Grazing

Desired conditions for livestock grazing within the forest environment are to maintain grazing capacity at a level that can produce sustained forage without damaging the forest ecology. This would complement the scenic integrity objectives for these areas.

Management Area Allocations

Management area allocations have grouped land areas by type and intensity of appropriate forest management. In this way, it has outlined groupings of areas that have similar scenic integrity objectives.

Minerals

While locatable minerals will remain available for all the activities related to mining those products, lands affected by these activities will eventually be reclaimed in an appropriate manner that meets or exceeds the scenic integrity objectives for that area. However, in all alternatives, negative impacts to the scenic integrity may result where valid existing rights are involved and mitigations to meet the assigned scenic integrity objectives are not implemented.

At-Risk Plants

While at-risk plants generally do not contribute to the overall scenic quality of an area, they do contribute to the overall visual variety and ecological interest of an area. There are several areas across the Nez Perce-Clearwater that have significant populations of at-risk plants. Some of these have been designated as research natural areas, with at-risk plants contributing variety to the type of settings available for visitors to enjoy.

Recommended Wilderness

Recommended wilderness varies between alternatives. Recommended wilderness and suitable wild and scenic river acres are the two main contributors to differences in the scenic integrity objectives across alternatives. Management actions to ensure these areas could still be designated wilderness in the future will likely complement the scenic integrity objectives of these areas and benefit the scenery resource. These areas would be managed to maintain natural processes for the most part, with a reduction in the discernible management actions compared to the desired scenic character.

Research Natural Areas

The objective for research natural areas is to monitor natural processes over time to better understand the dynamic forest processes that interact in the long-term for special vegetative communities. Retaining these areas in their natural conditions is critical to this objective and complements scenery goals of maintaining variety within the landscape. A scenic integrity objective of very high, indicating there would be little to no man-made activities occurring within these areas, will support the objective of maintaining the natural functions of these area.

Idaho Roadless Rule Areas

The themes assigned to these areas directly influence the management actions suitable to occur within them and, in turn, the possible affects to the scenery resource. In general, these areas would be dominated by use of fuels management operations to achieve desired vegetation conditions. Use of this management action over other tools would likely create scenic conditions that are well aligned with the scenic integrity objectives of these areas. These areas would continue to function naturally and be dominated by natural processes. The desired conditions outlined for these areas would be in keeping with the scenic integrity objectives assigned to them.

Social Sustainability

Social and economic sustainability of local communities is a critical component of forest planning. Providing forest products, recreation opportunities, and scenic settings for these communities is an important function of the Nez Perce-Clearwater. Goals for forest management to maintain sustainable outputs of forest products, opportunities for a variety of recreation pursuits, and scenic quality in critical viewsheds over the long-term would contribute to social sustainability. Production of these resources over the long-term would be designed to meet or exceed the scenic integrity objectives.

Soils Resource

While soils management does not directly affect the scenic quality of an area, improved soil conditions do encourage and maintain appropriate plant communities that contribute to the scenic character of the Nez Perce-Clearwater. Desired conditions to maintain soils through time to provide the appropriate conditions for optimum vegetative growth will contribute to the overall scenic quality of the Nez Perce-Clearwater.

Suitable Wild and Scenic Rivers

Plan components related to the designation of suitable Wild and Scenic Rivers would, in many cases, include a standard for scenic quality, as many of these rivers have scenery as one of their outstandingly remarkable values. This designation would complement the desired condition for scenery for these distinctive river segments. These areas would be managed to maintain natural processes for the most part, with a reduction in the discernible management actions compared to the desired scenic character.

Sustainable Recreation (including developed and dispersed recreation)

Maintaining scenic quality around developed recreation sites and dispersed sites across Nez Perce-Clearwater is one of the desired conditions for recreation. The scenic character creates the setting for that visitor experience. Maintenance of these resources supports the sense of place that visitors expect when they come to the Nez Perce-Clearwater. Maintaining this desired condition over time does require management of the components of that setting, including vegetation management.

The recreation opportunity spectrum complements scenery management in terms of the visual appearance of recreation sites, such as campgrounds, river access, and trailheads. Desired conditions for scenery management also apply to how the surrounding foreground, middle ground, and background National Forest System lands appear.

While not limiting recreation development, scenic integrity objectives may influence the design and location of recreation facilities, especially when they may be visible from critical viewing platforms. Desired conditions to maintain recreation settings in and around recreation facilities would be in keeping with desired conditions for scenery.

Development of visitor access routes across the Nez Perce-Clearwater, either by road or trail, is critical to support the recreation function. Bringing visitors to recreation opportunities, whether by car, motorized trail vehicle, or by foot, is part of their experience. The desired condition for scenery is to provide the desirable forest settings that support that use. Within the components for recreation, the recreation opportunity spectrum complements the scenery management guidelines.

To support recreation use, the desired condition for road and trail management is to develop an effective, efficient, and sustainable transportation system. These travelways can then be identified as scenic corridors and maintained with the appropriate scenic integrity objectives.

Timber

Plan components in the revised plan alternatives have detailed desired condition descriptions aimed at maintaining resilience and sustainability as a general goal. Maintaining a healthy and resilient landscape over time would enhance the short- and long-term character of the Nez Perce-Clearwater, and is complimentary with desired conditions for scenery, such as maintaining large tree structure and meadows that are open and clear of conifer encroachment. Both elements would increase the visual variety across the Nez Perce-Clearwater. Changes to the vegetation required to meet these desired conditions would need to be designed to meet or exceed the scenic integrity objectives of the area.

Plan components in the revised plan support a desired condition of maintaining ecological integrity and sustainability that resemble the natural range of variation. In the long-term, these goals are complimentary with desired conditions for scenery. Each alternative has a different time frame in which this will occur. Impacts to scenic quality will differ across alternatives, with changes to the vegetated landscape happening more frequently and at a broader scale in Alternatives W and X.

Watershed Management

All Land Management Plan alternatives provide detailed guidance for protection of watersheds, riparian areas, and aquatic habitats, which complement scenic quality desired condition goals. Desired conditions for watershed management would affect scenic integrity in a positive way in the long- and short-term.

Watershed Restoration Program

Restoration of water courses and wetlands, especially in critical viewsheds, would improve scenic quality in the long- and short-term. River related environments are a critical part of the scenic character of the Nez Perce-Clearwater and improvements to the river related environments over the long- and short-term will improve scenic quality.

Tribal Trust Responsibilities

Maintaining tribal treaty rights across the Nez Perce-Clearwater would complement scenery desired conditions aimed at maintaining critical historic and natural areas of the Nez Perce-Clearwater.

Wildlife

Plan objectives to improve wildlife habitat may have some effect on scenic integrity, as some species, such as elk, require openings on the landscape that may need to be maintained either by timber harvest or fuels management. Habitat restoration that requires these actions would need to meet or exceed the scenic integrity objectives.

Summary of Consequences

The No Action Alternative would not resolve the incongruent forest management direction for the scenery resource between the Nez Perce and the Clearwater National Forests. There would still be an inconsistent and unpredictable approach to scenery management and neither of the two existing approaches comply with current Forest Service directives.

All revised plan alternatives would resolve the need for change and would meet the 2012 Land Management Planning Rule requirements to consider the contribution of the Nez Perce-Clearwater scenery to the social and economic sustainability of the Nez Perce-Clearwater. All revised plan alternatives, the desired scenic character descriptions, mapped scenic integrity objectives, and the Land Management Plan components would result in the Nez Perce-Clearwater's scenery being managed in a way that recognizes the public's expectations and desire to enjoy the scenery, especially in critical viewsheds, and would allow for managing for scenic sustainability within the context of dynamic landscapes.

A comparison of the scenic integrity objectives proposed in the revised plan alternatives show how they generally vary from alternative to alternative based upon the amount and locations of recommended wilderness and suitable wild and scenic rivers. Table 339 compares the alternatives and their effects to the scenery resource. The action alternatives have very similar amounts of Very High scenic integrity objective assigned acres ranging from 1,253,456 to 1,253,490. The Preferred Alternative has fewer acres in the Very High scenic integrity objective class at 1,179,117 acres. Alternative Z has the highest amount of High scenic integrity objective assigned acres and Alternative X the least, with the other action alternatives falling in between. This difference corresponds to the greater amount of land recommended as wilderness and suitable wild and scenic river in Alternative Z and none in Alternative X. Alternative X has the highest amount of Moderate scenic integrity objective assigned acres and Alternative Z the least. The same reason above with regards to the opposite is true for High scenic integrity objective acres in these two alternatives. Alternatives W and Y and the Preferred Alternative are very similar in Moderate scenic integrity objective acres and are more like Alternative Z than X. No land in any of the revised plan alternatives was assigned a scenic integrity objective of very low.

Table 339. Summary of scenery integrity objectives (SIO) by acres, percent, and alternative (Alt)

SIO	No Action1	Alt W	Alt X	Alt Y	Alt Z	Preferred
Very High	1,135,433 acres 30%	1,253,457 acres 32%	1,253,456 acres 32%	1,253,461 acres 32%	1,253,490 acres 32%	1,179,117 acres 30%
High	440,396 acres 12%	548,717 acres 14%	322,701 acres 8%	559,817 acres 14%	601,130 acres 15%	472,631 acres 12%
Moderate	406,867 acres 11%	1,607,192acres 41%	1,833,200 acres 47%	1,596,333 acres 41%	1,555,135 acres 40%	1,763,316 acres 45%
Low	902,532 acres 24%	529,690 acres 13%	529,699 acres 13%	529,446 acres 13%	529,301 acres 13%	523,992 acres 13%

SIO	No Action1	Alt W	Alt X	Alt Y	Alt Z	Preferred
Very Low	838,157 acres 23%	0	0	0	0	0

[1]The No Action Alternative is based on the Visual Management System instead of the Scenery Management System. As a result, the scenic integrity objective terms are cross walked from the assigned visual quality objectives to compare the alternatives.

Data Source: Nez Perce-Clearwater GIS data.

3.4.4 Infrastructure

Infrastructure on the Nez Perce-Clearwater includes roads, bridges, facilities, airstrips, and dams. The transportation system for the Nez Perce-Clearwater is defined as the system of National Forest System roads, National Forest System trails, and airfields on National Forest System lands (36 CFR 212.1). This section focuses primarily on the National Forest System roads, which are an extensive network that includes approximately 7,680 miles of forest roads accessing approximately 1,331,040 acres, or 34 percent, of the Nez Perce-Clearwater.

Effects to National Forest System roads would vary amongst the alternatives and are described in detail in this section. Bridges, facilities, airfields, and dams are also described in this section. Effects to these resources would be similar under all of the alternatives.

The Nez Perce-Clearwater expects to maintain an appropriately sized and environmentally sustainable road system that is responsive to ecological, economic, and social concerns. The National Forest System roads would continue to provide access for recreation and resource management as well as to support watershed restoration and resource protection to sustain healthy ecosystems.

While infrastructure was not identified specifically as an issue during scoping, it is critical for management of the activities and resources on the Nez Perce-Clearwater. Comments received during scoping that are directly related to infrastructure, specifically roads, included access in wilderness areas and Idaho Roadless Areas, timber output, aquatic resources, and elk and big game security.

Relevant Laws, Regulations, and Policy

Federal Laws

Term Permit Act of March 4, 1915 (Pub. L. 63-293, Ch. 144, 38 Stat. 1101, as amended; 16 U.S.C. 497): This act provides direction authorizing occupancy of National Forest System lands for a wide variety of uses through permits not exceeding 30 years.

National Forest Roads and Trails Act of October 13, 1964 (Pub. L. 88-657, 78 Stat. 1089, as amended): This act declares that an adequate system of roads and trails should be constructed and maintained to meet the increasing demand for recreation and other uses. This act authorizes road and trail systems for the National Forests. It authorizes granting of easements across National Forest System lands, construction and financing of maximum-economy roads (Forest Service Manual 7705), and imposition of requirements on road users for maintaining and reconstructing roads, including cooperative deposits for that work.

Highway Safety Act of September 9, 1966 (Pub. L. 89-564, 80 Stat. 731, as amended): This act authorizes state and local governments and participating federal agencies to identify and survey accident locations; to design, construct, and maintain roads in accordance with safety standards; to apply sound traffic control principles and standards; and to promote pedestrian safety. The Highway Safety Improvement Program and the Safety Performance Management Measures Final Rules, effective April 14, 2016, address the requirements of the Moving Ahead for Progress in the 21st Century Act and the Fixing America's Surface Transportation Act. Updates to the existing Highway Safety Improvement Program requirements under 23 CFR § 924 are consistent with the Moving Ahead for Progress in the 21st Century Act and the Fixing America's Surface Transportation Act and clarify existing program requirements. The Safety Performance Management Measures Final Rule adds part 490 to title 23 of the CFR to implement the performance management requirements under 23 U.S.C. 150, including specific safety performance measure requirements for the purpose of carrying out the Highway Safety Improvement Program to assess serious injuries and fatalities on all public roads.

Federal Aid Highway Act of 1968, as amended (23 U.S.C. 109(a) and (h), 144, 151, 319, and 351): This act establishes the National Bridge Inspection Standards (23 CFR § 650, Subpart C) and the requirement that each state have a current inventory of bridges on all public roads, including National Forest System roads open to public travel (Forest Service Manual 1535.11).

Surface Transportation Assistance Act of 1978 (Pub. L. 95-599, as amended): This act supersedes the Forest Highway Act of 1958 and authorizes appropriations for Forest highways and public lands highways. It establishes criteria for Forest highways; defines Forest roads, Forest development roads, and Forest development trails, referred to as National Forest System roads and National Forest System trails in Forest Service regulations and directives; and limits the size of projects performed by Forest Service employees on Forest roads. The act establishes the Federal Lands Highway Program.

Secure Rural Schools and Community Self-Determination Act of October 30, 2000 (Pub. L. 106-393, 114 Stat. 1607; 16 U.S.C.500 note): This act provides provisions to make additional investments in, and create additional employment opportunities through, projects that improve the maintenance of existing infrastructure, implement stewardship objectives that enhance Forest ecosystems, and restore and improve land health and water quality.

Moving Ahead for Progress in the 21st-Century Act (MAP-21) of July 6, 2012 (Pub. L. 112-141): This act replaces the Federal Lands Highway Program with the Federal Lands Transportation Program and Federal Lands Access Program. This act authorizes funding for federal lands transportation facilities and federal lands access transportation facilities under a unified program, with policy similar to federal-aid highways and other public transportation facilities. It requires federal land management agencies to identify a comprehensive inventory of public federal lands transportation facilities that, at a minimum, includes the transportation facilities that provide access to high-use federal recreation sites or federal economic generators. As part of the Moving Ahead for Progress in the 21st Century enactment, Section 1111 amended Section 144 of Title 23 United States Code and directed the Federal Highway Administration to "consider a risk-based approach to determining the frequency of bridge inspections." Section 650.311(a)(3) of the National Bridge Inspection Standards (23 CFR 650 subpart C) states "certain bridges may be inspected at greater than twenty-four-month intervals, not to exceed forty-eight months, with written FHWA [Federal Highway Administration] approval." Additionally, in accordance with 23 CFR 650.311(a)(2), certain bridges require inspection at less than 24-month intervals.

Idaho Roadless Rule 36 CFR 294.22: This rule provided state-specific direction for the conservation and management of inventoried roadless areas within the State of Idaho. The rule integrated local management concerns with the national objectives for protecting roadless area values and characteristics. It designated a system of lands titled Idaho Roadless Areas and established five management themes for individual roadless areas: Wild Land Recreation; Primitive;

Special Areas of Historic and Tribal Significance; Backcountry and Restoration; and General Forest, Rangeland, and Grassland.

Executive Orders

Executive Order 13751: Safeguarding the Nation from the Impacts of Invasive Species (December 5, 2016)

Executive Order 13112: Invasive Species (February 3, 1999). Amended by Executive Order 13286 (28 February 2003)

Agency Regulations

36 CFR § 212—Travel Management*:* This final rule requires designation of those roads, trails, and areas that are open to motor vehicle use. Designations are made by class of vehicle and, if appropriate, by time of year. This rule prohibits the use of motor vehicles off the designated system, as well as use of motor vehicles on routes and in areas that is not consistent with the designations. Subpart B provides for a system of National Forest System roads, National Forest System trails, and areas on National Forest System lands that are designated for motor vehicle use. After these roads, trails, and areas are designated, motor vehicle use, including the class of vehicle and time of year, not in accordance with these designations is prohibited by 36 CFR § 261.13. Motor vehicle use off designated roads and trails and outside designated areas is prohibited by 36 CFR § 261.13. Subpart C provides for a system of National Forest System roads, National Forest System trails, and areas on National Forest System lands that are designated for over-snow vehicle use. After these roads, trails, and areas are designated, motorized over-snow vehicle use not in accordance with these designations is prohibited by 36 CFR § 261.14. Motorized over-snow vehicle use off designated roads and trails and outside designated areas is prohibited by 36 CFR § 261.14.

The Road Management Rule 2001*:* This rule "removes the [prior rule's] emphasis on transportation development and adds a requirement for science-based transportation analysis…The intended effect of this final rule is to help ensure that additions to the National Forest System network of roads are those deemed essential for resource management and use; that construction, reconstruction, and maintenance of roads minimize adverse environmental impacts; and, finally, that unneeded roads are decommissioned and restoration of ecological processes are initiated" (Federal Register Vol. 66, No 9, pg. 3206).

Subpart A of the Rule pertains to Administration of the Forest Transportation System: In part, Subpart A requires each unit of the National Forest System to: 1) identify the minimum road system needed for safe and efficient travel and for protection, management, and use of National Forest System lands (36 CFR (CFR) 212.5(b)(1)) and 2) identify roads that are no longer needed to meet forest resource management objectives (36 CFR 212.5 (b)(2)). In determining the minimum road system, the responsible official must incorporate a science-based roads analysis at the appropriate scale.

- International Building Code
- National Best Management Practices for Water Quality Management on National Forest System Lands – Volume 1: National Core BMP Technical Guide, April 2012: This is the first volume of guidance for the Forest Service, U.S. Department of Agriculture, and National Best Management Practices Program. The National Best Management Practices Program was developed to improve agency performance and accountability in managing water quality consistent with the Federal Clean Water Act and state water quality programs. Current Forest Service policy directs compliance with required Federal Clean Water Act permits and state regulations and requires the use of the National Best Management Practices Program to control nonpoint source pollution to meet applicable water quality standards and other Federal Clean Water Act requirements. It includes the National Best Management Practices Program for construction, operation, and maintenance of roads and motorized trails.

State and Local Laws

- Idaho Rules for Public Drinking Water Systems (IDAPA 58.01.08)
- Idaho's Wastewater Rules (IDAPA 58.01.16)

State and Local Plans

The Nez Perce-Clearwater has Cooperative Use Agreements for road and bridge maintenance with the PotlatchDeltic Timberland Real Estate Investment Trust and the Idaho Department of Lands under a statewide cost share agreement.

Methodology

Spatial Scale

The network of National Forest System roads may also include county, state, private, and other federal jurisdiction sections. The geographic scope of the road effects analysis is those National Forest System roads administered by the Nez Perce-Clearwater, as these roads are under the jurisdiction of the Forest Service and would be affected by varying degrees under each of the alternatives. For cumulative effects to roads, the geographic scope includes all National Forest System roads, including those administered by other entities.

The geographic scope of effects for bridges, facilities, airstrips, and dams, including cumulative effects, is the footprint of these resources. Although the National Forest System road network, as a whole, is included in the effects analysis, the effects of the alternatives are more evident in Management Area 3. A map of Management Area 3 can be found in Appendix A.

Temporal Scale

The temporal scope of the analysis is the life of the Land Management Plan. For cumulative effects, this analysis considers known past, present, and reasonably foreseeable future activities within the plan area over a 75-year period from 1960 to 2035. This period was selected to include the increase in the number of major infrastructure projects in the 1960s and 1970s and extends to 2035 because this date represents a reasonably foreseeable future for planning activities.

Past, Present, and Future Activities used in the Analysis

Past, present, and future activities included in the analysis include road construction, reconstruction, maintenance, and decommissioning. Information used to conduct the analysis largely comes from the INFRA module of the U.S. Forest Service's Natural Resource Manager Database. This database is a collection of web-based data entry forms, reporting tools, and geographic information system mapping tools that enables the Nez Perce-Clearwater to manage and report accurate information about constructed features and land units. Activities implemented by other entities that administer sections of roads within the National Forest System are not included in this database, with the exception of cost-share roads.

Adjacent road systems are maintained by Idaho Department of Transportation, Deer Creek Highway District, Whitebird Highway District, Idaho County Roads and Bridge Department, Kidder-Harris Highway District, Clearwater County Highway District, Clearwater County Roads and Bridge Department, North Latah County Highway District, Idaho Department of Lands, PotlatchDeltic, and other private entities. Effects from activities implemented by these other entities within the Nez Perce-Clearwater constitute a minor portion of the overall effects as the majority of the National Forest System roads are under the jurisdiction of the Forest Service.

For non-road infrastructure, routine and unplanned maintenance activities have occurred, are occurring, and will continue to occur. The scale of these activities on the Nez Perce-Clearwater is small and would be similar under all of the alternatives; therefore, effects from these activities was not analyzed in further detail.

Adjacent landowners include private lands, the PotlatchDeltic Real Estate Investment Trust, Western Pacific Timber LLC, Idaho Department of Lands, the Bureau Land Management, and other national forests. Adjacent Forest Service lands include the Payette National Forest, the Wallowa-Whitman National Forest, the Idaho Panhandle National Forest, the Lolo National Forest, the Salmon-Challis National Forest, and the Bitterroot National Forest. Changes in infrastructure initiated by these landowners that could have an effect on the Nez Perce-Clearwater infrastructure are mostly related to recreational use and timber harvesting activities.

Most roads on the Nez Perce-Clearwater were constructed during the 1960s through the 1980s. During this building era, more maintenance was also performed. Over time, maintenance levels have decreased due to reductions in funding and personnel, resulting in fewer miles of road being maintained annually and longer durations between maintenance activities for many of the roads. The rate of new road construction has slowed substantially, and new road construction is predominately limited to that needed for timber harvest access and road relocations for resource protection. The rate of road decommissioning has stayed largely consistent rate for the last several years.

Methods and Assumptions

INFRA data was used to determine the miles of Nez Perce-Clearwater National Forest System roads and their maintenance levels.

Geospatial analysis was used to identify the acreage of Nez Perce-Clearwater land within 1,600 feet of an existing road prism and the acreage of lands that are not within 1,600 feet of an existing road prism. This analysis assumes yarding timber harvest would be accomplished by widely available and commonly used equipment and was verified based on the 2014 to 2019 Timber Management activities and on the logging systems being utilized on the Nez Perce-Clearwater.

There is a direct correlation between the volume of commercial timber sale traffic generated from Forest Service management activities and volume of timber sold. Logging trucks hold roughly 5,000 board feet per truck, for a total weight of 80,000 pounds. Increases and decreases of volume sold would be proportionate to the number of logging trucks and other commercial traffic on the roadways.

The quantity of aggregate needed to maintain roads within timber management areas can also be determined by the volume of timber sold. The Forest Service evaluates the wear rates on forest roads every five years, which in turn indicates the volume of aggregate needed on the Nez Perce-Clearwater to replace aggregate that becomes worn out during timber management.

The wear rate calculated in 2018 was estimated to be 1 inch per 10 million board feet, varying by geologic parent material of the gravel, with basaltic and limestone gravels being more resilient than granitic gravels. Gravel pits on the Nez Perce-Clearwater are typically no larger than 5 acres, producing approximately 45,000 cubic yards of material each. Smaller staging areas of 2 to 4 acres are located across the Nez Perce-Clearwater for stockpiles of around 4,000 cubic yards of material at each location. A network analysis would need to be completed to estimate aggregate haul costs.

Increases and decreases in timber and fuels management activities could result in increases or decreases in Nez Perce-Clearwater or contracted personnel for management oversite, which would result in increases and decreases in needs for office, housing, and warehouse space. This would have an effect on how building resources are managed and would be addressed in the Facility Master Plan.

Measurement Indicators

The following measurement indicators were used in the road system effects analysis:

- Acres of Nez Perce-Clearwater lands that are within 1,600 feet from an existing road: This is an indicator of the likelihood of new road construction in an area. The 1,600-foot distance was selected as the evaluation distance, as most currently used yarding timber harvesting equipment has a maximum haul distance of around 1,600 feet. In areas that are beyond 1,600 feet from an existing road prism, new roads may be constructed to harvest timber in those areas.
- Acres of Recommended Wilderness: If new plan areas become designated as wilderness, there could be an impact on access. An access assessment would need to be conducted to determine where access to the wilderness would be provided. Roads within the wilderness could be cherry-stemmed or decommissioned and existing roads could be maintained or reconstructed, but no new road construction would occur in these areas.
- Acres of suitable for inclusion Wild and Scenic Rivers: If new plan areas become designated as Wild and Scenic River corridors, there could be an impact on the level of road maintenance, as these areas typically draw visitors and there would be more road use. It also could impact the availability of gravel for road resurfacing, as quality rock sources are often found adjacent to rivers and are located next to roads; however, aggregate pits typically are not allowed within a quarter mile of a Wild and Scenic River.
- Volume of timber to be sold as a surrogate for thousand board feet hauled: The volumes of timber proposed to be sold under the alternatives are used as a surrogate for the amount of hauling that would occur on the forest system roads. Higher amounts of hauling results in more wear on the aggregate surface and more road maintenance and aggregate would be needed, which could mean more gravel pits would be opened on the Nez Perce-Clearwater. Other effects

from higher haul rates include less public access on some roads during hauling and more required personnel, housing, office space, and vehicles to administer the timber harvest.

- Miles of roads maintained and improved: National Forest appropriations are allocated proportionally to the amount of timber management and recreational use on each Forest. Timber Management contracts include road maintenance responsibilities on haul routes to provide additional operators to perform road maintenance on National Forest System roads. Higher timber volumes result in more road maintenance and positive road modifications such as curve widening, improved sight distance, and replacement of failing or undersized culverts, which would be sized to pass flows from 100-year flood events.
- Under timber stewardship sales, watershed improvements can be accomplished, including installation of aquatic organism passage culverts; bridge improvements; additional gravel surfacing; and replacement of additional drainage structures with upsized culverts, retaining walls, landslide repairs; and forestwide road maintenance, such as road blading.
- Gravel surface replacement is currently accomplished on the Nez Perce-Clearwater using timber harvest receipts and approximately 25 percent of forest road maintenance is performed by timber purchasers. Roughly 23 percent of the road improvements for watershed benefits on the Nez Perce-Clearwater are a result of Timber Management and Stewardship receipts and another 50 percent is funded and supported by various partners, with the largest of those contributors being Bonneville Power Association and the Nez Perce Tribe.

Affected Environment

Existing Condition

National Forest System Roads

This section covers the development of the existing condition of the National Forest System roads that are under the jurisdiction of the Forest Service. They are wholly or partly within or adjacent to National Forest System lands. The Forest Service determines these roads are necessary for the protection, administration, and utilization of the National Forest System and for the use and development of its resources. Roads managed by public road agencies, such as states, counties, and municipalities that help provide access to National Forest System lands, are also informally considered part of the overall regional transportation system but do not fall under the jurisdiction or direction of the National Forest. These roads are not included in this evaluation.

During the 1960s through the 1980s, the National Forest Service road system expanded and resources were developed. Comprehensive area transportation plans began to be developed in the 1980s and continued through the 1990s. These plans provide a conceptual depiction of the road network necessary to access the identified land base for timber harvest. In general, these plans demonstrated that road densities ranging from 3 to 5 miles of road per section are necessary to access 50 to 70 percent of the land base. This density reflected using the full range of available harvest systems, including aerial systems.

A forest-scale roads analysis was completed by the Clearwater National Forest in 2002 and by the Nez Perce National Forest in 2005. The following were principal results of these analyses:

- Road maintenance funding is not adequate to maintain and sign roads to standard.
- Road access may not be adequate for future management needs.

- Management of the National Forest Service road system can impact cultural and traditional uses, such as plant gathering, access to traditional and cultural sites, and American Indian treaty rights.
- Some roads are causing adverse impacts.
- Existing roads may be needed for future management activities not currently planned.

One of the strategies adopted to address the lack of funding included the “ephemeral road system.” In this scenario, access would be developed to treat vegetation in accordance with disturbance regimes and then a portion of that access would be removed following treatment. Road densities of 1 to 3 miles per section, representing the main access routes, would be retained. Tertiary local roads would be removed through road decommissioning and reconstructed when treatments would be required again after regeneration.

On November 9, 2005, the Forest Service published the final rule “Travel Management: Designated Routes and Areas for Motor Vehicle Use” in the Federal Register. The 2005 Travel Management Rule requires National Forests to develop a minimum road system to accommodate resource needs. In 2015, a forest-level roads analysis was completed for the Nez Perce-Clearwater. This analysis established a minimum road system for arterial, collector, and important local class National Forest roads on the Nez Perce-Clearwater. This broad-scale analysis encompassed all existing National Forest System roads on the Nez Perce-Clearwater. The report provided an assessment of the road infrastructure and a set of findings and recommendations for revisions to the Nez Perce-Clearwater transportation system. The report provided information to Nez Perce-Clearwater managers regarding the minimum road system needed for safe and efficient travel and for administration, utilization, and protection of National Forest System lands.

The travel analysis report is used by the Nez Perce-Clearwater to prioritize maintenance needs and identify opportunities to decommission roads or put them into intermittent stored service as the Nez Perce-Clearwater works to identify the minimum number of routes needed for an efficient transportation system, as directed in 36 CFR § 212 subpart A.

The travel analysis report identified approximately 14 miles of National Forest System roads as “not likely needed for future use” that may be considered as candidates for conversion to another use, storage for future use, or removal through decommissioning. Other roads that were rated as “high risk” were identified as candidates for storage for future use, reconstruction, relocation of the road, or additional road maintenance. Roads considered “low risk” are the first to be considered for reduced road maintenance or a change to a lower maintenance level.

This same analysis indicated that, in 2015, the Nez Perce-Clearwater required $2,900,000 annually to maintain the open road system, which was well above the road budget at that time and well above current road budgets. Since the budgets are 33 to 50 percent lower than what is needed, other avenues of funding or reduced open road mileage need to be determined.

The travel analysis report and the Land Management Plan do not provide travel management decisions. Site-specific, project-level analysis under the National Environmental Policy Act is required to make travel management decisions, including road closure, storage, or decommissioning.

National Forest System Road Maintenance

National Forest System roads are designated by vehicle classifications and use design and maintenance standards for each road. Roads on the Nez Perce-Clearwater are generally constructed and maintained at a 14-foot width to allow for passage of most cars and trucks. Roads are typically constructed to grades of 10 percent or less to allow travel by most highway vehicles. The Forest

Service classifies maintenance of National Forest System roads by five levels, which are defined in Forest Service Handbook 7709.59, sec.62.32 and characterized in the “Guidelines for Road Maintenance Levels” (U.S. Department of Agriculture 2012a). These levels define the general design standards, uses, and associated type of road maintenance required. Road maintenance levels on the Nez Perce-Clearwater generally follow the definitions in the 2012 Guidelines for Road Maintenance Levels and are described below.

Of the approximately 7,682 miles of National Forest System roads on the Nez Perce-Clearwater, 3,799 miles, or 49 percent, of roads are operationally Maintenance Level 1 roads and are closed to all traffic; 2,003 miles, or 27 percent, are operationally Maintenance Level 2 roads and are suitable for high clearance vehicles; 1,572 miles, or 20 percent, are operationally Maintenance Level 3 roads and are suitable for passenger cars; 194 miles, or 3 percent, are operationally Maintenance Level 4 roads and are typically two lane gravel roads suitable for passenger cars; and 113 miles, or 2 percent, are operationally Maintenance Level 5 roads and are typically paved and suitable for passenger cars traveling at higher speeds.

Routine road maintenance work, such as brushing, blading, and ditch and culvert cleaning, is periodically performed on approximately 3,900 miles of Maintenance Level 2, 3, 4, and 5 roads as funding allows and, in most cases, they are kept in a drivable condition for their designed use. Annually, approximately 1,200 miles of road are maintained by force account, partners, and timber sales. The approximately 3,800 miles in Maintenance Level 1, which includes roads treated for intermittent stored service, do not receive routine maintenance work but may be maintained for resource protection.

Road Maintenance Level 1

Road Maintenance Level 1 includes roads that have been placed in storage for at least one year between intermittent uses. Basic custodial maintenance is performed to prevent damage to adjacent resources and to perpetuate the road for future resource management needs. Emphasis is normally given to maintaining drainage facilities and runoff patterns. Planned road deterioration may occur at this level. Maintenance Level 1 roads are not designated for motor vehicles as a road and are not shown as a road on the motor vehicle use map. They may be managed and designated as a motorized trail and shown on motor vehicle use maps as a motorized trail, and they may be available and suitable for non-motorized uses. Road entrances will be physically blocked or disguised, and culverts may be removed. Route markers should be installed but need not be visible from an open road at the entrance. Roads managed at this maintenance level are described as being in basic custodial care, which may include condition survey and mitigation measures for potential resource damage.

On the Nez Perce-Clearwater, Maintenance Level 1 roads may be taken out of storage for administrative use, at which time they are no longer Maintenance Level 1. These roads remain closed to public use but may be used by the Nez Perce-Clearwater and other authorized individuals during emergencies and to access the forest to conduct forest protection and management activities. The Nez Perce-Clearwater recognizes the travel Routes Data dictionary definition “roads receiving Level 1 Maintenance may be of any type, class, or construction standard, and may be managed at any other maintenance level during times when open for traffic. However, while being maintained at Level 1, they are closed to vehicular traffic, but may be available and suitable for non-motorized uses” (U.S. Department of Agriculture 2009a).

Road Maintenance Level 2

Road Maintenance Level 2 includes roads that are open for use by high-clearance vehicles. Passenger car traffic, user comfort, and user convenience are not taken into consideration. Warning signs and traffic control devices are not provided with the exception that some signing, such as W-18-1 ‘No Traffic Signs,’ may be posted at intersections. Motorists should have no expectations of being alerted to potential hazards while driving these roads. Traffic normally is minor, usually consisting of one or a combination of administrative, permitted, dispersed recreation, or other specialized uses. Maintenance Level 2 roads are maintained for use by high-clearance vehicles and log-haul but are not generally suitable for passenger cars (U.S. Department of Agriculture 2009b). Surface smoothness is not considered a priority and these roads may not be passable during periods of inclement weather. They have low traffic volume and low speed. Typically, they are local roads that connect to collectors and other local roads. They have water bars, drain dips, or cross drains as the preferred drainage treatments and the use of culverts, arches, and bridges is avoided when possible. These roads are subject to the requirements of Engineering Manual-7100-15 and the Manual on Uniform Traffic Control Devices for all signs. On the Nez Perce-Clearwater, these roads may be maintained at a higher level or reconstructed during forest management activities for a specified period of time for administrative and contractual use.

Road Maintenance Level 3

Road Maintenance Level 3 includes roads that are open and maintained for travel by a prudent driver in a standard passenger car during the normal season of use. User comfort and convenience are not considered priorities. Warning signs and traffic control devices are provided to alert motorists of situations that may violate expectations. They are typically single lane with turnouts visible from either direction or usually must be driven at low speeds. They may be local or collector roads and have low-to-moderate traffic volume. These roads typically connect to arterial and collector roads or other Maintenance Level 3 roads. They may include some dispersed recreation sites. Drainage is provided via a combination of drivable dips, culverts, arches, and bridges and these roads may have potholes or washboarding. These roads are subject to the requirements of Engineering Manual-7100-15 and the Manual on Uniform Traffic Control Devices for all signs.

Road Maintenance Level 4

Road Maintenance Level 4 includes roads that provide a moderate degree of user comfort and convenience at moderate travel speeds for prudent drivers in a standard passenger car during the normal season of use. Most roads are double lane and aggregate surfaced; however, some roads may be single lane with turnouts visible from either direction, and some may be paved. Roads in this maintenance level have moderate traffic volume and speeds. They usually are collectors and arterials and may connect to state and county roads and include some developed recreation areas. Drainage is provided primarily via culverts, arches, and bridges. These roads are subject to the requirements of Engineering Manual-7100-15 and the Manual on Uniform Traffic Control Devices for all signs.

Road Maintenance Level 5

Road Maintenance Level 5 includes roads that provide a high degree of user comfort and convenience for prudent drivers in a standard passenger car during the normal season of use. These roads are normally double lane, paved facilities, although some may be aggregate surfaced sections and may be dust abated. These roads have a smooth road surface, are often paved or chip-sealed with lane striping and have defined shoulders. Maintenance Level 5 roads inspire confidence in the traveler that hazards will be few and identified well in advance and the roadway is visually pleasing. They have high traffic volume and speeds and typically connect to state and county roads. These roads are usually an arterial or collector and they may include some developed recreation roads. Drainage is provided via culverts, arches, and bridges. These roads are subject to the requirements of Engineering Manual-7100-15 and the Manual on Uniform Traffic Control Devices for all signs.

Road Decommissioning and New Road Construction

As shown in Table 340 for the Clearwater National Forest and Table 341 for the Nez Perce National Forest, the total number of roads on the Nez Perce-Clearwater has been steadily decreasing since 1999. A total of about 1,625 miles of National Forest System roads and non-National Forest System roads have been decommissioned during this time. Most of this decommissioning took place on the non-system roads that were legacy roads from former timber harvest practices, which are no longer needed for new harvest techniques, and roads in unstable terrain or with failing drainage structures. However, there have been additions to National Forest System roads during this time as well. These additions include the construction of approximately 46 miles of new roads for vegetation, special uses, recreation management, and watershed improvements by moving roads away from sensitive stream habitats. Most of the increases are due to the need for better located roads that provide for a more stable, less impacting road system.

Table 340. Miles of roads decommissioned from 1999 to 2018.

Year	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008

Road Traffic, Visitor Use, and Access

Systematic road use data has not been collected on the Nez Perce-Clearwater for over 15-years; therefore, variability in road use was difficult to determine. Traffic count and visitor count data collected during three sampling events is documented in the following reports: the 2012 Engineering Analysis of Motorized Mixed Use, the 2014 Mixed Use Analysis Report, and the 2016 National Visitor Use Monitoring Report (U.S. Department of Agriculture 2018g).

National Visitor Use Monitoring Program data from the 2016 recreational use sampling event indicates there were approximately 763,000 visitors to the Nez Perce-Clearwater. Assuming every three visitors had a vehicle, then roughly 254,000 vehicles traveled on the Nez Perce-Clearwater annually, or between 700 to 1,200 vehicles per day forestwide. The range of 200 to 365 days was used to calculate the number of vehicles per day.

National Visitor Use Monitoring Program data correlates to road count data collected during the mixed-use analysis on main arterial roads taken over several weekends in 2011 and 2014, where the average daily count was 1,030 and 680, respectively. Of those counts, roughly 91 to 94 percent of the traffic was off-highway vehicle, passenger, or light pickup traffic (Mixed Use Analysis reports, 2012 and 2014). No fire suppression activity was recorded on the roads during the motorized mixed-use analysis.

Road and Trail Bridges

There are approximately 176 road bridges and 85 trail bridges under the jurisdiction of the Forest Service within the Land Management Plan area. Of the 176 road bridges, 169 are highway legal load bridges, 6 are weight-restricted, and 1 is closed due to travel management and condition. The

National Bridge Inspection Standards require all highway bridges on public roads to be rated for all legal loads and unrestricted routine permit loads, and they must be posted if there are any weight restrictions. Bridges are not usually posted if they have the capacity to carry the legal loads for posting described in the Manual for Condition Evaluation of Bridges or the Guide Manual for Condition Evaluation and Load and Resistance Factor Rating (LRFR) of Highway Bridges (AASHTO, 2003).

Prior to 2018, Forest Service policy required inspections to be performed every two years on every bridge under Forest Service jurisdiction. On June 8, 2018, the Federal Highway Administration issued risk-based, routine inspection interval implementation guidance that state transportation departments, federal agencies, and tribal governments can use as an alternate approach to Technical Advisory 5140.21 dated September 16, 1988, which was historically used to address the extended routine inspection interval. When state transportation departments, federal agencies, and tribal governments elect to use the 2018 guidance, they must submit their risk assessment criteria and a summary report to the Federal Highway Administration for approval.

Any new, rehabilitated, or structurally modified bridge should receive an initial inspection, be in service for at least 24 months, and receive its next routine inspection before establishing a risk-based, routine inspection interval. The assessment must be reviewed after each routine inspection to set the next inspection interval.

Trail bridges on the Nez Perce-Clearwater are generally inspected every five years by the Forest Service.

Facilities

The management of buildings and other structures is prescribed under Forest Service Manual 7310. Forests are mandated to develop a facilities master plan as a guide to facilities planning. The Nez Perce-Clearwater completed an updated Facility Master Plan in February 2018.

Administrative facilities are typically buildings and their appurtenances necessary to support the employees, equipment, and activities necessary for the management of the National Forests. Administrative facilities are separate from recreation facilities. Administrative facilities include fire stations, lookouts, offices, warehouses, communication towers, and shops as well as living quarters, such as barracks and individual residences. Living quarters are partially supported by rental receipts, while administrative and other facilities are financially supported through annual budget appropriations.

The Supervisor’s Office which serves the Nez Perce-Clearwater Forest is in Kamiah, Idaho. There are six ranger district offices within the Nez Perce-Clearwater: Palouse Ranger District in Potlatch, Idaho; North Fork Ranger District in Orofino, Idaho; Lochsa Ranger District in Kooskia, Idaho; Salmon River Ranger District near White Bird in Slate Creek, Idaho; Red River Ranger District in Elk City, Idaho; and Moose Creek Ranger District near Lowell, Idaho. Other major administrative building sites within the plan area include the Grangeville Air Center, Grangeville Dispatch, and Grangeville Office Annex.

There are approximately 487 Forest Service-owned administrative buildings within the Nez Perce-Clearwater, of which 261 are classified as being in poor condition. The rehabilitation or replacement of existing forest facilities that do not meet current operational standards and the disposal of those facilities that are considered surplus to the forest operational needs is a focus for the Nez Perce-Clearwater. The 2018 Nez Perce-Clearwater Facility Master Plan identifies 224 buildings to be retained for existing use, 6 buildings to be repurposed, 109 buildings to be retained for an alternate use, 148 buildings to be decommissioned, and 1 building to be acquired. There are four leased buildings within the plan area, which are the two former Supervisor's Offices and associated warehouses in Orofino, Idaho and Grangeville, Idaho. There are many historic buildings within the Land Management Plan area, including several sites that are listed on the National Register of Historic Places. See the Cultural Resources Section for further description of these properties.

Additional facilities within the Nez Perce-Clearwater include 12 work centers, 4 guard stations, and 39 lookouts. The Nez Perce-Clearwater also manages 13 drinking water systems and 20 wastewater systems for these work sites.

Airstrips

Public airstrips on the Nez Perce-Clearwater are considered infrastructure and are a segment of the transportation system. There are seven airstrips on the Nez Perce-Clearwater that are available for public use: Cayuse at Cayuse Creek in the North Fork drainage, Dixie at Dixie Guard Station, Fish Lake in the Lake Creek drainage of the Lochsa River, Moose Creek along the Selway River at Moose Creek Guard Station, Orogrande along Crooked River, Shear Airstrip along the Selway River at Shear Guard Station, and Wilson Bar along the Salmon River. The Fish Lake, Moose Creek, and Shear airstrips are located within the Selway-Bitterroot Wilderness and are managed as wilderness airstrips. Wilson Bar is managed as a Wild and Scenic River airstrip.

Dams

There are two dams within the Nez Perce-Clearwater plan area. Both are classified as low hazard dams and are not currently being operated.

- Erickson Dam is located on Erickson Creek, which is a tributary to the South Fork of the Clearwater River. It is an earthen dam with a height of 20 feet and normal storage of 8 acre-feet. It currently has no functioning outlet controls. The closest downstream community from Erickson Dam is Elk City, Idaho, which is approximately 10 miles away.
- Upper Bear Dam is in the Selway-Bitterroot Wilderness on Bear Creek, which is a tributary to the Selway River. It is an earthen dam with a height of 13 feet and normal storage of 82 acre-feet. It currently has no functioning outlet controls and has a condition index of 38. The closest downstream community from Upper Bear Dam is Lowell, Idaho, which is over 70 miles away.

These dams are inspected by the Nez Perce-Clearwater. The Idaho Department of Water Resources also inspects Erickson Dam.

Environmental Consequences

Effects Common to All Alternatives

Under all alternatives, including the No Action Alternative, effects to road bridges, facilities, airstrips, and dams would be similar: Road bridges within the Nez Perce-Clearwater would continue to be inspected and maintained or closed, if needed, due to condition in accordance with resource needs and access management direction. Facilities within the Land Management Plan area would be maintained or decommissioned in accordance with the Nez Perce-Clearwater Facility Master Plan. The seven existing airstrips would be maintained in serviceable condition and available for public use. The two existing dams would continue to be inspected. Removal or breaching of these dams should be considered if the action is deemed appropriate for resource enhancement since the dams are not currently used nor needed.

Road, bridge, and both recurrent and deferred facility maintenance would continue to occur, as funding allows. Physical conditions would continue to be addressed through maintenance activities and be based on public health and safety, resource protection, and mission priorities. Light detection and ranging remote sensing information has been used to verify and correct road data and to detect unclassified non-system roads. These non-system roads and roads with a history of high erosion or instability would continue to be evaluated for addition to the road system or decommissioning.

Annual operating budgets and supplemental funding would likely fluctuate, resulting in varying maintenance accomplishments from year to year. State and local government agencies with road management authority are expected to continue to maintain their existing road network within the Nez Perce-Clearwater. Some changes, such as widening, resurfacing, and bridge replacements, are probable but are dependent on budgets and funding allocations.

Timber harvest would continue to maintain roads within vegetative units. Stewardship sales and partners would continue to provide additional funds for stream habitat improvements for roads and bridges. Commercial traffic, such as timber hauling, can be expected to fluctuate to some degree depending on vegetation management activities. Market conditions and other external factors often influence activity levels. These traffic conditions are usually limited to relatively small geographic areas and short periods of time. Hauling occurs more often during the summer months but is not uncommon during the winter months.

The natural fire regimes would remain in a state of departure from the desired vegetation condition and the potential for uncontrolled wildfire to affect road and trail bridges, buildings, communication sites, and other infrastructure would continue to increase. Protection from fire for these improvements would continue to be needed and may increase as the forest condition continues in departure from the desired vegetation condition.

Access across the Nez Perce-Clearwater is influenced by a variety of factors. Given the mixed land ownership, including state lands and corporate timberlands, in and around the Nez Perce-Clearwater and the ongoing management actions taken on these lands, new access may arise through cooperative and cost-share agreements. Changes in ownership of private lands could result in continued requests for road access across National Forest System lands. Depending on the circumstances, these may be requests for Nez Perce-Clearwater or private road special-use authorizations. New access to National Forest System lands may be created, depending on the terms and conditions written into any new authorizations.

In Management Area 1, which comprises Wilderness, Wild and Scenic Rivers, and National Historic Landmark Areas, it is unlikely new roads would be constructed as such an action would require a change in the national designations of the Wilderness and National Historic Landmark areas. In addition, Wild and Scenic Rivers are by nature thinner and more difficult to locate additional roads. In Management Area 2, which includes lands within Idaho Roadless Areas, recommended wilderness areas, suitable wild and scenic rivers, parts of the Gospel Hump Geographic Area, and proposed and designated Research Natural Areas, there could be some decrease in road miles where access would be reduced, but roads could be relocated in Wild and Scenic River corridors for resource management. In Management Area 3, which includes the rest of the Nez Perce-Clearwater and consists of the areas with the majority of existing roads, trails, and structures, new road construction is anticipated to occur under all alternatives, with the highest levels of new construction under Alternatives W and X. New and relocated roads should be designed to minimize impacts to sensitive areas and optimize landing locations for harvesting equipment.

The following sections describe effects of the alternatives on National Forest System roads, which would vary under each alternative. Table 342 summarizes the anticipated effects between the alternatives for Nez Perce-Clearwater Forest System Roads.

Effects to No Action Alternative

Under the No Action Alternative, effects to roads would result from continued implementation of the 1987 Clearwater and Nez Perce Forest Plans. The geospatial analysis of the Nez Perce-Clearwater road system under the current forest plans indicates that 1,009,700 acres, or 83 percent, of the 1,217,682 acres in Management Area 3 are within 1,600 feet of a roadway and could be harvested from existing roads; therefore, a minor amount of additional roads for timber management may need to be constructed to access that acreage under implementation of the No Action Alternative.

Under the No Action Alternative, 1,139,059 acres would remain as designated Wilderness in Management Area 1 and an additional 197,695 acres of Wilderness are recommended. The Recommended Wilderness areas would continue to be managed as Idaho Roadless Areas with uses that would not preclude them from future Wilderness designation. The recommended Wilderness areas would be managed with no non-conforming uses, which means there would be no new road construction within that acreage and existing roads may be cherry-stemmed or decommissioned.

Under the No Action Alternative, 57,891 acres would remain as designated Wild and Scenic River and an additional 155,477 acres would be recommended for Wild and Scenic River designation. Wild and Scenic River corridors would continue to be managed under their approved river plans.

Under the No Action Alternative, the average annual timber volume that is anticipated to be sold is approximately 50 to 60 million board feet, which corresponds to roughly 12,330 commercial vehicles traveling the Nez Perce-Clearwater roads annually. The timber volume sold, and the subsequent commercial vehicle use, is anticipated to result in a need for replacement of around 18,800 cubic yards of aggregate material annually. This means an additional aggregate pit would need to be developed or an existing pit redeveloped annually.

The average annual timber harvest would cover roughly 1,200 acres of the approximately 1,489,736 acres in Management Area 2 and 2,600 acres of the approximately 1,217,682 acres in Management Area 3. Most of the road maintenance and commercial road use would be concentrated in those timber harvesting areas. Arterial and collector routes would need to be analyzed for improvements to a higher road maintenance management level. Roughly 25 percent of all road maintenance would be completed with funds from those sales.

The No Action Alternative would provide the current level of funding and options for performing road maintenance on the Nez Perce-Clearwater. As the amount of timber sold is directly proportional to the amount of funding National Forests receive, the lower rate of timber sold under the No Action Alternative would result in fewer miles of road being maintained and improved compared to the action alternatives.

Effects that Vary by Action Alternative

Alternative W

The geospatial analysis of the Nez Perce-Clearwater road system, under the current forest plans, indicates that 1,035,819 acres, or 84 percent, of the 1,238,906 acres in Management Area 3 is within 1,600 feet of a roadway and could be harvested from existing roads; therefore, additional roads for timber management may need to be constructed to access that acreage under implementation of Alternative W.

Under Alternative W, 1,139,059 acres would remain as designated Wilderness in Management Area 1 and an additional 856,933 acres would be recommended for Wilderness designation. The recommended Wilderness areas would be managed with no non-conforming uses, which means there would be no new road construction within that acreage and existing roads may be cherry-stemmed or decommissioned.

Under Alternative W, 57,891 acres would remain as designated Wild and Scenic River and an additional 64,587 acres would be recommended for Wild and Scenic River designation. This means road use could increase within that acreage, thereby increasing road maintenance needs, and new aggregate pit locations may be reduced, thereby reducing the amount of aggregate available for road resurfacing in these areas.

Under Alternative W, the average annual timber volume that is anticipated to be sold is approximately 215 to 241 million board feet, which corresponds to roughly 44,000 to 48,000 commercial vehicles traveling the Nez Perce-Clearwater roads annually. This would result in an average increase from about 12,330 to 46,100 commercial vehicles on the Nez Perce-Clearwater roads annually. This would almost quadruple the amount of commercial traffic on the roads. It would also require approximately 78,000 cubic yards of aggregate to be generated, which would be an increase of approximately 59,200 cubic yards annually. This means an additional one to two aggregate pits would need to be developed annually.

The average annual timber harvest would be roughly 800 acres of the approximately 1,468,512 acres in Management Area 2 and 11,800 acres of the approximately 1,238,906 acres in Management Area 3. The majority of the road maintenance and commercial road use would be concentrated in those timber harvesting areas. Arterial and collector routes would need to be analyzed for improvements to a higher road maintenance management level. Roughly 60 percent of all road maintenance would be completed with funds from those sales.

Alternative W would provide a higher level of funding and options for performing road maintenance on the Nez Perce-Clearwater. As the amount of timber sold is directly proportional to the amount of funding National Forests receive, the higher rate of timber sold under Alternative W would result in more miles of road being maintained and improved.

Alternative X

The geospatial analysis of the Nez Perce-Clearwater road system under the current forest plans indicates that 1,038,332 acres, or 83 percent, of the 1,244,330 acres Management Area 3 are within 1,600 feet of a roadway and could be harvested from existing roads; therefore, additional roads for timber management may need to be constructed to access that acreage under implementation of the No Action Alternative.

Under Alternative X, 1,139,059 acres would remain as designated Wilderness in Management Area 1, and no additional acres would be recommended for Wilderness designation. Roads would continue to be managed under the Idaho Roadless Area Rules.

Under Alternative X, 57,891 acres would remain as designated Wild and Scenic River, and no additional acres would be recommended as Wild and Scenic Rivers. Areas adjacent to non-designated rivers would remain available for aggregate supply, unless precluded by other circumstances.

Under Alternative X, the average annual timber volume that is anticipated to be sold is approximately 247 million board feet, which corresponds to roughly 50,200 commercial vehicles traveling the Nez Perce-Clearwater roads annually. This would more than quadruple the amount of commercial traffic on the roads. The timber volume sold, and the subsequent commercial vehicle use is anticipated to result in a need for replacement of around 86,000 cubic yards of aggregate material annually. This means an additional two or more aggregate pits would need to be developed annually.

The average annual timber harvest would be roughly 1,400 acres of the approximately 1,463,088 acres in Management Area 2 and 12,600 acres of the approximately 1,243,330 acres in Management Area 3. Most of the road maintenance and commercial road use would be concentrated in those timber harvesting areas. Arterial and collector routes would need to be analyzed for improvements to a higher road maintenance management level. Roughly 62 percent of all road maintenance would be completed with funds from those sales.

Alternative X would provide the highest level of funding and options for performing road maintenance on the Nez Perce-Clearwater. As the amount of timber sold is directly proportional to the amount of funding National Forests receive, the higher rate of timber sold under Alternative X would result in more miles of road being maintained and improved.

Alternative Y

The geospatial analysis of the Nez Perce-Clearwater road system under the current forest plans indicates that 1,017,009 acres, or 83 percent, of the 1,219,951 acres in Management Area 3 are within 1,600 feet of a roadway and could be harvested from existing roads; therefore, additional roads for timber management may need to be constructed to access that acreage under implementation of the No Action Alternative.

Under Alternative Y, 1,139,059 acres would remain as designated Wilderness in Management Area 1 and an additional 309,332 acres would be recommended for Wilderness designation. The recommended wilderness areas would be managed with no non-conforming uses, which means there would be no new road construction within that acreage and existing roads may be cherry-stemmed or decommissioned.

Under Alternative Y, 57,891 acres would remain as designated Wild and Scenic River and an additional 99,120 acres would be recommended for Wild and Scenic River designation. This means road use could increase within that acreage, thereby increasing road maintenance needs, and aggregate pit locations may be reduced, thereby reducing the amount of aggregate available for road resurfacing.

Under Alternative Y, timber outputs would be around 150 million board feet annually resulting in an average increase of commercial vehicle traffic from 12,00 to 28,000 on the Nez Perce-Clearwater roads annually. This would more than double the amount of commercial traffic on the roads. The timber volume sold, and the subsequent commercial vehicle use is anticipated to result in a need for replacement of around 45,000 cubic yards of aggregate material annually, which would be an increase of approximately 27,000 cubic yards annually. This means one additional aggregate pit would need to be developed annually.

The average annual timber harvest would be roughly 1,400 acres of the approximately 1,487,467 acres in Management Area 2 and 6,100 acres of the approximately 1,219,195 acres in Management Area 3. Most of the road maintenance and commercial road use would be concentrated in those timber harvesting areas. Arterial and collector routes would need to be analyzed for improvements to a higher road maintenance management level. Roughly 46 percent of all road maintenance would be completed with funds from those sales.

Alternative Y would provide moderately increased funding and options for performing road maintenance on the Nez Perce-Clearwater. As the amount of timber sold is directly proportional to the amount of funding National Forests receive, the moderately increased rate of timber sold under Alternative Y would result in more miles or road being maintained and improved.

Alternative Z

The geospatial analysis of the Nez Perce-Clearwater road system under the current forest plans indicates that 1,032,491 acres, or 84 percent, of Management Area 3 is within 1,600 feet of a roadway and could be harvested from existing roads; therefore, some additional roads for timber management may need to be constructed to access that acreage under implementation of the No Action Alternative.

Under Alternative Z, 1,139,059 acres would remain as designated Wilderness in Management Area 1 and an additional 474,659 acres would be recommended for Wilderness designation. The recommended wilderness areas would be managed with non-conforming uses, which means there would be new recreational uses; however, there would be no new road construction within that acreage and existing roads may be cherry-stemmed or decommissioned.

Under Alternative Z, 57,891 acres would remain as designated Wild and Scenic River and an additional 145,976 acres would be recommended for Wild and Scenic River designation. This means road use could increase within that acreage, thereby increasing road maintenance needs, and aggregate pit locations may be reduced, thereby reducing the amount of aggregate available for road resurfacing.

Under Alternative Z, timber outputs would be around 80 million board feet annually resulting in an average increase of commercial vehicle traffic from 12,000 to 14,000 on the Nez Perce-Clearwater roads annually. This would increase the amount of commercial traffic on the roads. It would also require a volume of aggregate generated to be 20,500 to 24,000 cubic yards, which would be an increase of approximately 4,000 cubic yards annually. This means no additional aggregate pits would need to be developed annually.

The average annual timber harvest would be roughly 1,200 acres of the approximately 1,472,540 acres in Management Area 2 and 4000 acres of the approximately 1,234,879 acres in Management Area 3. Most of the road maintenance and commercial road use would be concentrated in those timber harvesting areas. Arterial and collector routes would need to be analyzed for improvements to a higher road maintenance management level. Roughly 25 percent of all road maintenance would be completed with funds from those sales.

Alternative Z would provide a higher but comparable level funding to the No Action Alternative for performing road maintenance on the Nez Perce-Clearwater. As the amount of timber sold is directly proportional to the amount of funding National Forests receive, the lower rate of timber sold under Alternative Z would result in fewer miles or road being maintained and improved.

Preferred Alternative

For the Preferred Alternative, the geospatial analysis of the Nez Perce-Clearwater road system under the current forest plans indicates that 1,009,700 acres, or 81 percent, of the 1,240,340 acres in Management Area 3 are within 1,600 feet of a roadway and could be harvested from existing roads; therefore, a minor amount of additional roads for timber management may need to be constructed to access that acreage under implementation of the Preferred Alternative.

Under the Preferred Alternative, 1,231,638 acres would remain as designated wilderness in Management Area 1 and an additional 258,210 acres of wilderness are recommended in Mallard-Larkins, Hoodoo, and Meadow Creek. The recommended wilderness areas would continue to be managed as Idaho Roadless Areas with uses that would not preclude them from future wilderness designation. Two non-conforming uses would be allowed in the recommended wilderness areas: (1) Maintenance of existing buildings and currently available recreational rentals will remain, and (2) The use of chainsaws by administrative personnel, and through agreement by partners, for the maintenance of trails. A cherry stem will be recommended to maintain access on Elk Mountain Road, Forest Road 285.

The plan includes an objective to remove all other non-conforming uses within five years of the record of decision. The use and maintenance of Black Mountain Lookout will be impacted with the Mallard Larkins recommended wilderness area. This designation could create additional difficulties in staffing, maintenance, and repair of the lookout.

Under the Preferred Alternative, 57,891 acres would remain as designated wild and scenic rivers. An additional 61,849 acres would be recommended for wild and scenic river designation. Therefore, road use could increase within that acreage, thereby increasing road maintenance needs, and new aggregate pit locations may be reduced, thereby reducing the amount of aggregate available for road resurfacing in these areas.

Under the Preferred Alternative, 10 percent more motorized summer recreation opportunity spectrum area and 21 percent more motorized winter recreation opportunity spectrum area will be delineated. There would be a reduction in summer and winter non-motorized areas. This will likely not impact the road, building, or airstrip infrastructure very much, except for at trail heads. Trail heads will likely need to be made larger to accommodate more trailer traffic. It could cause additional mixed use of vehicles sizes that will need to be addressed when and where issues arise.

Under the Preferred Alternative, the average annual timber volume that is anticipated to be sold is approximately 190 to 210 million board feet, which corresponds to roughly 40,000 commercial vehicles traveling on Nez Perce-Clearwater roads annually. This would nearly quadruple the amount of commercial traffic on the roads compared to 2018. The timber volume sold, and the subsequent commercial vehicle use, is anticipated to result in a need for replacement of around 69,000 cubic yards of aggregate material annually. This means an additional one to two aggregate pits would need to be developed or redeveloped annually.

The average annual timber harvest acreage would be roughly 8,825 to 10,000 acres of the approximately 1,463,088 acres in Management Area 2 and 1,243,330 acres in Management Area 3. Most of the road maintenance and commercial road use would be concentrated in those timber harvesting areas. Arterial and collector routes would need to be analyzed for improvements to a higher road maintenance management level. Roughly 60 percent of all road maintenance would be completed with funds from those sales.

Cumulative Effects

Under the No Action Alternative, the incremental cumulative effects on roads would be minimal as the amount of new road construction, decommissioning, and maintenance activities that would occur during the planning timeframe would be very small compared to the overall Nez Perce-Clearwater road system. Roads would continue to be upgraded to the PACFISH and INFISH standards as roadwork is implemented. This means existing culverts would be upsized to pass 100-year flood events.

Under Alternative W, the road system would be used for timber management more extensively, which could result in more temporary area closures for public safety during haul periods; therefore, public access to those areas could be reduced. Public access could further be reduced due to closures for fuels management activities and for wildlife management. Higher timber harvest would also result in more temporary roads, which could have a cumulative effect on aquatic resources.

Like Alternative W, under Alternative X the road system would be used for timber management more extensively, which could result in more temporary area closures for public safety during haul periods; therefore, public access to those areas could be reduced. Public access could further be reduced due to closures for fuels management activities and for wildlife management. Higher timber harvest would also result in more temporary roads, which could have a cumulative effect on aquatic resources.

Under Alternative Y, the road system would be used for timber management somewhat extensively, which could result in temporary area closures for public safety during haul periods; therefore, public access to those areas could be reduced. Public access could further be reduced due to closures for fuels management activities and for wildlife management. Moderately higher timber harvest would also result in more temporary roads, which could have a cumulative effect on aquatic resources.

Under Alternative Z, the incremental cumulative effects on roads would be minimal as the amount of new road construction, decommissioning, and maintenance activities that would occur during the planning timeframe would be very small compared to the overall Nez Perce-Clearwater road system. Designation of additional Wild and Scenic Rivers would further reduce the locations where gravel pits could be located.

Under the Preferred Alternative, the road system would be used somewhat extensively for timber management, which could result in temporary area closures for public safety during haul periods; therefore, public access to those areas could be reduced. Public access could further be reduced due to closures for fuels management activities and for wildlife management. Moderately higher timber harvest would also result in more temporary roads, which could have a cumulative effect on aquatic resources.

Effects to Resource from Other Resources

Air Quality

Air quality impacts on infrastructure are expected to be minimal under all alternatives. If the Nez Perce-Clearwater were to become a non-attainment area within the planning timeframe, mechanized construction equipment would be subject to emissions reduction requirements. This could result in increased costs for infrastructure projects due to the cost of installing emissions reduction devices. If new or modified industrial facilities get proposed within the Land Management Plan area, the facilities would be subject to the Forest Service's air permit review process to ensure that air emissions will not adversely impact air quality related values of federally protected wilderness areas.

Carbon Storage

Management of carbon storage is not expected to impact infrastructure on the Nez Perce-Clearwater under any of the alternatives due to the scale of forest biomass compared to the footprint of existing and anticipated forest infrastructure.

Climate Change

Effects from climate change on infrastructure should be considered during infrastructure planning and maintenance activities under all alternatives. Culverts may need to be sized larger to handle increased flow volumes during spring runoff events and bridge structures may require more scour protection. Consideration should be given to locating facilities at higher elevations above streams and rivers to avoid flooding. Roads may be closed or relocated due to the potential for damage during high flow events. Seasonal closures may need to be adjusted to protect roads from traffic damage during wet conditions.

Cultural and Heritage

Effects from cultural and heritage resources on infrastructure would occur under all alternatives. Infrastructure listed or eligible to be listed on the National Register of Historic Places is subject to the National Historic Preservation Act and modifications to or demolition of these resources requires consultation with the State Historic Preservation Office. Requirements to protect viewsheds may limit where new infrastructure is constructed.

Ecology (other than fire ecology)

The general health of the forest has the potential to affect infrastructure under all alternatives. Trees killed by disease and pests could fall and block culverts and roads. Under Alternatives W and X, the forest vegetative desired condition would be achieved sooner, in 30- and 20-years respectively, than under Alternatives Y and Z, which would be in 50- and 100-years. The Preferred Alternative would achieve the vegetative desired condition in 35 to 40 years.

Economic Sustainability

Economic sustainability is anticipated to have little to no effect on infrastructure under all alternatives. Forest system roads provide access to economical sustainable resources Under Alternatives W and X, which would have higher timber output, economic sustainability would be higher, and more road construction, maintenance, and reconditioning would likely occur.

Fire Management

Fire management could have a protective effect on infrastructure as it would reduce the likelihood of events that could damage infrastructure. Fuels management activities, such as prescribed burning and fire suppression actions, are likely to continue under all alternatives. Administrative use of gated roads that normally prohibit motor vehicle use is likely when these management activities occur. Roads in road Maintenance Level 1 storage may be opened to facilitate suppression actions. These roads would likely be used for the duration of suppression efforts and post-fire work and then returned to their previous status. Suppression efforts should continue to provide structure protection to bridges, buildings, and communication sites.

Fisheries

Watershed improvement activities are likely to continue under all alternatives. The consequences to motor vehicle access to implement watershed improvements are expected to be minimal. Activities that would occur on roads that are generally not designated for motor vehicle use are treatments to reduce sediment production and transport sediment to surface waters or to provide for aquatic organism passage. Actions taken might include culvert removal, out-sloping of road prisms, or the removal of unstable fills. Watershed treatments will continue to be completed on roads that are designated for motor vehicle use and may result in traffic delays or temporary road closure of open roads while construction occurs.

Numerous Land Management Plan components related to infrastructure are designed to minimize the transport of sediment from roads to waterbodies. Generally, these Land Management Plan components would not affect the public use of roads except for the decommissioning of roads, which may restrict motorized travel depending on the site-specific decision. Road conditions on existing roads would have improved conditions through proper best management practices and maintenance and decommissioned roads would have improved hydrologic conditions due to the disconnection of the road from the stream system. See the following plan components for additional details: FW-DC-ARINF-01, FW-STD-ARINF-01, FW-STD-ARINF-02, FW- STD-ARINF-03, FW-STD-ARINF-07, FW-GDL-ARINF-01, FW-GDL-ARINF-02, FW-GDL-ARINF-03, FW-GDL-ARINF-04, FW-GDL-ARINF-06, FW-GDL-ARINF-07, FW-GDL-ARINF-08, FW-GDL-ARINF-09, FW-GDL-ARINF-10, and FW-GDL-ARINF-10.

Forest Products (other than timber)

The collection of forest products is not anticipated to affect infrastructure as existing infrastructure is generally used and these activities are expected to be low impact.

Invasive Species

Effects from invasive species on infrastructure could occur under all alternatives. If aggregate pits become infested with weeds, the pit would have to be closed and the area treated for invasives. The availability of certified weed-free straw for erosion and sediment control could limit construction activities or methods.

Lands and Lands Special Uses

Pursuit of easements and rights-of-way needs to continue to ensure continued access to Nez Perce-Clearwater roads. Lands special uses are not anticipated to influence infrastructure under any of the alternatives, as they do not permit uses of the infrastructure.

Livestock Grazing

Grazing is not anticipated to influence infrastructure at current levels. Increased levels of livestock grazing could have an effect, as roads could be damaged by heavier livestock traffic.

Management Area Allocations

Management Area 3 contains the most development. The alternatives for Management Area 2 could influence some roads. These effects would be site specific and depend upon road and wilderness recommendations regarding cherry-stemming of roadways, access for lookouts, and trail access.

Minerals

Proposals for exploration and development are regulated by existing mining law. Access and long-term or temporary road development are often associated with mineral exploration and development, but a site-specific analysis would be required prior to any approval for exploration or development activities.

If any mine reclamation activities occur, they would likely, but not always, use existing roads. These may be roads that are not currently designated for motor vehicle use. They would likely be used for the duration of the reclamation work and then returned to their previous status. New roads, trails, or other types of access may be approved for a proposed mining operation as long as the proposal is incident to mining and within the scope of the next logical phase of mining development and would be subject to a site-specific analysis.

The availability of suitable gravel for aggregate surfacing could affect the amount of road maintenance the Nez Perce-Clearwater can accomplish under all alternatives as quality rock sources on the Nez Perce-Clearwater are limited.

Rare Plants

The presence of rare plants or suitable habitat for those species could affect the location of new infrastructure under all alternatives. These resources would be identified during project level surveys and modifications to infrastructure design or location may be required to avoid or minimize impacts to rare plants.

Recommended Wilderness

Existing infrastructure within recommended wilderness would need to be assessed prior to wilderness designation and the need for access would have to be evaluated. Access to fire lookouts is anticipated to be maintained for public safety and resource protection. The need for access to other locations would need to be evaluated. Existing roads within the boundary of the proposed wilderness may be reduced to wilderness access points, such as cherry-stemmed or decommissioned.

Research Natural Areas

It is unlikely that there would be changes to infrastructure from research natural areas under any of the alternatives as these areas are typically devoid of infrastructure to protect the integrity of these sites.

Roadless Areas

There are roads within the Idaho Roadless Areas which serve as area boundaries. Since most of the proposed wilderness areas are in current Idaho Roadless areas, road management could change if the area becomes designated wilderness. If designated, a road system analysis would be needed to determine whether those roads stay open or are closed.

Scenery

The management of landscape character and scenic integrity objectives could affect the location of new infrastructure under all alternatives. These resources would be identified during project level surveys and modifications to infrastructure design or location may be required to avoid or minimize impacts to scenery.

Social Sustainability

Social sustainability is a complex issue and is related to firewood and food harvest, timber harvesting jobs, and livestock grazing on the Nez Perce-Clearwater. Timber harvest is addressed in the alternatives analysis and the other components of social sustainability are not anticipated to affect infrastructure as existing infrastructure is generally used, and these activities are expected to be low impact. There is local interest in historic infrastructure on the Nez Perce-Clearwater, which contributes to the social identity of the surrounding communities. Some of these historic buildings and structures may need the support of volunteer groups to be maintained for public enjoyment.

Soils

Soils could affect infrastructure under all alternatives. Landslides are a common occurrence on the Nez Perce-Clearwater, and unstable slopes slough above roads, causing soils and other debris to clog ditches and culverts, which in turn can cause damage to roads.

Suitable Wild and Scenic Rivers

Designation of additional Wild and Scenic Rivers and inclusion of additional eligible Wild and Scenic Rivers on the Nez Perce-Clearwater would likely affect infrastructure. Under Alternatives W, Y, and Z, aggregate pits would not be developed within a quarter mile of designated and eligible Wild and Scenic Rivers. As quality aggregate is often found near rivers, this could reduce the availability of suitable material for road resurfacing.

Sustainable Recreation

Recreation and access management and roads and motorized trails management would affect infrastructure under all alternatives, as it could change the level of road and facility maintenance. Movement towards the sustainable recreation concept could result in more partnerships and reduced financial burden on the Nez Perce-Clearwater.

Timber

Commercial timber harvest activities will generally result in road maintenance and reconstruction and the continued application of best management practices on existing National Forest System roads. New road construction is likely to be limited; temporary road construction would be used more commonly to meet short-term access needs. Administrative use of gated roads that normally prohibit motor vehicle use yearlong is likely when management activities, such as pre-commercial thinning, invasive weed treatments, or other noncommercial silvicultural treatments, are planned.

Under the No Action Alternative and Alternative Z, timber outputs would be lower and there would be less road maintenance since most road maintenance is accomplished through timber sales and road maintenance is funded from the sale activity. Under Alternatives W and X, timber harvest would be higher, which would result in more road maintenance as roads used for timber harvest would be maintained and, in some cases, reconstruction would be available to the public following completion of harvest. Under Alternative Y, there would be a moderate amount of timber harvest, which would result in an intermediate level of road maintenance. The Preferred Alternative should yield a higher level of maintenance than the existing condition and Alternative Z.

Water Resources

The following proposed forestwide standards, objectives, and guidelines would affect infrastructure under all alternatives:

FW-STD-RMZ-02. Staging of vehicles or heavy equipment, refueling, and fuel storage shall be located outside of riparian management zones to avoid water contamination. If no other location is appropriate and refueling or storage is needed within riparian management zones, locations must be approved by the Timber Contracting Officer, Contracting Officer, or their designee and have an approved spill containment plan.

FW-STD-RMZ-03. Herbicides, pesticides, and other toxicants and chemicals shall only be applied within riparian management zones when the activity does not retard attainment of aquatic and riparian desired conditions.

FW-STD-RMZ-05. Trees felled for safety shall be retained onsite unless more than what is needed to achieve aquatic and riparian desired conditions. Trees shall be directionally felled towards or into streams, where it is safe and practical to do so. If aquatic and riparian desired conditions for wood are met at the site, surplus wood can be transported to other aquatic and riparian restoration project sites. Exceptions to this standard are allowed in developed recreation and administrative sites where needed to address concerns for human safety or infrastructure and when not practicable to leave on site.

FW-GDL-RMZ-07. To reduce sediment delivery to streams during or after fire suppression activities, disturbed areas in riparian management zones, such as firelines, drop-points, camps, roads, and trails, should be restored by actions such as scattering slash piles, replacing logs and boulders, scarifying soils, re-contouring terrain, and reseeding with native species.

FW-STD-ARINF-04. New, replacement, and reconstructed stream crossing sites, such as culverts, bridges, and other permanent stream crossings, shall accommodate at least the 100-year flow, including associated bedload and debris.

FW-STD-ARINF-06. In fish bearing streams, construction, reconstruction, or replacement of stream crossings shall not impair passage of any life stages of native aquatic organisms, unless barriers are desired to maintain or prevent spread or invasion of non-native species in alignment with fish management agencies.

FW-GDL-ARINF-03. To reduce the risk of sediment delivery from gully formation or mass wasting when closing travel routes such as roads, skid trails, and temporary roads with physical barriers such as berms, drainage features should be left in a condition that will function without any maintenance for the planned duration of the closure.

FW-GDL-ARINF-07. To reduce sediment delivery from maintenance activities, such as road blading and snow plowing, avoid sidecasting into streams. Care should be taken when plowing snow so as not to include road soil. Breaks should be incorporated in the snow berms to direct water off the plowed surface.

FW-GDL-ARINF-11. Culverts and bridges in fish bearing and perennial streams should allow for passage of fish and other aquatic and riparian dependent species through the establishment of banks inside or beneath the crossing structure and mimicking the natural channel features, unless precluded by site characteristics such as bedrock or high channel gradient.

The watershed restoration program would have an effect on infrastructure as it would identify road and human use related issues on the watershed conditions. The program would work to identify and minimize human effects to the watershed by activities, such as, but not limited to, road decommissioning, road improvements, road relocation, bridge or culvert replacements, water quality improvements like stock pond relocation, abandoned mine land reclamation, additional toilet installation, and sediment controlling settling ponds. Increased timber harvest could provide additional funds for such projects through stewardship funds or projects that would improve water quality and provide for more road maintenance.

Tribal Trust Responsibilities

Tribal treaty rights would continue to be honored and all legally mandated trust responsibilities would continue to be fulfilled to the extent that they are determined to be applicable to National Forest System lands on the Nez Perce-Clearwater. Effects from tribal treaty rights on infrastructure are not anticipated under any of the alternatives.

Vegetation

Vegetation could have an effect on infrastructure under all alternatives. If vegetation can grow into the road prism or over infrastructure, the facility could become unsafe and unusable. Under all alternatives, it is expected that vegetation management would be implemented to ensure facilities remain free of nearby vegetation to protect these structures. Vegetation is expected to encroach on some Maintenance Level 1 roads, which would result in reduced drivability. Annual road maintenance, including brushing to remove roadside vegetation, would continue to occur under all alternatives.

Wildlife

Wildlife could influence roads within the Nez Perce-Clearwater under all alternatives as some roads may be closed for elk security and other wildlife needs.

Summary of Consequences

Table 342 contains a summary of potential plan consequences by alternative.

Table 342. Infrastructure summary of consequences by alternative

Measurement Indicator	No Action Alternative	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternative
Acres within 1,600 feet existing roads	1,009,717	1,035,819	1,038,332	1,017,009	1,032,491	1,009,700
Relative number of new and temp roads	lower	higher	higher	moderate	lower	Higher
Acres recommended wilderness	197,695	856,933	0	309,332	474,659	258,210
Acres suitable wild and scenic river	155,477	64,587	0	99,120	145,976	61,849
Average annual timber volume (MMBF)	55	228	237	133	65	200
Annual commercial traffic counts	9800–14,800	44,000–48,000	48,000–52,000	26,000–30,000	12,000–16,000	38,000–42,000
Cubic yards aggregate for roads	17,000–20,000	74,000–82,000	82,000–89,000	42,000–48,000	21,000–24,000	65,000–72,000
Additional pits required annually	0	1–2	2	1	0	1–2

Measurement Indicator	No Action Alternative	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternative
Percent roads maintained from timber sales	25	60	62	45	30	Still working
Miles of road maintained or improved	1200	1900	2000	1400	1250	Still working

3.4.5 Land Ownership and Land Uses

This report addresses land ownership administration and adjustments and lands special uses of National Forest System lands on the Nez Perce-Clearwater. The management of National Forest System land includes the surveying and marking of boundaries; acquisition and exchange of lands; handling of title claims and encroachments; acquisition of rights-of-way; and authorization and management of special uses to protect resource values and the interests of the federal government.

Adjustments of land ownership can occur through congressionally mandated or discretionary conveyances, exchanges, and acquisitions. The objectives of the Forest Service land ownership adjustment program (Forest Service Manual 5402) are to:

- achieve the optimum land ownership pattern to provide for the protection and management of resource uses to meet the needs of the nation now and in the future;
- avoid land use conflicts with non-federal landowners by settling land claims equitably and promptly; and
- provide resource administrators readily accessible and understandable title information affecting the status and use of the lands and resources they administer.

Land occupancy and use by private parties and other government entities is managed through the issuance of special-use authorizations, such as permits, term permits, leases, and easements. Authorized special uses on the Nez Perce-Clearwater include industrial or commercial uses, private uses, and a variety of recreational uses.

All occupancy, use, or improvements on National Forest System lands that are not directly related to timber harvest, grazing, mining activities, and recreation are referred to as “non-recreation special uses.” Typically, non-recreation special uses include uses such as roads, utilities, storage facilities, communications sites, research, and commercial filming. Use and occupancy of National Forest System lands may be authorized when such use is determined to be in the public interest.

Relevant Laws, Regulations, and Policy

Federal Laws

The following is a select set of the statutory authorities that govern landownership adjustments and the issuance and administration of special-use authorizations on the Nez Perce-Clearwater. They are briefly identified and described below to provide context to the management and evaluation of these resources. There are multiple other laws, regulations, and policies not described below that also guide the management of these programs; see Forest Service Manuals 2700, 5400, and 5500 for a comprehensive listing.

Laws and Executive Orders

Organic Administration Act of June 4, 1897 (16 U.S.C. 477-482, 551): This act authorizes the Secretary of Agriculture to issue rules and regulations for the occupancy and use of the National Forests. This is the basic authority for authorizing use of National Forest System lands for other than rights-of-way.

Preservation of American Antiquities Act of June 8, 1906 (16 U.S.C. § 431 et seq.): This act authorizes permits for archeological and paleontological exploration involving excavation, removal, and storage of objects of antiquity or permits necessary for investigative work requiring site disturbance or sampling that results in the collection of such objects.

Occupancy Permits Act of March 4, 1915 (16 U.S.C. § 497 et seq.), as amended: This act authorizes use and occupancy on National Forest System lands for recreational purposes, including resorts and recreation residences.

General Exchange Act of March 20, 1922 (16 U.S.C. 485, 486): This act authorized the Forest Service to consolidate its holdings in National Forests where a large percentage of private lands are intermingled with national forest lands. It makes possible the exchange of inholdings within national forests for private lands of equal value and within the same state.

Section 7 of the Granger-Thye Act of April 24, 1950 (16 U.S.C. 490, 504, 504a, 555, 557, 571c, 572, 579a, 580c-5801, 581i-1): This act authorizes special-use permits not to exceed 30-years in duration for the use of structures or improvements under the administrative control of the Forest Service and for the use of land in connection without acreage limitation.

Highway Act of August 27, 1958 (23 U.S.C. 317), supplemented by the Act of October 15, 1966 (49 U.S.C. 1651): This act authorizes the Federal Highway Administration to grant easements to states for highways that are part of the federal-aid system or that are constructed under the provision of Chapter 2 of the Highway Act. The Forest Service consents to the grant of these easements in a form agreed upon by the two agencies and upon the state highway agency's execution of stipulations. This is the only authority for granting rights-of-way for projects on the federal-aid system or projects constructed under the provisions of Chapter 2 of the Highway Act (Forest Service Manual 2731).

Wilderness Act of September 3, 1964 (16 U.S.C. 1131-1136): This act establishes requirements for special use authorizations in designated wilderness areas for temporary structures, commercial public services, and access to valid mining claims and non-federal lands. Under this act, Presidential approval is necessary for the establishment of new water facilities, power projects, and transmission lines. Except for the Alaska National Interest Lands Conservation Act of December 2, 1980, this act is the exclusive authority for rights-of-way occurring within designated wilderness areas.

Land and Water Conservation Fund Act of September 3, 1964, as amended (16 U.S.C. 4601-6a(c)): Section 4(c) of this act authorizes permits for recreation, such as group activities, organized events, motorized recreational vehicle use, and other specialized recreation activities of limited duration.

National Forest Roads and Trails Act of October 13, 1964 (16 U.S.C. 532-38): This act authorizes the Secretary of Agriculture to grant temporary or permanent easements to landowners who join the Forest Service in providing a permanent road system that serves lands administered by the Forest Service and lands or resources of the landowner. It also authorizes the grant of easements to public road agencies for public roads that are not a part of the federal-aid system (Forest Service Manual 2732).

Sisk Act of December 4, 1967, as amended (16 U.S.C. 484a): This act authorizes the exchange of lands with states and local governments.

Act of November 16, 1973 (30 U.S.C. 185): This act, amending Section 28 of the 1920 Mineral Leasing Act, authorizes the Forest Service to issue authorizations for oil and gas pipelines and related facilities located wholly on National Forest System land. When the land is under the jurisdiction of two or more federal agencies, authority for issuance is reserved to the United States Department of the Interior's Bureau of Land Management, subject to approval by the agencies involved.

Endangered Species Act of 1973 (16 U.S.C. 1531-1536, 1538-1540): This act provides for the conservation of endangered and threatened species and their habitats.

Federal Land Policy and Management Act of October 21, 1976 (43 U.S.C. 1761-1771): Title V of the Federal Land Policy and Management Act authorizes the Secretary of Agriculture to issue permits, leases, or easements to occupy, use, or traverse National Forest System lands. The Federal Land Policy and Management Act directs the United States to receive fair market value unless otherwise provided for by statute and provides for reimbursement of administrative costs in addition to the collection of land use fees (43 U.S.C. 1764(g)).

Alaska National Interest Lands Conservation Act of 1980 (16 U.S.C. 3210): The Alaska National Interest Lands Conservation Act (ANILCA) provides numerous authorities related to access that are specific to National Forests in Alaska. The provisions of section 1323(a) (16 U.S.C. 3210) of this act, however, apply to all National Forest System lands. This section provides that, subject to terms and conditions established by the Secretary of Agriculture, the owners of non-federal land within the National Forest System shall be provided adequate access to their land. Regulations implementing section 1323(a) are set forth in 36 CFR § 251, subpart D—Access to Non-Federal Lands. See Forest Service Manual 2701.3, paragraph 3, for the summary of the provisions of 36 CFR § 251, subpart D.

Small Tracts Act of January 12, 1983 (16 U.S.C. 521c-521i): This act authorizes the sale, exchange, or interchange of certain parcels of minimal size.

National Forest Ski Area Permit Act of 1986 (16 U.S.C. 497b): This act authorizes the Secretary of Agriculture to issue permits for ski areas and other snow sports and recreational uses on National Forest System lands.

Act of May 26, 2000 (16 U.S.C. 406l-6d): This act supplements the authority of the Secretary of Agriculture to regulate commercial filming and still photography on National Forest System lands. It also authorizes the Secretary to retain and spend land-use fees collected for commercial filming and still photography without further appropriation and provides for recovery of administrative and personnel costs in addition to the collection of the land use fee.

Federal Lands Recreation Enhancement Act of 2004 (16 U.S.C. 6801-6814): This act authorizes the Forest Service to charge standard and expanded amenity recreation fees and to require and charge fees for special recreation permits. Fee revenues may be retained and spent by the Forest Service in accordance with the act's requirements.

Cabin Fee Act of December 22, 2014 (16 U.S.C. 3193, 6901, 6201): This act directs the Forest Service to modify the Recreation Residence Program, as the program applies to units of the National Forest System derived from the public domain by implementing a simple, equitable, and predictable procedure for determining cabin user fees.

Code of Federal Regulations (CFR): The following regulations provide direction for the management of special uses on National Forest System lands:

- 36 CFR § 251— Land Uses, subparts A: Miscellaneous Land Uses; B: Special Uses; C: Appeal of Decisions Relating to Occupancy and Use of National Forest System Lands; D: Access to Non-Federal Lands; and E: Revenue-Producing Visitor Services in Alaska.
- 36 CFR § 254 — Landownership Adjustments, Subparts A: Land Exchanges; B: National Forest Town sites; C: Conveyance of Small Tracts.

Policy

The Lands Ownership and Adjustments program references the following policy manual and handbook direction:

- Forest Service Manual (FSM) 5400 (Landownership); Forest Service Handbook (FSH) 5409.13 (Land Acquisition Handbook); 5409.17 (Rights-of-Way Acquisition Handbook)
- FSM 5500 (Landownership Title Management); FSH 5509.11 (Title Claims, Sales, and Grants Handbook)
- The Lands Uses program references the following policy manual and handbook direction:
- FSM 2700 and FSH 2700 – Special Uses Management

Methodology

Spatial Scale

The effects analysis boundary for this report is the current number of acres administered by the Nez Perce-Clearwater, chosen due to the fact that potential project actions that may be considered within both the lands adjustment and lands uses programs will only be considered on National Forest System lands.

Temporal Scale

The time frame considered for the analysis of lands and lands uses is 15 years, as this is the anticipated time frame and expected life of the Land Management Plan.

Methods and Assumptions

The number of acres of National Forest System lands currently administered by the Nez Perce-Clearwater and the number of special-use authorizations currently issued were compared to potential changes that might result from implementation of any of the alternatives considered.

The aggregate number of acres in each alternative, as well as the management area description and direction for these acres, may have an impact on the lands adjustment and lands uses resource.

This is due to the assumptions that:

- if fewer acres of land are available for management, there may be fewer opportunities to provide lands uses authorizations for commercial and private entities; and
- the type of management area direction mix decided upon for National Forest System acres may impact or influence the numbers and types of lands uses authorizations that could be available for various entities.

Therefore, there may be a change in the types of uses authorized and the location of uses based on the suitability components for the various land allocations. The analysis will look at the number of special use authorizations administered, the types of uses authorized, and the location of the uses compared to potential changes that may result from implementation of the alternatives, such as existing and potential future uses that may not be suitable in recommended wilderness, backcountry areas, and other special areas.

Information sources

The Forest Service uses the Land Status Record System (LSRS) as the repository for all realty records and land title documents. The LSRS includes accurate information on ownership acreages, condition of title, administrative jurisdiction, rights held by the United States, administrative and legal use restrictions, encumbrances, and access rights on land or interests in land in the National Forest System.

The Forest Service uses the Special-Uses Database System (SUDS) to create and administer special-use authorizations. This data is supported by hard-copy files held at the Ranger District and Forest Supervisor’s Offices.

Measurement Indicators

Key indicators that will be looked at through this report include:

- Potential change to acres of National Forest System land administered – Land Adjustments and Lands Uses
- Potential change to the number of special use authorizations – Lands Uses

Affected Environment

Existing Condition

The Nez Perce-Clearwater currently contains 4,072,798 acres of land within its proclaimed boundary. Of that land, 3,935,456 acres are National Forest System lands in federal ownership and managed by the Forest Service. 137,342 acres within the proclaimed boundary are non-National Forest System lands managed by entities other than the Forest Service, such as other federal agencies, state or local governments, and private owners.

Public lands are generally retained in federal ownership to provide long-term values. The vision for the planning area is to retain in public ownership all lands currently under its administration that meet the long-term needs of maintaining the integrity of contiguous natural ecosystems, river frontage, riparian areas and wetland ecosystems, recreation and open space, scenery, clean air and water, and habitat for plant and animal populations. Through the methods available to the agency, the Forest Service acquires lands or mineral estates that enhance this vision. Lands or mineral estates that do not meet these needs may be disposed of using the limited authority available for the disposal of National Forest System lands. In all such cases, the primary guiding principle would be the greater public benefit.

Adequate access to public lands allows the Forest Service and the public to both enjoy and effectively manage National Forest System lands. Where access is inadequate to allow for the administration of National Forest System lands, the Forest Service actively pursues acquiring the needed access rights from non-National Forest System landowners.

Management of National Forest System lands on the Nez Perce-Clearwater is important to protect the public's estate interest in its national forest. Surveying and posting the national forest boundary, maintaining posted property lines, and defending public lands from trespass or encroachment are activities that maintain the integrity of the National Forest System.

The Nez Perce-Clearwater administers multiple types of non-recreation lands uses authorized by permits, term-permits, leases and easements ranging from research activities to more extensive uses such as water systems, communications facilities, roads, and utilities. Over half of the 389 currently issued land use authorizations are for transportation purposes, such as highways and roads for private land access, and water systems serving private property, such as ditches and water lines. Table 343 summarizes the types of use on the Nez Perce-Clearwater and the number of authorizations issued.

Table 343. Lands Uses Authorizations (Use codes 200-999)

Type of Use	Use codes	Number of authorizations
Agriculture	211-241	7
Community and Public Information Meetings	311-374	15
Feasibility, Research, Training, Cultural Resources, and Historical Feasibility	411-452	3
Industry	511-541 and 561-595	23
Energy and Gas Transmission	611-644	13
Transportation	711-771	227
Communication Uses	800-899	36
Water, Water Transmission	911-951	65
Total	**n/a**	**389**

Information taken from Special Uses Database System as of February 12, 2019

Environmental Consequences

Effects from No Action Alternative

The No Action Alternative identifies that there will be no changes to existing land management direction with implementation of the Land Management Plan. The Nez Perce-Clearwater will continue to accept and evaluate new requests for lands uses authorizations and evaluate the re-issuance of existing uses across the Nez Perce-Clearwater. The existing mix of congressionally designated areas, other protected areas, and general forest lands will remain the same as currently exists. With that, the Nez Perce-Clearwater will continue evaluating uses requests following screening criteria as outlined in applicable policy (36 CFR 251.54).

With this said, the No Action Alternative has slightly fewer acres allocated to the managed front-country lands found in Management Area 3 as compared to the action alternatives. Therefore, it can be expected that there may be slightly more lands use authorizations granted as the majority of existing uses are located within what would be classified as Management Area 3 lands.

Effects from Alternative Y

Alternative Y identifies the potential implementation of one item that would have an effect on the existing special use authorizations that are in the Pilot Knob Geographic Area. Currently, Pilot Knob is being used, in part, as an active communication site for a variety of uses, including both private and commercial mobile radio service.

Alternative Y identifies that existing communication site authorizations will be phased out as leases and permits expire and no new authorizations will be approved throughout the life of the Land Management Plan. Implementation of these steps would result in existing communication site lease and permit holders being required to remove their facilities from the Pilot Knob site. Furthermore, it is likely that current lease and permit holders would still require their current level of communication capability and request placement of these facilities at different locations, very likely on National Forest System lands.

Effects Common to Action Alternatives

Under all action alternatives, proposals for new land uses would be screened according to policy (36 CFR 251.54) and the authorized uses would be managed with terms and conditions that protect Nez Perce-Clearwater resources. New proposals for some special uses, such as power lines and communication towers, may not be suitable in protected and other special areas. Based on acreage land allocations in Management Area 3, Alternative Y would have the least number of acres that are suitable for lands uses, followed by Alternative Z, then W, then the Preferred Alternative, and then X (Refer to Management Area acres table in Chapter 2). It is important to note, however, that the amount of acreage typically suitable in Management Area 3 for issuance of lands uses authorizations varies very little among each of the action alternatives.

Alternatives that identify higher levels of Recommended Wilderness have the potential to reduce the number of lands uses authorizations that are granted. While this acreage is only *recommended* for Wilderness designation, if some of this land is eventually congressionally designated, the Nez Perce-Clearwater would be much less likely to issue lands uses authorizations in protected areas.

Similarly, alternatives that identify higher levels of Suitable Wild and Scenic Rivers also have the potential to reduce the number of lands uses authorizations that are granted. This is due to the understanding that potential Wild and Scenic River designation may result in some level of restrictions that would make it less likely to issue various lands uses authorizations.

Action alternatives will not impact the land ownership adjustment and boundary programs in a predictable way. Action alternatives identify different management strategies for existing National Forest System lands, whereas the land adjustment and boundary programs focus on the interaction with and interface between National Forest System and non-National Forest System lands. Access acquisition may be expected to increase with increased acreage being actively managed in Management Area 3; however, the relationship between access acquisition and management is highly specific to the conditions of the local area.

Cumulative Effects

The Nez Perce-Clearwater can expect requests for lands special-use authorizations to increase. As more private land is subdivided, an associated increase in requests for lands uses authorizations, such as road access and utilities, may result. Use of federal lands to facilitate energy transmission outlined within the Energy Policy Act of 2005 will likely continue to be an emphasis area to assist with the enhancement of these services to the American public. As technological advances, such as broadband

and fiber optic cable, are made, requests for modification of existing authorized communications sites and approval of new communication uses can reasonably be expected.

As human population increases expected trends include a greater use of National Forest System lands by the public, particularly those areas close to population centers. There is also expected to be more development of private lands adjacent to forest and on private inholdings within the forest boundary. Private access needs will likely increase. This may also result in challenges from other landowners to existing and perceived access to National Forest System lands, as private landowners are becoming more reluctant to grant easements. Access, in general, across all National Forest System lands is becoming more difficult to obtain. This is expected to continue.

Effects to Resource from Other Resources

Management Area Allocations

The slight variation of acreage in each alternative by management area allocation may have minor indirect and cumulative impacts to the lands and lands uses resource and are described in detail above.

Recommended Wilderness

The slight variation of Recommended Wilderness acreage identified by alternative may have minor indirect and cumulative impacts to the lands and lands uses resource.

Timber

The significant deviation with the amount of timber harvest identified by alternative may have minor indirect and cumulative impacts to the lands and lands uses resource. With the potential for new or enhanced road access due to timber harvest, the alternatives with higher amounts of harvest will have the potential to increase requests for access to adjacent private property.

There will be no indirect or cumulative impacts to the lands and lands uses resources from the following resource areas:

- Air Quality
- Carbon Storage
- Climate Change
- Cultural Heritage
- Designated Areas
- Ecology (other than fire ecology)
- Economic Sustainability
- Fire Management
- Fisheries
- Forest Products
- Infrastructure
- Invasive Species
- Livestock Grazing
- Minerals
- Rare Plants
- Research Natural Areas
- Roadless Areas
- Scenery
- Social Sustainability
- Soils

- Suitable Wild and Scenic Rivers
- Sustainable Recreation (including developed and dispersed recreation)
- Watershed (including watershed management and the watershed restoration program)
- Tribal Treaty Rights
- Vegetation
- Wildlife

Summary of Consequences

Table 344 includes of summary of potential plan consequences by alternative.

Table 344. Land ownership and land uses summary of consequences by alternative (Alt)

Indicator	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Potential change to acres of National Forest System land administered (Lands and Lands Uses)	No change	No change	No change	No change	No change	No change
Potential change to the number of special use authorizations (Lands Uses)	Highest potential for fewer lands use authorizations to be issued – due to less Management Area 3 acreage	Equal potential for more lands use authorizations to be issued – due to more Management Area 3 acreage than in the No Action Alternative	Equal potential for more lands use authorizations to be issued – due to more Management Area 3 acreage than in the No Action Alternative	Equal potential for more lands use authorizations to be issued – due to more Management Area 3 acreage than in the No Action Alternative	Equal potential for more lands use authorizations to be issued – due to more Management Area 3 acreage than in the No Action Alternative	Equal potential for more lands use authorizations to be issued – due to more Management Area 3 acreage than in the No Action Alternative

3.5 Production of Natural Resources

3.5.1 Timber

The Nez Perce-Clearwater contains valuable timber resources that provide products in demand by the American public, such as lumber, house logs, and pulpwood. Timber harvest may be used to supply timber products and moves vegetation towards desired conditions and meets other resource objectives, such as improving watershed condition, improving wildlife habitat, and restoring fire regimes. Timber harvest also provides jobs and income in logging and manufacturing of wood products.

Other special forest products include plant materials, such as firewood, that are gathered from National Forest System lands. Timber and other forest products are analyzed at a scale that comprises the National Forest System lands administered by the Nez Perce-Clearwater.

Timber harvest and timber production were raised as issues during public scoping, including desires to increase or decrease the amount of harvest, lands suitable for timber production, and volume outputs over time, as well as concerns for the impacts of harvest on other resources and a desire to limit this use.

Changes between draft and final environmental impact statement

Multiple changes were made for the FEIS; however, all changes are within the scope of the DEIS analysis, and address issues that the public has had an opportunity to comment on. This section details the key changes between the draft and final analysis for timber resources. See the forestlands section also, as the modeling changes between these resources are interconnected.

Analysis was added for the Preferred Alternative. With respect to timber resources, this alternative is similar to all action alternatives W, X, Y and Z, with one distinction being in the objective functions used in the timber scheduling model (PRISM), as described in this report and Appendix B. A minimum value for long term sustained yield was incorporated into the PRISM runs for the Preferred Alternative.

- Incorporated “coarse woody debris retained” metric as a measurement indicator for use in evaluating the effectiveness of each action alternative to achieve desired conditions and to correlate sustainability of harvest measurement indicator to long term site productivity.
- Incorporated the preferred alternative into the analysis of; lands suitable for timber production, forest products availability, long term sustainability of harvest levels, effects of climate change on timber production, wood product supply including projected timber sale quantity and projected wood sale quantity, and the number of acres treated to achieve desired conditions. In addition, all action alternatives were updated to incorporate changes in management area boundaries resulting from updated GIS analysis of recommended wilderness boundaries.
- Updated PRISM and SIMPPLLE model analysis to incorporate the preferred alternative and changes to plan components.
- Updated consequences section to incorporate changes in plan components associated with other resources.

Definitions and metrics compared for alternatives

The metrics for estimating timber volume outputs have changed from the 1982 Planning Rule which guided the current plans and the No Action Alternative, and those defined in the 2012 Planning Rule, which guide the action alternatives. The metrics defined in 1987 for the current forest plans are disclosed to describe the No Action Alternative. However, the No Action Alternative was also included in the modeling to calculate the metrics, as defined in the 2012 Planning Rule. The timber volume metrics from both planning rules and associated directives are defined as follows:

- Long-term sustained yield capacity, which applies to the No Action Alternative, is the highest uniform wood yield from lands being managed for timber production that may be sustained under a specified management intensity consistent with multiple-use objectives (36 CFR, 219.3 1982).
- Allowable sale quantity, which applies to the No Action Alternative, is the quantity of timber that may be sold from the area of suitable land covered by the Land Management Plan for a time period specified by the plan. This quantity is usually expressed on an annual basis as the “average annual allowable sale quantity” (36 CFR, 219.3 1982).
- Sustained yield limit, which applies to the action alternatives and does not vary by alternative, is the amount of timber meeting applicable utilization standards, which can be removed from a forest annually in perpetuity on a sustained-yield basis. It is the volume that could be produced in perpetuity on lands that may be suitable for timber production. Calculation of the limit includes volume from lands that may be deemed not suitable for timber production after further analysis during the planning process. The calculation of the sustained yield limit is not limited by land management plan desired conditions, other plan components, or the planning unit’s fiscal

capability and organizational capacity. The sustained yield limit is not a target but is a limitation on harvest, except when the plan allows for a departure.

- Projected wood sale quantity, which applies to the action alternatives, is the estimated quantity of timber and all other wood products that is expected to be sold from the plan area for the plan period. The projected wood sale quantity consists of the projected timber sale quantity, as well as other woody material such as fuelwood, firewood, or biomass. The projected wood sale quantity includes volume from timber harvest for any purpose based on expected harvests that would be consistent with the plan components. It is also based on the planning unit's fiscal capability and organizational capacity. It is not a target nor a limitation on harvest.
- Projected timber sale quantity, which applies to the action alternatives, is the estimated quantity of timber meeting applicable utilization standards that is expected to be sold during the plan period. As a subset of the projected wood sale quantity, the projected timber sale quantity includes volume from timber harvest for any purpose from all lands in the plan area based on expected harvests that would be consistent with the plan components. The projected timber sale quantity is also based on the planning unit's fiscal capability and organizational capacity. The projected timber sale quantity is not a target nor a limitation on harvest.
- Suitability of lands determines the appropriateness of various lands within a plan area for various uses or activities based on the desired conditions applicable to those lands. The terms "suitable and suited" and "not suitable and not suited" can be considered the same.
- Land that may be suitable for timber production refers to a preliminary classification in the process of determining lands that are suited for timber production. This preliminary classification excludes National Forest System lands that are not suitable for timber production based on the factors identified in 36 CFR 219.11(a)(1)(i), (ii), (iv), (v), and (vi); the preliminary classification is made prior to the consideration of the factor at 36 CFR 219.11(a)(iii), which identifies suitability based on objectives and desired conditions established by the plan for those lands.

Based on these definitions, the long-term sustained yield capacity and sustained yield limit can be seen as somewhat analogous but differ in what lands are included in the calculation and whether other multiple-use resource direction is considered. Long-term sustained yield capacity is based on lands deemed suitable for timber production and considers multiple-use resource objectives, whereas sustained yield limit is based on all lands that may be suitable for timber production, regardless of land allocation decisions. Similarly, allowable sale quantity and projected wood sale quantity are somewhat analogous but also differ in that projected wood sale quantity includes volumes from all lands, whereas allowable sale quantity only includes volumes from lands suitable for timber production. Further, allowable sale quantity was the maximum that could be produced, whereas projected wood sale quantity is not a limitation but is only an estimate. Therefore, it is not appropriate to compare the measures estimated using the 1982 Planning Rule directly against the measures calculated based on the 2012 Planning Rule and associated directives.

Timber suitability for the No Action Alternative was also updated to account for additional regulation and policy that changed the management situation since 1987, such as the designation of inventoried roadless areas. This was important to ensure that the depiction of the No Action Alternative accurately reflects what the management situation would be if this alternative were selected. As with timber volume outputs, this also allows for a direct comparison to the suitability determinations made for the action alternatives.

Relevant Laws, Regulations, and Policy

Federal Laws

Multiple-Use Sustained Yield Act of 1960: This act states that "it is the policy of the Congress that the national forests are established and shall be administered for outdoor recreation, range, timber, watershed and wildlife, and fish purposes…The Secretary of Agriculture is authorized and directed to develop and administer the renewable surface resources of the national forests for multiple-use and sustained yield of several products and services obtained there from…the achievement and maintenance in perpetuity of a high-level annual or regular periodic output of the various renewable resources of the national forests without impairment of the productivity of the land."

Forest and Rangeland Renewable Resources Planning Act of 1974 and **National Forest Management Act of 1976:** These acts set forth the requirements for Land and Resource Management Plans for the National Forest Service.

Organic Administration Act of 1897: This act established National Forests "to improve and protect the Forest within the boundaries, or for the purpose of securing favorable conditions of water flows, and to furnish a continuous supply of timber for the use and necessities of citizens of the United States."

Agency Regulations

36 CFR 219: The procedures of the 2012 National Forest System Land and Resource Management Planning Rule require the identification of areas suitable for timber production and the amount of timber which can be removed annually on a sustained-yield basis. In addition, the procedures require the analysis of the supply and demand situation for resource commodities.

36 CFR 223 – Sale and Disposal of National Forest System Timber, Special Forest Products, and Forest Botanical Products: This regulation allows that trees, portions of trees, and other forest products on National Forest System lands may be sold for the purpose of achieving the policies set forth in the Multiple Use Sustained Yield Act, as amended, and the Forest and Rangeland Renewable Resources Planning Act of 1974, as amended.

36 CFR 223.239 – Free Use by Individuals: This regulation provides regulations for free-use without a permit for members of Tribes with treaty or other reserved rights related to special forest products.

36 CFR 223.243 – Indian Tribes with Valid Treaty or other Reserved Rights: This regulation provides rules regarding harvest of special forest products by Tribes with treaty or other reserved rights.

36 CFR 261.6 – Timber and Other Forest Products: This regulation lists activities regarding timber and other products that are prohibited.

Policy

Forest Service Handbook 1909.12, Chapter 60: This policy sets forth the procedures for identification of lands as not suitable or suitable for timber production and methods for determining the sustained yield limit, the projected wood sale quantity, and the projected timber sale quantity.

State and Local Plans

Clearwater County Community Wildfire Protection Plan

Idaho County Natural Resources Plan

The Idaho County Natural Resources Plan, with respect to timber resources, focuses on forest vegetation restoration and a sustained flow of commodities from National Forest System lands. This plan also focuses on the need for resilient forests, actively managing lands that are classified as suitable for timber production and expresses concern over lands being lost to timber production and timber harvest. To determine consistency with the plan for timber resources, alternatives will be analyzed by the extent to which they provide a sustainable flow of timber products and maintain or increase the amount of land suitable for timber production and timber harvest. The extent to which forested vegetation is restored and resilience is increased will be analyzed in the Forestlands section.

Idaho County Wildland-Urban Interface Wildfire Mitigation Plan

Benewah County Natural Resources Plan

Latah County Community Wildfire Protection Plan

Shoshone County Fire Mitigation Plan

Methodology

Spatial Scale

Timber suitability was mapped using the best available geospatial information available. Lands that may be suitable for timber production were determined based on the factors required by National Forest Management Act and the 2012 Planning Rule, as described in Appendix B, and are the same for all alternatives. Of those lands that may be suitable, the lands that are suitable for timber production vary by alternative based on management objectives. Detailed documentation of the process used to map suitability can be found in the project record.

The analysis area for timber suitability, timber supply, timber harvest, and other forest products is comprised of the National Forest System lands administered by the Nez Perce-Clearwater. The primary analysis area for timber demand consists of five Idaho counties. A secondary economic analysis area is defined to account for all counties within the economic impact analysis area that contain infrastructure and communities that utilize timber from the Nez Perce-Clearwater. Refer to the Economic Sustainability Report for further details.

The counties included in the Primary Analysis Area included:

- Idaho County, Idaho
- Clearwater County, Idaho
- Lewis County, Idaho
- Nez Perce County, Idaho
- Latah County, Idaho

Counties included in the Secondary Analysis Area included:

- Benewah County, Idaho
- Adams County, Idaho
- Shoshone County, Idaho
- Mineral County, Montana
- Missoula County, Montana
- Ravalli County, Montana

All alternatives are identical in terms of vegetation and timber plan components and other elements that substantially influence timber production and harvest. The exception is Alternative Z, which requires retention of snags that are ten-inch diameter at breast height and larger. This distinction may reduce the amount of small diameter salvage timber available from lands administered under Alternative Z. The primary difference between alternatives include: the number of acres suitable for timber production, the number of unsuitable acres where timber harvest is allowed to achieve other resource objectives, the timing of harvest activities, and management intensity.

Temporal Scale

The temporal scale of this comparative analysis is 50-years. While the land management plan is expected to be in place for 15-years, quantitative effects were derived from the SIMPPLLE and PRISM models, which use whole decades as the modeling time steps. Furthermore, using the fifth-time step, rather than the first- or second-time step, more clearly demonstrates differences between alternatives and attainment of plan objectives.

Analysis models were run for 100-years to assess the stability of sustained yield capacity and targets for all modeled plan components for each alternative. Plan components and forest restoration strategies presented in the plan influence the quantities of merchantable timber available for harvest. Model runs of 100-years were used to examine required non-declining even flow constraints and to assess how each alternative effect long-term timber supply.

Past, Present, and Future Activities used in the Analysis

Capital investments within the region and adjacent county area have changed dramatically over time. The long-term sustained yield and allowable sale quantity established under the 1987 forest plans, in combination with harvest schedules developed for surrounding timber base ownerships have established the wood product supply for forest product processing facilities. The Nez Perce-Clearwater can only implement the land management plan within the context of a viable and competitive marketplace. Demand for timber and other forest products must remain at sufficient levels to support economically feasible vegetation management projects designed to trend forest vegetation towards the desired conditions detailed in the land management plan.

Methods and Assumptions

Timber harvest outputs, such as projected wood sale quantity, projected timber sale quantity, harvest by decade, and sustained yield limit, were modeled using Prism. Prism is a software modeling system designed to assist decision makers in exploring and evaluating multiple resource management choices and objectives. Models constructed with Prism apply management actions to landscapes through a time horizon and display outcomes for comparative analysis. Management actions are selected to achieve desired goals while complying with identified objectives and constraints. Prism outputs are used to display tradeoffs between alternatives and to predict sustainable timber harvest levels over time. The timber analysis is based on harvest schedule modeling conducted with the

PRISM model. The Prism model and assumptions associated with modeling are detailed in Appendix B.

Harvest prescriptions are generalized for this broad scale analysis. During implementation of the Land Management Plan under any alternative, site specific prescriptions and silvicultural practices would be tailored to the forest stand to be treated. Further, site specific mitigations and best management practices, such as those that apply in riparian management zones, would apply as described in the plan. These site-specific factors would not materially change the broad scale volume estimates made for planning purposes.

For the action alternatives, it is assumed that the management approaches described in Appendix 4 of the Land Management Plan would generally be followed.

Determination of projected timber sale quantity and projected wood sale quantity levels are made with respect to the achievement of long-term forest restoration strategies defined in the plan. Timber harvest is a tool used to achieve Land Management Plan objectives. In this context, success in achieving forest restoration objectives is dependent upon successfully marketing and selling timber products from the Nez Perce-Clearwater. Without timber markets, full restoration success is not likely. Demand for forest products is driven by local, regional, and national demand curves, which tend to change over time. Realization of projected timber sale quantity and projected wood sale quantity levels are partly dependent on open market economies, which fluctuate over time in response to natural supply and demand market curves.

Investments in forest product milling infrastructure and milling capacity are generally made by industry in response to the supply and demand curves discussed above. The local and regional forest products infrastructure has declined in recent decades in response to lower timber supplies from National Forest System lands, imports of finished forest products, improvements in milling technology, and cost of investment capital. The volume of timber offered by the Nez Perce-Clearwater has little impact on national supply and demand curves for forest products.

Best Available Science

The affected environment was described using Forest Service "cut and sold reports" from the Timber Sale Accountability database and treatment records in the Forest Activity Tracking System database. Information on the location and condition of other forest products that could be gathered is limited.

Vegetation plot data and a variety of geospatial data, such as soil and vegetation mapping, were used to determine the lands that may be suitable for timber production (see Appendix B). Yield tables were developed using the Forest Vegetation Simulator. This information, along with Prism modeling, was used to estimate acres treated by treatment type and volume outputs, as described in Appendix B. The actual timber harvest level that would occur during implementation of the plan is dependent on many variables, including the demand for forest products, resource management objectives and public engagement.

There is no incomplete or unavailable information for the timber analysis. This analysis was completed at the strategic level, using forest level data sources. Site-specific data at the project scale is expected to result in some changes to timber suitability and volume outputs. The data used is the latest available information. The effects of recent disturbances, including the fires of 2018, are not portrayed by this data. However, the analysis of alternatives includes the potential for future fire and, therefore, the relative comparisons at the programmatic scale remain valid.

Measurement Indicators

The issue statement from scoping and public collaboration relative to timber is:

The projected timber sale quantity should be increased or decreased to better provide for a balance of ecological sustainability and economic and social resiliency. The maximum regeneration harvest unit size should be increased or decreased.

This issue statement is addressed primarily in the Wood Product Supply analysis, as discussed below. However, the standards related to the maximum regeneration harvest unit size will be addressed in this Timber section and the effects of the maximum opening size will be addressed in the Forestlands section of the EIS. This timber analysis is framed to address the following areas:

- Identify lands suitable for timber production and unsuitable lands where timber harvest is allowed and the effects of those delineations
- The contribution of timber harvest to the ecological, economic, and social sustainability
- Maximizing benefits to the American people and demonstrating sustainability of harvest

To analyze the extent to which each alternative addresses the above needed findings, the following were chosen as indicators and measures.

Table 345. Measurement Indicators

Indicators	Measures
Timber Suitability	Acres suitable for timber production
Timber Suitability	Acres of unsuitable land where timber harvest is allowed
Wood Product Supply	Projected Timber Sale Quantity
Wood Product Supply	Projected Wood Sale Quantity
Wood Product Supply	Predicted Salvage
Wood Product Supply	Acres Harvest
Wood Product Supply	Firewood and biofuel availability
Sustainability of Harvest	Coarse woody debris retained
Sustainability of Harvest	Practices followed

Timber Suitability

Long-term production capacity is in part a function of timber suitability. Timber suitability as an indicator is intended to quantify the amount of timber that can be produced or harvested on the Nez Perce-Clearwater. This indicator shows how each alternative would affect the ability of the Nez Perce-Clearwater to produce or harvest timber based on the categorization of the land. For instance, when a river is found to be suitable for a designation of "wild," a corridor surrounding the river would be identified as not suitable for timber production or timber harvest. This indicator is intended to show the effect of delineating land such that timber harvest and production are precluded.

Wood Product Supply and Timber Harvest

Wood product supply is intended to show the effect each alternative has on the economic and social sustainability of the local communities. Projected timber sale quantity shows, in a quantifiable way, how merchantable sawtimber produced varies by alternative.

Projected wood sale quantity is "the estimated quantity of timber and all other wood products that is expected to be sold from the plan area for the plan period. The projected wood sale quantity consists of the projected timber sale quantity as well as other woody material such as fuelwood, firewood, or biomass that is also expected to be available for sale".

Biofuels and firewood are an important part of projected wood sale quantity and will be measured to display the effects each alternative would be expected to have on firewood supply and availability of biofuels.

Salvage harvest was raised as an important issue during public involvement. Because salvage harvest is not calculated as part of projected timber sale quantity or projected wood sale quantity; salvage harvest is predicted separately to provide an idea of how salvage harvest could vary based on the alternative selected. This is estimated by using the predicted fire amounts for each alternative, identifying total acreage where salvage harvest is permissible, and multiplying by the percentage of burned area historically salvaged on the Nez Perce-Clearwater.

Acres harvested is broken down by potential vegetation type group by management area to show the effect each alternative has on the proportion of the landscape being treated through timber harvest. This measure is intended to demonstrate the extent timber harvest would be used to produce commodities while trending the landscape toward desired conditions.

Firewood availability is important to local communities and contributes to social and economic sustainability. This indicator uses the disturbance expected by alternative, combined with acreage in the front country on which firewood gathering is permitted, to show how each alternative would be expected to affect the availability of firewood.

Sustainability of Harvest

The National Forest Management Act (U.S. Department of Agriculture 1976a) requires that timber harvest be carried out in such a way that the harvest is sustainable. Part of the need for change identified in revising the Land Management Plan was to incorporate best available scientific information into the revised plan. This indicator is intended to demonstrate, in a qualitative way, how the best available scientific information incorporated into all alternatives in the revised plan causes a difference in sustainability from the best available scientific information used in the 1987 Forest Plans.

Sustainability of harvest is dependent on maintaining long-term site productivity. Management of coarse woody debris is an essential part of long-term site productivity. The land management plan incorporates plan components designed to maintain sufficient coarse woody debris to promote long-term site productivity and, thus, promote sustainability of harvest levels. Coarse woody debris management objectives are based on work published by Graham et al. and are an integral part of maintaining the soils resource. Refer to the Soils Resource section (3.2.1.6) for a more detailed discussion of plan components and best management practices related to protecting and maintaining the soils resource.

Affected Environment

Existing Condition

Use and development of natural resources on the Nez Perce-Clearwater and surrounding lands played an essential role in the economy and growth of the area since early American settlement. Mining for gold and other minerals boomed in the late 1800s and tree cutting that occurred for fuelwood, mine timbers, and railways was extensive in accessible drainages. Harvest became associated with a demand for pulpwood during World War II and the need to support numerous small mills (U.S. Department of Agriculture 1986b, c). Demand for construction lumber dramatically increased following World War II.

The original mission of the Forest Service focused on protecting water and timber (Kline and Mazzotta 2012). These ecosystem services remain important today, along with wildlife habitat and recreational opportunities. Timber harvested on the Nez Perce-Clearwater provides a variety of wood products, such as sawlogs, veneer logs, and house logs, as well as logs used for pulpwood, posts and poles, firewood, furniture, and energy.

Timber suitability

Lands suitable for timber production were used to derive the allowable sale quantity in the 1987 Forest Plans. The plans determined 1,070,415 acres to be suitable for timber production on the Nez Perce National Forest and 987,700 suitable acres on the Clearwater National Forest (U.S. Department of Agriculture 1986b, c).

The National Forest Management Act directs forests to identify lands which are not suited for timber production. The act states in section 6(k):

the Secretary shall identify lands within the management area which are not suited for timber production, considering physical, economic, and other pertinent factors to the extent feasible, as determined by the Secretary, and shall assure that, except for salvage sales or sales necessitated to protect other multiple-use values, no timber harvesting shall occur on such lands for a period of 10 years (U.S. Department of Agriculture 1976a).

The assessment of suitable timberlands was accomplished using a geographical information system. Utilizing a geographical information system resulted in identifying consistent steps to determine suitability.

Criteria for determining lands not suitable for timber production are outlined in Forest Service Handbook 1909.12, Section 61. A two-step process is used: Step 1: Identify lands that are not suited for timber production based on legal and technical factors, as follows:

- Statute, executive order, or regulation prohibits timber harvest on the land or the Secretary of Agriculture or the Chief of the Forest Service has withdrawn the land from timber harvest, as described in Section 61.11.
- Technology is not currently available for conducting timber harvest without causing irreversible damage to soil, slope, or other watershed conditions, as described in Section 61.12.
- There is no reasonable assurance that such lands can be adequately restocked within five years after final regeneration harvest, as described in Section 61.13.
- The land is not forest land, as described in Section 61.14.

After subtracting the lands that are not suited from the total of National Forest System lands, the remaining lands are lands that **may be** suited for timber production and are considered in Step 2: From the lands that may be suited for timber production, identify the lands that are suited for timber production based on their compatibility with the land area’s desired conditions and objectives, as described in Section 61.2.

Step 2 varies by alternative, based on management area allocation and desired conditions of management areas. After determining lands that may be suited for timber production in Step 1, lands where management guidance and Land Management Plan components precludes timber production are subtracted to yield the total lands suitable for timber production. The subtracted lands are added to the sum of withdrawn lands from Step 1 to yield the total unsuitable lands. Table 346 displays the acres for each step for determining lands suitable for timber production for the No Action Alternative.

Table 346. Lands suitable for timber production for the No Action Alternative.

Suitability category	1987 Nez Perce Plan	1987 Clearwater Plan	No Action Alternative
Administrative Forest Boundary[1]	2,247,040	1,837,100	4,074,832
Non-Forest Lands[2]	-29,000	-24,400	-135,775
Forest Service Lands	2,218,040	1,812,700	3,939,056
Withdrawn Lands[3]	-1,005,250	-276,900	-1,231,638
Irreversible Resource Damage is Likely or Adequate Restocking Not Assured[4]	-132,916	-199,800	-189,203
Tentatively Suitable Timber Production Lands	1,079,874	1,336,000	2,518,215[5]
Lands where management guidance precludes timber production, where management requirements cannot be met, or not cost efficient to meet timber production objectives	-9,459	-348,300	-1,660,729
Lands Suitable for Timber Production	1,070,415	987,700	857,486[6]

[1]Change in GIS mapping technology.

[2]Change in lands not administered.

[3]Change in withdrawn lands is largely due to the addition of eligible wilderness designations which are no longer suitable for timber production as designated by Congress.

[4]The difference between irreversible damage and adequate restocking is due to higher quality data becoming available.

[5]62 percent of National Forest System lands.

[6]26 percent of National Forest System lands.

There have been changes to timber suitability as the forest plans have been implemented. These changes include de-facto reductions in lands suitable for timber production caused by the designation of inventoried roadless areas. There have also been changes in available vegetation data and land ownership status. To accurately portray the existing condition and the No Action Alternative, timber suitability was re-calculated to reflect these changes, as shown in Table 346. Roughly 1,200,629 fewer acres are suitable for timber production than in the original 1987 Forest Plans.

Refer to Appendix A for maps of lands suitable for timber production. The acres suitable for timber production in the existing condition are equivalent to that of the No Action Alternative. Harvest may occur on an additional one percent of National Forest System lands on the Nez Perce-Clearwater that are not suitable for timber production but where harvest may occur for purposes other than timber production. The existing acres unsuitable for timber production where harvest may occur for other purposes is equivalent to the 1,660,729 acres illustrated for the No Action Alternative (Table 346). The lands where harvest may occur include inventoried roadless areas. While harvest could occur in inventoried roadless areas, it would be greatly constrained by the 2008 Idaho Roadless Rule.

Wood product supply and Timber Harvest

Forest growth rates directly influence potential timber production over time. Site productivity is generally considered to be fixed based upon site attributes such as topography, soil type, and climate.

On the Nez Perce-Clearwater, site productivity in terms of tree growth is estimated to be between 20 and 225 cubic feet per acre per year on suitable lands with average rotation ages ranging from 80 to 120 years, depending on the species and site (U.S. Department of Agriculture 1987b).

The long-term sustained yield capacity calculated for the 1987 Forest Plans was 210 million board feet for the proclaimed Nez Perce National Forest and 429 million board feet for the proclaimed Clearwater National Forest. The allowable sale quantity, as defined for the 1987 Forest Plans, is 108 million board feet on the Nez Perce National Forest and 267 million board feet on the Clearwater National Forest, for a total of 375 million board feet. The actual annual timber volume of timber products offered averaged 46 million board feet for the period 1997 through 2018.

The 1990s saw a sharp decline in the volume harvested on both the Nez Perce and Clearwater National Forests. For the Clearwater National Forest, its lowest point in 2000 was 10 million board feet. The Nez Perce and Clearwater National Forests have achieved steady increases in timber volume sold since 2000 with a high of 87 million board feet sold in 2018 for the combined forests.

Figure 139 displays the total volume of timber cut and sold on the Nez Perce-Clearwater from 1997 to 2018. The amount illustrated includes sawtimber and all other timber products, which includes non-saw material, firewood, and posts and poles. Sawtimber volume sold has increased on average since the early 2000s. Firewood has been a consistent contributor to wood volume sold and has been particularly abundant in the last decade due to the availability of dead trees in areas affected by wildfire and mountain pine beetle. The last decade, more specifically 2008 to 2018, has seen an increase in sawtimber sold compared to the previous decade. This increase is due in part to the application of stewardship contracting and good neighbor authority granted by Congress. These authorities leverage partnership dollars and expertise to accomplish restoration projects.

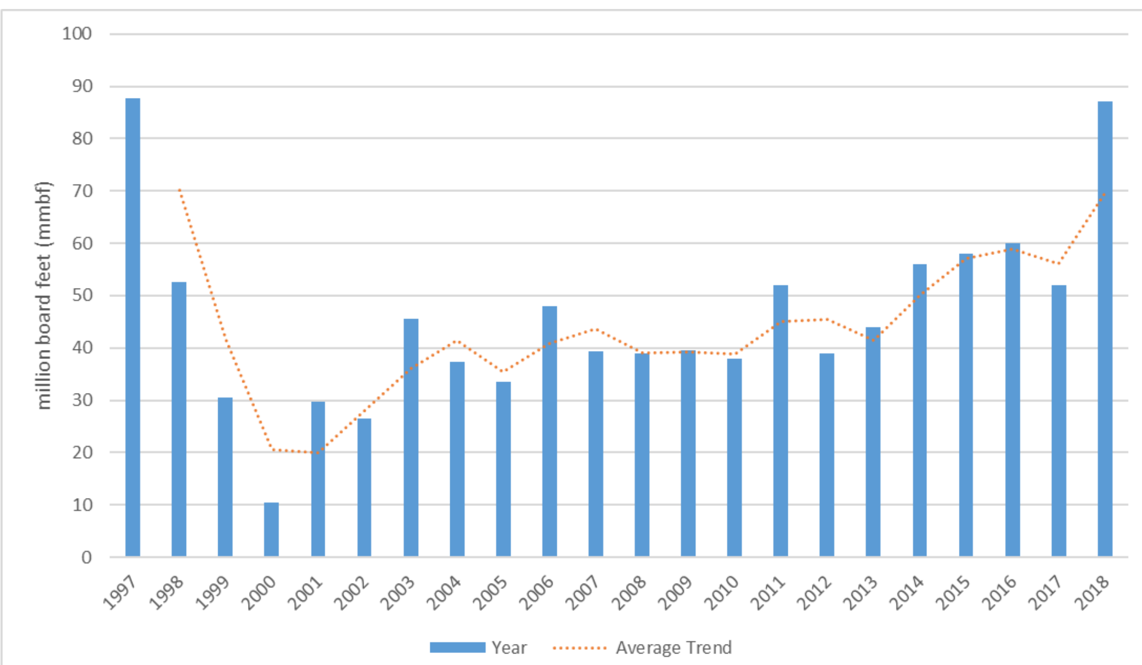

Figure 139. Timber product volume sold from the plan area (1997-2018).

Data Source: Retrieved from: Region 1 - Resource Management (usda.gov)

The supply and demand for timber is driven by regional, national, or global issues. Local drivers are small in scope and scale and generally have inconsequential effects on the overall market for timber and lumber products. Export demand, housing starts, home improvement trends, and interest rates are examples of larger national and global issues that affect the supply and demand for timber. Local environmental issues, as well as involvement by local, regional, and national special interest groups, have some impact on the supply of federal timber to the market within the plan area. Appeals have delayed projects or reduced the extent of proposals.

Figure 140 shows sawtimber volume sold by tree species. The primary species utilized for sawtimber include lodgepole pine, Douglas-fir, and grand fir. Intermediate quantities of sawtimber include subalpine fir, western hemlock, western redcedar, and Engelmann spruce. Very minor quantities of ponderosa pine and western larch are harvested. Salvage category is not recorded by species.

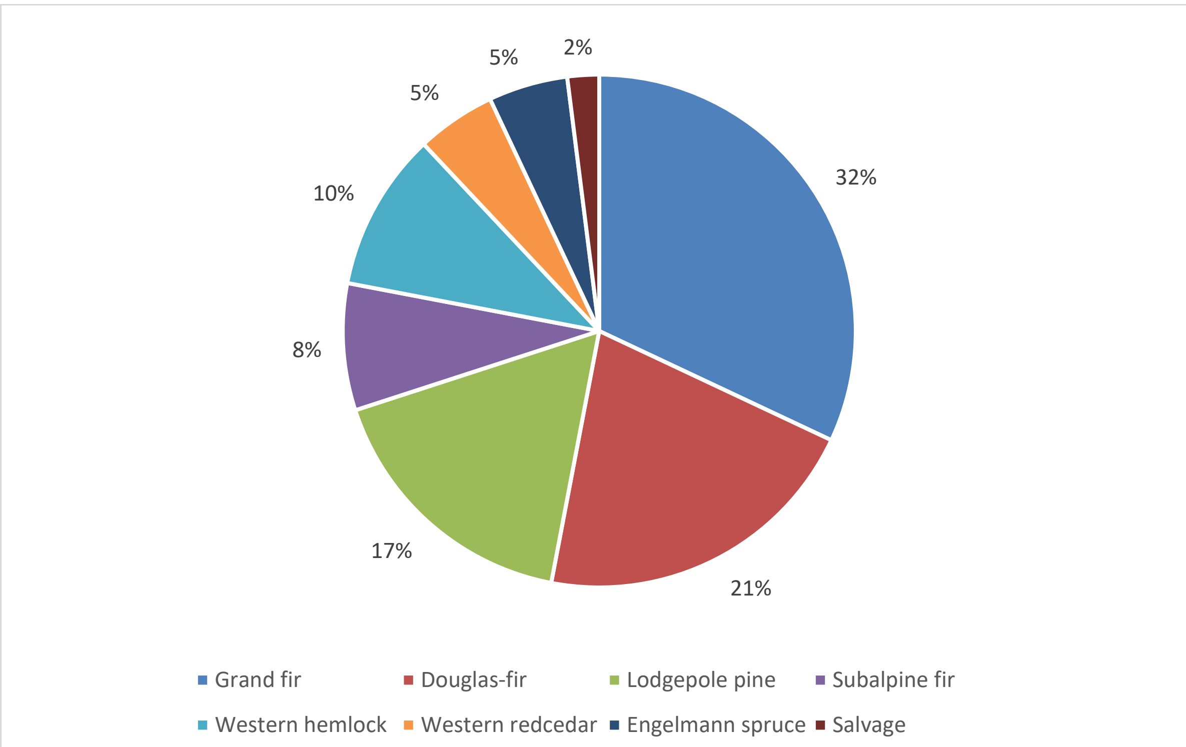

Figure 140. Percent of sawtimber harvest volume sold by species (1997-2018, in MMBF).

Data Source: Retrieved from: : Region 1 - Resource Management (usda.gov)

The largest factor reducing the stability and resiliency of the Nez Perce-Clearwater landscape over the past 100-years has been the introduction of white pine blister rust. This disease has dramatically decreased the composition of western white pine from the Nez Perce-Clearwater and left grand fir, Douglas-fir, lodgepole pine, and subalpine fir as the major species components of the Nez Perce-Clearwater. Those species are much more susceptible to root disease and insect infestations, and the result has been lower productivity on the lands that once supported vast stands of valuable and resilient white pine. Apart from that change, ecosystem drivers such as wildland fire continue to affect the Nez Perce-Clearwater, much as they have for centuries. Soils are productive and forests regrow quickly following disturbance. Climate varies over time but still supports the forests that are found here, which have been adapted to the climatic variations that have occurred.

Interrelated factors, such as site productivity, climate, disturbances, and human activities, influence the availability of timber. Stand replacing fires were common on the Nez Perce-Clearwater during the warm and dry climate period in the late 1800s. These fires, along with early forest practices, were followed by a relatively moist climate suitable for tree establishment and growth. In general, forest cover established quickly in the early 1900s in burned or cut-over areas. Large portions of the Nez Perce-Clearwater burned in the great fire of 1910. The moist conditions that prevailed during most of the next century limited the potential for wildfires and insect outbreaks. These factors, along with forest management policies, contributed to decades of successful fire suppression. Thus, relatively extensive continuous forests of the same age and density developed.

These forests were susceptible to drought stress when the climate shifted into a warm and dry phase in the 1980s. The buildup of fuels that resulted in some areas, along with the dry climate, resulted in more large wildfires. From 1987 to 2017 approximately 53 percent of the Nez Perce-Clearwater burned in wildfire. Of this, about 2.6 million acres burned in areas deemed suitable for timber production in the 1987 Forest Plans. Over this 30-year span of time, many of these acres experienced re-burns. Where stand-replacing fires occurred, forests were returned to an early successional stage of development, and it will be at least 50- to 80-years before the trees reach a size where commercial harvest may be feasible. Growth rates and species composition vary greatly across the forest and between potential vegetation type groups. Site productivity varies across the forest, which influences the rate of recovery following wildland fire events. Intensive silviculture practices, such as pre-commercial thinning, may improve the recovery rate and species composition of developing stands.

Timber demand

Ultimately, the United States market demand for lumber is a derivative for the demand for construction of residential and commercial structures. As a derived demand, lumber markets tend to reflect shifts in national housing construction rates. Across subsectors, residential construction is the single largest consumer of lumber nationwide. Housing starts are measured by the United States Census Bureau. Historical annualized rates are graphed in Figure 141. The losses and eventual recovery following the great recession are evident. Since 2008, starts have rebounded but to a steadier state rising and flattening out above one million annually. See www.census.gov/economic-indicators/ for additional information. Demand for new and remodeled housing can, and will, change over the planning decades but, for the present, markets which consume United States lumber are considered relatively healthy with room for growth.

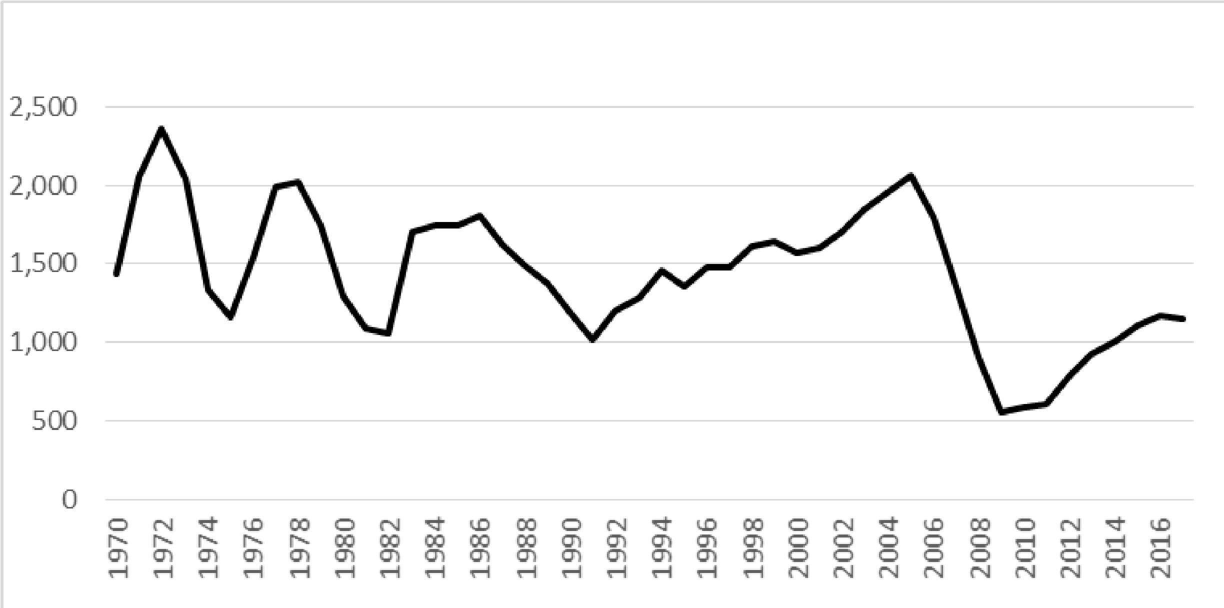

Figure 141. United States housing starts (in thousands of starts) by year.

Data Source: Census Bureau, census.gov/economic indicators

Firewood gathering for home heating is an important ecosystem service provided to the local area. The firewood itself provides an inexpensive heat source and gathering the firewood is often a family recreational activity. Small commercial firewood operations also meet a need for firewood among people who cannot gather their own wood.

Idaho forest products industry

Since the end of the 2007 to 2009 economic recession, the Idaho forest products industry has begun to rebound. This rebound is partly due to a recovery of United States housing starts which grew approximately ten percent between 2014 and 2016. However, there are continued annual fluctuations in the lumber export markets, as well as domestic lumber prices and sawlog prices. This slow economic recovery has spurred investment in Idaho's forest product sector, including increases in employment (Cook, Morgan, et al. 2016).

Lumber production in Idaho has increased slightly from 2014 averages by five percent. Sawmill capacity utilization has increased from 60 percent to 75 percent due in part to increased housing demand and rising lumber process (Cook, Morgan, et al. 2016).

Economic forecast modelling relative to the land management plan alternatives is presented in the Economic and Social Sustainability sections. These sections indicate that, in general, all alternatives will maintain or improve employment in the forest products industry within the analysis area.

Since the mid-1990s, Idaho's forest products industry has been sustained primarily by timber harvests from private and state lands. During 2015, private lands provided 62 percent of Idaho's timber harvest volume, while state lands provided 27 percent. About 11 percent of the timber harvest volume came from United States National Forest System lands. Approximately 39 percent, or 20.4 million acres, of Idaho's land is within the United States National Forest System. More than three-fourths of Idaho's timber resources are on federal lands, a total that does not include four million acres of federal forest lands in the National Wilderness Preservation System. Between 1947 and 1990, federal lands provided, on average, 43 percent of the timber harvested in the state. In 1990, federal timber harvests began a system-wide decline. In the past ten years, federal lands within Idaho have provided about ten percent of the harvest (Cook, Morgan, et al. 2016).

Today, approximately 88 primary forest product firms remain operating in Idaho. Forest product milling and processing facilities range widely in production capacity and products produced. Most of them are mid-sized firms with production capacities of up to 100 million board feet per year (Simmons and Morgan 2017).

Since the 1970s, the contribution of sawtimber coming from National Forest System Lands has declined substantially. In 1979, approximately 46 percent of timber harvest in Idaho was sourced from National Forest System Lands compared to 7 percent in 2006 (Brandt et al. 2012).

The current gap between mill capacity and timber harvest for all ownerships combined is partially explained by timber coming into the multi-county plan area from outside sources, including adjacent states. The majority of the timber harvested in the five-county area comes from private and state lands; thus, the demand for timber from the Nez Perce-Clearwater is affected by the supply of timber from other sources (Brandt et al. 2012).

Collectively, the multi-county plan area has a vastly shrunken capacity from historic industry levels. For the multi-county plan area, the total timber capacity and harvest levels have declined since 1980 but have indicated a slight increase over the last five years as illustrated in Figure 142. Demand for timber remains strong in the multi-county plan area resulting in competitive bids for offered timber (Cook, Morgan, et al. 2016). Competitive markets suggest the industry is capable of scaling in the short term to meet increased national lumber demand if timber supply remains elastic.

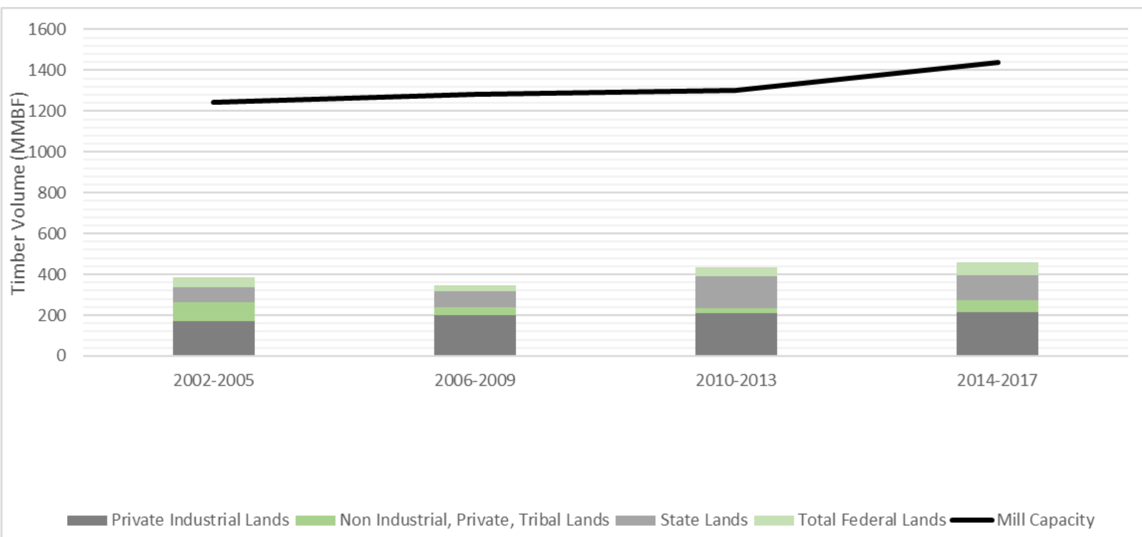

Figure 142. Five Idaho county timber sold versus mill capacity, 2002-2017.

Data Source: Bureau of Business and Economic Research, University of Montana, Idaho's Forest Products Industry and Timber Harvest, 2015

Relative to the multi-county plan area for the Nez Perce-Clearwater, timber production remains of economic importance. The demand for timber has changed over time. In 1987, there were 42 active primary wood product facilities in the primary multi-county plan area. However, by 2017, this number dropped to 21 (Simmons and Morgan 2017).

Timber harvest

Timber harvest is a tool used not only to provide timber products and contribute to the local economy but also to achieve multiple resource objectives. These objectives include, but are not limited to, reducing insect or disease impacts, improving wildlife habitat, increasing tree growth, improving timber productivity, reducing fuels and fire risk, and altering vegetation conditions to enhance forest resilience. All of these resource management objectives are incorporated into the desired conditions discussed in this plan.

Three main types of harvest are displayed:

- even-aged regeneration harvest, such as clearcutting, shelterwood, and seed-tree cuts;
- uneven-aged regeneration harvest, such as group selection and individual-tree selection; and
- intermediate harvest, such as commercial thins and improvement cutting.

Pre-commercial thinning and prescribed fire are included, as these are typically associated with harvest activities. Table 347 shows acres harvested from 1987 through 2018. Roughly 476,300 acres of harvest has been accomplished since 1987. The majority, 89 percent, occurred on lands suitable for timber production; the remainder occurred on unsuitable lands where harvest was implemented to accomplish other resource objectives. Even-aged harvest prescriptions were the most common, representing approximately 51 percent of harvest treatments. This is because the primary forest cover types treated by harvest are mixed species stands with a high composition of grand fir and Douglas-fir. These species have a high occurrence of root disease which limits options for natural regeneration. Artificial regeneration is used to establish seral species, such as ponderosa pine, western white pine, and western larch, which are generally resistant to root diseases and resilient under natural fire regimes.

Table 347. Harvest by type and decade for the Nez Perce-Clearwater, 1987-2018.

Silviculture Treatment	Even-aged timber harvest	Uneven-aged timber harvest	Intermediate harvest	Pre-commercial thinning[1]	Prescribed fire[2]
Nez Perce N.F. acres	198,837	51,862	147,831	21572	39,996
Clearwater N.F. acres	45,551	8,748	23,471	22,047	44,832
Total	244,388	60,610	171,302	43619	84,828
30-Year Annual Average	7,883	1,955	5,526	1,407	848

[1]Pre-commercial thinning acres includes both acres associated with commercial harvest and acres associated with naturally developed stands.

[2]Prescribed fire acres include prescribed fire associated with site preparation following harvest and prescribed fire used to achieve other resource objectives.

Data Source: FACTS.

Included in the acreage figures are salvage projects that occurred after wildfires. The volumes produced from salvage projects are part of the total volume sold in the past as depicted in Figure 143 however, per planning direction, these volumes are not part of the estimated future timber outputs over time shown in the environmental consequences section. In the past, salvage has occurred on a small proportion of burned acres on the Nez Perce-Clearwater. Since the 1990’s, salvage has occurred on about two percent of wildfire acres and was focused on lands suitable for timber production.

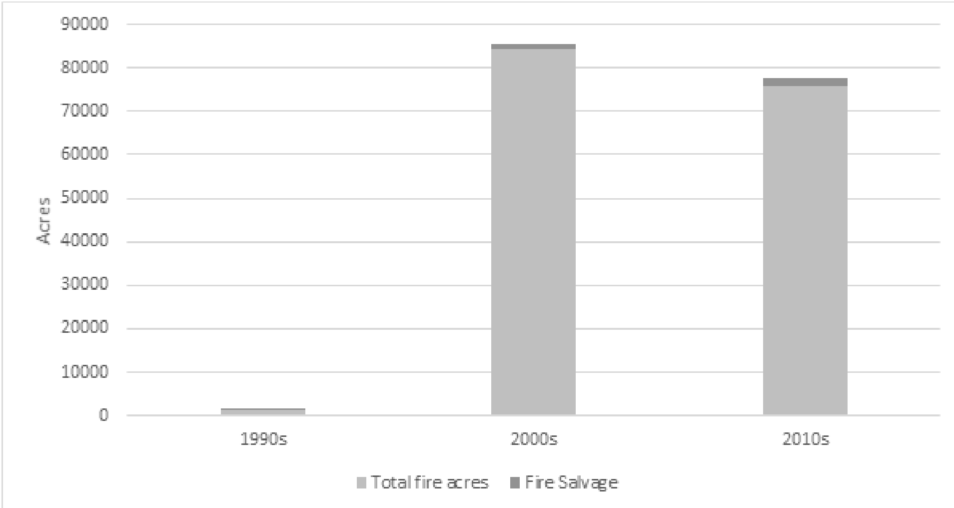

Figure 143. Fire salvage acres compared to total wildfire area burned by decade since 1990.

Data Source: FACTS.

Other activities associated with the tending of harvested stands occur on the Nez Perce-Clearwater, including reforestation, pre-commercial thinning, and prescribed burning. Stands treated with regeneration harvest are reforested either naturally from available seed or artificially through planting. Reforestation also occurs following natural disturbances. This activity tends to be focused on lands suitable for timber production to maintain appropriate forest cover but may also occur on other burned lands to meet other resource objectives. Pre-commercial thinning may occur on a subset of previously harvested areas to improve composition or density of young trees. Prescribed burning to reduce fuels or prepare seedbeds for reforestation are also common forest management activities.

Availability of firewood and other forest products

Special forest and botanical products include, but are not limited to, mosses, fungi including mushrooms, roots, bulbs, berries, seeds, wildflowers, forbs, sedges, grasses, nuts, ferns, boughs, bark, cones, burls, transplants, and Christmas trees. Huckleberries are also periodically commercially harvested in appropriate areas. Other than personal use and commercial firewood permits, the Nez Perce-Clearwater offers little in the way of commercial or personal use permits for special forest products due to the limited demand relative to the resources needed to administer the permits. Figure 144 illustrates the number of cords and sawlog equivalent volume of firewood sold under permit from 2000 to 2108. Forest access for firewood gathering is determined by the open road system identified in motorized travel plans for the Nez Perce-Clearwater. Availability of firewood is largely determined by effects of forest succession and disturbance processes, such as wildfire and insects and disease agents which result in tree mortality. Desired conditions defined for all alternatives are focused on maintaining disturbance processes, which operate under the ranges calculated for the natural range of variation. Forest management and natural disturbances can influence the supply of firewood and other forest products. For example, fire can increase availability of firewood, mushrooms, and thinning of young sapling stands; conifer regeneration can increase production of Christmas trees under favorable conditions.

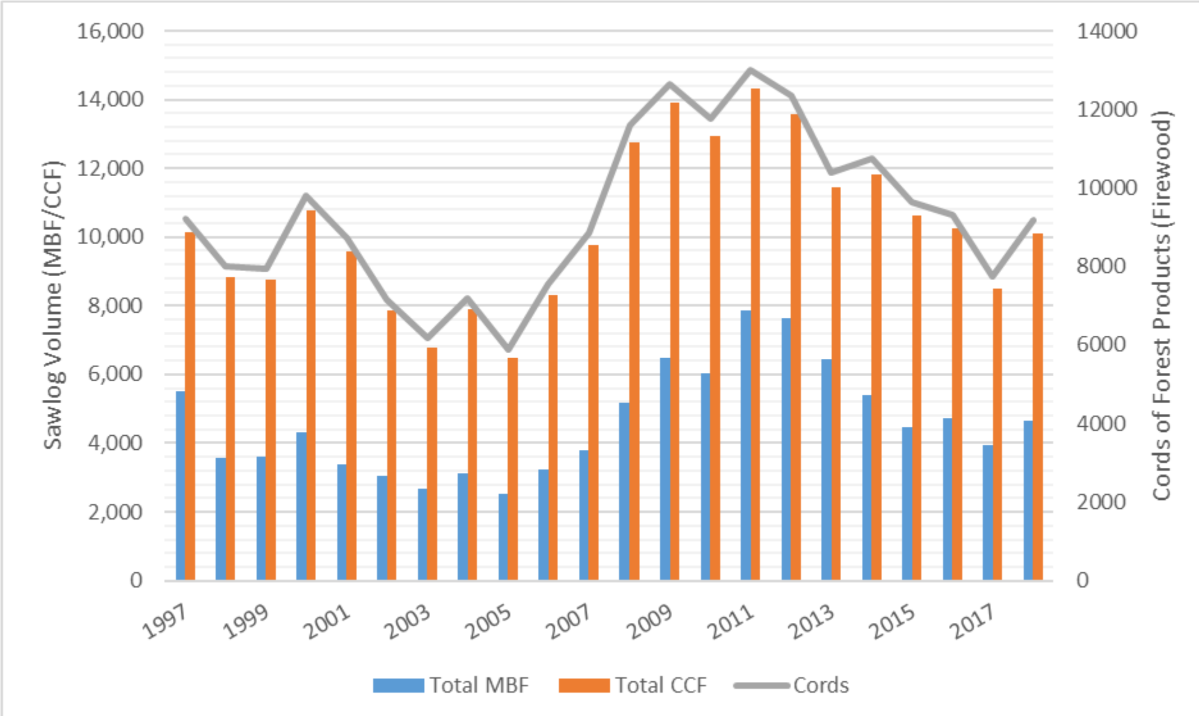

Figure 144. Number of cords of firewood from the plan area sold (2000-2018).

Data Source: TimberHarvestbyDecade.xlsx.

Special forest and botanical products have importance to the Nez Perce Tribe for traditional and cultural uses. As per current handbook direction, the Nez Perce-Clearwater considers treaty rights to include customary and traditional uses (including first foods and other historical uses) of plant material by Tribes to be part of the federal trust responsibility to Tribes. Nez Perce-Clearwater considers competitive market demands in determining which products would be excluded from or allowed for sale to commercial harvesters. When there is a shortage of any particular special forest product for tribal use, commercial permits would be issued only to the extent that the tribal use can be accommodated.

Benefits to people

Timber products and other forest products are identified as multiple uses and key ecosystem services provided by the Nez Perce-Clearwater. The economy of local communities can directly benefit from the use of these products. Please refer to the Economic and Social Sustainability sections for more information about multiple uses, key ecosystem services, and benefits to people.

Milling infrastructure within the plan area has remained relatively intact over the past decade. Bidding competition for timber sales and stewardship contracts has remained high. The capacity for logging and restoration services exists at a level adequate to accomplish Land Management Plan objectives for the No-Action Alternative. Implementation of any action alternative would require an increase in milling and biomass utilization infrastructure to achieve restoration objectives. Capacity includes mills within and adjacent to the plan area, as shown in Table 348.

Table 348. Forest products mills and processing facilities within the multi-county area.

County	Sawmills	Post and Pole Mill	Wood Chip Processing	Cedar Products	Pulp and Paper	Biomass, Bark, Fuel pellets
Idaho	2	1	0	1	0	1
Clearwater	2	0	0	1	0	0
Lewis	0	1	0	0	0	0
Nez Perce	0	1	0	0	0	1
Latah	1	1	1	1	1	1

Data Source: (Cook, Morgan, et al. 2016).

Environmental Consequences

Effects Common to All Alternatives

Timber Suitability

Lands suitable for timber production were determined following the 2012 Planning Rule and associated directives. Lands that *may* be suitable for timber production differ by alternative. Differences between alternatives of lands suitable for timber production are due to different allocations of lands suitable or eligible for other resources, as shown in Figure 145 and Table 349. The No Action Alternative represents eligible lands. These lands are physically and biologically capable of timber production and have not been administratively withdrawn. Based on management direction and desired conditions, land determined to be suitable for timber production varies by alternative and represent a subset of the lands that may be suitable for timber production.

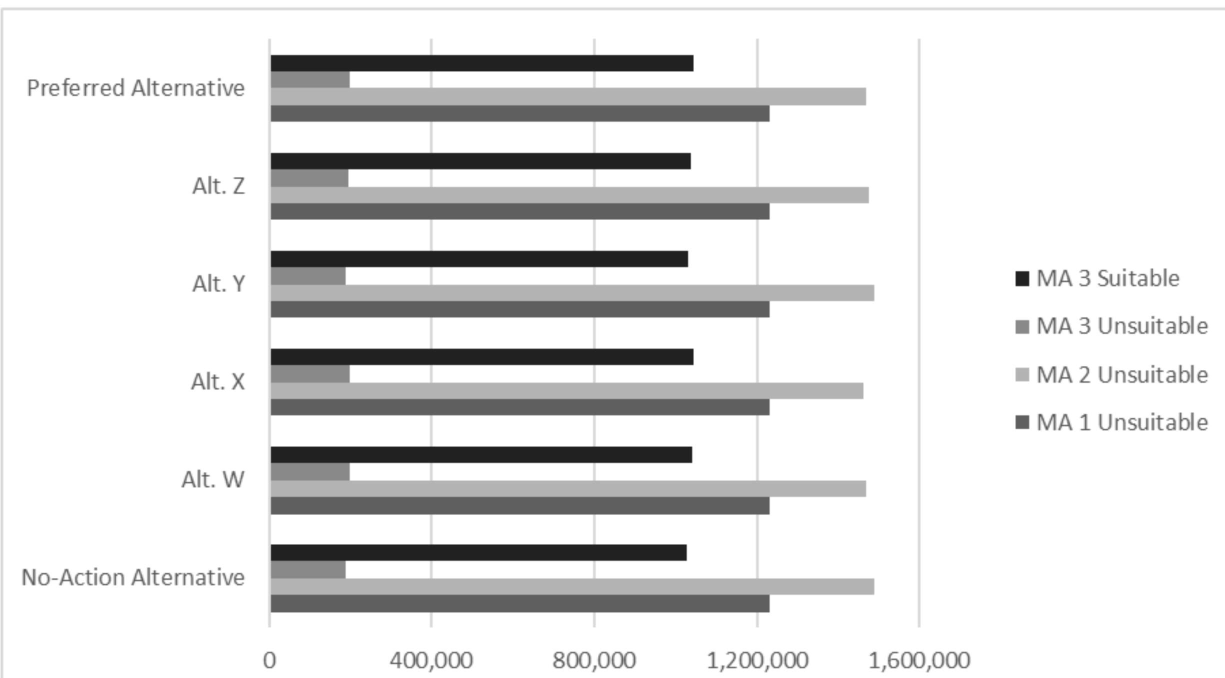

Figure 145. Determination of lands that may be suitable for timber production (in acres).

Data Source: VMap.

Table 349. Unsuitable lands where timber harvest is allowed (in acres), by alternative.

Land Classification Category	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Backcountry Restoration IRR Theme	377,575	377,575	377,575	377,575	377,575	377,575
Primitive IRR Theme	124,246	124,246	124,246	124,246	124,246	124,246
Special Areas of Historic or Tribal Significance IRR Theme	34,442	34,442	34,442	34,442	34,442	34,442
Riparian Management Zones (MA 3 Outer Zone Only)	85,658	89,180	90,017	85,952	88,618	89,387
Total Unsuitable Lands where timber harvest is allowed	621,920	625,442	626,279	622,214	624,880	625,649
Potential Treatment Acres per Decade	6,219	6,254	6,263	6,222	6,249	6,256

Data Source: VMap

Broad-scale information is used to determine suitability. Changes may occur at the project-scale level using site-specific data. Changes to lands suitable for timber production would be monitored during implementation of the plan.

In all alternatives, timber harvest is allowed on lands not suitable for timber production but suitable for timber harvest when consistent with management direction for the area. These lands are referenced as unsuitable lands where timber harvest is allowed. Timber harvest on these lands is not scheduled or managed on a rotation basis but does contribute towards projected sale quantities. Unsuitable lands where harvest would never be allowed are primarily within Management Area 1 and include designated wilderness, recommended wilderness, wilderness study act areas, research natural areas, wild and scenic river corridors, and primitive recreation settings, as well as the inner zone of all riparian management zones. Unsuitable lands where timber harvest is allowed are primarily within Management Area 2 and include areas designated as Special Areas of Historic or Tribal Significance, Primitive, and Backcountry Restoration theme in the Idaho Roadless Rule (36 CFR 294 Subpart C), as well as portions of Management Area 3 defined as the outer zone of riparian management zones (FW-STD-RMZ-01). Table 349 provides a summary of acres of unsuitable lands where timber harvest is allowed, by alternative.

Wood Product Supply and Timber Harvest

All alternatives provide for availability of timber. The availability of forest products would fluctuate based on disturbances, as well as the implementation of harvest projects. In addition, the actual amount of timber offered would be influenced by a variety of factors, including site-specific environmental analyses, public involvement, harvest methods, and administrative appeals and litigation (Morgan and Baldridge 2015). Site-specific project analyses would consider factors that are not well-represented by programmatic level modeling, such as specific design criteria that may apply to meet resource objectives like scenic integrity and wildlife habitat requirements.

Under all alternatives, the amount of harvest that occurs would be a function of Agency budgets as well as workforce and partnership capacities. The influence of reasonably foreseeable budget limitations was incorporated into the timber volume modeling.

Timber management primarily revolves around fuel reduction in the wildland-urban interface. In non-wildland-urban interface areas, timber management is focused on forest structure, species composition, and size class distributions appropriate for a given ecotone. Although watershed and wildlife habitat improvement are primary benefits at times, they are usually secondary benefits that accrue from accomplishing vegetation restoration objectives.

Where timber management is an option on the roaded portions of the Nez Perce-Clearwater, it can provide opportunities to reestablish early seral species, such as ponderosa pine, western white pine, and western larch, which have declined in abundance. Timber management can also restore forest structure where historically one- and two-storied forests now have a continuous canopy from ground to treetops. Where forest densities are higher than historic levels, timber harvest can reduce densities and decrease risks of damage from insects and disease and uncharacteristic wildland fire effects.

Timber management has the potential to improve forest resistance and resilience to stressors in areas identified for treatment, usually in the roaded portions of the forest. Timber management is a relatively slow process, taking two- to five-years from the beginning of planning to implementation. Therefore, timber management cannot respond quickly to rising threats; it works better as a long-term modification of forest composition and structure, helping the trees gradually achieve resistance and resilience.

With any alternative, timber volume offered is influenced by factors outside the authority of the Forest Service. For example, the United States Fish and Wildlife Service provides direction that limits harvest levels that presumptively protect threatened and endangered species. Further, conditions and activities on adjacent lands can limit harvest when certain conditions are needed at broader scales because harvest on other ownerships is taken cumulatively into account when assessing the environmental impacts of projects on National Forest System lands.

Under any alternative, if additional non-sawtimber infrastructure were developed in the nearby communities, new opportunities may arise that could enhance the amount and types of material utilized from National Forest System lands. For example, more biomass utilization could result in greater volume removal following pre-commercial thinning or fuels reduction treatments versus the disposal of material in burn piles and the resulting release of carbon.

Other Forest Products

Under all alternatives, personal use of special forest products is allowed across Management Area 3 and portions of Management Area 2, excepting areas where special restrictions may apply such as primitive or research natural areas.

Under all alternatives, commercial harvest of special forest products would not be allowed in designated wilderness, recommended wilderness, research natural areas, wild and scenic river designations, or national historic landmarks.

Fire may influence the availability of some special forest products, such as huckleberries and mushrooms. Future wildfire patterns and amounts have a high degree of uncertainty; all alternatives would have the potential to provide special forest products that are linked to fire. Timber harvest and other management activities may increase or decrease the availability of some special products. For example, the availability of Christmas trees may be increased after regeneration harvest. All alternatives propose some amount of harvest and would have the opportunity to affect the availability of associated products.

Areas that are suitable for commercial or personal use of special forest products and that allow access by road or trail would provide greater opportunities for gathering of special forest products. Conversely, the potential for over-harvest of special forest products may increase with greater access. In general, areas expected to have the most road access are those that are established in the plan as suitable for timber production because roads are more likely to exist for vegetation management purposes.

Sustainability of timber harvest

Sustainability of timber harvest is largely dependent on sustaining the productivity of the land base for which timber production is desirable. Productivity of forested ecosystems is dependent on both abiotic and biotic factors. Abiotic factors, such as climate, are not influenced by forest management at the plan or regional scales. Soil parent material and topographic features are considered static and are not influenced by forest management activities. Biotic components, such as species composition, vegetation densities and disturbance events, both influence and are influenced by forest management.

Plan components are developed to promote and sustain site productivity and, in turn, the sustainability of timber harvest. One of the primary missions of the Forest Service is to provide for a sustainable harvest of timber in perpetuity. To promote this mission directive, best available scientific information is utilized and developed to both maintain and enhance long-term site productivity. Research devoted to understanding the drivers of site quality and productivity has spanned many decades. Our understanding of forested ecosystems continues to grow as we endeavor to manage these systems for the benefit of the public.

Coarse down woody debris is a key component of soil formation and function in forested ecosystems (Graham et al. 1994) and is integral to soil productivity. Forest management practices designed to incorporate retention of coarse woody debris may help to promote long-term site productivity. The coarse woody debris management recommendations presented by Graham et al are an example of applying best available scientific information, which promotes site productivity and sustainability of timber harvest.

Table 350 compares the existing quantities of coarse woody debris with the desired conditions across all broad potential vegetation types for Management Areas 2 and 3. Existing amounts of coarse woody debris are typically within the specified ranges. Given that no active management is proposed for Management Area 1, no coarse woody debris desired conditions are specified.

Table 350. Coarse woody debris quantities (tons/acre) by management area and potential vegetation type.

Management Area	Potential Vegetation Type	Existing Condition	Desired Condition
MA 2	Warm Dry	8	7-15
MA 2	Warm Moist	14	17-33
MA 2	Cool Moist	11	9-18
MA 2	Cold	10	7-24
MA 3	Warm Dry	13	7-15
MA 3	Warm Moist	19	17-33
MA 3	Cool Moist	17	9-18
MA 3	Cold	13	7-24

Data Source: R1 Hybrid 2015 FIA dataset (Also see Soils Resource report).

Portions of the Nez Perce-Clearwater, particularly north of the Lochsa River, are referred to as the grand fir mosaic. This area is distinguished from surrounding habitat types by high soil moisture, cooler growing season conditions and understory vegetation dominated by bracken fern (*Pteridium aquilinum*) and western cone flower (*Rudbeckia occidentalis*). The grand fir mosaic is where pocket gophers (*Thomomys talpoides*) are common (Ferguson and Byrne 2000). Regeneration of these sites can be very difficult due to high levels of predation on planted seedlings. To improve regeneration success, Ferguson et al recommended forest management practices which have proven beneficial in improving seedling establishment and regeneration success (Ferguson and Byrne 2000). This is an example of applying best available scientific information that promotes sustainability of timber harvest.

Climate change

Climate is integrated into both the PRISM and SIMPPLLE models via ranges for species composition, size class, and density derived from the natural range of variation analysis. Climate is a major driver of vegetation change, which will affect each of the alternatives over time and, thus, may influence the availability of timber. Considerations for the potential effects to forests associated with climate change are described in the Forestlands section and Appendix B.

The lands that may be suitable for timber production were mapped with the best available information regarding vegetation and site potential. Lands at the margins of producing forest cover, where reforestation may not necessarily be assured due to harsh site conditions, were not included. The potential that future climate may further inhibit tree growth on sites that are currently suitable for timber production, particularly in the warm dry broad potential vegetation type, is unknown. It is possible that continued drought may cause shifts on some of the driest lands and, thus, the lands suitable for timber production could decrease in the future. It would be paramount to determine suitability at the project level during implementation of the plan to identify such areas. It is not possible to further anticipate possible decreases in expected timber volume outputs as a function of climate.

The expected change in climate in future decades could influence availability of other forest products as well. Increased frequency or severity of fire could cause changes or shifts on the landscape in plant species compositions or abundance. Uncertainty exists regarding possible effects of climate change on vegetation and on the availability and distribution of plants that may be gathered as special forest products.

Effects to No Action Alternative

The No Action Alternative is bounded by the Land Management Plan components found in the existing forest plans (U.S. Department of Agriculture 1986b, c) developed under the 1982 Planning Rule. The expected effects of plan components related to timber for the action alternatives is summarized in in the following table.

Table 351. Summary of 1987 Timber and Other Forest Products Plan Components.

Plan Components	Summary of expected effects
Forest-wide Timber Standard for Clearwater National Forest	Describes the requirements from the National Forest Management Act, such as requiring silvicultural prescriptions and using clearcutting only where it is the optimum method. This component is similar to components found in the draft land management plan and would ensure that timber activities are consistent with the law.
Forest-wide Timber Standard for	This standard for the design of transportation plans and logging systems would ensure that these are efficient and meet the needs of other resources.

Plan Components	Summary of expected effects
Clearwater National Forest	
Forest-wide Timber Standard for Clearwater National Forest	Describes the forty-acre opening maximum. In contrast to the action alternatives, this standard does not supply an exception to the size limit. This standard would ensure compliance with the National Forest Management Act regarding maximum size openings.
Forest-wide Timber Standard for Clearwater National Forest	This standard requires feasibility analyses of sales over one million board feet and would help ensure that timber sales are economically viable.
Forest-wide Firewood Standards	These components would help ensure a viable firewood program is provided.
Forest-wide Cultural Resources Standards	Ensure that cultural and historical sites are surveyed and protected from damage from timber harvest activities.
Forest-wide Wildlife & Fisheries Standards for Clearwater National Forest	Guide and/or limit timber harvest activities, including but not limited to elk hiding cover, elk thermal cover, bald eagles, gray wolves, plant species of concern, old growth, and snags.
Forest-wide Watershed, Soil, & Air Standards for Clearwater National Forest	Provides soil standards that would guide and/or limit timber harvest activities. Generally, more qualitative and less specific than the revised plan components found in the action alternatives.
Forest-wide Protection Standards for Clearwater National Forest	Help guide timber management to be used as a tool for preventative pest management, and guide the forest to harvest stands at high risk for mountain pine beetle attack and to break up contiguous natural fuel. The effect may be to lessen tree mortality where harvest is feasible.
Forest-wide Prescribed Fire Desired Conditions for Clearwater National Forest	Help ensure that prescribed fire that occurs in lands suitable for timber production would be conducted in a manner that enhances timber productivity.
Forest-wide Riparian Standards for Clearwater National Forest	Limit timber harvest in riparian areas and are less quantitative than the plan components found in the draft revised plan.
Management Areas for Clearwater National Forest	Describe what areas are suitable for timber production. They also state the required visual quality objectives and other resource objectives, such as recreation, wildlife, range, soil, water, and minerals, that would guide and potentially limit timber harvest.
Cultural Resource Management for Nez Perce National Forest	This component would ensure that cultural resources are protected.
Wildlife Coordination and Habitat Management; Wildlife Trees for Nez Perce National Forest	This standard includes elements that would guide and/or limit timber harvest activities, including but not limited to big game cover analysis, elk analysis areas, threatened and endangered species, snags, and downed woody debris.
Timber Management, Firewood, Reforestation, Timber Harvest for Nez Perce National Forest	Provide detailed guidance for timber and other forest products, including reforestation requirements, riparian considerations, soils, cultural resources, old growth forest, threatened and endangered species, and economic feasibility of timber sales. The standards help ensure compliance with law and policy.

Plan Components	Summary of expected effects
Soil, Water and Air Protection for Nez Perce National Forest	This standard includes components that would guide timber projects, such as sustaining site productivity.
Protection for Nez Perce National Forest	This standard would result in harvest being emphasized in stands at high risk to mountain pine beetle attack; break up continuous natural fuel accumulations, controlling insects and disease with silvicultural and biological practices; and use prescribed fire as appropriate.
Debris Control for Nez Perce National Forest	Guides where dozer piling can occur and the location and how much woody debris could be left after timber harvest.
Management Areas for Nez Perce National Forest	Management area guidance describes what areas are suitable for timber production. They also state the required visual quality objectives and other resource objectives, such as recreation, wildlife, range, soil, water, and minerals, that would guide and potentially limit timber harvest.

To provide a comparative basis between the No Action Alternative and the action alternatives, the management area designations developed for the action alternatives are superimposed onto the administrative boundaries of the Nez Perce and Clearwater National Forests. Management Area 1 is primarily designated wilderness areas, designated wild and scenic rivers, and national historic landmarks. Management Area 2 is primarily composed of Idaho Roadless Rule areas, eligible wild and scenic rivers, the Gospel Hump Multiple-Use Planning Area, and established and proposed research natural areas. Management Area 3 is composed of all remaining lands.

Timber Suitability

Timber suitability for the No Action Alternative is based on the 1987 Forest Plans, as amended and implemented, and shown in Table 351. The total land area considered suitable for timber management under the No Action Alternative is roughly 26 percent of the Nez Perce-Clearwater. Timber harvest would be allowed on lands unsuitable for timber production for purposes other than timber production, when consistent with other management direction. In the No Action Alternative, lands unsuitable for timber production where harvest is allowed represent roughly 14 percent of the Nez Perce-Clearwater, although harvest may be very limited in some of these areas depending on management direction and objectives, as well as existing vegetation conditions. The following sections further discuss timber suitability among all alternatives.

Wood Product Supply and Timber Harvest

Timber supply metrics for the No Action Alternative would theoretically be as described in the affected environment, including the allowable sale quantities which total 375 million board feet for the Nez Perce-Clearwater. However, due to regulatory changes on the landscape, including changes to the areas that may be suitable for timber production, the estimates in the 1987 Plans no longer reflect the management situation in the future if the No Action Alternative were selected. For this reason, and to make direct comparisons to the action alternatives, the allowable sale quantities in the 1987 Forest Plans were updated to display a projected timber sale quantity and projected wood sale quantity following current handbook requirements using the PRISM model. As required by the planning rule and handbook direction, the projected timber sale quantity and projected wood sale quantity reflect currently foreseeable budget levels.

The harvest levels achieved to date during the implementation of the 1987 Forest Plans are shown in the affected environment section. The PRISM model was used to estimate the expected acres of harvest treatments that would occur under the No Action Alternative, based on existing management direction found in the 1987 Forest Plans, as well as new laws and regulations and updated lands suitable for timber production.

Salvage harvest for the No Action Alternative is calculated in the same manner as the action alternatives. Salvage harvest acres are difficult to predict because salvage results from disturbance events which are unpredictable in both spatial and temporal scales. To estimate salvage acres and harvest volumes, disturbance acres are estimated by the SIMPPLE model. A percentage of each disturbance type is subject to salvage harvest based on historical averages. For example, if 100 acres of lodgepole pine were killed by mountain pine beetle and 50 percent of these acres were harvested to recover salvage volume, then 50 acres would be salvaged, and the yield associated with lodgepole pine is used to estimate the volume recovered.

Under the No Action Alternative, the availability of firewood is calculated in the same manner as the action alternatives. A specified percentage of disturbance acres within Management Area 3 are assumed to be available for firewood gathering.

Biofuel availability is assumed to derive from pre-commercial thinning and fuels reduction treatments. Wood fiber designated as biofuel is non-commercial sized material typically ranging from two to seven inches diameter at breast height. Based on desired conditions specified in the SIMPPLLE model, estimates of pre-commercial thinning and fuels reduction acres are calculated for each alternative. Cubic-foot volume per acre estimates include the sum of yield outputs for all treatment acres.

Sustainability of Harvest

As discussed in the affected environment and existing conditions section, sustainability of harvest is dependent on sustainability of long-term site productivity. The same best available scientific information would be applied under the No Action Alternative.

Effects Common to Action Alternatives

All action alternatives contain the same plan components for timber and other forest products. The land management plan was developed under the 2012 Planning Rule and all action alternatives provide direction for sustainable levels of forest products.

Effects that Vary by Action Alternative

Timber Suitability

Based on management guidance and desired conditions, the lands suitable for timber production vary by alternative, as shown in Table 352.

The No Action Alternative has the least amount of land suitable for timber production by a small fraction compared to the action alternatives. Alternative X and the Preferred Alternative have the most lands suitable for timber production, with about 15,479 and 14,039 more acres, respectively, than the No Action Alternative. Alternatives W, Y, and Z represent midpoint values. Nevertheless, overall values are somewhat similar for all alternatives. The lands suitable for timber production on the Nez Perce-Clearwater in in the No Action Alternative and all action alternatives represent roughly 26 percent of the total forested landscape. There is relatively little variance because of primary factors that do not vary by alternative, such as the inherent capability of the land and designations, such as wilderness and inventoried roadless areas. Unsuitable lands differ by the number of acres proposed as recommended wilderness and eligible suitable wild and scenic river designations.

Table 352. Lands suitable for timber production (in acres) by alternative.

Land Classification Category	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
A. Total NFS lands in the plan area	3,939,056	3,939,056	3,939,056	3,939,056	3,939,056	3,939,056
B. Lands not suited for timber production – withdrawn lands.	1,231,638	1,231,638	1,231,638	1,231,638	1,231,638	1,231,638
C. Lands that may be suited for timber production (A-B)	2,707,418	2,707,418	2,707,418	2,707,418	2,707,418	2,707,418
D. Total lands suited for timber production because timber production is compatible with the desired conditions and objectives established by the plan	1,028,480	1,041,522	1,043,959	1,029,983	1,037,058	1,042,519
E. Lands not suited for timber production because timber production is not compatible with the desired conditions and objectives established by the plan (C-D)	1,678,938	1,666,897	1,663,460	1,677,436	1,670,360	1,664,899
F. Total lands not suited for timber production (B+E)	2,910,576	2,897,534	2,895,097	2,909,073	2,901,998	2,896,536

Table 353 displays the lands suitable for timber production by alternative in each management area. The No Action Alternative has the least acres suitable for timber production across all management areas, while all other alternatives have similar amounts. By a small margin, Alternative X and the Preferred Alternative have the largest number of suitable acres across all management areas.

Table 353. Acres and percent of national forest system land suitable [1] for timber production by management area and alternative.

Management Area	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
MA 1 Suitable	0	0	0	0	0	0
MA 1 % Suitable	0%	0%	0%	0%	0%	0%
MA 2 Suitable	0	0	0	0	0	0
MA 2 % Suitable	0%	0%	0%	0%	0%	0%
MA 3 Suitable	1,028,480	1,041,522	1,043,959	1,029,983	1,037,058	1,042,519
MA 3 % Suitable	26.1%	26.4%	26.5%	26.2%	26.3%	26.5%

[1]Suitable acres include both acres suitable for timber production in Management Area 3 and acres suitable for timber harvest (unsuitable acres where timber harvest may occur to achieve other resource objectives) in Management Areas 2 and 3. Management Area 1 acres are classified as unsuitable.

Table 354 displays the acres of lands unsuitable for timber production by alternative in each management area and the associated percentage for each category. The No Action Alternative and all Action Alternatives have the same percentage of acres unsuitable for timber production across all management areas. Alternative X has the largest number of unsuitable acres across within Management Area 3 and the least acres within Management Area 2.

Table 354. Acres and percent of national forest system land unsuitable for timber production by alternative and management area.

Management Area	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
MA 1	1,231,638	1,231,638	1,231,638	1,231,638	1,231,638	1,231,638
MA 1	100%	100%	100%	100%	100%	100%
MA 2	1,489,735	1,468,512	1,463,088	1,487,457	1,474,157	1,467,078
MA 2	100%	100%	100%	100%	100%	100%
MA 3	189,203	197,385	200,372	189,969	196,122	197,385
MA 3	16%	16%	16%	16%	16%	16%

Total acres of National Forest System lands unsuitable for timber production where harvest may occur. Excludes lands where harvest would not be permitted for any purpose, such as designated wilderness, wilderness study areas, recommended wilderness, research natural areas, or wildland recreation settings. For the No Action Alternative, additional areas are excluded based on management area direction that prohibits harvest.

To the extent that recommended wilderness and backcountry restoration themes vary by alternative, so too does the area where harvest may be allowed on lands unsuitable for timber production. Table 355 compares the acres of unsuitable lands where harvest may occur for each management area. The total acres, as well as those that are within inventoried roadless areas found in Management Area 2, are displayed. This distinction is useful because within inventoried roadless areas only very limited harvest could occur per the 2008 Idaho Roadless Rule. The acres shown do not include non-forested vegetation types where no harvest would occur.

Table 355. Unsuitable lands where timber harvest may occur per decade, by alternative.

Management Area	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
MA 1 - Unsuitable lands where timber harvest may occur	0	0	0	0	0	0
MA 2 - Unsuitable lands designated under the Backcountry Restoration Theme	377,575	377,575	377,575	377,575	377,575	377,575

Wood Product Supply

Projected timber and wood sale quantities were estimated using the Prism model based on reasonably foreseeable budget levels (Table 356 through Table 361). The model was run with a mix of objective functions based on the specific objectives for each alternative. Alternatives W and X target moving towards vegetation desired conditions as quickly as possible while meeting other resource constraints. Alternatives Y and Z had the same objective functions as W and X but the model was allowed to achieve desired conditions over a 50-and 100-year period, respectively. The Preferred Alternative was modelled similarly to Alternatives W and X in that the objective function was to achieve desired conditions within the specified time frame of 35 to 40 years. However, the distinctive variation within the Preferred Alternative is to also achieve the maximum sustained yield output following attainment of desired conditions. Model outputs are average annual outputs, which are averaged across projected decades. The model was constrained to harvest from both lands suitable for timber production and unsuitable lands where harvest may occur. These designations differ by alternative and influence the total acres available for timber harvest. All alternatives achieve the desired timber volume outputs within the time frames specified to accomplish the desired conditions. While Alternative X would generate the most volume, the Preferred Alternative achieves a volume between Alternative W and Alternative Y and achieves the highest non-declining even-flow volume through time.

Table 356. No Action Alternative – Average annual projected timber and wood sale quantities with reasonably foreseeable budget, PRISM model; sustained yield of 45 MMCF/241 MMBF.

Data Source: ptsw_pwsq_rev_FEIS.xlsx

The effects on timber production are related to both the number of acres classified as suitable for timber production and acres classified as unsuitable lands where harvest may occur, as well as the objective functions of the model. Alternative X and the Preferred Alternative have slightly more suitable acres than the other action alternatives. Alternative X represents a departure alternative with 20 MMBF above the sustained yield limit, which generates the highest projected timber and wood sale quantities in the short-term. The Preferred Alternative generates yields below Alternative X and W but maintains a higher level of sustained yield over the next fifty years. The No Action Alternative and Alternatives Y and Z do less to meet the desired future vegetation conditions due to the extended time frame for implementation as described further in subsequent sections of this report.

Alternative W was modeled to represent harvest levels at the sustained yield limit of 241 MMBF. Implementation of Alternative W was scheduled to achieve desired conditions within 30 years. While Alternative W does achieve harvest levels at or near the sustained yield limit, the pace of desired condition attainment results in a decline of long-term timber yield over the next fifty years.

The sustained yield limit is constant at 241 MMBF except for Alternative X which is modeled as a departure alternative. As shown above, Alternative X, with a budget constraint, estimates a projected timber sale quantity slightly above (20 MMBF) the sustained yield limit for the first decade and second decades. Alternative X was modeled to allow for a departure from the sustained yield limit up to 261 MMBF per year based on departure analysis for the first two decades.

Alternative Y was modeled to achieve a projected timber sale quantity of twice the current harvest average but delay attainment of desired conditions until year 50. Due to limiting harvest over the first five decades, Alternative Y does not perform as well as Alternatives W and X and the Preferred Alternative at promoting preferred dominance types. Alternative Z was modeled to constrain timber harvest on both lands suitable for timber production as well as unsuitable lands where harvest may occur to analyze potential effects to Canada lynx and fisher habits. Given the time span of the Alternative Z projection, it does not produce meaningful results for comparison of projected timber sale quantity or projected wood sale quantity.

Development of the PTSQ objectives for the Preferred Alternative differs from the other action alternatives in that a minimum long-term sustained yield limit was set. The PRISM model was used to calibrate the highest long-term sustained yield limit possible following attainment of desired conditions for forested vegetation. Harvest volumes for the Preferred Alternative are expected to fluctuate between 190-210 MMBF per year over the first 4 decades of plan implementation. Following attainment of desired conditions, the harvest volumes are expected to fluctuate between 145 and 160 MMBF per year under the Preferred Alternative. This strategy of maximizing short term harvest volumes while also maximizing long term yields generates the best results in terms of reducing departure of forested vegetation to within the natural range of variation estimates.

The consequences related to attainment of projected timber sale quantity between alternatives are driven by the difference in the allocation of suitable lands and unsuitable lands where harvest is allowed, as well as the implementation schedule (pace and sale of restoration). The differences between alternatives related to unsuitable lands where harvest is allowed is driven by differences in the acres classified as recommended wilderness and recommended wild and scenic river designations. Additionally, the application of non-declining even flow constraints influenced attainment of projected timber sale quantity targets for all alternatives. Non-declining even flow, or non-declining yield, means that the volume from a certain land area is steady or increasing into the future. See Appendix B for further information.

Timber Demand

National and international market forces, as well as trade policies, have increased demand for regional timber. According to the Bureau of Business and Economic Research annual outlook in 2017, primary wood product sales, labor income, and employment levels are all up from previous years. The COVID-19 global pandemic caused short term shortages of timber products at all scales. Post pandemic demand for forest products is increasing in response to increases in demand for housing.

Alternative selection for the Nez Perce-Clearwater plan would not directly affect timber demand but may have some impact on timber supply elasticity and solvency for regional or state firms. Flexible timber supply chains are important for mills remaining in Idaho and the five-county area to compete and scale to meet national and international lumber demand. As observed in Figure 146, remaining mills in the region have an estimated additional capacity. Alternatives W and X and the Preferred Alternative would make a positive contribution to the regional timber supply in the short term. Considering the non-declining even-flow quantities projected by the model, Alternative X would contribute most to the regional timber supply in the short-term, but the Preferred Alternative contributes most over the fifty-year projection period.

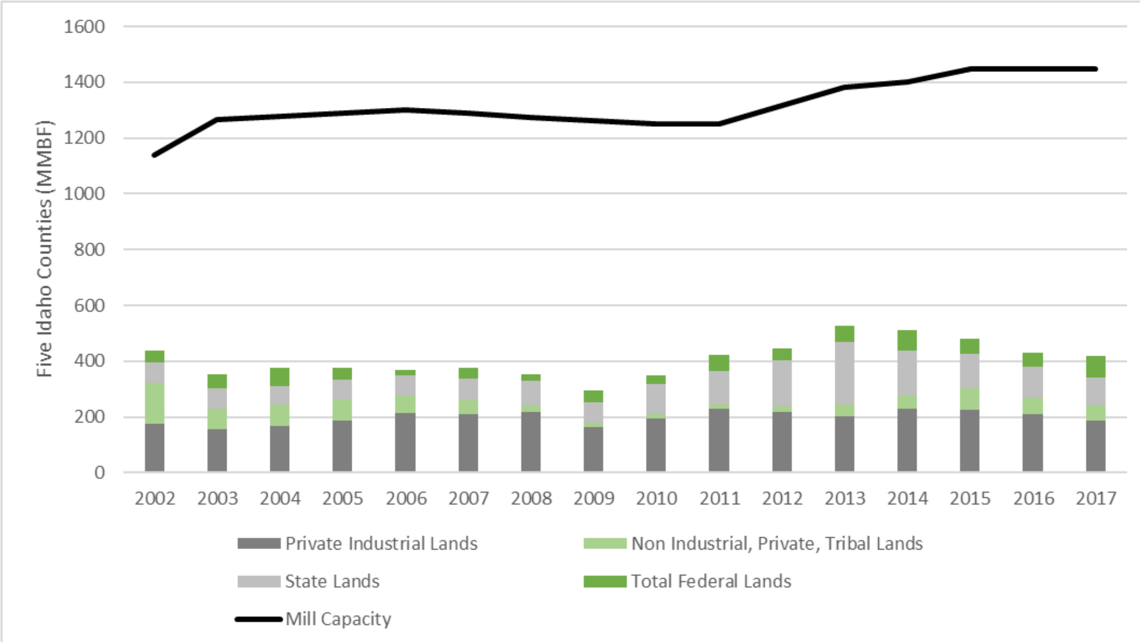

Figure 146. Timber sold versus mill capacity (in MMBF) for five Idaho counties, 2002-2017.

Data Source: Bureau of Business and Economic Research, University of Montana, Idaho's Forest Products Industry and Timber Harvest, 2015

Generally, substitution occurs where there is a mix of public and private land forests available to a mill. However, in the five-county area, the Nez Perce-Clearwater Preferred Alternative selection may have a direct impact on supply availability and, subsequently, sawlog prices.

The influence over timber supply also directly relates to area employment. Statewide, timber industry employment has dropped over the past decade in response to both mill closures and investments made by regional mills to increased efficiencies. See the Economic Sustainability and Social Sustainability sections for more information.

Timber Harvest

Table 362 and Table 363 display the projected acres of harvest that may occur to achieve the volumes shown in the previous section, assuming reasonably foreseeable budget constraints. Acres harvested are a mix of silvicultural prescriptions, including even-aged regeneration, such as clearcut, seed-tree, and shelterwood, and non-regeneration harvest, such as commercial thinning.

Table 362. Average annual treated acres by treatment type and alternative for Decade 1.

Management Area Vegetation Management Practices	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred

Data Source: PRISM – NPC_Alts_Outputs_111820.xlsx

Projected treatment acres for Management Area 2 and 3 combined for both short term (20 years) and long term (50 years) are illustrated in Figure 147. Differences in acres treated between comparative periods and alternatives is due to the different pace and scale specific to each alternative, as well as the ratio of mechanical treatments and prescribed fire. Desired conditions for forested vegetation are constant for all alternatives. Given that the No-Action Alternative implements fewer harvest acres than the action alternatives, higher levels of prescribed fire are utilized to achieve desired conditions. Alternative X is designed to achieve desired conditions within 20 years. This results in implementing a high level of both mechanical harvest treatments and prescribed fire to meet desired conditions within two decades and a subsequent reduction in treated acres between the second and fifth decades. Both Alternative Y and the Preferred Alternative indicate an increase in treatment acres between short term and long-term projections. This is due to a projected increase in the application of prescribed fire to maintenance acres treated during the first 20 years.

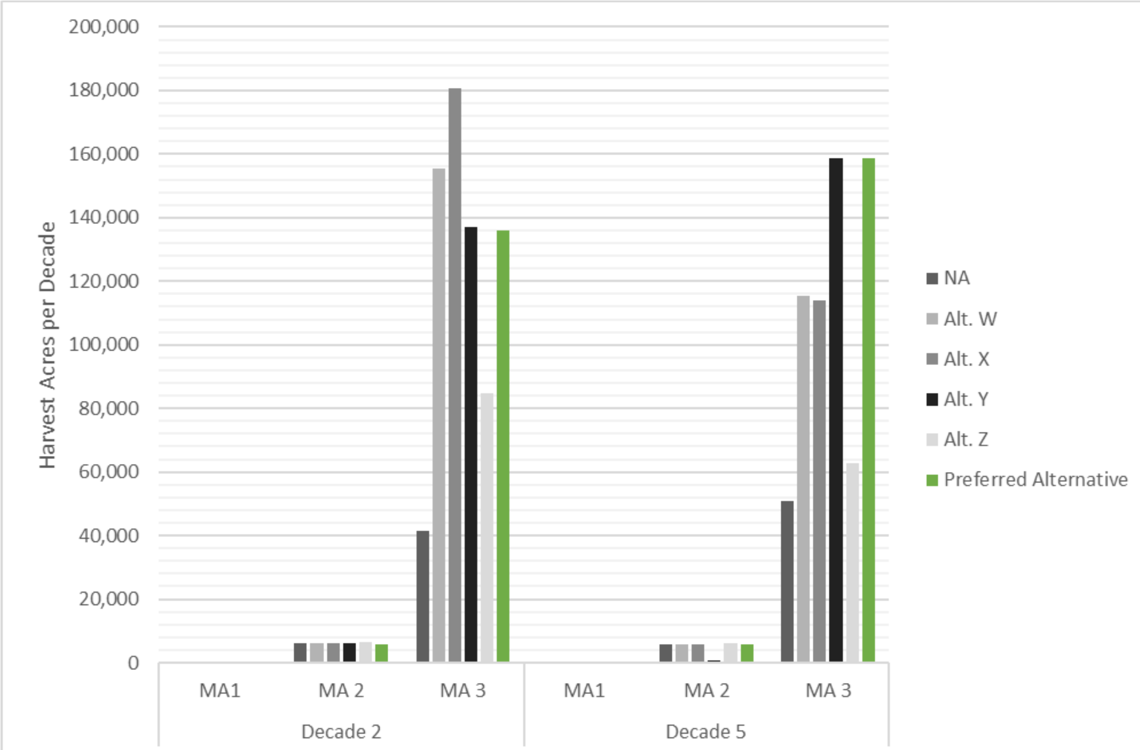

Figure 147. Harvest acres by decade for each Management Area.

Data Source: PRISM – Treatment_Tables_Graphs.xlsx

Alternative Z treats less acres per decade overall due to the long-time horizon (100 years) allowed to achieve desired conditions. With Alternative W and X, the constrained budget run shows substantially greater acres harvested in the short term because of the objective function to maximize timber volume. This aggressive short-term strategy to achieve desired conditions results in a decline in long term yields. Alternative Y falls in the middle between Alternatives W, X, and the Preferred Alternative. Acres treated per decade are generally lower in the Preferred Alternative compared to Alternatives W and X but promote higher yields following attainment of desired conditions. To achieve these treatment acres, budgets and management partnerships would have to be sustained through the entire rotational period for each alternative.

The differences in the alternatives with respect to acres of projected harvest and timber volume outputs can also be demonstrated by the vegetation types associated with the stands the model chose to harvest to meet the objective functions of each alternative (Figure 148). In all alternatives, the model prioritized the warm moist potential vegetation type group. This potential vegetation type is primarily composed of grand fir and associate species of Douglas-fir and lodgepole pine. The model was driven to do this based on the desired conditions that were supplied, such as looking for opportunities to increase the amount of western white pine, western larch, and ponderosa pine and to increase the abundance of large size classes. All alternatives prioritized treatment acres in the same order. The total acres treated in each potential vegetation type is similar across alternatives because the ratio of potential vegetation type acres is similar. There are more warm moist potential vegetation type acres available to the model for attainment of objectives functions than warm dry potential vegetation type acres, with the cold potential vegetation type having the least acres available for treatment. Site productivity is generally highest within the warm moist potential vegetation type group. To achieve harvest targets, the model prioritized treatment of the warm moist potential vegetation type group where average per acre volume yields and growth rates are highest.

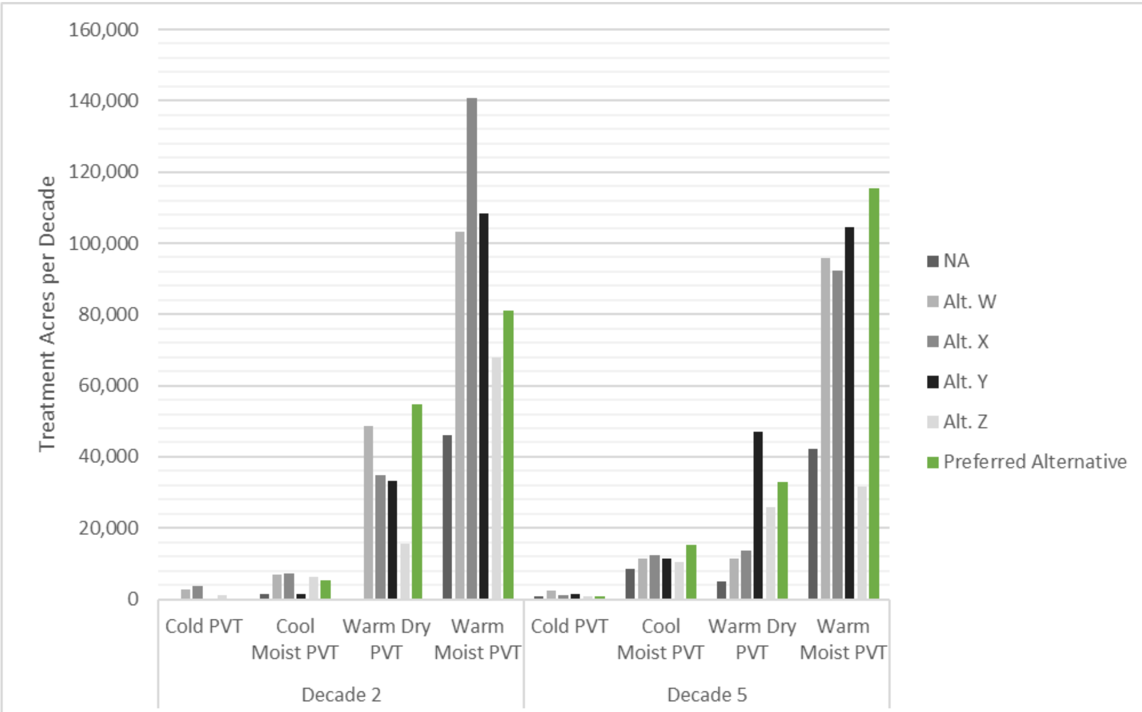

Figure 148. Projected harvest acres by potential vegetation type (PVT) by decade and alternative.

Data Source: PRISM – PRISM – Treatment_Tables_Graphs.xlsx.

PRISM optimized choices to maximize desired condition attainment using only desired conditions for dominance type, size class, and density class. More complex parameters for desired conditions were not feasible in the model design. These are very broad depictions of the desired condition at the forest-wide scale. While the model optimized these broad depictions of the desired condition by focusing treatments in warm moist and warm dry potential vegetation type groups in all alternatives, the results should not be misinterpreted to indicate that harvest treatments would not also be appropriate in cool moist and cold forests to contribute to other desired conditions, such as individual tree species presence, vertical structure, or landscape pattern patch size. Refer to the Forestlands section for a more detailed discussion of vegetation desired conditions.

Other Forest Products

Commercial use of other forest products is not allowed in Management Area 1, which is composed of designated wilderness, recommended wilderness, wilderness study areas, research natural areas, and wild and scenic river corridors. The differences between alternatives are driven primarily by the acres included in Management Area 2 (Idaho Roadless Rule areas) with designations of recommended wilderness, suitable and eligible wild and scenic rivers, and proposed research natural areas. The No Action Alternative is the only alternative that contains eligible wild and scenic rivers as defined under the 1982 Planning Rule. Access for the public to acquire other forest products is generally limited to the roaded front country referred to as Management Area 3. Table 364 summarizes acres where commercial use of special forest products is not allowed in Management Area 2. Acres within Management Area 2 do not differ by alternative relative to the restrictions for commercial use of forest products. Commercial use of special forest products is greatest in Alternative X and the Preferred Alternative, and least in the No Action Alternative.

Table 364. Acres by Idaho Roadless Rule theme where commercial use of special forest products is not allowed in Management Area 2.

Idaho Roadless Rule Categories	All Alternatives
Management Area 2	1,427,763
Backcountry Restoration	835,649
Land Management Plan Special Area	12,805
Primitive	311,155
Special Area of Historic or Tribal Significance (Includes 71 acres of the Lolo National Historic Trail administered by the Lolo National Forest)	21,020
Wild Land Recreation	247,133
Grand Total	1,427,763

Data Source: VMap.

Sustainability of timber harvest

Sustainability of timber harvest on lands suitable for timber production, as well as lands suitable for timber harvest, is integrated into the desired conditions for terrestrial vegetation. Best available scientific information is incorporated into the plan components, which inform each alternative. Standards and guidelines for the management and protection of the soils and coarse woody debris resource are applied to each alternative. Sustainability of timber harvest is required under the National Forest Management Act of 1976. The effects of the continued application of best available scientific information will promote the continued maintenance and improvement of site quality and productivity. As site productivity is maintained and enhanced through application of best available scientific information, sustainability of timber harvest is also maintained.

Effects Analysis

Effects from Land Management Plan components associated with terrestrial vegetation

The revised plan for the action alternatives contains detailed desired conditions for terrestrial vegetation. Timber harvest is one of the tools available to help move the forest toward those conditions. Although these desired conditions, or any similar metrics, are not enumerated in the existing 1987 Forest Plans, in practice, the Nez Perce-Clearwater would likely be managed in the spirit of these desired conditions under the No Action Alternative. The desired conditions translated into the PRISM model included the desired distribution of vegetation type species composition, size, and density classes. The most substantial desired shifts include an increase in western white pine, western larch, and ponderosa pine cover types and an increase in seedling/sapling and very large size classes. The potential types, locations, and frequency of future harvest would be influenced by these desired conditions. For example, harvest treatments may commonly be designed to increase the abundance of large size classes, open forests, or intolerant species compositions to contribute to the desired conditions of the forest.

The desired conditions for vegetation were a key component in the PRISM modeling to ensure the future projected harvest types and volumes would be consistent with the plan components for terrestrial vegetation. Prescribed burning, natural stand growth, and natural disturbances, such as wildfire and bark beetles, were also included in the model.

Figure 149 displays the relative performance of each alternative in terms of achieving forest plan desired conditions for dominance type, size class distribution and canopy cover density as projected with the PRISM model. This analysis assigns penalty points for acres not meeting forest vegetation desired conditions. Penalty points represent the degree of departure from desired conditions at the forestwide scale. Departure is assessed at each decadal time step (period 1 through period 10) of the model projection for a total of 10 decades (100 years). This analysis is also useful for comparing the pace and scale of forest restoration across alternatives.

The "horizontal bars" represent cumulative departure over 10 decades (x-axis at the top). This represents the scale of restoration. The lines represent Departure at each point in time (y-axis on the left). This represents the pace of restoration. The dots represent the point at which each alternative is intended to achieve desired conditions for dominance type, size class distribution and cover type density. As discussed above, Alternative W is designed to achieve desired conditions within 30 years, Alterative X within 20 years, Alternative Y within 50 years, Alternative Z within 100 years and the Preferred Alternative between 35 and 40 years.

Fewer penalty points indicate vegetation conditions were closer to the desired condition. Alternatives W and X and the Preferred Alternative indicate similar results in terms of moving the forest toward the desired conditions based on cumulative penalty points (horizontal bars on graph). The Preferred Alternative differs by less than ten percent from the cumulative penalty point totals of Alternatives W and X. At the forestwide scale, the Preferred Alternative performs best at achieving desired conditions. Alternative Z incurs the most penalty points, indicating it does not achieve the desired conditions as well as the other alternatives. Desired conditions for species composition, size class distribution, and density are not used as constraints on attainment of PTSQ and PWSQ objectives. The PTSQ and PWSQ objectives are obtained as a result of achieving desired conditions.

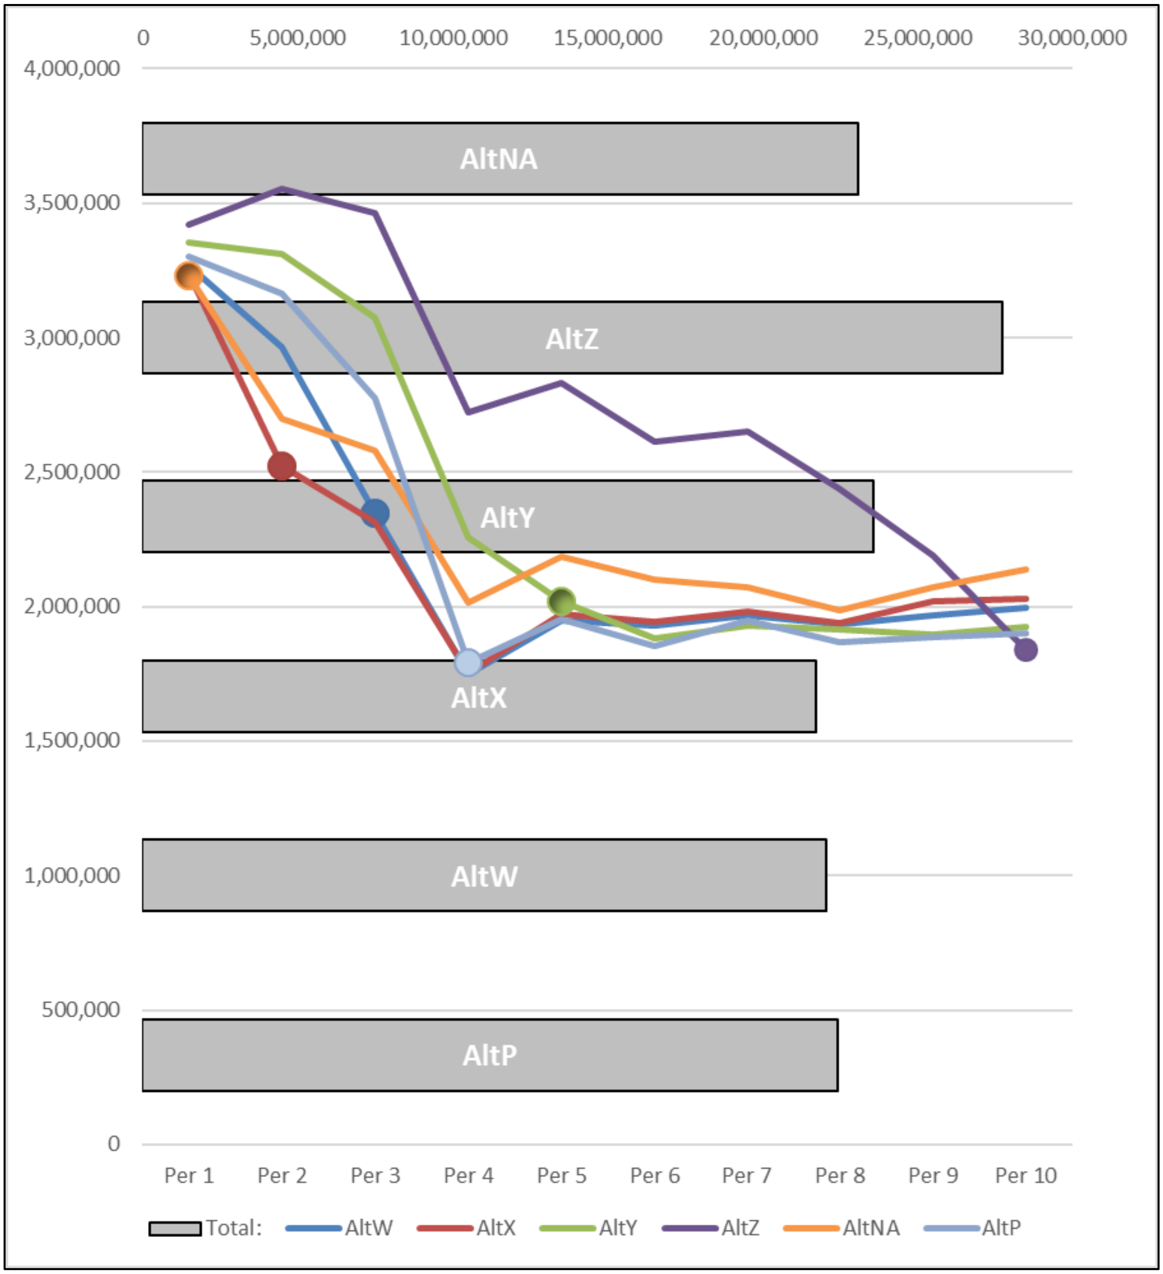

Figure 149. Desired condition PRISM penalty points by alternative under constrained budget.

Data Source: PRISM – NPC_Alts_Outputs_111820.xlsx.

The desired condition penalty points provide a relative comparison of how well treatments in PRISM contribute to terrestrial vegetation desired conditions; however, these results do not include dynamic interactions between treatments and ecological processes over time. To accomplish this, the PRISM results were incorporated into the SIMPPLLE model. Refer to the Forestlands section and Appendix B for more information on how each alternative meets the desired conditions for vegetation over time as modeled with the SIMPPLLE model.

Effects from Land Management Plan components associated with fire, fuels, insects and disease

Plan components related to the management of natural disturbances and prescribed fire would have effects to timber. Insects, disease, prescribed fire, and wildfire can affect the production of timber by killing and damaging trees. Conversely, these events can also provide for thinning of the forest and, while economic loss of specific trees may occur, can contribute to the long-term forest health and timber productivity depending on the site and severity of disturbance.

Under all action alternatives, plan components associated with prescribed burning and other fuels management would generally complement timber management, and vice versa, because all treatments would be designed to move towards desired vegetation conditions. Plan components in the No Action Alternative would also ensure that burning on lands suitable for timber production would complement timber production; less specificity is provided for lands unsuitable for timber production, as these lands are managed to achieve desired conditions for other resources.

The PRISM model included prescribed burning to move the forest toward desired future conditions. Burning treatments were applied as site preparation burns to promote reforestation, maintenance burns to manage stand density within harvested stands, and stand-alone burning prescriptions which typically support resource objectives other than timber management. Table 365 displays the acres of projected prescribed burning by alternative as an average per decade over the first three decades. The ability to achieve burning is highly uncertain and dependent upon many factors including prescribed burning windows, which are highly dependent on weather conditions. Prescribed burning is the primary tool used in the model, as well as in practice, to achieve desired conditions in Management Area 2. The No Action Alternative and Alternatives W and X project similar prescribed burning results for Management Area 2. Alternative Z utilizes prescribed burning to a lesser extent over the first three decades. Alternatives Y and the Preferred Alternative exhibit similar results.

Table 365. Average acres burned[1] per decade by alternative, reasonably foreseeable budget.

Management Area	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
MA 1	0	0	0	0	0	0
MA 2	62,937	58,599	64,184	42,597	11,101	45,386
MA 3	88,731	23,856	37,218	30,472	42,667	9,643

[1]Burning includes prescribed burning in harvested stands, as well as stand-alone ecosystem burning in forested vegetation types only. Additional burning would be expected to occur in non-forested vegetation types.

Data Source: PRISM model.

Prescribed burning treatment acres within Management Area 3 is more variable. The Preferred Alternative utilizes prescribed burning the least due to greater use of commercial thinning prescriptions. Alternatives W, Y, X, and Z utilize progressively more prescribed burning treatments to achieve desired conditions. The No Action Alternative utilizes the most prescribed fire considering both Management Areas 2 and 3. These results are directly correlated with the number of acres treated through timber harvest. If the model cannot achieve desired conditions through timber harvest, more prescribed fire is substituted to achieve desired conditions.

The SIMPPLLE model included a predicted amount of wildfire on the Nez Perce-Clearwater based on current fire suppression success and historic fire starts, as well as potential insect and disease activity. Refer to the Forestlands section for a summary of the acres affected. Under the action alternatives, plan components recognize the importance of these processes on the landscape. The No

Action Alternative emphasizes the control of these disturbances on lands suitable for timber production.

Under all alternatives, potential for salvage treatments exists to harvest dead and damaged timber after natural disturbances or sanitation treatments are utilized to attempt to slow or impede insect and disease infestations from spreading. The degree to which these harvests are undertaken would depend upon the risks associated with wildfire potential, infestation spread into healthy stands, public safety, the presence of high value resources, and the resource emphasis of the area. The risks would all be determined at the site-specific project level of analysis and decision. Sanitation and salvage treatments are not part of the estimated timber volume outputs over time. In the past, fire salvage has occurred on a small proportion, about two percent, of burned acres on the Nez Perce-Clearwater. In general, it would not be expected that future salvage would occur to a much greater degree than has been done in the past; however, the potential for future salvage would depend on the type and location of future fire events. It is possible that increasing large fires in lands suitable for timber production could result in an increased amount of salvage harvest, as permitted by plan components. This activity could result in additional volume outputs beyond what is predicted by the projected timber sale and wood sale quantities. These plan components are not considered constraints on attainment of PTSQ or PWSQ objectives.

Effects from Land Management Plan components associated with recreation opportunity settings

Recreation opportunity settings are mapped designations that may influence access for harvest or how much timber harvest can occur on the landscape for all alternatives, as described in the Land Management Plan. The existing 1987 Forest Plans, also known as the No Action Alternative, utilized the visual quality objective methodology, a system analogous to the recreation opportunity spectrum. The recreation opportunity spectrum was not used in the modelling process to restrict harvesting or prescribed burning treatments nor restrict attainment of desired conditions for forest vegetation.

The recreation opportunity spectrum utilizes six classes that describe settings ranging from highly modified and developed, to primitive and undeveloped. Each class defines and sets broad management direction for specified motorized access and recreation settings. Recreation opportunity classes vary by alternative in size and location across the Nez Perce-Clearwater and influence potential vegetation treatments, particularly timber harvest. Generally, the rural and roaded natural classes provide the most opportunity for suitable roaded access and levels of development that support timber harvest and other vegetation treatments. The semi-primitive motorized class would allow for some timber harvest but at reduced levels from the rural and roaded natural classes. Timber harvest is essentially prohibited in the semi-primitive non-motorized and primitive classes.

Given that the primitive recreation opportunity spectrum class is associated with wilderness and classified as unsuitable acres, this designation is accounted for in the modelling process and has no impact on potential timber harvest. Semi-primitive non-motorized is primarily associated with unsuitable lands designated under the Idaho Roadless Rule area in Management Area 2. Approximately one percent of Idaho Roadless Rule areas are subject to harvest. Harvest is restricted to the backcountry restoration, Land Management Plan special areas, primitive, and special areas of historic or tribal significance themes and may only occur to achieve other resource objectives.

The acres allocated to summer recreation opportunity settings by action alternative are shown in Table 366 for lands suitable and unsuitable for timber production. From the perspective of summer recreation opportunity spectrum classes, Alternative X would allow for the most opportunity for timber harvest with 57.5 percent of the summer recreation opportunity spectrum categories in roaded classes. Alternative Z would offer the least opportunity with 42.6 percent in roaded classes. The other alternatives offer intermediate levels of opportunity, with Alternative W at 46.8 percent, No Action Alternative at 44.7 percent, and Alternative Y at 43.8 percent in roaded classes.

Table 366. Acres of summer recreation opportunity spectrum classes by action alternative, for lands suitable and unsuitable for timber production.

Alternative by Suitability Class	Primitive[2]	Semi-Primitive Non-Motorized	Semi-Primitive Motorized	Roaded Natural	Rural
Alternative W Suitable	22	8,024	371,270	514,377	116,360
Alternative W Unsuitable	1,167,405	917,130	542,414	262,980	39,073
Alternative X Suitable	11	9,161	371,670	515,139	116,362
Alternative X Unsuitable	1,167,462	495,766	688,740	335,673	39,071
Alternative Y Suitable	11	7,273	369,307	506,668	115,843
Alternative Y Unsuitable	1,184,141	1,017,851	384,124	314,249	39,590
Alternative Z Suitable	11	6,881	371,510	512,709	116,360
Alternative Z Unsuitable	1,184,141	1,067,210	345,334	295,829	39,073
Preferred Alternative Suitable	0	17,885	76,841	1,023,595	122,019
Preferred Alternative Unsuitable	1,139,059	624,187	886,665	46,490	2,315

[1]Alternative Y varies slightly from Alternative Z in terms of recreation opportunity spectrum classes in unsuitable lands and are within a few hundred acres for all classes. These differences are negligible in the context of the timber analysis, and the relative amounts and trends are the same. The acres for suitable lands are the same.

[2]The small inclusion of primitive in suitable lands for all Alternatives is likely the sum of tiny mapping errors.

Data Source: GIS

Primitive settings are not suitable for timber production and no harvest is allowed. Plan components in the Land management plan ensure that no vegetation management occurs. This setting often corresponds to designated and recommended wilderness. Natural processes are the drivers of vegetation change.

Semi-primitive non-motorized areas are not suitable for timber production, although limited amounts of harvest can occur to maintain desired vegetation conditions. These areas are often, but not always, associated with inventoried roadless areas and limitations on harvest from the 2008 Idaho Roadless Rule may also apply. These areas typically have poor access and either natural processes or prescribed fire would be drivers of vegetation change more often than timber harvest.

Semi-primitive motorized settings may or may not be suitable for timber production based on other factors and harvest for other purposes is generally allowed. Harvest would be expected to occur at low to moderate levels. This recreation opportunity spectrum is considered a constraint on attainment of desired conditions for species composition, size class distribution, and density.

Roaded natural settings are suitable for timber production and harvest is generally allowed. Typically, good road access and vegetation management may be evident while in harmony with the scenic character of the area. Harvest may be a commonly used tool in these areas to affect vegetation change.

Effects from Land Management Plan components associated with scenery management

Scenic integrity objectives (SIO) are also mapped allocations that may influence timber harvest intensity and distribution of harvest units on the landscape for all action alternatives, as described in the plan components in the Revised Forest Plan. Scenic objectives are consistent with recreation opportunity spectrum classes and timber suitability and are inherently reflected in the timber projections shown in previous sections of this report. In all alternatives, a scenic integrity objective of high makes up a substantial portion of unsuitable lands, which is largely driven by inventoried roadless areas and wild and scenic river corridors. High scenic objectives may also occur on suitable lands based on viewpoints and other criteria. All alternatives are similar with respect to the proportions of scenic integrity objectives identified as high, moderate, and low across lands suitable for timber production as illustrated in the following Table.

Table 367. Acres of scenic integrity objectives by Management Area and alternative

Management Area / SIO	Alt. NA	Alt. W	Alt. X	Alt. Y	Alt. Z	Preferred Alternative
MA1/ High	123,062	53,344	74,897	74,812	74,798	74,642
MA1 / Very High	1,108,576	1,178,293	1,156,741	1,156,826	1,156,840	1,156,996
MA2/ High	535,779	552,610	326,324	564,220	604,917	400,979
MA2/ Low	146	427	427	145	0	427
MA2/ Moderate	953,811	915,468	1,136,329	923,069	867,447	1,065,671
MA3/ High	7,478	43	43	43	43	926
MA3/ Low	444,242	529,110	529,646	529,110	529,020	524,394
MA3/ Moderate	765,962	709,760	714,648	690,831	705,992	715,021
Total Acres	3,939,056	3,939,056	3,939,056	3,939,056	3,939,056	3,939,056

Harvest may be precluded in areas with a very high scenic quality objective where the valued landscape character should be intact, and landscapes generally reflect natural ecological processes only. Such areas typically correspond to primitive recreation opportunity settings, including wilderness, recommended wilderness, wilderness study act areas, and research natural areas.

Areas with a high scenic integrity objective primarily correspond to inventoried roadless areas, wild and scenic river corridors, portions of the Gospel Hump geographic area, and the Lolo Trail National

Historic Landmark corridor. Timber production and harvest may be allowed on limited areas in some of these areas, but scenery and other regulatory limitations would result in low to moderate amounts of harvest. This scenic integrity objective requires that landscape character appear intact and management activities do not dominate the landscape.

Areas with a moderate scenic integrity objective are often suitable for timber production or harvest for other purposes, depending on other factors. These landscapes may appear slightly altered, although management activities remain visually subordinate to the overall landscape character.

Areas with low scenic integrity objectives are also often suitable for timber production or harvest for other purposes. These landscapes may appear altered and management activities are visible.

The existing 1987 Forest Plans, also referred to as the No Action Alternative, do not include the scenic management system or associated scenic integrity objectives as described above for the action alternatives. However, visual quality objectives, as described for the visual management system (U.S. Department of Agriculture 1974c), were specified by management area, as shown in Table 368.

Table 368. Acres of visual quality objective for lands suitable and unsuitable for timber production in the No Action Alternative.

Visual Quality Objective	Lands Suitable for Timber Production	Lands Unsuitable for Timber Production
Preservation	0	1,231,638
Retention	27,645	403,250
Partial Retention	93,828	304,065
Modification	336,461	551,692
Maximum Modification	374,065	439,931

Data Source: GIS.

In areas with a preservation visual quality objective, only ecological changes are allowed; no timber harvest would occur. Primarily wilderness and recommended wilderness have this objective. No lands suitable for timber production have a visual quality objective of preservation.

A retention visual quality objective allows for management activities which are not visually evident. While some harvest could be allowed, these lands are generally not suitable for timber production and may correspond to designations such as inventoried roadless areas.

A partial retention visual quality objective indicates that management activities must remain visually subordinate to the characteristic landscape. Some of these lands are suitable for timber production and harvest on unsuitable lands, although the type and rate of harvest would likely be less than lands with a modification or maximum modification objective.

With a modification visual quality objective, management activities, such as timber harvest, may visually dominate the original characteristic landscape. This is the most common visual quality objective on the Nez Perce-Clearwater for both lands suitable and unsuitable for timber production.

Under the maximum modification visual quality objective, management activities, such as timber harvest, may visually dominate the original characteristic landscape. Scale is the primary difference between modification and maximum modification.

Under all alternatives, additional site-specific scenery requirements would influence project design and potentially the amount, type, or location of harvest activities. Scenery plan components are potential constraints on attainment of PTSQ and PWSQ objectives.

Effects from Land Management Plan components associated with inventoried roadless areas

Inventoried roadless areas are not suitable for timber production and the extent of roadless areas vary by alternative as a function of recommended wilderness acres. Timber harvest may be allowed but is limited under the 2008 Idaho Roadless Rule as a function of the designated roadless rule theme. The legal requirements for management of inventoried roadless areas would influence timber harvest and outputs under all alternatives. Recommended wilderness areas may be adjacent to inventoried roadless areas and harvest may be further restricted. Therefore, to the extent that recommended wilderness areas vary by alternative, so too does the amount of inventoried roadless areas where harvest may occur.

Table 352 compared the area of unsuitable lands where harvest may occur across alternatives, including inventoried roadless areas. Table 369 displays the acres of inventoried roadless areas where harvest could potentially occur within inventoried roadless areas that are not also recommended wilderness, primitive recreation settings, or where harvest is otherwise prohibited. The estimate of unsuitable acres is the same for all action alternatives and is confined to the area within one mile of any open road within the inventoried roadless area. Unsuitable acres are also limited to only those Idaho Roadless Rule themes for which timber harvest is allowed, including backcountry restoration, primitive, and special areas of historic or tribal significance.

Table 369. Lands (in acres) where harvest may occur in inventoried roadless areas under all action alternatives.

Inventoried Roadless Areas	Harvestable Acres
Acres of Inventoried Roadless Area Classified as Unsuitable Lands where harvest may occur to achieve other resource objectives	536,263
% Of Nez Perce-Clearwater	14
% Of Management Area 2	38

Data Source: GIS.

In inventoried roadless areas where harvest may be allowed, the legal requirements of the 2008 Idaho Roadless Rule would limit the purposes for which harvest could occur for ecosystem restoration and to achieve desired conditions for other resources. Possible purposes of harvesting would include improving at-risk species habitat or maintaining or restoring ecosystem composition and structure within the natural range of variation. Appendix E of the revised plan provides guidance for implementing activities in inventoried roadless areas. The effect of this direction would be to limit the acres of harvest and volume outputs that may occur. Timber harvest in inventoried roadless areas also requires additional analysis and receives a great deal of both public and agency scrutiny.

The PRISM model was formulated to allow limited harvest in inventoried roadless areas not precluded by any other designations as a possible option in the management solution to move towards desired future conditions. Plan components related to management of inventories roadless areas are not considered constraints on attainment of PTSQ and PWSQ objectives.

Effects from Land Management Plan components associated with recommended wilderness

Recommended wilderness designations have little impact on potential timber outputs. This is because recommended wilderness areas tend to be in areas that do not contain lands that may be suitable for timber production and tend to be in designated inventoried roadless areas where harvest is greatly limited, as described in the preceding section. In short, timber harvest would be limited in these areas regardless of whether they are recommended as wilderness due to other restraining factors. Across all alternatives, there are no (0%) acres of recommended wilderness that are suitable for timber production. Alternative W has the greatest acres of recommended wilderness that were classified as unsuitable acres were timber harvest can achieve other resource objectives and represents the highest degree to which potential timber harvest was forgone for recommended wilderness. Several recommended wilderness areas including East Meadow Creek, West Meadow Creek and Bighorn-Weitas contain roaded access which provides opportunities to manage vegetation to achieve other resource objectives. A recommended wilderness designation would limit management options, preclude mechanical vegetation treatment options, and rely only on the use of wildland fire to achieve desired conditions. Plan components related to recommended wilderness areas are not considered constraints on attainment of PTSQ and PWSQ objectives.

Effects from Land Management Plan components associated with livestock grazing

In all alternatives, livestock grazing would occur both in lands suitable for timber production and in unsuitable areas where harvest occurs for other purposes. Acres of land suitable for timber production that are also within current livestock allotments are shown in Table 370 by alternative. Alternative X has the most lands where harvest could occur in livestock allotments because it has the most lands suitable for timber production and no recommended wilderness areas. The Preferred Alternative has the second highest number of acres suitable for timber production followed by Alternatives W, Z, Y and the No Action Alternative, in descending order of suitable acres. By contrast, the No Action Alternative has the largest number of active grazing allotment acres within lands unsuitable for timber production. In descending order of active grazing allotment acres, Alternative Y has the most acres of all the action alternatives, followed by Alternatives Z, W, and the Preferred Alternative.

Table 370. Acres where timber harvest can occur within livestock allotments.

	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Acres suitable for timber production	410,597	415,068	416,341	411,601	414,160	416,082
Acres unsuitable for timber production	195,696	191,226	189,952	194,692	192,133	190,212

Data Source: GIS.

Management direction that addresses livestock grazing and timber harvest and production would have similar results across all alternatives. While grazing and trampling from livestock can damage seedlings and saplings, plan components would ensure that grazing is managed to avoid impacting the regeneration of forests impacted by harvest, fire, or other disturbances. Plan components would also ensure that grazing is managed in a manner that would not lower site productivity through damages, such as compaction, and would not preclude the production of timber or other forest products under any alternative. The action alternatives also contain plan components that would encourage grazing activities that complement timber stand tending goals, and vice versa, where appropriate, such as reducing fine fuels to lower fire risk or utilizing forage stimulated by harvest. Plan components related to livestock grazing are not considered constraints on attainment of PTSQ and PWSQ objectives.

Effects from Land Management Plan components associated with watershed and conservation watershed network management

Watershed plan components exist for all alternatives but are more specific in the action alternatives than in the No Action Alternative. These components may affect timber management in that the scale and types of harvest would be influenced by the desired conditions intended to protect watershed function and water quality. Watershed and conservation watershed network plan components will result in limiting harvest, such as when forest cover needs to be retained to limit erosion. This may also limit vegetation management including timber harvest intended to reduce fuel loading to buffer effects of potential high severity wildfire and lesson crown fire potential. The management direction in the action alternatives recognizes more flexibility in these scenarios than the No Action Alternative. The action alternatives also include components that specifically address conservation watershed network and restoration strategies. In all alternatives, plan components related to reducing sediment by limiting or reducing road miles may limit access for timber harvest or reduce feasibility due to the cost of accessing some areas. Such limitations are more explicitly identified in the action alternatives than in the No Action Alternative but the impacts to future management would be similar for all alternatives. Plan components associated with watershed and conservation watershed network management are considered constraints on attainment of PTSQ and PWSQ objectives.

Effects from Land Management Plan components associated with soils management

Under all alternatives, plan components related to soils would generally benefit the timber resource by ensuring that soil productivity and future timber growth is maintained in the long-term. Standards and guidelines related to soils would have the general impact of limiting timber production and harvest in some areas to the extent that activities that may be detrimental to soils, such as repeated compaction and operating equipment on steep slopes or under saturated soil moisture conditions, would be restricted. Such restrictions have been applied to recent timber management activities and continuing these practices would help sustain future timber production and are generally the same for all alternatives. The action alternatives provide greater specificity in the standards and guides for soils than the No Action Alternative, particularly with respect to allowable detrimental disturbance and post-treatment ground cover requirements. Plan components related to soils management are not considered constraints on attainment of PTSQ and PWSQ objectives.

Effects from Land Management Plan components associated with aquatic habitat and riparian areas

Measures to protect aquatic habitat and riparian areas would apply under all alternatives. Refer to the Soils Resources, Water Resources, Ecology, and Wildlife sections for information detailing the vegetation management that is allowed in these areas. The desired conditions, management restrictions, and other regulations that apply to areas near streams, water bodies, and wetlands would limit the amount of timber that may be harvested and affect the types of harvest systems used or may reduce operational feasibility of harvest.

Under all alternatives, riparian management zones would be established. Riparian management zones (RMZ) are superimposed onto riparian areas. Due to changing topography, slope, and slope position, riparian management zones typically include both riparian areas and upland areas. The width of the zones depends on the class of stream and both inner and outer management zones are defined. These management zones are exclusion zones which define limitations specific to vegetation management and harvest. Limitations are more stringent in the inner riparian zones where management must specifically benefit the aquatic resource. In the outer riparian management zones, vegetation management may occur to achieve a wide range of desired conditions if it does not preclude achievement of desired conditions for riparian resources and wildlife in the inner zone. No salvage harvest or fuelwood cutting could occur in the inner riparian management zone and no clearcutting could occur in any part of the riparian management zones. Other standards and guidelines related to landing and road construction would also apply.

Riparian areas, as defined by any alternative, are not suitable for timber production because management requirements and constraints preclude planning a scheduled flow of timber products. However, harvest may occur when consistent with management restrictions and desired conditions for the riparian resources. Under all alternatives, riparian management zones were excluded from the mapping of lands suitable for timber production due to the difficulty in mapping explicit ecotone boundaries. Rather, riparian management zones associated with water features are unsuitable inclusions. Within each riparian management zone, the inner management zone is classified as unsuitable for timber harvest and the outer management zone is classified as unsuitable lands where harvest may occur to achieve other resource desired conditions or objectives.

Across all action alternatives, unsuitable lands where timber harvest may occur to achieve other resource objectives are all associated with outer riparian management zones. All inner riparian management zones are classified as unsuitable lands where timber harvest is prohibited. Within Management Area 2, the differences between alternatives is driven by differences in total acreage of unsuitable lands where timber harvest may occur to achieve other resource objectives. Alternative W has the largest percentage of unsuitable lands associated with outer riparian management zones. Both the Preferred Alternative and Alternative X have the lowest percentage of unsuitable lands associated with outer riparian management zones.

At the forestwide scale, differences in outer riparian management zone acreage between alternatives is negligible. It is estimated that only one percent of the outer riparian management zone may be managed to achieve desired conditions each decade. For this reason, it is unlikely that desired conditions for riparian vegetation will be achieved. Natural disturbance events will continue to dominate forest succession and vegetation pattern within riparian areas. For the No Action Alternative, suitability was defined differently under the 1987 Plans and are not relevant to Management Area 3. Plan components associated with aquatic habitat and riparian areas are considered potential constraints on attainment of PTSQ and PWSQ objectives.

Riparian management zone guidance associated with fish-bearing perennial streams would have the potential to limit timber harvest on one to two percent of lands suitable for timber production or other lands where harvest could occur, depending on alternative. However, vegetation management could occur within the outer riparian management zones identified for the action alternatives. The most stringent guidance would apply to the inner riparian management zones, which would not differ substantially from the size of streamside management zones.

Previous harvest has occurred in the riparian zones for perennial fish-bearing streams before 1995 when the PACFISH and INFISH regulations were adopted. Since 1995, only minimal pre-commercial thinning has been accomplished in riparian management zones. Over the last 80 years, fire suppression has limited natural fire disturbance within defined riparian management zone areas. During this same span of time, forested riparian corridors have increased in density and species composition has shifted toward climax species dominance. Forest succession has begun to shift species composition within riparian management zones toward a dominance of conifer species and reduced composition of hardwood species, such as cottonwood, birch, willows, and alder. The current forested riparian ecosystems are not functioning within the natural range of variation for fire return interval or species composition and age class distribution. The continued practice of excluding riparian management zones from vegetation management will further jeopardize these important ecotones and threaten fisheries and riparian habitats.

Based on the extent of riparian management zones in potential harvest areas and because harvest may occur to some degree, the potential impact of the management restrictions in riparian areas is not likely so great that the projected timber volumes and expected harvest treatments generated by the PRISM model would be affected to a great degree with respect to the programmatic timber analysis.

Effects from Land Management Plan components associated with the Lolo Trail National Historic Landmark

The Lolo Trail National Historic Landmark runs through the Nez Perce-Clearwater plan area. Many stretches of this trail lie within designated wilderness, where timber harvest is prohibited. Other stretches are in inventoried roadless, where timber harvest is largely constrained. However, some stretches of this trail are also located in areas where harvest could occur, including both areas that are suitable for timber production and those unsuitable for timber production where harvest can occur for other purposes. In these areas, harvest may occur but would be constrained by plan components associated with the trail, which are designed to maintain a high or very high scenic integrity objective within half a mile of either side of the trail.

The lands where some form of harvest is permitted within half a mile of the Lolo Trail National Historic Landmark are shown in Table 371. Alternatives W and Y and the Preferred Alternative have identical acreage adjacent to the Lolo Trail that are suitable for timber production, with Alternative X having the most and Alternative Z the least. Alternative Z has the most lands unsuitable for timber production where harvest may occur to achieve other resource objectives and adjacent to the Lolo Trail; Alternative W has the least. The differences between alternatives are largely as a function of recommended wilderness areas. In these areas, the types of harvest and amount of volume removed may be limited or may be more complex to implement to meet the guidelines associated with the trail. Plan components associated with the Lolo Trail National Historic Landmark are not considered constraints on attainment of PTSQ and PWSQ objectives given the limited scale of this resource.

Table 371. Acres where harvest may occur within half a mile on either side the Lolo Trail National Historic Landmark.

	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Lands Suitable for Timber Production	27,506	27,506	27,618	27,506	26,964	27,506
Lands Unsuitable for Timber Production where Harvest may Occur	26,268	8,369	31,180	31,239	31,780	31,239

Data Source: VMap.

Effects from Land Management Plan components associated with elk management

Under all alternatives, the management of elk habitat is commensurate with managing for vegetation desired conditions. Management of elk habitat is focused on four components, including improved nutrition, distance from open motorized access, habitat use in context of elk use of slopes, and vegetation interspersion. Plan components do not vary by alternative or management area. The potential influences of elk management plan components cannot be explicitly modeled and quantified with PRISM or SIMPPLLE models but can be inferred from vegetation management plan components and modelled vegetation response to management.

Elk management plan components focused on improved nutrition are not likely to restrict timber harvest. Elk plan components may influence selection of treatment locations and the distribution of treatments focused on areas with the highest potential to produce high quality forage for elk. Management guidelines focused on access management are driven more specifically by forest level travel management decisions than road systems developed for timber harvest units. Most roads utilized for timber harvest unit access are temporary roads, which may or may not be accessible to the public. Elk management guidelines may influence the construction of new road segments proposed for timber access relative to location and closure status.

Given the scale of analysis for ecosystem restoration projects; elk management components focused on topographic position of elk habitats are not likely to influence decisions related to location of timber harvest units. Forest-wide vegetation plan components are focused on moving vegetation towards desired conditions across all broad potential vegetation type groups located on all topographic positions. Arrangement of harvest units on the landscape are intended to reflect landscape forest patterns and variation in patch size resulting from natural fire regimes. Elk management components focused on vegetation interspersion are compatible with vegetation management components. Plan components associated with elk management are not considered constraints on attainment of PTSQ and PWSQ objectives.

Effects from plan components associated with Canada lynx management

All alternatives would incorporate the Northern Rockies Lynx Management Direction (U.S. Department of the Interior 2017c). This direction would influence timber activities in potential lynx habitat, which is identified based on potential vegetation types. Refer also to Appendix 8 of the Land Management Plan. For the timber resource, the impacts of lynx management would have the greatest effect on lands suitable for timber production but would also influence harvest that occurs on unsuitable lands.

The management guidance that would influence timber production and harvest in potential lynx habitat includes not allowing harvest in multi-storied forest except in specified situations, possibly limiting the extent of regeneration harvest depending on how much stand initiation habitat is present in each lynx analysis unit, and not allowing pre-commercial thinning in stand initiation habitat. Some exceptions and considerations would apply, including, but not limited to, treating lands adjacent to administrative sites, treating lands in the wildland urban interface, and conducting treatments to restore whitebark pine. The lynx management direction also notes the potential for vegetation management to occur that would help develop desired habitat characteristics. This may influence the type of harvest conducted in some areas; for example, uneven-aged harvests may be used to help develop multi-storied forests.

Although the management constraints are only required in occupied lynx habitat, the guidance is considered on all lands as per Regional Office direction. This focus on applying lynx habitat guidance on all lands creates potential conflicts with the restoration of both western white pine and whitebark pine. Occupied lynx habitat has been identified by the United States Fish and Wildlife Service. However, because the guidance should be considered on all lands and there is potential for occupied habitat to change, lynx constraints are analyzed across the entire Nez Perce-Clearwater. Lynx constraints were applied to the PRISM model. The projected harvest quantities, types, and volume outputs shown in this section reflect lynx management direction to the extent possible. These constraints included:

- Limiting the percent of areas that can have a regenerating harvest or prescribed burn
- Not allowing pre-commercial thinning in certain vegetation types
- Not allowing treatment in multistoried[25] habitat

Table 372 compares the area suitable for timber production with those areas also characterized as potential lynx habitat, by alternative. This illustrates the magnitude of potential impact to lynx habitat and are similar across all alternatives. In general, potential lynx habitat influences approximately 20 percent of lands suitable for timber production under each alternative.

Table 372. Potential lynx habitat (acres and percent) within lands suitable for timber production, by alternative.

	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Acres Suitable for timber production	1,028,480	1,041,522	1,043,959	1,029,983	1,037,058	1,042,519
Acres of potential lynx habitat in areas suitable for timber production	211,759	212,218	212,769	211,894	209,253	212,209
Percent of land suitable for timber production in potential lynx habitat	20.6%	20.4%	20.4%	20.6%	20.2%	20.4%

Source: Vmap.

Plan components associated with Canada Lynx management are considered potential constraints on attainment of PTSQ and PWSQ objectives. See Appendix B for more information. Also see the Forestlands section for a description of effects from lynx management on vegetation management and desired conditions.

Effects from plan components associated with fisher habitat management

Alternative Z and the Preferred Alternative incorporate management direction for fisher. This direction would influence timber activities in potential fisher habitat. Refer also to Appendix C for a detailed discussion on fisher habitat. For the timber resource, the impacts of fisher management would have the greatest effect on lands suitable for timber production but would also influence harvest that occurs on unsuitable lands.

The management guidance that would influence timber production and harvest in potential fisher habitat includes maintaining connectivity between large patches of mature trees where mature trees occupy approximately 50 percent of the forest cover type. The remaining forest cover type is

[25] The definition of multistoried habitat as used in context of lynx habitat is not the same as the silviculture context. Please refer to the Northern Rockies lynx Management Direction (2007) for an explanation of how multistoried habitat is defined.

composed of a mosaic of height and age classes in a distribution that reflects natural disturbance patterns. Large trees and snags of 20-inch plus diameter at breast height are distributed in both patches and scattered within the habitat. Fisher management direction also notes the potential for vegetation management to occur that would help develop desired habitat characteristics. This may influence the type of harvest conducted in some areas; for example, uneven-aged harvests may be used to help develop multi-storied forests which provide multiple canopy layers needed to provide denning and resting habitats.

Fisher constraints were applied to the PRISM model for specific habitat types primarily associated with the warm moist potential vegetation type group. The projected harvest quantities and volume outputs shown in this section reflect fisher management direction to the extent possible. These constraints included:

- Limiting regeneration harvest and / or prescribed burning which results in a canopy opening to ten percent of fisher habitat per decade.
- Openings in canopy cover created through vegetation management are expected to last for up to 20-years.
- In overlap areas with potential lynx habitat, lynx management guidelines are imposed.

Table 373 compares the lands suitable for timber production and the proportion of those lands that are also in potential fisher habitat for Alternative Z and the Preferred Alternative. Potential fisher habitat influences approximately 57 percent of lands suitable for timber production within the warm moist potential vegetation type group. The remaining balance of suitable fisher habitat occur within the warm dry and cool moist potential vegetation types. Plan components associated with fisher habitat management are considered potential constraints on attainment of PTSQ and PWSQ objectives.

Table 373. Acres potential fisher habitat within lands suitable for timber production.

	Alt Z	Preferred
Total lands suitable for timber production	1,037,058	1,042,520
Acres of potential fisher habitat in land suitable for timber production	600,000	600,000
Percent of land suitable for timber production in potential fisher habitat	58%	57%

Data Source: SIMPPLLE.

Cumulative Effects

There are many factors that influence timber harvest. The demand for timber products and supply from other sources, policy, regulations, and litigation all affect the amount of timber that may be harvested from the Nez Perce-Clearwater. Budgets and partnership capacity also impact timber supply. The effects that past activities have had on components of forest vegetation, such as forest composition and structure or landscape pattern, were discussed in the “Affected Environment” section and are reflected in the current condition.

Increasing human population

Increasing human populations is an additional stressor that may affect management of forested lands both locally and nationally, which results in growing demands and pressures on public lands. Locally, present populations are increasing in some counties surrounding the plan area but are declining or stable in other areas. Refer to the Economic Sustainability and Social Sustainability sections for more information. These changes may lead to increased tensions between the demand for timber and changing societal desires related to the mix of other uses public lands may provide. The sustainable use of other forest products may become increasingly vulnerable and require permitting and limitation of use.

Management of Adjacent Lands

Portions of the Nez Perce-Clearwater adjoin other national forests, each having its own forest plan. The Nez Perce-Clearwater is also adjacent and intermixed with lands of other ownerships, including private lands, other federal lands, tribal lands, and state lands. Some management areas contain inholdings of such lands, while others are more un-fragmented in terms of ownership. Harvesting or conversion of forests on adjacent lands would affect vegetation conditions at the landscape level. State law applies to all harvest activities regardless of ownership; therefore, basic resource protections would be consistent. However, harvest practices on other lands would not necessarily be conducted to meet the same desired conditions as those outlined in the Nez Perce-Clearwater Land Management Plan.

Some adjacent lands are subject to their own resource management plans. The cumulative effects of these plans, in conjunction with the Nez Perce-Clearwater Land Management Plan, are summarized in Table 374 for those plans relevant to the timber resource. The project record contains a summary of all resource plans considered.

Table 374. Summary of cumulative effects to timber from other resource management plans.

Resource plan	Summary of effects
Forest/Land Management Plans of Adjacent National Forests	The Nez Perce-Clearwater shares boundaries with the Idaho Panhandle, Payette, Willowa Whitman, Bitterroot, and Lolo National Forests. The Lolo and Bitterroot are currently in Land Management Plan under the 2012 Planning Rule. The Idaho Panhandle National Forest has implemented a hybrid forest plan consisting of both 1982 and 2012 planning rules. All of the forest plans contain plan direction that meets the requirements of the National Forest Management Act, such as limitations on harvest, reforestation practices, and maximum sized openings. Generally speaking, management of the timber resource is consistent across national forests due to consistency in law, regulation, and policy. The management of the specific areas that are adjacent would be complementary across boundaries.
Idaho Forest Practices Act (Bauer et al. 1988)	The forest action plan is complementary to the timber management on the Nez Perce-Clearwater by including strategies related to increased resilience, wildfire safety, and, most especially, providing forest products. The cumulative effect would likely be additive in terms of the amount of timber harvest treatments that occur across the landscape and in a broader sense moving towards at least some of the vegetation desired conditions as described in the land management plan.
Nez Perce Tribe Forestry and Fire Management Plan (Nez Perce Tribe Forestry and Fire Management Division)	The forestry and fire management plan is complementary to timber management on the Nez Perce-Clearwater by including strategies related to increased resilience, wildfire safety, wildlife habitat management, and providing forest products. The cumulative effect would likely be additive in terms of the amount of timber harvest treatments that occur across the landscape and in a broader sense moving towards at least some of the vegetation desired conditions as described in the land management plan.
United States Army Corps of Engineers, Walla Walla District, Dworshak Five Year Vegetation Management Plan (2015-2020) (U.S.	The five-year vegetation management plan contains plan direction that meets the requirements of the National Forest Management Act, such as limitations on harvest, reforestation practices, and maximum sized openings. Generally speaking, management of the timber resource is consistent with Nez Perce-

Resource plan	Summary of effects
Army Corps of Engineers 2015)	Clearwater due to consistency in law, regulation, and policy. The management of the specific areas that are adjacent would be complementary across boundaries.
Idaho State Wildlife Action Plan (Idaho Department of Fish and Game 2017b)	Vegetation management recommendations presented in the 2015 Idaho State Wildlife Action Plan are consistent with Land Management Plan objectives under the land management plan.
County wildfire protection plans	Some county wildfire protection plans map and define the wildland urban interface. The Nez Perce-Clearwater notes that these areas may be a focus for hazardous fuels reduction and other plan components, such as the Northern Rockies Lynx Management Direction, and have guidance specific to these areas. Treatments, including harvest, may be emphasized in these areas more so than others.

Timber Demand

The demand for wood products allows for successful vegetation management and timber sales from the Nez Perce-Clearwater. If demand for wood products increases, so too will demand for timber sales from the Nez Perce-Clearwater. Alternatively, if demand decreases and mills close there may be less desire for Nez Perce-Clearwater timber. A decrease in demand may reduce the amount of timber sold regardless of the alternatives. Lower wood quantity may contribute to total public and private land timber supply chain elasticity, especially for mills isolated from other ownership and highly dependent on Nez Perce-Clearwater Forests. If enough timber is collectively removed from markets, it would have the effect of increasing sawlog prices and decreasing operating profits for existing mills.

Effects from Other Resources

Access and Infrastructure

In all alternatives, limits related to road access on existing roads as well as construction of both permanent and temporary new roads could impact the ability to conduct harvest on portions of the forest due to the lack of economically feasible access. The magnitude of this influence cannot be calculated but is implied within recreation opportunity settings that are included in the timber model.

Mining and Mineral Extraction

Mining undergoes site-specific analysis to determine effects and required mitigation and effects to vegetation from mining is determined at the project level. Generally, the impacts to timber from mineral extraction on the forest are localized and at the forest-wide scale they would be insignificant.

Wildlife Management

Plan components for wildlife may limit specific actions, such as timber harvest. In all alternatives, plan components for species, such as bats and raptors, would limit disturbances caused by harvest to specific areas during certain sensitive time periods but these locations and restrictions would not be so extensive as to alter the general expected harvest levels.

Conclusion

The following conclusions are based on the timber and other forest products resource analysis:

- Timber suitability: The No Action Alternative has the least amount of land suitable for timber production and Alternative X has the most, but all alternatives are relatively similar. In all alternatives, timber harvest has the potential to occur in lands that are unsuitable for timber production to achieve other objectives. Alternative X has the largest number of unsuitable lands where harvest may occur because it has no recommended wilderness areas. The Preferred Alternative has the second largest number of unsuitable lands where harvest may occur, and Alternative W has the least. Harvest from lands unsuitable for timber production are expected to be minimal for all alternatives. Alternative Z has the most unsuitable lands suitable for designation as wild and scenic rivers. The greatest impact to timber suitability is constraints associated with riparian areas, conservation watershed networks, fisher and lynx habitat, and the recreation opportunity spectrum. Individually, these constraints have little impact at the forestwide scale but will cumulatively constrain attainment of the PTSQ and PWSQ objectives at the management area scale.

- Wood Product supply: Alternative X is modelled to produce the highest level of timber outputs; Alternatives W, the Preferred Alternative, Alternative Y, Alternative Z, and the No Action Alternative result in progressive decreases in timber outputs.
- Timber demand: The trend for timber demand is independent of alternatives, but alternatives may offer different supply chain flexibility for the forest products industry.
- Potential Timber Sale Quantity: Alternatives W and X and the Preferred Alternative are similar in terms of expected harvest treatment acres; Alternative Z would treat fewer acres over a longer period and achieve less volume outputs. Alternative X does more than the other alternatives to achieve vegetation desired conditions due to greater number treatment acres. The Preferred Alternative will produce harvest levels between Alternatives W and X but will maintain a higher level of timber output following attainment of desired conditions.
- Sustainability of Timber Harvest: Long term sustained yield timber outputs are modeled for each alternative. These sustained yield outputs are maintained through time through the application of Land Management Plan components intended to protect soil resources and maintain coarse woody debris needed to maintain long term site productivity.
- Other forest products: Special and other forest products such as firewood, huckleberries and mushrooms would remain available into the future to a similar degree in all alternatives. Areas where commercial use of other forest products may vary relate to the extent that recommended wilderness varies by alternative.

3.5.2 Energy and Minerals

As directed by the Organic Administration Act of 1897 and the Multiple-Use Sustained-Yield Act of 1960, the National Forests are managed by the Forest Service for continuous production of renewable resources on National Forest System lands. Renewable resources include timber, clean water, wildlife habitat, forage for livestock, and outdoor recreation. Although not renewable, minerals are resources of the National Forests and are important to the nation’s welfare.

Forest Service Role in Minerals Management

In the Mining and Minerals Policy Act of 1970, Congress declared that, in the interest of the nation, it is the continuing policy of the federal government to foster and encourage private enterprise in the development of domestic mineral resources and the reclamation of mined land. This federal policy applies to National Forest System lands.

The Forest Service recognizes the importance of mineral resources to the well-being of the nation and encourages bona fide mineral exploration and development. However, it also recognizes its responsibility to protect the surface resources of the lands under its care. Thus, the Forest Service is faced with a double task – to make minerals from National Forest System lands available to the national economy and, at the same time, minimize the adverse impacts of mining activities on other resources.

Land management planning, as mandated by the National Forest Management Act of 1976, is a principal tool for ensuring that mineral resources are given proper consideration. Before plans are approved, specialists evaluate resource activities, including existing and potential mineral development. Planners and decision makers then formulate plans to minimize potential resource conflicts and maximize the various uses and values of National Forest System lands. Since mineral resources are often subsurface, relatively rare, and governed by certain preferential laws, land management planning procedures provide for the availability of minerals and development of mineral operations where possible.

Minerals management of National Forest System lands requires interagency coordination and cooperation. Although the Forest Service is responsible for the management of the surface resources on National Forest System lands, the Bureau of Land Management is primarily responsible for management of government-owned minerals. Since it is not possible to separate mineral operations from surface management, the agencies have developed cooperative procedures to accommodate their respective responsibilities.

Mineral exploration and mining activity on the Nez Perce-Clearwater falls into three federally recognized legal and regulatory mineral categories – locatable, mineral materials, and leasable.

Locatable

Locatable minerals are those that may be "located" with a mining claim under the General Mining Law of 1872, as amended. There are four types of claims: lode, placer, millsite, and tunnel. Locatable minerals include, but are not limited to, gold, silver, copper, lead, zinc, platinum, precious gems, uranium, bentonite, and chemical grade limestone. Lands that are open to location under the Mining Law of 1872 guarantee U.S. citizens the right to prospect and explore lands reserved from the public domain and open to mineral entry. The right of access for exploration and development of locatable mineral is guaranteed.

Mineral Materials

Also known as salable minerals, mineral materials include common variety mineral materials, such as common varieties of sand, rock, stone, cinders, gravel, pumice, clay, most building stone, and other similar materials. The Forest Service has the authority to dispose of these materials on public lands through a variety of methods. The disposal of these materials is discretionary.

Leasable

According to the amended Mineral Leasing Act of 1920, leasable minerals include coal, phosphate, potassium, oil, oil shale, gas, and sodium resources that occur on public domain lands. The Mineral Leasing Act was amended to include minerals associated with lands acquired by the United States. The Geothermal Steam Act of 1970 also incorporated geothermal resources. Additionally, locatable minerals on acquired lands may fall under the Mineral Leasing Act; however, their leasing is at the discretion of the Forest Service and is subject to all standards and guidelines for other resources.

This report neither evaluates nor provides information in support of a decision to approve any mining-related activity on the Nez Perce-Clearwater. The Forest Service itself generally does not initiate exploration or development of mineral or energy resources. Rather, external parties and market forces drive proposals for access to, exploration for, and development of mineral resources. Management of the Nez Perce-Clearwater's minerals program supports the goal of environmentally sound energy and minerals development and reclamation; therefore, operations on the Nez Perce-Clearwater are required to be conducted in a manner that minimizes adverse environmental impacts to surface resources. Minerals related proposals require a site-specific National Environmental Policy Act review to evaluate compliance with applicable laws, regulations, and the Land Management Plan.

Relevant Laws, Regulations, and Policy

With respect to National Forest System land management, mineral resources are divided into three groups: locatable minerals, salable minerals, and leasable mineral materials. The authority of the Forest Service to influence and regulate the exploration, development, production, and reclamation phases of mining operations varies with each group. Therefore, the Forest Service manages mineral resource programs that are specific to each group. Minerals management on National Forest System lands is subject to laws, regulations, and Forest Service policies in the Forest Service Manual 2800, Forest Service Handbook 2800, and 36 Code of Federal Regulations 228.

Locatable Minerals

The Forest Service is obligated to process, administer, and manage mining operations on National Forest System lands that are conducted under the authorities of the following laws and regulations:

- United States Mining Laws of May 10, 1872
- Organic Administration Act of 1897 (Ch. 2, 30 Stat. 11, as amended; 16 U.S.C. 477-482, 551)
- Public Law 91-631, entitled the Mining and Minerals Policy Act of 1970

Regulations promulgated on September 1, 1974, enacted 36 CFR 228 Subpart A, which "sets forth rules and procedures through which use of the surface of National Forest System lands, in connection with operations authorized by the United States mining laws, which confer a statutory right to enter upon public lands to search for minerals, shall be conducted so as to minimize adverse environmental impacts on National Forest System surface resources." Additional direction for locatable mineral management can be found in Forest Service Manual 2810.

All lands on National Forests are open to operations under the General Mining Law of 1872, as amended, except those formally withdrawn from mineral entry by Congress or the Secretary of the Interior or otherwise exempted. The General Mining Law grants every United States citizen the right to prospect and explore public domain lands that are open to mineral entry. This right of access is guaranteed; that is, denying access to minerals on public land is not a Forest Service discretionary action. Upon discovering a valuable mineral deposit, citizens have the right to locate a mining claim and remove the mineral resources.

If the land is open to mineral entry and the mining claim is properly filed with the Bureau of Land Management, the claimant has legal title to the minerals. The Bureau of Land Management's mining claim database lists active, closed, and pending mining claims recorded on public lands. The status of mining claims can change on an annual basis and new claims can be recorded at any time throughout the year.

Any person proposing to conduct operations that might significantly disturb surface resources must submit a Notice of Intent. After evaluating the Notice of Intent, if it is determined that the operations will significantly disturb surface resources, a Plan of Operations and an environmental analysis will be required.

The Forest Service works with mining claimants to provide reasonable access to their claims, minimize adverse environmental impacts on surface resources, and ensure reasonable reclamation of lands affected by mining operations. To protect surface resources, the Forest Service reviews mining plans of operations submitted by the claimant; discloses impacts of the proposed mining operations in a site-specific environmental document; approves only those activities that are reasonably necessary for the proposed operation; monitors operations to ensure environmental standards are met; and ensures prompt and reasonable reclamation of disturbed areas.

Mineral Materials

Often referred to as saleable or common variety minerals, mineral materials are subject to the amended Materials Act of 1947. These minerals are disposed of by sale through issuance of free-use permits or under contracts for in-service needs. Mineral materials include petrified wood and common varieties of sand, rock, stone, cinders, gravel, pumice, clay, and other similar materials. Such common variety mineral materials include deposits that tend to be commonly available; although they have economic value, they do not have a distinct and special value. These minerals are most commonly used as building, landscaping, and construction materials. Management direction for mineral materials is found in 36 CFR 228, Subpart C, and Forest Service Manual 2850. The Forest Service mineral material policy states that the disposal of mineral material will occur only when the authorized officer determines that the disposal is not detrimental to the public interest and that the benefits to be derived from the proposed disposal will exceed the total cost and impacts of resource disturbance.

Surface management authority

Organic Administration Act of June 4, 1897 (30 Stat. 11, as amended; 16 U.S.C. § 473 et seq.): This act provides the Secretary of Agriculture the authority to regulate the occupancy and use of National Forest System lands. It provides for the continuing right to conduct mining activities under the general mining laws if the rules and regulations covering the National Forest are complied with. This act recognizes the rights of miners and prospectors to access National Forest System lands for all proper and lawful purposes, including prospecting, locating, and developing mineral resources.

Multiple-Use Sustained-Yield Act of June 12, 1960 (P.L. 86-517, 74 Stat. 215; 16 U.S.C. 528 et seq.): This act requires that National Forest System lands be administered in a manner that considers the values of the various resources when making management decisions and specifically provides that nothing in the act be construed to affect the use or administration of the mineral resources on National Forest System lands.

Wilderness Act of September 3, 1964 (P.L. 88-577, 78 Stat. 890; 16 U.S.C. § 1121, et seq.): Subject to valid rights existing prior to January 1, 1984, this act provides that wilderness areas are withdrawn from all forms of appropriation and disposition under the mining and mineral leasing laws. Subsequent acts designating additional National Forest System lands as wilderness may contain specific provisions concerning mineral activities. Patents issued under the mining laws for mining claims staked after passage of this act within wilderness areas shall reserve the surface rights to the United States. The act provides for reasonable access to valid mining claims and other valid occupancies inside wilderness areas. The act also requires the survey of wilderness areas by the United States Geological Survey on a planned, recurring basis consistent with the concept of wilderness preservation to determine the mineral values that may be present.

National Environmental Policy Act of 1969, January 1, 1970 (P.L.91-190, 83 Stat. 852; 42 U.S.C. § 4331 et seq.): This act requires federal agencies to use a systematic interdisciplinary approach to ensure the integrated use of natural and social sciences in planning and decision making. It also requires an analysis of probable environmental effects of proposed federal actions. Generally, decisions on mineral and energy development are subject to this law.

Forest and Rangeland Renewable Resources Planning Act of August 17, 1974 (P.L. 93-378, 88 Stat. 476; 16 U.S.C. § 1600 et seq.): This act directs the assessment of all resources on National Forest System lands to determine the desired level of future production from Forest Service programs. Once approved, the policy statement and recommended program serve as a guide to future Forest Service planning and a basis for future budget proposals.

National Forest Management Act of October 22, 1976 (P.L. 94-588, 90 Stat. 2949; 16 U.S.C. § 1600 et seq.): The act requires the Forest Service to establish a comprehensive system of land and resource planning, including the development and maintenance of a comprehensive and detailed inventory of lands and resources. The act also specifies the use of a systematic interdisciplinary approach to achieve integrated consideration of the physical sciences into planning for the management and use of National Forest System lands and resources.

The Clean Water Act (33 U.S.C. 1251 et seq.), as amended: This act sets goals to eliminate discharges of pollutants into navigable water, protect fish and wildlife, and prohibit the discharge of toxic pollutants in quantities that could adversely affect the environment. Executive Order 12088 requires the Forest Service meet the requirements of the act. Refer to sections 303(d), 313, 401, 402, and 404 of the Clean Water Act.

The Endangered Species Act (16 U.S.C. 1531-1544): Section 7(a) of this act requires federal agencies to consult with the United States Fish and Wildlife Service and the National Marine Fisheries Service, as appropriate, to ensure that their actions are not likely to jeopardize the continued existence of endangered or threatened species or adversely modify or destroy their critical habitats. As required under the Endangered Species Act, biological assessments and consultation under Section 7 would be completed for this decision. The action alternatives are not expected to result in a jeopardy biological opinion for any listed species.

Section 106 of the National Historic Preservation Act (16 U.S.C. 470): This act requires that federal agencies evaluate the effects of their actions on historical, archaeological, and cultural resources and afford the Advisory Council on Historic Preservation opportunities to comment on the proposed undertaking.

Leasable Minerals

The Mineral Leasing Act of 1920 established a comprehensive system for managing oil and gas and other leasable minerals on federal lands. Since then, numerous modifications have amended this law, including the Mining and Minerals Policy Act of 1970. Forest Service management direction for oil and gas resources is found in 36 CFR 228, Subpart E, and Forest Service Manual 2820.

Leasable minerals under federal ownership, including oil, gas, potassium, phosphate, sodium, and others, are available for development in accordance with the United States Department of the Interior Bureau of Land Management leasing program. The Forest Service role in managing leasable mineral resources is to consult with the Bureau of Land Management about proposals that involve National Forest System land and, in some cases, provide an opinion on whether leases for these commodities should be issued and to specify any required surface resource protections.

Mineral management authorities

U.S. Mining Laws Act of May 10, 1872 (17 Stat. 91, as amended, 30 U.S.C. § 22 et seq): This act, often referred to as the General Mining Law of 1872, sets forth the principles of discovery, right of possession, assessment work, and patent for hard-rock minerals on lands reserved from the public domain. The law applies to lode, placer, mill-site claims, and tunnel sites. Except as otherwise provided, all valuable mineral deposits and the lands in which they are found are free and open to exploration, occupation, and purchase under regulations prescribed by law.

Weeks Law Act of March 1, 1911 (P.L. 61-435, 72 Stat. 1571, as amended, 16 U.S.C. § 480 et seq): This act authorized the federal government to purchase lands for stream-flow protection and maintain the acquired lands as National Forests.

Mineral Resources on Weeks Law Lands Act of March 4, 1917 (P.L. 64-390, 39 Stat. 1149, 16 U.S.C. § 520): This act authorizes the Secretary of Agriculture to issue permits and leases for prospecting, developing, and using hard-rock minerals on lands acquired under the authority of the act. This authority was later transferred to the Secretary of the Interior.

Mineral Leasing Act of February 25, 1920 (P.L. 66-146, 41 Stat. 437 as amended, 30 U.S.C. § 181 et seq.): This act authorizes the Secretary of the Interior to issue leases for the disposal of certain minerals, including coal, phosphate, sodium, potassium, oil, oil shale, gilsonite, and gas. The act applies to National Forest System lands reserved from the public domain, including lands received in exchange for timber or other public domain lands and lands with minerals reserved under special authority.

Mining Claims Rights Restoration Act of August 11, 1955 (P.L. 359) (30 U.S.C. § 621 et seq.): This act authorizes the location of mining claims on public lands withdrawn for power purposes.

Clarke-McNary Act of June 7, 1924 (P.L. 68-270, 43 Stat. 653 as amended, 16 U.S.C. § 505 et seq.): All lands to which title is accepted under Section 7 of this act become National Forest lands subject to all laws applicable to the lands acquired under the Weeks Act of March 1, 1911.

Reorganization Plan No. 3 of 1946 (60 Stat. 1097; 5 U.S.C. Appendix): This plan transferred the functions of the Secretary of Agriculture with respect to permits and leases for hard-rock minerals on acquired Weeks Law land to the Secretary of the Interior. However, consent by the Secretary of Agriculture for the issuance of permits or leases is required.

Mineral Materials Act of July 31, 1947 (P.L. 80-291, 61 Stat. 681, as amended, 30 U.S.C. § 601 et seq.): This act provides for the disposal of mineral materials on the public lands through bidding, negotiated contracts, and free use.

Mineral Leasing Act for Acquired Lands of August 7, 1947 (P.L. 80-382, 61 Stat. 913, as amended, 30 U.S.C. § 351 et seq.): This act extends the provisions of the mineral leasing laws to federally owned mineral deposits on acquired National Forest System lands and requires the consent of the Secretary of Agriculture prior to leasing.

Multiple Use Mining Act of July 23, 1955 (P.L. 84-167, 69 Stat. 368, as amended, 30 U.S.C § 601 et seq.): This act requires the disposal of common varieties of sand, stone, gravel, pumice, pumicite, and cinders under the provisions of the Materials Act of July 31, 1947, and gives the Secretary of Agriculture the authority to dispose of these materials. It also provides that rights under any mining claim located under the mining laws are subject to the right of the United States to manage and dispose of surface resources.

Geothermal Steam Act of December 24, 1970 (P.L. 91-581, 84 Stat. 1566, 30 U.S.C. § 1001 et seq.): This act provides the Secretary of the Interior the authority to lease National Forest System lands for geothermal steam development, subject to the consent and conditions the Secretary of Agriculture may prescribe.

Mining and Minerals Policy Act of December 31, 1970 (P.L. 91-631, 84 Stat.1876, 30 U.S.C. § 21a): This act states that the continuing policy of the federal government is to foster and encourage private enterprise in the development of economically sound and stable domestic mining and minerals industries and the orderly and economic development of domestic mineral resources.

Federal Coal Leasing Amendments Act of August 4, 1976 (90 Stat. 1083; 30 U.S.C. § 201 et seq.): This act amended the Mineral Lands Leasing Act of February 25, 1920, by specifying that coal leases on National Forest System lands may be issued only after the consent of the Secretary of Agriculture and adherence to conditions the Secretary may prescribe. The act also provides that no lease shall be issued unless the lands involved in the lease have been included in a comprehensive forest land and resource management plan and the sale is compatible with said plan. The act authorizes the issuance of a license to conduct exploration for coal.

Federal Land Policy and Management Act of October 21, 1976 (P.L. 94-579, 90 Stat. 2743, 43 U.S.C. § 1701 et seq., 7 U.S.C. § 1212a, 16 U.S.C. § 478a, 1338a): This act defines procedures for the withdrawal of lands from mineral entry. It reserves to the United States the rights to prospect for, mine, and remove the minerals in lands conveyed to others and requires the recordation of claims with the Bureau of Land Management.

Surface Mining Control and Reclamation Act of August 3, 1977 (P.L. 95-87, 91 Stat. 445, 30 U.S.C. § 1201-1328): This act provides for cooperation between the Secretary of the Interior and each state when regulating surface coal mining. It also restricts or prohibits surface coal mining operations on National Forest System lands, subject to valid existing rights and compatibility determinations.

Energy Security Act of June 30, 1980 (P.L. 96-294, 94 Stat. 611, 42 U.S.C. § 8855): This act directs the Secretary of Agriculture to process applications for leases and permits to explore, drill, and develop resources on National Forest System lands, notwithstanding the current status of the forest land and resource management plan.

National Materials and Minerals Policy, Research and Development Act of October 2, 1980 (94 Stat. 2305; 30 U.S.C. §1601-1605): This act restates congressional intent to promote policies that provide for an adequate and stable supply of materials while considering long-term needs, a healthy environment, and natural resource conservation. The act also requires the Secretary of the Interior to improve the availability and analysis of mineral data in federal land use decision making.

Omnibus Parks and Public Lands Management Act of 1996 (P.L. 104-333, 110 Stat. 4093, 16 U.S.C. § 497c): This act automatically withdraws from all forms of appropriation under the mining laws, and from disposition under all laws pertaining to mineral and geothermal leasing, all lands located within the boundaries of ski area permits.

Federal Onshore Oil and Gas Leasing Reform Act of 1987 (30 U.S.C. § 181 et seq.): This act expands the authority of the Secretary of Agriculture in the management of oil and gas resources on

National Forest System lands. The Bureau of Land Management cannot issue leases for oil and gas on National Forest System lands over the objection of the Forest Service. The Forest Service must approve all surface disturbing activities on National Forest System lands before operations commence.

Federal Cave Resources Protection Act of 1988 (102 Stat. 4546; 16 U.S.C. § 4301 et seq.): This act provides for protection and preservation of caves on federal lands.

Energy Policy Act of 2005 (P.L. 109-58; 42 U.S.C 15801 et seq.): This act directs federal agencies to undertake efforts to ensure energy efficiency and the production of secure, affordable, and reliable domestic energy.

Mineral Withdrawals

The Secretary of the Interior has the authority to withdraw lands in federal ownership, effectively removing an area of federal land from settlement, sale, location, or entry for the purpose of limiting activities under those laws to maintain other public values in the area or reserving it for a particular public purpose or program. Withdrawals are also used to transfer jurisdiction over federal land from one department, bureau, or agency to another.

Public lands may also be withdrawn and reserved for military training and testing in support of national defense requirements. An Act of Congress authorizes military withdrawals and reservations of 5,000 or more acres; military withdrawals of less than 5,000 acres are by Secretarial Order.

There are four major categories of formal withdrawals:

- Administrative withdrawals are made by the President, Secretary of the Interior, or other authorized Executive Branch Officer. Examples include Executive Orders, Presidential Proclamations, Secretarial Orders, Public Land Orders, Departmental Orders, United States Geological Survey Orders, and Bureau of Land Management Orders. Currently, only public land orders signed by the Secretary or Assistant Secretary of the Interior are used for administrative withdrawals. However, the President still has authority to make emergency withdrawals.
- Presidential Proclamation withdrawals are made by the President pursuant to the authority under the Antiquities Act of 1906. The President may use this authority to designate landmarks, historic and prehistoric structures, and other objects of historic or scientific interest.
- Congressional withdrawals are legislative actions taken by Congress in the form of public laws. Examples include Wilderness designations, creation of National Parks, and Wild and Scenic River designations, among others.
- Federal Power Act or Federal Energy Regulatory Commission withdrawals are established under the authority of the Federal Power Act of June 10, 1920. Such withdrawals are automatically created upon filing an application for hydroelectric power development with the Federal Energy Regulatory Commission. Federal Energy Regulatory Commission power project withdrawals are different from power site reserves, power site classifications, waterpower designations, and reservoir site reserves; all of which are administrative withdrawals.
- **Gospel-Hump Wilderness**, Nez Perce National Forest, Idaho - Pub. L. 95–237, §4(a), Feb. 24, 1978, 92 Stat. 43.
- **Frank Church-River of No Return Wilderness**, Boise, Challis, Payette, Salmon, Bitterroot, and Nez Perce National Forests, Idaho.- Pub. L. 96–312, §3, July 23, 1980, 94 Stat. 948; Pub. L.

98–231, §1, Mar. 14, 1984, 98 Stat. 60; Pub. L. 111–11, title III, §3308, Mar. 30, 2009, 123 Stat. 1137.

- **Selway-Bitterroot Wilderness,** Bitterroot, Clearwater, Nez Perce, and Lolo National Forests, Idaho and Montana - Pub. L. 88–577, §3, Sept. 3, 1964, 78 Stat. 891; Pub. L. 96–312, §4, July 23, 1980, 94 Stat. 949.

Other Geologic Resources

Current guidelines relative to fossils are based largely on the Organic Act of 1897, the Preservation of American Antiquities Act of 1906, the Paleontological Resources Preservation Act, the Federal Land Policy and Management Act, the Surface Mining Control and Reclamation Act, and Forest Service regulations published at Chapter 36 Code of Federal Regulations Part 291 (36 CFR 291.10-13). Vertebrate fossils, such as bones, bone fragments, teeth, and tracks, are not available for collection by the public and commercial fossil collection is not permitted on any National Forest. Collection of vertebrates, invertebrates, plants, and trace fossils as part of scientific studies, mitigation, or conservation efforts is allowed only by qualified researchers that have been issued permits for specific projects or research (36 CFR 291.14).

Code of Federal Regulations

36 CFR 228 — Minerals: These regulations set forth rules and procedures governing use of the surface of National Forest System lands in conjunction with operations authorized by the general mining laws, mineral material disposal laws, and oil and gas leasing.

- Subpart A: Locatable Minerals
- Subpart B: Leasable Minerals (reserved)
- Subpart C: Disposal of Mineral Materials
- Subpart D: Miscellaneous Minerals Provisions
- Subpart E: Oil and Gas Resources

36 CFR 251 — Land Uses

43 CFR 2300 — Land Withdrawals

Executive Orders

Executive Order 13817 of December 20, 2017: This Executive Order titled “A Federal Strategy to Ensure Secure and Reliable Supplies of Critical Minerals” requires federal agencies to identify, reduce foreign dependence, develop recycling and reprocessing technologies, improve geologic mapping, and streamline the permitting process for critical minerals.

Executive Order 13211 issued May 18, 2001: This Executive Order titled “Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use” requires federal agencies to prepare and submit a Statement of Energy Effects to the Office of Management and Budget describing the effects of certain regulatory actions on energy supply distribution or use.

Executive Order 13212 issued May 18, 2001: This Executive Order titled “Actions to Expedite Energy-Related Projects” requires federal agencies to take actions, to the extent consistent with applicable law, to expedite projects that will increase the production, transmission, or conservation of energy.

State and Local Laws

The Idaho Stream Channel Protection Act requires that the stream channels of the state and their environment be protected against alteration for the protection of fish and wildlife habitat, aquatic life, recreation, aesthetic beauty, and water quality. This means Idaho Department of Water Resources must approve in advance any work within the beds and banks of a continuously flowing stream.

Idaho State Water Quality Standards provide water quality for the protection and propagation of fish, shellfish, and wildlife and recreation in and on the water (fishable and swimmable conditions), where attainable, and consider the use and value of state waters for public water supplies, propagation of fish and wildlife, recreation, agricultural and industrial purposes, and navigation.

Forest Service Agreement No. 18-MU-11015600-080 – Memorandum of Agreement and Memorandum of Understanding between the Idaho Department of Water Resources and the United States Department of Agriculture Forest Service Northern, Intermountain, and Pacific Northwest Regions: The purpose of this memorandum of agreement and memorandum of understanding is to document the cooperation between the parties to implement the Idaho Stream Channel Protection Act within Idaho on lands administered by the Forest Service.

Interagency agreements

The Forest Service has entered into interagency agreements with agencies within the U.S. Department of the Interior to cooperate and coordinate in the management of federally owned minerals within National Forest System lands. The principal agreements include:

- November 8, 1946, agreement with the Bureau of Land Management detailing procedures for mineral leases and permits administered under Section 402 of the President's Reorganization Plan No. 3 of 1946;
- May 18, 1957, memorandum of understanding with the Bureau of Land Management describing work procedures for land applications, mining claims, and patents;
- March 4, 1977, cooperative agreement with the United States Geological Survey concerning oil and gas operations;

- May 20, 1980, memorandum of understanding with the Bureau of Land Management describing the coordination of activities under the federal coal management program;
- November 26, 1980, cooperative agreement with the United States Geological Survey for operations under solid mineral leases and permits;
- December 3, 1981, memorandum of understanding with the United States Geological Survey and the Bureau of Land Management for the geothermal steam leasing program;
- July 31, 1990, memorandum of understanding with the Office of Surface Mining Reclamation and Enforcement describing the management of surface coal mining operations on National Forest System lands;
- November 11, 1991, interagency agreement with the Bureau of Land Management describing the procedures by which the Forest Service can authorize the Bureau of Land Management to offer National Forest System lands for oil and gas leasing; and
- November 19, 1991, interagency agreement with the Bureau of Land Management describing the procedures for coordinated administration of oil and gas operations on federal leases within the National Forest System.

Methodology

Spatial Scale

The acres available for locatable mineral resource development are determined by subtracting the number of acres withdrawn from mineral entry from the total number of Nez Perce-Clearwater acres. Acres that are withdrawn from mineral entry are a matter of record. By law, the Bureau of Land Management keeps official records in the General Land Office.

The number of acres that are available for disposal of mineral materials is determined by subtracting the number of acres where the Forest Service has exercised its discretion to refrain from authorizing the disposal of mineral materials from the total number of acres on the Nez Perce-Clearwater.

The number of acres that are available for leasing proposals is determined by subtracting the number of acres that are legally unavailable from the total number of acres on the Nez Perce-Clearwater.

Lands legally unavailable for leasing include:

- lands withdrawn from mineral leasing by an Act of Congress or by an order of the Secretary of the Interior;
- lands recommended for wilderness allocation by the Secretary of Agriculture;
- lands designated by statute as wilderness study areas, unless oil and gas leasing are specifically allowed by the statute designating the study area; and
- lands within areas allocated for wilderness or further planning in Executive Communication 1504.

Information Sources

The Bureau of Land Management keeps official records on active, closed, and pending mining claims on public lands. Current records are kept in the Land and Mineral System Reports database, known as LR2000. These records are the source for documentation of mining claims on the National Forest. Published and unpublished mineral resource assessments and maps produced by the Forest

Service, Bureau of Land Management, United States Geological Survey, and Idaho Geologic Survey were reviewed to determine the mineral potential for the National Forest.

Analysis Area

The analysis area is the National Forest lands within the Nez Perce-Clearwater.

Temporal Scale

The temporal scale considered in this analysis for indirect effects is the duration of the planning timeframe, or 15 years.

The temporal scale for cumulative effects would be the duration of the 1987 Plan and effects through the duration of the planning timeframe.

Affected Environment

Locatable

The Nez Perce-Clearwater has a historic connection to mining. Discovery of placer gold occurred in the late 1850s and these deposits were mined extensively in the early 1860s. Small-scale and medium-scale sized placer and dredging operations mined and then reworked the deposits in many locations on lands contained within the Nez Perce-Clearwater through the 1940s. Lode discoveries were mined by moderately sized surface and underground operations during this same period. Generally, growth in locatable exploration and mining development remained flat after the 1940s because of the closure of gold mines by the War Production Board in 1942. Higher gold prices renewed interest and mining development on the Nez Perce-Clearwater in the 1980s and then again in the early 2000s. Today, small-scale placer and dredging operations continue to be the dominate type of mining on the Nez Perce-Clearwater.

Past activities have included, and future activities may include, exploration for locatable minerals and underground or surface mining. In general, the geology of the Nez Perce-Clearwater possesses a low- to high-grade mineralization in many areas. Mineralized zones could include precious metals, such as gold and silver; strategic rare earth element deposits; and base metal deposits, such as copper, lead, zinc, molybdenum, and manganese. Although many types of minerals could be mined on the Nez Perce-Clearwater, gold is the only mineral tied to a significant trend. However, copper and other locatable deposits potentially exist in different locations on the Nez Perce-Clearwater and future development proposals are probable if the demand for these commodities continues to increase.

At present, the Nez Perce-Clearwater has approximately five approved Plans of Operations for small lode and placer mining and one approved exploration activity investigating larger deposits. Annually, the Nez Perce-Clearwater expects to administrate 40 to 50 Plans of Operation for suction dredging and receives 20 to 30 Notices of Intent. Notices of Intent generally propose small-scale mineral exploration activities that range from mineral prospecting with hand tools to small-scale placer operations. Currently, there are no large or medium sized mines operating on the Nez Perce-Clearwater. However, because of new technology in mineral exploration and mining techniques, mineral deposits once considered below grade could become in demand and the potential for mineral development would then increase.

Many claims were patented under the General Mining Law of 1872, as amended, whereby they became privately owned land within the National Forest boundaries. However, the amount and size of inactive or active mining operations on privately owned land is currently unknown.

Mineral Materials

Mineral materials, such as gravel, riprap, and crushed aggregate, for road maintenance, road construction, recreation sites, and trailheads has been and will continue to be in use on the Nez Perce-Clearwater. Other mineral material uses include contract work, culvert replacement, and repair of damage caused by fire, floods, and landslides. The mineral materials used are primarily derived from Forest Service pits and quarries located in the planning area. The type, volume, and source of locations for in-service use varies year by year and according to need. Current mineral material exploration and development on the Nez Perce-Clearwater is low and is expected to remain the same or slightly increase as in-service projects develop or as these nonrenewable resources are depleted.

Leasable

There is no leasable mineral exploration or mining activity for coal, oil, or gas on the Nez Perce-Clearwater at this time. Sources of nonrenewable energy are rated as having a very low mineral potential on the Nez Perce-Clearwater (National Energy Policy Development Group 2001). In general, interest in leasable mineral resources on the Nez Perce-Clearwater is low because of past unsuccessful attempts to locate and develop these resources. No exploration or development of other nonrenewable energy sources is expected during the planning period.

Renewable Energy

Renewable energy resources include biomass, wind, solar, geothermal, and hydroelectric energy. With the exception of biomass being used as a by-product of timber operations and an occasional solar panel being used to power a remote site, no renewable energy is being produced on the Nez Perce-Clearwater.

The continuous wilderness, wild and scenic river corridors, and recommended wilderness make it highly unlikely that a transmission corridor would be developed through the Nez Perce-Clearwater to support development of wind, solar, hydroelectric, or geothermal resources. Additionally, solar, wind, and geothermal renewable energy sources are rated as having a low potential across the Nez Perce-Clearwater (U.S. Department of Agriculture and U.S. Department of the Interior 2008, Zvolanek et al. 2013, Dansart et al. 1994, Ross 1971, U.S. Department of Agriculture and U.S. Department of Energy 2005). Development of these resources is not expected during the planning period.

Hydroelectric power has been considered and numerous power site withdrawals have been made on many of the major rivers within the Nez Perce-Clearwater. However, the trend is not to build dams on National Forest System lands because dams can impede fish migration and detract from the wild and scenic qualities of rivers. Hydroelectric renewable energy is rated as having a low potential across the Nez Perce-Clearwater (Conner et al. 1998). Development of hydroelectric power is not expected during the planning period.

Biomass used for the production of commercial energy has a moderate to high potential (O'laughlin et al. 2012). Biomass energy has been used for many years as a by-product of logging operations and continues to be in high demand at the personal level and an overall valuable public commodity. Biomass has the highest potential for future consumption of all the renewable resources on the Nez Perce-Clearwater.

Abandoned Mines

A complete field inventory of abandoned mining lands on the Nez Perce-Clearwater has not been compiled; however, over 700 surface and underground prospects were identified in the Mineral Resources Data System maintained by the United States Geological Survey and the Database of Mines and Prospects maintained by the Idaho Geological Survey. The historic prospects and mining sites on the Nez Perce-Clearwater range in size and level of disturbance from small-scale hardrock and placer exploration to larger surface and underground producing mines. Some of the abandoned mine sites could have significant safety and health hazards, or both, because of open shafts, emissions of toxic gases, falling debris, and environmental contamination.

Nine abandoned mining sites are scheduled for mitigation in 2020. Future abandoned mining lands remediation will be, in part, dependent on financial resources and other Forest Service priorities.

Methods and Assumptions

Mineral demand, exploration, and production vary dependent upon a number of external factors and most are highly unpredictable. An evaluation of historic production can provide context or a qualitative estimation of mineral needs and production, which are directly related to mineral exploration. However, both are dependent on the mineral being mined and the type of mining necessary to extract the resource profitably.

Measurement Indicators

Calculating the acres currently available for locatable, saleable, and leasable resources is accomplished by subtracting areas withdrawn from mineral entry from the total acres of the Nez Perce-Clearwater. The potential for mineral development is reflected in the number of mining claims or leases in a given area and the distribution of known mineral resources.

Energy and minerals measurement indicators include:

- Locatable minerals acres available for mineral entry
- Salable minerals acres available for disposal of mineral materials
- Leasable minerals acres available for leasing proposals

Environmental Consequences

Effects Common to All Alternatives

Energy and mineral development can have significant effects to physical and biological resources. These effects are discussed in other sections of this document. The alternatives vary in their influence on mineral, geological, and energy resources primarily through differences in management area designation.

The direction to protect forest resources from adverse impacts associated with access to exploration and extraction of mineral resources is derived from the laws, regulations, and policies described in the “Regulatory Framework” section. These are independent of Land Management Plan direction and are the same for each alternative evaluated. Therefore, the resources potentially at risk of the effects of mineral project activities will be managed similarly.

Common effects of mineral development include:

- vegetation stripping
- soil disturbance
- topsoil and vegetative matter stockpiling
- potential for erosion and sedimentation
- water consumption
- creation of access trails and roads
- waste rock, overburden and ore stockpiling
- tailings disposal
- noise
- fuel storage
- aircraft use
- tunneling
- blasting
- nonhazardous waste storage
- fugitive dusting
- atmospheric emissions
- facilities development
- vehicle and equipment operation
- wastewater treatment
- reclamation and restoration

Idaho Roadless Rule

The Idaho Roadless Rule does not restrict any authorized mineral activity prior to October 16, 2008.

Road construction or reconstruction associated with mining activities within Idaho Roadless Rule areas may only be approved after evaluating other access options.

Road construction or reconstruction associated with mining activities within Idaho Roadless Rule areas must be conducted in a manner that minimizes effects on surface resources and must be consistent with land management plan components.

Roads constructed or reconstructed within Idaho Roadless Rule areas must be decommissioned upon completion of the project or expiration of the lease, permit, or other authorization.

Locatable

The Idaho Roadless Rule does not affect mining activities conducted pursuant to the General Mining Law of 1872.

Mineral Materials

The Forest Service will not authorize the sale of common variety mineral materials in Idaho Roadless Areas designated as Wild Land Recreation, Special Areas of Historic or Tribal Significance, or other Primitive themes.

The Forest Service may authorize the use or sale of common variety mineral materials and associated road construction or reconstruction to access these mineral materials in Idaho Roadless Areas designated as Backcountry and Restoration only if the use of these mineral materials is incidental to an activity otherwise permissible in backcountry and restoration areas.

The Forest Service may authorize the use or sale of common variety mineral materials and associated road construction or reconstruction to access these mineral materials in Idaho Roadless Areas designated as General Forest, Rangeland, and Grassland only if the use of these mineral materials is incidental to an activity otherwise permissible in General Forest, Rangeland, and Grassland areas.

Leasable

The Forest Service will not recommend, authorize, or consent to road construction, road reconstruction, or surface occupancy associated with mineral leases in Idaho Roadless Areas designated as Wild Land Recreation, Special Areas of Historic or Tribal Significance, or Primitive themes.

The Forest Service will not recommend, authorize, or consent to road construction or road reconstruction associated with mineral leases in Idaho Roadless Areas designated as Backcountry or Restoration. Surface use or occupancy without road construction or reconstruction is permissible for all mineral leasing unless prohibited in the land management plan.

The Forest Service will not recommend, authorize, or consent to road construction or reconstruction associated with mineral leases in Idaho Roadless Areas designated as General Forest, Rangeland, and Grassland theme; except such road construction or reconstruction may be authorized by the responsible official in association with phosphate deposits as described in Figure 3-20 in section 3.15 Minerals and Energy in the Roadless Area Conservation; National Forest System Lands in Idaho Final Environmental Impact Statement. Surface use or occupancy without road construction or reconstruction is permissible for all mineral leasing unless prohibited in the land management plan components.

Designated Wilderness

The Frank Church-River of No Return, Selway Bitterroot, and Gospel Hump Wilderness areas have been withdrawn from mineral entry and are not available for new leases or claims for locatable minerals, mineral materials, or leasable minerals. Designated wilderness acreage does vary with each alternative but total acreage within Management Area 1A is equal across all alternatives. The acreage in Management Area 1A would be managed to be consistent with the legislation for which the area is designated and either withdrawn from mineral entry or mitigated at the project level. Mining activities may still occur in designated wilderness areas if the proponent has demonstrated a valid existing right.

Valid existing rights occur when unpatented mining claims on National Forest System lands are properly located prior to an area being designated as a wilderness area; properly maintained thereafter under the applicable law; supported by a discovery of a valuable mineral deposit within the meaning of the United States mining laws prior to an area being congressionally designated as a wilderness area and said discovery has been continuously maintained since that date; and continue to be valid.

Recommended Wilderness

Recommended wilderness acreage does vary with each alternative. However, recommended wilderness areas are not withdrawn from mineral entry and are available for new leases or claims if the social and ecological characteristics that provide a basis for wilderness designation are maintained and protected. Therefore, the effects of minerals management would be the same with all alternatives, and the social and ecological characteristics that form the basis of wilderness designation would be protected and maintained.

Wild and Scenic Rivers

Designated acreage for Wild and Scenic Rivers for all alternatives is 11,336 acres. Under all alternatives, designated rivers would be managed according to the Wild and Scenic River Act and Forest Service policy. Management Area 1B direction is that they be managed to protect their free-flowing condition and outstandingly remarkable values. Therefore, the management of designated wild and scenic rivers under Forest Service policy would be the same for all alternatives and the wild and scenic corridors are withdrawn from mineral entry.

National Historic Landmarks

Near identical acreage is selected for all alternatives to protect National Historic Landmarks. Mitigation measures would be identified at the project level to protect National Historic Landmarks and, therefore, has the same effects for all alternatives.

Research Natural Areas

Both proposed and established Research Natural Areas have the potential to be withdrawn from mineral entry. Designated Research Natural Areas total 6,169 acres for Alternatives W, X, and Z and Preferred Alternative, 5,388 acres for the No Action Alternative, and 5,549 acres for Alternative Y. Proposed Research Natural Areas total 965 acres for all alternatives. Research Natural Areas would be managed to meet regional standards and the Land Management Plan.

Mineral Withdrawals

The economic effect of mineral withdrawals on mineral resources would depend on the mineral resource potential of the area. If the potential is high, a withdrawal of the area would preclude the opportunity for future mining and development of a valuable economic resource. If the potential is low, the economic value of mineral resources would be low and a mineral withdrawal may not be necessary. Other available options for protecting sensitive resources, such as populations of special-status species and their habitat, should be explored before withdrawal is recommended for wilderness, research natural areas, and other areas having special designation.

Effects that Vary by Alternative

No Action Alternative

Direction for minerals resource management in the 1987 Plans is based on Forest Service policy and federal law and regulations applicable to locatable, salable, and leasable mineral resources. Together, the laws, regulations, and policies minimize the adverse effects of minerals projects on the Nez Perce-Clearwater while concurrently supporting sound energy and mineral exploration and development.

Future protection of surface resources under the No Action Alternative would be the same as current protection under the 1987 Plans. The 1987 Plans manage mineral operations with operating plans, bonds, and reclamation and provide for timely analysis and processing of mineral prospecting, exploration, and development proposals. Access to accomplish closures of abandoned mine features and to mitigate any other potential hazards would continue as guided by the 1987 Plans.

Overall, the No Action Alternative ranks behind Alternative X in acreage available for mineral entry and would have less effects to minerals management, exploration, development, and production than the Preferred Alternative and Alternatives Y, Z, and W, respectively.

Locatable Minerals

The No Action Alternative has 1,166,599 acres identified as Roadless, 26,269 acres identified as Gospel Hump MPA 2 lands and 1,217,683 acres identified in Management Area 3. Combining these acres totals 2,410,551 acres available for locatable mineral entry. However, within Roadless, 197,695 acres are identified as recommended wilderness. If designated and subject to valid and existing rights, these acres could be withdrawn from mineral entry; the remaining 2,180,863 acres would be open to mineral entry in the No Action Alternative.

Mineral Materials

Management Area 1 is not open for mineral materials entry under all alternatives. Mineral material development is possible in Management Area 2 if classified with a backcountry and restoration theme. Mineral material development can only occur to support projects that are consistent with the land management plan and if use of the materials is incidental to an authorized activity. It is impossible to predict mineral material development and production necessary to support future authorized activities within a backcountry and restoration theme. For this reason, 1,217,683 acres within Management Area 3 are open for discretionary disposal of mineral materials in the No Action Alternative.

Leasable Minerals

Management Areas 1 and 2 are not open for leasable mineral entry under all alternatives. Management Area 3 has 1,217,683 acres open for discretionary leasing in the No Action Alternative.

Alternative W

Alternative W has the least amount of acreage open to mineral entry of all alternatives analyzed. Alternative W would have the greatest impact of all the alternatives to minerals management, exploration, development, and production.

Locatable Minerals

Alternative W has 583,771 acres identified as Roadless, 26,710 acres identified as Gospel Hump MPA 2 lands and 1,238,907 acres identified in Management Area 3. Combining these acres totals 1,849,388 acres available for locatable mineral entry. However, within Roadless, 856,932 acres are identified as recommended wilderness and 5,424 acres are identified for a suitable wild and scenic river classification. If designated and subject to valid and existing rights, these acres could be withdrawn from mineral entry; the remaining 969,164 acres would be open to mineral entry in Alterative W.

Mineral Materials

Management Area 1 is not open for mineral materials entry under all alternatives. Mineral material development is possible in Management Area 2 if classified with a backcountry and restoration theme. Mineral material development can only occur to support projects that are consistent with the land management plan if use of the materials is incidental to an authorized activity. It is impossible to predict mineral material development and production necessary to support future authorized activities within a backcountry and restoration theme. For this reason, 1,238,907 acres within Management Area 3 are open for discretionary disposal of mineral materials in Alternative W.

Leasable Minerals

Management Areas 1 and 2 are not open for leasable mineral entry under all alternatives. Management Area 3 has 1,238,907 acres open for discretionary leasing in Alternative W.

Alternative X

Alternative X provides for the availability of the most acreage open to mineral entry of all the alternatives. Alternative X allows the Forest Service to meet the desired outcome of current directives and regulations for minerals management on National Forest System lands. The Forest Service minerals management mission is to encourage, facilitate, and administer the orderly exploration, development, and production of mineral and energy resources on National Forest System lands to help meet the present and future needs of the nation.

Locatable Minerals

Alternative X has 1,412,587 acres identified as Roadless, 28,498 acres identified as Gospel Hump MPA 2 lands and 1,244,331 acres identified within Management Area 3. Combining these acres totals 2,685,416 acres available for locatable mineral entry. Unlike the other alternatives, Alternative X has zero acres for potential designation. Minimizing mineral withdrawals provides the most favorable opportunity for locatable minerals management, exploration, development, and production.

Mineral Materials

Management Area 1 is not open for mineral materials entry under all alternatives. Mineral material development is possible in Management Area 2 if classified with a backcountry and restoration theme. Mineral material development can only occur to support projects that are consistent with the land management plan and if use of the materials is incidental to an authorized activity. It is impossible to predict mineral material development and production necessary to support future authorized activities within a Backcountry and Restoration theme. For this reason, 1,244,331 acres within Management Area 3 is open for discretionary disposal of mineral materials in Alternative X.

Leasable Minerals

Management Areas 1 and 2 are not open for leasable mineral entry under all alternatives. Management Area 3 has 1,244,331 acres open for discretionary leasing in Alternative X.

Alternative Y

Alternative Y follows the Preferred Alternative in acreage open to mineral entry and would have similar impacts to minerals management, exploration, development, and production as Alternative Z.

Locatable Minerals

Alternative Y has 1,056,894 acres identified as Roadless, 26,269 acres identified as Gospel Hump MPA 2 lands and 1,219,951 and acres identified in Management Area 3. Combining these acres totals 2,303,114 acres available for locatable mineral entry. However, within Roadless, 309,332 acres are identified as recommended wilderness and 22,687acres are identified for a suitable wild and scenic river classification. If designated and subject to valid and existing rights, these acres could be withdrawn from mineral entry; the remaining 1,912,167 acres would be open to mineral entry in Alternative Y.

Mineral Materials

Management Area 1 is not open for mineral materials entry under all alternatives. Mineral material development is possible in Management Area 2 if classified with a backcountry and restoration theme. Mineral material development can only occur to support projects that are consistent with the land management plan and if use of the materials is incidental to an authorized activity. It is impossible to predict mineral material development and production necessary to support future authorized activities within a Backcountry and Restoration theme. For this reason, 1,219,951 acres within Management Area 3 is open for discretionary disposal of mineral materials in Alternative Y.

Leasable Minerals

Management Areas 1 and 2 are not open for leasable mineral entry under all alternatives. Management Area 3 has 1,219,951 acres open for discretionary leasing in Alternative Y.

Alternative Z

Locatable Minerals

Alternative Z has 828,436 acres identified as Roadless, 26,687 acres identified as Gospel Hump MPA 2 lands and 1,233,180 acres identified for all other uses in Management Area 3. Combining these acres totals 2,088,303 acres available for locatable mineral entry. However, within Roadless, 569,755 acres are identified as recommended wilderness and 8,711 acres are identified for a suitable wild and scenic river classification. If designated and subject to valid and existing rights, these acres could be withdrawn from mineral entry; the remaining 1,477,093 acres would be open to mineral entry in Alterative Z.

Mineral Materials

Management Area 1 is not open for mineral materials entry under all alternatives. Mineral material development is possible in Management Area 2 if classified with a backcountry and restoration theme. Mineral material development can only occur to support projects that are consistent with the land management plan and if use of the materials is incidental to an authorized activity. It is impossible to predict mineral material development and production necessary to support future authorized activities within a backcountry and restoration theme. For this reason, 1,233,180 acres within Management Area 3 is open for discretionary disposal of mineral materials in Alternative Z.

Leasable Minerals

Management Areas 1 and 2 are not open for leasable mineral entry under all alternatives. Management Area 3 has 1,233,180 acres open for discretionary leasing in Alternative Z.

Preferred Alternative

Locatable Minerals

The Preferred Alternative has 1,114,736 acres identified as roadless, 28,498 acres identified as Gospel Hump MPA 2 lands and 1,240,340 acres identified for all other uses in Management Area 3. Combining these acres totals 2,383,574 acres available for locatable mineral entry. However, within roadless, 258,210 acres are identified as recommended wilderness and 1,319 acres are identified for a suitable wild and scenic river classification. If designated and subject to valid and existing rights, these acres could be withdrawn from mineral entry; the remaining 2,073,807 acres would be open to mineral entry in the Preferred Alternative.

Overall, the Preferred Alternative ranks behind Alternative X and the No Action Alternative in acreage available for mineral entry and would have less effects to minerals management, exploration, development, and production than Alternatives Y, Z, and W, respectably.

Mineral Materials

Management Area 1 is not open for mineral materials entry under all alternatives. Mineral material development is possible in Management Area 2 if classified with a backcountry and restoration theme. Mineral material development can only occur to support projects that are consistent with the land management plan and if use of the materials is incidental to an authorized activity. It is impossible to predict mineral material development and production necessary to support future authorized activities within a backcountry and restoration theme. For this reason, 1,240,340 acres within Management Area 3 is open for discretionary disposal of mineral materials in the Preferred Alternative.

Leasable Minerals

Management Areas 1 and 2 are not open for leasable mineral entry under all alternatives. Management Area 3 has 1,240,340 acres open for discretionary leasing in the Preferred Alternative.

Cumulative Effects

No cumulative effects are expected to occur from the development of renewable or nonrenewable leasable resources because of a low suitability potential for development on the Nez Perce-Clearwater, lack of transmission lines, and low occurrence of those resources. Leasing of National Forest System lands is possible but not expected during the planning period.

The development of locatable minerals, primarily gold, could continue in the planning area that are available to mineral entry under the mining laws of the United States. The direct, indirect, and cumulative effects of mineral development of individual plans of operation will be addressed in separate environmental analyses. The Forest Service retains the authority to determine the measures needed to protect surface resources.

No indirect or cumulative effects from the development of wind or solar energy on the Nez Perce-Clearwater will occur until the feasibility of development on a specific site is determined and a project is permitted. Although the capability of wind generation exists on the Nez Perce-Clearwater, the feasibility of wind tower placement is currently unknown and not likely to occur during the planning period.

Groundwater resources on the Nez Perce-Clearwater could be affected by any of the activities in this section but are more likely to occur in response to development of geothermal or oil and gas resources. No effect to groundwater is expected from these activities until completion of an appropriate environmental analysis of an individual project and application for permit to drill is granted. The effects to groundwater and surface water from the mining of locatable minerals are addressed through analysis of the effects of individual or grouped plans of operation.

Requests for approval of small lode and placer mining operations may occur but it is not possible to predict how many may be submitted in any given year or how many may be approved. Since Congress has imposed a moratorium on the patenting of mining claims, there would be no change in the acres of patented lands unless Congress lifts the moratorium.

Mineral material use can be expected to continue for in-service needs and as a salable commodity that would result in the further depletion of this non-renewable mineral resource on the Nez Perce-Clearwater.

Reclamation is anticipated to increase on the Nez Perce-Clearwater as more mine adits and shafts are identified and prioritized for closure or gating. Similar efforts are underway on other state, tribal, and federal lands. This would be a beneficial cumulative effect in combination with efforts on other lands.

Effects to Resource from Other Resources

Minerals Management

No large-scale mineral projects are anticipated during the planning period. Mineral proposals undergo site-specific National Environmental Policy Act analysis to determine required mitigation measures and effects to other resources.

Patented mining lands could contribute to the effects for many resources but the status or number of active or inactive mining operations or mineral production on privately held land is unknown.

Other Resources

There is no effect that would result in any change in the lands available for locatable minerals, mineral materials, or leasable minerals development from the following resources: air quality; climate change; carbon storage; designated wild and scenic rivers; ecology; economic sustainability; fire management; forest products; infrastructure; invasive species; lands and special uses; livestock grazing; rare plants; scenery; social sustainability; soils; sustainable recreation; timber; tribal trust responsibilities; watershed; designated wilderness; vegetation; or wildlife.

Fire Management

Fire and fuels management direction under any of the alternatives could temporarily displace mining operations or exploration activities but the effects would be short term and virtually negligible. No cumulative effects are anticipated.

Indirect effects to minerals management by designated wilderness, recommended wilderness, wild and scenic rivers, national historic landmarks, and research natural areas is discussed in the Effects Common to All Alternatives section.

Effects to Other Resources from Mineral Management

There will be no indirect or cumulative effect to the following resources from locatable minerals, leasable minerals, or salable minerals management: climate change; heritage; designated wild and scenic rivers; ecology; economic sustainability; fire management; forest products; infrastructure; invasive species; lands and special uses; livestock grazing; social sustainability; soils; timber; tribal treaty rights; watershed; designated wilderness; and vegetation.

At Risk Plant Species

Development of energy and mineral resources has the potential to adversely impact special status species through all phases of development. Impacts include mortality to individual at-risk plants or entire populations, as well as habitat loss and fragmentation. Under plan components, at-risk species habitat quality would remain similar between the action and no action alternatives. Threats would be reduced for at-risk plants by the action alternatives plan components including FW-STD-AREM-01, which calls for avoidance of wetlands and riparian areas in mineral operations and requires the use of native revegetation efforts as part of operations to reduce invasive species.

Air Quality

Vehicle and heavy equipment operations, including on and off-road travel and recreational vehicle use, release combustion gases and particulates to the air, both of which contribute to concentrations of pollutants. Most emissions are confined locally and are temporary. Large road or facility construction projects and sizeable mining operations could contribute enough particulates over time to affect local air quality. Concentrations of pollutant emissions would be calculated during every site-specific environmental review of future proposed large-scale mineral actions. Regardless of which alternative is implemented, large-scale mining operations will be managed to mitigate or avoid adverse impacts to air quality. No cumulative effects are anticipated for minerals management on air quality because no large-scale mineral operations are anticipated during the planning period.

Carbon Storage

Carbon sequestration would be affected by vegetation stripping for large-scale mining operations. However, at the end of mine life, the project area would be reclaimed and allowed to revegetate. No cumulative effects from large-scale mining are expected to occur during the planning period.

Small-scale mineral exploration projects are typically short-term and reclaimed annually. At the forestwide scale, no cumulative effects are expected.

Cultural and Heritage

The effects of mineral management to known areas of cultural significance will be addressed in separate environmental analyses and mitigated at the project level. No cumulative effects to known areas of cultural significance are expected.

Fisheries

The effects of mineral management to fisheries and fisheries habitat will be addressed in separate environmental analyses and mitigated at the project level.

Infrastructure

Access and road development, whether long-term or temporary, are often associated with mineral exploration and development, but a site-specific analysis is required prior to any approval of exploration or development activities. Any mine reclamation activities would likely use existing roads. These may be roads that are not currently designated for motor vehicle use. They would probably be used for the duration of the reclamation work and then returned to their previous status. No cumulative effects are expected.

Minerals

Indirect effects to minerals are described in the alternatives section of this document. Cumulative effects vary with each alternative and are dependent on the amount and availability of access and acreage withdrawn from mineral entry. Common environmental effects from mineral exploration or mining are described in the environmental effects section of this document.

Scenery

Mining activities can involve major landform alteration, as well as form, line, color, and texture contrasts, resulting in adverse scenic impacts. The majority of lands outside of Management Area 1 would be suitable for locatable minerals in all alternatives. Therefore, the impacts from minerals management would be similar in all alternatives. No cumulative effects to scenery are expected during the planning period because no large-scale mining operations are anticipated.

Recreation

Recreation could be affected by abandoned mine closures, mineral exploration, and extraction in all alternatives. Short-term effects might include noise and visual impacts from open-pit or underground mining operations. Over the long-term, effects might include development from a more naturally appearing landscape; new underground or open-pit mines and physical structures; and new roads and road corridors constructed for mining or drilling operations that might change the recreation setting. Mineral facilities could affect visitors, depending on the location of development and the setting affected.

Watershed

The use of best management practices to improve or maintain water quality and quantity and to minimize negative effects to watershed condition, such as channel damage, would be implemented in accordance with law, regulation, and policy. This will result in incremental improvements to existing watershed conditions because of the use of current science and technology to minimize negative effects from approved projects. Historic surface and underground mining are a ground-disturbing activity by definition and cause many effects, some irreversible, to the environment. Historic mining activity can have adverse effects on water quality caused by excess sediment and pollutants from areas of waste rock dumps or processed ore. Water quantities may also be impacted since large volumes of water are generally necessary for present day commercial mining activities. However, because the Nez Perce-Clearwater has numerous historic mining districts with historic mineral production, there is a potential that within the next few decades renewed exploration and extraction could occur. In combination with off-forest mining activity, mining on the Nez Perce-Clearwater may have cumulative adverse effects on water quality, water quantity, and watersheds.

To protect water quality, riparian areas, and stream channels, the Nez Perce-Clearwater proposes standards and guidelines that include the requirement of a reclamation plan and bond for mining activities in riparian management zones (FW-STD-AREM-01); limiting mine waste in riparian management zones (FW-STD-AREM-02); limiting mineral operation in riparian management zones unless strict adherence to guidance is followed (FW-GDL-AREM-01, FW-GDL-AREM-02); controlling water flow paths to maintain water quality and to prevent biological, chemical, or industrial pollutants from being delivered to water bodies (FW-GDL-AREM-03); and the guidelines for use of best management practices (FW-GDL-AREM-04).

Vegetation

Generally, the impacts to terrestrial vegetation from mineral operations are localized and, at the forestwide scale, they would be insignificant and not have a cumulative effect.

Wildlife

Impacts to wildlife from minerals and energy activities could include the potential alteration or removal of habitat, increased fragmentation, and the potential for human-caused mortality from high-speed traffic or high traffic levels on roads. Mining activities could impact habitats for aquatic furbearers and waterfowl locally. The overall threat impact is low for the Nez Perce-Clearwater for multiple use wildlife.

Summary of Consequences

Table 375 provides a summary of potential consequences on energy and minerals, by alternative. Alternative X provides the highest available acres; Alternative W provides the smallest number of acres for mineral development.

Table 375. Summary of potential changes to acres available for mineral development, by alternative (Alt)

Measurement Indicator	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Acres Available for Locatable	2,410,551	1,849,388	2,685,416	2,303,114	2,088,303	2,383,574
Acres Available for Locatable with Designated Areas	2,180,863	969,164	2,677,624	1,912,167	1,477,093	2,073,807
Acres Available for Saleable and Leasable	1,217,683	1,238,907	1,244,331	1,219,951	1,233,180	1,240,340

3.5.3 Livestock Grazing

Livestock grazing has been, and continues to be, an important multiple use of National Forest System lands within the Nez Perce-Clearwater. Livestock grazing has been a legitimate use of public lands since the inception of the National Forest System and has become an import part of the culture of the rural western United States. The term rangeland refers to areas where natural vegetation consists principally of grasses, forbs, grass-like plants, and shrubs that are suitable for grazing or browsing (U.S. Department of Agriculture 2012d). The objectives for Forest Service management of rangelands include managing range vegetation to provide ecosystem diversity and environmental quality, while also maintaining relationships with allotment permittees, meeting the public's needs for rangeland uses, providing for livestock forage, maintaining wildlife food and habitat, and providing opportunities for economic diversity.

Rangeland management is an essential part of the Forest Service multiple-use strategy. Livestock grazing on National Forest System lands contributes to the social and economic importance of rural communities and to the associated traditional cultural landscapes. Although rangelands provide a variety of ecosystem services, such as wildlife habitat, recreation, watershed functions, carbon sequestration, and biodiversity conservation, these lands have primarily been managed for forage production and livestock grazing.

Forage is a provisionary ecosystem service in that it is a tangible product from the ecosystem that humans use for nutrition, materials, or energy. Forage is managed by the Forest Service to be sustainable, ensuring that it will be available for future generations while still providing the other rangeland ecosystem services. To accomplish this, the Nez Perce-Clearwater has delineated livestock grazing areas into allotments. Each grazing allotment is managed and monitored to be responsive to current Federal and State environmental laws and regulations and to be consistent with land management plans. In addition to natural grasslands and meadows, allotments within the Nez Perce-Clearwater contain forage producing areas called transitory range. Transitory range is defined as forested lands that are suitable for grazing by livestock for a limited time following a timber harvest, fire, or other landscape event (Spreitzer 1985).

Grazing permits for each allotment are issued to eligible commercial livestock owners. Livestock grazing management is established through land management plans, Forest Service grazing guidance, and individual allotment management plans. Allotment management plans are revised and updated to ensure that livestock grazing management decisions are based on existing and future ecological, social, cultural, and economic conditions.

The successful management of livestock grazing use on the Nez Perce-Clearwater relies upon the maintenance of healthy, functioning rangelands. Refer to the discussions for non-forested vegetation in the Forestlands section that focus on the health of those plant communities utilized for grazing purposes, and how revised plan components would affect the plant communities upon which livestock grazing depend for forage.

Changes Between Draft and Final

Comments received since the proposed action and draft environmental impact statement were published have been used where appropriate to improve the Land Management Plan and have helped inform this final environmental impact statement. Comments centered on providing for grazing opportunities on suitable rangelands, balancing forage use by domestic livestock with ecosystem functions, and regulating grazing activities by implementing more stringent standards and guidelines or enforcing compliance with existing grazing permit requirements.

Multiple minor changes were made for the final environmental impact statement; all changes are within the scope of the draft environmental impact statement analysis and address issues that the public had an opportunity to comment on. With respect to livestock grazing, there were changes to the livestock grazing (GRZ) and aquatic and riparian livestock grazing (ARGRZ) plan components that were driven from commenters and internal Forest Service suggestions. As a result of public input, an additional alternative was developed called the Preferred Alternative; its analysis was the same as other action alternatives. An objective was added to state the annual animal unit months the Forests intend to make available (FW-OBJ-GRZ-01). Allotment boundary lines and riparian management zones were updated in the Nez Perce-Clearwater geographic information system database and acres were adjusted in the analysis.

Relevant Laws, Regulations, and Policy

The Nez Perce-Clearwater will follow all laws, regulations, and policies that relate to managing National Forest System land. The Land Management Plan is designed to supplement, not replace, direction from these sources. Other Forest Service direction, including laws, regulations, policies, executive orders, and Forest Service directives (manual and handbook), are not repeated in the Land Management Plan.

Federal Laws

Organic Administration Act of 1897: This act provides the main statutory basis for the management of forest reserves. The act states that no National Forest may be established except to improve and protect the forest within its boundaries, for the purpose of securing favorable conditions of water flows, and to furnish a continuous supply of timber for the use and necessities of citizens of the United States. It also authorizes the Secretary of Agriculture to promulgate rules and regulations to control the use and occupancy of the National Forests.

Bankhead-Jones Farm Tenant Act of 1937: This act directs the Secretary of Agriculture to develop a program of land conservation and use to correct maladjustments in land use and to assist such things as control of soil erosion, reforestation, preservation of natural resources, and protection of fish and wildlife.

Granger-Thye Act of 1950: This act provides for issuance of grazing permits for a term of up to 10 years. It also provides for the use of grazing receipts for range improvement work.

Multiple-Use Sustained-Yield Act of 1960: This act provides that National Forests are established and administered for several purposes, including livestock grazing. This act also authorizes the Secretary of Agriculture to develop the surface renewable resources of National Forests for multiple use and sustained yield of the services and products to be obtained from these lands without impairment of the productivity of the land.

Wilderness Act of 1964: This act provides that livestock grazing, and the activities and facilities needed to support grazing, are allowed to continue in wilderness areas when such grazing was established before the wilderness was designated.

National Environmental Policy Act of 1970: This act directs all federal agencies to consider and report the potential environmental impacts of proposed federal actions. The act also established the Council on Environmental Quality.

Clean Water Act of 1972: This act sets the basic structure for regulating discharges of pollutants to the waters of the United States.

Endangered Species Act of 1973: This act protects animal and plant species currently in danger of extinction, labeled as endangered, and those that may become endangered in the foreseeable future, referred to as threatened. The act provides for the conservation of ecosystems upon which threatened and endangered species of fish, wildlife, and plants depend, both through federal action and by encouraging the establishment of state programs.

Forest and Rangeland Renewable Resource Planning Act of 1974: This act directs the Secretary of Agriculture to develop a process for the revision of National Forest System lands resource management plans. This includes the identification of the suitability of lands for resource management.

Federal Land Policy and Management Act of 1976: This act states that public lands will be managed in a manner that will provide food and habitat for fish, wildlife, and domestic animals.

Public Rangelands Improvement Act of 1978: This act recognizes the need to correct unsatisfactory conditions on public rangelands by increasing funding for maintenance and management of these lands. The act also commits to inventory rangeland conditions and trends and management to maintain and improve conditions.

Rescission Act of 1995: This act directs the Forest Service to complete site-specific National Environmental Policy Act analyses and decisions for grazing allotments on a regularly scheduled basis based on permit requirements.

Agency Regulation

36 CFR 222, subparts A and C: provides the authority to administer the grazing and livestock use permit system.

36 CFR 219.10: requires land management plans developed under the 2012 Planning Rule must include plan components for integrated resource management to provide for ecosystem services and multiple uses including forage for grazing.

Policy

Forest Service Manual 2200: This manual provides direction for rangeland administration on National Forest System lands.

Forest Service Manual 1920 Section 1921.02: This manual includes references to rangeland management in terms of sustaining multiple use and maintaining long-term health and productivity of the land consistent with the Multiple-Use Sustained-Yield Act.

Forest Service Handbook 2209.13: This handbook supplies direction for permit administration on National Forest System lands.

USDA Environmental Compliance, Policy on Range, Departmental Regulation, Number 9500-5, April 21, 1988: This regulation sets forth Departmental Policy relating to range services and coordination of range activities among agencies of the U.S. Department of Agriculture and other executive agencies, organizations, and individuals.

Other Agreements and Plans

The following agreements and plans support the Forest Service's rangeland management program:

Memoranda of understanding for forage reserves: Forage reserves are allotments under a term grazing permit but may be used by other permittees that have been temporarily displaced due to wildland fire, drought, or other situations that have made forage unavailable.

Non-use for resource protection agreements: These agreements may be established to provide long-term non-use to allow rangelands to recover, provide forage on a temporary basis to allow resource recovery on other grazing units, provide temporary resolution of conflicts created by predation on livestock, or provide supplemental forage in times of drought to assist area livestock operators and lessen the resource impacts of grazing.

Allotment management plans: Developed through site-specific environmental analysis, an allotment management plan uses Land Management Plan direction and current issues to determine desired conditions and a broad strategy for meeting desired conditions. These plans describe site-specific grazing strategies, stocking, structural and non-structural range improvement needs, and coordination with other resources.

Treaty with the Nez Perce 1855 ARTICLE 3: "The exclusive right of taking fish in all the streams were running through or bordering said reservation is further secured to said Indians: as also the right of taking fish at all usual and accustomed places in common with citizens of the territory, and of erecting temporary buildings for curing, together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land."

Methodology

Analysis Area

The spatial scale of this analysis is the entire Nez Perce-Clearwater plan area, focusing on the range allotments located within the National Forests. All lands within the Nez Perce-Clearwater National Forest boundary and other lands that are jointly used in allotment grazing systems form the geographic scope for cumulative effects. Areas outside existing allotments may be analyzed for livestock grazing through future site specific National Environmental Policy Act analyses. The timeframe for considering livestock grazing related effects is the anticipated life of the plan, about 15 to 20 years.

Methods and Assumptions

The livestock grazing section includes both quantitative and qualitative analysis. Animal unit month (AUM)[26] objectives were based on currently permitted animal unit months on active allotments from the Natural Resource Manager database and historic grazing data for vacant allotments.

A geographic information system analysis to calculate acres was used to quantify a particular impact. For example, alternatives may vary by the extent of forest canopy reduction each year by timber harvest or wildland fire. Forest canopy openings within allotments may equate to an increase in transitory forage available to livestock in the near future.

The following assumptions are used to determine the degree of impacts on livestock grazing. These assumptions are based on previous assessments, professional judgment, and Forest Service rangeland management and planning directives.

- Current active and vacant allotments are suitable for livestock grazing. Although an area may be deemed suitable for use by livestock in the land management plan, a project-level analysis for allotment management planning would evaluate the site-specific impacts of the grazing activity in order to authorize and dictate the management of livestock grazing in a specific allotment. Smaller inclusions of specially allocated lands within allotments, such as developed recreation sites or research natural areas, may not be suitable for livestock grazing.
- Grazing use would be managed similarly in all alternatives. The land management plan does not make changes to allotment boundaries, active or vacant allotment status, or the amount or type of grazing that may be permitted in the future, however, the plan does provide guidance for future grazing authorizations, including standards and guidelines that must be adhered to in future planning.
- The grazing system in each allotment would remain the same as it is currently, and permitted animal unit months for each active allotment is not expected to increase or decrease unless changed through a site-specific analysis, allotment management plan updates, or permit modifications. Plan components applicable to livestock grazing (including the end of season stubble height guideline) would be incorporated through permit modification(s), reissuance of existing term permits, issuance of new term grazing permits, or as allotment management plan revisions and sufficiency reviews occur.
- Past livestock grazing was more extensive than present authorized livestock grazing. Some areas of past resource degradation may be evident because of past grazing practices.
- Additional effort on the part of the grazing permittee may be necessary to ensure land management plan standards and guidelines are implemented.
- Mitigations for impacts to, or from, livestock use would be addressed in a site-specific analysis for allotments.

[26] An animal unit month or AUM is the amount of oven-dry forage (forage demand) required by one animal unit for a standardized period of 30 animal-unit-days. This would be 780 pounds dry weight forage for a 1,000-pound cow for one month (using 26 pounds per day per cow). AUM is not synonymous with animal month or head month. A head month is defined as one month's use and occupancy of the range by one animal. For grazing fee purposes, it is a month's use and occupancy of range by one weaned or adult cow (with or without calf), bull, yearling steer or heifer, horse, mule, or other applicable permitted animal.

Limitations

The livestock grazing analysis is limited to cattle grazing in active and vacant allotments within the Nez Perce-Clearwater. It does not discuss permitted horse grazing or grazing by pack stock, such as horses and mules, which are used primarily in conjunction with recreational activities.

Information Sources

The science of assessing rangelands is evolving as certain concepts and ecological processes are becoming better understood (Pellant et al. 2020). General concepts for maintaining or moving towards desired rangeland condition focus on aspects of ground cover, species composition, vegetation utilization, and the presence or absence of invasive species as indicators.

Information sources include current scientific literature, Forest Service reports and databases, the forest plan monitoring reports, allotment administration summaries, and other documentation. Data used to summarize the existing condition for livestock grazing came from completed livestock grazing analyses and the Forest Service Natural Resource Manager database, which includes grazing allotment, permitted use, and range improvement data.

Measurement Indicators

This analysis focuses on the sustainability of permitted livestock grazing on the Nez Perce-Clearwater as an economic contributor to local communities. The amount of permitted grazing, notable influences on forage production and availability, and allotment management complexity are key factors in determining permitted livestock grazing sustainability. Table 376 outlines the livestock grazing indicators and measures used to compare differences between alternatives.

Table 376. Livestock grazing indicators and measures.

Indicator	Measures
Permitted use that contributes to economic and social sustainability	Animal Unit Months Acres and percentage of National Forest System land in active grazing allotments
Forage production and availability that provides an ecosystem service	Acres of early seral openings created within allotments, primarily through timber harvest and prescribed fire treatment, to potentially increase transitory range Acres of invasive species infestations treated within allotments Acres of conifer encroachment reduced with allotments
Allotment management complexity due to potential added difficulty for livestock management from proposed plan components and land allocations	Acres and percent of Riparian Management Zones within allotments Acres of recommended wilderness within allotments Acres of eligible and suitable wild and scenic rivers corridors[1] within allotments Number of allotments with low gradient streams Miles of low gradient streams within allotments Number of allotments having streams with potential for Endangered Species Act and Species of Conservation Concern redds Number of allotments within Conservation Watershed Network

[1]Wild and scenic rivers are bounded by a corridor that extends one-quarter mile on each side of the river segment, measured from the high-water mark.

Affected Environment

The Forest Service has undergone many changes in its management of rangelands. In the early 1800s, free forage on unclaimed public domain lands allowed the building of cattle and sheep empires. The ranges soon became over-grazed, overstocked, and overcrowded. Congress stepped in the early 1900s and designated the Forest Service as a grazing control agency. By 1907, the Forest Service had established its system of range regulation. This includes permits, limits on herd size, grazing seasons, allotments, and rental fees.

Livestock grazing has occurred on the Nez Perce-Clearwater for over a hundred years and prior to the establishment of the National Forest System in 1905. The Nez Perce Tribe had a grazing program predating the Treaty of 1855.

Records indicate livestock grazing has been authorized by the Nez Perce National Forest since 1911 ((U.S. Department of Agriculture 1943)), although domestic livestock grazing dated back to the 1860s. It reached its peak when 70,456 head of sheep were permitted in 1918 and 13,992 head of cattle were permitted in 1919 ((U.S. Department of Agriculture 1987b)). Sheep grazing declined rapidly during World War II. Grazing on the Clearwater National Forest dates back to the early 1900s. This early use was mainly sheep grazing which took advantage of the high forage production resulting from large wildfires. Use peaked in 1934 and then rapidly decreased as brush and forest canopy increased and falling snags rendered the burn acres unusable ((Space 1981)).

Many rural communities continue to be dependent upon ranching for their economic livelihood and many of these ranches rely on federal land grazing for a portion of the season. As discussed in the Economic Sustainability section, the direct employee contribution to local communities from livestock grazing is 56 average annual jobs. These jobs are dependent on Forest Service resource programs and agency operations.

The Nez Perce-Clearwater contributes to the economic and social well-being of people by providing opportunities for economic diversity and by promoting stability for communities that depends on range resources for their livelihood. Although the grazing program on the Nez Perce-Clearwater is relatively small compared to some other Forests in the Northern Region, access to public lands for forage is central to many producers in the area. According to the Interior Columbia Basin Ecosystem Management Project Economic and Social Conditions of Communities report, Grangeville, Orofino, White Bird, Riggins, Elk City, Kamiah, Kooskia, and other communities in the region relied on forage produced on Nez Perce-Clearwater Forests lands for approximately 4 to 6 percent of the total forage base of their respective counties ((U.S. Department of Agriculture 2014f)). Continuance of livestock grazing can help to sustain businesses and employment opportunities.

In general, the grazing management program helps to ensure a reliable and consistent level of native rangeland forage for permitted commercial livestock production. This resource helps local ranches maintain an economical operation. A properly managed grazing program on the Nez Perce-Clearwater is integral to meeting desired resource conditions and maintaining the economic and social sustainability of local communities.

Permitted Livestock and Grazing Use

Of the approximately 4 million National Forest System acres within the Nez Perce-Clearwater, 612,766 acres, or about 15 percent, are within active grazing allotments. Grazing allotments occur along the western boundary (Figure 150) and southwest portion (Figure 151) of the Nez Perce-Clearwater. Allotments are a designated area of land available for permitted livestock grazing (36 CFR 222). A grazing allotment can include National Forest System and non-National Forest System lands. Permits are issued for the use of allotments or portions of allotments. Allotments are in active status when grazing permits have been issued, allotments are in vacant status when they do not have a grazing permit issued, and allotments are in closed status when they have been closed to livestock grazing by an administrative decision or action (Forest Service Manual 2205).

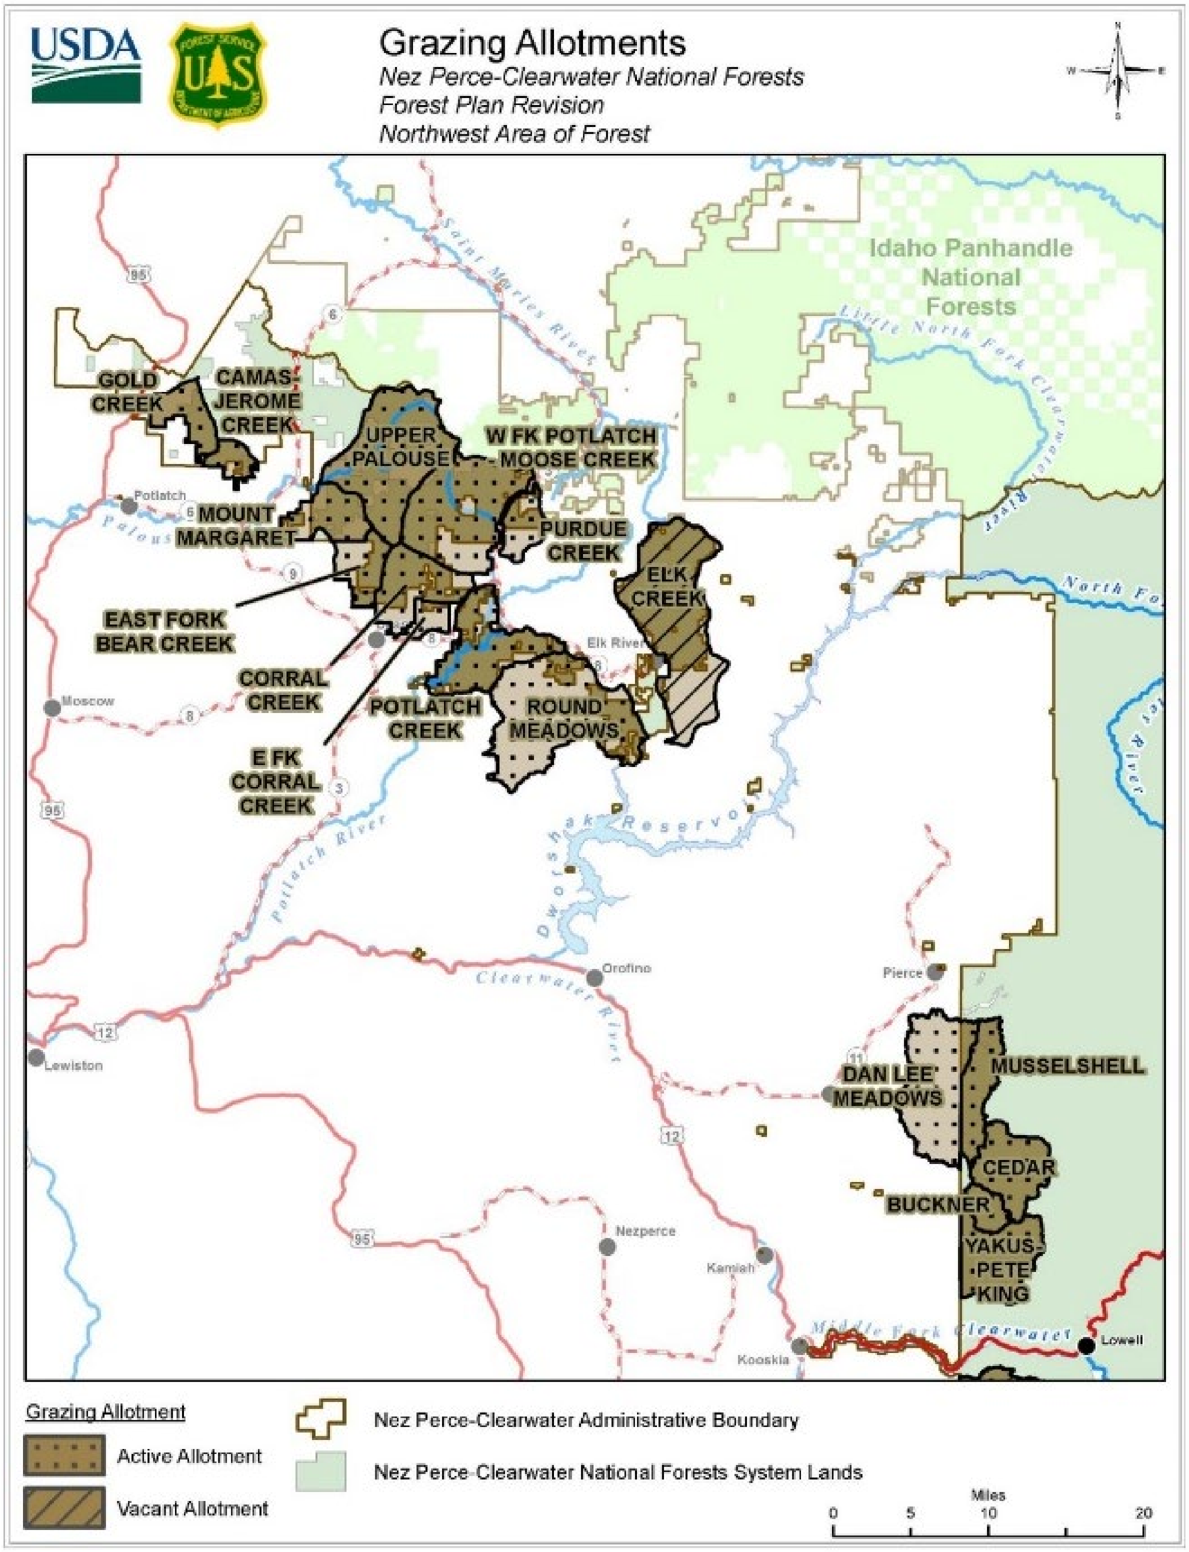

Figure 150. Grazing allotments in the northwest portion of the plan area.

Data Source: Nez Perce-Clearwater Geographic Information System.

*Beginning May 2024, the Cedar Allotment will become vacant, and the Musselshell Allotment will be administratively closed.

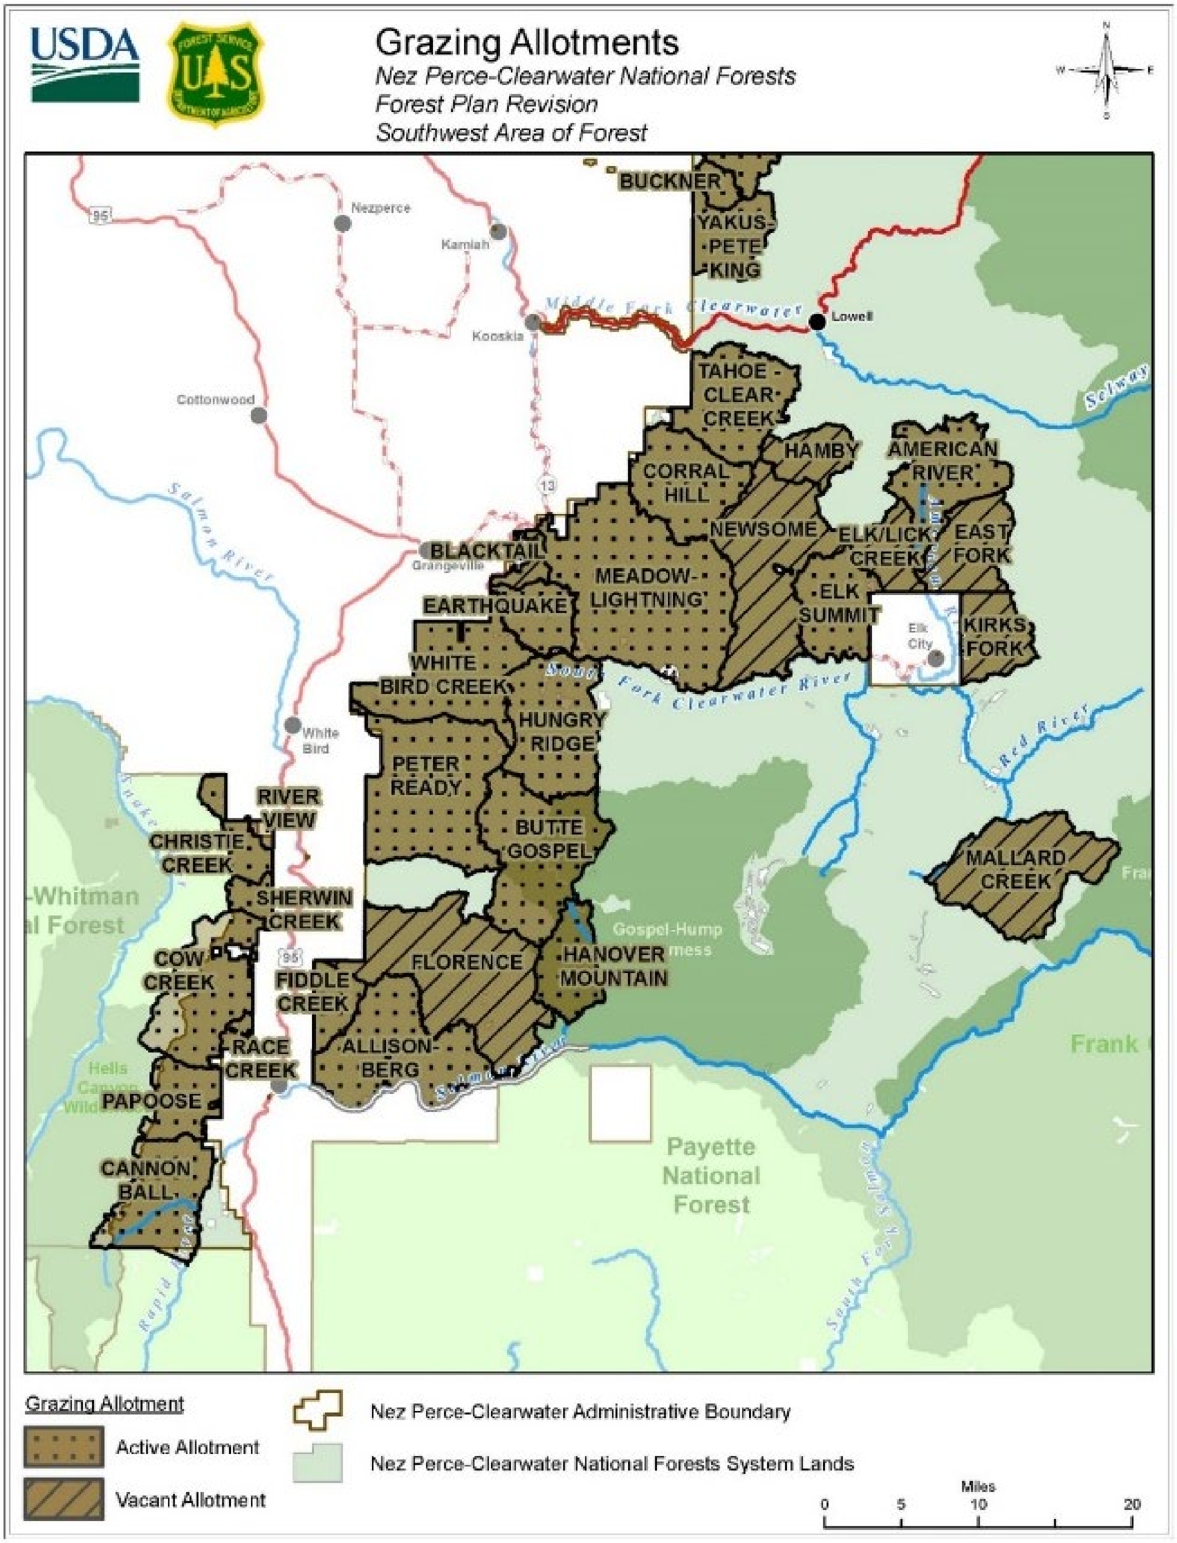

Figure 151. Grazing allotments in the southwest portion of the planning area.

Data Source: Nez Perce-Clearwater Geographic Information System.

Within the Nez Perce-Clearwater, there are currently 34 permittees authorized to graze livestock on 36 active range allotments. The number of permittees vary as term permits expire and become activated. All active grazing allotments are permitted for cattle grazing. Current grazing information for the Nez Perce-Clearwater is summarized in Table 377. Beginning May 2024, the Cedar Allotment will become vacant, and the Musselshell Allotment will be administratively closed.

Table 377. Livestock grazing statistics for the Nez Perce-Clearwater.

Grazing Information	Number
Permitted Cattle[1]	4,590
Permitted Cattle Animal Unit Months (Active Allotments)	29,861
Grazing Permittees (Permit Entities)	34
Active Allotments	36
Active Allotment Acres on Nez Perce-Clearwater lands	612,766
Vacant Allotments	9
Vacant Allotment Acres on Nez Perce-Clearwater lands	647,296

[1]One cattle number is equal to 1 cow and calf pair or 1 steer or 1 bull; calves greater than 6 months old are counted as cattle.
Data Source: Forest Service INFRA database, 2020; Nez Perce-Clearwater geographical information system data.

Permitted season of use varies by allotment, with some seasons starting as early as May 1 and some ending as late as October 31. The quantity of authorized livestock grazing is generally referred to in terms of an animal unit month. An animal unit month is defined as the amount of dry forage required by one mature cow of approximately 1,000 pounds, or its equivalent, with a grazing duration of 30 days.

Nez Perce-Clearwater livestock grazing records for 2020 show 4,590 head of cattle or cow and calf pair were permitted to graze at various times throughout the year, with a primary grazing season of June 1 through September 30. A total of 29,861 animal unit months for cattle were authorized to graze under a term grazing permit on National Forest System lands. Table 378 provides acres, number of permitted cattle, and animal unit month amounts for each active grazing allotment by Nez Perce-Clearwater ranger district. There are currently no designated forage reserve allotments on the Nez Perce-Clearwater that could be used by permittees that have been temporarily displaced due to wildland fire, drought, or other situations that have made forage unavailable.

Table 378. Summary of ranger district, allotment acres, livestock numbers, and animal unit months by active grazing allotment.

[3]Allotments do not contain streams with Endangered Species Act listed fish.
Data Source: Forest Service INFRA database, 2020; Nez Perce-Clearwater geographical information system data.

There are nine vacant grazing allotments on the Nez Perce-Clearwater totaling 217,172 acres (Table 379). Based on historic grazing records, approximately 940 head of cattle were permitted, and 4,476 animal unit months were authorized to graze on these vacant allotments. Current vacant allotments would need allotment level National Environmental Policy Act analyses and the development of an allotment management plan before being designated as active allotments.

Table 379. Summary of ranger district, allotment acres, livestock numbers, and animal unit months by vacant grazing allotment.

Allotment Name	Ranger District	Total Allotment Acres	Allotment Acres on Nez Perce-Clearwater Lands	Livestock Numbers	Permitted Animal Unit Months

As noted in Table 378 and Table 379, allotment acres on Nez Perce-Clearwater lands are different than the total allotment acres for particular allotments. These allotments have allotment boundaries that extend onto other national forests, state land, or private land. There are approximately 14,900 acres of Wallowa-Whitman, 900 acres of Payette, and 83,950 acres of non-Forest Service lands occurring within active and vacant allotments.

The Allison-Berg Allotment is the only domestic sheep allotment on the Nez Perce-Clearwater. Approximately 2,875 animal unit months were previously authorized to graze under a term grazing permit. The permit allowed for 1,483 ewe and lamb pair in the spring and summer grazing season and 2,301 mature sheep or goat in the fall and winter grazing season. In 2009, the term grazing permit was modified due to potential conflicts between domestic sheep grazing and native bighorn sheep. The permit modification states that domestic sheep grazing would not be authorized until an appropriate National Forest Management Act and National Environmental Policy Act analysis examines this potential conflict. Domestic sheep have not grazed on the allotment since 2007.

At the time the Nez Perce and Clearwater forest plans were developed in 1987, there was permitted grazing use of 58,000 animal unit months and 112 livestock grazing allotments (Table 380). Animal unit months permitted on the Nez Perce-Clearwater have decreased by approximately 48 percent since 1987 (Table 380).

Over the past several years, many allotments have been vacated and closed for a variety of reasons. Reduced transitory range, diminished range conditions, poor or nonexistent access, and economic considerations have forced permittees to discontinue use on some of the Forest's more remote and short-season allotments. Although the number of allotments have decreased since 1987, it is not all due to closures. Several allotment boundary delineations have been altered, and allotments have been combined.

Table 380. Permitted grazing in 1987 Nez Perce and Clearwater forest plans compared to current permitted use on active allotments.

Indicator	Nez Perce 1987 Forest Plan	Clearwater 1987 Forest Plan	Combined 1987 Forest Plan Total	Current Permitted Use on Active Allotments
Animal Unit Months	42,000	16,000	58,000	29,861
Cattle (Number)	6,600	1,700	8,300	4,590
Sheep (Number)	3,400	0	3,400	0
Permittees (Number)[1]	65	65	130	34
Allotments (Number)	59	53	112	36

[1]Number is an overestimate because a single permittee could have permits on both Forests.

Data Source: 1987 Nez Perce and Clearwater Forest Plans ((U.S. Department of Agriculture 1987b, a))

Livestock Grazing Management

Commercial livestock grazing on National Forest System lands are generally authorized through the issuance of a term grazing permit. Typically, grazing permits are issued to qualifying entities, referred to as permittees, for a period of 10 years and are generally re-issued upon expiration to the existing permittee. Permits include terms and conditions for grazing use and describe the responsibilities of the permit holder. Permitted livestock numbers and seasons of use are often based on past actual and permitted use levels but are also based on the site conditions.

Site-specific National Environmental Policy Act (NEPA) analysis for each allotment or set of allotments is completed during the allotment management planning process. The analysis evaluates potential impacts caused by permitted livestock grazing on a variety of resources, including rangeland resources, soils, federally listed threatened and endangered species, species of conservation concern, riparian habitat, and water quality. Allotment management plans contain the pertinent livestock management direction from the project-level NEPA decisions and include a general monitoring plan. Once approved, the allotment management plan becomes a part of the permit.

The allotment management plan establishes site-specific goals and objectives and provides management strategies to maintain or move towards desired condition and address resource issues and concerns. These strategies may include allowable use levels for riparian and upland vegetation, seasons of use, pasture rotations, thresholds for stream bank disturbance caused by livestock, and a schedule for implementing range-improvement projects, such as fences and water developments. This plan also includes requirements for monitoring and inspections, payment of grazing fees, ownership of livestock and base property, livestock management, range improvement maintenance and construction, and other terms as appropriate.

Annual operating instructions state the specific requirements and actions for the current year that are necessary to implement the project-level decision, allotment management plan, and term grazing permit. The annual operating instructions identify the obligations of the permittee and the Forest Service and articulates annual grazing management requirements, standards, and monitoring necessary to document compliance. Annual operating instructions are typically issued to allotment permittees during annual meetings prior to the grazing season. The instructions outline the number of permitted livestock, timing and duration of use, allowable use for riparian areas and uplands, applicable forest plan standards, permittee management requirements and practices, monitoring requirements, and site-specific mitigation measures.

Allotments are inspected throughout the season and are documented in allotment management summaries. Inspections determine if annual operating instructions are being followed, including timing, intensity, and location of stock. It also includes such items as maintenance of range improvements per permit terms and conditions. Compliance problems with the terms and conditions of grazing permits are documented and follow-up actions are initiated in the following year's annual operating instructions. Generally, if compliance issues occur on an allotment, range inspections are done jointly with permittees in order to try and jointly resolve the issues where possible.

Allotment management plans are revised periodically to ensure resource issues and concerns are adequately addressed and to ensure consistency with Forest Service regulatory guidance. Site-specific National Environmental Policy Act (NEPA) analysis for each allotment or set of allotments is completed at the time of the allotment management plan revision. The Nez Perce-Clearwater is operating under a schedule to revise and update allotment management plans tied to the Rescissions Act of 1995 (Public Law 104-19), Section 504(a), which requires each National Forest System unit to identify all allotments for which NEPA analysis is needed. These allotments must be included in a schedule that sets a timeline for the completion of the required environmental analysis.

Livestock must be managed properly to ensure the long-term sustainability of the resource base. Proper grazing management depends in part on determining correct livestock numbers per area of land, known as the stocking rate. Stocking rate is often expressed as acres per animal unit month. Animal unit months authorized by permit are allotment specific, thus they can be highly variable and need to be evaluated at the allotment planning level and not the at the forest plan level. Key factors influencing proper stocking on any given parcel of land include, but are not limited to, permittee management knowledge and effectiveness, topography, water availability, plant communities and their distribution, aspect, slope, forage palatability, current year's precipitation and seasonal distribution, wildland fire, drought, wildlife effects, recreational activities, and livestock age and size. Stocking rate adjustments can be and have been made through permit modifications where sufficient information indicates that a change is needed to achieve healthy range conditions.

Allotment management integrity relies heavily upon the maintenance of the related infrastructure such as fences, corrals, and water developments. There are approximately 240 miles of fence and about 160 water developments related to the management of allotments.

Rangeland Capability

Capability is an ecological assessment and is the initial step in the determination of suitability. Capability is defined as the ability of a unit of land, based on defined physical and biological attributes, to support a particular use or suite of products while maintaining ecosystem sustainability (Forest Service Manual 1905). Capability depends upon current resource conditions and site conditions such as climate, slope, landform, soils, and geology, as well as the application of management practices, such as silviculture or protection from fire, insects, and disease. It is not a determination of grazing capacity.

Capable rangelands produce forage or have inherent forage producing capabilities, and if accessible, can be grazed on a sustained yield basis. On the Nez Perce-Clearwater, livestock tend to congregate on more gentle terrain such as valley bottoms, riparian areas, meadows, and ridgetops.

Capability on the Nez Perce-Clearwater has been assessed periodically, both across the forest and within allotments. Examples of information utilized in capability assessments are forage production at a certain pounds per acre, slope, distance to water, and soil erosion potential. Range forage capability is not static, especially where factors such as timber encroachment, weed invasion, and natural wildland fire occur. Utilizing the Forest Service VMap existing vegetation geospatial database, approximately 2,055,439 capable range acres occur on the Nez Perce-Clearwater. In addition to vegetation type, aspect, slope, and elevation were used to assess capability. Within the active grazing allotments, there are 220,090 capable range acres, or 36 percent of active allotments. Livestock are not precluded from lands that may be modeled as not capable.

Rangeland productivity is an estimate of the annual production of rangeland vegetation in non-forested areas. Using the Normalized Difference Vegetation Index, an estimated 27,686 productive acres were identified in 2021 in active allotments. The highest productive acres occurred in the Allison-Berg, Cannon Ball, and Cow Creek allotments. The acres have remained fairly consistent since 1987 with slight variances in the level of forage resource productivity from year to year.

Rangeland Suitability

As noted in 36 CFR 291.7(e)(1)(v), specific lands within a plan area will be identified as suitable for various multiple uses or activities based on the desired conditions applicable to those lands. The plan will also identify lands within the plan area as not suitable for uses that are not compatible with desired conditions for those lands. The suitability of lands need not be identified for every use or activity. Suitability identifications may be made after consideration of historic uses and of issues that have arisen in the planning process.

Determining the suitability of a specific land area for a particular use or activity is usually based upon the desired condition for that area and the inherent capability of the land to support the use or activity. The National Forest Management Act does not impose a requirement to make suitability determinations for all multiple uses.

At the land management plan level, the suitability determination provides basic information regarding the potential of the land to produce resources and supply goods and services in a sustainable manner, as well as the appropriateness of using that land in a given manner. The 1987 Nez Perce and Clearwater forest plans are supported by a grazing suitability analysis that was done in the mid-1980s. Identified allotments were deemed suitable for permitted livestock grazing. Current active and vacant allotments are a subset of those allotments and therefore, suitable for livestock grazing.

Although an area may be deemed suitable for use by livestock in a land management plan, a project-level analysis evaluating the site-specific impacts of the grazing activity, in conformance with the National Environmental Policy Act (NEPA), is required in order to authorize livestock grazing on specific allotment(s). Broad suitability determinations are made across the livestock grazing allotments and more site-specific suitability determinations are applied for particular areas. Livestock grazing allotments may include smaller inclusions that are not appropriate for domestic livestock grazing when analyzed at the site-specific level, for example developed recreation sites. In these instances, livestock grazing may be found to be not suitable or suitable, but with restrictions.

Rangeland Conditions - Forage Productivity and Availability

Based on Forest Inventory and Analysis (FIA) plots non-forested vegetation types occur on only 5 percent of the Nez Perce-Clearwater. As discussed in the non-forested vegetation portion of the Forestlands section, the Nez Perce-Clearwater contains approximately 31,800 acres of grassland and 14,900 acres of meadow. An additional 3,000 acres of possible meadow have been encroached by conifers.

Specific information regarding the condition of the non-forest vegetation within the planning area or livestock grazing allotments is limited. Sampling and evaluation of grassland vegetation is generally conducted as a component of allotment NEPA analysis, but current allotment analysis information is relatively sparse on the Nez Perce-Clearwater. Forage is considered grassland vegetation, riparian and meadow vegetation, palatable grass and herbaceous vegetation produced under a timber canopy, and, to a lesser extent, shrub foliage.

Grasses dominate the xeric and mesic grassland broad potential vegetation groups and some dry forest types. Native plant communities include forb mixes of Idaho fescue, bluebunch wheatgrass, prairie junegrass, tufted hairgrass, mountain brome, needlegrass, and mixed grass. Common non-native species include timothy, orchard grass, Kentucky bluegrass, and annual brome. In some places, grass, forb, and shrub communities occur as a transitional type in the earliest stages of forest succession. For information on non-forested vegetation, see the Forestlands section pertaining to xeric and mesic grasslands, xeric shrubland or woodlands, riparian or wetland vegetation, and xeric ecotones and savannas.

Forest Service VMap data estimates that within the active allotments, 9 percent of the acres are categorized as herb, 4 percent as shrub, and 87 percent as tree. Based on Northern Region Broad potential vegetation type (PVT) group delineations, within active allotments, there is only 1 percent categorized as grassland, 1 percent as mesic shrubland, and the other 98 percent as forested vegetation types.

Rangeland forage is an important ecosystem service. Ecosystem services act as the primary bridge between ecological and social and economic systems. In Idaho and other western states, it is estimated that the majority of beef cows are produced on ranches that have at least 5 percent of their grazing capacity on federal rangeland (Torell et al. 1996). Cattle grazing on federal lands rarely spend the entire year on those lands. Rather, federal lands complement the forage resources of western ranches, that use state- or privately-owned lands other parts of the year. Approximately 40 percent of the beef cows in the western states have spent time on federal lands (Torell et al. 1996).

Forage is defined as the plants or parts of plants consumed by grazing or browsing animals. The amount of forage available for consumption varies according to a number of factors. Some plant species are unpalatable. Certain parts of many plants are not consumed. Moreover, only parts of plants can be consumed if they are to maintain vigor and keep their place in the plant community. Some areas of rangeland are not appropriate for grazing by livestock because of steep slopes, fragile soils, distance to water, poisonous plants, etc.

Key stressors that could affect the ability of the plan area to sustain domestic livestock that depend on the forage produced on the Nez Perce-Clearwater are uncharacteristic wildfires, invasive plant species, tree succession that lessens transitory range, conifer encroachment in grasslands and meadows, drought, and changing climate. These stressors are intensified by climate change, although conditions can vary substantially from year to year.

Conifer encroachment into meadows, shrublands, and grasslands has resulted in the loss of useable forage throughout the Nez Perce-Clearwater. Conifer encroachment is primarily a result of wildfire exclusion over the last 100 years. For example, timber canopy closure and encroachment has reduced forage production by at least 20 percent over the past 60 years on the Christie Creek Allotment on the Nez Perce National Forest (U.S. Department of Agriculture 2011c). There is approximately 4,080 acres of conifer encroachment in grasslands and shrublands in the active livestock grazing allotments.

Invasive plant species have greatly increased from historical levels and contribute to changes in vegetation composition and structure. For instance, biological diversity has changed in the Salmon and Selway River canyons as a result of noxious weed infestations and resultant loss of native grasslands. In some areas, perennial grassland vegetation has declined as annual grasses, such as cheatgrass, have expanded. More recently, exotic annual grasses are being replaced by even more aggressive invasive plant species. This decline in vegetation from native perennial grasses to exotic annual grass to invasive plant species has resulted in the significant decline in native plant production. For example, in the Christie and Sherwin allotments, usable forage in some areas has dropped from roughly 250 to 25 pounds per acre (U.S. Department of Agriculture 2011c). Allotment grazing capacities decline as forage production declines. Approximately 30 percent of the Christie and Sherwin allotments have converted to conditions undesirable for grazing, resulting in a loss of 74 animal unit months of forage capacity (U.S. Department of Agriculture 2011c).

Invasive forage species can substantially affect the structure and diversity of plant communities, as well as the seasonal palatability on some grazing allotments. Maintaining intact native bunchgrass communities can be the effective biotic resistance and reduce the magnitude invasive plants (Chambers et al. 2007, Prevey et al. 2010). As of 2022, there were 99,135 acres of inventoried invasive species occurring within grazing allotments and 83,824 acres occurring in active allotments. The dominant species are spotted knapweed, meadow and orange hawkweed, oxeye daisy, gypsy flower, Canada thistle, yellow star-thistle, common crupina, and rush skeletonweed. Climate change stressors, such as increased temperature and drought, are likely to increase the risks of and extent of invasive species on the Nez Perce-Clearwater.

Increased air temperatures influence soil moisture and cause gradual changes in the abundance and distribution of tree, shrub, and grass species, with more drought tolerant species becoming more competitive. Drought can generally be defined as a deficiency from the average or expected precipitation over a given period of time. Drought is different than other natural disasters, such as hurricanes and tornadoes, which have a clear start and end time and clearly defined impacts. Instead, drought creeps up slowly and is difficult to predict. Therefore, managers face constant uncertainty about how droughts will develop. Drought can impact livestock operations by altering rangeland conditions, such as diminished forage production or decreased drinking water that may not be well dispersed. The concentration of livestock around remaining water sources that have not dried out could lead to overuse and degradation of rangeland resources.

Watershed Condition

The watershed condition classification (WCC) process (Potyondy and Geier 2011) is one of the steps included in the Watershed Condition Framework and is a methodology that characterizes watershed condition based on indicators and attributes related to watershed processes. Subwatersheds are ranked in one of three discrete classes that reflect the level of watershed health or integrity — functioning properly, functioning at risk, and impaired function.

In 2011, the Nez Perce-Clearwater completed the watershed condition classification for 220 HUC12 subwatersheds. All or portions of 81 HUC12 subwatersheds occur within livestock grazing allotments. For subwatersheds located within allotments, the overall watershed condition classification was 21 percent rated as functioning properly, 67 percent rated as functioning at risk, and 7 percent rated as impaired (Table 381). Individual watershed condition class indicators directly related to livestock grazing and rangeland health are rangeland vegetation, riparian and wetland vegetation, invasive species, and water quality. Table 381 displays the percent of subwatersheds within livestock grazing allotments by condition class for these indicators. Although many of the subwatersheds had indicators rated as functioning at risk or impaired function, livestock grazing is only one of the many activities or factors affecting those indicators. These ratings will be reassessed in the future to assess change.

Table 381. Percent of subwatersheds within livestock grazing allotments by watershed condition class.

Indicator	Percent of Allotment Acres Functioning Properly	Percent of Allotment Acres Functioning at Risk	Percent of Allotment Acres Impaired Function
Overall WCC classification	21	67	12
Rangeland vegetation condition	50	23	27
Riparian and wetland vegetation condition	17	42	41
Invasive species condition	55	37	8
Water quality	46	18	36

Data Source: 2011 Nez Perce-Clearwater Watershed Condition Class Assessment.

Livestock Management Complexity

The 1987 Nez Perce and Clearwater forest plans contain general forestwide direction that was developed for range management and standards for livestock grazing specific to particular management areas. Items that make livestock grazing management more complex include designated wilderness, wild and scenic rivers, research natural areas, special areas, and national historic landmarks; protecting habitats for threatened, endangered, and sensitive fish, plants, and animals; and adhering to State of Idaho water quality standards. These items often require intensive livestock management and may necessitate fewer permitted livestock or a shortened season of use to mitigate impacts. Reducing permitted grazing could have substantial, negative local economic impacts. Some permittees may operate with limited financial resources, constraining their ability to change practices, make new investments, and absorb animal unit month cutbacks.

Designated Wilderness

The Nez Perce-Clearwater manages the entire Gospel-Hump Wilderness and portions of the Selway-Bitterroot and Frank Church-River of No Return Wilderness areas. Although 59,000 acres of the Hells Canyon Wilderness are located on the Nez Perce-Clearwater, the area is administratively managed by the Wallowa-Whitman National Forest.

Portions of eight livestock grazing allotments occur within three designated wilderness areas (Table 382). The Mallard Creek vacant allotment has a one percent portion located within the Frank Church-River of No Return wilderness. There are four grazing allotments that at least partially lie within the Gospel-Hump Wilderness, with almost all of Hanover Mountain Allotment and about half of the Butte Gospel Allotment occurring within the wilderness area. Pieces of three active allotments occur within the Hells Canyon wilderness on the Wallow-Whitman portion of the allotments. No allotments occur within the Selway-Bitterroot wilderness.

Each wilderness area is managed according to its own designating legislation and management plans specific to that wilderness area. Livestock grazing is suitable in the wilderness areas, although forage utilization is more restrictive. Livestock grazing management is expected to administer existing range allotments in accordance with wilderness values, maintain natural vegetative composition, and not exceed historical level of livestock (U.S. Department of Agriculture 1987b).

Table 382. Grazing allotments within designated wilderness.

Allotment Name	Allotment Status	Designated Wilderness Area	Wilderness Acres on Nez Perce-Clearwater	Wilderness Acres on Wallowa-Whitman	Percent of Total Allotment Acres within wilderness
Mallard Creek	Vacant	Frank Church-River of No Return	400	0	1
Butte Gospel	Active	Gospel-Hump	19,074	0	49
Florence	Vacant	Gospel-Hump	346	0	1
Hanover Mountain	Active	Gospel-Hump	15,327	0	99
Hungry Ridge	Active	Gospel-Hump	47	0	Less than 1
Cannon Ball	Active	Hells Canyon	0	2,749	11
Cow Creek	Active	Hells Canyon	0	4,497	15
Papoose	Active	Hells Canyon	0	969	7

Data Source: Nez Perce-Clearwater Geographic Information System

Designated Wild and Scenic Rivers

The Nez Perce-Clearwater administers all or part of three designated wild and scenic rivers. Approximately 3,760 acres, or 15 percent, of the Cannon Ball active allotment occur within the Designated Rapid River Wild and Scenic River. The segment of Rapid River located on the Nez Perce-Clearwater is classified as wild. Management direction for designated rivers is found in the Wild and Scenic Rivers Act and the Act that designated the river if not designated under the Wild and Scenic Rivers Act. Rapid River was designated in 1975 by the Hells Canyon National Recreation Area Act.

Livestock grazing is allowed within the designated river area provided it does not substantially interfere with public use or detract from the values which caused the river to be included in the National Wild and Scenic River System. Structures and improvements within a wild river area are accepted, if they are necessary to support the range activities, provided the area retains a natural appearance and the structures harmonize with the environment.

The Nez Perce 1987 Forest Plan direction for range management in the Rapid River Wild and Scenic River specifies that non-structural distribution control methods and biological methods to control noxious weeds are emphasized and native species of grasses are favored (U.S. Department of Agriculture 1987b).

Water Quality

The Idaho Department of Environmental Quality uses water quality standards (IDAPA 58.01.02) to determine if Idaho's waters are being adequately protected. The Idaho Department of Environmental Quality 303(d)/305(b) Integrated Report is a compilation of information about the water quality status of all Idaho waters and is a requirement of the Clean Water Act. The most current U.S. Environmental Protection Agency approved report is the 2022 Idaho Department of Environmental Quality 303(d)/305(b) Integrated Report (State of Idaho Department of Environmental Quality 2022a). There are 24 active allotments and seven vacant allotments containing streams not meeting State of Idaho water quality standards and not supporting beneficial uses (State of Idaho Department of Environmental Quality 2022b). Fifty percent of the streams in allotments are water quality limited: 725 miles in active allotments and 266 miles in vacant allotments. Impairments include temperature, sedimentation, *Escherichia coli* (E. coli), and fecal coliform.

At-Risk Native Species and Habitat

In some of the allotments there are potential adverse interactions between domestic livestock and native species. Actions to avoid or mitigate these risks can create additional allotment management complexity. Emphasis on protecting habitats for threatened endangered, and sensitive fish, plants, and animals can require more rigorous livestock oversight.

Twelve livestock grazing allotments, all located on the Nez Perce half of the plan area, include lynx habitat. No lynx habitat is located within livestock grazing allotments on the Clearwater. The Northern Rockies Lynx Management Direction (U.S. Department of Agriculture 2007e) contains management guidance pertaining to livestock grazing management in lynx habitat. The management direction only applies to occupied lynx habitat. Because the Nez Perce currently has unoccupied lynx habitat, the direction should be “considered,” recognizing that lynx may be present but would not have to be followed until such time as lynx occupy the unit. Any authorization or re-authorization of grazing allotments are supposed to consider the management direction.

Spalding’s catchfly (*Silene spaldingii*) is a perennial herb that is listed as threatened under the Endangered Species Act by the U.S. Fish and Wildlife Service. Livestock grazing is an identified management activity that can potentially threaten Spalding’s catchfly habitat or populations. As noted in the At-Risk Plant Species section, the three known occurrences of Spalding’s catchfly on the Nez Perce-Clearwater occur within livestock grazing allotments. Although some effects have been noted, livestock use generally does not appear to be a major impact due to managed livestock distribution in relation to population locations, fencing around sites, and low stocking levels in the allotments involved.

Protection of threatened or endangered species fish habitat may have the largest influence on livestock grazing on federal lands. Some permittees could be economically affected if conditions on their federal allotment require more intensive management actions or a reduction in stocking in order to manage for improved riparian and at-risk aquatic species habitat.

In 1995, the Nez Perce and Clearwater National Forest Plans were amended to implement an interim strategy for managing anadromous fish-producing watersheds on National Forest System lands. The direction included standards that protect or minimize effects to listed fish from livestock grazing, primarily in riparian areas. These include modifying grazing practices, locating new facilities outside of riparian areas, relocating or closing facilities, and limiting livestock handling efforts (Standards GM-1, 2, and 3). Federally listed fish occupy streams within or adjacent to 24 out of 36 allotments, approximately 67 percent of the active allotments on the Nez Perce-Clearwater.

Most livestock grazing pastures or allotments include some riparian areas, and managing livestock in those areas is one of the most contentious issues facing rangeland managers. This issue is complex because livestock operators and land managers most resolve conflicting economic and environmental issues as well as other concerns. Riparian areas are often the primary, and sometimes the only, watering places for livestock grazing on allotments. Traditional management strategies, practices, and thinking are often inadequate and difficult to change (Leonard et al. 1997).

Livestock grazing tends to have the greatest impact on low-gradient riparian and wetland areas; fine-textured soils with a minimal amount of rocks, cobbles, or boulders; and areas with naturally available water (Kauffman and Krueger 1984). The magnitude of impacts depends on the timing of use; the kind and class of livestock; the intensity, duration, and frequency of grazing; and the associated management practices, including the level of active permittee management and involvement.

Funding available to national forests to monitor livestock grazing implementation can be limited and monitoring methods are varied. While no one method works everywhere, stubble height has been extensively studied, and is widely put in practice as a trigger for cattle movement or an end of season monitoring indicator (Clary and Webster 1990, Clary and Leininger 2000, Goss and Roper 2018).

Riparian stubble height measurements within Nez Perce-Clearwater grazing allotments are conducted by range specialists periodically during the grazing season. Most of the data is collected along lower gradient stream reaches. Table 383 displays the existing riparian stubble height objectives as documented in Annual Operating Instructions and the range of measured riparian stubble heights at the end of growing season within pastures for years 2015 to 2020. Overall, stubble height objectives are generally achieved. Because measurements are taken at different locations within the pastures it is difficult to establish trend.

Table 383. Annual Operating Instruction (AOI) riparian stubble height objectives for active allotments on the Nez Perce-Clearwater and range of stubble heights* within allotments by monitoring year.

[1]Height or percent-maintained objective for utilization of all herbaceous vegetation remaining along the greenline or floodplain at the end of the growing season.

Data Source: Nez Perce-Clearwater range allotment monitoring summary.

Other factors or land designations occuring within allotments can also make livestock management more complex. For example, the inclusion of research natural areas, special areas, national historic landmarks, or cultural resource sites can require require more intensive livestock management or fencing to mitigate impacts.

Environmental Consequences

This section describes the effects of implementing the Action Alternatives on livestock grazing. The Action Alternatives are described in Chapter 2. Effects are analyzed in relation to the No Action alternative. In conjunction with this analysis, a discussion of the social and economic impacts related to livestock grazing can be found in section 3.8 Economic Sustainability and 3.9 Social Sustainability.

Effects Common to All Alternatives

Effects from the management of sustainable recreation, cultural resources, minerals, system roads and motorized trails, wildfire, designated wilderness, designated wild and scenic rivers, research natural areas, and special areas would be the same for all alternatives. All alternatives retain the

Northern Rockies Lynx Management Direction for managing Canada lynx habitat. Emphasis on managing livestock grazing to maintain and improve riparian conditions is expected to continue under all alternatives. See the Effects to Livestock Grazing from Other Resources section below for more information on each of these resources.

Permitted Livestock Use

Livestock grazing is likely to be sustained within the planning area over the next 15 to 20 years under all alternatives. Figure 150 and Figure 151 delineate the grazing allotments on the Nez Perce-Clearwater. None of the alternatives close any allotments, change the existing allotment boundaries, convert status, or alter permitted animal unit months. Existing suitable acres would not change between any of the alternatives. None of the alternatives stipulate any direction regarding allotment specific administration, such as pasture on and off dates and rotations. Under all alternatives, changes to livestock management and allowable forage use levels at the site-specific scale would be made during the allotment management planning process.

Under all alternatives, the permitted use of the existing active grazing allotments would continue. However, animal unit month levels may be reduced as site-specific allotment changes are needed. Based on current rangeland and riparian conditions and the need to revise or review allotment management plans for allotments, changes in the amount of permitted animal unit months are difficult to predict. Project-level analysis and allotment-specific monitoring will continue to determine site-specific prescriptions, future stocking rates, and other management adjustments to meet desired conditions under all alternatives. Permitted animal unit months over the long term could possibly decrease under all alternatives due to more intensive management of riparian areas or habitats for threatened, endangered, or at-risk species. Should additional allotments become vacant in the future, they could be considered for use as forage reserves, opportunities to enhance management or improve resource conditions through combination with adjacent allotment(s), retention of vacant allotment status for potential use demands in the future, or allotment closure based on resource conflicts, conservation opportunities, or economic considerations.

Forage Production and Availability

Management direction under all alternatives allows for some level of vegetation treatments, such as timber harvest, prescribed fire, and to allow wildfire to provide resource benefits where feasible. Vegetation should move towards a desired mix of conditions from these treatments and thus provide a secondary benefit of improving forage conditions and transitory range in the future.

Conifer canopy closure, conifer and shrub encroachment into grasslands and meadows, and the spread of invasive plant species all can reduce available forage for livestock. The degree to which future management actions address each of these ecological processes would influence the potential loss or increase in available forage. For the foreseeable future, management under any of the alternatives would continue to provide forage production and productive livestock grazing. Acres available for livestock grazing would be the same under all alternatives. Grazing use would be managed similarly in all alternatives.

Climate Change

Over the life of the plan, certain environmental influences may negatively impact rangeland health and forage production. If climatic temperatures significantly increase, there may be changes in vegetation resulting in a shift from more mesic, moist plant associations to more xeric, dry communities. As a result, it is expected that bare ground may increase within these plant communities as rangeland sites become drier during extended periods of drought (Pellant et al. 2004). Invasive plant species would likely continue to spread and increase in abundance and density. Timber canopy may continue to close in areas where wildfires or other disturbances do not occur, and some grasslands and shrublands may see additional conifer encroachment and conversion to a conifer-dominated community. Conversely, there is potential that wildfire may play a larger role in shaping vegetation in some areas, perhaps promoting non-forested vegetation communities, particularly given warmer climate regimes. Transitory range acreage may fluctuate as forested stands become more open due to timber harvest, fuels treatments, insects, disease, and wildland fire. Over time and through succession, forest canopies would likely close in once again until the next disturbance.

Climate change may affect vegetation, which in turn could affect livestock grazing. Potential effects include, but are not limited to, changes in type, amount, and distribution of precipitation, which directly affects type, abundance, and distribution of vegetation. Lower-elevation grassland and shrubland habitats are expected to become drier and habitat zones shift upward in elevation (Finch 2012). The result of these potential changes could be an increase in suitable forage for cattle grazing at higher elevations within an allotment. On the other hand, lower elevation rangeland communities may mature earlier in the season, resulting in reduced palatability earlier in the grazing season. Reduced palatability, combined with warmer temperatures, could affect livestock distribution and potentially increase livestock concentrations in riparian and meadow areas. Additional livestock management may be necessary to avoid riparian use levels being reached earlier than anticipated, increasing the risk of removal of livestock from the pasture or allotment earlier than the permitted off date.

Increases in atmospheric carbon levels and higher temperatures would likely make invasive species, especially annual grasses, more competitive and adaptable, which may allow some species to expand to higher elevations as well as become more difficult to control due to reduced chemical efficacy (Ziska et al. 2004). Not only will some species become more invasive, but the array of species would continue to change (Scott et al. 2013).

It is possible for climate change to impact resource use within a short timeframe, which could change the suitability and utilization of forage. For example, there have been periods of increased summer temperature and decreased summer precipitation over a 15- to 20-year planning period which would indicate that the potential for changes in the suitability and utilization of forage within a grazing allotment may change within a planning period. This could cause beneficial or negative impacts to the permitted use of a grazing allotment for suitability and utilization. Annual fluctuations of temperatures and precipitation would affect forage palatability under all alternatives.

Temperature is projected to increase 5 to 10 degrees Fahrenheit by 2100 in the Western Rockies subregion, including increases in both the annual mean monthly minimum and annual mean monthly maximum (Halofsky, Peterson, et al. 2018a, b). Heat stress inflicts heavy economic losses on livestock production through reduced feed consumption, reduced production efficiency in terms of weight gain, and reduced reproductive efficiency.

Although rangeland managers and permittees are already experienced with harsh and variable conditions, they may not be prepared for the accelerating and exacerbating impacts under future climate change (Ash et al. 2012). The impacts to livestock grazing from climate change remain to be fully understood. However, the Forest Service has a variety of administrative tools to help adapt to unexpected situations, as well as short- and long-term changes in resource conditions. Examples of administrative changes include stocking adjustments and adjusting management practices. The impact of climate change to livestock grazing could include limited use of allotments due to less available forage or rapid seasonal changes in palatability. Livestock grazing operations will most likely need to increase flexibility for uncertainty, variability, and increasing stress from individual factors in the face of changing climate. See section 3.2.3 Climate Change and Carbon for more discussion.

The effects from climate change on livestock grazing would be the same for all alternatives, although the Action Alternatives speak to and incorporate climate change adaptation and offer potential adaptation strategies in Appendix G.

Effects of the No Action Alternative

Management Direction under the Current Plans

The existing 1987 Nez Perce Forest Plan (U.S. Department of Agriculture 1987b) and the Clearwater Forest Plan (U.S. Department of Agriculture 1987a) provide the current direction being used by the Nez Perce-Clearwater to address livestock grazing. Both the Nez Perce and Clearwater forest plans projected increases in animal unit months due to increases in transitory range from increased early seral openings created by timber harvest.

The Clearwater Forest Plan goal for rangelands is to manage livestock grazing land consistent with the protection and management of other resources. The Clearwater Forest Plan contains the following standards for range:

1. Coordinate livestock grazing on timber cutting units as necessary to provide for tree regeneration. Livestock grazing on lands designated for timber production may be permitted if the silvicultural prescription and allotment management plan are specifically designed to meet regeneration goals.
2. Construct roads across permanent range meadows only if no other feasible alternative exists.
3. Control noxious weeds on a case-by-case basis if their presence may conflict with the range resource or become detrimental to other resources and uses.
4. Develop water sources outside riparian areas to obtain livestock distribution.

The Nez Perce Forest Plan goal for rangelands is to provide a sustained yield of resource outputs at a level that will help support the economic structure of local communities and provide for regional and national needs. The Nez Perce Forest Plan contains the following standards for range:

1. Coordinate livestock grazing on timber harvest units as necessary to provide for tree regeneration. Livestock grazing on lands designated for timber production may be permitted under one of the following conditions: a) Regeneration is established and is of adequate size or b) the silvicultural prescription and allotment management plan are specifically designed to meet regeneration goals.
2. In areas with poor or fair range conditions, intensive grazing systems, range improvements, and reductions of stock will be implemented to improve conditions.
3. Implement a weed control program to confine present infestations and prevent establishment of new areas of noxious weeds. The Nez Perce will favor biological control for noxious weeds that have effective host insects. Where biological control is not effective, a combination of hand grubbing and spot application of herbicides will be used. This program will be coordinated with

county, state, and other federal agencies. All National Environmental Policy Act requirements will be completed prior to using any herbicides.

4. Extend or build fences to maintain control of livestock when management activities, such as timber harvest, remove natural allotment boundaries.
5. Complete range analysis and allotment management plans every decade for all allotments.
6. Provide forage for elk needs in allotment management plans on all allotments that include elk winter range. The assumption is made that available forage is not a limiting factor on summer habitat.
7. Use grazing systems and cultural practices to reduce erosion by maintaining, improving, or reestablishing vegetative cover.
8. Minimize adverse impacts on riparian areas by maintaining or developing intensive grazing systems.

Both the Nez Perce and Clearwater forest plans included goals and standards for livestock grazing in specific management areas, such as administrative sites, developed recreation sites, timber production ground, big game summer and winter range, high fishery areas, the Lolo Trail, designated wild and scenic rivers, designated wilderness, research natural areas, and riparian areas. Standards ranged from not allowing livestock grazing to allowing, but with certain restrictions.

In 1995 the Nez Perce and Clearwater national forest plans were amended to implement an interim strategy for managing anadromous fish-producing watersheds on National Forest System lands. The following standards protect or minimize effects to listed fish from livestock grazing, primarily in riparian areas:

1. GM-1: Grazing practices, such as accessibility of riparian areas, length of grazing season, stocking levels, or timing of entry shall be modified if the practice retards or prevents attainment of Riparian Management Objectives or are likely to adversely affect listed anadromous fish. Grazing may be suspended if modified practices are not effective in meeting Riparian Management Objectives and avoiding adverse effects on listed anadromous fish.
2. GM-2: New livestock handling or management facilities will be located outside of Riparian Habitat Conservation Areas. Assure existing livestock handling or management facilities inside Riparian Habitat Conservation Areas do not prevent attainment of Riparian Management Objectives or adversely affect listed anadromous fish. Facilities will be relocated or closed where Riparian Management Objectives cannot be met.
3. GM-3: Livestock trailing, bedding, watering, salting, loading, and other handling activities will be limited to areas and times that will not retard or prevent attainment of Riparian Management Objectives or adversely affect listed anadromous fish.

Effects of the No Action Alternative

Under the current plans, grazing management as outlined in the affected environment section would continue, with revisions of allotment management plans and associated protections for other resources following direction from the existing plans. Grazing management would continue to provide the livestock animal unit months authorized in term Forest Service grazing permits. The current plans allowed for increasing the amount of animal unit months across the national forests, mainly from the transitory range being created from timber harvest. However, riparian and aquatic concerns would most likely keep permitted animal unit months stable or slightly reduced as more allotment management plans are updated and management prescriptions are improved to move riparian areas toward desired conditions.

Permitted Livestock Use

Under the No Action Alternative, permitted animal unit months for cattle would remain at current levels. Approximately 29,861 animal unit months are authorized to graze under term grazing permits on 36 active allotments. There is also a term permit for domestic sheep grazing on the Allison-Berg Allotment, authorizing 2,875 animal unit months. The permit was modified to non-use for domestic sheep grazing in 2009 due to potential conflicts with native bighorn sheep. Under the No Action Alternative, the non-use agreement for the Allison-Berg Allotment for domestic sheep grazing would remain in effect until site specific National Environmental Policy Act analysis examines the compatibility of domestic sheep grazing in core bighorn sheep habitat. A subsequent record of decision would be made regarding suitability of domestic sheep grazing and would describe any appropriate conditions and constraints necessary to mitigate conflicts.

Forage Production and Availability

Transitory forage is produced each year within the forested habitat types in those areas where canopy cover allows adequate sunlight for grass and browse production. The total production of forage from transitory range is generally consistent from one year to the next; as the forest canopy on some sites begins to close, the forested canopy on other sites is opening due to timber harvest, wildland fire, or insect and disease. Under the No Action Alternative, the present forested canopy may be closing at a rate faster than in past decades due to reduced annual timber harvest and prescribed fire acres. This could result in a gradual reduction in transitory forage. The current level of timber harvest of approximately 4,300 average annual acres and prescribed fire of approximately 5,560 average annual acres will form the baseline for comparison of transitory forage production with the proposed Action Alternatives.

Allotment Management Complexity

Presently, grazing allotments are managed to achieve protection and enhancement of a variety of resources. Each grazing allotment has its own unique set of management requirements to address the resources within its boundaries. Most grazing allotments have some comparable management requirements associated with common resources, such as riparian and upland forage. Some allotments have management requirements associated with a less common resource element, such as wilderness, wild and scenic rivers, and rare plant habitat. Under current management, grazing permittees understand and anticipate the amount of time and money it would require to adequately manage livestock within their allotment. The current level of allotment management under the No Action Alternative forms the baseline for comparison with the Action Alternatives.

In summary, under the No Action Alternative grazing management as outlined in the affected environment section would continue, with revisions of allotment management plans and associated protections for other resources following guidance from the 1987 plans. Grazing management would continue to provide the livestock annual unit months authorized in term grazing permits. The 1987 plans allowed for increasing the amount of animal unit months, mainly from the transitory range being created from timber harvest, although riparian and aquatic concerns would most likely keep permitted numbers stable.

Effects Common to Action Alternatives

The plan components that support permitted livestock grazing and use are common for all Action Alternatives. Most of the plan components associated with forage production and availability and rangeland health are also the same for all Action Alternatives. The complexity of allotment management that could result from aquatic ecosystems plan components are the same for all Action Alternatives.

Permitted Livestock and Grazing Use

Many rural communities continue to be dependent upon ranching for their economic livelihood and many of these ranches rely on federal land grazing for a portion of the season. Continuance of livestock grazing could help to sustain businesses and employment opportunities.

The Land Management Plan Action Alternatives acknowledge the contribution of livestock grazing to the social and economic sustainability of local communities (FSH 1909.12 23.23(d)(2)(a)) by including desired condition FW-DC-GRZ-03, which affirms that livestock grazing on the Nez Perce-Clearwater contributes to agricultural businesses and local employment opportunities, as well as supporting traditional lifestyles. The Action Alternatives also include an objective to annually provide conditions which support approximately 29,800 to 34,400 animal unit months, recognizing that allotment site-specific conditions may require adjustments in permitted or annually authorized animal unit months (FW-OBJ-GRZ-01). Examples of conditions that may result in adjustments include wildland fire, drought, vacant allotment conversions, vacant allotment closures, or increases in transitory forage within grazing allotments.

Forage Production and Availability

The 2012 Planning Rule requires that Land Management Plans must include plan components for integrated resource management to provide for ecosystem services and multiple uses, such as forage for grazing (36 CFR 219.10(a)). The Action Alternatives include desired conditions for the Nez Perce-Clearwater to provide forage for domestic livestock grazing consistent with the capacity of the land to produce sustained forage for multiple uses (FW-DC-GRZ-01) and that transitory forage within grazing allotments is available for livestock grazing following the reduction in conifer overstory from fire and timber harvest (FW-DC-GRZ-02).

To allow forage plants to maintain vigor, root development, and soil cover, guideline FW-GDL-GRZ-03 specifies that general upland forage utilization should not exceed 35 to 55 percent. Specific utilization guidelines should be applied during grazing allotment authorization or reauthorization, which consider variables such as ecological condition of the vegetation, timing and duration of use, and other resource values in the area. Forage utilization values should be adapted over time based on long-term monitoring and evaluation of conditions and trends.

Allowable use in current term grazing permits are within the ranges required by the FW-GDL-GRZ-03, so grazing permits would not need to be modified in the short-term. As allotment management plans are revised, the appropriate level of utilization would be determined for the specific allotment, but within the ranges proposed in the revised forest plan. Factors that would be considered for utilization during allotment management plan development, include site-specific ecological conditions, vegetative health, timing and duration of use, and other resource values in the area.

The Nez Perce-Clearwater contains a mosaic of forest, grassland, meadows, and shrubland vegetation. Meadows, grasslands, and shrublands support native plant communities and forage for livestock and other animals within the planning area. These non-forested areas provide the bulk of the forage capacity on many grazing allotments within the Nez Perce-Clearwater. Livestock have a natural tendency to graze these areas as they are generally accessible and provide palatable and nutritious forage. The Land Management Plan includes six desired conditions that promote meadows, grasslands, and shrublands health (FW-DC-GS-01 to 06). These desired conditions cover bluebunch wheatgrass habitat type groups, fescue habitat type groups, xeric shrubland habitat type groups, wetland graminoid and riparian shrub habitat type groups, and vegetation occurring on Mollisol soils. The desired conditions also emphasize invasive plant species either are not present or occur with low cover, and conifers are absent or occur as scattered individuals. The Land Management Plan includes an objective to maintain existing meadows and grasslands by reducing conifer encroachment into meadows and grasslands on a minimum of 500 acres every 5 years (FW-OBJ-GS-01).

Invasive plant species have the potential to substantially decrease livestock forage by displacing native plants, especially in the grasslands and the warm dry forested vegetation types. The prevention, detection, control, and restoration program for invasive species is the same for all alternatives as described in the Invasive Species section. Although the No Action Alternative includes direction for noxious weed control, the scope and objectives were limited. The Action Alternatives include a desired condition promoting invasive species either are not present or occur at low levels to allow watersheds, vegetation communities, and aquatic ecosystems to retain their inherent resilience and resistance to respond and adjust to disturbances. Plant communities retain their historic diversity and provision of values to fauna (FW-DC-INV-01).

To reduce the probability of establishment or expansion of invasive weeds, guideline FW-GDL-INV-01 requires management activities prone to significant soil disturbance or exposure to be planned and implemented with design features to address the potential spread of invasive weeds. All Action Alternatives have the same objective of treating 6,000 acres annually to contain or reduce non-native invasive plant density, infestation area, or occurrence (FW-OBJ-INV-01). Despite aggressive invasive species treatments, invasive plant species may continue to persist and possibly expand in some remote areas. Forage production for livestock may decline in future years, but overall forage capacity should remain adequate for current levels of permitted grazing animal unit months for the next 15 years.

Allotment Management Complexity

Protection of threatened or endangered species habitat and associated riparian areas may have the largest influence on livestock grazing on federal lands. The Land Management Plan recognize potential adverse interactions between domestic livestock and native species and provides appropriate plan components to avoid or mitigate these risks. (FSH 1909.12 23.23(d)(1)(e). The aquatic ecosystems plan components have the potential to increase allotment management complexity.

Some permittees could be economically affected if conditions on their allotment require more intensive management actions or a reduction in stocking in order to manage for improved riparian and at-risk aquatic species habitat. To address protection of threatened or endangered species habitat and riparian and stream habitat improvement needs, changes in livestock management may require constructing additional range infrastructure and water developments, adjusting forage use levels, or increasing herding efforts in addition to routine management practices. All these actions cumulatively increase the overall permit administration cost for a grazing permittee.

Riparian Areas

Management and protection of aquatic ecosystems, including riparian and wetland communities, are emphasized under all alternatives. Standard FW-STD-WTR-04 specifies that where aquatic and riparian desired conditions are being achieved, projects shall maintain those conditions. Where aquatic and riparian desired conditions are not yet achieved, and to the degree that project activities would contribute to those conditions, projects shall restore or not retard attainment of desired conditions. The phrase "do not retard" is described as not disrupting or setting back natural rates of recovery.

Standard FW-STD-ARGRZ-01 necessitates livestock grazing to be authorized or reauthorized only when measures are included in the authorization to avoid or mitigate adverse effects to fish and riparian habitat that may result from grazing practices. Where livestock grazing is found to prevent or retard attainment of aquatic and riparian desired conditions, grazing practices shall be modified by practices such as adjusting accessibility of riparian areas to livestock, length of grazing season, stocking levels, or timing of grazing. Additionally, where livestock trailing, bedding, watering, salting, loading, off road vehicle use for managing or gathering livestock, and other related activities in riparian management zones are adversely affecting aquatic resources, annual operating instructions shall include measures to mitigate or relocate to other areas or times (FW-STD-ARGRZ-02). To reduce localized impacts resulting from concentrated livestock use and associated trampling, guideline FW-GDL-GRZ-01 specifies that livestock salting should be excluded from riparian areas, meadows, designated sensitive plant habitat, seedling conifer regeneration areas, aspen restoration areas, and prescribed restoration areas.

Table 384 provides acres of riparian management zone within active allotments and the percent of riparian areas within each active allotment. Approximately 13 percent of active grazing allotments on the Nez Perce-Clearwater are located within riparian management zones.

Over the last 20 years, much has been accomplished to protect aquatic resources through altering grazing practices. This has occurred on active allotments through implementation of PACFISH and INFISH standards incorporated into the 1987 forest plans and through revision of allotment management plans. The existing direction for anadromous fish and riparian management in the No Action Alternative and the proposed plan components for aquatics ecosystems in the Action Alternatives specify stringent management requirements for livestock grazing. Allotments with greater amounts of riparian areas, especially those with salmon, steelhead, or bull trout habitats, necessitate a higher level of management.

Although riparian management does not vary appreciably between the No Action and Action Alternatives, it is a notable consequence to the livestock grazing program on the Nez Perce-Clearwater and to permittees. Implementing and adhering to proposed aquatic ecosystems plan components would add a higher complexity to managing livestock. Impacts to permittees might include increased time, labor, and capital investments in order to consistently meet grazing use levels. Some permittees would be able to meet livestock grazing plan components in the Action Alternatives and as a result be able to graze their permitted season and numbers. Other permittees may not be able to meet standards and may have to reduce livestock use to comply with utilization levels and new management strategies. Over time, some permittees may elect to vacate their allotments due to the workload and financial impacts associated with adhering to aquatic ecosystems plan components.

Low Gradient Streams and Stubble Height

Streams with lower gradients are the most sensitive to grazing impacts (Rosgen 1996). Proposed guideline FW-GDL-ARGRZ-01 establishes minimum end of season stubble heights of 4 to 6 inches along the greenline for low gradient streams. Alternative use and disturbance indicators and values may be used if they are based on site capability, relevant science, monitoring data, and meet the purpose of this guideline.

Stubble height is a meaningful and relatively easily determined metric related to riparian vegetation, has been found to correlate with instream habitat quality (Roper 2020), and has been widely used as an end-of-season monitoring indicator (U.S. Department of Agriculture 2022e). End of season stubble height (greenline vegetation height) has been shown to be a good indicator of two primary factors: 1) the effect of grazing on the physiological health of herbaceous, hydrophytic plants, and 2) the ability of the vegetation to provide streambank protection and bank building function. Stubble height criteria should be used where streambank stability is dependent upon herbaceous plants.

Clary and Webster(1990) recommended that in the Intermountain West, a minimum stubble height of approximately 4 to 6 inches should remain at the end of the grazing season to maintain plant vigor and provide for bank protection and for sediments to be deposited. However, 8 inch stubble height was the optimal length to retain sediment deposits (Abt et al. 1994, Thornton et al. 1997). Similarly, Clary and Leininger (2000) indicated that 4 to 6 inch stubble height would be necessary to protect willow and vulnerable streambanks. Clary (1999) found that 3.9 inches protected most of the stream attributes while 5.6 inches was needed to protect all stream attributes. Higher average stubble height at the end of season is more likely to provide plants with enough growth during the season to retain vigor in the following season (Clary 1995, Boyd and Svejcar 2012). While height at the end of the growing season still needs more study, positive relationships between higher stubble height at the end of the season and stream habitat conditions have been found (Goss 2013).

Table 383 displays the current stubble height objectives directed in annual operating instructions by allotment as established by specific allotment National Environmental Policy Act (NEPA) or allotment management plans. Of the 36 active allotments, 33 allotments have stubble height objectives between 4 and 6 inches, so already meet the guideline. These allotment specific stubble height objectives would be retained until new objectives are established through site specific NEPA, as guided by FW-GDL-ARGRZ-01. Three allotments have a stubble height objective of 65 percent, or 35 percent utilization. Once the revised Land Management Plan is in place, the term grazing permits for these allotments will be modified to meet FW-GDL-ARGRZ-01 with the appropriate level of utilization for each allotment.

As shown in Table 384, there are approximately 416 miles of streams of low gradient streams (based on average of 3 percent gradient) that occur within active allotments, about 15 percent of the total stream miles within active livestock grazing allotments.

Depending on stubble height requirements, some Annual Operating Instructions may require more strict guidance and the transition may necessitate more active management on the part of the permittee. However, oftentimes livestock movement has been triggered by other resource constraints, including herbaceous forage utilization, shrub utilization, or stream bank disturbance. The effect of possibly more restrictive green line stubble heights may be more burdensome to those permittees with more accessible stream reaches within their allotments.

Fish Redds

Proposed standard FW-STD-ARGR-03 states during livestock grazing authorizations, re-authorizations, or updates to annual operating instructions, measures should be included to prevent livestock trampling of fish redds (that is, spawning nests) of federally listed fish species and species of conservation concern. This standard is a refinement of grazing standards GM-1 and GM-3 in current forest plans, as amended by PACFISH and INFISH, highlighting the importance of redd protection. The federally listed fish species on the Nez Perce-Clearwater are Snake River spring and summer Chinook salmon in the Salmon River Basin, Snake River fall Chinook salmon, Snake River sockeye salmon, Snake River steelhead trout, and Columbia River bull trout. As shown in Table 384 and Table 385, federally listed fish occur in 24 out of 36 active allotments and seven out of nine vacant allotments, which accounts for approximately 70 percent of all allotments.

Mitigation measures to protect fish redds from trampling have been implemented on the Nez Perce-Clearwater for federally listed fish species since consultation with the U.S. Fish and Wildlife Service and National Oceanic and Atmospheric Administration Fisheries Service was completed on the PACFISH and INFISH amendments to the 1987 forest plans in 1998 (U.S. Department of the Interior 1998, U.S. Department of Commerce 1998). Additionally, allotment management plans for allotments with federally listed fish species also contain project design measures to restrict trampling of redds from livestock. Annual operating instructions for those allotments containing streams with federally listed species provide specific direction and mitigation measures for protection of redds. These measures include identifying redd locations through redd surveys conducted by Forest Service fisheries biologists. If fish redds are identified, mitigation measures, such as changing the date for livestock entry into a pasture containing active spawning, temporary or permanent fencing of identified redds or areas of redd concentrations, or use of herding by the grazing permittee to keep cattle away from spawning areas, would be implemented. Implementation of proposed plan direction would continue to move resource conditions within allotments toward desired conditions.

Pacific lamprey and Snake River spring and summer Chinook salmon in the Clearwater River Basin were identified as a species of conservation concern in the Regional Forester's Species of Conservation Concern list (Marten 2019). These species are also included in Standard FW-STD-ARGR-03 requiring measures to be included in annual operating instructions to prevent livestock trampling of fish redds. Species of conservation concern fish occur in 19 out of 36 allotments, approximately 56 percent of allotments. No known impacts to lamprey and spring and summer Chinook salmon fish redds from livestock trampling have been documented on the Nez Perce-Clearwater.

As with the protection measures associated with federally listed fish redds, surveys by Forest Service fisheries biologists would be necessary to determine where species of conservation concern fish redds are located. It can be assumed that mitigation measures would be like those agreed to by the U.S. Fish and Wildlife Service and National Oceanic and Atmospheric Administration Fisheries Service for protection of Endangered Species Act listed fish redds. Although these fish species, for the most part, occupy the same rivers as federally listed fish, there would be additional time, funding, and personnel needed to conduct surveys, perform evaluations, and coordinate with other resource specialists. The capacity to conduct surveys and evaluations would be dictated by fiscal year budgets. There is no legal mandate to protect species of conservation concern redds from livestock trampling. As a result, protection measures would be implemented throughout the life of the plan as fish redds are located and prioritized based on vulnerability.

Conservation Watershed Network

The Conservation Watershed Network is intended to provide a pattern of protection across the landscape in which the habitat of Endangered Species Act listed fish and species of conservation concern receives special attention and treatment. Conservation Watershed Networks are the highest priority for restoration actions for the aquatic environment. Twenty of 36 active livestock grazing allotments are located within watersheds included in the Conservation Watershed Network (Table 384). This designation and associated plan components could cause increased allotment management complexity, potentially requiring more time, labor, and funds to administer allotments.

Standard FW-STD-CWN-01 requires that in Conservation Network Watersheds not meeting aquatic and riparian desired conditions, activities shall be designed and implemented in a manner that supports or contributes towards the recovery of federally listed species and the achievement of these desired conditions and does not retard them when evaluated at the HUC12 subwatershed scale. The phrase “do not retard” is described as not disrupting or setting back natural rates of recovery.

Standard FW-STD-CWN-01 is very similar to existing PACFISH standard GM-1, which requires modification of grazing practices that retard attainment of riparian management objectives or adversely affect listed anadromous fish. The Nez Perce-Clearwater has interpreted and implemented PACHFISH standard GM-1 for over 20 years in a manner that allows permitted livestock grazing and riparian and stream habitat recovery to occur at the same time. Permitted livestock grazing and improving riparian and stream habitat conditions are not exclusive. The rate of improvement in the riparian zone may be slower to some degree with the presence of livestock grazing and other multiple uses authorized by the Multiple Use Sustained Yield Act.

Effects that Vary by Action Alternative

The potential change in available transitory forage resulting from the modification of forest canopy cover varies by Action Alternative. The complexity of allotment management that could result from the designation of recommended wilderness and proposed eligible and suitable wild and scenic rivers also varies by Action Alternative.

Forage Production and Availability

The 2012 Planning Rule requires that land management plans must include plan components for integrated resource management to provide for ecosystem services and multiple uses, such as forage for grazing (36 CFR 219.10(a)). Forage is an ecosystem service that provides an important benefit to local communities. Vegetation management, such as timber harvest, prescribed fire, and wildfire can provide transitory forage that would be available for livestock and wildlife grazing. Transitional forage capacity decreases over time as the forest canopy grows back and shades out the herbaceous understory. In general, permitted livestock grazing on the Nez Perce-Clearwater is dependent upon transitory forage within the active allotments. As more transitory forage becomes available, livestock have the tendency to distribute themselves throughout the allotment and reduce their reliance on sensitive areas, such as meadows and riparian areas. With increased availability of transitory forage and improved livestock distribution, grazing permittees may experience less need for persistent management of the allotment and gain a financial advantage.

Timber harvest could also open grazing areas that were previously inaccessible to livestock because of natural barriers. This could result in livestock control and management conflicts. If this were to occur, additional range improvements may be needed to control or influence livestock movements. In addition, if livestock use is inhibiting regeneration of trees through trampling or grazing, livestock may need to be temporarily excluded from these areas, which would offset potential gains in transitory range for a time. FW-GDL-GRZ-01 requires that salting for livestock not be placed in conifer seedling regeneration areas.

The acres suitable for timber production are the most likely to be harvested, although harvest may occur in other areas as well. As noted in Table 370 in the Timber section, only about 70 percent of the livestock grazing allotment acres are suitable for timber production. A mix of silvicultural prescriptions would be used in the harvested areas, including even-aged regeneration, such as clearcut, seed-tree, and shelterwood, and non-regeneration harvest, such as commercial thinning. Transitory forage is available in the openings created by even-aged regeneration harvest. Of the projected timber harvest levels identified in Table 386, about 50 to 70 percent is expected to be even-aged regeneration harvest. Similarly, only a portion of the acres burned through prescribed fire or wildfire would create transitory forage.

Vegetation treatments would need to be within an existing allotment to affect the amount of forage for livestock grazing. Because the locations of treatments cannot be predicted, the projected forestwide acres of timber harvest and prescribed burning shown in Table 386 are used to compare the relative probability of creating transitory range across alternatives. The differences between alternatives are mainly a function of the level of active vegetation management proposed that is expected to maintain and enhance transitory forage. Alternative X proposes the most acres of vegetation treatment, which would correspond to the highest opportunity for transitory forage. Alternative W, the Preferred Alternative, and Alternative Y, in descending order, also propose high amounts of timber harvest and prescribed fire, corresponding to a high potential for transitory forage creation. The No Action Alternative and Alternative Z propose the least amount of vegetation treatment and therefore, a moderate possibility for transitory forage production. There is a high degree of variation, spatially and temporally, in the amount and location of wildfire, therefore calculating the amount of transitory forage created by wildfire is difficult to predict.

Table 386. Projected Vegetation treatments that could create potential transitory forage for livestock grazing.

Management Action	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Timber harvest average annual acres	4,300	12,600	14,000	7,500	3,700	8,825–10,000
Prescribed burning average annual acres	5,560	7,345	8,330	8,020	6,450	6,800
Potential for transitory forage	Low	High	Highest	Moderate	Low	High

Data Source: Overview of alternatives in Chapter 2.

Transitory rangeland is considered as capable range, but conifer regeneration would slowly come back into the harvest units or burn areas within approximately 10 to 20 years. Transitory rangeland would therefore only provide increased forage for approximately a 10- to 20-year timeframe. However, transitory range would improve livestock grazing by providing increased forage and additional foraging areas which would have been inaccessible or void of herbaceous forage prior to vegetation treatment.

Allotments that occur in designated wilderness, such as Butte Gospel and Hanover Mountain, would have no increase in transitory range from timber harvest but instead would rely on wildfire to create openings and maintain grasslands.

Allotment Management Complexity

The complexity of allotment management may vary by alternative due to changes in land designation within allotments, such as recommended wilderness and proposed eligible and suitable wild and scenic rivers. These management designations have the potential to affect access to and within allotments and require more intensive livestock management.

Recommended Wilderness

Recommended wilderness areas are lands that have wilderness characteristics and may be suitable for inclusion in the National Wilderness Preservation System. Recommendation of wilderness through this Land Management Plan is a preliminary administrative determination. Livestock grazing was determined suitable in the recommended wilderness areas in the Land Management Plan action alternatives (MA2-SUIT-RWILD-05). Although recommended wilderness allocation would primarily be administrative in scope for administration of livestock grazing allotments, some of the on-the-ground management practices, especially concerning motorized travel, may be subject to increased review for authorization.

As shown in Table 387, Action Alternatives W, Y, and Z propose 18,251 acres of recommended wilderness in the Cannon Ball Allotment, which comprises approximately 84 percent of the allotment on Nez Perce-Clearwater lands. Currently, 2,750 acres of the total acres within the Cannon Ball Allotment occur in the designated Hells Canyon wilderness area on the Wallowa-Whitman National Forest (Table 382). Action Alternative Z proposes 1,720 acres of recommended wilderness in the American River Allotment, approximately 7 percent of the allotment. Alternative X does not propose any recommended wilderness. There is no recommended wilderness within livestock grazing allotments under the No Action or Preferred Alternatives.

Permittees that have allotments within portions of recommended wilderness, could potentially have increased administrative terms and conditions that make it more difficult to operate as compared to alternatives with less recommended wilderness allocation. Alternative Z has the most recommended wilderness overlap with allotments and would have the most potential for increased allotment complexity, possibly increasing labor and operating expenses and time to manage the allotment. Since these recommended wilderness areas already occur in Idaho Roadless areas, change in access to and within allotments is expected to be minor.

Table 387. Recommended wilderness within active allotments by alternative.

Indicator	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Number of active allotments containing recommended wilderness	0	1	0	1	2	0
Acres of recommended wilderness within active allotments	0	18,251	0	18,251	19,973	0
Allotment Name	na	Cannon Ball	na	Cannon Ball	Cannon Ball, American River	na

Data Source: Data Source: Nez Perce-Clearwater Geospatial Information System database.

As in existing designated wilderness, if recommended wilderness were to become designated wilderness through an Act of Congress, livestock grazing and the activities and facilities necessary to support a livestock grazing program could potentially continue in accordance with Congressional

Grazing Guidelines if deemed suitable. Although permitted livestock grazing is authorized in designated wilderness areas, it is recognized that allotment administration within wilderness areas is often more restrictive, time consuming, and expensive to the permittee.

Eligible and Suitable Wild and Scenic Rivers

Rivers identified as eligible or suitable for inclusion as part of the Wild and Scenic Rivers system will be managed to protect the river-related outstandingly remarkable values identified for the river and protect the free-flowing nature and quality of the water. They will also be managed to maintain their preliminary classifications of wild, scenic, or recreational. These protection measures will be maintained until a decision is made on the future use of the river and adjacent lands through an Act of Congress or a determination that the river is not suitable for inclusion. Livestock grazing is suitable in proposed wild and scenic rivers (MA2-SUIT-E&SWSR-05), although management is required to protect identified river values. Livestock grazing in eligible wild and scenic rivers is also suitable in the No Action Alternative.

Wild and scenic rivers are bounded by a corridor that extends one-quarter mile on each side of the river segment, measured from the high-water mark. Although livestock grazing is allowed in eligible and suitable wild and scenic rivers, due to the importance of the areas, there is added scrutiny. Livestock management may become more time and labor intensive, and livestock grazing impacts may need to be evaluated more often.

Error! Reference source not found. displays the number of active allotments with proposed eligible or suitable wild and scenic rivers and the amount of allotment acres that would occur within the wild and scenic river corridor. The No Action Alternative has the most eligible wild and scenic river acres occurring within active livestock grazing allotments and the most active allotments. This is followed by Alternative Y, W, and Z in respective descending order. There is no recommended eligible and suitable wild and scenic river proposed in Alternative X.

Table 388. Eligible and suitable wild and scenic rivers within active allotments by alternative.

Indicator	No Action[1]	Alt W[2]	Alt X	Alt Y[3]	Alt Z[4]	Preferred[5]
Number of active allotments with eligible and suitable wild and scenic rivers	8	3	0	7	5	1
Acres of eligible and suitable wild and scenic rivers within active allotments	12,382	3,235	0	8,375	6,914	1,733

[1]No Action – Allison-Berg, Butte Gospel, Earthquake, Elk Summit, Hungry Ridge, Meadow-Lightening, Peter Ready, and White Bird Creek allotments.

[2]Alternative W – Allison-Berg, Butte Gospel, and Hungry Ridge allotments.

[3]Alternative Y – Allison-Berg, Butte Gospel, Earthquake, Elk Summit, Hungry Ridge, Meadow-Lightening, and White Bird Creek allotments.

[4]Alternative Z – Allison-Berg, Butte Gospel, Corral Hill, Hungry Ridge, and Meadow-Lightening allotments.

[5]Preferred Alternative – Allison-Berg Allotment.

Data Source: Nez Perce-Clearwater Geospatial Information System database.

If eligible or suitable wild and scenic rivers were to become designated wild and scenic rivers in the future, permitted livestock grazing could continue, but livestock grazing, and associated activities, would have to maintain and not degrade the outstandingly remarkable values for which the river was designated. It is recognized that allotment administration is often more restrictive, time consuming, and expensive to the permittee within areas designated as a wild and scenic river due to the added scrutiny.

Cumulative Effects

Portions of the Nez Perce-Clearwater adjoin other national forests, each having its own land management plan. The Nez Perce-Clearwater is also intermixed with lands of other ownerships, including private lands, other federal lands, and state lands. Management of grazing allotments on adjacent national forests, Bureau of Land Management, and Idaho Department of Lands is generally similar to livestock management on the Nez Perce-Clearwater. Livestock management on private lands can vary widely depending upon the individual resource and financial objectives of the landowner. No integrated ranch plans involving private ranches and Nez Perce-Clearwater allotments exist.

Livestock grazing, timber harvest, or conversion of rangeland or forests on adjacent lands could affect vegetation conditions at the landscape level. Such changes in vegetation composition and structures could potentially affect the land's capability to be grazed. Most public rangelands, including both Idaho Department of Lands and Bureau of Land Management lands, are expected to remain undeveloped and suitable for livestock grazing in the foreseeable future. Private lands surrounding the plan area could potentially be affected by a conversion to agricultural lands or residential development. Development of these private lands could affect wildlife connectivity and overall landscape function of National Forest System lands within the plan area. Future development of private lands adjacent to the Nez Perce-Clearwater boundary could also affect the spread of invasive plant species, increase fire protection responsibilities and costs, as well as increasing the complexity of grazing livestock on the Nez Perce-Clearwater in some areas.

Some adjacent lands are subject to their own resource management plans. The cumulative effects of these plans in conjunction with the Nez Perce-Clearwater Land Management Plan are summarized in Table 389 for those plans applicable to the livestock grazing resource.

Table 389. Summary of cumulative effects to livestock grazing from other resource management plans.

Resource Plan	Description and Summary of Effects
Adjacent National Forest Land Management Plans (U.S. Department of Agriculture 2010d, 2018h, 1987d, 1986a, 2015c)	The forest plans for National Forest System lands adjacent to the Nez Perce-Clearwater include the Payette, Wallowa-Whitman, Bitterroot, Lolo, and Idaho Panhandle National Forests. All plans address terrestrial vegetation. Management of vegetation is generally consistent across all national forests due to conformance with law, regulation, and policy. The cumulative effect would be that the management of vegetation and grazing would be generally complementary. This includes specific landscapes and features that cross Nez Perce-Clearwater boundaries, such as the Snake River canyon, Salmon River canyon, and the Continental Divide.
Bureau of Land Management Resource Management Plans (U.S. Department of the Interior 2009)	Bureau of Land Management lands adjoining the Nez Perce-Clearwater are managed by the Cottonwood field offices. The Cottonwood Bureau of Land Management resource management plan was recently revised. This management plan contains components related to resilient terrestrial vegetation and livestock grazing and would likely be complementary to the plan components for the Nez Perce-Clearwater.
State of Idaho	Lands owned by the State of Idaho and administered by the Idaho Department of Lands and Idaho Department of Agriculture are managed for sustainability of rangeland resources. Grazing systems may be season long or employ a form of pasture rotation.

Resource Plan	Description and Summary of Effects
Idaho's State Wildlife Action Plan (Idaho Department of Fish and Game 2017b)	This plan describes a variety of vegetation conditions related to habitat for specific wildlife species. This plan would likely result in the preservation of these habitats on state lands, specifically wildlife management areas. This plan would interact with forest plans and be complementary to the efforts to manage grasslands and other grazing areas.
County resource management plans	Counties within and adjacent to the plan area have developed resource management plans that describe the desires and objectives of the particular county regarding management of the natural resources located on public lands located within the county. Goals and objectives for livestock management and rangeland health are compatible with the revised Nez Perce-Clearwater Land Management Plan. For example, plans emphasize the desire for continuation of public land grazing while promoting rangeland health. County plans advocate for protecting of traditional economic structures, including agriculture. There is also a shared desire for rangeland plant communities to be dominated by native grasses and forbs.
Soil and Water Conservation Districts	Resource Conservation Plans stress proper grazing management, appropriate livestock stocking levels, and promote vegetation improvement practices.

Based on the predicted increase in public use, it is expected that the impact of recreational uses could increase as the population of local communities increases, and as more people nationwide continue to look for places to recreate. Increased public use, changing values, and potential desire for other uses from National Forest System lands may make grazing on these lands more time consuming and expensive for permittees. Vegetation management and the use of prescribed fire would likely increase to address vegetative health, fuel loads, and public safety. These trends could result in short-term expenses and long-term benefits to livestock grazing.

Livestock grazing, especially for cattle, would continue to be a major component of local economies within the plan area for the foreseeable future. Cattle, and to a lesser extent, horses that graze the national forests during the spring, summer, and fall months, are provided forage from private lands during late fall, winter, and early spring. Forage from private lands during this period is in the form of native grass pasture and irrigated or dry land hay. The availability of private lands in the surrounding area that can provide summer forage is somewhat limited. This demand for grazed forage, especially during the months of June through October, is greater than National Forest System lands can supply. Productive lands associated with the lands surrounding the plan area are generally used for crops, including spring and winter wheat and canola. Demand for grazing on National Forest System lands is expected to remain high, especially for livestock operators whose private lands are adjacent to the Nez Perce-Clearwater.

Native grassland or forest lands converted to grassland near the plan area are generally obligated to cattle grazing. Some of these grasslands may produce forage at less than their full potential due to the abundance of exotic annual grasses and other invasive plant species. Livestock production from the Idaho Department of Lands is expected to stay relatively stable in the plan area for the foreseeable future. Grazing on private lands fluctuates with the market values of beef and the landowner's economic and land management objectives. Grazing on non-federal lands is expected to remain in high demand. Possible future reductions in grazing on Nez Perce-Clearwater lands due to reduced forage capacity from increases in invasive plant species and forest canopy closure, or tighter administrative constraints could put added grazing pressure and demand on private land and Idaho Department of Lands land leases.

Livestock grazing is influenced by the multiple effects described throughout this analysis. These include effects that impact the allocation of forage resources between livestock and wildlife, and adjustments to protect tribal trust responsibilities, riparian areas, fisheries, threatened and endangered species, cultural and historical resources, and water quality. Livestock management must also take into consideration potential adjustments due to drought, wildland fire, and timber harvest. All of these factors add to the complexity and expense for the ranching operations that are permitted to graze livestock on the national forest (Rimbey and Torell 2011).

Livestock management is generally considered more difficult on National Forest System lands than on private lands for many of the reasons previously presented. In addition, the business of livestock management is subject to factors often not under the control of livestock operators, such as tourism; land values and potential subdivision of ranches; labor prices and availability; domestic and foreign demand for livestock products; markets and meat prices; Forest Service budgets and farm programs; fuel prices; predator control; social values; and federal policy. Because of, and in many cases despite of, the effects and unpredictability described above, livestock grazing is expected to continue at, or below, the current permitted level into the future.

Effects to Livestock Grazing from Other Resources

Timber Harvest and Fuels Treatments Management

Timber harvest and fuels treatments activities can create ground disturbance. Any ground-disturbing activity has the potential to expose a site to invasive plant species, leading to a decline of biodiversity and changes in organic matter composition and nutrients. Invasive species have the potential to substantially decrease livestock forage. To reduce the probability of establishment or expansion of invasive weeds, guideline FW-GDL-INV-01 requires management activities prone to significant soil disturbance or exposure to be planned and implemented with design features to address the potential spread of invasive weeds.

Livestock are attracted to forage created by timber harvest openings. If livestock use is inhibiting regeneration of trees through trampling or grazing, livestock may need to be temporarily excluded from these areas. Allotment management could become for time and labor intensive. In addition, guideline FW-GDL-GRZ-01 requires that salting for livestock not be placed in conifer seedling regeneration areas.

Timber harvest could provide beneficial effects to livestock grazing. Timber harvest, primarily even-aged regeneration, and some fuels treatments could provide transitory forage that would be available for livestock grazing. The effects to livestock grazing from timber harvest varies by Action Alternatives. See the forage production and availability in the Effects that Vary by Action Alternative discussion for more information.

Wildland Fire Management

Disruption of historical fire patterns and proliferation of invasive plant species have caused a widespread reduction in rangeland condition and productivity. Wildland fire may act as a natural disturbance factor as well as a valuable management tool for allotment management. It is a key ecological driver in many ecosystems, facilitating nutrient cycling and promoting the growth of grasses and forbs over woody species. Periodic fire maintains a number of major grasslands, shrub steppe, and savanna ecosystems (Maczko and Hidinger 2008).

The land management plan includes a desired condition that expresses the full range of fire management activities, including both prescribed fire and natural wildfire, are recognized and used by Nez Perce-Clearwater administrators as an integral part of achieving ecosystem sustainability, including interrelated ecological, economic, and social components, such as improved ecosystem resilience and wildlife habitat, protection of property, other values at risk, and public safety (FW-DC-FIRE-02).

Prescribed fire is a tool to emulate natural processes and manipulate forested vegetation. It is a management tool often preferred in roadless areas. As with timber harvest, prescribed fire can open existing forest canopies and allow for an increase in herbaceous forage and understory shrub production. All Action Alternatives propose similar levels of prescribed fire, ranging between 6,450 to 8,330 average annual acres, depending on alternative. There is a high degree of variation, spatially and temporally, in the amount and location of wildfire, therefore calculating the amount of transitory forage created by wildfire is difficult to predict.

Prescribed fire and wildfire suppression activities could increase the potential for invasive species introduction and establishment. Guideline FW-GDL-FIRE-02 requires design features to address the spread of invasive species during planned ignitions and direction to follow national and regional guidelines to prevent invasive species transport on wildland fire mobile equipment. To reduce the probability of establishment or expansion of invasive plant species guideline FW-GDL-INV-03 specifies when rehabilitating areas burned by wildfire and affected by wildfire suppression, measures should address invasive species management as part of post-fire habitat restoration.

Wildland fire management can have different short-term and long-term effects on livestock grazing. Effects depend upon burning conditions and burn type, and the results and timing of a wildfire are much less predictable compared to a prescribed fire. Prescribed burning, depending on vegetation type, can often result in an increase in forage production and availability. Areas that are typically grazed may need to defer use prior to a prescribed burn to ensure there is sufficient fine fuels to meet the burn objectives and possibly defer use following a prescribed burn to allow for vegetation recovery, depending upon local conditions. This deferment requires that the permittee be flexible in management and involved in considerable advance planning and coordination. Application of prescribed fire may be more difficult in livestock grazing allotments due to the need to protect fences and water developments.

A wildfire can have similar effects as prescribed fire but is likely to have unplanned adverse effects as well. Wildfire may result in the entirety of an allotment being burned, resulting in forage unavailability, with permittees being forced to move livestock to other lands in their operation (such as private or state). On rare occasions, large, quick-moving wildfires may also overrun livestock that cannot escape, which results in direct financial loss for a permittee. Wildfire may remove allotment infrastructure, which results in direct financial loss for the Forest Service and permittees. Wildfire may remove trees and open forest understories to a flush of grass and forb production for many years. Similar to prescribed fire, wildfire can have the effect of recycling nutrients and improving the quality and quantity of forage for livestock and wildlife. However, since timing, location, and burn conditions are not controllable, wildfires are less likely to provide the same amount of positive effects as prescribed burns. The effects to livestock grazing from wildfire would be similar for all alternatives.

Meadows, Grasslands, and Shrublands Management

The Nez Perce-Clearwater contains a mosaic of forest, grassland, meadows, and shrubland vegetation. Meadows, grasslands, and shrublands support native plant communities and forage for livestock and other animals within the planning area. The land management plan includes six desired conditions that promote meadows, grasslands, and shrublands health (FW-DC-GS-01 to 06). The desired conditions emphasize invasive plant species either are not present or occur with low cover.

The Land Management Plan includes an objective to maintain existing meadows and grasslands by reducing conifer encroachment into meadows and grasslands on a minimum of 500 acres every 5 years (FW-OBJ-GS-01). The beneficial effects from meadows, grasslands, and shrublands management would be the same under all Action Alternatives.

At-Risk Plants Management

Protection of federally listed threatened and endangered plants and other at-risk plants and their habitats has had, and would continue to have, an impact to some grazing allotments. Currently, management direction is in place to protect threatened, endangered, and sensitive plants when potential impacts are determined. As an example, a population of Spalding's catchfly located on Center Ridge within the Christie Sherwin Allotment has been excluded from livestock by fencing for several years.

To ensure adequate protection is given to threatened, endangered, and at-risk plants, proposed guideline FW-GDL-GRZ-02 addresses the need for evaluation and protection of plants and their habitats from livestock grazing. Most grazing allotments on the Nez Perce-Clearwater would not be impacted by the need for protection of threatened, endangered, and at-risk plants. Mitigation measures identified to protect threatened, endangered, and at-risk plants would have relatively minor impacts to grazing allotments and permittees. Protection measures may include small enclosure fencing or minor changes to the grazing system. FW-GDL-GRZ-03 directs that utilization occurs at levels that would maintain vegetative vigor and community health and planning considers the condition, timing, and use of the resource along with other values of the area. This guideline promotes the maintenance of overall health of grassland habitats to prevent habitat degradation which harms at-risk species. The effects from at-risk plant management would be the same for all action alternatives.

Invasive Species Management

Invasive plant species are a serious threat to a variety of plant communities within the Nez Perce-Clearwater. Invasive species have the potential to substantially decrease livestock forage when left unchecked. Impacts are similar between all alternatives, including the current plans. Infestation levels of invasive plants would likely remain steady to slightly increasing over time. Some species may contract in density as new treatment and biological options become available, while other invasive species could expand in range and density.

To reduce the probability of establishment or expansion of invasive weeds, guideline FW-GDL-INV-01 requires management activities prone to significant soil disturbance or exposure to be planned and implemented with design features to address the potential spread of invasive weeds.

Invasive plant species may spread and become established in a number of ways. Pathways are the means and routes by which invasive species are introduced into new environments. Pathways for invasive plant spread can include wind, water, wildlife, humans, pack and saddle stock, motorized and non-motorized vehicles and equipment, and permitted livestock. Invasive plant species spread is occurring both within and outside of active grazing allotments. Since livestock grazing on the Nez Perce-Clearwater is one of several potential pathways influencing invasive plant species spread, permittees would be encouraged to implement invasive plant prevention measures associated with livestock grazing. This may include confining livestock to a weed-free pasture before entering allotments on National Forest System lands, washing vehicles or equipment entering National Forest System lands, restricting off-road travel as part of the grazing permit, and feeding saddle horses weed-free hay during allotment authorized use periods. Access to areas may be temporarily closed or delayed for invasive species management activities. Although these actions may be more labor and time intensive, it could have positive effects for rangeland vegetation and livestock forage under all alternatives.

All action alternatives have the same objective of treating 6,000 acres annually to contain or reduce non-native invasive plant density, infestation area, or occurrence (FW-OBJ-INV-01). Early detection and rapid response to new invaders will be a priority. Protection or enhancement for other resource concerns will be considered when developing invasive weed treatment priorities. Invasive species treatments and prioritization would need to continue to evolve in order to manage new weed species, expanding infestations, and possible herbicide resistance under all alternatives.

Soil Resource Management

Maintenance or restoration of soil productivity or function is emphasized under all Action Alternatives. Desired conditions for soil resources focus on maintaining or restoring soil productivity and function to contribute to the long-term resilience of ecosystems (FW-DC-SOIL-01), maintaining soil organic matter and down woody material (FW-DC-SOIL-02), and retaining the unique properties of volcanic ash-influenced soils (FW-DC-SOIL-03). In addition, standard FW-STD-SOIL-01 specifies that land management activities shall be designed and implemented in a manner that maintains soil function and productivity, and standard FW-STD-SOIL-02 requires that impaired soil function created through management activities shall be rehabilitated to reestablish soil function to the appropriate site potential.

While these proposed plan components provide constraints to the permittees, they are not extensively more restrictive than measures found in the 1987 forest plans and in current allotment direction. Although some soil restoration activities have occurred within allotments over the last 30 years, primarily regarding road decommissioning, soil restoration activities are expected to increase under all Action Alternatives (FW-OBJ-WTR-05). Soil restoration areas could be enclosed by fencing in the short- or long-term depending on site condition.

Management approaches for soil resources in Appendix 4 of the Land Management Plan reference the methods most applicable to determining effects to soils. These include biologic integrity, soil stability, and hydrologic function, which are the main groups of indicators used in the multi-agency technical reference Interpreting Indicators of Rangeland Health (Pellant et al. 2020) compiled by the Bureau of Land Management.

Water Resources Management

The Idaho Department of Environmental Quality uses water quality standards (IDAPA 58.01.02) to determine if Idaho's waters are being adequately protected. The Idaho Department of Environmental Quality 303(d)/305(b) Integrated Report is a compilation of information about the water quality status of all Idaho waters and is a requirement of the Clean Water Act. The most current U.S. Environmental Protection Agency approved report is the 2022 Idaho Department of Environmental Quality 303(d)/305(b) Integrated Report (State of Idaho Department of Environmental Quality

2022b). There are 24 active allotments and seven vacant allotments containing streams not meeting State of Idaho water quality standards and not supporting beneficial uses. Fifty percent of the streams in allotments are water quality limited: 725 miles in active allotments and 266 miles in vacant allotments. Impairments include temperature, sedimentation, *Escherichia coli* (E. coli), and fecal coliform.

Livestock grazing has the potential to increase temperature, sedimentation, *Escherichia coli* (E. coli), and fecal coliform. The proposed Land Management Plan components for protecting water resources are designed to ensure that activities, including livestock grazing, do not impede attainment of desired conditions. Desired condition FW-DC-WTR-05 emphasizes that water quality meets or exceeds applicable state water quality standards, fully supports designated beneficial uses, and is of sufficient quality to support surrounding communities, municipal water supplies, and natural resources. The national forest has no documented lands or areas that are delivering water, sediment, nutrients, or chemical pollutants that would result in conditions that violate the State of Idaho's water quality standards.

To restore watersheds with streams not meeting State of Idaho's water quality standards, the Land Management Plan requires management activities in watersheds with approved total maximum daily loads to be designed to comply with the total maximum daily load allocations following project implementation (FW-STD-WTR-06). To maintain water quality and minimize the sediment that is generated and delivered to watercourses from active livestock trailing, guideline FW-GLD-ARGRZ-02 requires new grazing authorizations and re-authorizations to include measures to relocate or "harden" livestock trail stream crossings and approaches when necessary to achieve aquatic desired conditions. To maintain quality and quantity of water flows to, within, or between groundwater dependent ecosystems, guideline FW-GLD-ARGRZ-03 requires new or reconstructed spring developments be protected from livestock trampling. While these proposed plan components provide constraints to the grazing program and permittees, they are not extensively more restrictive than measures found in current allotment direction, which include the amended 1987 forest plan PACFISH and INFISH standards.

Additionally, project-specific best management practices (BMPs), including both federal and state BMPs, shall be incorporated into project planning as a principal mechanism for controlling non-point pollution sources, to meet water quality desired conditions, and to protect beneficial uses (FW-STD-WTR-02). Best management practices for livestock grazing management can be found in the Soil and Water Conservation Practices handbook (U.S. Department of Agriculture 1988a) and the National Best Management Practices for Water Quality Management on National Forest System Lands Technical Guide (U.S. Department of Agriculture 2012b). Controlling livestock distribution within a pasture or allotment, adjusting season of use to maintain and protect soil and water resources, and moving livestock when prescribed utilization levels are reached are a few examples of best management practices.

Effects of water resources management on livestock grazing are the same for all Action Alternatives. Managing allotments to not increase water temperature, sedimentation, *Escherichia coli* (E. coli), and fecal coliform could become more time and labor intensive for range allotment managers and permittees.

Aquatic and Riparian Ecosystem Management

Management and protection of aquatic ecosystems, including riparian and wetland communities, are emphasized under all alternatives. Standard FW-STD-WTR-04 specifies that where aquatic and riparian desired conditions are being achieved, projects shall maintain those conditions. Where aquatic and riparian desired conditions are not yet achieved, and to the degree that project activities would contribute to those conditions, projects shall restore or not retard attainment of desired conditions.

Livestock management in riparian areas may become more time and labor intensive under the revised Land Management Plan compared to the 1987 forest plans. The proposed Land Management Plan components for protecting aquatic ecosystems are designed to ensure activities, including livestock grazing, do not impede attainment of desired conditions. Standards and guidelines FW-GDL-GRZ-01, FW-STD-ARGRZ-01, FW-STD-ARGRZ-02, FW-STD-ARGRZ-03, and FW-GLD-ARGRZ-01 require new grazing authorizations and re-authorizations to include measures to avoid or mitigate adverse effects to aquatic resources, which may include monitoring and adjustment of grazing practices as necessary to promote healthy aquatic ecosystems. FW-GLD-ARGRZ-02 requires new grazing authorizations and re-authorizations to include measures to relocate or "harden" livestock trail stream crossings and approaches when necessary to achieve aquatic desired conditions. FW-GLD-ARGRZ-03 requires new or reconstructed spring developments be protected from livestock trampling. While these proposed plan components provide constraints to the grazing program and permittees, they are not extensively more restrictive than measures found in current allotment direction, which include the amended 1987 Forest Plan PACFISH and INFISH standards.

Livestock grazing has the potential to create impacts to riparian areas and meadows. These areas are usually grazed first before livestock move to other areas. Riparian areas provide shade and escape from flies, in addition to water and forage. Excessive or concentrated use by livestock in riparian zones can reduce bank stability through vegetation removal and bank trampling, increase soil compaction and erosion, cause stream widening or down cutting, and can change vegetation composition (Platt 1991). Recommendations by Clary and Webster (1990) called for residual stubble or regrowth of at least 4 to 6 inches in height to provide plant vigor maintenance, bank protection and sediment entrapment. Low gradient streams are more sensitive to grazing than are steeper gradient streams. Streams with gradients less than 2 percent, and to a lesser extent, less than 4 percent, are the most sensitive to grazing impacts (Rosgen 1996) because their banks are unconfined by topography (Montgomery and Buffington 1997) and depend upon vegetation to secure streambanks. Proposed guideline FW-GDL-ARGRZ-01 establishes minimum end of season stubble heights of 4 to 6 inches along the greenline for low gradient streams. Alternative use and disturbance indicators and values may be used if they are based on site capability, relevant science, monitoring data, and meet the purpose of this guideline. Stubble height guidelines may place limitations on grazing but would help provide for better vegetation and streambank conditions.

The Land Management Plan also includes objectives to restore 50 to 100 miles of stream and riparian habitat every 5 years (FW-OBJ-WTR-02) and improve soil and watershed conditions on 3,000 to 4,000 acres every 5 years (FW-OBJ-WTR-05). To protect restored areas, enclosures may be used for period of time to exclude livestock from the area. This could mean less forage and more intensive management.

Overall, riparian conditions in grazing allotments are expected to be maintained where they currently meet desired conditions and improve where they do not. When degraded conditions are documented at specific sites, changes to annual operating instructions would be developed to guide attainment of desired conditions. The effect to livestock grazing permittees regarding aquatic and riparian management would be consistent among Action Alternatives.

Wildlife Management

Grazing livestock share habitat resources with big game and other wildlife. There is a 40 to 80 percent dietary overlap between elk and cattle and a similar, though smaller, dietary overlap with deer (Hansen and Reid 1975, Wallmo et al. 1973). Elk grazing patterns have been shown to be strongly influenced by livestock grazing, as they seek areas of forage regrowth following grazing by livestock (Crane et al. 2001). On the other hand, livestock grazing, and associated permit administration, may temporarily displace wildlife, especially elk, from choice foraging areas within an allotment. Competing use for forage and wildlife displacement would be considered and possibly mitigated when developing an allotment management plan, especially in elk calving areas or areas popular for wildlife viewing or big game hunting.

Upland and riparian forage utilization standards found in existing allotment management plans and annual operating instructions are intended to ensure adequate forage remains for wildlife following grazing by livestock. Proposed Land Management Plan guideline FW-GDL-GRZ-03 places limits on the extent of forage utilization by livestock. This proposed guideline is similar to existing utilization standards and should not result in a substantial change to existing management on current livestock allotments. One notable change may be the amount of monitoring may need to increase to demonstrate that guidelines are being met. Upland use levels are rarely exceeded, let alone approached on most Nez Perce-Clearwater allotments, as riparian areas primarily drive livestock management actions.

Livestock management structures, such as fencing, can harm or deter the natural movement of wildlife. To help mitigate the potential risk, guideline FW-GDL-WLMU-02 specifies that new fencing installation or reconstruction should be designed to reduce barriers to wildlife movement, except when fencing is for the purpose of restricting wildlife movement. Water developments are primarily used to help disperse livestock grazing to avoid overgrazing near other watering places. These water developments are also used by wildlife. Although a benefit to wildlife, there is the potential for animals to be become trapped. To reduce the potential risk, guideline FW-GDL-WL-03 stipulates that new and reconstructed livestock water developments should be designed to prevent animal entrapment and facilitate animal escape. Similar management direction for wildlife compatible range structures is currently followed, so the proposed plan components should not result in a noticeable change to existing livestock management.

Disease transmission from domestic animals, particularly domestic sheep and goats, is considered a primary threat to bighorn sheep populations. Standard FW-STD-WL-02 is specific to domestic sheep grazing in the vicinity of bighorn sheep habitat. It states that to prevent disease transmission between wild sheep and domestic sheep and goats, domestic sheep and goat grazing (excluding pack goats) shall not be authorized in or within 16 miles of bighorn sheep occupied core herd home ranges. Under the No Action Alternative, there is a permit for domestic sheep grazing in the Allison-Berg Allotment authorizing 2,875 animal unit months. Although, due to the potential conflict with bighorn sheep, the permit has been modified to not allow domestic sheep grazing until an updated National Environmental Policy Act analysis is complete. The allotment is within a bighorn sheep core herd home range; therefore based on standard FW-STD-WL-02, domestic sheep grazing would not be authorized under all Action Alternatives, so the permit would be terminated. Future sheep or goat grazing in areas greater than 16 miles from bighorn sheep occupied core herd home ranges would require a site-specific risk assessment prior to determining whether to authorize sheep or goat occupancy by permit.

The effects from wildlife management add to the complexity of allotment management. The effects would be the same for all Action Alternatives.

Northern Rockies Lynx Management Direction

The No Action and action alternatives retain the direction for managing Canada lynx habitat from the March 2007 Record of Decision for the Northern Rockies Lynx Management Direction (NRLMD) (U.S. Department of Agriculture 2007e), which provides guidelines for grazing management. Guidelines are designed to minimize potential adverse effects and improve habitat conditions. The U.S. Fish and Wildlife Service found in the analysis included in the biological opinion for the NRLMD that application of the measures in most cases, had no effects or discountable effects to lynx (U.S. Department of the Interior 2017a).

Twelve livestock grazing allotments, all located on the Nez Perce half of the plan area, include lynx habitat. No lynx habitat is located within livestock grazing allotments on the Clearwater. The Northern Rockies Lynx Management Direction contains one objective and four guidelines pertaining to livestock grazing management in lynx habitat. The management direction only applies to occupied lynx habitat. Since the Nez Perce currently has unoccupied lynx habitat, the direction should be "considered," recognizing that lynx may be present, but would not have to be followed until such time as lynx occupy the unit. Any authorization or re-authorization of grazing allotments should consider the management direction.

Table 390 displays the amount of lynx habitat located within livestock grazing allotments. Two allotments that include 60,668 acres of lynx habitat are vacant and are not currently grazed. Approximately 72,627 acres are located in active allotments. Only about eight percent of the lynx habitat in the plan area overlaps with grazing allotments. See the Allotment and Lynx Habitat Overlap map in Appendix A.

Table 390. Acres of lynx habitat by livestock grazing allotment and percent of allotment.

Allotment Name	Status	Acres of Lynx Habitat	Percent of Allotment
Allison-Berg	Active	6,308	17
Butte Gospel	Active	22,261	57
Cannon Ball	Active	4,983	19
Cow Creek	Active	2,589	9
Fiddle Creek	Active	1,253	15
Florence	Vacant	27,681	52
Hanover Mountain	Active	6,387	41
Hungry Ridge	Active	6,218	20
Mallard Creek	Vacant	32,987	89
Papoose	Active	2,416	18
Peter Ready	Active	13,246	28
White Bird Creek	Active	6,967	21
Total	**Vacant**	**60,668**	**n/a**
Total	**Active**	**72,627**	**n/a**

Tribal Trust Responsibilities

The Nez Perce Tribe has ancestral and treaty-reserved rights to uses and resources on the Nez Perce-Clearwater. Indian treaty rights are property rights held by the sovereign Indian tribes who signed the treaties. Under the Nez Perce Treaty of 1855 and subsequent treaties, the Nez Perce Tribe was reserved separate reservation lands but also retained certain rights to hunt, fish, graze, and gather on the lands ceded to the United States. These rights retained on ceded lands are known as "off-reservation treaty rights" or "other reserved rights."

The Land Management Plan includes desired conditions promoting vegetative conditions that provide a sustainable diversity of habitats necessary to provide plant and animal species that are of tribal importance (FW-DC-TT-01), and emphasizing that culturally important botanical species are present and vigorous in quantities that are harvestable and accessible to Nez Perce tribal members (FW-DC-TT-03). Standard FW-STD-TT-01 specifies that agency proposed actions shall consider Treaty Rights and impacts to American Indian religious and cultural sites, practices, and treaty-reserved resources and access to those resources over the long-term.

Tribal trust responsibilities could make allotment management more complex. Maintaining tribal trust responsibilities could constrain livestock grazing in particular locations, especially in meadow and riparian areas. Due to changing climates and potential increase in drought and invasive species infestations, forage and water resources may become more limited, thus intensifying the potential conflict between livestock grazing and maintaining plant species important to the Nez Perce Tribe.

Plan components in the meadows, grasslands, and shrublands; livestock grazing; and aquatic and riparian livestock grazing sections emphasize the need to support native plant communities and forage for animals throughout the planning area and include standards and guidelines to reduce the impacts to resources from livestock grazing and protect important botanical species.

Cultural Resources Management

Livestock grazing can contribute to the deterioration of cultural and historical resources through physical contact, such as hoof action or rubbing on structures. They can also remove or alter vegetation that protects sites from erosion and make these resources more visible for unauthorized collection. In cases where the level of impact is unacceptable, the impacts could be mitigated with fencing, relocation of watering developments, or with changes in grazing management. Under all alternatives, plan components are in place to ensure the protection of cultural and historic sites and resources. If livestock are excluded from a site or forage use levels are reduced, total animal unit months on an allotment may be reduced. The potential for these effects is the same for all alternatives.

Recreation Management

Recreational use is expected to increase on the Nez Perce-Clearwater. Recreation management can alter livestock grazing in several ways. Achieving reasonably uniform livestock distribution across an allotment is one objective of livestock management because it allows the optimal use of available forage. Areas with concentrated human activity are generally avoided by livestock. Concentrated or frequent recreation use along roads and near popular areas can cause livestock to avoid grazing or passing through an area and work directly against a permittee's attempts to distribute livestock evenly. Fences are a common solution but require installation and maintenance and can be costly. Fencing of roadways may result in a safer travelway for motorists and livestock but may also result in a loss of forage available to permitted livestock.

Livestock grazing may annoy some recreationists because of smells, flies, noise, and manure on trails and around campsites. People using camping or picnic sites on the national forest sometimes become concerned with livestock in and around their recreation sites. Cattle are occasionally shot by national forest users, or struck and injured, or killed by vehicles, resulting in a direct economic loss. Livestock grazing was determined not suitable in developed recreation sites (FW-SUIT-REC-06) in the land management plan action alternatives. Livestock grazing was also excluded from developed recreation sites in the No Action alternative. Livestock are generally excluded from developed recreation sites by fencing of campgrounds.

Higher levels of summer recreation could create increased levels of potential conflicts with livestock grazing, and oftentimes may complicate livestock management and make it more expensive. For example, gates may be left open and livestock inadvertently or purposely relocated. Winter recreation and motorized over-snow vehicle use would not impact livestock grazing because the permitted grazing season would not occur during the winter months.

Increased recreational uses on the Nez Perce-Clearwater would most likely make grazing on the national forest more expensive for permittees under any alternative. Livestock allotments are primarily located within the roaded landscapes on the Nez Perce-Clearwater. With expected increases in visitation vehicle collisions with livestock on system roadways and vandalism to range improvement, infrastructure could increase. These effects from recreational use would be the same under all alternatives.

System Road and Motorized Trail Management

The primary impact to livestock grazing from roads and trails management is focused on the level of motorized access to and on an allotment. Generally, the greater ease and availability of motorized access into and throughout an allotment, the more efficient and cost effective it is to manage livestock and maintain structural improvements. Livestock are trailed or trucked to and from grazing allotments along roads, and permittees access cow camps using roads and motorized trails. The effects from road and motorized trail management and maintenance levels would be the same under all alternatives.

Ecosystem Services Management

Ecosystem services are the benefits the National Forests provide to area residents, visitors, and the American public. Ensuring ecosystem services are provided is critical to providing for ecologic, social, and economic sustainability. The Land Management Plan includes a desired condition that is important for promoting sustainable forage for livestock grazing. It states that the Nez Perce-Clearwater provides ecosystem services to area residents and visitors. Key benefits the Nez Perce-Clearwater provides include clean water; clean air; wood products, including timber and firewood; forage; hunting, trapping, and fishing; fish; cultural values, including heritage values, subsistence food gathering, and spiritual and inspirational values; scenery; recreation; and flood control and soil stabilization (FW-DC-ES-01).

Livestock are trailed or trucked to and from grazing allotments along roads, and permittees access cow camps using roads and motorized trails. Generally, the greater ease and availability of motorized access into and throughout an allotment, the more efficient and cost effective it is to manage livestock and maintain structural improvements. The Land Management Plan includes a guideline to help ensure access for management of livestock grazing allotments. Guideline FW-GDL-ES-01 specifies that to provide for social and economic sustainability of rural communities, access to activities such as recreation, hunting, fishing, gathering, egress, and wildfire management should continue to be provided for on routes or in areas designated as open to motorized use in the summer and winter. If a route is identified as adversely affecting aquatic ecological values, rerouting and route improvement should be considered prior to closure, to preserve motorized access opportunities. If a route or area needs to be closed, alternate motorized access to maintain social and economic sustainability of rural communities should be provided. The beneficial effects from ecosystem services management would be the same under all Action Alternatives.

Designated Wilderness

The Nez Perce-Clearwater manages the entire Gospel-Hump Wilderness and portions of the Selway-Bitterroot and Frank Church-River of No Return Wilderness areas (See maps in Appendix 1). The Mallard Creek vacant allotment has a 1 percent portion located within the Frank Church-River of No Return wilderness. There are four grazing allotments that at least partially lie within the Gospel-Hump Wilderness, with almost all of Hanover Mountain Allotment and about half of the Butte Gospel Allotment occurring within the wilderness area. Only about 1 percent of the Florence and Hungry Ridge allotments are located within the wilderness. See Table 382 in the Affected Environment section for more specific information for allotments within designated wilderness.

Minor infrastructure associated with the management of these allotments includes fences, water lines, and water tanks. In designated wilderness, livestock grazing “and activities and the necessary facilities to support a livestock grazing program, would be permitted to continue in wilderness areas, when such grazing was established prior to classification of an area as wilderness” in accordance with Congressional Grazing Guidelines (FSM 2323.2, WO Amendment 2300-90-2). There is to be “no curtailment of grazing permits or privileges in an area simply because it is designated wilderness.” Wilderness designation should not prevent the maintenance of existing fence or other livestock improvements, nor the construction and maintenance of new fences or improvements which are consistent with allotment management plans which are necessary for the protection of the range.

Livestock grazing was determined suitable in the designated wilderness areas in the land management plan action alternatives (MA1-SUIT-WILD-05), per designating legislation and management plans specific to that wilderness area. Livestock grazing in designated wilderness is also suitable in the No Action alternative. The Land Management Plan includes a standard for designated wilderness that specifies management activities within designated wilderness areas shall preserve wilderness character as required by the Wilderness Act, as well as each wilderness area’s enabling legislation and its specific management plan (MA1-STD-WILD-01). Access to and within allotments in designated wilderness areas is more difficult and adds to allotment management complexity. The effects would be the same for all alternatives.

Designated Wild and Scenic Rivers

The Nez Perce-Clearwater administers all or part of three designated wild and scenic rivers. Approximately 3,760 acres, or 15 percent, of the Cannon Ball active allotment occur within the Designated Rapid River Wild and Scenic River. The segment of Rapid River located on the Nez Perce-Clearwater is classified as wild.

Livestock grazing was determined suitable in the designated wild and scenic rivers in the land management plan action alternatives (MA1-SUIT-DWSR-05). Livestock grazing in designated wild and scenic rivers is also suitable in the No Action alternative. Livestock grazing is allowed within the designated river area provided it does not substantially interfere with public use or detract from the values which caused the river to be included in the National Wild and Scenic River System.

Structures and improvements within a wild river area are accepted, if they are necessary to support the range activities, provided the area retains a natural appearance and the structures harmonize with the environment.

Although livestock grazing is allowed in designated wild and scenic rivers, due to the importance of the area, there is added scrutiny. Livestock management may become more time and labor intensive and livestock grazing impacts may need to be evaluated more often. The effects would be the same for all alternatives.

Recommended Wilderness

Recommended wilderness areas are lands that have wilderness characteristics and may be suitable for inclusion in the National Wilderness Preservation System. Congress reserves the authority to make final decisions on wilderness designation. The Forest Service preserves the opportunity for recommended wilderness areas to be included in the National Wilderness Preservation System by protecting and maintaining the ecological and social characteristics that provide the basis for their suitability for wilderness designation.

The Preferred Alternative proposes 258,210 acres of recommended wilderness in three areas, but no livestock grazing allotments occur within the recommended areas. Livestock grazing was determined suitable in the recommended wilderness areas in the land management plan Action Alternatives (MA2-SUIT-RWILD-05). The No Action Alternative specifies to not establish any new allotments in recommended wilderness. Access to and within allotments in recommended wilderness areas is more difficult and adds to allotment management complexity, although recommended wilderness areas are currently within Idaho Roadless Rule areas. Although livestock grazing is allowed in recommended wilderness, due to the importance of the area, there is added scrutiny. Livestock management may become more time and labor intensive and livestock grazing impacts may need to be evaluated more often.

Eligible and suitable wild and scenic rivers

Rivers identified as eligible or suitable for inclusion as part of the Wild and Scenic Rivers system will be managed to protect the river-related outstandingly remarkable values identified for the river and protect the free-flowing nature and quality of the water. They will also be managed to maintain their preliminary classifications of wild, scenic, or recreational. These protection measures will be maintained until a decision is made on the future use of the river and adjacent lands through an Act of Congress or a determination that the river is not suitable for inclusion. Under the Preferred Alternative, the Allison-Berg Allotment is the only allotment containing an eligible or suitable wild and scenic river, which is the Salmon River.

Livestock grazing was determined suitable in the designated wild and scenic rivers in the land management plan action alternatives (MA2-SUIT-E&SWSR-05). Livestock grazing should be managed to protect identified river values (FSH 1909.12, Chapter 80, Section 84.3(10)). Livestock grazing in eligible wild and scenic rivers is also suitable in the No Action Alternative. Although livestock grazing is allowed in eligible and suitable wild and scenic rivers, due to the importance of the area, there is added scrutiny. Livestock management may become more time and labor intensive and livestock grazing impacts may need to be evaluated more often.

Research Natural Areas

Research Natural Areas (RNAs) are permanently established to maintain areas of natural ecosystems and areas of special ecological significance. These protected natural areas include unique ecosystems or ecological features, rare or sensitive species of plants and animals and their habitat, or high-quality examples of widespread ecosystems. There are four research natural areas located within five active livestock grazing allotments and two natural research areas located within three vacant allotments (Table 391). Mud Springs Ridge is a proposed natural research area and would be established through a separate decision by the Regional Forester.

Table 391. Research natural areas within livestock grazing allotments.

Research Natural Area	Allotment	Status	Acres
Four-Bit Creek	Cedar	Active	1.3
Mud Springs Ridge	Cow Creek	Active	277
Mud Springs Ridge	Sherwin Creek	Active	11
No Business Creek	Peter Ready	Active	1
O'Hara Creek	American River	Active	54
O'Hara Creek	Elk/Lick Creek	Vacant	22
Upper Newsome Creek	Hamby	Vacant	2
Upper Newsome Creek	Newsome	Vacant	1190

Data Source: Nez Perce-Clearwater Geographic Information System database.

Livestock is generally excluded from research natural areas in the No Action Alternative. In the 1987 Clearwater Forest Plan, livestock grazing is not permitted in research natural areas. The 1987 Nez Perce Forest Plan excluded livestock grazing unless it was necessary to preserve the vegetation for which the research natural area was established.

Livestock grazing was determined suitable within research natural areas in the Land Management Plan Action Alternatives, as specified in the individual research natural area establishment reports (MA2-SUIT-RNA-06). During project level analysis for allotment management planning, it may be found that smaller inclusions, such as research natural areas, may not be appropriate for domestic livestock grazing when analyzed at the site-specific level. In these instances, livestock grazing may be found to be not suitable or suitable but with restrictions. Protection measures may include small enclosure fencing or minor changes to the grazing system. The effects would be the same for all Action Alternatives.

Geographic Areas Management

The Lolo Trail National Historic Landmark contains two congressionally designated National Historic Trails: the Lewis and Clark National Historic Trail and the Nez Perce (Nee-Me-Poo) National Historic Trail. There are three active allotments on Nez Perce-Clearwater lands that contain portions of the landmark. The Buckner Allotment contains a 283-acre segment of the corridor, while the Cedar Allotment contains 3,990 acres, and the Musselshell Allotment includes 775 acres. The Landmark does extend into the Dan Lee Meadows Allotment, but off Nez Perce-Clearwater lands.

Livestock grazing was determined not suitable within the Lolo Trail National Historic Landmark in the Land Management Plan Action Alternatives, except in the following current active allotments: Buckner, Cedar, and Musselshell (GA-SUIT-NHL-06). Beginning May 2024, the Cedar Allotment will become vacant, and the Musselshell Allotment will be administratively closed. Although livestock grazing is allowed in the Landmark in three allotments, due to the importance of the site, there is added scrutiny and livestock management may become more time and labor intensive, and livestock grazing impacts may need to be evaluated more often. Under the No Action Alternative livestock grazing is allowed in the Landmark but requires specialized livestock grazing management to prevent adverse impacts upon cultural resources and recreation.

The Salmon River geographic area contains all or portions of the Allison-Berg, Butte Gospel, Cannon Ball, Christie Creek, Cow Creek, Fiddle Creek, Florence, Hungry Ridge, Papoose, Peter Ready, Race Creek, Riverview, Sherwin Creek, and White Bird Creek allotments. These 14 allotments cover approximately 191,320 acres of the geographic area.

The Pilot Knob geographic area contains all or portions of the Elk Summit, Meadow-Lightening, and Newsome Creek allotments. These three allotments cover approximately 20,966 acres of the geographic area.

No suitably determinations were made for the Salmon River and Pilot Knob geographic areas in the Land Management Plan. During project level analysis for allotment management planning, it may be found that smaller inclusions, such as geographic areas, may not be appropriate for domestic livestock grazing when analyzed at the site-specific level. In these instances, livestock grazing may be found to be not suitable or suitable, but with restrictions. Protection measures may include small enclosure fencing or minor changes to the grazing system. The effects would be the same for all Action Alternatives.

Special Areas

Special areas are a category of administratively designated areas defined as an area or feature managed to maintain its unique special character or purpose (36 CFR 219.19). Such areas are protected and managed for public use and enjoyment and are identified due to their unique or special characteristics. Special areas are not congressionally designated but are administratively designated by the Chief of the Forest Service, regional forester, or forest supervisor. There are six special areas located in three active and two vacant allotments (Table 392). The Clear Creek Basalt Glades and Sing Lee Fen are newly proposed special areas identified during the revised Land Management Plan process.

Table 392. Special areas within livestock grazing allotments.

Special Area	Allotment	Status	Acres
Clear Creek Basalt Glades	Tahoe-Clear Creek	Active	267
Giant Cedar Grove	Elk Creek	Vacant	44
Lewis and Clark Cedar Grove	Cedar[1]	Active	58
Morris-Perkins Cedar Grove	Elk Creek	Vacant	48
séewisníme (Place of Mussels)	Musselshell[1]	Active	163
Sing Lee Fen	Newsome	Vacant	25

[1]Beginning May 2024, the Cedar Allotment will become vacant, and the Musselshell Allotment will be administratively closed.

Data Source: Nez Perce-Clearwater Geospatial Information System database. There are no suitability determinations made for special areas in the Land Management Plan Action Alternatives. The No Action Alternative also does not determine suitability or provide direction for livestock grazing in special areas. During project level analysis for allotment management planning, it may be found that smaller inclusions, such as special areas, may not be appropriate for domestic livestock grazing when analyzed at the site-specific level. In these instances, livestock grazing may be found to be not suitable or suitable, but with restrictions. Protection measures may include small enclosure fencing or minor changes to the grazing system. The effects would be the same for all Action Alternatives.

Summary of Consequences

The amount of permitted grazing, notable influences on forage production and availability, and allotment management complexity are key factors in determining permitted livestock grazing sustainability. All alternatives maintain the current level of animal unit months.

Forage production and availability are enhanced through creation of transitory forage in allotments and improvement of rangelands by removing encroaching conifers and controlling invasive species. Alternative X proposes the most acres of vegetation treatment, which would correspond to the highest opportunity for transitory forage. Alternative W, the Preferred Alternative, and Alternative Y, in descending order, also propose high amounts of timber harvest and prescribed fire, corresponding to a high potential for transitory forage creation. The No Action Alternative and Alternative Z propose the least amount of vegetation treatment and therefore, a moderate possibility for transitory forage production. All Action Alternatives propose the same upland forage utilization amounts and propose the same amount of encroaching conifers and invasive species.

The aquatic ecosystems plan components included in the Action Alternatives have a high potential to increase allotment management complexity, with a moderate potential in the No Action Alternative. Alternatives W, Y and Z propose increased amounts of recommended wilderness and eligible and suitable wild and scenic rivers within active grazing allotments, potentially adding to the complexity of managing livestock on those allotments affected. The No Action Alternative does not include any recommended wilderness in allotments but has the highest amount of eligible wild and scenic river acres within allotments. Alternative X proposes no recommended wilderness or eligible and suitable wild and scenic rivers. The Preferred Alternative increases the amount of eligible and suitable wild and scenic rivers within active grazing allotments but does not propose any recommended wilderness within active grazing allotments.

Overall, Alternatives X and the Preferred Alternative maintain the current the levels of permitted use, propose a high potential for transitory forage production, and have a lower allotment management complexity compared to other alternatives. Table 136 provides a summary of potential consequences to livestock grazing, by alternative.

3.6 Designated and Recommended Areas

This section includes analyses of potential effects on designated areas, recommended areas, Research Natural Areas, and special areas.

3.6.1 Designated Areas

The term designated area refers to a specific area on a landscape that has been established by statute, regulation, or policy. Once established, the designation continues until a subsequent decision by the appropriate authority removes the designation. Designated areas within the Nez Perce-Clearwater have been given permanent designation to maintain their unique special character or purpose. Some designated areas were established by statute or law, while others were established through other administrative processes. Certain purposes and restrictions are usually established for designated areas, particularly for those areas that have been designated by law.

This section analyzes the effects of a range of alternatives to the following designated areas:

- Designated Wilderness Areas
- Designated Wild and Scenic Rivers
- Idaho Roadless Areas
- National Recreation Trails
- Mallard-Larkins Pioneer Area
- Northwest Passage Scenic Byway, effects to the following designated areas are discussed elsewhere in Chapter 3
- National Historic Landmark and associated National Historic Trails
    - ♦ Lolo Trail National Historic Landmark
    - ♦ Nez Perce National Historic Trail
    - ♦ Lewis and Clark National Historic Trail
- Research Natural Areas

Designated Wilderness

Passage of the Wilderness Act of 1964 established areas of land designated to provide visitors opportunities for solitude, primitive and unconfined recreation, natural conditions, challenge, and risk. Wilderness is also important for the maintenance of species diversity, protection of threatened and endangered species, protection of watersheds, scientific research, and various social values. Nez Perce-Clearwater designated wildernesses include the highest concentration of areas where the sights, sounds, and influence of humans are largely unnoticeable. The existing wilderness areas are managed to preserve wilderness character. Five qualities help describe wilderness character (Landres et al. 2015).

- **Untrammeled.** Wilderness is essentially unhindered and free from modern human control or manipulation.
- **Naturalness.** Wilderness ecological systems are substantially free from the effects of modern civilization.
- **Undeveloped.** Wilderness is essentially without permanent improvements or modern human occupation.
- **Outstanding opportunities for solitude or a primitive and unconfined type of recreation.** Wilderness provides outstanding opportunities for people to experience solitude or primitive and unconfined recreation, including the values of inspiration and physical and mental challenge.
- **Other features of value.** Wilderness may contain ecological, geological, or other features of scientific, educational, scenic, or historical value.

Relevant Laws, Regulations, and Policy

Federal Laws

Wilderness Act of September 3, 1964 (16 U.S.C. 1131-1136): This act provides the statutory definition of wilderness and management requirements for these congressionally designated areas. The act established a National Wilderness Preservation System to be administered in such a manner as to leave these areas unimpaired for future use and enjoyment as wilderness. This act established the Selway-Bitterroot Wilderness.

Central Idaho Wilderness Act of July 23, 1980 (P.L. 96-312, 94 Stat. 848): This act provided for the establishment of the River of No Return Wilderness.

98 S. 2354: This bill renamed the "River of No Return Wilderness" in the State of Idaho as the "Frank Church-River of No Return Wilderness." The bill was signed into law on March 14, 1984 and became Public Law 98-231.

Endangered American Wilderness Act of 1978 (P.L. 95-237, 92 Stat. 40), February 24, 1978: This act provided for the establishment of the Gospel-Hump Wilderness.

National Forest Management Act of 1976, as amended (16 U.S.C. 1600): This act provides that management direction for wilderness be incorporated into forest plans and sets minimum standards for the content of the plans.

Regulation

Wilderness-Primitive Areas (**36 CFR 293**): This regulation defines a wilderness-primitive area and provides direction on objectives; control of uses; maintenance of records; establishment, modification, or elimination of a wilderness area, commercial enterprises, roads, motor vehicle use, grazing of livestock, permanent structures, and commercial services; and other topics.

National Forest Wilderness (**36 CFR 261.18**): This regulation prohibits the following in National Forest wilderness: possessing or using a motor vehicle, motorboat, or motorized equipment, except as authorized by federal law or regulation; possessing or using a hang glider or bicycle; landing of aircraft or dropping or picking up of any material, supplies, or person by means of aircraft, including a helicopter except as authorized by federal law or regulation.

Planning Rule (36 CFR 219.7): This rule states that in developing a proposed plan revision, the responsible official shall identify existing designated areas and determine whether to recommend any additional areas for wilderness designation. Forest plans must include components for appropriate management of existing or proposed designated areas.

Forest Service Manual 2320: This manual provides direction for the management of wilderness.

Methodology

It is assumed that designated wildernesses are retained and will be managed according to enabling laws, regulations, and policy, as well as by Land Management Plan components. This analysis assumes that there will be no changes to designated wilderness boundaries or direction for the life of the plan. Under all alternatives, it is assumed that, when designations and land allocations overlap, management activities would follow the management direction for each land allocation, with the most restrictive direction applying when direction conflicts except where the enabling legislation dictates which direction applies. In the case of the Middle Fork Clearwater wild and scenic river designation and the overlapping Selway- Bitterroot designated wilderness, wilderness direction is to be followed if it conflicts with wild and scenic river direction. For the Salmon designated wild and scenic river and the overlapping Frank Church-River of No Return designated wilderness, the wild and scenic river direction is to be followed if it conflicts with the wilderness direction.

Information sources

Information sources include the Nez Perce-Clearwater geographic information system data for mapping and the National Visitor Use Monitoring project for wilderness recreation trends and data. Note that acreages used in the analysis, which are generated by the geographic information system, differ from U.S. Forest Service official acreages due to refinement of mapping technology between the date of designation and current date.

Analysis area

The geographic scope of the analysis is all National Forest System lands administered by the Nez Perce-Clearwater. All lands within the Nez Perce-Clearwater boundary form the geographic scope for cumulative effects. The temporal scope of the analysis is the anticipated life of the plan.

Indicators and Measures

The alternatives will be evaluated by comparing the following qualitative indicator:

- Effects of the Land Management Plan direction and how well it supports and protects the values associated with the designated wilderness areas.

This indicator is intended to ensure management of designated wilderness on the Nez Perce-Clearwater maintains the five qualities of wilderness character mentioned above.

Affected Environment

Nationally, the Forest Service oversees 37 million acres of wilderness across its National Forests and Grasslands. Currently, the Nez Perce-Clearwater manages approximately 23.7 percent of National Wilderness Preservation System lands within Idaho and 1 percent within the National Wilderness Preservation System. Approximately 1,139,059 acres, just under 30 percent, of the Nez Perce-Clearwater is within three designated wildernesses (Table 393). Portions of the Frank Church-River of No Return, portions of the Selway-Bitterroot, and the Gospel-Hump Wilderness lie within the Nez Perce-Clearwater.

Table 393. Wildernesses with acres on the Nez Perce-Clearwater.

Wilderness	National Forest(s)	Nez Perce-Clearwater acres	Total Acres
Frank Church-River of No Return	Boise[1], Bitterroot, Nez Perce-Clearwater, Payette and Salmon-Challis[2], and Bureau of Land Management lands	110,236	2,359,948
Selway-Bitterroot	Bitterroot, Lolo[3], and Nez Perce-Clearwater[4]	823,151	1,348,663
Gospel-Hump	Nez Perce-Clearwater	205,672	205,672

[1]Management of acres located on the Boise National Forest have been assigned to the Challis National Forest (now combined with the Salmon to form the Salmon-Challis National Forest)

[2]Primary management for the Frank Church-River of No Return is provided by the Salmon-Challis National Forest

[3]Management of acres located on the Lolo National Forest have been assigned to the Bitterroot National Forest

[4]Primary management for the Selway-Bitterroot is provided by the Bitterroot National Forest

Primary recreational activities within the wildernesses include backpacking, hiking, horseback riding, hunting, fishing, and boating. Many visitors use the services of an outfitter and guide operating under Nez Perce-Clearwater special-use permits in wilderness areas.

National Visitor Use Monitoring (NVUM) data regarding wilderness visitation has been collected for the Nez Perce-Clearwater since 2006. Table 394 shows the number and percentage of wilderness visits compared to the total forest visits.

Table 394. Forest and wilderness visits.

Year	Total Nez Perce-Clearwater Visits	Visits within Designated Wilderness	Percent
2006*	689,000	30,000	4.4
2011*	481,000	21,000	4.4
2016	763,000	76,000	10

*Years are combined totals for the Nez Perce and Clearwater National Forests individual NVUM data since the forests were not combined at the time of data collection.

In 2016, National Visitor Use Monitoring data (U.S. Department of Agriculture 2018g) indicated 62 percent of the visitors to designated wilderness were male and 38 percent female. This is very similar to the overall forest visitation gender breakdown of about 60 percent male and about 40 percent female. The largest percentage, 61 percent, of designated wilderness visitors are ages 20 to 59. Those under age 20 represent about 16 percent of designated wilderness visitors, and the remaining about 23 percent of visitors are 60 or older. These age distributions are similar to those for general forest visitation. About 56 percent of forest visitors are 20 to 59 years old, about 16 percent are under age 20, and 28 percent are 60 or older. Comparing by decade, though, indicates that overall forest visitors are often older than designated wilderness visitors. About 20 percent of general forest visitors are ages 60 to 69, the highest percentage of visitors by decade. Comparatively, the highest percentages of designated wilderness visitors are ages 30 to 39 and 50 to 59, comprising 17 percent of each. Designated wilderness visitors ages 60 to 69 represent about 16 percent of visitation. General forest visitors between 30 and 39 and 50 to 59 represent about 15 percent each.

Selway-Bitterroot Wilderness

Congress designated the Selway-Bitterroot as a wilderness area in 1964 encompassing 1,348,663 acres straddling the Bitterroot Mountains and the Idaho-Montana border. The portion on the Nez Perce-Clearwater contains approximately 823,151 acres.

The Bitterroot Mountains form a rugged, glacier-carved border between Idaho and Montana. On both sides of this border is the Selway-Bitterroot Wilderness, the third largest wilderness in the Lower 48 states. Only the 600-foot-wide Nez Perce Trail, an unimproved dirt road also known as the Magruder Corridor, separates the Selway-Bitterroot from the Frank Church-River of No Return Wilderness and forms the southern boundary of the Selway-Bitterroot Wilderness. U.S. Highway 12 forms the northern boundary.

Except for the high crest of the Bitterroot Mountains, the area is dominated by ridges broken with raw granite peaks. Below the ridges are deep canyons covered with thick coniferous forest. Hidden low valleys are rich with old-growth cedar, fir, and spruce, with Ponderosa pine dominating open grassy slopes along the rivers.

Approximately 1,800 miles of hiking, backpacking, and equestrian trails wind through the area providing access to both the Montana and Idaho sides of the mountains, but many trails in the area are unmaintained and rugged. Travel by foot and stock can be challenging but rewarding. The one million plus acres of wilderness provide many opportunities for primitive unconfined recreation and solitude, though many portions of the area are untrailed and rarely traveled. This lack of human presence provides vast tracts of undisturbed habitat for wildlife, such as elk, deer, moose, black bears, mountain lions, and wolves. The Selway-Bitterroot Wilderness and the Frank Church-River of No Return Wilderness make up the core of the Bitterroot Ecosystem Recovery Zone for the federally threatened grizzly bear.

The Selway River, a designated Wild and Scenic river, lies mostly within the Selway-Bitterroot Wilderness. This river rushes out of the mountains of Idaho and is joined by flows from the Moose Creek drainage and lower down the Lochsa River. The Selway is a premier whitewater river offering a wild, remote, and self-reliant river experience.

Frank Church-River of No Return Wilderness

Congress designated the Frank Church-River of No Return Wilderness in 1980, designating 2,359,948 acres divided between the Bitterroot, Nez Perce-Clearwater, Payette, and Salmon-Challis National Forests, as well as the Bureau of Land Management. About 110,236 acres of the wilderness are located on the Nez Perce-Clearwater. Aside from areas of Alaska, nowhere else in the United States provides a wilderness experience to match the sheer magnitude of the Frank Church-River of No Return, the largest contiguous unit of the National Wilderness Preservation System in the Lower 48 states. It is second in size only to California's Death Valley Wilderness, which consists of many non-contiguous pieces. The Frank Church-River of No Return area encompasses and combines two previous Primitive Areas (the Idaho and Salmon Breaks); portions of five national forests; and a small swath of land managed by the Bureau of Land Management. Senator Frank Church played a key role in the passage of the Wilderness Act of 1964 and his name was added to the Wilderness in 1984, shortly before his death.

Two rivers, the Main Salmon and the Middle Fork of the Salmon, as well as other waterways, comprise the heart of the Frank Church-River of No Return Wilderness Area. All the Middle Fork of the Salmon and most of the Main Salmon are designated Wild and Scenic rivers. The Main Salmon forms the southern boundary of the portion of the wilderness within the Nez Perce-Clearwater. The Middle Fork of the Salmon runs north to join the Main Salmon east of the Nez Perce-Clearwater. Reaching 6,300 feet from the river bottom, the canyon carved by the Main Salmon is deeper than most of Earth's canyons, including the Grand Canyon of the Colorado River. This fast-moving waterway has been dubbed the River of No Return. In the northeastern corner of the wilderness, the Selway River flows north into the nearby Selway-Bitterroot Wilderness. Usually trout fishing rates from good to excellent. Unlike the sheer walls of the Grand Canyon, these rivers rush below wooded ridges rising steeply toward the sky, beneath eroded bluffs and ragged, solitary crags.

The Salmon River mountains dominate the interior of the wilderness. Without a major crest, these mountains splay out in a multitude of minor crests in all directions and rise gradually to wide summits. East of the Middle Fork, the fabulous Bighorn Crags form a jagged series of summits, with at least one topping 10,000 feet. The Crags surround 14 strikingly beautiful clear water lakes. Hiking up from the rivers into the mountains brings sudden elevation changes. Great forests of Douglas-fir and lodgepole pine cover much of the area, with spruce and fir higher up and Ponderosa pine at lower altitudes. The forests are broken by grassy meadows and sun-washed, treeless slopes.

This area is a dry country, with as little as 10 inches of precipitation falling near the rivers. As much as 50 inches may fall on the mountaintops, but much of it is snow. Despite the dryness, wildlife abounds. As many as 370 species have been identified in a single year, including eight big game animals.

Wildfire has been allowed to play its natural role in the wilderness. Tens of thousands of acres have burned without the interference of humans, producing a mosaic of vegetation from severely burned timber stands in some areas to lightly burned grass slopes and understory in other areas.

A network of 296 maintained trails, comprising approximately 2,616 miles, provides access to this seemingly endless area, crossing rivers and streams on 114 bridges. This is a paradise for horse packers with 32 Forest Service Roads leading to 66 trailheads. Despite the extensive trail system, an amazing 1.5 million acres remains trail-free. Small planes can land on several primitive airstrips dating back to the days before wilderness designation. Jet boats are allowed on the Main Salmon. Dozens of outfitters offer float, jetboat, horse packing, backpacking, and ski trips through various parts of the wilderness.

There is one vacant grazing allotment that partially lies within the Frank Church-River of No Return wilderness. About 402 acres of the 36,733-acre Mallard Creek allotment lie within the wilderness. This is about one percent of the allotment. This use is allowed and is expected to continue in the future.

Gospel Hump Wilderness

The U.S. Congress designated the Gospel-Hump Wilderness in 1978 through the Endangered American Wilderness Act. It has a total of 205,672 acres, all of which are located on the Nez Perce-Clearwater. The southern boundary of the Gospel-Hump Wilderness is the Main Salmon and the Frank Church-River of No Return Wilderness.

Long before the explorers Lewis and Clark first laid eyes on this region in 1805, the Nez Perce Indians were hunting the elk, deer, and black bears whose descendants still roam here. Discovery of gold in the 1860s brought a flood of miners into central Idaho that did not subside until after the turn of the century. Another brief gold rush occurred during the Great Depression; remnants of gold mining operations are still evident today.

Elevations in the Gospel-Hump Wilderness range from 1,970 feet at the Wind River pack bridge on the Salmon River to 8,940 feet at the summit of Buffalo Hump. The northern portion contains relatively gentle, heavily forested country that sweeps up the glaciated divide between the South Fork of the Clearwater River and the Main Salmon River, which flows out of the nearby Frank Church-River of No Return Wilderness. From the divide, the terrain becomes steep and sparsely vegetated along the Salmon River Breaks.

Moose, mountain goats, bighorn sheep, mountain lions, wolves, and anadromous fish live here. The area sees extreme variations in weather, with temperatures sometimes exceeding 100 degrees Fahrenheit along the Salmon River while snow whitens the high country. Seasonal roads of fair to poor quality surround the wilderness, offering access to trails that lead from the Salmon River Breaks into the high country. Many hikers would classify the high country as very challenging and often impassable due to late snows.

There are four grazing allotments that at least partially lie within the Gospel-Hump Wilderness (Table 395). Almost all of Hanover Mountain allotment, about 50 percent of the Butte Gospel allotment, about 1 percent of the Florence allotment, and less than 1 percent of the Hungry Ridge allotment lie within the Gospel-Hump Wilderness. This use is allowed and is expected to continue in the future.

Table 395. Grazing allotments at least partially within the Gospel Hump wilderness.

Allotment Name	Allotment Status	Wilderness Acres	Total Acres
Butte Gospel	Active	19,125	38,896
Florence	Vacant	340	53,205
Hanover Mountain	Active	15,337	15,472
Hungry Ridge	Active	47	31,521

Data Source: GIS data.

Environmental Consequences

Management of designated wilderness is defined by the Wilderness Act of 1964 (Public Law 88-577), which defined wilderness as a place:

"in contrast with those areas where man and his own works dominate the landscape…where earth and its community of life are untrammeled by man, where man himself is a visitor who does not remain…an area of undeveloped Federal lands retaining its primeval character and influences, without permanent improvements or human habitation, which is protected and managed to preserve its natural condition."

Further direction can be found in the Wilderness Act of 1964, subsequent area specific legislation, Forest Service manual and handbook direction, and in wilderness specific management plans. Project-specific proposals within designated wilderness are also evaluated through Land Management Plan direction and a minimum requirement analysis to evaluate how the proposal may affect wilderness values. Commercial uses of wilderness are controlled by special-use permits and the plans of operation that are required under the special-use permit.

Effects Common to All Alternatives

Direction for wilderness management is detailed in laws, regulations, agency policy, and specific management plans. Therefore, management under the action alternatives, Preferred Alternative, and the No Action Alternative would not differ. There is no change in the amount of designated wilderness under any alternative. All alternatives would maintain and perpetuate the qualities of wilderness character and public values, including, but not limited to, opportunities for scientific study, education, physical and mental challenge, stimulation, and inspiration. A primitive experience would be maintained for all three wilderness areas under all alternatives and natural ecological processes and disturbances would remain the primary forces affecting the composition, structure, and patterns of vegetation. All alternatives would continue to be managed to perpetuate the enduring resource of wilderness and minimize impacts from uses and activities prohibited by the Wilderness Act.

All alternatives would carry forward the need for wilderness patrols, rehabilitation of any impacted sites, wilderness education, and wilderness-specific management plans. These activities are common to all alternatives.

Cumulative Effects

Generally, wilderness areas are in a more natural vegetation condition, in terms of composition and structure, than non-wilderness areas. Large tracts of land relatively free of human-caused disturbance and natural ecological processes and disturbances are the primary forces that contribute to maintaining biological diversity while minimizing the effects of human development on habitat connectivity. Designated wilderness areas on the Nez Perce-Clearwater provide outstanding opportunities to experience solitude and primitive and unconfined recreation, including the values of inspiration and physical and mental challenge. They provide undeveloped areas without permanent improvements or modern human occupation and areas that are essentially free from modern human control or manipulation. The Landscape Assessment completed by the Clearwater Basin Collaborative in 2014 indicates that the disturbance restoration needs within no harvest zones, of which designated wilderness is a part, are about 35 percent of coniferous forests and lower than the percent needed for the suitable timber base of the Nez Perce-Clearwater (Haugo and Benton 2014). This trend is likely to continue as natural processes continue to determine the composition and structure of the wildernesses.

Population growth and development increases the need for public open space. Growth in Missoula and Ravalli counties in Montana; Idaho, Kootenai, Latah, and Nez Perce counties in Idaho; and Asotin and Spokane counties in Washington is likely to increase recreational use of the Nez Perce-Clearwater, which may include an increase in wilderness use. Increased recreational use may impact maintenance of the wilderness character, particularly opportunities for solitude and natural quality. Examples of potential impacts include increased opportunity for crowding in high use areas, soil compaction or erosion, and threats to native plant species from the spread of noxious weeds from sources outside the wilderness. The effects of urbanization and population growth on wilderness use and resource conditions are likely to be gradual and to extend well beyond the planning period. These areas may be affected by management of adjacent lands, such as sights or sounds from vegetation treatments, motorized use, or private development.

Effects to Resource from Other Resources

Land Allocations

Designated wilderness may contain other allocations, such as designated or eligible wild and scenic river corridors or research natural areas. Where land allocations overlap, the more protective direction applies; therefore, wilderness management components and regulations would prevail.

Fire Management

As described in the 1964 Wilderness Act, naturally ignited wildfire should be allowed to burn to maintain or protect the long-term ecological processes of designated wilderness. Where these fires can burn there could be temporary loss of vegetation, short term reduction in water quality due to sedimentation, or short-term air pollution from wildfire smoke; however, these effects are part of the natural ecological processes. Exceptions may occur when a more direct attack is needed to protect life or adjacent property or mitigate risks to responders. Some fires would require actions to be taken to minimize or mitigate effects to identified infrastructure, cultural sites, or other values at risk, and may require a minimum requirement decision guide (MRDG) to conduct such actions to maintain the wilderness character of the areas. These decisions are documented in the Wildland Fire Decision Support System (WFDSS).

Nevertheless, when natural fires are suppressed in fire adapted ecosystems, there could be detrimental effects to ecosystem processes, wildlife habitat, and biodiversity (Keane et al. 2002).

Vegetative Management

These lands are withdrawn from timber production and, therefore, are not suitable for timber production or timber harvest. There would be no effect to designated wilderness from timber harvest.

Recreation and Access

The Frank Church-River of No Return, Selway-Bitterroot, and Gospel-Hump Wildernesses may be affected by increasing recreational use. Visitors to the wilderness may affect others' solitude and camping may negatively affect vegetation and water quality through site compaction and improper disposal of human waste. In all alternatives, plan components are provided to protect the wilderness character from these potential effects. Plan components prohibit motorized and mechanized recreation use within wilderness, except for the mobility impaired. Stock and hiking use on trails may negatively affect natural vegetation by introducing noxious weeds and may also reduce water quality.

Scenery Management

In all alternatives, the scenery of designated wilderness is protected by plan components. The current plans assigned to wilderness across both forests a visual quality objective of preservation equivalent to a very high scenic integrity objective. In the revised plan alternatives, the scenic integrity objective is very high for all designed wilderness, and, in this respect, the revised plan alternatives are more equally protective of scenery in designated wilderness than the current plans.

Permitted Livestock Grazing Management

Livestock grazing permits and allotments within designated wilderness will not change due to this Land Management Plan. Grazing and necessary facilities to support the grazing within designated wildernesses would continue and remain permitted.

Minerals Management

The Frank Church-River of No Return, Selway-Bitterroot, and Gospel-Hump Wildernesses have been withdrawn from mineral entry and are not available for new leases or claims. Surface and mineral rights within the wilderness are entirely federal.

Designated Wild and Scenic Rivers

Congress passed the National Wild and Scenic Rivers System Act in 1968 (1968) for the purpose of preserving rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The act is recognized for safeguarding the special character of these rivers while also allowing for their appropriate use and development. The act promotes river management across political boundaries and public participation in developing goals for river protection.

For wild and scenic rivers, the designated management boundaries generally average 0.25-mile on either bank in the lower 48 states. The purpose of this 0.25-mile management corridor is to protect river-related values. For management purposes, river segments are classified as wild, scenic, or recreational.

- Wild River: Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.
- Scenic River: Those rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped but accessible in places by roads.
- Recreational River: Those rivers or sections of rivers that are readily accessible by road or railroad that may have some development along their shorelines and that may have undergone some impoundment or diversion in the past.

The Nez Perce-Clearwater has three designated Wild and Scenic Rivers: Middle Fork Clearwater River, Salmon River, and Rapid River. The Middle Fork Clearwater includes the Lochsa and Selway Rivers. Designated Wild and Scenic River acres within the Nez Perce-Clearwater's administrative boundary total approximately 57,891 acres.

Relevant Laws, Regulations, and Policy

Wild and Scenic Rivers Act of October 2, 1968 (Pub. L. 90-542, 82 Stat. 906, as amended): This act established the National Wild and Scenic Rivers System with three classes of river systems: wild, scenic, and recreational. The purpose of the act is to protect the river "for the benefit and enjoyment of present and future generations."

Methodology

It is assumed that designated wild and scenic rivers will be managed according to enabling laws, regulations, and policy, as well as by Land Management Plan components. This analysis assumes that there will be no changes to designated wild and scenic rivers boundaries or direction for the life of the plan. Under all alternatives, it is assumed that, when designations and land allocations overlap, management activities will follow the management direction for each land allocation, with the most restrictive direction applying when direction conflicts, unless otherwise directed through enabling legislation.

Affected Environment

Middle Fork Clearwater River, including the Selway and Lochsa Rivers

On October 2, 1968, Congress designated the Middle Fork Clearwater as part of the Wild and Scenic River System through the Wild and Scenic Rivers Act. This river system includes three uniquely named rivers — the Middle Fork Clearwater River, the Lochsa River, and the Selway River — covering parts of the Nez Perce-Clearwater and Bitterroot National Forests. On the Nez Perce-Clearwater, designated rivers include 64 miles of the Lochsa River from the Powell Ranger Station to Lowell, Idaho; 58 miles of the Selway River from the Nez Perce National Forest boundary with the Bitterroot National Forest near Goat Creek to Lowell, Idaho; and 23 miles of the Middle Fork Clearwater River from Lowell, Idaho, to the Upper Kooskia Bridge in Kooskia, Idaho.

When designated, the five river segments were defined and classified as either wild or recreational segments. No segments were classified as scenic. Those river segments with adjacent roads were designated recreational and the others wild. Of the total five segments, four are within the Nez Perce-Clearwater, as outlined in Table 396.

Table 396. Classification of Middle Fork Clearwater Wild and Scenic River within Nez Perce-Clearwater.

River	Segment	Miles	Classification
Lochsa	Lowell to Powell Ranger Station	64	Recreational
Middle Fork Clearwater	Kooskia to Lowell	23	Recreational
Selway	Lowell to Selway-Bitterroot Wilderness boundary	22	Recreational
Selway	Selway-Bitterroot Wilderness boundary to Nez Perce-Clearwater boundary	36	Wild

Note: This river system contains additional miles within the administrative boundaries of the Bitterroot National Forest.

Under the Wild and Scenic River Act, outstandingly remarkable values were assigned to all segments of the Middle Fork Clearwater River. In 2002, as part of the Snake River Basin water rights adjudication, the outstanding remarkable values were validated for all segments of the river. During the validation process in 2002, the determination was made that all the original outstandingly remarkable values should still be defined for the Middle Fork Clearwater, with one exception. Geology was not defined as an outstandingly remarkable value in 2002 but was in 1968. The other outstandingly remarkable values were defined in both 1968 and 2002. These values include scenery; recreation; fish; wildlife; prehistory, history, and, potentially, traditional and cultural use; water quality; and vegetation and botany.

Scenery Outstandingly Remarkable Value

The Lochsa flows through a narrow, steep-sided canyon surrounded by rugged forested mountains. Many rock outcrops and a steep gradient form rapids. The Black Canyon gorge, with towering granite walls and cascading waterfalls, becomes the focal point during rainy fall and spring periods. Large shrub fields, resulting from the 1910 and 1934 fires, are visible on the upper slopes. These brush fields, along with deciduous trees, provide fall color. The eastern portion of the river corridor is heavily timbered with cedar, larch, Douglas-fir, and other species; the hillsides are more rounded and less rugged but the fall beauty of the larch trees provides contrasting color (U.S. Department of Agriculture 2003d).

The upper Selway River, considered a wild segment, has fast flowing, clear water with numerous riffles and pools. The stream cascades over large boulders and rocks. Rocky outcrops and sheer cliffs rise from the waterline along the river canyon with an occasional open meadow. From Paradise to Selway Falls the river is only accessible by trail. The Wild River Study (U.S. Department of Agriculture 1964) found that "narrow bottom steep-walled canyons possess a beauty difficult to describe with words." The 48-mile segment, from just below Whitecap Creek near Paradise Guard Station to just upstream of Selway Falls, is only accessible by trail through a rugged landscape (U.S. Department of Agriculture 2002d).

The Lower Selway, designated as a recreational segment, begins with Selway Falls. The falls have been described as a place of rare beauty, as white-water tumbles and falls over immense boulders in the narrow canyon (U.S. Department of Agriculture 1964). From here, the canyon widens to create a more pastoral landscape with rolling green hills adjacent to the river. Heavily timbered with cedar, Douglas-fir, and grand fir, the slopes of the lower Selway are intermingled with open, grassy meadows. The river is much wider, with numerous islands and gravel bars. The water's edge and the islands have a variety of coniferous and deciduous vegetative species (U.S. Department of Agriculture 2002d).

The Middle Fork Clearwater has a much broader river canyon than its tributaries, the Lochsa and the Selway. The river is wider and slower moving. The hillsides surrounding the river are rounded and covered to the north by dry grasslands and Ponderosa pine forest and to the south by Douglas-fir and Western redcedar. Near Syringa, Idaho, the vegetative mix changes as elevation and moisture increase. Douglas-fir and Western redcedar forests are interspersed with large brush fields created by fire activity in the early 1900s. This deciduous vegetation provides visual variety in the summer and seasonal color in the fall that enhances the scenic beauty of the river environs. Rock outcrops are found throughout the valley. In the lower portion of the valley, there are unique columnar basalt cliffs adjacent to the riverbanks with basalt formations in the river. The lower river valley, with its gentle topography, allows for broad views of the valley slopes and rock outcrops. The river often appears mirror-like, reflecting the images of the vegetation and rocky ledges found on its banks.

Recreation Outstandingly Remarkable Value

The Lochsa River provides whitewater and scenic floating opportunities, as well as riverside camping and hiking opportunities. The river drops an average gradient of 31 feet per mile with many rapids. The Nez Perce-Clearwater has identified 63 major Class II or greater rapids within the 64-mile length, with more than half that are classified as Class IV (U.S. Department of Agriculture 2002b). On the river, kayakers and rafters dominate recreational use during the peak spring and summer floating season. With many boat launch sites and easy access from U.S. Highway 12, there are different options for single and multi-day trips. In the river corridor, there are nine developed campgrounds with 195 camping units. Highway turnouts provide opportunities for boaters to scout rapids and for visitors to pull over to enjoy scenery. During spring runoff, it is common to see numerous cars parked in the highway turnouts watching huge waves and roiling whitewater as kayakers and rafters run the rapids. Along the Lochsa Corridor, in the 6 miles between Old Man Creek and the Historical Lochsa Ranger Station, five suspension bridges provide foot and stock access via trails to the Selway-Bitterroot Wilderness directly from U.S. Highway 12 (U.S. Department of Agriculture 2002b).

The Selway River drops 7,641 feet in 99 miles. With an average drop of 28 feet per mile in the Upper Selway, the wild river corridor has a considerable number of rapids and high velocity flow with a limited number of slow water recovery pools below rapids. This provides a very challenging and potentially dangerous river, especially during peak flows from mid-May through mid-June (U.S. Department of Agriculture 2002d). This wild segment has only one permitted boat launch per day with up to 16 people, so it provides outstanding opportunities for solitude and a primitive recreation experience (U.S. Department of Agriculture 1976b). The natural beauty of the canyon, combined with the challenge of the rapids and solitude, make the Selway one of the highest quality whitewater float-boating rivers in the country. The wild river corridor is also renowned for stock use and camping, with several trailheads in the river corridor providing access to the Selway-Bitterroot Wilderness (U.S. Department of Agriculture 2002d).

The lower Selway, is the recreation segment, and is readily accessible due to its proximity to the Northwest Passage Scenic Byway, also known as the Lewis and Clark Highway or U.S. Highway 12. This roaded, natural setting provides for both motorized and non-motorized recreation and interaction between users. This corridor provides a wide range of river-related opportunities, including sightseeing, day use, recreational floating and tubing, swimming, picnicking, developed and dispersed camping, fishing, hunting, and hiking on riverside trails (U.S. Department of Agriculture 2002d).

Diverse recreation opportunities abound where motorists, recreation vehicle users, bicyclists, and campers can enjoy dispersed and developed recreation sites along the Middle Fork Clearwater. Easily accessible from the scenic Lewis and Clark Highway, the river corridor affords a wide range of recreation opportunities and access for sightseeing, day use, developed and dispersed camping, fishing, hunting, swimming, and hiking on riverside trails. The calmer waters and the lower elevation of the Middle Fork River provide fishing opportunities for most of the year. It provides a wide range of floating experiences for both commercially permitted and private floaters (U.S. Department of Agriculture 2002d).

Fish Outstandingly Remarkable Value

The Middle Fork Clearwater River and its tributaries play a vital role in the Nez Perce-Clearwater management of sensitive, threatened, and endangered fish species. The Middle Fork Clearwater subbasin is considered a core area for recovery of at-risk salmonids in the upper Columbia River basin. The river and its tributaries provide crucial habitat for threatened and endangered species listed on the Endangered Species Act, including steelhead trout (*Oncorhynchus mykiss* subspecies) and bull trout (*Salvelinus confluentus*). Additionally, spring Chinook salmon (*Oncorhynchus tshawytscha*) have been reintroduced to the river system. Westslope cutthroat trout (*Oncorhynchus clarkii lewisi*) are also present and listed as a U.S. Forest Service Northern Region sensitive species. The Middle Fork Clearwater River functions as a critical migration corridor, connecting the Lochsa and Selway populations of listed fish with the South Fork Clearwater and Lower Clearwater River and tributaries. It provides relatively contiguous distribution of populations and suitable habitat so that the biological needs of the species can be met (U.S. Department of Agriculture 2002c).

Wildlife Outstandingly Remarkable Value

The river corridor provides a diversity of high-quality habitat for wildlife of national and regional significance. Most species rely on habitat conditions alternated by large-scale forest disturbances, particularly fire. The 2002 assessment of Endangered Species Act listed species included the bald eagle, gray wolf, lynx, and grizzly bears (U.S. Department of Agriculture 2002b). The bald eagle and gray wolf have since been delisted due to recovery. Grizzly bears are listed as threatened but not currently occupying the Bitterroot Ecosystem (U.S. Department of Agriculture 2002a). The river corridor and adjacent areas continue to provide habitat for these species. Species of particular interest found in the Middle Fork Clearwater and tributaries include the fisher, Coeur d'Alene salamander, spotted frog, and harlequin duck in the aquatic habitats. Wolverine, bighorn sheep, and Rocky Mountain goats are also present. Critical habitats of the Middle Fork Clearwater River include bald eagle wintering areas and harlequin duck migration routes (U.S. Department of Agriculture 2002c).

Prehistory, History and Traditional/Cultural Use Outstandingly Remarkable Value

Native American people, mostly the Nez Perce, have inhabited and traveled the Middle Fork of the Clearwater for 10,000 years according to cultural resource data. The Lochsa River roughly parallels the "Lolo Trail," which was used by Native Americans as a travel and trade route between the Columbia River basin and the Northern Plains. The Lolo Trail National Historic Landmark is located on ridges north of the Lochsa River and mostly outside the river corridor. Lewis and Clark followed this trail in 1805 and 1806. One of the most significant historical aspects of the Middle Fork Clearwater River is that it was the home and traditional use area of the Looking Glass Band of Nez

Perce. They were involved in the Battle of the Clearwater during the Nez Perce War in 1877 and many fled over the Lolo Trail through Montana (U.S. Department of Agriculture 2002b).

The Landmark encompasses both the Lewis and Clark and the Nez Perce (Nimiipuu) National Historic Trails. The Nez Perce (Nimiipuu) National Historic Trail was designated by Congress to commemorate the 1877 flight of the non-treaty Nez Perce from their homelands in eastern Oregon, Idaho, and Washington. The Landmark and trails are accessed from several points within the Lochsa River corridor (U.S. Department of Agriculture 2002b).

Hundreds of cambium scarred trees remain as evidence from early winter travelers who stripped the bark from trees for food. This use has been documented to have occurred from the early 1700s to the early 1900s.

The rivers are part of the lands ceded by the Nez Perce Tribe in the 1855 treaty. The river corridor is an important area for exercising treaty rights due to the numerous usual and accustomed fishing and camping sites. Members of the Tribe continue to use the river corridor area to hunt; gather roots, berries, and culturally significant plants; and access springs and fountains for drinking or traditional purposes (1855).

In addition to the designated historic trails, properties within the Lochsa corridor are on the National Register of Historic Places. The Lochsa Historical Ranger station complex has been stabilized and interpreted for the public. Additionally, there is a Japanese internment camp where several hundred Japanese-Americans were held for several years during World War II (U.S. Department of Agriculture 2002b).

The Selway corridor is also important for the Nez Perce-Clearwater history, with several historic building complexes that are listed on the National Register of Historic Places. The Moose Creek Ranger Station, near the upper Selway River, is maintained to perpetuate the rustic character of the 1920s. The Fenn Ranger Station was built to accommodate the Selway and Middle Fork Ranger District in 1935. When built, it served as a model for the modern ranger station that would replace the original log structures. This classic station is situated on a serene flat overlooking the Lower Selway River. The Magruder Ranger Station, located on the Upper Selway River on the Bitterroot National Forest, began as a tent camp prior to 1919 and currently serves as a recreation rental and an administrative site. This site is listed on the National Register of Historic Places (U.S. Department of Agriculture 2002d).

Numerous prehistoric Nez Perce religious and cultural sites have been identified in the river corridor, which is within ceded lands for the Nez Perce Tribe and contains values and sites related to religious activities, fishing, hunting, and gathering. There is a strong connection between tribal members and the associated salmon and steelhead fishery. In the 1855 Treaty, the Nez Perce Tribe reserved the right to fish, hunt, and gather roots and berries (1855).

Water Quality Outstandingly Remarkable Value

The Middle Fork Clearwater River, including the Lochsa and the Selway, has exceptionally pure, clear, clean water. In comparison to other rivers in the region, the waters are "unusually clear," except during high run-off and heavy storms. Previous studies found that the "unusually clear" water is one of the principal attractions of the river. The water quality of the Lochsa River is extremely high and supports a healthy and diverse population of aquatic species, including anadromous fish. The clear, cold waters flowing over coarse gravels provide good spawning habitat for resident and anadromous fish. Changes in water quality are linked to natural events, such as fire and climatic extremes (U.S. Department of Agriculture 2002c).

Idaho Department of Environmental Quality direction is to improve or maintain water quality conditions to support beneficial uses. Section 303(d) of the Clean Water Act stipulates that states must identify and prioritize water bodies that are water quality limited, including water bodies that do not meet water quality standards. For waters identified on this list, states must develop a total maximum daily load (TMDL) for the pollutants, set at a level to achieve water quality standards. Table 397 lists the water quality status for the Middle Fork Clearwater, Lochsa, and Selway Rivers, as designated in the Endangered Species Act approved 303(d)/305(b) 2012 integrated report (State Technical Services Office 2012, State of Idaho Department of Environmental Quality 2014). The Middle Fork Clearwater and Selway Rivers have no 303(d) listed streams and are fully supporting beneficial uses (Lucas 2017)

Table 397. Water Quality Status of Middle Fork Clearwater, Lochsa, and Selway Rivers.

River	Status
Middle Fork Clearwater River and approximately 35 tributaries	Fully supporting beneficial uses
Upper Selway River and tributaries	Fully supporting beneficial uses
Lower Selway River	Not assessed
Lower Selway River tributaries	Fully supporting beneficial uses
Lochsa River	303(d) listed for water temperature and not supporting the cold-water aquatic life beneficial use
Lochsa River tributaries (lower portion of subbasin)	303(d) listed for water temperature and not supporting the cold-water aquatic life beneficial use
Lochsa River tributaries (mid and upper portion of subbasin)	Fully supporting beneficial uses

Data Source: 2012 Integrated report (State Technical Services Office 2012, State of Idaho Department of Environmental Quality 2014).

The Lochsa River and several tributaries in the lower portion of the subbasin are 303(d) listed for water temperature. Beneficial uses and water quality criteria and standards are identified in the State of Idaho Water Quality Standards and Wastewater Treatment Requirements (IDAPA 58.01.02). Designated beneficial uses for the Lochsa River are cold-water aquatic life, salmonid spawning, primary contact recreation, domestic water supply, and special resource waters. The stream segments designated on the 303(d) list are not supporting the cold-water aquatic life beneficial use. The State of Idaho standard for cold-water biota includes water temperatures of 72 degrees Fahrenheit or less with a maximum daily average not greater than 66 degrees Fahrenheit (IDAPA 16.01.02250,02.c.ii.). The lack of vegetative shading due to stream adjacent roads is the primary cause of stream temperature exceedance. Although the Lochsa River and its tributaries are not meeting the cold-water aquatic life beneficial use based on state water quality standards, they still support federally listed fish species and other important aquatic organisms.

Vegetation or Botany Outstandingly Remarkable Value

Mild temperatures and abundant rainfall harbor a rare forest ecosystem that is a globally unique combination of Pacific coastal and Rocky Mountain biotic elements. The Middle Fork Clearwater canyons support relics of a 25-million-year-old Miocene flora that once extended across the northwest before the appearance of the Cascade Mountains; the canyons are considered a refugium of the mesic-temperate Miocene flora. The refugium environment is most strongly expressed at the confluence of the Selway and Lochsa rivers where they meet to form the Middle Fork Clearwater River. The lush understory vegetation of the lower slopes and valley bottoms is characterized by maidenhair fern (*Adiantum pedatum*) and a high diversity of fern species.

There are two research natural areas in the designated Lochsa Wild and Scenic River corridor. The Lochsa Research Natural Area preserves examples of the disjunct Pacific coast vegetation that includes the Pacific dogwood (*Cornus nuttallii*) and 14 other species that are rarely found inland. The Dutch Creek Research Natural Area is distinguished by stands of northwest paper birch, which was established after multiple catastrophic burns limited seed sources for conifers. These research natural areas have been used for research of aquatic and riparian plant communities, the refugium ecosystem, and Pacific dogwood (U.S. Department of Agriculture 2002b). The O'Hara Research Natural Area, in the Selway corridor, represents unique habitats and species including coastal disjunct habitat and species. Aquatic features are a primary focus of this research natural area with a network of streams ranging from first to fifth order, anadromous fish, and a series of cascades and waterfalls through narrow canyons and wet streamside meadows used by elk and moose (U.S. Department of Agriculture 2002d).

Other Management Practices

The river corridor includes a variety of recreation sites, including developed and dispersed campsites, river access sites, picnic areas, trailheads, and interpretive sites. In the assessment for the Land Management Plan (U.S. Department of Agriculture 2014i), each recreation site within the Middle Fork Clearwater's corridor was assigned a development standard adapted from the Recreation Sites Development Scale Direction (WO_2309.13.10). The recreation sites located in the river corridors provide a mix of site development levels. The site development levels are generally Level 2, minimal site modification, and Level 3, moderate site modification. The Recreation Facility Analysis and Five-Year Program of Work for the Nez Perce-Clearwater (U.S. Department of Agriculture 2014m) includes a listing of planned changes at each recreation site. There are currently no plans for expansion at recreation sites in the river corridor.

Within the Middle Fork Clearwater Wild and Scenic River system, the Nez Perce-Clearwater has acquired approximately 168 scenic and conservation easements, offering partial land interest of private lands in the Middle Fork Clearwater, Lochsa, and Selway River Wild and Scenic River corridors since the designation of these rivers in 1968. These easements include about 4,000 acres of private lands within the designated river boundaries.

The Wild and Scenic Rivers Act (WSRA) authorizes the Secretary of Agriculture to acquire lands and interests in lands within the authorized boundaries of a wild and scenic river (WSRA, Section 6(a)(1)). These easements were acquired because the Nez Perce-Clearwater "desires to administer such land to protect the scenic, recreational, geologic, fish and wildlife, historic, cultures and other similar values of the free-flowing Middle Fork Clearwater including the Lochsa and the Selway Rivers and their immediate environments and to prevent any developments that will tend to mar or detract from their scenic, recreational, geologic, fish and wildlife, historic, cultural or other similar values" (WSRA, Section 1(b)) (U.S. Department of Agriculture 1976b).

These easements allow the Nez Perce-Clearwater to influence how private lands are managed. The easements restrict land uses that may be inconsistent with river values including development of buildings, management of timber and other vegetation, farming and ranching activities, mining, and road construction. They limit commercial use of lands and buildings; limit residential development to single family residences; restrict building heights; and define colors, building materials, distance from the river, utilities, and signing. Easements require most development and land management activities on these private lands to be approved by the Nez Perce-Clearwater.

Major Roads

U.S. Highway 12 parallels the entire designated length of the Middle Fork Clearwater and Lochsa Rivers and continues east to the Montana border and beyond. Two highway maintenance stations exist within the river corridor, Fleming, and Bald Mountain, and one outside the corridor, Powell. All three are located on Nez Perce-Clearwater land, where a Special Use Permit is required. County Road 223 parallels the lower 5 miles of the Selway River.

Salmon River

The Salmon River was designated a Wild and Scenic River on July 23, 1980, with segments classified as wild and recreational. Of the total 125 miles, 56 miles are located within the Nez Perce-Clearwater. The Nez Perce-Clearwater designated section is located between Salmon Falls and Long Tom Bar near Vinegar Creek and is classified as wild. The remaining portions of the designated river lie within the Salmon-Challis National Forest to the south.

The Salmon River travels through portions of the Gospel-Hump and Frank Church-River of No Return Wilderness areas. The river management plan is incorporated into the Frank Church-River of No Return Wilderness management plan (U.S. Department of Agriculture 2003b). This document meets the requirements of a comprehensive river management plan for the Salmon River. It is important to note that the Central Idaho Wilderness Bill (P.L. 96-312) dictates that the portions of the Wild and Scenic River that travel through these wilderness areas be managed per the Wild and Scenic Rivers Act, not the Wilderness Act, despite the Section 10b of the Wild and Scenic Rivers Act requirement that the more restrictive provisions of either law apply when there is a conflict.

The Salmon River designated segments cover approximately 9,200 acres. In the 1987 Nez Perce Forest Plan, these acres are identified as Management Area 8.1 (U.S. Department of Agriculture 1987c). The Salmon River Resource Assessment (U.S. Department of Agriculture 2000a) validated the following outstanding remarkable values for the Salmon River as part of the Snake River Basin water adjudication process — recreation; geology; fisheries; wildlife; historic, cultural, and traditional uses; water quality; and vegetation.

Rapid River

Rapid River was added to the national Wild and Scenic Rivers System through the Hells Canyon National Recreation Area Act in 1975. When designated, approximately 26.8 miles were classified as wild. The river was designated as part of the National Recreation Area, rather than through a Wild and Scenic River study. As a result, it was not established with outstandingly remarkable values assigned. Outstandingly remarkable values have since been assigned to the river and are specified in the Hells Canyon National Recreation Area Comprehensive Management Plan (U.S. Department of Agriculture 2003a). The plan identified “traditional use/cultural” prehistoric cultural resources, historic cultural resources, scenery, fisheries, and water quality as the outstanding remarkable values for Rapid River and described them in Appendix K of the Final Environmental Impact Statement associated with that plan (U.S. Department of Agriculture 2003a). This document also serves as the comprehensive river management plan for the Rapid River since it identifies outstandingly remarkable values, establishes programmatic direction for these values, and provides specific direction relative to Section 7 of the Wild and Scenic River Act for protecting the river from harmful effects of water resource projects (U.S. Department of Agriculture 2003a).

The Rapid Wild and Scenic River is part of the Hells Canyon National Recreation Area, although it extends eastward beyond the boundary of the National Recreation Area. Approximately 13 miles of the Rapid Wild and Scenic River are located within the Nez Perce-Clearwater. This is the section located between the Nez Perce-Clearwater boundary up to the Hells Canyon Wilderness boundary on the main stem Rapid River and the West Fork of the Rapid River from the confluence up to the Payette National Forest boundary near Wyant Camp. Management of the Rapid Wild and Scenic River is coordinated between the Wallowa-Whitman, Payette, and Nez Perce-Clearwater National Forests (U.S. Department of Agriculture 2003a).

Approximately 4,200 acres of the designated Wild and Scenic River boundary lie within the Nez Perce-Clearwater. The land area within the Rapid River classified river boundary is identified as Management Area 8.3 in the Nez Perce Forest Plan (U.S. Department of Agriculture 1987c).

Rapid River is also located within the boundaries of the designated Rapid River Idaho Roadless Area, which is located on portions of both the Nez Perce-Clearwater and the Payette National Forests. The Idaho Roadless Rule (36 CFR 294) defers to previous management plans for the designated wild and scenic river corridors but applies to the management of the surrounding roadless area. Of the total 78,700 acres in the roadless area, 21,000 acres are located within the Nez Perce-Clearwater. Of these acres, approximately 4,300 acres of designated wild and scenic river corridor are managed under the Land Management Plan special area designation and the remaining 16,700 acres fall within the wildland recreation theme, the most restrictive of Idaho Roadless Rule themes (U.S. Department of Agriculture 2008d).

Environmental Consequences

Effects Common to All Alternatives

Under all alternatives, designated rivers would be managed according to the Wild and Scenic River Act, Forest Service policy, and management area direction for Wild and Scenic Rivers. The three rivers would be managed to protect their free-flowing condition, water quality, and outstandingly remarkable values. Therefore, the management of wild and scenic rivers under Forest Service policy would be the same for the No Action Alternative, the action alternatives, and the Preferred Alternative.

Cumulative Effects

The cumulative effects to the designated Wild and Scenic Rivers within the Nez Perce-Clearwater boundary are assessed based on a spatial boundary of the Nez Perce-Clearwater and the named rivers and streams contained therein. The temporal bound is the life of the Land Management Plan.

Cumulative effects to the designated rivers could result from the expansion of populations in the nearby urban areas. As the population increases, it is likely that the demand for water-based recreational opportunities such as fishing, rafting, kayaking, and similar uses will also increase. As a result, demand for more or larger capacity access points may also increase. Since the designations of the rivers as Wild and Scenic Rivers, water-related activities have been steadily increasing. The pressures of these demands are occurring not only within developed access and recreation sites but in dispersed sites as well. The impacts on these sites are likely to continue to occur since indirect effects to water quality and outstandingly remarkable values may occur.

Management activities generally take place outside of designated wild and scenic rivers unless an action is needed to help protect or enhance the water quality, free-flowing nature, or identified outstandingly remarkable values. Therefore, it is not expected that there will be any additional cumulative direct or indirect effects to the designated rivers unless the effects are in response to a need to protect one of the qualities of the river segments. A site-specific analysis should be conducted at that time to address the effects from that action to the designated river segment.

Effects to Resource from Other Resources

Management Area Prescription

The Wild and Scenic River Act and management area direction for designated wild and scenic rivers protects the free-flowing conditions, water quality, and outstandingly remarkable values for which the river was designated. All alternatives have the same miles of designated rivers.

Fire Management

Wildland fire, both planned and unplanned ignitions, could change the outstandingly remarkable values present in a river segment, especially segments with outstandingly remarkable values of scenery or historic resources. Plan components address using fire as a permissible tool to maintain ecological conditions within river corridors if it protects or enhances the free-flowing conditions, water quality, and outstandingly remarkable values for which the wild or recreational river was designated.

Vegetative Management

Rivers with a classification of wild are not suitable for timber production and timber harvest is not allowed. There would be no effects from timber harvest on those segments. On rivers with a recreational classification, timber production is unsuitable, but timber harvest is suitable for multiple-use purposes, for salvage logging, and to achieve desired vegetation conditions. Any timber harvest would protect or enhance the free-flowing conditions, water quality, or outstandingly remarkable values for which the recreational segment was designated.

Recreation and Access

Impacts from recreational use and management within designated river segments are anticipated to remain about the same or possibly rise as an increasing regional population leads to increasing demand for water-related activities. Although river corridors may be used for camping, canoeing, hiking, and other activities, the impacts are expected to remain at existing levels in part due to permit systems in place along much of the designated stretches of river. On those stretches where permits are not necessary for overnight use, there may be increasing use as the population increases. Creation of new dispersed camping and day-use sites may occur as a result. Trail maintenance work should be expected to have little if any impact in the river corridors. The use of motorized and mechanical equipment on designated Forest Service roads, trails, and backcountry airstrips is prohibited on wild and scenic river segments classified as wild, except as provided for by the authorized officer upon a determination that such use is necessary for the administration of the river or to protect and enhance the values for which the river was designated. Consistent with FSM 2354.420, motorized use may be permitted if such use is compatible with other management direction, public use of the resource, and resource attributes of the river. Motorized use is prohibited if the use causes, or is likely to cause, considerable adverse effects on the resource. Normally, motorized use will be prohibited in a wild river area.

Mineral Development

Anticipated effects from minerals management would be low under all alternatives. In accordance with FSM 2816.3, subject to valid existing rights, the minerals in federal lands within designated wild and scenic rivers are withdrawn from all forms of appropriation under the mining laws, and from operation of the mineral leasing laws, as of the date of the Wild and Scenic Rivers Act or inclusion of a river into the National Forest System.

The potential for leasable minerals is low across most of the Nez Perce-Clearwater, and, currently, there are no permits or operating plans for exploration within the designated river corridors. Although the potential for locatable minerals does exist, there are no valid existing rights, therefore no potential for mining operations within the corridors. Mineral materials are present and could potentially be used for construction purposes, but, generally, proposals for development of mineral materials do not occur and allowing such development would be at the discretion of the Nez Perce-Clearwater.

Idaho Roadless Areas

The 2001 Roadless Rule was published to ensure inventoried roadless areas sustained their values into the future. The roadless areas were initially identified during the Roadless Area Resource Evaluations of 1972 (RARE I) and 1979 (RARE II). The 1970s processes for inventoried undeveloped areas typically exceeded 5,000 acres and met the minimum criteria for wilderness consideration under the Wilderness Act. After the 2001 Roadless Rule, the State of Idaho and the U.S. Forest Service published the 2008 Idaho Roadless Rule, which identified 34 roadless areas across the Nez Perce-Clearwater. Sixteen of these roadless areas are located on the Nez Perce Forest, encompassing 497,000 acres, and 18 are located on the Clearwater National Forest, encompassing 984,000 acres, for a total of approximately 1,481,000 acres of undeveloped area.

Idaho Roadless Rule Areas are managed under the Idaho Roadless Rule of 2008. While a management allocation may allow activities, such as vegetation management in a roadless area, it does not require it. If such activities are proposed, they would need to be further evaluated in site-specific National Environmental Policy Act analysis prior to approval and implementation. Management direction for all Idaho Roadless Rule Areas on the Nez Perce-Clearwater has been proposed in the Land Management Plan and for each alternative.

These areas provide a range of primitive and semi-primitive recreation opportunities. Roadless area recreation levels vary from low to moderate depending upon their location. Use levels tend to be lower than the developed portions of the Nez Perce-Clearwater, where roads allow easier access to developed and dispersed recreational opportunities. Roadless areas provide a myriad of resource benefits, including undeveloped fisheries and wildlife habitat, biological diversity, and year-round dispersed motorized and non-motorized recreation.

Each roadless area was evaluated through the forest planning process to determine if it provides wilderness characteristics and whether it should be recommended for wilderness (Appendix E). Areas not recommended for wilderness through the forest planning process may still be considered for wilderness by Congress and would remain roadless areas under the Land Management Plan unless Congress designates them.

In 2008, the Idaho Roadless Rule established management direction for roadless areas in Idaho. The Rule designates 250 Idaho Roadless Areas and establishes five management themes that provide prohibitions with exceptions or conditioned permissions governing road construction, timber cutting, and discretionary mineral development. The themes are Wild Land Recreation; Primitive;

Backcountry/Restoration; Special Areas of Historic and Tribal Significance; General Forest, Rangeland and Grassland; and Land Management Plan Special Areas.

The Idaho Roadless Rule identifies the relation of the Rule to land management plans as follows:

"The provisions set forth in this subpart shall take precedence over any inconsistent land management plan component. Land management plan components that are not inconsistent with this subpart will continue to provide guidance for projects and activities within Idaho Roadless Areas; as shall those related to protection of threatened and endangered species. This subpart does not compel the amendment or revision of any land management plan (36 CFR 294.28d)."

Roadless areas will continue to be managed under the permissions and exceptions of the Idaho Roadless Rule. For areas that are recommended for wilderness, the authorized official may pursue an Idaho Roadless Rule theme change from the Chief of the U.S. Forest Service. The Idaho Roadless Rule primarily deals with road construction and reconstruction; timber cutting, sale, and removal; and mineral activities.

Relevant Laws, Regulations, and Policy

Idaho Roadless Rule (36 CFR 294 Subpart C): This rule provides state-specific direction for the conservation of inventoried roadless areas in the National Forest within the State of Idaho.

Methodology

Information sources

The geographic information system is the primary information source.

Analysis area

The geographic scope of the analysis is National Forest System lands administered by the Nez Perce-Clearwater. The temporal scope of the analysis is the anticipated life of the plan.

Measurement Indicators

The following measurement indicator was used for this analysis:

- Acres of Idaho Roadless Rule areas by Recreation Opportunity Spectrum Class

Affected Environment

The Nez Perce-Clearwater has approximately 1,481,565 acres in 34 different inventoried roadless areas (Table 398). This constitutes about 36 percent of the lands administered by the Nez Perce-Clearwater. Roadless areas would continue to be managed under the 2008 Idaho Roadless Rule and compatible Land Management Plan direction. There are no open roads within the roadless areas.

Table 398. Idaho Roadless Area acres by Idaho Roadless Rule management themes.

Idaho Roadless Area	Total Acres	Backcountry/ Restoration	Land Management Plan Special Areas	Primitive	Special Areas of Historic and Tribal Significance	Wild Land Recreation
Adjacent to Gospel-Hump Wilderness	2,383	2,383	0	0	0	0
Bighorn-Weitas	254,901	247,386	295	0	7,221	0
Clear Creek	9,170	9,170	0	0	0	0

Idaho Roadless Area	Total Acres	Backcountry/ Restoration	Land Management Plan Special Areas	Primitive	Special Areas of Historic and Tribal Significance	Wild Land Recreation

Total	1,481,565	835,649	38,287	311,154	49,341	247,133

[1]Lolo Creek is administered by Lolo National Forest.

Data Source: GIS data.

The Final Environmental Impact Statement for the Idaho Roadless rule projected that 0.16 percent of the 9,340,300 acres managed under the Idaho Roadless Rule would be affected by timber removal or road construction in the first 15 years. For the nearly 1,500,000 acres of roadless areas on the Nez Perce-Clearwater, this would total 2,400 acres over the 15-year period, or approximately 160 acres per year (U.S. Department of Agriculture 2008d). In the 10-year period from October 2008 to

September 2018, approximately 1,800 acres were affected through community protection zone fuels reduction, constructed fuel breaks during wildfires, and removal of post-fire roadside hazard trees (Table 399). This estimate of 1,800 acres in the first 10 years is slightly more than the Idaho Roadless Rule projection of 2,400 acres over a 15-year period. However, several extreme fire seasons have occurred during that time and much of the tree removal has been tied to fire and post-fire hazard activities.

Table 399. Past harvest activity in Idaho Roadless Rule Areas

Activity	Acres
Community Protection Zone fuels reduction	373
Constructed fire lines	231
Post fire-roadside hazard tree removal	1,194
Total harvest in Idaho roadless areas	1798

Data Source: GIS data.

These 1,800 acres affected by past harvest activity in Idaho Roadless Rule Areas include projects with completed National Environmental Policy Act decisions that are underway, including the Orogrande fuels project where approximately 280 acres were logged; clearing for temporary road construction in the West Fork Crooked River Roadless Area; and the Lowell wild and urban interface project, with a signed decision to log 93 acres in the Rackliff-Gedney Roadless Area. Approximately 24.3 miles of fuel breaks were constructed in roadless areas during the major fire seasons of 2012 and 2015. Fuel breaks are typically 30-foot-wide vegetation free zones. Therefore, converting these fuel breaks to acres results in approximately 88 acres of fuel breaks within portions of seven roadless areas. Many of these have been rehabilitated since the fires. The exception is a large fuel break constructed in 2015 during the Blue Fire to protect the Dixie and Comstock communities. It is 5.9 miles long and roughly 200 feet wide, equaling 143 acres of cleared land.

The combined total of 88 acres from the narrower fires lines plus 143 acres for the Blue Fire line in the Gospel Roadless Area equals 231 acres total of cleared vegetation in recent years. Roadside hazard trees following wildfire have been cut to maintain safe public access within or adjacent to roadless areas. This timber removal is generally within 200 feet of existing open roads. This totaled approximately 1,200 acres in 17 different roadless areas following the 2012 and 2015 fire seasons.

Environmental Consequences

No roadless areas are proposed to change from being roadless areas. In some alternatives, some roadless areas fall within or are a part of other management areas. There are Idaho Roadless Rule areas within Management Area 1, Designated Wild and Scenic Rivers; and Management Area 2, Recommended Wilderness Areas, Suitable Wild and Scenic Rivers, Research Natural Areas, and Proposed Research Natural Areas. All inventoried roadless areas would continue to be managed in alignment with the prohibitions and exceptions of the 2008 Idaho Roadless Rule, but those inventoried roadless areas that are also in another management area designation within an alternative may have restrictions beyond those in the Idaho Roadless Rule due to Land Management Plan components for those management area designations. The Idaho Roadless Rule does not discuss all the activities that may affect other designations and is less potentially restrictive than the other designation. In cases where multiple management areas are present, the Idaho Roadless Rule direction will stand in conjunction with the other management area restrictions.

Effects of No Action Alternative

In the No Action Alternative, all 34 Idaho Roadless areas would continue to be managed under their current roadless rule themes. When the 2008 Idaho Roadless Rule was being developed, the roadless areas where current 1987 Forest Plans recommended wilderness areas overlapped were assigned to the wildland recreation theme (U.S. Department of Agriculture 2008c). This includes a portion of the Mallard-Larkins, Hoodoo, North Fork Spruce-White Sands, and Sneakfoot Meadows roadless areas. Additionally, Rapid River is currently managed under the wildland recreation theme. See Table 398 above for the management themes for all roadless areas. Table 400 shows the roadless rule area acres that overlap with one or more other land management designations or allocations. Due to overlapping allocations and rounding, total acreages may not match total acreages of roadless areas.

Table 400. Idaho Roadless Rule Area acres with other designations or allocations under the current forest plan.

Designation or Allocations	Acres
Designated Wild and Scenic River Corridor	26,113
Designated National Historic Landmark	28,391
Designated Research Natural Area	6,483
Eligible Wild and Scenic River Corridor	58,564
Recommended Wilderness	197,695
Total within other designations or allocations	**317,247**

Data Source: GIS data.

Effects Common to Action Alternatives

No roadless areas will be added or subtracted under the Land Management Plan. Likewise, no roadless area themes will be changed under the Land Management Plan. Across all alternatives, the roadless areas will remain the same; although overlapping land management allocations change under some alternatives, which could affect the management of the roadless areas. Table 401 shows the acres of roadless area theme retained across all alternatives. Specifics of which roadless area includes which themes can be found in Table 398.

Table 401. Idaho Roadless Rule Area acres by theme.

Theme	Acres
Backcountry/Restoration	835,649
Land Management Plan Special Area	38,287
Primitive	311,154
Special Area of Historic or Tribal Significance	49,341
Wild Land Recreation	247,133
Total	**1,481,565**

Data Source: GIS data.

Effects of Action Alternatives

Under all alternatives, Idaho Roadless Rule Areas will be managed according to the Idaho Roadless Rule and Management Area 2 unless they are overlain by other land allocations by alternative. Across alternatives, there are roadless areas that are also recommended for wilderness, found suitable for wild and scenic rivers, or are within proposed research areas. If the roadless area also falls within one or more of these land allocations, plan components associated with that land allocation would be applied to the roadless area in addition to the management restrictions associated with the roadless area's theme.

Table 402, Table 403, Table 404, and Table 405 display the roadless area acreages that are within other land allocations by alternative. Those roadless areas overlapping with existing designations are retained across all alternatives so there is no change to the number of acres within designated wilderness, designated wild and scenic rivers, designated national historic landmarks, or designated research natural areas. All revised plan alternatives have some acreage of roadless areas that do not have additional allocations. Where allocations overlap, the more protective components would apply. Due to overlapping allocations and rounding, total acreages may not match total acreages of roadless areas.

Table 402. Idaho Roadless Rule Area acres with other allocations under Alternative W.

Allocations	Acres
Suitable Wild and Scenic River Corridor	10,076
Recommended Wilderness	856,932
Proposed Research Natural Areas	307
Total within other designations or allocations	**867,315**

Total within other designations or allocations	**593,146**

Data Source: GIS data.

In addition to the impacts of overlapping land allocations, the roadless characteristics may be affected by alternatives and associated plan components. Some of the nine roadless characteristics have been discussed collectively due to their interconnected nature.

- High-quality or undisturbed soil, water, and air; diversity of plant and animal communities; habitat for threatened, endangered, proposed, candidate, and sensitive species and for those species dependent on large, undisturbed areas of land: Approximately 38 percent of the Nez Perce-Clearwater, totaling 1,481,565 acres, is in Idaho Roadless Rule areas. All alternatives retain the Idaho Roadless Rule themes as they currently exist. These themes and the associated restrictions on management activities ensure most of the acres would have limited management activities that could significantly alter the landscape or interrupt natural processes. It is anticipated that less than 1 percent of the area will have any timber harvest over the life of the Land Management Plan. Even though the alternatives have various acreages available for summer motorized recreation, it is anticipated that few new motorized routes would be developed during this time period. Wildland fire is expected to be used as a tool for ecosystem restoration across this landscape. However, fire is recognized as a natural process that routinely occurs in, and affects, the vegetative conditions of the area. Therefore, all alternatives would provide large, undisturbed areas and ecological conditions that support high-quality or undisturbed soil, water, and air and overall ecosystem health to support indigenous plants and animals.
- Data Sources of public drinking water: There is no expected change across alternatives to the roadless characteristic for sources of public drinking water. In all alternatives, these characteristics would remain protected whether they are in a roadless area without an overlapping land allocation or not.
- Primitive, semi-primitive motorized, and semi-primitive non-motorized classes of dispersed recreation and natural-appearing landscapes with high scenic quality: All alternatives distribute more than 86 percent of the roadless rule areas as summer primitive, semi-primitive non-motorized, or semi-primitive motorized. Alternative X has the least amount with only 86 percent, which is 3 percent less than Alternative Y. The Preferred Alternative has the highest amount with 97 percent. Alternatives W, Y, and Z are comparable around 90 percent. The No Action Alternative is approximately 92 percent within these three classes.

Splitting these three recreation opportunity spectrum classes into non-motorized versus motorized reveals a bit more of a difference across alternatives.

Alternative W is very similar to the No Action Alternative regarding motorized versus non-motorized classes within roadless areas. Alternative W has 62 percent of the roadless areas in a non-motorized class and the No Action Alternative has 64 percent. Under Alternative W, all acres that are within the Backcountry/Restoration theme and not overlapped by recommended wilderness land allocations are classified in a motorized class. The overlapping recommended wilderness acres are classified into one of the non-motorized classes. Of all alternatives, Alternative W has the highest recommended wilderness acres, but these recommended wilderness acres are spread across the different roadless area themes so there are some large portions of Backcountry/Restoration roadless areas classified as motorized. The No Action Alternative has the fewest acres of recommended wilderness, except Alternative X, and the most acres of eligible or suitable wild and scenic rivers. Therefore, each of these alternatives has significant areas of overlapping allocations.

Alternative X, at 35 percent, and the Preferred Alternative, at 42 percent, provide the least amount of area restricted to non-motorized recreational activities. Alternative X has no recommended wilderness or suitable wild and scenic rivers, therefore no overlapping land allocations. Alternative X also allocates all backcountry restoration themed Idaho Roadless Areas as motorized.

Alternative Y, at 70 percent, and Alternative Z, at 76 percent, would provide the most area available for non-motorized recreation. This is due to the allocation of backcountry restoration themed Idaho Roadless Areas as non-motorized, except some existing motorized trail corridors and some specific loop opportunities that connect these existing motorized trails. Under these alternatives, recreationists seeking roadless experiences with motorized access would have the least available acres for their desired opportunity.

The Preferred Alternative has the fewest number of acres recommended for wilderness of all the action alternatives and second fewest number of acres of eligible and suitable wild and scenic rivers. The Preferred Alternative also allocates most of these Idaho Roadless Areas as motorized, except portions of Bighorn-Weitas, Weir-Post Office Creek, and Lochsa Face to provide a non-motorized corridor for wide-ranging wildlife species. The Preferred Alternative provides the closest balance between motorized, at 58 percent, and non-motorized, at 42 percent, of all the alternatives.

Although the alternatives allocate acres classified as motorized, this does not necessarily mean that there are motorized trails on the ground in these areas. A decision regarding establishing motorized trails within the suitable motorized recreation opportunity spectrum classes would occur in site-specific National Environmental Policy Act analysis and decisions.

Maps displaying the recreation opportunity spectrum and overlapping Idaho roadless rule areas can be found in Appendix A.

Table 406 displays the acres of Idaho roadless rule areas by recreation opportunity spectrum across the alternatives.

Table 406. Idaho Roadless Rule Areas acres by summer recreation opportunity spectrum classes and alternative.

Summer Recreation Opportunity Spectrum Class	No Action Alternative	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternative
Primitive	126,276	30,350	30,350	47,028	47,028	0

Total Roadless Area Acres	1,489,735	1,468,505	1,463,082	1,487,434	1,481,637	1,467,079

Data Source: Nez Perce-Clearwater GIS data.

All alternatives distribute more than 89 percent of the roadless rule areas as winter primitive, semi-primitive non-motorized, or semi-primitive motorized. At 89 percent, the No Action Alternative is the only alternative with less than 95 percent of the roadless areas in those three classes. When broken down by motorized versus non-motorized winter use, Alternatives X and Z both have 96 to 97 percent of the roadless areas suitable for over-snow vehicle use. This is due to a lack of recommended wilderness under Alternative X and the suitability of over-snow vehicle use in recommended wilderness areas within Alternative Z. As a result, very little of either alternative's roadless areas are unsuitable for over-snow use. The bulk of both alternatives is in semi-primitive motorized classification.

Alternative W, where the highest acres of recommended wilderness overlap with roadless areas, the smallest acreage is classified as motorized winter use at 41 percent. This is about 10 percent higher than the No Action Alternative.

The No Action Alternative classifies 32 percent of the roadless areas as one of the motorized classes. Therefore, all action alternatives would have more motorized recreation opportunity spectrum classified acres than the No Action Alternative. As with the summer classifications, those recreationists seeking both a roadless experience and a motorized winter experience would find them in all alternatives except for Alternative W, which has a higher number of acres classified as suitable for over-snow motorized use.

The Preferred Alternative is most like Alternative Y. Seventy-two percent of the Idaho Roadless Areas would be available for motorized recreation. This alternative has the fewest acres recommended for wilderness and the second fewest found suitable as wild and scenic rivers. Therefore, it has the least overlapping allocations of all the action alternatives. Most of the areas not recommended or suitable would be open for motorized recreation. Alternative Y has 77 percent in a motorized class, which is primarily influenced by the smaller acres of recommended wilderness in this alternative. In the roadless areas where the land allocations overlap over-snow vehicle use would not be suitable. Table 407 outlines the acres in each winter recreation opportunity spectrum class by alternative.

Table 407. Idaho Roadless Rule acres by winter recreation opportunity spectrum classes and alternative.

Winter Recreation Opportunity Spectrum Class	No Action Alternative	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternative
Primitive	135,647	0	0	0	0	0
Semi-primitive non-motorized	882,827	864,915	39,994	345,028	39,994	399,453
Non-motorized Total	1,018,474	864,915	39,994	345,028	39,994	399,453
Semi-primitive motorized	311,511	574,765	1,370,642	1,075,839	1,375,899	1,026,111
Roaded Natural	159,407	28,833	52,453	66,601	56,721	41,514

Winter Recreation Opportunity Spectrum Class	No Action Alternative	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternative
Rural	345	0	0	0	0	0
Motorized Total	471,263	603,598	1,423,095	1,142,440	1,432,620	1,067,625
Total Roadless Area Acres	1,489,737	1,468,513	1,463,089	1,487,468	1,472,614	1,467,078

Data Source: Nez Perce-Clearwater GIS data.

Reference landscapes: All alternatives retain the Idaho Roadless Area themes as they currently exist. These themes, and the associated restrictions on management activities, ensure that most of the areas will have limited management activities that would significantly alter the landscape or interrupt natural processes. It is anticipated that less than 1 percent of the area will have any timber harvest over the life of the Land Management Plan. Even though the alternatives have various acreages available for summer motorized recreation, it is anticipated that few new motorized routes would be developed during this period. Therefore, all alternatives provide ample opportunity for reference landscapes to compare those areas of the Nez Perce-Clearwater that will be primary for management activities.

Traditional cultural properties and sacred sites: There is no expected change across alternatives to the cultural properties and sacred site roadless characteristics. In all alternatives these characteristics would remain protected whether they are in a roadless area without an overlapping land allocation or not.

Cumulative Effects

Population growth and development increases the demand for public open space. Growth in Missoula and Ravalli counties in Montana, as well as Spokane, Washington, and various communities in north Idaho, is expected to increase recreational use of the plan area, including within inventoried roadless areas. The effects of urbanization and population growth on inventoried roadless areas and resource conditions are likely to be gradual and to extend beyond the planning period. This is not likely to change management of the roadless areas but may influence public demand for recreational opportunities within the roadless areas.

Inventoried roadless area characteristics are changed by development, such as roads, timber management, and recreation facilities. The development of roads and the management of vegetation has affected roadless areas in the past. However, since the passage of the Idaho Roadless Rule, development within roadless areas has been greatly reduced and all alternatives will retain the existing roadless character.

Effects to Resource from Other Resources

Management Area

The Idaho Roadless Rule limits road construction and reconstruction; timber cutting, sale and removal; and mineral activities to varying levels depending on the roadless area theme. Overlapping land allocations and designations and associated Management Area 1 and 2 plan components may further restrict activities within roadless areas.

Fire Management

In all alternatives, plan components for fire management encourage management response as appropriate to wildfires that may occur within inventory roadless areas and provide opportunities for natural fire to promote or enhance the ecological attributes of these areas.

Vegetative Management

Idaho Roadless Rule (36 CFR 294 Subpart C) (2008) direction must be followed for vegetative treatments within roadless areas where Idaho Roadless rules apply unless an overlapping land allocation further restricts the vegetation management options within the area.

The existing roadless character may be modified where timber harvest occurs. In Management Area 2, timber harvest is expected to be limited and generally would be done for purposes that would result in retaining the natural integrity of the ecosystem. Timber harvest that is done to reduce hazardous fuels may be more intensive and change the undeveloped character, to some degree, until the vegetation re-grows. This is most likely to happen on the edges of a roadless area nearer communities. Primitive recreation opportunities would be unchanged unless temporary roads are constructed, which is permitted under specific circumstances in the Idaho Roadless Areas in Management Area 2.

Under the Idaho Roadless Rule, temporary road construction is permitted in community protection zones or where there is a significant risk of wildland fire to at-risk communities or municipal water supply systems and there is no other reasonable option to reduce the risk to these communities or water systems. While there are about 36,200 acres within community protection zones (U.S. Department of Agriculture 2008e), it is unlikely that all acres would meet the criteria for no other option being available to reduce the risk to the communities or water systems. Determination of whether a temporary road would be necessary and would be the only reasonable option would be made at project level, site-specific National Environmental Policy Act analysis. If temporary roads are constructed, it may take longer for an area to return to its natural state than if timber harvest without temporary road construction were to take place.

Table 408 displays the Idaho Roadless Rule areas with community protection zones and their acreages within the community protection zones. As projected in the Final Environmental Impact Statement for the Idaho Roadless rule, a total of 1,500 acres over the first 15 years, or approximately 100 acres per year, are expected to be affected by timber harvest or road construction within the community protection zones (U.S. Department of Agriculture 2008d). Therefore, even if a portion of the community protection zone is determined to require temporary road construction or timber harvest to reduce the risk to a community or water system, the number of acres affected would remain relatively small.

Table 408. Idaho Roadless Rule Area acres with Backcountry/Restoration Community Protection Zones.

Idaho Roadless Rule Area Name	Community Protection Zone Acres
Lochsa Face	1,100
Moose Mountain	700
Clear Creek	2,400
Dixie Summit- Nut Hill	500
Gospel Hump	16,600
Lick Point	2,300
Little Slate Creek North	400
Mallard	3,600
West Fork Crooked River	5,500
West Meadow Creek	3,100

Idaho Roadless Rule Area Name	Community Protection Zone Acres
Total	**36,200**

Data Source: GIS data.

Recreation and Access

Recreational opportunities are managed through the management area plan components and the recreation opportunity spectrum class the lands are within. Within the roadless areas, most opportunities are primitive and semi-primitive recreation. The Idaho Roadless Rule does not restrict motorized or mechanized use within roadless areas, it restricts road building.

Therefore, travel management for motorized trails determines what is or is not allowed for motorized trails within the roadless areas. While motorized trails may be permissible by a roadless rule theme, they may not be appropriate to manage overlapping land allocations or may not be appropriate in site specific analysis for that roadless area.

All the alternatives distribute more than 89 percent of the roadless rule areas as winter primitive, semi-primitive non-motorized, or semi-primitive motorized. The No Action Alternative is the only alternative with less than 95 percent of the roadless areas in those three classes. Eighty-nine percent of the No Action Alternative is in one of those classes. Alternatives X and Z both have 96 percent of the roadless areas suitable for over-snow vehicle use. This is due to a lack of recommended wilderness under Alternative X and the suitability of over-snow vehicle use in recommended wilderness areas within Alternative Z. As a result, very little of either alternative's roadless areas are unsuitable for over-snow use. The bulk of both alternatives is in semi-primitive motorized classification.

Alternative Y has 77 percent in a winter motorized class, which is primarily influenced by the smaller acres of recommended wilderness in this alternative. In the roadless areas where the land allocations overlap over-snow vehicle use would not be suitable. Under Alternative W, where the highest acres of recommended wilderness overlap with roadless areas, the smallest acreage is classified as motorized winter use at 41 percent. This is about 10 percent higher than the No Action Alternative. The No Action Alternative classifies 32 percent of the roadless areas as one of the motorized classes. Therefore, all action alternatives would have more motorized recreation opportunity spectrum classified acres than the No Action Alternative. As with the summer classifications, those recreationists seeking both a roadless experience and a motorized winter experience would find them in all alternatives except for Alternative W, which has a higher number of acres classified as suitable for over-snow motorized use. Table 407 outlines the acres in each winter recreation opportunity spectrum class by alternative. The Preferred Alternative provides the most balance between summer motorized, 58 percent, and non-motorized, 42 percent, recreation but keeps 72 percent of the area open to winter motorized use.

Mineral Development

The Idaho Roadless Rule specifies permissible activities associated with mineral development, as well as saleable, locatable, and leasable minerals by theme. For those roadless areas where there is no overlapping land allocation, the applicable roadless theme direction would dictate whether mineral development is permissible. For those areas within other allocations in addition to roadless areas, the more restrictive permissions for mineral development would apply. Mineral development plan components do not vary by alternative except in association with overlapping land allocations.

Road construction and reconstruction associated with mining activities within Idaho Roadless areas may only be approved after evaluating other access options and must be conducted in a manner that minimizes effects on surface resources and must be consistent with land management plan components. Roads constructed or reconstructed within Idaho Roadless areas must be decommissioned upon completion of the project or expiration of the lease, permit, or other authorization. There would be no change to this direction for those roadless areas where no other overlapping land allocation exists. In these areas, if road construction is undertaken, the impacts to the roadless character and general low development character would be temporarily impacted during the duration of the project. After project completion, the effects of road building would likely be retained for a period until natural processes return the area to its un-roaded state.

Alternative W has the least amount of acreage open to mineral entry of the alternatives. This is in part due to the large amounts of recommended wilderness and suitable wild and scenic rivers. Therefore, the largest amount of roadless area acreage would also be restricted to mineral entry under Alternative W. Alternative X has the least amount of overlapping land allocations with roadless and would retain the largest number of acres where mineral entry could occur if the criteria of the roadless area there are met.

Mineral Materials

The Nez Perce-Clearwater will not authorize the sale of common variety mineral materials in Idaho Roadless Areas designated as Wild Land Recreation, Special Areas of Historic or Tribal Significance, or Primitive themes. The Nez Perce-Clearwater may authorize the use or sale of common variety mineral materials and associated road construction or reconstruction to access these mineral materials in Idaho Roadless Areas designated as Backcountry/Restoration only if the use of these mineral materials is incidental to an activity otherwise permissible in Backcountry/Restoration theme areas. In the case of roadless areas within the Backcountry/Restoration theme, if road construction is undertaken, the impacts to the roadless character and general low development character would be impacted during the duration of the incidental activity.

Locatable Minerals

The Idaho Roadless Rule does not affect mining activities conducted pursuant to the General Mining Law of 1872. There are no expected effects to the roadless areas by retention of this allowance with the roadless areas under a Land Management Plan.

Leasable Minerals

All roadless areas fall within Management Areas 1 and 2, which are not open for leasable mineral entry under all alternatives. Therefore, there is no expected effect to roadless areas from leasable minerals impacts.

Recommended Wilderness

There are many overlapping roadless areas and recommended wilderness areas. In these locations, the management decisions would follow the most restrictive of the two land allocations.

Under Alternatives W and Y and the Preferred Alternative, no motorized over-snow or mechanized travel would be suitable within recommended wilderness. As a result, those roadless areas that are recommended wilderness within these alternatives would also be found unsuitable for motorized over-snow and mechanized travel. Under Alternative Z, these uses would be found suitable. Under Alternative X, there is no recommended wilderness. Over-snow and mechanized travel being found suitable does not necessarily imply that those uses would occur or be allowed. Therefore, the finding that these uses are suitable within the roadless areas that are also recommended wilderness does not inherently allow motorized over-snow use or mechanized use within these areas. It is unknown whether these uses will be allowed in the future and whether they will increase or remain the same within the roadless areas.

Eligible and Suitable Wild and Scenic Rivers

There are many overlapping roadless areas and eligible and suitable rivers. In these locations the management decisions would follow the most restrictive of the two land allocations.

In all alternatives, motorized over-snow use, motorized travel, and mechanized travel is suitable, although in wild classified segments, the motorized use may only occur if the outstandingly remarkable values are protected. In cases where a wild segment overlaps with roadless area that is within a Backcountry/Restoration theme where a road may be permissible if it meets the criteria associated with resource protection, health, and safety of a permissible limited mineral exception, a road may be built that may alter and effect the low development of the roadless area and its roadless characteristics.

Summary of Consequences

The Idaho Roadless Rule roadless area boundaries and acreages are established as a part of the 2008 Idaho Roadless Rule and would not change in any alternative. These lands would continue to be managed under the guidance established by the 2008 Idaho Roadless Rule, with more restrictive guidance provided by additional designations or land allocations. Changes in the acres of overlapping land allocations and associated plan components may affect the roadless areas. These overlapping land allocations are more restrictive than the roadless rule permissions and prohibitions, which would generally reduce the development scale of the roadless areas (Table 409). Under Alternative X, only 5 percent of the roadless area acres are also in an overlapping land allocation. Under this alternative, most of the roadless area acres would be managed based on restrictions and permissions of the Idaho Roadless Rule. Under Alternative W, 61 percent of the roadless area acres also reside within another land allocation, which is likely to further restrict management actions within these roadless areas.

Table 409. Idaho Roadless Rule Area acres with other overlapping designations or allocations by alternative.

Overlapping	No Action Alternative	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternative
Yes	315,230	897,794	68,978	424,671	653,129	366,900
No	1,166,335	583,771	1,412,587	1,056,894	828,436	1,114,736
Total	1,481,565	1,481,565	1,481,565	1,481,565	1,481,565	1,481,565
Percent Overlapping	21	61	5	29	44	25

Data Source: GIS data.

As with the overlapping land allocations, the other influence on the roadless rule areas are restrictions and opportunities based on the recreation opportunity spectrum class allocations. These are influenced by overlapping land allocations, as well as specific guidance based on alternatives. Table 410 presents the acres and percent of summer motorized and non-motorized acres within Idaho Roadless Rule areas across the alternatives. Under Alternative W, where the highest amount of overlapping land allocations exists, the motorized access opportunities are still quite high, only less than those of Alternative X where there is very little overlapping land allocation. Under Alternative Z and Alternative Y, the motorized access opportunities are both similar despite much larger differences in the overlapping land allocations. These two alternatives are also the two alternatives where the motorized classes are lower than the No Action Alternative and would reduce the suitable for motorized acres from the current condition. The Preferred Alternative provides the closest balance between summer motorized and non-motorized recreation use.

Table 410. Idaho Roadless Rule Area acres and percent in summer motorized or non-motorized recreation opportunity spectrum (ROS) class by alternative.

Lumped Summer ROS class	No Action Alternative	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternative
Non-motorized acres	945,745	915,296	495,069	1,031,944	1,080,742	603,292
Non-motorized percent	64	62	33	70	73	42
Motorized acres	535,891	566,341	986,569	449,694	400,895	863,787
Motorized percent	36	38	67	30	27	58

Data Source: Nez Perce-Clearwater GIS data.

Table 411 presents the acres and percent of winter motorized and non-motorized acres within Idaho Roadless Rule areas across the alternatives. Under Alternative W, where the highest amount of overlapping land allocations exists, the motorized access opportunities are the lowest, just below half of the roadless areas. All other Action Alternatives have high acres of motorized recreation opportunity spectrum classes above 70 percent. Alternatives X and Z, despite having vastly different overlapping land allocations, have the same amount of motorized classified acres due to the caveat under Alternative Z for over-snow use in recommended wilderness areas. The Preferred Alternative provides approximately 72 percent of the area for winter motorized use. All action alternatives include more winter motorized classified acres than the No Action Alternative, providing more suitable acres for this use.

Table 411. Acres and percent of Idaho Roadless Rule Areas in winter motorized or non-motorized recreation opportunity spectrum classes by alternative across the Nez Perc-Clearwater.

Lumped Winter ROS class	No Action Alternative	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternative
Non-motorized acres	1,018,474	864,914	39,994	345,028	39,994	399,453
Non-motorized %	68%	58%	3%	23%	3%	28%
Motorized acres	471,262	603,598	1,423,095	1,142,439	1,432,546	1,026,111
Motorized %	32%	41%	96%	77%	96%	72%

Data Source: Nez Perce-Clearwater GIS data.

National Recreation Trails

The National Trails System Act of 1968 established not only a system of nationwide historic trails but also scenic and recreation trails. There are no scenic trails on the Nez Perce-Clearwater but there are eight recreation trails. Unlike historic and scenic trails, recreation trails are designated by the Secretary of the Department whose jurisdiction they fall into. The requirements for designation include connecting people to local resources and improving their quality of life.

Relevant Laws, Regulations, and Policy

National Trails System Act of October 2, 1968 (Pub. L. 90-543, 82 Stat. 919, as amended): This act was signed into law by President Lyndon B. Johnson on October 2, 1968. The purpose of the act was "to promote the preservation of, public access to, travel within, and enjoyment and appreciation of the open-air, outdoor areas and historic resources of the nation." This act authorized three types of trails: 1) national scenic trails, 2) national recreation trails, and 3) connecting-and-side trails. In 1978, national historic trails were also added to the national trail system. National scenic trails and national historic trails may only be designated by Congress. National recreation trails may be designated by the Secretary of Interior or the Secretary of Agriculture. Through designation, these trails are recognized as part of the American National Trail System.

Trails for America in the 21st Century (Executive Order 13195): This order was signed by President Clinton in 2001 to achieve the common goal of better establishing and operating the American national system of trails. The order addresses development and management of national scenic and historic trails by protecting trail corridors.

Methodology

It is assumed that designated national recreation trails are retained and will be managed according to established reports, as well as laws, regulations, policy, and Land Management Plan components. This analysis assumes that there will be no changes to the designated national recreation trails or direction for the life of the plan. Under all alternatives, it is assumed that, when designations and land allocations overlap, management activities would follow the management direction for each land allocation, with the most restrictive direction applying when direction conflicts.

Information sources

Information sources include the Nez Perce-Clearwater geographic information system data for mapping, the INFRA database for trail design and maintenance information, and the National Recreation Trail Database by American Trails. Note that acreages used in the analysis, which are generated by the geographic information system, differ from the U.S. Forest Service official acreages due to refinement of mapping technology between designation and current day.

Analysis area

The geographic scope of the analysis is all National Forest System lands administered by the Nez Perce-Clearwater. All lands within the Nez Perce-Clearwater boundary form the geographic scope for cumulative effects. The temporal scope of the analysis is the anticipated life of the plan.

Indicators and Measures

The alternatives will be evaluated by comparing the effects of the Land Management Plan direction and how well it supports and protects the values associated with the designated national recreation trails.

Affected Environment

National recreation trails provide a variety of outdoor recreation uses. Table 412 displays the trails by area, name, and mileage on the Nez Perce-Clearwater and designated use by alternative.

Table 412. Nez Perce-Clearwater national recreation trails.

Trail Name	Trail Numbers	Designation Year	Miles	Designated Use
Anderson Butte, comprised of Boundary Trail and Kirks Fork Trail	835; 830	1979	14.80	Motorized
East Boyd-Glover Roundtop, comprised of East Boyd Trail and Glover Trail	703; 704	1979	23.00	Motorcycle
Colgate Licks Nature	1091	1979	1.25	Hiking
Meadow Creek	726	1980	15.00	Mechanized
Elk Creek Falls	740	1988	2.10	Mechanized
Idaho Giant Red Cedar	748	1988	0.50	Mechanized
White Pine Trail[1]	224; 224A; 224B	1979	3.62	Mechanized
Lochsa River Historic Trail[1]	unknown	1991	16.00	Mechanized
DeVoto Grove Interpretive[2]	789	NA	NA	NA

[1]Listed in the National Recreation Trail Database but their designation establishment reports have not been located.
[2]This trail is being considered for designation but has not been designated at this time.
Data source: INFRA database and National Recreation Trail Database by American Trails.

Environmental Consequences

Neither the existing Nez Perce nor Clearwater Forest Plans outlined plan components to address these specially designated trails. Therefore, if the No Action Alternative is selected, this lack of direction in the forest plans will be retained.

In all action alternatives, the plan components do not vary, nor do the location of trails vary by alternatives. Under the revised plan alternatives, the national recreation trails would meet the purpose of the National Trails System Act, which is "to promote the preservation of, public access to, travel within, and enjoyment and appreciation of the open-air, outdoor areas and historic resources of the Nation."

Cumulative Effects

The eight national recreation trails on the Nez Perce-Clearwater contribute to a system of over 1,200 individual national recreation trails in all 50 states. National recreation trails benefit from the prestige and increased visibility of being a part of the National Trail System. National recreation trails can often compete for additional funding or for state or federal grant opportunities.

Effects to Resource from Other Resources

Vegetation and Timber Management

Some stretches of the trails may be in areas where timber harvest could occur. This may alter the experience on the trail but is permissible.

Fire Management

Both natural and management-ignited fires could change the scenery visible from the trails, including charred vegetation in the short-term as well as re-growth in the longer term.

Watershed, Riparian, and Aquatic Management

The revised plan alternatives provide more detailed guidance than the current plans for protection of watersheds, riparian areas, and aquatic habitats. Plan components and activities related to aquatics would generally have little effect on national recreation trails. Where the trails cross or parallel streams, plan components related to riparian management zones would help maintain the natural character of those areas and complement the management of the trail.

Sustainable Recreation Management

In all alternatives, recreation opportunity spectrum settings are specified that are consistent with the desired conditions of the trails.

Scenery Management

In all alternatives, the Land Management Plan scenic integrity objectives may influence the design or the location of on-the-ground projects that would be visible from any of the listed critical viewing platforms. In those cases, design features or mitigations may be required to meet or exceed the assigned scenic integrity objective, which describes the maximum threshold of visual dominance and deviation from the surrounding scenic character.

Methodology

It is assumed that the scenic byway is retained. This analysis assumes that there will be no changes to the designation for the life of the plan. Under all alternatives, it is assumed that when designations and land allocations overlap, management activities would follow the management direction for each land allocation, with the most restrictive direction applying when direction conflicts.

Information sources

Information sources include the Nez Perce-Clearwater geographic information system data and the Federal Highway Administration America's Byways database.

Analysis Area

The geographic scope of the analysis is all National Forest System lands administered by the Nez Perce-Clearwater. All lands within the Nez Perce-Clearwater boundary form the geographic scope for cumulative effects. The temporal scope of the analysis is the anticipated life of the plan.

Indicators and Measures

The alternatives will be evaluated by comparing the effects of the Land Management Plan direction and how well it supports and protects the values associated with the scenic byway.

Affected Environment

Visitors enjoy this 202-mile-long route for its views like those seen by Lewis and Clark, as well for access to the Lochsa River and Clearwater River opportunities for fishing, swimming, boating, camping, wildlife viewing, and hiking. While this route is designated for the history of the Lewis and Clark Expedition, it travels through the Nez Perce Reservation and provides access to the Nee-Mee-Poo Trail and the Lolo National Historic Landmark to the north of U.S. Highway 12.

Mallard-Larkins Pioneer Area

The Mallard-Larking Pioneer Area is a portion of the Mallard-Larkins Roadless Area. There are no expected effects among alternatives than those associated with the Mallard-Larking Roadless Area.

Northwest Passage Scenic Byway

The Northwest Passage Scenic Byway follows U.S. Highway 12 from Lolo Pass at the Idaho and Montana border to Lewiston, Idaho, at the Idaho and Washington border. This scenic byway loosely follows the route of the Lewis and Clark Expedition as they journeyed past clear rivers, deep canyons, and rugged mountains 200 years ago in search of the Northwest Passage. This 202-mile-long road was designated as a Scenic Byway in 2002 and an All-American Road in 2005. This route was the last section of U.S. Highway 12 built. Work on the Lewiston to Lolo Pass section began in 1920 with the final section completed in 1962.

Environmental Consequences

The existing forest plans do not provide specific direction for the scenic byway. The land surrounding the byway is managed primarily via management direction for designated wild and scenic rivers. The road parallels the designated Middle Fork Clearwater Wild and Scenic River for most of its distance through the Nez Perce-Clearwater and falls within this corridor. The route would continue to be managed in association with the wild and scenic river corridor direction.

Cumulative Effects

There are no expected cumulative effects to the scenic byway different from those to the wild and scenic river corridor.

3.6.2 Recommended Areas

Changes between draft and final environmental impact statement

As described below, five indicators were selected to show how elements are affected by recommended wilderness management area allocation. These numerical values are presented in tables and narrative throughout this section. Readers will note that these numbers have changed from those in the Draft Environmental Impact Statement. The changes in trail miles for motorized and mechanized use are a result of more accurately identifying trails that are affected by recommended wilderness and Recreation Opportunity Spectrum classifications. Recognizable on-the-ground trail termini were identified that would aid in administration of any current or subsequent trail closures. They are not just those trail segments that are within the recommended wilderness areas. Acres suitable for winter motorized use were recalculated after adjustments to Recreation Opportunity Spectrum classifications and updated data including current closures on the Nez Perce-Clearwater.

Additionally, boundary adjustments were made to the Mallard-Larkins recommended wilderness that result in an increase of 5,146 acres.

These adjustments include the addition of the Bear Creek drainage from the Forest boundary and south to Minnesaka Creek. An addition of 3,943 acres. This area has no roads or system trails, appears completely affected by natural events without human intervention, offers undiminished opportunity for solitude or primitive and unconfined recreation, and contributes to ecosystem underrepresentation and potentially coastal disjunct species.

Another adjustment to the western boundary is the continuation of Dog Creek to its headwaters below Grassy Point as the boundary rather than the metes and bounds survey and ridgeline above. This includes an area that was heavily logged during the white-pine salvage era and has had repeated fires since. Although evidence of this activity is apparent these features are becoming more obscure as brush and tree species continue to grow and other ecological processes affect the area. Aside of the waning evidence of man, the geologic and ecologic characteristics of this area is consistent with the rest of the landscape of Goat Ridge, of which it is a part. Anticipated management of this area is for continued use of wildland fire to move the area toward its desired condition.

These areas are in Management Area 2 with a primitive roadless area classification, they are not in the suitable timber base and no commercial harvest is planned or anticipated throughout the life of the Plan. Manageability of the western boundary of the recommended wilderness is improved by these two additions which use readily apparent natural features to define the area rather than metes and bounds survey lines without regard to landform. In addition, the Bear Creek area is adjacent to a slender portion of recommended wilderness on the Idaho Panhandle National Forest. These additions complete the ecological connection along Goat Ridge and with the area north of the ridgeline from Mallard Peak to the Little North Fork Clearwater River; the boundary between Forests.

Recommended wilderness areas are lands that have wilderness characteristics and may be suitable for inclusion in the National Wilderness Preservation System. The starting point for this assessment of recommended wilderness areas for the Land Management Plan is the roadless areas as identified in the Idaho Roadless Rule. The Idaho Roadless Rule identified 34 roadless areas on the Nez Perce-Clearwater; 16 areas on the Clearwater National Forest and 18 areas on the Nez Perce National Forest. These lands are generally free from roads and other constructed features and have a high potential to provide solitude or a primitive and unconfined type of recreation. Recommended wilderness areas also provide for species diversity, protection of threatened and endangered species, protection of watersheds, scientific research and other ecological processes, and social values. Recommendation of wilderness through this Land Management Plan is a preliminary administrative determination and will receive further review and possible modification by the Chief of the Forest Service, the Secretary of Agriculture, and the President of the United States. Congress reserves the authority to make final decisions on wilderness designation.

The wilderness recommendation process occurs in four primary steps: inventory, evaluation, analysis, and recommendation. The wilderness inventory, evaluation, and analysis process are included within Appendix E. Recommended wildernesses considered in this Land Management Plan process will vary by alternative. Table 413 shows recommended wilderness areas by alternative.

Table 413. Recommended wilderness areas by alternative (Alt)

Recommended Wilderness[2]	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Bighorn Weitas	No	Yes	No	No	No	No
East Meadow Creek	No	Yes	No	Yes	Yes	Yes
Hoodoo	Yes	Yes	No	Yes	Yes	Yes
Mallard Larkins	Yes	Yes	No	Yes	Yes	Yes
Meadow Creek- Upper North Fork	No	Yes	No	No	Yes	No
Moose Mountain	No	Yes	No	No	No	No
North Fork Spruce- White Sand	No	Yes	No	No	Yes	No
North Lochsa Slope	No	Yes	No	No	No	No
Pot Mountain	No	No	No	No	Yes	No
Rapid River	No	Yes	No	Yes	Yes	No
Rawhide	No	No	No	No	Yes	No
Sneakfoot Meadows	Yes	Yes	No	No	Yes	No
West Meadow Creek	No	No	No	No	Yes	Yes
Elk Summit[1]	Yes[1]	Yes	No	No	Yes	No
Lakes[1]	Yes[1]	Yes	No	No	Yes	No
Storm Creek[1]	Yes[1]	Yes	No	No	Yes	No

[1]These recommended wilderness areas listed in the 1987 Clearwater Forest management plan (No Action Alternative) have changed names or been absorbed into other recommended wilderness areas. Elk Summit, Lakes, and Storm Creek are now part of the North Fork Spruce-White Sand Idaho Roadless Area and recommended wilderness under Alternatives No Action, W and Z.

Data Source: Recommended Wilderness Process Appendix E.

[2]Depending on the alternative, recommended wilderness may include all or portions of Idaho Roadless Areas.

Relevant Laws, Regulations, and Policy

36 CFR § **219 Sec. 219.7(v)**: This regulation requires identification and evaluation of lands that may be suitable for inclusion in the National Wilderness Preservation System and determines whether to recommend any such lands for wilderness designation.

Forest Service Manual 1923 – Wilderness Evaluation, 1923.03 – Policy: This manual directs the agency that all areas that may be suitable for inclusion in the National Wilderness Preservation System must be inventoried and evaluated for recommendation as designated wilderness areas during plan development or revision.

Forest Service Handbook 1909.12 Chap. 70: This direction contains the framework for evaluating and recommending lands for inclusion in the National Wilderness Preservation System.

Methodology

The directives contain the framework for the wilderness recommendation process. Forest Service Handbook 1909.12, Chapter 70 identifies a four-step process – Inventory, Evaluation, Analysis, and Recommendation. The primary function of the identification and inventory step is to identify all lands within the plan area that may have wilderness characteristics, as defined in the Wilderness Act of 1964, using a transparent process. In the inventory step the most recent roadless inventory was used, following the names and boundaries of areas as described in the Idaho Roadless Rule. Although some of these areas had different names and configurations in the past, the names and acreages from the Idaho Roadless Rule will be referred to within this report. Lands included in the inventory were documented and identified on a map and were carried forward for further evaluation.

An interactive map was made available on the Nez Perce-Clearwater's website displaying an initial identification and inventory of lands that may be suitable for inclusion in the National Wilderness Preservation System. The wilderness inventory area, comprised of 1,481,637 acres, was separated into 34 named areas. The methodology specifically looked at inventoried roadless areas managed by the Nez Perce-Clearwater.

Thirty-three out of the 34 Idaho Roadless Areas went through a wilderness evaluation. Appendix E documents the wilderness evaluation worksheet and narrative for each area. The Lolo Creek roadless area has a total acreage of 17,500 acres but only 100 acres are managed by the Nez Perce-Clearwater, with the remainder managed by the Lolo National Forest. For this reason, the Lolo Creek roadless area will be managed consistent with the prescriptions decided upon by the Lolo National Forest and was dropped from this evaluation.

Consistent with Forest Service manual direction, an analysis of that data was conducted to determine the degree to which each area met the five wilderness characteristics as described in the Wilderness Act of 1964; therefore warranting further consideration for recommendation as wilderness through this Land Management Plan process. The analysis presents a synopsis of the data for each roadless area as a rationale to move an area forward or to drop it from further consideration. See Appendix E for further explanation.

Measurement Indicators

The indicators were developed based on the issue statements developed from the scoping comments and comments made to the draft wilderness evaluation to show how elements are affected by recommended wilderness management area allocation:

- Changes in wheeled motorized opportunities compared with the existing condition
- Changes in motorized over-snow vehicle opportunities compared with the existing condition
- Changes in trail miles that allow mechanized transport compared with the existing condition
- Changes in amount of commercial use of permanent structures
- Acres of underrepresented ecological groups of the National Wilderness Preservation System

Analysis area

The geographic scope of the analysis is the National Forest System lands administered by the Nez Perce-Clearwater. All lands within the Nez Perce-Clearwater boundaries form the geographic scope for cumulative effects. The temporal scope of the analysis is the life of the plan.

Affected Environment

The 1987 Forest Plans recommended about 198,200 acres for wilderness (Table 414) all within the boundaries of the Clearwater National Forest. More recent GIS data shows the area as 197,695 acres. These areas are Elk Summit, Hoodoo, Lakes, Mallard Larkins, Sneakfoot Meadows, and Storm Creek. There were no wilderness recommendations in the Nez Perce National Forest Plan.

Table 414. Existing recommended wilderness area 1987 Forest Plan and GIS acres

Recommended Wilderness Area	1987 Forest Plan Acres	GIS Acres
Elk Summit	3,300	3,453
Hoodoo	113,000	111,988

Recommended Wilderness Area	1987 Forest Plan Acres	GIS Acres
Lakes	4,000	3,500
Mallard- Larkins	66,700	66,377
Sneakfoot Meadows	8,700	9,465
Storm Creek	2,500	2,912
Totals	198,200	197,695

Data Source: 1987 Forest Plans and Nez Perce-Clearwater GIS data.

The 1987 Clearwater National Forest plan standards for recommended wilderness state that the management standards for these areas will meet a visual quality objective of preservation and will manage all uses to maintain wilderness qualities and retain semi-primitive settings. Travel management in existing recommended wilderness areas was addressed in the Clearwater Travel Planning Record of Decision, dated October 31, 2017. Under this direction, areas that are currently managed as recommended wilderness prohibit mechanized transport, including mountain bicycles or game carts, and motorized equipment, including e-bikes and motorized over-snow vehicles. Road construction, timber harvest, and mineral activities may only be allowed to the extent permitted in the Idaho Roadless Rule.

Both designated and recommended Wilderness is recognized as one way in which underrepresented ecosystems are protected (Loomis and Echohawk 2002), as well as a way to potentially protect more of these ecosystems. An initial study (Loomis and Echohawk 2002) in 1998 and a subsequent one in 2015 (Dietz et al. 2015) examined how well the National Wilderness Preservation System captures the diversity of ecosystems across the United States. These two studies evaluated the province-level eco-regional boundaries described by (Bailey 1995) and Aycrigg et.al. (2013) finer scale vegetation communities.

The Wilderness Society used these papers to assess the Nez Perce-Clearwater Idaho Roadless Rule Areas and their representation of underrepresented ecosystems as part of the recommended wilderness process. Appendix E lists the nationally underrepresented ecosystems in these portions of the Nez Perce-Clearwater and was used as part of the evaluating criteria as described in Appendix E. As shown in Table 415, about 70 percent of the Nez Perce-Clearwater is within an underrepresented ecosystem. Of this, 24 percent are already within the National Wilderness System in one of the designated wildernesses. Another 36 percent are within designated Idaho roadless rule areas and a final 3 percent are within the 1987 forest plan recommended wilderness areas. Some of the acres within Idaho roadless rule areas are also recommended wilderness so the totals do not equal one hundred percent of the forestwide acres but most of the underrepresented acres on the Nez Perce-Clearwater are within one of these existing designations.

Table 415. Acres and percent of underrepresented ecological groups forestwide by land allocation

Land Allocation	Acres	Percent
Designated wilderness	649,363	24%
Idaho roadless rule areas	962,275	36%
Recommended wilderness	92,855	3%
Forestwide	2,677,378	70%[1]

[1]Percent total Nez Perce-Clearwater Forest that is within an underrepresented ecosystem.

Data Source: The Wilderness Society data analysis

Environmental Consequences

Effects under the No Action Alternative

The No Action Alternative would retain the recommended wildernesses as described in the 1987 Clearwater Forest Plan as per the Clearwater Travel Management decisions, dated January 2012 and October 2017. There are no recommended wilderness areas described in the 1987 Nez Perce Forest Plan. Table 416 lists the indicators that were used to evaluate effects to the existing recommended wilderness areas, which will be compared to the action alternatives. There are a total of 197,695 acres within these six recommended wilderness areas.

Table 416. Indicator values for recommended wilderness under the No Action Alternative

Indicator	Value
Acres of recommended wilderness	197,695
Change in miles of trails open to wheeled motorized use	0
Change in acreage of suitable motorized over-snow vehicle areas	0
Change in miles of trails open to nonmotorized mechanized transportation	0
Change in commercial rental (buildings and structures) units	0
Acres of underrepresented ecological groups of the National Wilderness Preservation System	94,335

Data Source: Nez Perce-Clearwater GIS data and The Wilderness Society data.

There would be no change to any of the indicators to assess the effects to recommended wilderness across alternatives. The fifth indicator, underrepresented acres within recommended wilderness, is not a measure of change across alternatives and was not part of the 1987 forest plan. It is therefore listed in the table by the acres of underrepresented ecosystems within each of the existing recommended wilderness areas. Under the existing condition within these areas there are 328 miles of trail closed to motorized and mechanized transport, and 197,695 acres closed to motorized over-snow use. There would be no changes to these indicators under the No Action alternative.

The 197,695 acres of recommended wilderness when combined with the 1,139,059 acres of designated wilderness would bring the total acreage to about 1,336,754 acres or about 33.9 percent of the Nez Perce-Clearwater that is in designated or recommended wilderness. Forest Service Handbook 1909.12, Chapter 70 states, "All plan components applicable to a recommended wilderness must protect and maintain the social and ecological characteristics that provide the basis for wilderness recommendation." Consistency with this direction and Land Management Plan components, would provide a primitive setting on approximately 34 percent of the Nez Perce-Clearwater where wheeled motorized use, motorized over-snow vehicle use, and mechanized transport, including bicycles and game carts, would be prohibited.

The No Action Alternative includes approximately 94,335 acres of underrepresented ecological groups or about three percent of the available underrepresented ecosystem acres on the Nez Perce-Clearwater. If added to the acres of underrepresented ecosystems in designated wilderness 27 percent of the forestwide underrepresented acres would be within one of these allocations.

The six recommended wilderness areas that would be retained under the No Action Alternative are listed in Table 417, with their indicator values. All recommended wilderness areas are on the

Clearwater National Forest. There would be no recommended wilderness areas on the Nez Perce National Forest under this alternative.

Table 417. No Action Alternative indicator values by recommended wilderness area

Recommended Wilderness Area	Indicator 1 (acres)	Indicator 2 (miles)	Indicator 3 (acres)	Indicator 4 (miles)	Indicator 5 (Number)	Indicator 6 (acres)
Elk Summit	3,453	0	0	0	0	2,279
Hoodoo	111,988	0	0	0	0	46,810
Lakes	3,500	0	0	0	0	2,310
Mallard-Larkins	66,377	0	0	0	0	37,569
Sneakfoot Meadows	9,465	0	0	0	0	3,445
Storm Creek	2,912	0	0	0	0	1,922
Total	197,695	0	0	0	0	94,335

Indicator 1 = acres of recommended wilderness. Indicator 2=change in miles of trails open to wheeled motor use. Indicator 3=change in acreage of suitable motorized over-snow vehicle areas. Indicator 4=change in miles of trails open to mechanized transportation. Indicator 5=change in commercial rental (buildings and structures) units. Indicator 6=Acres of underrepresented ecological groups of the National Wilderness Preservation System.

Data Source: Nez Perce-Clearwater GIS data and The Wilderness Society data.

Wilderness Characteristics under the No Action Alternative

This section provides a brief narrative of the wilderness characteristics for recommended wilderness areas. Refer to the Final Environmental Impact Statement Appendix E for a more detailed description of these characteristics for each roadless area:

- Apparent Naturalness
- Solitude and Primitive and Unconfined Recreation
- Practicability of areas less than 5,000 acres – All areas analyzed in the final environmental impact statement, except Storm Creek in the No Action Alternative, are greater than 5,000 acres and are not discussed in this section
- Presence of Ecological, Geological or other features of Scientific, Educational, Scenic or Historical Value
- Manageability to Preserve Wilderness Characteristics

No Action Alternative – 197,695 acres

Hoodoo, Mallard Larkins, Sneakfoot Meadows (including Lakes and Elk Summit), and Storm Creek

This is the only alternative that identifies Storm Creek as a separate area because it was identified this way in the 1987 Forest Plan. All other alternatives incorporate Storm Creek, Lakes, and Elk Summit in the North Fork Spruce-White Sand roadless area.

Apparent Naturalness

The Hoodoo, Mallard Larkins, and Sneakfoot Meadows (including the Lakes and Elk Summit areas), and Storm Creek roadless areas retain a high degree of natural integrity and appearance with few man-made developments or evidence of timber harvest. The Mallard Larkins area includes two fire lookouts, one rental cabin, and a special use Snotel site that detracts from its apparent naturalness when a visitor is in proximity to them. Except for these minor intrusions these three areas appear natural, ecological systems appear to be functioning, and the areas retain their primeval character.

Solitude, Primitive, and Unconfined Recreation

Generally, these areas provide ample opportunity for solitude and primitive and unconfined recreation. However, each of the areas have some sites that attract visitors and often have multiple people at the same time. When this occurs, the opportunity for solitude in or near these areas, or on trails that access them, is reduced. Hoodoo is bounded by Forest Road #581, a popular road on the southern side. Sneakfoot Meadows is bounded by Forest Road #360 to the east and Forest Road #362 on the northwest, as well as Forest Road #358 that penetrates the area. Mallard Larkins has roads that penetrate the area and have been excluded from the roadless area. Noise from these roads reduces solitude for short distances into the areas. Topography and vegetative screening affect how far these impacts occur. Each of these areas have viewpoints that offer broad vistas beyond the area's boundary. Many of these vistas include evidence of timber harvest, roads, or human habitation that reduces the sense of solitude or primitive and unconfined recreation. These factors are inconsistent with wilderness character, reduce the apparent naturalness and the opportunity for quiet solitude or primitive and unconfined recreation, and may disrupt use of an area by some wildlife species where they occur. These activities could also increase the need for management actions to improve education, respect for, and compliance with wilderness values and boundaries. Other than these localized exceptions and intrusions, the vast majority of these 197,695 acres offer an opportunity for solitude, self-reliance, challenge, and adventure without the evidence of human presence or manipulation.

Presence of Ecological, Geological, or Other Features of Scientific, Educational, Scenic, or Historical Value

From one-third to over half of each of these areas supports ecosystems that are underrepresented in the national wilderness preservation system. Hoodoo has the most acres of modeled whitebark pine habitat of any of the roadless areas. The other areas also contain significant modeled whitebark pine habitat. Approximately two-thirds of each area is within the natural range of variability and most watersheds are functioning properly; Hoodoo does have portions of watersheds functioning at risk. High mountain peaks, rugged rock formations, and high mountain lakes are geological features of interest that add to the high scenic character and overall wilderness character of these areas.

Manageability to Preserve Wilderness Characteristics

A significant portion of these three roadless areas are adjacent to other roadless areas. Additionally, approximately one-third of Sneakfoot Meadows is adjacent to the Selway Bitterroot Wilderness. More than half of Mallard Larkins and almost half of Hoodoo is adjacent to front country or other ownership. A minimum number of mining claims and no grazing occur in these areas. Over-snow use is historic and well established in portions of Hoodoo and Sneakfoot Meadows. Mountain bike use is also high in portions of Hoodoo, moderate in portions of Mallard Larkins, and to a lesser degree in Sneakfoot Meadows. Summer motorized activity in these areas occurs but is minimal and not well established. These motorized and mechanized activities have continued in these areas despite being administratively prohibited in Hoodoo, Mallard-Larkins and Sneakfoot Meadows since 2012.

The boundaries with front country could increase the intrusion of sights and sounds into the roadless areas as management activities occur proximate to those areas. This increases the opportunity to see timber harvest, roads, and human habitation from viewpoints within the area. This would reduce the opportunity for solitude and primitive and unconfined recreation. The presence of motorized winter and summer mechanized activity also increases potential intrusion of sights and sounds not compatible with a wilderness experience.

Effects that Vary by Action Alternative

Alternative W - 856,932 acres

Alternative W includes 10 areas as recommended wilderness totaling 856,932 acres. These areas would be managed in a summer and winter primitive or semi-primitive non-motorized recreation opportunity spectrum setting. Motorized equipment and mechanized travel would not be suitable, including aircraft and unmanned aerial systems, except for administrative use by federal, state, and local agencies.

Additionally, the construction of new structures or buildings would not be suitable unless explicitly needed to protect resources or administer the area. The maintenance of existing buildings and structures, and measures to protect those buildings and structures, would be allowed. Replacement of existing buildings, unless explicitly needed to protect resources or administer the area, would not be allowed. Continued commercial use of the four rental cabins – Liz Butte Cabin, Liz Creek Cabin, Scurvy Mountain Lookout, and Meadow Creek Station – would be allowed under this alternative.

There are several existing roads open to high clearance vehicles within recommended wilderness areas under this alternative. The East Meadow Creek recommended wilderness area contains two roads – Forest Service Road 285 Elk Mountain, extending 8.9 miles, and Forest Service Road 357 Running Creek, covering 10.4 miles – that would be excluded from the recommended wilderness area and remain open to motorized travel. The Sneakfoot Meadows recommended wilderness area has one road, Forest Service Road 358, which would remain open to motorized vehicles leading into Kooskooskia Meadows for 2.1 miles, after-which the trail is non-motorized. Within the Hoodoo recommended wilderness area, the Fish Lake trail would remain open to motorized travel for approximately 4.5 miles, after-which the trail is non-motorized. This motorized route is excluded from the recommended wilderness areas.

Alternative W finds use of motorized equipment and mechanical transport to be suitable for administrative use by agency personnel, partners, and members of the public under agreement with the Nez Perce-Clearwater that preserves or improves the wilderness characteristics of the area and to maintain infrastructure and trails. All other motorized equipment and mechanized travel use would be prohibited by the public.

There are 1,110 miles of system trails associated with recommended wilderness areas under Alternative W, with 285 miles currently open to motorized travel. Including the motorized trails, there are 648 miles that are currently open to nonmotorized mechanical transport. Table 418 describes the summer and winter recreation opportunity spectrum classes within the recommended wilderness areas of Alternative W. Under this alternative there are no acres in a summer or winter recreation opportunity motorized class. Mechanized transport would also be not-suitable Therefore, the motorized and mechanized activities and uses that are not allowed in the forest plan's record of decision could begin to be removed after site-specific analysis is completed. Mechanical transport on system trails within recommended wilderness areas could decrease from 648 miles to 0 miles through this process. Likewise, wheeled motorized use on designated routes could decrease from 285miles to 0 miles within recommended wilderness areas after site-specific analysis is completed. Finally, the winter motorized suitable acres in the recommended wilderness areas could also be reduced to zero under this alternative.

Table 418. Acres of recommended wilderness in summer and winter recreation opportunity spectrum classes (ROS) under Alternative W

Category	Summer ROS acres	Winter ROS acres
Primitive	24,080	0
Semi-primitive non-motorized	832,852	856,932
Non-motorized Total	856,932	856,932
Semi-primitive motorized	0	0
Roaded Natural	0	0
Rural	0	0
Motorized Total	0	0
Total Acres	856,932	856,932

Data Source: Nez Perce-Clearwater GIS data.

This alternative would result in the greatest reduction to miles suitable for summer wheeled motorized use and mechanized transport, and least acres suitable for motorized over-snow vehicle use on the Nez Perce-Clearwater. Displacement of both wheeled and over-snow motorized vehicles and mechanized travel on the Nez Perce-Clearwater would occur if a site-specific decision prohibited these uses. Should these closures occur, use might become concentrated in areas that remain suitable for motorized wheeled and motorized over-snow vehicle, causing some users to have negative experiences or go elsewhere to an off-forest location or to other lands open to motorized use and mechanical transport. Areas allowing for motorized over-snow vehicle use would decrease by 639,514 acres as a result of acres of recommended wilderness. Total acres suitable for winter over-snow motorized access across the Forest, by these and other changes, would decrease by 578,556 acres as compared to the No Action alternative.

In this alternative, the construction of new buildings or structures would not be allowed unless explicitly needed to protect resources or administer the area. Maintenance of current buildings and structures, and measures to protect those buildings and structures, would be permitted. The replacement of existing buildings, unless explicitly needed to protect resources or administer the area, would not be allowed.

Alternative W includes 503,305 acres of underrepresented ecological groups, which is higher than all the other alternatives. This is the amount this alternative would add of underrepresented ecological groups to the National Wilderness Preservation System if these areas were designated as wilderness.

The total amount of recommended wilderness when combined with existing designated wilderness, 1,139,059 acres, would bring the total acreage to about 1,995,991 acres or about 50.67 percent of the Nez Perce-Clearwater that is in designated or recommended wilderness. These acres would provide a primitive and/or semi-primitive non-motorized setting on the Nez Perce-Clearwater, where wheeled motorized use, motorized over-snow vehicle use, and mechanical transport, such as bicycles and game carts, would decrease. The primitive setting is characterized by large, remote, wild, and predominantly unmodified landscapes with no motorized activity and a lower probability of seeing other people. Primitive settings are managed for quiet solitude away from roads, people, and development. There are few facilities or developments. Semi-primitive non-motorized settings are characterized by areas of the Nez Perce-Clearwater that are managed for non-motorized use. Uses may include hiking and equestrian trails, mountain bikes, and other non-motorized mechanized vehicles. Rustic facilities may be present, usually for administrative or resource protection purposes. These areas provide for the opportunity for exploration, challenge, and self-reliance. This alternative provides opportunity for a primitive or semi-primitive non-motorized recreation opportunity spectrum setting through recommending 856,932 acres for wilderness designation.

Alternative W has more recommended wilderness than the other alternatives (Table 419 and Table 420). There would be a five-year objective for removing those activities or uses that are not allowed in the Land Management Plan's record of decision.

Table 419. Change in indicator values under Alternative W

Indicator	Value
Acres of recommended wilderness	856,932
Change in miles of trails open to wheeled motorized use	-285
Change in acreage of suitable motorized over-snow vehicle areas	-578,556*
Change in miles of trails open to nonmotorized mechanized transportation	-648
Change in commercial rental (buildings and structures) units	0
Acres of underrepresented ecological groups of the National Wilderness Preservation System	503,305

Data Source: Nez Perce-Clearwater GIS data.

*Value includes changes by ROS in all Idaho Roadless Areas

Table 420. Alternative W indicator values by recommended wilderness area

Recommended Wilderness Area	Indicator 1 (acres)	Indicator 2 (miles)	Indicator 3 (acres)	Indicator 4 (miles)	Indicator 5 (Number)	Indicator 6 (acres)
Bighorn Weitas	254,901	-152	-254,901	-353	0	159,823

Indicator 1 = acres of recommended wilderness. Indicator 2=change in miles of trails open to wheeled motor use. Indicator 3=change in acreage of suitable motorized over-snow vehicle areas. Indicator 4=change in miles of trails open to mechanized transportation. Indicator 5=change in commercial rental (buildings and structures) units. Indicator 6=Acres of underrepresented ecological groups of the National Wilderness Preservation System.

Data Source: Nez Perce-Clearwater GIS data.

Wilderness Characteristics under Action Alternatives

Alternative W – 856,932 acres

Bighorn Weitas, East Meadow Creek, Hoodoo, Mallard Larkins, Meadow Creek–Upper North Fork, Moose Mountain, North Fork Spruce–White Sand, North Lochsa Slope, Rapid River, Sneakfoot Meadows

Apparent Naturalness

Bighorn Weitas has three historic lookout towers and two other cabins. Mallard Larkins has two fire lookouts, one rental cabin, and a special use SNOTEL site. The Meadow Creek Ranger Station is in the East Meadow Creek area and is used as a recreation rental. In addition, there are 22 trail bridges scattered among these areas. The Bighorn Weitas area is surrounded by, and adjacent to, roads and has some cherry-stemmed roads that intrude into the area. East Meadow Creek includes 19 miles of low-standard roads either adjacent to or bisecting the area. Mallard Larkins has cherry-stemmed roads that penetrate and have been excluded from the roadless area. There are a significant number of acres with noxious weeds, generally associated with these roads and some trails. Grazing is nonexistent in all areas except Rapid River, which is completely in a grazing allotment. Many of the areas have had roadside hazard tree removal along these roads but no other timber harvest is readily apparent. Except for these man-made roads, structures, and associated impacts, these 856,932 acres appear natural with ecosystems functioning without human influence.

Solitude, Primitive and Unconfined Recreation

Most acres in these areas are in either a primitive or semi-primitive non-motorized recreation opportunity class. However, due to their adjacency to open roads, they also include semi-primitive motorized or roaded natural recreation opportunity classes. Hoodoo has one motorized trail penetrating the interior. This is a six-mile-long all-terrain vehicle trail to Fish Lake that is cherry-stemmed out of the roadless area. Hoodoo also has Forest Road #581B, approximately 1 mile long, that accesses Toboggan Hill. It is also cherry-stemmed out of the roadless area. Due to topography and dense vegetation, with few exceptions, the sights and sounds associated with these roads and trails do not penetrate far into the areas. North Lochsa Slope is a notable exception with noise from Forest Road #500 and with U.S. Highway 12 obvious in much of the area. Hiking, backpacking/camping, horseback riding, hunting, fishing, and sightseeing are popular activities. Winter motorized use is popular and well established in Bighorn Weitas, Hoodoo, North Fork Spruce–White Sand, and Sneakfoot Meadows, despite administrative closure to this activity in Hoodoo and Sneakfoot Meadow. Mountain biking is becoming increasingly popular in these areas as well. Moose Mountain has little to no winter motorized use or mountain biking. The presence of man-made structures, adjacent and interior roads, motorized trails, winter motorized activities, and the overall popularity of these areas for primitive recreation affect portions of these areas. Most of these 856,932 acres, however, offer ample opportunity for solitude, unconfined recreation, adventure, and challenge.

Presence of Ecological, Geological or Other Features of Scientific, Educational, Scenic or Historical Value

Most of the recommended wilderness areas contain ecosystems that are underrepresented in the national wilderness preservation system and about two-thirds of the acres are within their natural range of variability. East Meadow Creek and Hoodoo include substantial acreage that is modeled whitebark pine habitat, while the others only have some whitebark pine habitat. Mallard Larkins supports one of the largest Rocky Mountain goat populations in northern Idaho; Hoodoo also supports a goat population. Generally, water quality is good, and watersheds are functioning properly, except in North Lochsa Slope which includes six miles of stream that are impaired due to high water temperature. The East Meadow Creek area borders Meadow Creek, a principle tributary of the Selway River, which is recognized as an important watershed, supporting Chinook salmon, steelhead, bull trout, red band trout, and westslope cutthroat trout.

The Lolo Trail National Historic Landmark separates Bighorn Weitas and North Lochsa Slope and is a corridor of historic and Nez Perce significance. Bighorn Weitas, East Meadow Creek, North Lochsa Slope, and Sneakfoot Meadows all contain research natural areas. The North Lochsa Slope and Rapid River areas include or are bounded by a designated wild and scenic river. These features add to the scenic, historic, and cultural values of these areas that draw visitors specifically to enjoy them.

Manageability to Preserve Wilderness Characteristics

Bighorn-Weitas, Hoodoo, Mallard Larkins, Meadow Creek-Upper North Fork, and Rapid River share a large portion of their boundary with front country. Approximately one-third of the boundaries of Moose Mountain, North Fork Spruce-White Sand, and North Lochsa Slope are adjacent to front country. East Meadow Creek and most of Sneakfoot Meadows are bounded by wilderness or other roadless areas. Sights and sounds from activities in the front country can be apparent in some locations in roadless areas, reducing the opportunity for solitude and primitive recreation.

Bighorn Weitas, Hoodoo, North Fork Spruce-White Sand, and Sneakfoot Meadows are popular snowmobile areas. Mountain biking is also popular in Bighorn Weitas, Hoodoo, Mallard Larkins, North Lochsa Slope, and to a lesser degree in North Fork Spruce-White Sand and Sneakfoot Meadows. Snowmobiling and mountain biking are continuing in all these areas despite being administratively prohibited in Hoodoo and Sneakfoot Meadows. These activities are inconsistent with wilderness character and reduce the apparent naturalness and the opportunity for solitude or primitive and unconfined recreation and may disrupt use of an area by some wildlife species where they occur. These activities could also increase the need for management actions to improve education of, respect for, and compliance with wilderness values and boundaries.

Alternative X – 0 acres

There are no areas recommended for wilderness in this alternative (Table 421 and Table 422). Therefore, the 1987 Forest Plan recommended wilderness areas would no longer be managed as recommended wilderness. Under this alternative, some wilderness characteristics within inventoried roadless areas would be maintained by the requirements of the Idaho Roadless Rule, which limits building roads and timber harvest, although motorized use is not prohibited. Refer to the Sustainable Recreation and Idaho Roadless Rule Area sections for additional information. The Nez Perce-Clearwater would continue to provide a primitive recreation opportunity spectrum experience in the existing designated wilderness of 1,139,059 acres, or 29 percent, of the Nez Perce-Clearwater.

Although Alternative X has no recommended wilderness, the summer recreation opportunity spectrum for the existing recommended wilderness areas would be a semi-primitive non-motorized classification. Therefore, there would be no change in motorized access from the existing condition as described under the No Action Alternative. Mechanized access is not restricted by this classification therefore there would be an increase of 328 miles open to mechanized use that are closed under the existing condition.

Under this alternative the winter recreation opportunity spectrum classification would be semi-primitive motorized. Therefore, areas allowing for motorized over-snow vehicle use would increase by 278,893 acres as a result of these changes. Total acres suitable for winter over-snow motorized access across the Forest, by these and other changes, would increase by 288,342 acres as compared to the No Action alternative.

Because this alternative recommends no additional areas for wilderness, opportunities for solitude and remoteness in a primitive setting would decrease across the Nez Perce-Clearwater. Therefore, this alternative provides the least amount of primitive setting of all the alternatives.

Alternative X includes 0 acres of underrepresented ecological groups, which is lower than all other Alternatives. This is the amount this alternative would not add to underrepresented ecological groups to the National Wilderness Preservation System since these areas would not be recommended.

Table 421. Change in indicator values under Alternative X

Indicator	Value
Acres of recommended wilderness	0
Change in miles of trails open to wheeled motorized use	0
Change in acres of suitable motorized over-snow vehicle areas	+278,390*
Change in miles of trails open to nonmotorized mechanized transportation	+328
Change in the number of commercial rental (buildings and structures) units	0
Acres of underrepresented ecological groups of the National Wilderness Preservation System	0

Data Source: Nez Perce-Clearwater GIS data.

*Value includes changes by ROS in all Idaho Roadless Areas

Table 422. Alternative X indicator values by recommended wilderness area

Recommended Wilderness Area	Indicator 1 (acres)	Indicator 2 (miles)	Indicator 3 (acres)	Indicator 4 (miles)	Indicator 5 (number)	Indicator 6 (acres)
None	0	0	+278,390	+328	0	0

Indicator 1 = acres of recommended wilderness. Indicator 2=change in miles of trails open to wheeled motor use. Indicator 3=change in acreage of suitable motorized over-snow vehicle areas. Indicator 4=change in miles of trails open to mechanized transportation. Indicator 5=change in commercial rental (buildings and structures) units. Indicator 6=Acres of underrepresented ecological groups of the National Wilderness Preservation System.

Data Source: Nez Perce-Clearwater GIS data.

Alternative X – 0 acres

34 Roadless Areas, No Recommended Wilderness

Under this alternative, none of the 1,481,637 acres of roadless areas would be recommended for wilderness. However, these areas would still retain many of the wilderness characteristics that are present in them today. Although the Idaho Roadless Rule allows for limited management actions and motorized and mechanized recreation activities, it is anticipated that any activity would occur on less than one percent of these lands per decade. Therefore, the roadless values and wilderness characteristics of these 1,481,637 acres are expected to remain present and largely intact through the planning cycle.

Alternative Y

Alternative Y would recommend 4 areas for recommended wilderness totaling 309,306 acres. These areas would be managed in either a primitive or semi-primitive non-motorized recreation opportunity spectrum setting, with motorized and nonmotorized mechanized travel prohibited, including aircraft and unmanned aerial systems, excepting administrative use by federal, state, or local agencies. Additionally, the existing recommended wilderness areas of Sneakfoot Meadows and North Fork Spruce-White Sand would be under a summer semi-primitive non-motorized classification. Trails currently closed would remain closed to motorized use. However, trails currently closed to mechanized transport would be suitable for this activity.

The construction of new structures or buildings would not be suitable unless explicitly needed to protect resources or administer the area. The maintenance of existing buildings and structures, and measures to protect those buildings and structures, would be allowed. Replacement of existing buildings, unless explicitly needed to protect resources or administer the area, would not be allowed. Continued commercial use of one rental cabin, Meadow Creek Station, within these recommended wilderness areas would be allowed under this alternative.

There are several existing roads open to high clearance vehicles within recommended wilderness areas under this alternative. The East Meadow Creek recommended wilderness area contains two roads – Forest Service Road 285 Elk Mountain, 8.9 miles, and Forest Service Road 357 Running Creek, 10.4 miles – that penetrate the area, are excluded from the area, and would remain open to motorized travel. Within the Hoodoo recommended wilderness area, the Fish Lake trail at 4.1 miles would be closed to motorized travel pending site-specific analysis.

Alternative Y finds use of motorized equipment and mechanical transport to be suitable for administrative use by agency personnel, partners, and members of the public under agreement with the Nez Perce-Clearwater that preserves or improves the wilderness characteristics of the area and to maintain infrastructure and trails. All other motorized equipment and mechanical transport by the public would be prohibited. There are 449 miles of system trails within Alternative Y's recommended wilderness areas, with 42 miles currently open to motorized travel. There are 117 miles that are currently open to mechanized transport, including motorized trails. Several areas within the Alternative Y recommended wilderness areas are currently managed as recommended wilderness, and as such, currently do not allow for mechanized transport. Table 423 describes the summer and winter recreation opportunity spectrum classes within the recommended wilderness areas of Alternative Y. Under this alternative there are no acres in a motorized class. Therefore, the motorized and mechanized activities or uses that are not allowed in the Land Management Plan's record of decision could begin to be removed after site-specific analysis is completed. Mechanized transport on system trails within recommended wilderness areas could decrease from 117 miles to 0 miles through this process. Likewise, wheeled motorized use on designated routes could decrease from 42 miles to 0 miles within recommended wilderness areas after completion of site-specific analysis. Finally, the winter motorized suitable acres could also be reduced to zero.

Table 423. Acres of recommended wilderness in summer and winter recreation opportunity spectrum classes (ROS) under Alternative Y

Category	Summer ROS	Winter ROS
Primitive	24,080	0
Semi-primitive non-motorized	285,226	309,306
Non-motorized Total	309,306	309,306
Semi-primitive motorized	0	0
Roaded Natural	0	0
Rural	0	0
Motorized Total	0	0
Total Acres	309,306	309,306

Data Source: Nez Perce-Clearwater GIS data.

This alternative and Alternative W would result in the most changes to wheeled motorized use, mechanized transport, and motorized over-snow vehicle use opportunities on the Nez Perce-Clearwater (Table 424 and Table 425). Displacement of motorized, both wheeled and over-snow vehicles, and mechanized transport on the Nez Perce-Clearwater could occur if a site-specific decision is completed that prohibits these uses in recommended wilderness. Should these closures occur, use might become concentrated in areas that remain suitable for motorized wheeled and motorized over-snow vehicle, causing some users to have negative experiences or go elsewhere to an off-forest location or to other lands open to motorized use and mechanized transport.

Table 424. Change in indicator values under Alternative Y

Indicator	Value
Acres of recommended wilderness	309,332
Change in miles of trails open to wheeled motorized use	-42
Change in acres of suitable motorized over-snow vehicle areas	-30,937*
Change in miles of trails open to nonmotorized mechanized transportation	-59
Change in the number of Commercial rental (buildings and structures) units	0
Acres of underrepresented ecological groups of the National Wilderness Preservation System	174,723

Data Source: Nez Perce-Clearwater GIS data.

*Value includes changes by ROS in all Idaho Roadless Areas

Table 425. Alternative Y indicator values by recommended wilderness area (RWA)

Recommended Wilderness Area	Existing RWA Dropped	Indicator 1 (acres)	Indicator 2 (miles)	Indicator 3 (acres)	Indicator 4 (miles)	Indicator 5 (number)	Indicator 6 (acres)
East Meadow Creek	n/a	96,856	-40	-96,856	-61	0	65,572
Hoodoo	n/a	100,680	-2	+11,332	-7	0	42,084
Mallard Larkins	n/a	90,855	0	-24,478	-4	0	51,424
Rapid River	n/a	20,941	0	-1,286	-45	0	15,643
n/a	Sneakfoot Meadows	n/a	0	+9,465	+20	n/a	n/a
n/a	NF Spruce White Sand	n/a	0	+9,865	+38	n/a	n/a
Total acres		**309,332**	**-42**	**-91,958**	**-59**	**0**	**174,723**

Indicator 1 = acres of recommended wilderness. Indicator 2=change in miles of trails open to wheeled motor use. Indicator 3=change in acreage of suitable motorized over-snow vehicle areas. Indicator 4=change in miles of trails open to mechanized transportation. Indicator 5=change in commercial rental (buildings and structures) units. Indicator 6=Acres of underrepresented ecological groups of the National Wilderness Preservation System.

Data Source: Nez Perce-Clearwater GIS data.

In this alternative, the construction of new buildings or structures would not be allowed unless explicitly needed to protect resources or administer the area. Maintenance of current buildings and structures, and measures to protect those buildings and structures, would be permitted. The replacement of existing buildings, unless explicitly needed to protect resources or administer the area, would not be allowed.

Alternative Y includes 174,723 acres of underrepresented ecological groups, which is higher than Alternative X and lower than Alternatives W and Z. This is the amount this alternative would add of underrepresented ecological groups to the National Wilderness Preservation System if these areas were designated as wilderness.

The total amount of recommended wilderness when combined with existing designated wilderness, 1,139,059 acres, would bring the total acreage to about 1,448,391 acres, or about 36.8 percent, of the Nez Perce-Clearwater that is in designated or recommended wilderness. These acres would provide a primitive or semi-primitive non-motorized setting on the Nez Perce-Clearwater where wheeled motorized use, motorized over-snow vehicle use, and mechanized transport, including bicycles and game carts, would be prohibited. The primitive setting is characterized by large, remote, wild, and predominantly unmodified landscapes with no motorized activity and a lower probability of seeing other people. Primitive settings are managed for quiet solitude away from roads, people, and development. There are few facilities or developments. Semi-primitive non-motorized settings are characterized by areas of the Nez Perce-Clearwater that are managed for non-motorized use. Uses may include hiking and equestrian trails, mountain bikes, and other non-motorized mechanized vehicle. Rustic facilities may be present, usually for administrative or resource protection purposes. These areas provide for the opportunity for exploration, challenge, and self-reliance. This alternative provides additional opportunity for a primitive or semi-primitive non-motorized recreation opportunity spectrum setting by 7.8 percent through recommending 309,306 acres for wilderness designation.

Alternative Y has more recommended wilderness than Alternative X and the Preferred Alternative, and less than Alternatives W and Z. There would be a five-year objective for removing those uses that are inconsistent with wilderness designation.

Alternative Y – 309,332 acres
East Meadow Creek, Hoodoo, Mallard Larkins, and Rapid River

Apparent Naturalness

The East Meadow Creek and Mallard Larkins roadless areas each have administrative structures and recreation rentals. All the areas have trail bridges. These facilities are not readily apparent, except when a visitor is in proximity to them. East Meadow Creek has 19 miles, Mallard Larkins has 1.1 miles, and Hoodoo has 0.5 miles of interior roads. Roadside hazard tree removal has occurred along the interior roads or adjacent roads. Except for these minor intrusions, these areas appear natural, ecological systems appear to be functioning, and the areas retain their primeval character.

Solitude, Primitive, and Unconfined Recreation

These areas are predominantly in either a primitive or semi-primitive non-motorized recreation opportunity class. However, due to their adjacency to open roads, they also include semi-primitive motorized or roaded natural recreation opportunity classes. Hoodoo, Mallard Larkins, and Rapid River share a large portion of their boundary with front country. East Meadow Creek is bounded by wilderness or another roadless area. The sights and sounds from activities in the front country can be apparent in roadless areas, reducing the opportunity for solitude and unconfined recreation. Hoodoo and Mallard Larkins also have motorized trails penetrating the interior. Due to topography and dense vegetation, with few exceptions, the sights and sounds associated with these roads and trails, or activities in the front country, do not penetrate far into the areas. Winter motorized use is popular and well established in the Hoodoo area despite being administratively closed to this activity. Mountain biking is popular in portions of Hoodoo and Mallard Larkins. East Meadow Creek, Hoodoo, and Mallard Larkins are large areas with few developments. Except for the intrusions from roads and motorized and mechanized use, there is ample opportunity for solitude. These areas also include large, wild landscapes that offer challenge, adventure, and self-reliance to support primitive and unconfined recreation when not in proximity to the sights and sounds from activities inconsistent with wilderness character.

Presence of Ecological, Geological or Other Features of Scientific, Educational, Scenic or Historical Value

Most areas contain ecosystems that are underrepresented in the national wilderness preservation system and two-thirds to three-fourths of the acres are within their natural range of variability. East Meadow Creek and Hoodoo include substantial acreage that is modeled whitebark pine habitat, while the others have some whitebark pine habitat. Mallard Larkins supports one of the largest Rocky Mountain goat populations in northern Idaho; Hoodoo also supports a goat population. Generally, water quality is good, and watersheds are functioning properly. The East Meadow Creek area borders Meadow Creek, a principal tributary of the Selway River, which is recognized as an important watershed, supporting Chinook salmon, steelhead, bull trout, red band trout, and westslope cutthroat trout. High mountain peaks, rugged rock formations, and high mountain lakes in Hoodoo and Mallard Larkins are geological features of interest that add to the high scenic character and overall wilderness character that draws visitors to these areas. Hot springs and the Meadow Creek National Recreation Trail draw visitors to the Meadow Creek roadless area, and the Rapid River Wild and Scenic River draws visitors to the Rapid River roadless area.

Manageability to Preserve Wilderness Characteristics

Portions of the Hoodoo roadless area include a popular snowmobile area. Mountain biking is also popular in Hoodoo and Mallard Larkins. These activities are inconsistent with wilderness character and reduce the apparent naturalness and the opportunity for quite solitude and primitive and unconfined recreation and may disrupt use of an area by some wildlife species where they occur. These activities could also increase the need for management actions to improve education, respect, and compliance with wilderness values and boundaries in these areas.

Alternative Z – 569,755 acres

Alternative Z would have 10 areas for recommended wilderness totaling 569,755 acres. These areas would be managed in a summer primitive or semi-primitive non-motorized recreation opportunity spectrum, with motorized travel prohibited, excluding recreational and administrative use of aircraft and unmanned aerial systems. The winter recreation opportunity spectrum for these areas would be primarily semi-primitive motorized and would allow for motorized over-snow vehicle use. Bicycles and other forms of mechanized transportation would also be allowed year-round.

Additionally, the construction of new structures or buildings would not be suitable unless explicitly needed to protect resources or administer the area. The maintenance of existing buildings and structures, and measures to protect those buildings and structures, would be allowed. Under this alternative the replacement of existing buildings and structures would be allowed. Commercial rental of existing structures would not be allowed under this alternative. Meadow Creek Station is the only existing commercial rental within these recommended wilderness areas.

There are several existing roads open to high clearance vehicles within recommended wilderness areas under this alternative. The East Meadow Creek recommended wilderness area contains two roads –Forest Service Road 285 Elk Mountain, 8.9 miles, and Forest Service Road 357 Running Creek, 10.4 miles – that are currently open and could be closed to motorized travel pending a site-specific analysis. The Sneakfoot Meadows recommended wilderness area has one road, Forest Service road 358, which could also be closed to motorized vehicles leading into Kooskooskia Meadows for 2.1 miles pending a site-specific analysis. Within the Hoodoo recommended wilderness area the Fish Lake trail would remain open to motorized travel.

Alternative Z finds use of chainsaws and other motorized equipment and mechanical transport to be suitable for administrative use by agency personnel, partners, and members of the public under agreement with the Nez Perce-Clearwater. Administratively, this use would be permitted to accomplish restoration activities, to accomplish administrative work that protects and or enhances the wilderness characteristics of the area, or to maintain infrastructure and trails to facilitate access into areas.

There are 725 miles of system trails within Alternative Z's recommended wilderness areas, with 146 miles currently open to motorized travel. There are six areas within the Alternative Z recommended wilderness areas that are currently managed as recommended wilderness or have prohibitions on mechanized transport, and as such, do not allow for mechanized transport. However, under this alternative the amount of trail miles open to nonmotorized mechanized transport would increase to 325 miles. Table 426 describes the summer and winter recreation opportunity spectrum classes within the recommended wilderness areas of Alternative Z. Under this alternative there are no acres in a motorized class. Therefore, the motorized trail use that is not allowed in the Land Management Plan's record of decision could begin to be removed after site-specific analysis is completed.

Table 426. Acres of recommended wilderness in summer and winter recreation opportunity spectrum classes (ROS) under Alternative Z

Category	Summer ROS	Winter ROS
Primitive	34,750	0
Semi-primitive non-motorized	532,595	0
Non-motorized Total	567,345	0
Semi-primitive motorized	0	464,338
Roaded Natural	0	10,143
Rural	0	0
Motorized Total	0	474,481
Total Acres	567,345	474,659

Data Source: Nez Perce-Clearwater GIS data.

There could be a decrease from 146 miles to 0 miles available to wheeled motorized use on designated routes within recommended wilderness areas after site-specific analysis is completed. The winter motorized suitable acres could increase by 217,348 acres because in this alternative all recommended wilderness acres are within a winter semi-primitive motorized or roaded natural class. This suitability finding does not ensure that all acres of recommended wilderness would be accessible for winter over-snow vehicle use.

A larger amount of the forest would be found suitable for winter over-snow use than the current 1987 plans find suitable and would result in the largest increase to winter over-snow motorized use since all recommended wilderness acres would be suitable for over-snow use. Under the No Action Alternative, only 7 percent of recommended wilderness areas would be suitable for winter over-snow use; but, under this alternative, 100 percent of the recommended wilderness areas would be suitable. Likewise, the miles of trail suitable for mechanized travel within the recommended areas would also be retained under this alternative. Wheeled motorized travel would be reduced in this alternative for the recommended wildernesses. This alternative has more acres of recommended wilderness than Alternative Y and less than Alternative W so it would cumulatively reduce the amount of wheeled suitable acres across the forest compared to Alternative Y and expand the amount compared to

Alternative W. Displacement of wheeled motorized vehicles on the Nez Perce-Clearwater could occur if a site-specific decision is completed that prohibits these uses in recommended wilderness. Should these closures occur, use might become concentrated in areas that remain suitable for motorized wheeled transport causing some users to have negative experiences and/or go elsewhere to an off-forest location or to other lands open to motorized use.

Alternative Z includes 333,078 acres of underrepresented ecological groups, which is higher than Alternatives X and Y and lower than Alternatives W. This is the amount this alternative would add of underrepresented ecological groups to the National Wilderness Preservation System if these areas were designated as wilderness.

The total amount of recommended wilderness when combined with existing designated wilderness, 1,139,059 acres, would bring the total acreage to about 1,708,814 acres, or about 43.4 percent, of the Nez Perce-Clearwater that is in designated or recommended wilderness. These acres would provide summer recreation opportunities that are consistent with the recreation opportunity spectrum classification of semi-primitive non-motorized or primitive on 57 percent of the Nez Perce-Clearwater, where wheeled motorized use would decrease. The primitive setting is characterized by large, remote, wild, and predominantly unmodified landscapes with no motorized activity and a lower probability of seeing other people. Primitive settings are managed for quiet solitude away from roads, people, and development. There are few facilities or developments. Semi-primitive non-motorized settings are characterized by areas of the Nez Perce-Clearwater that are managed for non-motorized use. Uses may include hiking and equestrian trails, mountain bikes, and other non-motorized mechanized transport or equipment. Rustic facilities may be present, usually for administrative or resource protection purposes. These areas provide for the opportunity for exploration, challenge, and self-reliance. This alternative provides opportunity for a primitive or semi-primitive non-motorized recreation opportunity spectrum setting through recommending 569,755 acres for wilderness designation.

Alternative Z has more recommended wilderness than Alternative X, Y, and the Preferred Alternative, and less than Alternative W (Table 427 and Table 428). Therefore, it would provide the second highest amount of recommended wilderness setting on the Nez Perce-Clearwater.

Table 427. Change in indicator values under Alternative Z

Indicator	Value
Acres of recommended wilderness	569,755
Change in miles of trails open to wheeled motorized use	-146
Change in acres of suitable motorized over-snow vehicle areas	+278,383*
Change in miles of trails open to nonmotorized mechanized transportation	+325
Change in the number of Commercial rental (buildings and structures) units	-1
Acres of underrepresented ecological groups of the National Wilderness Preservation System	333,078

Data Source: Nez Perce-Clearwater GIS data.

*Value includes changes by ROS in all Idaho Roadless Areas

Table 428. Alternative Z indicator values by recommended wilderness area

Recommended Wilderness Area	Indicator 1 (acres)	Indicator 2 (miles)	Indicator 3 (acres)	Indicator 4 (miles)	Indicator 5 (number)	Indicator 6 (acres)
East Meadow Creek	96,856	-16	0	+33	-1	65,180
Hoodoo	147,039	0	+111,986	+5	0	61,462

Indicator 6=Acres of underrepresented ecological groups of the National Wilderness Preservation System.

Data Source: Nez Perce-Clearwater GIS data.

Alternative Z – 569,755 acres

East Meadow Creek, Hoodoo, Mallard Larkins, Meadow Creek-Upper North Fork, North Fork Spruce-White Sand, Pot Mountain, Rapid River, Rawhide, Sneakfoot Meadows, West Meadow Creek

Apparent Naturalness

The East Meadow Creek, West Meadow Creek, and Mallard Larkins roadless areas each have administrative structures. East Meadow Creek and Mallard Larkins also have recreation rentals. Six of the areas have trail bridges. These facilities are not readily apparent, except when a visitor is in proximity to them. East Meadow Creek has 19 miles, West Meadow Creek has 10.7 miles, Hoodoo has 0.5 miles, Mallard Larkins has 1.1 miles, and Meadow Creek-Upper North Fork has 0.3 miles of interior roads. Roadside hazard tree removal has occurred along some of these interior roads and adjacent roads. Various species of noxious weeds are present in all areas, with a significant number of acres in East Meadow Creek, Mallard Larkins, Pot Mountain, and West Meadow Creek. Most noxious weed infestations are associated with adjacent roads and some interior trails. Meadow Creek-Upper North Fork has had past mining activity, which is still apparent today in the headwaters of the North Fork Clearwater River. Grazing is nonexistent in all areas except Rapid River, which is completely in a grazing allotment and a small portion of West Meadow Creek. Evidence of grazing is readily apparent in these areas. Except for these intrusions, these areas appear natural, ecological systems appear to be functioning without human intervention, and the areas retain their primeval character.

Solitude, Primitive, and Unconfined Recreation

These areas are predominantly in either a primitive or semi-primitive non-motorized recreation opportunity class. However, due to their adjacency to open roads, they all also include semi-primitive motorized or roaded natural recreation opportunity classes. Rawhide, with its small size and adjacency to a well-traveled road, provides about half of its area in a roaded natural setting.

Hoodoo, Mallard Larkins, Meadow Creek-Upper North Fork, Pot Mountain, Rapid River, and West Meadow Creek share a large portion of their boundary with front country. East Meadow Creek, North Fork Spruce-White Sand, Sneakfoot Meadows, and Rawhide are predominantly adjacent to wilderness or other roadless areas. Sights and sounds from activities in the front country can be apparent in roadless areas, reducing the opportunity for solitude and unconfined recreation. Due to topography and dense vegetation, with few exceptions, the sights and sounds associated with these roads, trails, and activities in the front country do not penetrate far into most areas. However, roadless areas with roads penetrating the interior via cherry stems increase the amount of area impacted by the sights and sounds associated with motorized use of these roads. Additionally, the topography and lack of dense vegetation in Rawhide allows sights and sounds to be pervasive in most of the area; the potential for solitude here is minimal.

Winter motorized use is popular and well established in Hoodoo, North Fork Spruce–White Sand, and Sneakfoot Meadows, despite administrative closure to this activity in Hoodoo and Sneakfoot Meadows. Mountain biking is popular in portions of Hoodoo, Mallard Larkins, Pot Mountain, and West Meadow Creek. East Meadow Creek, Hoodoo, Mallard Larkins, and West Meadow Creek are large areas with few developments. Except for the intrusions from roads and motorized and mechanized use, or from increased contact with other visitors in popular areas, there is ample opportunity for solitude in most of these areas if one is to leave well-traveled routes. These areas also include large, wild landscapes that offer challenge, adventure, and self-reliance to support primitive and unconfined recreation when not in proximity to the sights and sounds from activities inconsistent with wilderness character.

Presence of Ecological, Geological or Other Features of Scientific, Educational, Scenic or Historical Value

A large percentage of each area contains ecosystems that are underrepresented in the national wilderness preservation system and about two-thirds of the acres are within their natural range of variability. East Meadow Creek, Hoodoo, and West Meadow Creek include substantial acreage that is modeled whitebark pine habitat, while the other areas have some whitebark pine habitat. East Meadow Creek, Pot Mountain, and Sneakfoot Meadows contain research natural areas.

Mallard Larkins supports one of the largest Rocky Mountain goat populations in Northern Idaho; Hoodoo also supports a mountain goat population. Wolverine female denning habitat occurs in Hoodoo, Mallard-Larkin, Meadow Creek-Upper North Fork, Pot Mountain, and Sneakfoot Meadows. The other areas in this alternative do not contribute substantially to wolverine denning habitat. The East Meadow Creek and West Meadow Creek areas border Meadow Creek, a principal tributary of the Selway River, which is recognized as an important watershed, supporting Chinook salmon, steelhead, bull trout, red band trout, and westslope cutthroat trout.

High mountain peaks, rugged rock formations, and high mountain lakes in Hoodoo and Mallard Larkins are geological features of interest that add to the high scenic character and overall wilderness character that draws visitors to these areas. Hot springs and the Meadow Creek National Recreation Trail draw visitors to the Meadow Creek roadless area, and the Rapid River Wild and Scenic River draws visitors to the Rapid River roadless area.

Manageability to Preserve Wilderness Characteristics

Hoodoo, Mallard Larkins, Meadow Creek-Upper North Fork, Pot Mountain, Rapid River, and West Meadow Creek share a large portion of their boundary with front country. Approximately one-third of the boundary of North Fork Spruce-White Sand is adjacent to front country. East Meadow Creek, North Fork Spruce-White Sand, Sneakfoot Meadows, and Rawhide are predominantly adjacent to wilderness or other roadless areas.

Boundaries with front country increases the intrusion of sights and sounds into the roadless areas as management activities occur proximate to those areas. This also increases the opportunity to see timber harvest, roads, and human habitation from viewpoints within the area. This would reduce the opportunity for solitude and primitive and unconfined recreation.

Portions of Hoodoo, North Fork Spruce-White Sand, and Sneakfoot Meadows are popular snowmobile areas. Mountain biking is popular in portions of Hoodoo, Mallard Larkins, Pot Mountain, and to a lesser degree in Sneakfoot Meadows as well. Motorized summer activity in these areas is minimal and not well established. The presence of motorized winter and summer mechanized activity also increases potential intrusion of sights and sounds not compatible with a wilderness experience. These activities are inconsistent with wilderness character and reduce apparent naturalness and the opportunity for quite solitude and primitive and unconfined recreation. These activities could also increase the need for management actions to improve education, respect, and compliance with wilderness values and boundaries.

Preferred Alternative – 263,357 acres

The Preferred Alternative recommends three areas for wilderness, totaling 263,357 acres. These include portions of the Mallard-Larkins, Hoodoo, East Meadow Creek, and West Meadow Creek Idaho Roadless Areas. These areas would be managed under the semi primitive non-motorized class of the Recreation Opportunity Spectrum for both summer and winter. Motorized and nonmotorized equipment and mechanized travel by the public would not be suitable in these areas. The use of chainsaws and other motorized equipment and mechanical transport would be suitable for administrative use by agency personnel, partners, and members of the public under agreement with the Nez Perce-Clearwater. These tools would be permitted to accomplish restoration activities, to accomplish administrative work that protects and or enhances the wilderness characteristics of the area, or to maintain infrastructure and trails to facilitate access into the areas. Administrative use of aircraft and unmanned aerial systems would be suitable. The use of prescribed fire is suitable. Use of biological agents would also be suitable for the control of insects and disease.

No commercial use of permanent structures, except recreation rentals, would occur. Currently, the Meadow Creek Ranger Station is used as a recreation rental and that use would continue. Existing structures would remain in place and maintenance and replacement of these structures may occur as needed. The construction of new structures or buildings would not be suitable unless explicitly needed to protect resources.

Roads adjacent to the areas would remain open or closed as determined through travel planning decisions. The boundary of the recommended areas would be set back 300 horizontal feet from the center line of these roads. The Meadow Creek Recommended Wilderness Area has one road that penetrates the interior of the area. This road, Forest Road #285, would remain open and excluded from the recommended wilderness area. The recommended wilderness area boundary would be set 300 horizontal feet either side of the center line of this road. The Hoodoo Recommended Wilderness Area has one road that penetrates the interior. Road #581B is a short road that accesses Toboggan Hill. This road remains closed to public motorized and mechanized travel. Road 705 penetrates the Mallard-Larkins Recommended Wilderness Area but was excluded from the roadless area.

Boundary Adjustments from Idaho Roadless Rule Areas for Recommended Wilderness Areas

Hoodoo – 108,276 acres

The Preferred Alternative excludes a portion of the Hoodoo Idaho Roadless Area that includes Road 295, Trail 419 and Fish Lake to the northern boundary of the roadless area. An additional exclusion offsets the recommended wilderness boundary 150 feet from the Divide Trail #738 for the length of the trail adjacent to the recommended wilderness area. These exclusions provide opportunity for non-motorized mechanized use such as mountain biking, in an area that was popular for this activity prior to closure through the 2017 travel management decision. These adjustments provide opportunity for this non-motorized activity without encroachment into the recommended wilderness area.

This alternative also excludes a southern portion of the Hoodoo Idaho Roadless Area in the Williams Range area. This includes an area from Blacklead Mountain, following the North Fork Ranger District boundary north of Williams Peak, Goat Lake and Williams Lake, then southeast along Williams Creek to Road 595. This exclusion will provide for high mountain over-snow vehicle use in an area that was popular for this activity prior to closure in 2012, while reducing encroachment into the recommended wilderness.

Mallard-Larkins – 82,286 acres

The Preferred Alternative excludes from the Mallard-Larkins recommended wilderness the southern portion of the Mallard-Larkins Idaho Roadless Area of approximately 35,500 acres that has a Backcountry Restoration theme. This area was not included in the RARE II, or 1987 Clearwater Forest Plan recommended wilderness nor was it covered under the 2017 Clearwater Travel Management Decision. The area is bounded by numerous motorized routes suitable for a variety of motorized vehicles and has interior trails popular for motorcycle travel. This area would be under a summer and winter semi-primitive motorized recreation opportunity spectrum classification, suitable for year-round motorized activities.

This alternative also excludes from recommended wilderness that portion of the Mallard-Larkins Idaho Roadless Area west of the Mallard-Larkins Pioneer Area and south of Minnesaka Creek to the Forest boundary. This includes the Smith Ridge portion of the IRA, south and west of the cherry-stem exclusion area associated with Forest Road 700 to the roaded area and motorized trail along the North Fork Clearwater to the western Forest boundary. It also includes a small portion of the northern slopes of Smith Ridge below the cherry stem to the Little North Fork Clearwater and Minnesaka Creek. This area has an Idaho Roadless Rule theme of Primitive but is bisected by primary travel routes and additional secondary roads that were originally excluded from the Idaho Roadless Area. An unidentified corridor through this area has been proposed to complete the GEM trail, a motorized trail from Elk City to Pierce, Idaho. In this area the trail would use existing open roads but would also require reconstruction and construction of a section of an existing closed road to connect with a road on Idaho state land.

Meadow Creek – 72,795 acres

The Preferred Alternative excludes the southern portion of the East Meadow Creek Idaho Roadless Area from the Meadow Creek recommended wilderness area. This excluded area includes all of the roadless area east of Road 285 and south of Road 357 and Trail 533 to the Selway-Bitterroot Wilderness boundary, approximately 32,700 acres. A corridor 300 horizontal feet either side of center line along Road 285 from the junction with Road 357 north to the terminus of the road at the intersection with Trail 517 is also excluded from the recommended wilderness. Road 285 and Road 357 would remain open to summer motorized use, but beyond that the area encompassing the East

Meadow Creek Idaho Roadless Area would be in a summer recreation opportunity spectrum class of semi-primitive non-motorized, not suitable for summer motorized use. The 32,700-acre excluded area would be in a winter semi-primitive motorized classification suitable for motorized over snow vehicle use as currently available under the 1987 Nez Perce Forest Plan.

This alternative also excludes approximately 107,000 acres of the 115,973-acre West Meadow Creek Idaho Roadless Area from the Meadow Creek recommended wilderness. This area is currently open to and popular for summer and winter motorized recreation. The excluded area would be in a summer and winter semi-primitive motorized recreation opportunity spectrum classification, suitable for year-round motorized activities. Although suitable for summer motorized, some trails that enter into the recommended wilderness area would be closed to motorized use at designated trail termini outside of the recommended area to facilitate user compliance and agency implementation and enforcement of these closures.

The 263,357 acres of recommended wilderness combined with the 1,139,059 acres of existing designated wilderness would bring the total acreage to about 1,402,416 acres, or about 35.6 percent, of the Nez Perce-Clearwater that is in designated or recommended wilderness. These acres would provide summer recreation opportunities that are consistent with the recreation opportunity spectrum classification of semi-primitive non-motorized or primitive on the Nez Perce-Clearwater, where public wheeled motorized use would be prohibited. The primitive setting is characterized by large, remote, wild, and predominantly unmodified landscapes with no motorized activity and a lower probability of seeing other people. Primitive settings are managed for quiet solitude away from roads, people, and development. There are few, if any, facilities or developments. Semi-primitive non-motorized settings are characterized by areas of the Nez Perce-Clearwater that are managed for non-motorized use. Uses may include hiking and equestrian trails, mountain bikes, and other non-motorized mechanized transport equipment. Rustic facilities may be present for administrative or resource protection purposes. However, under the Preferred Alternative, motorized and nonmotorized equipment and mechanized travel by the public would not be suitable in these areas. These areas provide for the opportunity for exploration, challenge, and self-reliance.

There are 380 miles of system trails within the Preferred Alternative's recommended wilderness areas, with 60 miles currently open to motorized travel and 108 miles that are currently open to mechanized transport. Table 429 describes the summer and winter recreation opportunity spectrum classes within the recommended wilderness areas of the Preferred Alternative. Under this alternative, there are no acres in a motorized class. Therefore, the motorized trail use that is not allowed in the Land Management Plan's record of decision could begin to be removed after site-specific analysis is completed.

Table 429. Acres of recommended wilderness in summer and winter recreation opportunity spectrum (ROS) classes under the Preferred Alternative

Category	Summer ROS	Winter ROS
Primitive	0	0
Semi-primitive non-motorized	263,357	263,357
Non-motorized Total	0	0
Semi-primitive motorized	0	0
Roaded Natural	0	0
Rural	0	0
Motorized Total	0	0

Category	Summer ROS	Winter ROS
Total Acres	0	0

Data Source: Nez Perce-Clearwater GIS data.

This alternative has the least number of acres recommended for wilderness except Alternative X, which has no recommended wilderness. All action alternatives reduce the miles of trails suitable to wheeled motorized use compared to the existing condition (Table 430 and Table 431).This alternative would result in the smallest loss of trails suitable for wheeled motorized use of all action alternatives as compared to the No Action alternative. Alternatives W, Y, and Preferred would reduce the acres suitable for motorized over-snow vehicle use, and alternatives X and Z would add acres suitable for this use. The Preferred alternative would reduce the least acres suitable for this use. Three action alternatives would reduce the miles of trail suitable for mechanized transportation. The Preferred Alternative reduces less miles than Alternatives W and Y. Alternatives X and Z would add miles of trail suitable for this use. Except for Alternative X, which has no recommended wilderness, the Preferred Alternative has the least acres of underrepresented ecological groups of all action alternatives.

Table 430. Change in indicator values under the Preferred Alternative

Indicator	Value
Acres of recommended wilderness	263,357
Change in miles of trails open to wheeled motorized use	-2
Change in acres of suitable motorized over-snow vehicle areas	-117,641*
Change in miles of trails open to nonmotorized mechanized transportation	-14
Change in the number of Commercial rental (buildings and structures) units	0
Acres of underrepresented ecological groups of the National Wilderness Preservation System	142,065

Data Source: Nez Perce-Clearwater GIS data.

*Value includes changes by ROS in all Idaho Roadless Areas

Table 431. Preferred Alternative indicator values by recommended wilderness area (RWA)

Recommended Wilderness Area	Existing RWA Dropped	Indicator 1 (acres)	Indicator 2 (miles)	Indicator 3 (acres)	Indicator 4 (miles)	Indicator 5 (number)	Indicator 6 (acres)
East Meadow Creek	n/a	72,795	-60	-64,156	-99	0	50,233
Hoodoo	n/a	108,276	0	+3,290	+31	0	45,259
Mallard Larkins	n/a	82,286	0	-14,890	-4	0	46,573
n/a	Sneakfoot Meadows	n/a	+20	+9465	+20	n/a	n/a
n/a	NF Spruce-White Sand	n/a	+38	+9,865	+38	n/a	n/a
Total		263,357	-2	-56,426	-14	0	142,065

Indicator 1 = acres of recommended wilderness. Indicator 2=change in miles of trails open to wheeled motor use. Indicator 3=change in acreage of suitable motorized over-snow vehicle areas. Indicator 4=change in miles of trails open to mechanized transportation. Indicator 5=change in commercial rental (buildings and structures) units. Indicator 6=Acres of underrepresented ecological groups of the National Wilderness Preservation System.

Data Source: Nez Perce-Clearwater GIS data.

These recommended areas would contribute the following wilderness characteristics, values, and opportunities to the Nez Perce-Clearwater.

East Meadow Creek – 72,795 acres

Apparent Naturalness

This area shows some sign of human impacts. At one time, there were many sheep grazing allotments in the East and West Meadow Creek roadless areas. The effects of this grazing have largely vanished, except evidence of the stock driveways which are apparent to the knowledgeable observer. Two adjacent lookout towers can be seen from some parts of the area and the Meadow Creek Ranger Station, which consists of multiple structures and is used as a recreation rental, is within the area. While this is clearly a man-made facility, its historic context and natural-appearing aesthetics blend well with its primitive setting. The facility is not visible, except when a visitor is on site. Trail bridges, remnant mining, range fences, old firelines, and localized invasive weeds provide evidence of human use in the area and provide minor detractions from the area's apparent naturalness.

Virtually all of the upper Meadow Creek drainage burned in 1919 and much of it is now covered with dense timber, except where large recent fires have burned. The area generally appears natural, vegetation in most of the area is within the natural range of variation, and long-term ecological processes are intact and operating naturally.

Solitude, Primitive, and Unconfined Recreation

Meadow Creek has a well-developed trail system that provides access through much of the area. A few of these trails are heavily used, especially during hunting season. Road #357 borders the area to the southeast and provides access to the trailheads for Trails #530, #531, #533, and #535 into the Selway-Bitterroot Wilderness. Road #285 enters the area from the south and provides cherry-stemmed motorized access to Windy Saddle and near Elk Mountain and trailheads for non-motorized Trails #513, #517, #529, and #647. Road #290 accesses the northern end at Indian Hill lookout and non-motorized Trails #602, #603, and #621. Away from these roads and popular trails, the area provides mostly a primitive and semi-primitive non-motorized recreation setting. Visitors in proximity to nearby open roads and motorized trails may experience audible and/or visual intrusions to their experience. Likewise, when traveling along the many trails of the area, encounters with others is likely as this area is popular for a variety of activities. However, Meadow Creek is adjacent to the Selway-Bitterroot Wilderness and this vast area offers numerous places where one can go with little chance of encountering another person away from these trails. Together, these undeveloped roadless areas offer unlimited opportunity for solitude, adventure, challenge, and primitive and unconfined recreation. Primitive and unconfined recreational uses of the area include hiking, fishing, hunting, backpacking, and, for a select few, kayaking. Three outfitters operate in the area.

Ecological, geologic, or other features of scientific, educational, scenic, or historical value

Meadow Creek is part of the aboriginal territory of the Nez Perce Tribe and is among the lands that have important hunting and fishing areas for the tribe. The present-day Green Mountain Trail #541 is believed to be one of the original routes of the Southern Nez Perce Trail, as well as Trails #502 and #581 in the Bargamin Creek drainage south of the recommended wilderness area. Over 76 percent of the area consists of ecological types that are currently underrepresented in the national wilderness preservation system. Additionally, over 15,000 acres are in modeled white pine habitat, a high elevation species currently in decline. Though not a unique geologic feature, hot springs are located along Warm Springs Creek at the southern end of the area. The Meadow Creek National Recreation Trail enters the area from the north to the historic Meadow Creek Ranger Station. The area provides habitat for an abundance of wildlife typical of the plan area. Hunted species include elk, black bear, moose, wolves, and whitetail deer. The area contains large amounts of habitat for the federally listed threatened Canada lynx and federally listed candidate wolverine. The area contains minor amounts of maternal denning habitat for wolverines. Lower elevations in the meadow creek area contain fisher habitat. The Meadow Creek Recommended Wilderness Area would contribute to the Bitterroot Recovery Zone once grizzly bears move into the area because it would provide additional secure habitat adjacent to the Selway-Bitterroot and Frank Church-River of No Return Wilderness areas that make up the Bitterroot Recovery Zone.

Meadow Creek is an important fisheries watershed on the Nez Perce-Clearwater. The watershed supports spring and summer Chinook, steelhead, westslope cutthroat trout, bull trout, and red band trout. The westslope cutthroat trout is known to have high genetic integrity.

Manageability

The east portion of the recommended wilderness area is currently managed under the primitive theme of the Idaho Roadless Rule, the second most restrictive theme, which includes very limited permissions and exceptions for timber cutting, sale or removal, road construction or reconstruction, and mineral activities. Exceptions include: to improve threatened, endangered, proposed, or sensitive species habitat; to maintain or restore the characteristics of ecosystem composition, structure, and processes; and to reduce the risk of uncharacteristic wildland fire effects to an at-risk community or municipal water supply system. Management is primarily to maintain roadless characteristics. The west portion of the recommended wilderness area is currently managed under the backcountry restoration theme of the Idaho Roadless Rule, which includes limited permissions and exceptions for timber cutting, sale, or removal; road construction and reconstruction; and mineral activities. This includes the following exceptions: to reduce hazardous fuel conditions within or outside of a community protection zone with conditions; to reduce the risk of uncharacteristic wildland fire effects; to improve threatened, endangered, proposed, or sensitive species habitat; and to maintain or restore the characteristics of ecosystem composition, structure, and processes.

The eastern edge of the area is bordered by the Selway-Bitterroot Wilderness. The southeast boundary is defined by a short section of Road #285 then along Road #357. The remainder of the boundary is defined by trails, except a short section that follows the hydrologic divide between Meadow Creek and East Meadow Creek from Granite Peak to Meadow Creek. With that small exception, the well-defined and maintained trails and roads make a readily apparent and manageable boundary. Snowmobile use occurs on Road #285 to Elk Mountain and Road #357. These roads provide access to popular play areas around Elk Mountain and in Bargamin and Running Creeks. This will pose some management issues to prevent this use from occurring into the recommended wilderness area.

Hoodoo – 108,276 acres

Apparent Naturalness

The name "Great Burn" has been attached to the area by several groups and stems from the large wildfires which denuded much of the area during the early 1900's, primarily on the Idaho-side. Except for upper Moose, Pollack, and Swamp Creeks, much of the area north of Kelly Creek is still primarily covered with shrubs with scattered individual and small groups of trees. The area south of Kelly Creek has regenerated largely to lodgepole pine.

The area retains a high degree of natural integrity and appearance. Human activities have resulted in relatively minor and isolated impacts. The area does not include Forest Service Administrative sites or recreation rentals. Use on several of the main trails are the only real detractions from the natural integrity and appearance of the area.

The vegetation in 73 percent of the roadless area is within the natural range of variation and over 40 percent of the area consists of ecological types underrepresented in the National Wilderness Preservation System. Three ecosystems are found within the area – cedar-hemlock-pine, western spruce-fir, and alpine meadows and barren terrain. The cedar-hemlock-pine group represents the lower elevations. Where trees are found, it is represented primarily by western redcedar, grand fir, Douglas-fir, and larch, with very small amounts of western white pine on the Idaho-side. Ponderosa pine is found at the lower and drier elevations.

Solitude, Primitive, and Unconfined Recreation

This area may be accessed by vehicle from forest roads paralleling the boundaries or from dead-end roads. Access from the west is via Road #255 and from Road #581. These roads connect the North Fork Clearwater Basin to the Lochsa Basin, eventually reaching Highway 12. Road #581 is the southwest boundary, providing numerous access points to the roadless area. From the north, the area can be accessed from Road #250 to Road #295, then to the Osier Ridge lookout from Road #737. From the east, the area can be accessed through the Lolo National Forest on Road #7734.

A well-established trail system emanates from these access roads, providing access to the major drainages and ridgelines throughout the area. From these trails, visitors have unlimited opportunity to venture into exceptional wild country; from mountain ridges and peaks above the timberline to mid-slopes shrouded in dense brush and trees to steep drainage bottoms that contain fast-moving, crystal-clear streams. The vastness, scenic beauty, varied vegetation, and topography of the area provides ample opportunity for quite solitude, challenge and primitive and unconfined recreation. Primary activities are hiking, backpacking, horseback riding, fishing, big-game hunting, photography, and the pursuit of a wilderness experience.

Ecological, geologic, or other features of scientific, educational, scenic, or historical value

Hoodoo is one of three roadless areas on the Nez Perce-Clearwater where mountain goats are known to exist and inhabit the high country along the state line divide. These are unusual in the area and are scenic and wild to view. The area provides habitat for an abundance of wildlife typical of the Nez Perce-Clearwater. Hunted species include elk, black bear, mountain goats, moose, wolves, and whitetail deer. The mountain goat herd in the Hoodoo area is perhaps the second largest herd in the plan area. Two species of conservation concern have been observed in the Hoodoo area – harlequin ducks and fishers. The area contains large amounts of habitat for the federally listed threatened Canada lynx and federally listed candidate wolverine.

Species occurring in the Hoodoo recommended wilderness identified in the Regional Forester’s sensitive species list include the gray wolf, western pearlshell mussel, and westslope cutthroat trout. The area also provides habitat for lesser-known species, including boreal owls, rocky mountain tailed frogs, the Idaho giant salamander, and the American marten. The Hoodoo area provides a landscape that adds connectivity to the Bitterroot Ecosystem from other ecosystems like the Northern Continental Divide, Cabinet Yaak, and Selkirk ecosystems, which are located north and east of the Bitterroot ecosystem. Generally, the primitive, undisturbed condition of this area provides important habitat and connection to other areas for a variety of wide-ranging species.

Approximately 44 percent of the area consists of ecological types that are currently underrepresented in the national wilderness preservation system. The vegetation in the area includes over 15,000 acres of modeled whitebark pine habitat (Landguth et al. 2017), a high elevation species currently in decline.

Kelly Creek and its North, Middle, and South Forks flow through this roadless area and have been noted as having high scenic value in the Nationwide Rivers Inventory and reaffirmed as having "outstandingly remarkable" scenic value in the 2017 Nez Perce Clearwater National Forest Wild and Scenic River eligibility review. The water quality in the Hoodoo Roadless Area is generally high with 13 of the 17 sub-watersheds categorized as Watershed Condition Class 1, functioning properly, and encompass 93 percent of the Roadless Area.

Manageability

The recommended wilderness area portion of the Hoodoo Roadless Area is currently managed under the wildland recreation theme, the most restrictive theme of the 2008 Idaho Roadless Rule. The cutting, sale, or removal of timber is prohibited, except for personal or administrative use, as provided for in 36 CFR Part 223 or where incidental to the implementation of a management activity not otherwise prohibited by the Idaho Roadless Rule.

Much of the area is bounded by other roadless areas (58%) with the remainder adjacent to front country (42%). There are no adjacent private lands. Most of the boundary is well defined on major terrain, other recognized features, or roads and trails. In a few locations, however, terrain features are less prominent, and boundaries are difficult to locate on the ground. The management of boundaries shared by other roadless areas is generally not challenging since management is similar.

Recurrent winter motorized use (snowmobiling) was long established in the Idaho side of the roadless area until it was banned with the 2012 Clearwater Travel Plan decision. Despite this closure, incursions by these winter motorized sports enthusiasts has continued. Access to four keys area of high elevation bowls has been from near Powell on the south and from Hoodoo Pass from the north. Snowmobilers cite the unique opportunity, solitude, beauty, and high challenge level for this type of remote snowmobiling experience. The Preferred Alternative recommended wilderness area boundary excludes the most popular riding areas, generally with a well-defined topographic feature, such as prominent ridgelines. Boundary posting, information boards at trailheads, and focused enforcement will be essential to reduce this banned use in the area.

Mountain biking occurs in the area on the Divide Trail #738 and in the Goose Creek area on Trail #414. The Preferred Alternative excludes these areas from the recommended wilderness area. The Divide Trail is open to non-motorized mountain bikes in its entirety, with the recommended wilderness area boundary set 150 horizontal feet from the trail center. The Goose Creek area is excluded from the recommended wilderness area, as it lies north of the boundary established around Fish Lake. As with snowmobiling, boundary posting, information boards at trailheads, and focused enforcement will be essential to restrict this encroaching use and increase compliance in the recommended wilderness area.

Mallard-Larkins – 82,286 acres

Apparent Naturalness

Although there are numerous rock outcroppings, talus slopes, and barren areas, a large proportion of the area is heavily vegetated, ranging from mountain grasslands and meadows to dense mixtures of numerous tree and shrub species. Approximately 80 percent of the land was burned over in 1910 and much of it again in 1919, 1920, and 1924. Where conditions are favorable, stands of lodgepole pine, Douglas-fir, grand fir, Engelmann spruce, larch, western red cedar, western white pine, and mountain hemlock exist since some escaped the fires but most regenerated afterwards. Where the soils are thin and conditions severe, such as on the higher ridges and steep south facing slopes, shrubs still dominate the sites. The lands above 6,000 feet are subalpine in character, supporting mountain hemlock, subalpine fir, and lodgepole pine. Two thirds of the area are within the natural range of variation. Three major streams drain into the main North Fork of the Clearwater, which is outside the roadless area boundary. They include Isabella Creek, Collins Creek, and Skull Creek. Water quality is high and shows minimal undesirable human impact on natural physical or biological processes.

A large portion of the area is undisturbed by man except for trails. However, there are two Forest Service administrative sites, both fire lookouts, at Black Mountain and Mallard Peak and two electronic sites, one at Black Mountain and one on an unnamed ridge west of Perceptor Point. The lookouts are visible from many of the high peaks in the Mallard-Larkins Pioneer Area and the lone electronic site is visible from limited vantage points. Additionally, the dramatic vistas afforded by these peaks allow visitors to see beyond the recommended wilderness area into areas where timber harvesting and other human activity has occurred and is apparent in the middle ground and background. With these few exceptions, the area appears natural and ecological processes are functioning properly, without the influence of man.

Solitude, Primitive, and Unconfined Recreation

The Mallard-Larkins Recommended Wilderness Area is generally accessible by moderate to low standard gravel and dirt roads. Road #715 provides the eastern boundary, Road #252 and Road #5371 provide a portion of the southeastern boundary, and Road #247 establishes the southern boundary. Access from the west is by Roads #700 and #705. Interior access, with some exceptions, is provided over a network of low standard fire control and administrative trails. The roadless area is large and complex, composed of generally steep, rocky ridges and deep canyons. For this reason, much of the area is not accessed by trails.

The area offers a high degree of solitude. The varied terrain and the vastness enable the visitor to experience complete solitude in many areas. Except for the Five Lakes Butte area, cross-country travel is a definite challenge involving a higher degree of risk over the rugged terrain, steep narrow canyons, and densely vegetated slopes. These conditions offer ample opportunity for adventure, challenge, and primitive and unconfined recreation. Screening by both vegetation and topographic features is high in most of the area except from the high peaks and other scattered vantage points.

Concentrations of people around Five Lakes Butte and encounters with travelers along the system trails may tend to disrupt the solitude at certain times. Viewing of activities outside the area, such as logging and roads, is possible from numerous high ridges along the northern and southern boundaries. In addition, the Black Mountain Lookout is used during the summer season and serviced via helicopter, which detracts from the solitude in proximity to that area and flight corridor. Due to the large size of the area and lack of interior roads, the area provides mostly primitive and semi-primitive non-motorized recreation settings. The area provides roaded natural settings near the boundary along adjacent roads. Recreation uses are primarily hiking, horseback riding, hunting, and fishing. Several outfitters operate in the roadless area.

Ecological, geologic, or other features of scientific, educational, scenic, or historical value

Approximately 55 percent of the area consists of ecological types that are currently under-represented in the national wilderness preservation system, and much of the high elevation areas are modeled whitebark pine habitat. The Heritage Cedar Grove, which is a large stand of very old, large western red cedar located near the junction of Elmer Creek and Jug Creek, is a good example of the large cedar stands that were prevalent in association with riparian areas and pre-settlement areas and is an attraction for visitors. Within the recommended wilderness area, Isabella Creek and Elmer

Creek were identified as exhibiting characteristics that best exemplify core coastal refugia, a unique vegetative type.

The area provides habitat for an abundance of wildlife typical of the plan area. Hunted species include elk, black bear, mountain goats, moose, wolves, and whitetail deer. The mountain goat herd in the Mallard Larkin area is the largest herd in the plan area. The Mallard Larkin area contains fisher habitat at lower elevations and habitat for the federally listed threatened Canada lynx and federally listed candidate wolverine. Wolverine female denning habitat is abundant in this recommended wilderness area. Species occurring in the Mallard-Larkins recommended wilderness identified in the Regional Forester's sensitive species list include the gray wolf and westslope cutthroat trout. The area provides a landscape that adds connectivity to the Bitterroot Ecosystem from other ecosystems like the Cabinet Yaak and Selkirk, which are located north of the Bitterroot ecosystem. Generally, the primitive, undisturbed condition of this area provides important habitat and connection to other areas for a variety of wide-ranging species.

The Mallard-Larkins Pioneer Area was designated by the Regional Forester in 1969 as a special administrative unit. While much of this area is on the Idaho Panhandle National Forest, the portion on the Nez Perce-Clearwater contains many high peaks with dramatic views, mountain lakes, and rushing streams. The special area was set aside for its outstanding scenic, roadless, and primitive recreational qualities. The area includes three dramatic waterfalls, some of the largest on the Forest, located in Cliff Creek, Lost Pete Creek, and Falls Creek. Mallard, Heart, and Isabella Peaks and Black Mountain offer unique viewing and photographing opportunities of mountain goats during the spring and summer months.

Manageability

The recommended wilderness area portion of the roadless area is managed under two different roadless themes from the 2008 Idaho Roadless Rule – wildland recreation and primitive. Most of the area up to the Divide with the Idaho Panhandle National Forest is wildland recreation, the most restrictive theme. This represents the area recommended for wilderness in the 1987 Clearwater Forest Plan. The primitive theme, the next most restrictive, is a section of the recommended wilderness area along the southern and western boundaries adjoining the core.

The roadless area boundary of Mallard-Larkins uses forest roads, system trails, topographic features including streams, ridges and elevation, and cross-country for short sections. The majority of the boundary is readily identifiable but the infrequent cross-country sections would require signing for identification. In general, the area is bounded on the north by trails along the Forest boundary with the Idaho Panhandle National Forest, on the east by Road #715, the southeast by Road #5371 and the Indian Henry Ridge Trail #101, down a ridge to Skull Creek, following Skull Creek to the confluence with the North Fork Clearwater River, along the North Fork to Star Ridge, up and over Star Ridge, then using streams, ridges, elevation and Road # 705 to go around managed land in Isabella Creek, then along Dog Creek until it goes over Smith Ridge near Grassy Point, then along Minnesaka Creek to the confluence with the Little North Fork Clearwater River, then continuing along the Forest boundary as described above. It would be beneficial to locate and post this boundary, where needed, soon to avoid confusion later. The vastness of the area provides a manageable area with premiere wilderness character and opportunity for a wilderness experience. However, many vantage points offer views that include readily apparent managed land and active travel corridors. Depending on a visitor's location these could be in the foreground, middle ground, or background and would diminish opportunity for solitude and primitive and unconfined recreation.

Summer motorized incursions continue to occur into the area that may present a persistent enforcement challenge. Adequate boundary marking, trail maintenance, and reconstruction that makes this use more difficult, and concentrated enforcement may help to eliminate this use over time.

Recommended Wilderness Areas

Cumulative Effects

Cumulative effects are the past, present, and reasonably foreseeable future effects from management activities on the Nez Perce-Clearwater and adjacent lands.

It is recognized that all wilderness characteristics may not be fully realized at all times in any given recommended area. Reasonable and foreseeable future actions on National Forest System lands include vegetation management, mining, increased recreational use, wildland fire management, and reduction of fuels in the wildland-urban interface. Generally, the sights and sounds within a recommended wilderness area are used to determine effects on wilderness characteristics. However, depending on proximity to the recommended area boundary, as well as physical characteristics of the area, activities outside of a recommended area can degrade opportunities for solitude, primitive and unconfined recreation, and apparent naturalness. Some activities may be transient and temporary with only short-term impacts, such as noise from logging activities. Other activities may be long-term or permanent and provide potential constant degradation of some wilderness characteristics. Long-term conditions such as increasing populations and associated construction and life noise, increased recreational use of areas in or outside of the wilderness area, or increased and regular traffic on nearby roads or trails could degrade the sights, sounds, and opportunity for solitude normally associated with wilderness.

Growth in Lolo, Ravalli, and Missoula counties in Montana and counties in Idaho proximate to the Nez Perce-Clearwater is likely to increase recreational use, including use within the recommended wilderness areas. The effects of urbanization and population growth on recommended wilderness use and resource conditions are likely to be gradual and to extend well beyond the planning period. Increased recreational use may negatively affect wilderness characteristics, particularly the opportunity for solitude and natural quality. Examples of potential impacts include increased crowding, soil compaction or erosion, proliferation and expansion of dispersed camp sites, user-created trails, threats to native plant species from the spread of noxious weeds, and disruption to wildlife use and utility of an area.

Currently, the Nez Perce-Clearwater manages approximately 23.7 percent of the designated wilderness within Idaho and 1 percent of the National Wilderness Preservation System. Alternative W could potentially add the most acres to the National Wilderness Preservation System, followed by Alternatives Z and Y. The Preferred Alternative would add the least acres of recommended wilderness, except the No Action Alternative and Alternative X which recommends no additional areas for recommended wilderness.

Depending on the alternative, six recommended wilderness areas on the Nez Perce-Clearwater border other National Forests – Hoodoo, Mallard Larkins, Meadow Creek-Upper North Fork, Rawhide, East Meadow Creek, and Rapid River (Table 432). The Mallard Larkins recommended wilderness area shares about 33 miles of boundary with the Idaho Panhandle National Forest, which has recommended their portion of the Mallard Larkins area, approximately 80,200 acres, as recommended wilderness. The Meadow Creek-Upper North Fork and Rawhide recommended wilderness areas share boundaries with both the Idaho Panhandle and Lolo National Forests and do not have additional areas recommended as wilderness on those National Forests. The Hoodoo recommended wilderness area shares a border with the Lolo National Forest for approximately 47 miles. The Hoodoo, or Great Burn as it is referred to on the Lolo, has an additional 89,530 acres recommended as wilderness on that National Forest. The East Meadow Creek recommended wilderness area boarders the Bitterroot National Forest portion of the Selway Bitterroot Wilderness area, with about 19 miles of shared boundary. The Rapid River recommended wilderness area borders the Payette National Forest for approximately 6 miles. The current Payette National Forest plan does not recommend the bordering area for wilderness.

Table 432. Recommended wilderness areas (RWA) bordering other forests

RWA name	Nez Perce Clearwater acres (varies by Alternative)	Adjoining National Forest RWA acres	Total RWA acres (varies by Alternative)
East Meadow Creek	72,795	0	72,795
Hoodoo, aka Great Burn	101,000-151,000	89,530	190,530-240,530
Mallard Larkins	77,139-91,000	80,200	157,339-171,339
Meadow Creek-Upper North Fork	42,000-43,000	0	42,000-43,000
Rawhide	5,861	0	5,861
Rapid River	21,000	0	21,000

Effects to Resource from Other Resources

Management Area Allocations

Management area allocations vary between alternatives. Wilderness, ecological, and social characteristics that provide the suitability for inclusion in the National Wilderness Preservation System would be protected and maintained under the No Action Alternative and Alternatives W, Y, Z, and the Preferred Alternative.

Fire Management

All alternatives allow wildland fire to be used as a restoration tool to protect and/or enhance the wilderness characteristics of these areas. This provides options for the restoration of recommended wilderness areas. Wildfire is managed to play its natural role while managers evaluate point protection of values at risk. Following minimum impact suppression tactics would also serve to protect wilderness characteristics.

Fuel treatments including timber cutting, sale, and removal and other mechanical silvicultural treatments may occur to the extent permitted in the Idaho Roadless Rule (Part II 36 CFR 294, 2008) and to preserve or improve wilderness character. However, it is not anticipated that any timber harvest would be proposed in recommended wilderness.

Vegetative Management

These lands are not suitable for timber production; as stated above, timber cutting, sale, and removal may occur to the extent permitted in the Idaho Roadless Rule (Part II 36 CFR 294, 2008) to preserve or improve wilderness characteristics. However, it is highly unlikely that any timber harvest would be proposed in recommended wilderness. Most lands within recommended wilderness are within inventoried roadless areas that have high to outstanding wilderness characteristics, primarily due to restrictions on road building and timber harvesting not occurring in much of these areas. Inventoried roadless areas are identified as not suitable for timber production; therefore, there are very few acres within recommended wilderness where timber production would have been considered suitable. Refer to the Timber section for more information.

Vegetation management options would change in the future if recommended wilderness areas were designated as wilderness. Refer to the Forestlands section, the At-Risk Plant section, and the Fire Management section for additional information on these effects to vegetation management.

Recreation and Access

Alternative W contains the greatest amount of recommended wilderness, and all identified areas would be managed under a summer recreation opportunity spectrum classification of primitive or semi-primitive non-motorized in addition to prohibiting modes of mechanized transport. This would represent a decrease of 285 miles of trails currently open to wheeled motorized use and a decrease of 648 miles of trails currently open to mechanized transport. Additionally, recommended wilderness areas under Alternative W would be managed with a winter recreation opportunity spectrum classification of semi-primitive non-motorized, reducing the amount of acreage open to motorized over snow travel by 578,556 acres. Conversely, this alternative contains the greatest acreage and trail miles suitable only for non-motorized and or non-mechanized transport, such as hiking, skiing, and stock use.

Alternative X includes no recommended wilderness areas. However, the recommended wilderness areas in the 1987 Forest Plan, closed to motorized use in the 2017 travel management decision, would be in a summer recreation opportunity spectrum classification of semi-primitive non-motorized. Therefore, there would be no change in miles of trails open to wheeled motorized use in these areas as compared to the No Action alternative. However, these recommended areas would be opened to mechanized transport and this alternative offers an increase of 328 miles of trails. Under this alternative, the areas that were managed as recommended wilderness would be opened to winter motorized use and would be managed with the winter recreation opportunity spectrum of semi-primitive motorized. This would be an increase of 278,390 acres.

Alternative Y includes four areas totaling 309,332 acres of recommended wilderness. All identified areas would be managed under a summer recreation opportunity spectrum classification of primitive or semi-primitive non-motorized in addition to prohibiting modes of mechanized transport. This would represent a decrease of 42 miles of trails currently open to wheeled motorized use and a decrease of 59 miles of trails currently open to mechanized transport. This would be the third smallest reduction of trails open to motorized and mechanized transport of all alternatives. Additionally, recommended wilderness areas under Alternative W would be managed with a winter recreation opportunity spectrum classification of semi-primitive non-motorized, reducing the amount of acreage open to motorized over snow travel by 30,937 acres. This is the second smallest reduction of all action alternatives.

Alternative X, which recommends no areas for wilderness consideration, would not affect the amount of trail miles open for motorized use. The summer recreation opportunity spectrum would remain primitive or semi-primitive non-motorized. However, these recommended areas would be opened to mechanized transport and this alternative offers an increase of 328 in miles open to mechanized transport. Under this alternative, the areas that were managed as recommended wilderness would be opened to winter motorized use and would be managed with the winter recreation opportunity spectrum of semi-primitive motorized. This would be an increase of 278,390 acres.

The Preferred Alternative areas would be managed under a summer recreation opportunity spectrum classification of semi-primitive non-motorized, in addition to determining modes of mechanized transport as unsuitable. The Preferred Alternative has more acres of recommended wilderness than the No Action Alternative and Alternative X and less than Alternatives W, Y, and Z. There would be a decrease in the number of trails currently open to wheeled motorized use by 2 miles and 14 miles of trails currently open to mechanized transport. These minimal changes in motorized and mechanized access are due in large part to determining the Sneakfoot Meadows and North Fork Spruce-White Sand roadless areas suitable for motorized and mechanized access while eliminating them from recommended wilderness areas, representing an increase of 58 miles in these areas. Additionally, the reduction of mechanized access is influenced by the removal of Trail 738, the Stateline Trail, from the Hoodoo recommended wilderness area. This exclusion represents approximately 31 miles of trail opened to mechanized transport that is currently closed. Mechanized use along this trail could result in sights and sounds that reduce opportunity for solitude or primitive recreation within the Hoodoo recommended wilderness as do adjacent roads, motorized trails and even hiking trails that increase opportunity for human encounters from outside of the recommended area. Such intrusions are dependent on many factors but are usually localized and of short duration except where major highways or primary routes provide regularly occurring traffic.

Recommended wilderness areas under the Preferred Alternative would be managed with a winter recreation opportunity spectrum classification of semi-primitive non-motorized. The Preferred Alternative has more acres of recommended wilderness than the No Action Alternative and a reduction of winter motorized recreation opportunity spectrum classes with a corresponding decrease in the amount of acreage suitable to motorized over snow travel by 117,641 acres.

Of all the action Alternatives, the Preferred Alternative would have the lowest impact on the number of trail miles that are currently open to motorized and mechanized summer travel and winter motorized over snow travel. Under this alternative the summer recreation opportunity spectrum would be managed as primitive or semi-primitive non-motorized. There would be a 2-mile decrease in trail miles open to motorized summer use, mostly in the Pot Mountain recommended wilderness area, and a 14-mile decrease in mechanized transport opportunities. Winter opportunities under the recreation opportunity spectrum of semi-primitive motorized would decrease by 112,494 acres under this alternative.

Alternative Z contains the second largest amount of recommended wilderness, less than Alternative W and more than No Action and Alternatives X , Y, and the Preferred Alternative. Under this alternative the summer recreation opportunity spectrum would be managed as primitive or semi-primitive non-motorized. However, these lands would be open to mechanized transport, unlike Alternatives W, Y and the Preferred Alternative. This will cause a decrease in the amount of trail miles open to wheeled motorized use by 146 miles and an increase in the amount of trail miles open to mechanized transport by 325 miles. Since this alternative would have a winter recreation opportunity spectrum of semi-primitive motorized across all recommended wilderness areas, there would be an increase of 278,383 acres open to motorized over snow travel; a similar increase as Alternative X and half the increase of Alternative W.

Under all alternatives new road construction or reconstruction would not be suitable in recommended wilderness areas and very limited in Idaho Roadless Rule areas, which limits the amount of new access on the Nez Perce-Clearwater. Since all recommended wilderness areas are within Idaho Roadless Rule areas, effects from road construction and reconstruction would be minimal compared to current conditions. Therefore, road construction in Idaho Roadless Areas is expected to have little to no impact on recommended wilderness areas. Recommended wilderness boundaries with Management Area 3 lands could provide from sights and sounds associated with road construction not congruent with wilderness character.

Recommended wilderness is not suitable for developed recreation facilities that provide for user comforts such as picnic tables, fire grills, and vault toilets. These areas are generally in the primitive recreation opportunity spectrum setting, providing challenges and predominantly unmodified landscapes, and are managed for adventure and quiet solitude away from roads, people, and development.

Wildlife and Fish Management

Recommended wilderness areas are characterized by a natural environment where ecological processes such as natural succession, wildfire, and insects and disease function with a limited amount of human influence. Impacts from visitation do not detract from the natural setting. However, recommended wilderness is suitable for restoration activities where the outcomes will protect the wilderness character of the area if the ecological and social characteristics that provide the basis for each area's suitability for wilderness recommendation are preserved. Restoration activities or management activities for wildlife and fish could include monitoring; relocation of animals; habitat improvements, such as use of prescribed fire; removal of non-native fish species; and stream improvements. Refer to the 'Wildlife' and 'Aquatic Ecosystems and Fisheries' sections for additional information. If these practices are implemented while maintaining wilderness characteristics they will enhance these values. Close collaboration between managing agencies is necessary to the success of these practices.

Minerals Management

Mineral activities, as allowed, may only be to the extent permitted in the Idaho Roadless Rule (36 CFR 294.25- Mineral Activities in Idaho Roadless Areas). This would not change if an area became recommended wilderness. Therefore, there would be no changes in cumulative effects from current condition because of any alternative. There are currently no claims for leasable minerals within these areas. Sights, sounds, and ecosystem impacts of mining and mineral related activities interior and proximate to the recommended area could reduce the apparent naturalness and opportunity for solitude and primitive and unconfined recreation. It could also potentially impact ecological and geological, and historical features. Manageability could be affected by established rights associated with mining activity in a recommended area.

Summary of Effects

Table 433 provides a summary of effects to recommended wilderness by alternative.

Table 433. Recommended Wilderness Area indicator values by alternative (Alt)

Indicator	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Acres of recommended wilderness	197,695	856,932	0	309,332	569,755	263,357
Change in miles of trails open to wheeled motorized use	0	-285	0	-42	-146	-2
Change in acreage of suitable motorized over-snow vehicle areas	0	-578,556	+278,390	-30,937	+278,383	-117,641
Change in miles of trails open to nonmotorized mechanized transportation	0	-648	+328	-59	+325	-14
Change in commercial rental (buildings and structures) units	0	0	0	0	-1	0
Acres of underrepresented ecological groups of the National Wilderness Preservation System	94,335	503,305	0	174,723	333,078	142,065

Data Source: Nez Perce-Clearwater GIS data.

The recommended wilderness areas offer vast landscapes that possess a high level, although to varying degrees, of wilderness attributes in terms of their wilderness characteristics and character. Activities that may be permitted in or near these areas have potential to enhance or diminish these values. The same could be said for every Wilderness and recommended wilderness in the Bitterroot ecosystem. While such impacts may occur, these recommended wilderness areas offer unbounded opportunity for natural processes to proceed untrammeled, areas that will remain natural in their state largely unaffected by external activities, and vast enough, quite enough, and challenging enough to find solitude and unconfined recreation limited only by one’s abilities, skills, and quest for adventure.

Wild and Scenic Rivers (Eligible and Suitable)

Beginning in 2017, under the direction of the 2012 Planning Rule, a Wild and Scenic River eligibility and suitability study was conducted on the Nez Perce-Clearwater. The 2017 eligibility process, as outlined in FSH 1090.12 Ch. 80, included a review of all named rivers and streams, collectively referred to as rivers, within and bordering the Nez Perce-Clearwater. These rivers were assessed to determine whether they were free flowing, had outstandingly remarkable values and had unimpaired water quality. All rivers found eligible were then analyzed for their suitability status, as outlined in FSH 1909.12 Chapter 80, under the direction of the 2012 Planning Rule which states “eligible river segments may be evaluated for their suitability for inclusion in the Wild and Scenic River System during the plan revision process” . The eligibility and suitability studies are included in Appendix F. This process identified 88 streams as eligible. The suitability status of these eligible rivers varies by plan alternative, as outlined below under environmental consequences.

For eligible and suitable rivers, a corridor of a quarter mile on either side of the river mean high water mark, 320 acres, will serve as the defined area of that river or segment. For management purposes, identified eligible and suitable Wild and Scenic River segments are classified as wild, scenic, or recreational.

- Wild - Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted.
- Scenic - Those rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped but accessible in places by roads.
- Recreational - Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

Changes between draft and final environmental impact statement

Glover Creek was inadvertently identified as eligible and included in the Draft EIS. Its eligibility was based solely on the presence of the Coeur d'Alene salamander. The Coeur d'Alene salamander was reviewed for its potential as a wildlife species outstandingly remarkable value but was determined not to be a wildlife species that warrants designation as an outstandingly remarkable value. This species did not meet the screening criteria as a wildlife ORV for the following reasons: the species is water dependent but not river dependent; it is not a species of conservation concern and therefore was not identified as having regional or national significance; while it has narrow habitat characteristics it has an area of distribution from the Selway River north into Southern British Columbia, including parts of Western Montana; and, a study by the Idaho Department of Fish and Game determined that populations were present at 95% of previously surveyed locations and the populations are stable. Five percent are of unknown status (Cassirer et al. 1994).

Since the Coeur d'Alene salamander was the only element that determined Glover Creek's eligibility, and this species was not a wildlife outstandingly remarkable value, Glover Creek was removed from eligible status, and no further analysis of eligibility or suitability was conducted.

Consistent with Forest Service Handbook 1909.12, Chapter 80, 83.11, river segments previously found suitable through earlier study but not yet congressionally designated do not need to be reevaluated unless changed circumstances warrant consideration of a change in river status. Upon review as documented in the Final Environmental Impact Statement Appendix F, there are no changed conditions in the Salmon River segment that would warrant further consideration. Given that there are no changed conditions, Bureau of Land Management affirmation of suitability, and congressional direction to manage the lower Salmon under Wild and Scenic guidelines, this segment of the lower Salmon River retained its status as suitable for inclusion in the National Wild and Scenic Rivers System. Therefore, the eligible status identified for the Salmon River in the Draft Environmental Impact Statement was changed to suitable status in the Final Environmental Impact Statement.

Relevant Laws, Regulations, and Policy

Laws and Regulations

Organic Administration Act of 1897: This act states that one aspect of the mission of the national forests is to "provide favorable conditions of water flow."

Department of Agriculture Organic Act of 1944: This act provides direction on the establishment and protection of water rights.

Clean Water Act: The Federal Water Pollution Control Act, or Clean Water Act, is the principal law regulating discharges of pollutants to the waters of the United States. It provides direction intended to restore and maintain the chemical, physical, and biological integrity of the nation's waters.

Multiple-Use Sustained-Yield Act of 1960: Congress has affirmed the application of sustainability to the broad range of resources over which the Forest Service has responsibility. The Multiple-Use Sustained-Yield Act confirms the Forest Service's authority to manage the national forests and grasslands "for outdoor recreation, range, timber, watershed, and wildlife and fish purposes" (16 U.S.C. § 528) and does so without limiting the Forest Service's broad discretion in determining the appropriate resource emphasis or levels of use of the lands of each national forest and grassland.

Wild and Scenic Rivers Act of 1968: States the policy that certain selected rivers, with their immediate environments, shall be preserved in free-flowing condition and protected for the benefit and enjoyment of present and future generations. The Act established the National Wild and Scenic River System, designated initial rivers in that system, and prescribed methods and standards for the addition of rivers.

Endangered Species Act of 1973, as amended: Section 7(a)(1) supports biotic sustainability by requiring that "all . . . federal agencies shall . . . utilize their authorities in furtherance of the purposes of this act by carrying out programs for the conservation of endangered species and threatened species." Section 7(a)(2) includes direction that federal agencies, in consultation with the U.S. Fish and Wildlife Service, will not authorize, fund, or conduct actions that are likely to jeopardize the continued existence of any threatened or endangered species or result in the destruction or adverse modification of their critical habitat.

The National Forest Management Act (16 U.S.C. 1600–1614, August 1974, as amended 1976, 1978, 1980, 1981, 1983, 1985, and 1990): This act directs the Forest Service to manage for a diversity of habitats to support viable populations (36 CFR § 219.19), and recognizes the fundamental need to protect and, where appropriate, improve the quality of soil, water, and air resources (Section 5(C)).

36 CFR part 219, subpart A: This regulation provides integrated resource management for multiple use. It states the responsible official shall consider "Aesthetic values, air quality, cultural and heritage resources, ecosystem services, fish and wildlife species, forage, geologic features, grazing and rangelands, habitat and habitat connectivity, recreation settings and opportunities, riparian areas, scenery, soil, surface and subsurface water quality, timber, trails, vegetation, viewsheds, wilderness, and other relevant resources and uses."

36 CFR 219.20: Requires conservation and protection of soil and water resources.

36 CFR 219.8 – Sustainability - (a)(4): Requires the Chief of the Forest Service to establish requirements for national best management practices for water quality in the Forest Service Directive System.

36 CFR 251.9: Authorizes the Chief of the Forest Service to enter into agreements with municipalities to restrict the use of National Forest System lands from which water is derived to protect the municipal water supplies.

2001 Roadless Area Conservation Rule (36 CFR § 294 subpart B; 66 FR 3244-3273): This rule includes a prohibition on road construction and road reconstruction in inventoried roadless areas and prohibits timber cutting, sale, or removal except in certain circumstances.

2012 Planning Rule: The rule requires Forests to maintain the diversity of plant and animal communities and support the persistence of native species within the plan area. Forests are directed to use a “complementary ecosystem and species-specific approach to provide for the diversity of plant and animal communities” and to maintain species persistence in their planning.

Policy

Forest Service Manual 1920: Land Management Planning, 1924 – Wild and Scenic River Evaluation: Establishes the policy for identification and management of eligible and suitable rivers to protect the values that provide the basis for their inclusion in the NWSR system as required by the 2012 Planning Rule.

Forest Service Handbook 1909.12: Land Management Planning, Chapter 80 – Wild and Scenic Rivers: Provides guidance on the determination of eligibility, suitability, and recommendation for designation of wild and scenic rivers for legislatively mandated or Forest Service-identified study rivers.

Forest Service Manual 2670: As an implementing rule of the 1976 National Forest Management Act: Requires federal land managers to maintain viable populations of all native and desirable non-native species, with special care taken to assure that federally listed species can recover. Actions that may cause a species to become listed as threatened or endangered are to be avoided.

Forest Service Manual 2380: This manual outlines Forest Service policy and direction for the management of scenic resources.

Forest Service Manual section 2380.31: This manual requires the use of the basic concepts, elements, principles, and variables defined in the ‘Agriculture Handbook 701 – Landscape Aesthetics: A Handbook for Scenery Management’ (U.S. Department of Agriculture 1995b), referred to as the scenery management system (SMS).

Snake River Recovery Plan (Snake River Basin Steelhead and Snake River Spring/Summer Chinook Salmon): The National Marine Fisheries Service has released final recovery plans for Snake River spring and summer Chinook salmon and steelhead in 2017 (National Oceanographic and Atmospheric Agency 2017).

Columbia River Bull Trout Recovery Plan and Recovery Unit Implementation Plans: The Columbia River bull trout recovery plan was completed in 2015. Recovery actions were developed in cooperation with federal, state, tribal, local, and other partners.

PACFISH and INFISH Amendments: In the early 1990s, concerns about stream habitat degradation in the Western United States, as well as the potential loss of salmon, trout, and char populations, increased (Nehlsen et al. 1991, Rieman and McIntyre 1993). In response, the Forest Service and Bureau of Land Management completed three broad reaching documents that amended forest plans across the west to improve their conservation function.

Nez Perce Tribe Department of Fisheries Resource Management Plan (2013–2028): The Nez Perce Tribe’s Fisheries Resource Management Plan includes a set of management goals and management objectives to achieve those goals. Management objectives include those related to achievement of escapement goals for anadromous fish, including habitat management of key populations within the Nez Perce-Clearwater such as Lolo Creek, the Potlatch River, the Upper South Fork Clearwater River, the Lochsa River, Meadow Creek, Moose Creek, and the Upper Selway River. Habitat management objectives include emphasis on watershed restoration within a "ridge-to-ridge" management philosophy where stream habitat is degraded. Fish management goals are consistent with those described in the Idaho Department of Fish and Game five-year management plan and within the Snake River recovery and implementation plans (National Oceanographic and Atmospheric Agency 2017), as the Nez Perce Tribe has worked closely with these agencies.

State and Local Laws

Idaho State Water Plan, November 2012: Provides a set of policies that guide the use, management, development, and conservation of water for all citizens.

Idaho Comprehensive State Water Plans for the North Fork Clearwater and South Fork Clearwater Rivers: These provide river-specific guidance for the development, management, and protection of the water and related resources.

Idaho Department of Fish and Game Five-year Fisheries Management Plan (2019): This management plan includes statewide principles related to management of fisheries and habitat; public involvement; rules such as fishing regulations; access; importation and introductions; cooperation with other agencies, Indian Tribes, outfitters and guides; habitat restoration and protection; and mitigation.

Methodology

Information sources and analysis

The information source is the Nez Perce-Clearwater geographic information system. See Appendix F for detailed information on the sources used.

Analysis area

The geographic scope of the analysis is the lands administered by the Nez Perce-Clearwater. All lands within the Nez Perce-Clearwater boundary form the geographic scope for cumulative effects, and the temporal scope is the life of the plan.

Measurement Indicators

- Miles and acres of eligible and suitable wild and scenic rivers

Affected Environment

Eligible Rivers

The 1987 Clearwater Forest Plan identified three stream segments as being potentially eligible for Wild and Scenic River designation. The forest plan was amended in 1990 to add four more stream segments, for a total of seven. Management direction for these streams is contained in forestwide management direction provided in the 1987 Clearwater National Forest Plan, as amended, and the Forest Service Handbook. Eligible Wild and Scenic River segments within the Clearwater National Forest are listed in Table 434**.**

Table 434. Eligible Wild and Scenic Rivers on the Clearwater National Forest

Stream	Section	Miles	Potential Classification	Primary ORV	Source
Cayuse Creek	Mouth to Silver Creek	31.5	Scenic	Not listed	1987 Forest Plan
Fish Creek	Mouth to Hungry Creek	4.7	Recreation	Not listed	1990 Forest Plan amendment no. 2
Hungery Creek	Entire length	13.8	Wild	Fisheries	1990 Forest Plan amendment no. 2
Kelly Creek	Mouth to bridge on Forest Road 581	11.2	Recreation	Recreation	1987 Forest Plan
Kelly Creek	Bridge on Forest Road, 581 to North and Middle Fork Kelly Creek confluence	15.0	Wild	Recreation	1987 Forest Plan
Little North Fork River	Clearwater NF River portion	4.3	Defer to Idaho Panhandle National Forest	Recreation	1990 Forest Plan amendment no. 2
North Fork Clearwater River	Dworshak high pool to Kelly Creek	62.8	Recreation	Recreation	1987 Forest Plan
White Sand Creek (aka Colt Killed Creek)	Mouth to Wilderness boundary	13.7	Recreation	Not Listed	1990 Forest Plan amendment no. 2

Data Source: Clearwater 1987 Forest Plan and Nez Perce-Clearwater GIS data.

The 1987 Nez Perce Forest Plan identified nineteen river segments, totaling 376 miles, as being potentially eligible for Wild and Scenic River designation. Eligible Wild and Scenic Rivers do not have a unique management area designation in the Nez Perce Forest Plan. Management direction for these streams is contained in the forestwide management direction provided in the 1987 Nez Perce Forest Plan, as amended by Forest Plan Amendment Number 1, and the Forest Service Handbook.

It should be noted that the previous Land Management Plan process recommended that two stream segments, Bear Creek Complex and Three Links Creek, be dropped from eligibility. Because no decision was issued for Land Management Plan, those streams remain eligible Wild and Scenic River segments.

Following the 1987 Forest Plan, additional analysis was conducted on the 15 tributaries of the Upper Selway River, including Running Creek, Bear Creek Complex, Moose Creek Complex, Three Links, and West Fork Three Links creeks and Gedney and West Fork Gedney creeks, to determine suitability for designation. An environmental impact statement was prepared in 1995, yet no decision was issued, and the streams' status as eligible rivers remains as described in the 1987 Clearwater National Forest Plan. Eligible Wild and Scenic River segments within the Nez Perce National Forest are listed in Table 435.

Table 435. Eligible Wild and Scenic Rivers on the Nez Perce National Forest, and their potential Outstandingly Remarkable Values

Stream	Section	Potential Classification	Miles	Potential ORVs	Source
Bargamin Creek	Mouth the headwaters	Wild	25.6	C, F, R, S, T&E, V, W	1987 Forest Plan
Bear Creek Complex	Mouth to headwaters, including Cub Creek, Brushy Fork Creek, Paradise Creek, and Wahoo Creek	Wild	71.0	C, F, G, R, S, T&E, V, W	1987 Forest Plan
Johns Creek	Mouth to headwaters	Wild	18.4	F, R, S, W	1987 Forest Plan
Lake Creek	Headwaters to wilderness boundary	Recreation	3.9	C, G, R, S, T&E, V, W	1987 Forest Plan
Lake Creek	Wilderness boundary to Crooked Creek	Wild	9.8	C, G, R, S, T&E, V, W	1987 Forest Plan
Meadow Creek	Mouth to Slims Campground	Recreation	1.2	C, G, R, S, T&E, V, W	1987 Forest Plan
Meadow Creek	Headwaters to Slims Campground	Wild	43.1	C, G, R, S, T&E, V, W	1987 Forest Plan
Moose Creek Complex	Mouth to headwaters, including East Fork, North Fork, West Fork, and Rhoda creeks	Wild	84.6	C, F, G, R, S, T&E, V, W	1987 Forest Plan
Running Creek	Mouth to headwaters	Wild	16.9	F, G, R, W	1987 Forest Plan
Salmon River	Confluence with Little Salmon River to Long Tom Bar	Recreation	26.2	C, F, R, S, W	1987 Forest Plan
Slate Creek	Wilderness boundary to mouth	Recreation	16.0	C, F, G, R, S	1987 Forest Plan
Slate Creek	Headwaters to Wilderness Boundary	Wild	6.3	C, F, G, R, S	1987 Forest Plan
South Fork Clearwater	Mouth to confluence with Red River	Recreation	62.9	F, G, R. S	1987 Forest Plan
White Bird Creek	Confluence of North Fork and South Fork to Salmon River	Recreation	5.8	C, F, G	1987 Forest Plan
Three Links Creek	Mouth to headwaters, including West Fork	Wild	20.7	C, F, G, R, S, V	1987 Forest Plan
West Fork Gedney Creek	Headwaters to wilderness boundary	Wild	5.0	C, F, G, R, S, V	1987 Forest Plan

Potential Outstanding Remarkable Values (ORVs): C = Cultural, F = Fisheries, G = Geologic, R = Recreation, T&E = Threatened and Endangered Species or Habitat, S = Scenic, V = Vegetation, W = Wildlife

Data Source: Nez Perce 1987 Forest Plan and Nez Perce-Clearwater GIS data.

Environmental Consequences

Effects Common to the No Action Alternative, Alternatives W, Y, and Z, and the Preferred Alternative

Rivers found eligible within the No Action Alternative, suitable within Alternatives W, Y, and Z, or eligible or suitable under the Preferred Alternative would continue to be managed according to Forest Service policy regarding eligible and suitable Wild and Scenic Rivers, including the quarter mile area on either side of each rivers high water mark. Alternatives W, Y, and Z and the Preferred Alternative would also be managed according to Management Area 2 guidance to protect their free-flowing condition and outstandingly remarkable values, maintain water quality, and continue to meet their preliminary classification of "recreational", "scenic", or "wild." Both eligible and suitable rivers are given the same interim protection measures as outlined by Forest Service Handbook (FSH) 1909.12 Chapter 80.

Effects to the No Action Alternative

Under the No Action Alternative, the Nez Perce-Clearwater will continue to manage all eligible rivers as determined by the 1987 amended forest plans as eligible and consistent with management direction found in FSH 1909.12 Chapter 80. This alternative identified 29 stream segments as eligible, totaling 574.4 miles with 183,808 acres. The No Action Alternative provides protection for several stream segments that are not found in any of the other alternatives. Slate Creek, Whitebird Creek, and Lake Creek are only covered by the No Action Alternative. Additionally, although overlapping portions are covered in other alternatives, the No Action Alternative includes several river segments that are off forest and were not evaluated under the action alternatives. This includes portions of the North and South Forks of the Clearwater River, Salmon River, Slate Creek and Whitebird Creek. These river segments that are outside of the administrative boundary of the Nez Perce-Clearwater, not including acreage on other forests, amount to 10,954.8 acres, or 34.2 miles.

Although the No Action Alternative encompasses the greatest acreage and river miles, these river segments are further away from final designation decision than rivers considered in other alternatives. This alternative would maintain the status of these rivers as eligible and defer a suitability study to a later date. A suitability study provides the basis for determining which eligible rivers or river segments should be recommended to Congress as potential additions to the National System. Due to the unknown outcome of a future suitability determination on rivers in the No Action Alternative, a direct comparison to the action alternatives is unwarranted, as it would be speculative.

Effects that Vary by Action Alternative

Alternative W

Under Alternative W, suitable wild and scenic rivers would be managed according to Forest Service policy and Management Area 2 direction and would be managed to sufficiently protect free flow and the identified outstandingly remarkable values.

This alternative would place 12 streams in suitable status, encompassing a total of 232.7 stream miles with 74,464 acres. Of this, 114.3 stream miles encompassing 36,576 acres would be managed as a recreational or scenic river under Forest Service policy and Management Area 2c direction (Table 436). A total of 118.4 additional miles encompassing 37,888 acres would be managed as wild under the above listed direction (Table 437). Alternative W has more river miles classified as suitable wild and scenic than Alternative X but less than Alternatives Y and Z.

Table 436. Summary of Alternative W Suitable Recreational and Scenic River segments

Stream	Classification	Miles	Acres	ORVs
Cayuse Creek	Scenic	4.5	1,440	R, F
Cayuse Creek	Recreation	1.7	544	R, F

Alternative X

Under Alternative X, no rivers were found suitable and would be managed under other Land Management Plan directions and in accordance with the Idaho Comprehensive State Water Plans. There are two State Water Plans that cover the area managed by the Nez Perce-Clearwater: one for the North Fork Clearwater drainage and one for the South Fork Clearwater drainage. These plans provide some level of protection but are not as encompassing as Forest Service policy for rivers found eligible or suitable. For example, eligible or suitable wild and scenic rivers are given an interim boundary of a quarter mile from the mean high-water mark, whereas state identified natural and recreation rivers only extend protections into the riparian area. State designated natural rivers have prohibitions on the construction or expansion of dams or impoundments, hydropower projects, and water diversion works. Additionally, new dredge or place mining activities and sand and mineral extraction within the stream bed, as well as stream bed alteration, would be prohibited. For state designated rivers classified as recreational, those same prohibitions would apply except for stream bed alteration for the purposes of maintenance and construction of bridges and culverts and the instillation of fisheries enhancement structures. Furthermore, mineral, sand, and gravel extraction and recreational suction dredging are allowed on the North and South Fork(s) of the Clearwater River(s).

For a full list of rivers covered by Idaho State Comprehensive Water Plans and their values and designations see Appendix K.

Under this alternative, all rivers will be afforded protections derived from other plan components that protect waterways and riparian areas. These components buffer the streams by 300 feet, which is significantly less than the quarter mile corridor for suitable wild and scenic rivers.

Alternative Y

Under Alternative Y, suitable wild and scenic rivers would be managed according to Forest Service policy and Management Area 2 direction and would be managed to sufficiently protect free flow and the identified outstandingly remarkable values.

This alternative would place 14 streams in suitable status, encompassing a total of 346.1 stream miles with 110,752 acres. Of this, 219.5 stream miles encompassing 70,240 acres would be managed as a recreational or scenic river under Forest Service policy and Management Area 2c direction (Table 438). Additionally, 126.6 miles encompassing 40,512 acres would be managed as wild under the above listed direction Table 439). Alternative Y has more river miles classified as suitable wild and scenic than Alternative W and X but less than Alternative Z.

Alternative Z

Under Alternative Z, suitable wild and scenic rivers would be managed according to Forest Service policy and Management Area 2 direction and would be managed to sufficiently protect free flow and the identified outstandingly remarkable values.

This alternative would place 37 streams in suitable status, encompassing a total of 455.48 stream miles with 145,757.3 acres. Of this, 122.81 stream miles encompassing 39,302.2 acres would be managed as a recreational or scenic river under Forest Service policy and Management Area 2c direction (Table 440). Additionally, 332.67 miles encompassing 145,757.3 acres would be managed as wild under the above listed direction (Table 441). Alternative Z has more river miles classified as suitable wild and scenic than all other action alternatives.

Preferred Alternative

Under the Preferred Alternative, eligible and suitable wild and scenic rivers would be managed according to Forest Service policy and Management Area 2 direction and would be managed to sufficiently protect free flow and the identified outstandingly remarkable values.

This alternative would place 11 rivers in suitable status, encompassing a total of 233.4 river miles with 74,687 acres. Of this, 128 river miles, encompassing 40,959 acres, would be managed as a recreational or scenic river under Forest Service policy and Management Area 2 direction (Table 442). Additionally, 105.4 miles, encompassing 33,728 acres, would be managed as wild under the above listed direction (Table 443).

Table 442. Summary of Preferred Alternative Suitable Recreational and Scenic River segments

Stream	Classification	Miles	Acres	ORVs
Cayuse Creek	Scenic	4.5	1,440	R, F
Cayuse Creek	Recreation	1.7	544	R, F
Colt Killed Creek	Scenic	13.7	4,383	R, S, F, W
Fish Creek	Scenic	20.2	6,464	F, W
Fish Creek	Recreation	0.9	288	F, W

Data Source: Data Source: Appendix F and Nez Perce-Clearwater GIS data.

This alternative would also place one river in eligible status, encompassing a total of 4.3 river miles with 1,376 acres that would retain wild and scenic river interim protection measures. This 4.3 river miles would be managed as wild (Table 444). The Preferred Alternative has more river miles classified as suitable wild and scenic than Alternative W and X, but less than Alternatives Y and Z. The Preferred Alternative has more miles classified as eligible with interim protections than Alternatives W, X, Y, and Z.

Table 444: Summary of Preferred Alternative Eligible[1] Wild River segments

Cumulative Effects

Cumulative effects are the potential impacts to wild and scenic rivers from the alternatives when combined with past, present, and reasonably foreseeable actions. The lands within the Nez Perce-Clearwater boundary, and the named rivers and streams contained therein, form the geographic scope for evaluating cumulative effects. The temporal bound is the life of the Land Management Plan.

To integrate the contribution of past actions to the cumulative effects of the proposed action and alternatives, existing conditions are used as a proxy for the impacts of past actions. This is because existing conditions reflect the aggregate impact of all prior actions that have affected wild and scenic rivers and might contribute to cumulative effects. Water-related activities, such as fishing, rafting, kayaking, and similar uses, are expanding as the population in the nearby urban and rural areas increases and access points are developed. These activities have been steadily increasing and occur mostly at dispersed sites and some developed recreation sites, such as along the North Fork and South Fork of the Clearwater River, and Salmon River.

Management direction for eligible and suitable rivers is found in FSM 1909.12, Chapter 80, Section 84. Management activities generally take place outside of suitable wild and scenic river corridors, unless an action is needed to help protect the identified outstandingly remarkable value, improve the free flow characteristics, or maintain existing access and infrastructure. For example, if invasive weeds were discovered in an eligible or suitable river corridor, there might be a need to take some action, such as hand pulling or herbicide application, to eradicate or prevent further spread.

Effects to Resource from Other Resources

The following are consequences to eligible and suitable wild and scenic rivers from Land Management Plan components associated with other resource programs or management activities.

Fire Management

Natural, unplanned ignitions and prescribed fires are used as tools to maintain ecological conditions within river corridors. These fire management components may be used so long as they maintain the outstandingly remarkable values and free flowing nature of the identified rivers. In a wild segment, prescribed fire and wildfires managed to meet resource objectives may be used to restore or maintain habitat for threatened, endangered, or sensitive species or restore the natural range of variability. In scenic and recreational segments, plan components for fire management would encourage an appropriate management response to wildfires and provide opportunities for natural fire to promote and/or enhance the characteristics of these areas.

Vegetative Management

For rivers found eligible or suitable and classified as wild, the cutting of trees and other vegetation is not allowed within the corridor except when needed to maintain a primitive recreation experience, to protect users, or to protect outstandingly remarkable values. For this reason, there would be minimal effects from timber harvest on these segments. On eligible or suitable rivers classified as scenic or recreational, a range of vegetation management and timber harvest is allowed within the corridor if these practices are designed to protect users or protect, restore, or enhance the river environment and its outstandingly remarkable values. For this reason, there would be minimal effects from timber harvest on these segments.

Recreation and Access

Eligible and suitable wild rivers and their corridors will have restricted development of recreation facilities and infrastructure. New major public-use areas, such as development level 4 and 5 campgrounds, interpretive centers, or administrative headquarters, should not be constructed in these river corridors. Minimum facilities, such as toilets, should be constructed only where necessary to protect and enhance water quality or outstandingly remarkable values. All facilities should be located and designed to harmonize with the primitive character and natural and cultural settings of the river corridor and be screened from view from the river to the extent possible. Additionally, roads, airfields, and railroads are generally not compatible with wild river classification and would not be authorized. Plan components would prevent actions that would preclude classification of the river as wild. New trail construction should generally be designed for non-motorized uses. Motorized travel on land or water is generally not compatible with a wild classification. However, it may be permitted when deemed to be necessary if it is carefully defined and the effects are mitigated.

Eligible and suitable rivers classified as scenic will allow for new roads or railroads to occasionally parallel the river or bridge the river if such construction protects outstandingly remarkable values, including the rivers free-flowing character. Bridge crossings and other roads leading to river access are allowed. Recreational classified rivers allow for roads and railroads to parallel the river if construction protects outstandingly remarkable values and the rivers free-flowing character. New facilities in scenic river corridors, such as development level 3 campgrounds, toilets, and boat ramps, are allowed within the river corridor if they are located and designed to harmonize with their natural and cultural settings, protect outstandingly remarkable values, and be screened from view from the river to the greatest extent possible.

Rivers classified as recreational may have new recreation, administrative, and river access facilities located in the river corridor close to the river. These facilities will be designed to harmonize with their natural and cultural settings, protect outstandingly remarkable values, and be screened from view from the river to the greatest extent possible. Additionally, new roads, railroads, and airfields would be permitted to parallel the river if such construction fully protects free flow and river values.

For rivers classified as recreational or scenic, motorized travel on land and water may be permitted, prohibited, or restricted to protect the outstandingly remarkable values and free flow.

Mineral Development

Saleable Minerals: On eligible and suitable wild river segments, collection and disposal of saleable minerals would be prohibited. On eligible and suitable rivers classified as scenic or recreational, saleable mineral disposal will be allowed if the outstandingly remarkable values, water quality, and free flow are protected. Mineral materials are present and could potentially be used for construction purposes but, generally, proposals for development of mineral materials do not occur and allowing such development would be at the discretion of the Nez Perce-Clearwater.

Leasable Minerals: On all eligible and suitable wild and scenic rivers, leases, licenses, and permits under mineral leasing laws must include conditions necessary to protect the values of the river corridor that make it suitable for inclusion into the National System. The potential for leasable minerals is low across most of the Nez Perce-Clearwater and, currently, there are no permits or operating plans for exploration within the eligible and suitable corridors.

Locatable Minerals: Existing or new mining activity on eligible and suitable rivers classified as wild, scenic, or recreational are subject to regulations in 36 CFR part 228 and must be conducted in a manner that minimizes surface disturbance, sedimentation, pollution, and visual impairment.

Anticipated effects from minerals management would be low under all alternatives. Eligible and suitable rivers potentially classified as wild, scenic, or recreational are not withdrawn from mineral entry and are suitable for mineral exploration and development as long as the outstandingly remarkable values for which the river was deemed eligible are maintained and protected.

Summary of Effects

A summary of Wild and Scenic River indicator values among alternatives are presented in Table 445.

Table 445. Eligible and Suitable Wild and Scenic Rivers indicator values by alternative (Alt)

Indicator	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Number of suitable or eligible wild and scenic rivers segments	29	12	0	14	37	11 suitable 1 eligible
Total miles	574.4	232.7	0	346.1	519.3	237.6
Total acres	183,808	74,464	0	110,752	166,176	76,032

Data Source: Data Source: Appendix F and Nez Perce-Clearwater GIS data.

3.6.3 Research Natural Areas

Research natural areas are permanently established to maintain areas of natural ecosystems and areas of special ecological significance. These protective designations were made in an attempt to maintain natural ecosystem components and processes and are cooperatively identified and managed with the U.S. Department of Agriculture Forest Service Rocky Mountain Research Station. These areas form a long-term network of ecological reserves established as baseline areas for non-manipulative research and the maintenance of biodiversity. They are administratively designated by the U.S. Forest Service Northern Region Regional Forester, with research station director concurrence. In some cases, stewardship management is needed to maintain or restore the target plant communities in research natural areas, including actions such as invasive weed control or prescribed fire. These management activities are also coordinated between the national forests and the research station.

The Nez Perce-Clearwater has 18 designated research natural areas and two proposed research natural areas (pRNA) that were first proposed in the 1987 Forest Plan and continue to be proposed under all alternatives. An additional two candidate research natural areas (cRNA) and the expansion of an existing research natural area would be formally proposed under the action alternatives.

- Designated research natural areas are those that have been formally established by a decision signed by the regional forester, with concurrence of the research station director, after being vetted through the Nez Perce-Clearwater and Rocky Mountain Research Station via forest planning, during revision, or by amendment.
- Proposed research natural areas have been vetted through the Nez Perce-Clearwater and Rocky Mountain Research Station via forest planning, either in revision or by amendment, but have not been established by a regional forester decision.
- Candidate research natural areas have not been fully vetted by the Nez Perce-Clearwater and the Rocky Mountain Research Station and have not been included in a forest plan decision.

Research Natural Areas serve three important functions:

- **Reference Areas —** Research natural areas serve as benchmarks for monitoring and evaluating the sustainability and impacts of land management practices on lands with similar ecosystems. To determine the impact of management on an area, it is useful to have, as a control, a similar area maintained in natural condition for comparison. Research natural areas contribute to ecosystem management by providing these controls.
- **Biological Diversity —** Research natural areas provide protection for biological diversity. A representative research natural areas system provides some degree of assurance that a wide array of plant and animal species will be afforded a high degree of protection in the future. This protection may be most important for soil microorganisms, fungi, insects, and other forms of biological diversity on which ecosystems often depend the most but about which we know the least. Research natural areas also can be selected to help protect specific populations of threatened, endangered, or sensitive species.
- **Research —** Research natural areas provide sites for research into how ecosystems function since the ecological and evolutionary processes influencing them are functioning in a relatively natural state. They serve as sites for monitoring long-term change in ecosystems, such as global climate change and shifting patterns in the landscape, that result from such disturbances as fire, floods, and insect epidemics. Research projects in an identified research natural area can greatly increase our understanding of particular ecosystems and improve the quality of ecosystem management. Research natural areas also serve an important educational function by providing excellent examples of ecosystems in a relatively natural condition, with functioning ecological processes.

Relevant Laws, Regulations, and Policy

Federal Laws

Organic Administration Act of June 4, 1897 (16 U.S.C. 477-482, 551): This act authorizes the Secretary of Agriculture to issue rules and regulations for the occupancy and use of the National Forests.

National Forest Management Act of 1976 (16 U.S.C. 1600): This act states that the Secretary of Agriculture shall "promulgate regulations" under the principles of the Multiple-Use Sustained-Yield Act of 1960 to "provide for the diversity of plan and animal communities based on the suitability and capability of the specific land area" and to maintain tree species diversity within the context of multiple-use objectives.

Agency Regulations

36 CFR 219.7 — Special Designations: This regulation states that, in developing a proposed plan revision, the responsible official shall identify existing designated areas and determine whether to recommend any additional areas for designation. Forest plans must include components for appropriate management of existing or proposed designated areas. Furthermore, the planning rule requires Forests to maintain the diversity of plant and animal communities and support the persistence of native species within the plan area. Forests are directed to use in their planning a "complementary ecosystem and species-specific approach to provide for the diversity of plant and animal communities" and to maintain species persistence. These requirements are partially filled by the inclusion of research natural areas based upon high species diversity.

36 CFR 219.9 — Diversity of Plant and Animal Communities: This regulation states that the responsible official will evaluate whether the plan components provide the ecological conditions necessary to contribute to the recovery of federally listed species, conserve proposed and candidate species, and maintain a viable population of species of conservation concern in the plan area. Evaluation would consider components that provide for ecosystem integrity and diversity and species-specific components. This requirement is partially filled by the inclusion of research natural areas that often have numerous occurrences of at-risk species.

Policy

Forest Service Manual 4063: This policy directs management of research natural areas as part of a national network of ecological areas allocated in perpetuity for research and education and to maintain biological diversity on National Forest System lands. Research natural areas are co-managed by the appropriate national forest and the U.S. Forest Service Research Station.

Forest Service Manual 4063.03: This policy states forest plans shall include analysis of, and recommendations for, the establishment of any proposed research natural areas.

Northern Region Natural Areas Assessment: This policy provides an assessment of plant community types needed to fulfill the regional spectrum of types to be placed in research natural area status in the U.S. Forest Service Northern Region (Chadde et al. 1996).

Establishment records for each research natural area

These records provide information on the natural features, plant communities, and species present in each research natural area, as well as management guidance.

State and Local Plans

Representativeness Assessment of Research Natural Areas on National Forest System lands in Idaho (Rust 2000).

Methodology

Spatial Scale

The geographic scope of the analysis is the lands administered by the Nez Perce-Clearwater. All lands within the Nez Perce-Clearwater boundary form the geographic scope for cumulative effects.

Temporal Scale

The temporal scope is the life of the plan.

Past, Present, and Future Activities used in the Analysis

Research natural areas provide reference conditions or settings that are reserved to represent the range of plant communities and species in the region. As such, they are generally ecologically intact and have had few, if any, past activities that have had meaningful impacts to these resources. Some research natural areas have seen peripheral recreational use, grazing activity, or fire. Research natural areas are generally excluded from management activities, but some uses may occur in the future as directed by the establishment records or on a case-by-case basis after review by Nez Perce-Clearwater officials and the U.S. Forest Service Research Station to establish need and policy compliance. Vegetation management, weed control, and grazing are examples of activities that potentially could occur in the future management of some research natural areas on the Nez Perce-Clearwater. Unplanned disturbances would likely be from wildfire or low-levels of recreational use.

Methods and Assumptions

Specialists from the Nez Perce-Clearwater and U.S. Forest Service Northern Regional Office, with research scientists from the Rocky Mountain Research Station, have identified the lands on the Nez Perce-Clearwater that possess characteristics that make them suitable for research natural area establishment. Information and management guidance for each research natural area are provided within the establishment records. A guidebook on research natural areas also provides a synopsis of the natural features protected in each research natural area and information about use of the areas for research (Evenden et al. 2001).

Measurement Indicators

- Number of research natural areas
- Number of proposed research natural areas
- Number of candidate research natural areas
- Number of research natural area expansions
- Acres of research natural areas
- Acres of proposed research natural areas
- Acres of research natural area expansion
- Supports research natural area values

Affected Environment

Existing Condition

The National Forest Management Act of 1976 directs the Forest Service to establish research natural areas typifying important forest, shrubland, grassland, alpine, and aquatic ecosystems. In addition to their value as reference areas for research and monitoring, research natural areas help maintain biological diversity by conserving assemblages of common and rare species, plant communities relatively undisturbed by human actions, and unique landscape features. The *1983 Northern Region Guide* (U.S. Department of Agriculture 1983) included a matrix of habitat types, community types, and aquatic features targeted for inclusion in the Northern Region's research natural area system. Major revision of this 1983 regional guide for research natural areas was completed in 1996 (Chadde et al. 1996), giving new targeted plant communities and other features for inclusion in research natural areas. Many research natural areas have been formally established over the past 30 years, including 18 on the Nez Perce-Clearwater. Two proposed research natural areas that were in the current forest plan, one expansion of a designated research natural area, and two new candidate research natural areas are included under the action alternatives. Target assignments from the 1996 assessment yet filled on the Nez Perce-Clearwater are not included in this document but could be added in the future as information and opportunity arise.

The established research natural areas on the Nez Perce-Clearwater are permanently designated for the purpose of conserving biodiversity, conducting non-intrusive research and monitoring, and fostering education. They serve as high-quality representative areas of the major forms of vegetative variability found in the Nez Perce-Clearwater, and they present reference areas for the study of natural ecological processes, including disturbances and climate change. Table 446 lists the 18 existing research natural areas on the Nez Perce-Clearwater, with a brief description of each following the table. Two long-proposed research natural areas, Fenn Mountain and Rhodes Peak, are also included. Upper Hemlock Creek, Mud Springs Ridge, and expansion of the Bull Run research natural areas were not formally included in the 1987 plan or with an amendment to the plan so these are listed as candidate research natural areas in the existing condition.

Table 446. Designated, Proposed and Candidate Research Natural Areas

Research Natural Areas	Designated	Proposed	Candidate	Acres[1]
Aquarius	●			3,709
Bald Mountain	●			369
Bull Run Creek	●			383
Bull Run Creek Expansion			●	370
Chateau Falls	●			198
Dutch Creek	●			302
Elk Creek	●			6,957
Fenn Mountain		●		603
Fish Lake	●			753
Four-Bit Creek	●			392
Grave Peak	●			379
Lochsa River	●			1,508
Moose Meadow Creek	●			940
Mud Springs Ridge			●	288
No Business Creek	●			1,385
O'Hara Creek	●			7,049
Rhodes Peak		●		307
Sneakfoot Meadow	●			1,946
Square Mountain Creek	●			704
Steep Lakes	●			797
Fred Rabe Upper Hemlock Creek			●	1,378
Upper Newsome Creek	●			1,192
Warm Springs Creek	●			537

[1]Acre values are derived from close Geographic Information System mapping following the boundary descriptions included in the research natural areas establishment records. The acre values given in the records are often estimates based upon older mapping methods; thus, the values given here are considered most accurate.

Existing Research Natural Areas

Aquarius Research Natural Area

Aquarius Research Natural Area is located along the North Fork of the Clearwater River at the upper end of Dworshak Reservoir. This section of the North Fork is a low elevation canyon characterized by relatively warm temperatures and high precipitation. This combination of climatic factors, which is rather unusual in the Northern Rocky Mountains, is responsible for an extraordinary assemblage of disjunct and endemic plant and animal taxa and unique vegetation types found in the area. The Aquarius Research Natural Area encompasses a cross section of the canyon that contains many of these rare and unique elements and is widely considered by scientists as the most unique biological area in the Northern Rocky Mountains. Some of the plant associations present at Aquarius fill regional assignments for representative habitat types.

Bald Mountain Research Natural Area

Bald Mountain Research Natural Area is located along the divide separating the North Fork Clearwater basin from that of the Lochsa River. Uncommon, open habitats caused by snow transfer and droughty soils are the primary features of this research natural areas. Represented habitats are green fescue and beargrass with forested habitats in the mountain hemlock and subalpine fir forest types.

Bull Run Creek Research Natural Area

This area is in the Bull Run Creek drainage approximately four air miles south-southwest of Elk River on the Palouse Ranger District. This research natural area was designated for highly diverse vegetation that includes a variety of mesic forest types growing over basalt, with ponds, grasslands, scree, several plant species of conservation concern, coastal disjunct plants, basalt outcrops, and an arid plant component not found in the Clearwater Basin. The vegetative diversity of the juxtaposed arid and mesic communities is unparalleled on the Nez Perce-Clearwater.

Chateau Falls Research Natural Area

The Chateau Creek basin was selected as a research natural area for the presence of several waterfalls. The numerous falls range from a few feet to as high as 65-feet. These require very steep topography with geologic strata of differing resistance to erosive forces that provide aquatic and geologic features of scientific value. In addition to the cascades, the research natural area contains small grasslands, shrublands, and forests in early to mid-succession following several wildfires in the early 1900s that provide opportunities for forest succession and recovery studies.

Dutch Creek Research Natural Area

Dutch Creek was the site of several high severity wildfires in the early 1900s. The fires were hot enough to damage soils and remove the seed source of conifers typical for the area. As a result, the research natural area is largely composed of northwest paper birch that rarely forms extensive stands in the local forest types. There is opportunity for long-term successional studies and investigation of this species effects on forest soils.

Elk Creek Research Natural Area

The major feature of the Elk Creek Research Natural Area is the extreme range in elevation, 6,371 feet, which provides a diverse assemblage of vegetation along a steep elevational gradient in the Idaho Batholith. Especially good examples of the more xeric grassland, mountain mahogany, and Ponderosa pine types are found at lower elevations. As elevation increases, the forests support Douglas-fir and grand fir that give way to subalpine fir and whitebark pine in the higher elevations. These diverse forests fulfill target habitats identified for representation within research natural areas on the Nez Perce-Clearwater. There are also two subalpine lakes, one with fish, and a large population of a rare, endemic plant species.

Fish Lake Research Natural Area

The Fish Lake Research Natural Area is situated in a steep-walled glacial trough that contains a mid-elevational, 29-acre, productive, morainal lake that contains grass and sedge wetland communities, as well as native fish. This lake provides excellent opportunities to study moose lentic productivity interrelationships. The local forests contain several cool forest habitats, at least two of which were assigned for research natural areas inclusion. Also, a depositional boulder field moraine is found below the lake.

Four-Bit Creek Research Natural Areas

The Four-Bit Creek Research Natural Area in the Eldorado basin of the Clearwater Mountains is representative of the most productive forest lands in the Northern Rocky Mountains. Western redcedar habitat types occupied by mixed species in an advanced stage of succession dominate the research natural area providing almost every habitat type that occurs in that forest series in Idaho. The Lewis and Clark National Historic Trail and the Lolo Trail National Historic Landmark pass immediately adjacent portions of the research natural areas adding historical interest.

Grave Peak Research Natural Area

The Grave Peak Research Natural Area is a raw, glacially carved, fire scarred, rocky subalpine cirque basin in the Selway-Bitterroot Wilderness. The park-like basin supports five small lakes and open forests of subalpine fir, whitebark pine, spruce, and uncommon subalpine larch over mountain heather and other high-elevation plants. There are also small sedge meadows and wetlands. The research natural area is representative of subalpine country of low biological productivity but high-water yield and scenic value.

Lochsa River Research Natural Area

The Lochsa River Research Natural Area is located on both sides of the Lochsa River and includes Apgar and Glade Creek. Designation is primarily for one of the few refugia of coastal disjunct species that are of very limited distribution. Included are three permanent high-energy streams through a dense mesic forest canopy, which have a high diversity of habitats that yield a highly diverse macroinvertebrate assemblage.

Moose Meadow Creek Research Natural Area

Moose Meadow Creek Research Natural Area was designated to include moderately high elevation wet meadows and poor fens containing interesting and unusual plant species, a moderate gradient stream, and forests of subalpine fir, spruce, and lodgepole pine that are comprised of habitat types not included in other research natural areas.

No Business Creek Research Natural Area

The No Business Creek Research Natural Area includes a significant altitudinal range of 4,680 feet. As a result, it contains a great diversity of plant associations and forest types. It provides one grand fir habitat type and three subalpine forest habitat types that were assigned by regional direction for research natural areas. In addition, it contains several other forest types including Douglas-fir, Ponderosa pine, and mountain mahogany, one of which is the largest know specimen in Idaho. Other noteworthy inclusions are Pacific yew, white alder, and possibly the only maidenhair fern occurrence in the Salmon River basin. Tailed frogs are also present. The geology is granite in the upper elevations and limestone below and the water is of unusually high alkalinity.

O’Hara Creek Research Natural Area

O’Hara Creek provides one of the largest research natural areas on the Nez Perce-Clearwater. It contains at least seven forest habitat types assigned to the Nez Perce-Clearwater for inclusion in the research natural area system, as well as a complete aquatic system containing first to fifth order streams. These streams include several waterfalls and contain beaver ponds and wet riparian meadows. The rich forest includes several coastal disjunct plant communities that also support rare and endemic species, several of which are species of conservation concern.

Sneakfoot Meadow Research Natural Area

Sneakfoot Meadow provides examples of low gradient meandering streams and an extensive diverse graminoid and forest wetland complex that includes sphagnum bogs and fens. The surrounding forest provide three subalpine habitat types in various stages of succession. The meadows provide habitat for important moose and elk populations throughout the year.

Square Mountain Creek Research Natural Area

This research natural area was established to contribute several subalpine forest habitat types to the research natural area system. Also included are extensive subalpine aquatic systems, including streams, meadows, and a lake. It is the type locality for an endemic sensitive plant species and supports the federally threatened whitebark pine.

Steep Lakes Research Natural Area

Steep Lakes Research Natural Area features a pair of subalpine lakes of similar characteristics, except that the lower lake contains golden trout while the upper lake is fishless. This situation provides a long-term research opportunity as baseline lakes that could be used to monitor chemical and biological conditions and the effects of a fish population on the invertebrate community. There are also four subalpine fir forest habitat types and three mountain hemlock habitat types, some of which are assigned targets for research natural areas inclusion. Some of the mountain hemlocks are in an old growth state. The two primary basins have different fire histories that provide an opportunity for comparative successional studies. Additional vegetative diversity is found in wet subalpine meadows and Sitka alder stands.

Upper Newsome Creek Research Natural Area

This research natural area was selected due to its old growth climax stands of grand fir with an understory of Pacific yew. Grand fir reaches excellent development in this part of Idaho. The rich forest types are often referred to as the Grand Fir Mosaic, which requires planning and management to maintain productivity. These forest types are important for wildlife and include occurrences of at least two rare plant species.

Warm Springs Creek Research Natural Area

Warm Springs Creek Research Natural Area was established for the presence of two thermal springs and a diverse array of forest communities. Included are two habitat types assigned to the Nez Perce-Clearwater for inclusion in the research natural area system.

Proposed Research Natural Areas

Fenn Mountain Proposed Research Natural Area

This previously proposed research natural area is located 18 air miles east-northeast of Lowell, Idaho, in the Selway-Bitterroot Wilderness of the Lochsa-Powell Ranger District. Selection is based upon Regional Office direction to include high elevation aquatics, subalpine vegetation communities, and rocky habitats not represented in the research natural area system. This research natural area was formally proposed by the 1987 Forest Plan and retained here.

Rhodes Peak Proposed Research Natural Area

This previously proposed research natural area is located 11.5 air miles north-northwest of Powell, Idaho, in the Hoodoo, also known as Great Burn, roadless area on the Lochsa-Powell Ranger

District. Selection is based upon Regional Office direction to include high subalpine and alpine habitats and uncommon vegetative communities not represented in the research natural areas system. This research natural area was formally proposed by the 1987 Forest Plan and retained here. A preliminary establishment record has been written but has not been formally completed.

Candidate Research Natural Area

Bull Run Creek Expansion

See the general description provided under the Bull Run Research Natural Area in the above Existing Research Natural Areas discussion. The best representation of many of these features were excluded at the time of original designation because they occurred on adjacent private land. In the mid-1990s, this ground came to the Forest Service in a land exchange. Internal and external interest have been calling for an expansion to include these areas since that time. With this expansion, the total acreage of the Bull Run Research Natural Area will be 753 acres.

Mud Springs Ridge Proposed Research Natural Area

This candidate research natural area on the Salmon River Ranger District is approximately 3.5 air miles northwest of Lucile, Idaho. The intact and unusually diverse grassland communities of Mud Springs Ridge are not represented in the research natural areas system. One federally threatened plant species, one sensitive species, and at least four local endemic plant species are well represented here. The site also includes under-represented Ponderosa pine forests and shrub communities. This area is the site of ongoing monitoring and provides substantial opportunities for range and invasive species research.

Fred Rabe Upper Hemlock Creek Proposed Research Natural Area

This candidate research natural area is in the Hemlock Creek basin, within the Big Horn-Weitas roadless area of the North Fork Ranger District, approximately 10 miles east of Pierce, Idaho. The proposal is based upon aquatics and various meadow communities within the Grand Fir Mosaic forest, as well as a core, high priority vegetative community called for in the regional research natural areas assessment. This research natural area was recommended in the mid-1990s with local vetting completed at that time; however, proposal in a forest plan or an amendment to such has never occurred.

Environmental Consequences

Effects Common to All Alternatives

Under all alternatives, the 18 existing research natural areas would maintain their designations. In these areas, direction in the establishment records and Forest Service Manual 4063 would be followed to conserve the plant associations or other features for which they were established.

The two existing proposed research natural areas listed under the 1987 Forest Plans, Fenn Mountain and Rhodes Peak, could be recommended to become established through a separate decision by the regional forester. Final establishment would take place upon completion of the establishment records and the Research Station Director’s concurrence.

The potential for additional research natural areas in the future would exist under any alternative. *The Northern Region Status and Needs Assessment for Research Natural Areas* (Chadde et al. 1996) recommended additional unrepresented plant associations on each national forest in the U.S. Forest

Service Northern Region so that the entire range of associations could be represented in the research natural areas network.

All research natural areas are directed to be managed to perpetuate natural ecosystems and encourage scientific research with minimum human interference. Each research natural area is managed in accordance with its establishment record.

Effects to No Action Alternative

The existing 1987 Forest Plans include components for research natural areas that would apply to the No Action Alternative. The research natural areas included in this alternative are the 18 designated and 2 proposed research natural areas, as listed in the 1987 Plans. Potential research natural areas at Mud Springs Ridge, Upper Hemlock Creek, and the expansion of the Bull Run Research Natural Area would be recommended as candidates. The expected effects from plan components for existing research natural areas under the 1987 Plans are summarized in Table 447.

Table 447. Summary of existing plan components for research natural areas.

Plan component	Expected effects
Clearwater National Forest Management Area 1	The standards for Management Area 1 would ensure that within research natural areas the following activities would not occur: fish and wildlife improvements; livestock grazing; timber harvest; mineral development; special use permits; developments of trails; roads or facilities; utility corridors; and general motor vehicle use, except where research natural areas values would not be adversely affected. The visual quality objective would be retention. Insect and disease levels would not be controlled unless included within a congressionally designated area that reflects such management. Unplanned ignitions would burn under prescribed conditions unless there is a threat to persons, property, or uniqueness of the area.
Nez Perce National Forest Management Area 6	The standards for Management Area 6 would ensure that within research natural areas the following activities would not occur: recreational activities that could interfere with research; timber harvest; grazing unless necessary to maintain vegetation for which the research natural areas was established; mineral development; no roads or trails unless necessary for objectives or commensurate with use; building construction unless needed for research natural areas objectives; and utility corridors. Fire management would follow fire management plans and prescribed fire would be allowed only to perpetuate vegetation for which the research natural areas were established. There would be no debris removal, fire hazard reduction or planting of trees. Insect and disease would not be controlled unless adjacent suitable lands were severely threatened.

Effects Common to Action Alternatives

The action alternatives would be the same as the No Action Alternative with respect to the designated research natural areas. The retention of the Fenn Mountain and Rhodes Peak proposed research natural areas are also the same across all alternatives. The action alternatives include the items contained in the existing condition with the addition of the formal proposal Upper Hemlock Creek and Mud Springs Ridge to proposed research natural area status. Also, the expansion of the existing Bull Run research natural area is proposed under revision. These proposals have all been vetted with local and agency interests but have not been included in forest planning until this revision. The plan components and effects of the action alternatives would be as described above under Effects Common to All Action Alternatives because the existing and proposed research natural areas are included in each action alternative without variation. The effects of the new plan components may vary slightly in respect to effects as compared to the components of the 1987 Forest Plans. This would primarily be due to more emphasis on following establishment record direction and policy with less emphasis on detailed plan components.

The candidate research natural areas, Mud Springs Ridge and Upper Hemlock Creek, and the Bull Run expansion have been reviewed and would be formally proposed by this plan revision under all action alternatives. All could be recommended to become established through a separate decision by the regional forester. Final establishment would take place upon completion of the establishment record based on the Research Station Director's concurrence.

All action alternatives include the plan components and potential effects on research natural areas listed in Table 448.

Table 448. Summary of proposed plan components' potential effects on research natural areas.

Plan component	Potential effects
MA2-DC-RNA-01	Designated and proposed research natural areas maintain a representation of natural systems found on the Nez Perce-Clearwater as a baseline for research, monitoring, and education by the agency, academia, and public interests. Wildfire, insects, and pathogens, along with other processes and disturbances, continue to affect vegetation, reflecting the dynamic nature of the systems they represent. Research natural areas contribute to ecological sustainability and biological diversity.
MA2-STD-RNA-01	Within designated and proposed research natural areas, do not authorize the collection of forest products for commercial purposes and personal use purposes, including firewood.
MA2-STD-RNA-02	Do not authorize uses that threaten or interfere with the objectives or purposes for which a Research Natural Area is established.

Cumulative Effects

The existing vegetation conditions within the designated areas reflect the contributions of past management actions and ecological processes. Management activities are very limited within research natural areas and restricted to management activities needed to maintain the features for which the research natural area was established. Management activities will generally continue to take place outside of the existing and proposed research natural areas, and it is unlikely that these activities would influence the research natural areas. Control of invasive weeds is an action that may have occurred in the past within research natural areas, and it is the most likely management activity to occur within research natural areas in the future, in coordination with the Rocky Mountain Research Station. This would have a positive effect through the control of invasive weeds or prevention of their spread and would not result in any change to research natural area designations. Prescribed fire or other vegetation management may occasionally be used to maintain features for which the research natural area was established. Such activities would also only be conducted in coordination with the Rocky Mountain Research Station and would also have a positive effect that would not result in any change to the designation.

Under all alternatives, the network of research natural areas would contribute to the understanding of key ecosystems and plant communities by being part of the broader array of sites that are designated across other national forests in the region. This network would continue to contribute to the conservation of biological diversity and provide for research and educational opportunities in the plan area. Similar designations are not known to occur on lands of private ownership, nor on state lands in the area, increasing the importance of maintaining them on National Forest System lands.

Effects to Resource from Other Resources

Aquatic Ecosystems and Soil Management

Activities related to watershed, soil, riparian, or aquatic habitat would generally not occur in research natural areas, and there would be little to no effect related to the management of these resources.

Fire Management

Desired conditions for research natural areas state that these lands are generally naturally appearing, with natural processes, including fire, functioning naturally with limited human influences. One of the purposes of research natural areas is to serve as baseline areas for the study of these processes and their effects on ecosystems. Management of unplanned wildfire ignitions in or near research natural areas would be guided by the direction provided in each individual research natural area's establishment record, the Forest Service Manual 4063, and other regulatory documents and consultation with Rocky Mountain Research Station scientists to ensure that natural fires are allowed to burn only within a prescription designed to accomplish objectives specific to the research natural areas. If the values associated with the research natural area are at risk of degradation or loss due to fire, fire management strategies would likely include measures aimed at protecting those values, if possible. On the other hand, fire as a natural process may be desired and allowed to occur within a research natural area to perpetuate natural ecological processes within these areas depending upon the nature of the fire and the habitats potentially affected in the research natural area. Prescribed fire would only be implemented to serve or maintain values for which the research natural areas was established.

Timber and Vegetation Management

Under all alternatives, research natural areas are not suitable for timber production. The existing forest plans prohibit timber harvest for any purpose in these areas and timber management should have no effect. The Land Management Plan allows that some vegetation treatments could occur where consistent with site establishment records and plans. In such cases, the forest supervisor, with the concurrence of the research station director, may authorize management practices that are necessary for invasive weed control or to preserve the vegetation for which the research natural area was created (Forest Service Manual 4063.3). As stated in the manual, limited use of vegetation management may occur within research natural areas in situations where the vegetative type would be lost or degraded without management. The criterion is that management practices must provide a closer approximation of the naturally occurring vegetation and the natural processes governing the vegetation than would be possible without management. These practices may include prescribed burning.

Livestock Grazing and Management

The Land Management Plan, under the action alternatives, allows for grazing to occur where consistent with site establishment records and plans. Generally, site records would preclude this. Therefore, grazing would have minimal impact.

Wildlife management

Activities related to wildlife management would generally not occur within research natural areas and there would be little to no effect.

Recreation and scenery management

Generally, managing for primitive recreation opportunities would not result in substantial impacts to the natural vegetation and natural processes in these areas. Motorized use generally is not permitted within research natural areas but in some cases is allowed on roads or trails that are adjacent to or may form a portion of the unit's boundary. Such uses are established by precedent, the establishment record, or through the forestwide travel planning that incorporates research natural areas considerations and policies. Motorized routes allowed through this travel planning are not expected to impact values associated with these areas under any alternative.

Cultural, historic, and tribal resource management

Activities related to cultural, historic, and tribal resources would generally not occur in research natural areas and there would be little to no effect.

Road access and infrastructure

All action alternatives are similar in terms of plan components for road access and infrastructure. New road and trail construction or other infrastructure and facilities would not generally occur in research natural areas under any alternative because Forest Service Manual 4063 prohibits new roads, trails, fences, or signs on an established research natural area unless they contribute to the objectives or protection of the area.

Minerals management

Research natural areas are available for minerals activities unless withdrawn for mineral entry. However, per Forest Service Manual 4063, proposals to offer federal mineral, oil, and gas leases would be evaluated by the regional forester, with concurrence of the Research Station Director, using standards set forth in Forest Service Manual 2820. The proposal with recommendation is forwarded by the regional forester to the Chief for the final decision.

Other plan components

Research natural areas are primarily intended to provide reference condition to support research and support other unique elements. They are frequently used for public education by a number of public entities.

Summary of Consequences

Table 449 provides the number and acres of research natural areas and proposed research natural areas among alternatives. The indicator evaluating the effects of Land Management Plan direction and support for research natural areas values are also included. All alternatives fulfill this indicator, with the action alternatives providing more proposed research natural areas to better fulfill regional assignments and the purpose of the program.

Table 449. Summary of potential consequences to research natural areas (RNA) by alternative.

Indicator	No Action Alternate	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternate
# of RNAs	18	18	18	18	18	18
# of proposed RNAs	2	4	4	4	4	4
# of candidate RNAs	2	0	0	0	0	0

Indicator	No Action Alternate	Alternate W	Alternate X	Alternate Y	Alternate Z	Preferred Alternate
# of RNA expansions	0	1	1	1	1	1
RNA acres	29,500	29,500	29,500	29,500	29,500	29,500
Proposed RNA acres	910	2,576	2,576	2,576	2,576	2,576
Candidate RNA acres						
Acres RNA expansion	0	370	370	370	370	370
Supports RNA Values	Yes	Yes	Yes	Yes	Yes	Yes

Conclusion

All action alternatives provide for a network of research natural areas across the Nez Perce-Clearwater by including the existing designations of 18 research natural areas equaling 29,490 acres and 4 proposed research natural areas on 2,576 acres and 1 expansion of an existing research natural area totaling 370 acres. The 1987 Forest Plans more explicitly prohibit management activities within research natural areas than does the revised plan, which allows for slightly more flexibility when uses are consistent with the site establishment record and standards in Forest Service Manual 4063.

3.6.4 Special Areas

Special areas are a category of administratively designated areas defined as an area or feature managed to maintain its unique special character or purpose (36 CFR 219.19), including those that may be botanical, geological, recreational, scenic, zoological, paleontological, or historical in nature. Such areas are protected and managed for public use and enjoyment and are identified due to their unique or special characteristics. Special areas are not congressionally designated but are administratively designated by the Chief of the Forest Service, regional forester, or forest supervisor (Forest Service Manual 2372). The 1987 Clearwater Forest Plan lists 12 special areas, while the Nez Perce Forest Plan includes none. One special area is no longer designated and three will be rescinded with this plan. Four new special areas are proposed.

Special areas are classified as follows, depending upon their special characteristics or unique values(s):

- **Scenic Area** – a unit of land with outstanding natural beauty that requires special management to preserve this beauty.
- **Geologic Area** – a unit of land with outstanding formations or unique geological features of the Earth's development, such as caves, fossils, dikes, cliffs, or faults.
- **Botanical Area** – a unit of land that contains plant specimens, plant groups, or plant communities that are significant because of their form, color, occurrence, habitat, location, life history, arrangement, ecology, rarity, or other features.
- **Zoological Area** – a unit of land that contains animal specimens, animal groups, or animal communities that are significant because of their occurrence, habitat, location, life history, ecology, rarity, or other features.

- **Paleontological Area** – a unit of land that contains fossils of plants and animals, shellfish, early vertebrates, coal swamp forests, early reptiles, dinosaurs, and other prehistoric plants or animals.
- **Historical Area** – a unit of land possessing a significant site or a concentration of sites, buildings, structures, or objects united historically or prehistorically by plan or physical development. Memorial areas are included in this definition.
- **Recreational Area** – a unit of land that has been administratively designated for particular recreation opportunities or activities, such as hiking, rock hounding, recreational mining, photography, or other special activity.

The Nez Perce-Clearwater includes special areas that are classified as Geologic, Botanical, Historical, and Recreational, some with a dual classification.

Relevant Laws, Regulations, and Policy

Federal Laws

Organic Administration Act of June 4, 1897 (16 U.S.C. 477-482, 551): This act authorizes the Secretary of Agriculture to issue rules and regulations for the occupancy and use of the National Forests.

The National Forest Management Act of 1976: This act states that the Secretary of Agriculture shall "promulgate regulations" under the principles of the Multiple-Use Sustained-Yield Act of 1960 to "provide for the diversity of plant and animal communities based on the suitability and capability of the specific land area" and to maintain tree species diversity within the context of multiple-use objectives.

Agency Regulations

36 CFR 219.7: *This regulation s*tates that in developing a proposed plan revision, the responsible official shall identify existing designated areas and determine whether to recommend any additional areas for designation. Forest plans must include components for appropriate management of existing or proposed designated areas. Furthermore, the 2012 Planning Rule requires forests to maintain the diversity of plant and animal communities and support the persistence of native species within the plan area. Forests are directed to use in their planning a "complementary ecosystem and species-specific approach to provide for the diversity of plant and animal communities" and to maintain species persistence. The 2012 Planning Rule also states that, in plan revision, the responsible official shall identify existing designated areas and determine whether to recommend any additional areas for designation. Forest plans must include components for appropriate management of existing or proposed designated areas. This requirement is partially filled by the inclusion of special areas based upon high species diversity.

36 CFR 219.9: *This regulation s*tates that the responsible official will evaluate whether the plan components provide the ecological conditions necessary to contribute to the recovery of federally listed species, conserve proposed and candidate species, and maintain a viable population of species of conservation concern in the plan area. Evaluation would consider components that provide for ecosystem integrity and diversity and species-specific components.

Policy

Forest Service Manual 2372: *This policy c*ontains purpose, policy, and guidance for administrative designation and management of special areas.

Forest Service Handbook 1909.12.5: The directives provide specific information regarding implementation of the 2012 Planning Rule, including identifying at-risk species and guidance for development of plan components to provide ecological sustainability for at-risk species. The directives state that plan components developed for ecosystem integrity are expected to provide conditions that will maintain the persistence or contribute to the recovery of native species within the plan area. They also state that if components for ecosystem diversity are not adequate to do that for at-risk species, then species-specific plan components should be developed. The establishment of special areas for botanical purposes contributes to the fulfillment of direction.

Methodology

Spatial Scale

The geographic scope of the analysis is the lands administered by the Nez Perce-Clearwater. All lands within the Nez Perce-Clearwater boundary form the geographic scope for cumulative effects.

Temporal Scale

The temporal scope is the life of the plan.

Past, Present, and Future Activities used in the Analysis

Special areas provide areas of unique and special character for public use and enjoyment. The noteworthy features are often unique habitats or conditions that generally represent natural features that are generally ecologically intact and have had few, if any, past activities that have had meaningful impacts to these resources. Some special areas have seen past uses but these have not contributed to a condition that has compromised the features for which the area is designated. Future management activities may occur in special areas if they do not compromise the features for which the special areas exist or the public's ability to enjoy these areas. Thus, there are a number of potential management activities that could occur depending upon the resources present and possibly the magnitude of the potential disturbance. Generally, special areas include features that are not conducive to many management activities, but some could potentially host various vegetation management, weed control, and grazing activities. Some historical or cultural areas could be subjected to human uses, such as plant utilization or recreation. Unplanned disturbances would likely be from wildfire or recreational use. Human uses and impacts could increase as population increases in the future.

Methods and Assumptions

Specialists from the Nez Perce-Clearwater and Regional Office, with input from various public interests, have identified the lands on the Nez Perce-Clearwater that possess characteristics that make them suitable for special area establishment. Documentation of conditions within the special areas comes from reports and records for individual areas, where available, and from local and regional Forest Service resource specialist knowledge. The areas acknowledge and highlight the special natural features of the Nez Perce-Clearwater, as well as provide the opportunity for public appreciation, education, and enjoyment.

Measurement Indicators

- Number of special areas
- Acres of special areas
- Supports special areas direction

Affected Environment

Existing Condition

No special areas were designated in the 1987 Nez Perce Forest Plan. The 1987 Clearwater National Forest plan included 12 special areas. One of these areas, Oviatt Creek Fossil Beds on the Palouse Ranger District, is no longer designated as a special area. It was transferred out of public ownership as part of a land exchange with Amendment 11 in 1994. The remaining 11 special areas encompass 584 acres, as outlined in Table 450.

Table 450. Currently designated special areas

Special Interest Area Name	District	Classification	Acres
Colgate Licks	Lochsa and Powell	Geologic or Historic	50
Devoto Cedar Grove	Lochsa and Powell	Botanical or Historic	20
Elk Butte Mountain Hemlock	Palouse	Special Feature	118
Giant Cedar Grove	Palouse	Botanical	23
Giant Western White pine	Palouse	Special Feature	20
Grand Fir and Subalpine Fir Record Trees	Lochsa and Powell	Special Feature	40
Heritage Cedar Grove	North Fork	Botanical	50
Lewis and Clark Cedar Grove	Lochsa and Powell	Historic	30
Morris and Perkins Cedar Grove	Palouse	Botanical	33
Séewisníme (Place of Mussels)[1]	Lochsa and Powell	Historic	50
Walde Mountain Botanical Area	Lochsa and Powell	Botanical	150

Source: Acres from the 1987 Forest Plan.

[1] Formerly designated Special Area Musselshell Meadows in 1987 Plan. The Revised Land and Resource Management Plan would change the name to séewisníme.

Six additional areas are currently proposed for special areas designation; two under classification as botanical areas, one of which is classified as both botanical and historical, two under historical, and one as recreational. These are as described as follows:

Clear Creek Basalt Glades Botanical Area

These basalt outcrops and glades are located approximately five miles southeast of Syringa, Idaho, on the Moose Creek District. The area provides unique botanical communities, including several rare and uncommon species and unusually intact and weed free arid grasslands composed of an uncommon form of rhizomatous bluebunch wheatgrass. The floral displays provide intense coloration of the landscape that change dramatically with changes in moisture through the spring and summer. These botanically significant communities abruptly merge into a western redcedar grove with unusually large Pacific yew, small wetlands, and riparian shrub habitats.

Elk Creek Falls Recreational Area

Elk Creek Falls is located approximately three miles south of the town of Elk River, Idaho, on the Palouse District. The highly popular area consists of three main waterfalls located within a natural setting of moist forests and grassland bluffs. Since 1977, the area has been managed for nonmotorized, dispersed recreation associated with hiking and viewing the waterfalls. This area is included as a special area because the special management area it fell under in the 1987 Forest Plan is not included in the new plan.

Wispin'iitpe Botanical and Historical Area

Wispin'iitpe; which means: As one travels out of the timber, upon coming over the divide; begins at Lolo Pass and includes Packer Meadow. This extensive meadow system includes a wide variety of habitats, including grasslands, moist meadows, sedge flats, shrub swamps, peatlands, diverse forb, and cold forest communities. Several rare and uncommon plant species grow here including carnivorous plants. It also supports a substantial stand of camas that is popular for viewing during bloom periods and provides cultural values for Native Americans. The Lewis and Clark trail passes through these meadows and the expedition camped here.

The Lolo Pass Visitor Center is a historical landmark site on the Lewis and Clark Highway, bordering Montana and Idaho. It is located near the area where Meriwether Lewis and William Clark took eleven days in September of 1805 to traverse the grueling Lolo Pass through the Bitterroot Mountains. The dangerous terrain, harsh weather conditions, and near-starvation resulted in the most arduous portion of the entire expedition in which the men resorted to eating some of their own horses to survive. The visitor center is also located on the Nez Perce National Historic Trail, a path followed by a band of Nez Perce Indians while fleeing from the U.S. Calvary in 1877 to avoid being forced onto a reservation.[27]

Sing Lee Fen Botanical Area

This botanical area is approximately ten miles northwest of Elk City, Idaho, on the Red River District. It was first suggested as a botanical area in 2002 with the Newsome Creek Ecosystem Analysis at the Watershed Scale. The fen is a complex of sphagnum peatlands that support many unique community elements and are of fragile nature. Tertiary sediments along Sing Lee Creek contribute to the prevalence of perched water areas and unusual hydrology of the area. The acidic environment is inhospitable to tree species and help the fen resist encroachment. The diverse botanical community supports the many unusual or rare species present, including carnivorous plants and at least four species of sphagnum moss. Habitats include fens, sedge flats, a pond, and coniferous swamp within a grand fir forest. Tailed frogs have been identified in Sing Lee Creek.

Colt Killed Creek Campsite Historical Area

The Colt Killed Creek Campsite is located on the grounds of the Powell Ranger Station, within the Nez Perce-Clearwater National Forests. The probable site of the encampment has been developed to include a helipad, parking area, and numerous outbuildings. The creek branch described by William Clark of the Corps of Discovery was filled in by the USFS sometime after the 1950s, but the "Small Island" in the Lochsa River remains intact.

By Clark's account, September 14, 1805, was a miserable slog. Persevering through rain, hail, and snow, the fatigued expedition struggled over steep mountainsides made nearly impassable by a plethora of fallen tim-ber. They ended the day "Encamped opposit a Small Island at the mouth of a branch on the right side of the river which is at this place 80 yads wide, Swift and Stoney, here we wer compelled to kill a Colt for our men & Selves to eat for the want of meat & we named the South fork Colt killed Creek, and this river we Call Flathead River." The horsemeat was a welcome addition to the paltry food rations. Gass wrote, "none of the hunters killed any thing except 2 or 3 pheasants; on which, without a miracle it was impossible to feed 30 hungry men and upwards, besides some Indians. So Capt. Lewis gave out some portable soup, which he had along, to be used in cases of necessity. Some of the men did not relish this soup, and agreed to kill a colt; which they

[27] https://www.nps.gov/places/lolo-pass-visitor-center.htm

immediately did, and set about roasting it; and which appeared to me to be good eating."
https://www.nps.gov/places/colt-killed-creek-campsite.htm

Smoking Place Historical Area

Smoking Place is located within the Nez Perce-Clearwater National Forests, along Forest Road 500, also known as the Lolo Motorway.

On June 27, 1806, the expedition proceeded east on the rugged Lolo Trail. Clark wrote, "we halted by the request of the Guides a fiew minits on an ellevated point and Smoked a pipe on this eminance the nativs have raised a conic mound of Stons of 6 or 8 feet high and erected a pine pole of 15 feet long. from hence they informed us that when passing over with their families some of the men were usually Sent on foot by the fishery at the enterance of Colt Creek to take fish and again meet the party at the quawmash glade on the head of Kooskoske river. from this place we had an extencive view of these Stupendeous Mountains principally Covered with Snow like that on which we Stood; we were entirely Serounded by those mountains from which to one unacquainted with them it would have Seemed impossible ever to have escaped […] after haveing Smoked the pipe and Contemplating this Scene Sufficient to have dampened the Spirits of any except Such hardy travellers as we have become, we continued our march."

The rock cairn originally described by Clark is no longer extant; a smaller cairn now marks the landscape. The site is a component of the Lolo Trail National Historic Landmark.

Environmental Consequences

Effects Common to All Alternatives

All special areas are directed to be managed for public use and enjoyment of the special or unique features for which they are designated. Under all alternatives, eight existing special areas would maintain their designations. These special areas include Colgate Licks, Devoto Cedar Grove, Giant Cedar Grove, Heritage Cedar Grove, Lewis and Clark Grove, Morris and Perkins Grove, Musselshell Meadows, and Walde Mountain. Direction in the establishment records and Forest Service Manual (FSM) 2372 would be followed in these areas to conserve the features for which they were established.

The potential for additional special areas in the future would exist under any alternative. As areas with special characteristics or unique values are identified they could be designated following criteria outlined in the Forest Service Manual 2372.

Effects Common to Action Alternatives

All action alternatives would retain eight special areas from the 1987 Clearwater Forest Plan and rescind designation for three special areas (FSM 2372.2). In addition, six new special areas will be designated, including the Clear Creek Basalt Glades, Elk Creek Falls, Wispin'iitpe, Colt Killed Creek Campsite, Smoking Place, and Sing Lee Wetland. Special area designation for the action alternatives is summarized in Table 451.

Table 451. Special Areas under the action alternatives

Special Area Name	District	Classification	Acres
Clear Creek Basalt Glades	Moose Creek	Botanical	267

Special Area Name	District	Classification	Acres
Colgate Licks	Lochsa and Powell	Geological and Historical	39
Devoto Cedar Grove	Lochsa and Powell	Botanical and Historical	15
Elk Creek Falls	Palouse	Recreational	443
Giant Cedar Grove	Palouse	Botanical	44
Heritage Cedar Grove	North Fork	Botanical	153
Lewis and Clark Cedar Grove	Lochsa and Powell	Historical	58
Morris and Perkins Cedar Grove	Palouse	Botanical	48
séewisníme (Musselshell Meadow)	Lochsa and Powell	Historical	163
Wispin'iitpe	Lochsa and Powell	Botanical and Historical	336
Sing Lee Fen	Red River	Botanical	25
Walde Mountain	Lochsa and Powell	Botanical	82
Colt Killed Creek Campsite	Lochsa and Powell	Historical	159
Smoking Place	Lochsa and Powell	Historical	173

Source: Acres from current GIS mapping.

It should be noted that the acre values given here are different from those listed under the Existing Condition, which were taken from the existing forest plans. This is in part due to more precise mapping in some cases. In others, the original maps may not exist, or current mapping exercises have placed boundaries that may be adjusted based upon refined information or purpose. Completion of specific management plans may alter boundaries slightly in the future and would be adjusted through a plan amendment if necessary.

Table 452 provides a summary of potential effects on Special Areas from proposed plan components under all action alternatives.

Table 452. Summary of proposed plan components' potential effects for Special Areas under action alternatives

Plan component	Potential effects
GA-DC-SA-01	Special Areas provide for public use and enjoyment and protect areas with scenic, geological, botanical, zoological, paleontological, archaeological, or other special characteristics or unique values on the Nez Perce-Clearwater. Education and interpretation of these areas promote public awareness of these special features.
FW-DC-SCENERY-01	The Nez Perce-Clearwater's scenery reflects the natural and cultural range of variability within the landscape's varied ecological regions in relation to viewing contexts and expectations for the viewsheds. This is reflected in the scenic character descriptions.
FW-DC-SCENERY-02	The Nez Perce-Clearwater's scenery, as described by the scenic integrity objectives (Table 19 in the LMP), reflects a range of variation that considers social and economic values, ecosystem processes, resilient landscapes, and communities.

Plan component	Potential effects
FW-DC-ED-01	Interpretation and educational opportunities enhance the visitor's understanding and appreciation for the rich natural and cultural history of the Nez Perce-Clearwater and build support for public lands. Interpretive and educational opportunities focus on relevant themes (for example, heritage and cultural resources, ecosystem processes and restoration, invasive species, wildlife [including human interactions with wildlife], sustainable public lands, and the history of Nez Perce-Clearwater associated with logging, mining, trapping, settlement, and rivers).
FW-DC-ED-02	A variety of educational and interpretive opportunities are available, as appropriate, for the development scale of sites through a variety of methods to reach the broadest audience. New and emerging technologies (for example, electronic media, mobile device based) are a source of interpretation to reach a variety of people of different ages and cultures.

Forest Service Manual 2372 provides direction in the management of these areas and provides the basis for site-specific management plans where they exist. Specific policy guiding management of special areas is provided in Forest Service Manual 2372.03 and Forest Service Manual 2372.4, which guides potential developments, occupancy, and use of an area.

Effects under the No Action Alternative

The existing Clearwater Forest Plan includes components for the 11 existing special areas that would apply to the No Action Alternative. The expected effects from plan components are summarized in Table 453. In general, special areas are to be managed under similar restrictive direction as research natural areas in the 1987 Plan; the Elk Creek Falls Recreational Area is under the direction of Management Area A2 of the 1987 Plan.

Table 453. Summary of existing plan components' potential effects to special areas under the no action alternative

Plan component	Potential effects
Management Direction, Special Areas Objectives	Protection of special areas will be similar to research natural areas but designed primarily for public use and interpretation.
Management Area A2, Elk Creek Falls Recreational Area	Provide opportunities to view waterfalls and maintain a natural appearing setting. Manage foreground to meet visual quality objectives of retention, middle and background, to meet or exceed partial retention. Design facilities to meet visual quality objectives of retention. Manage for old growth dependent and nongame wildlife; prohibit livestock grazing; timber producing land is classified as unsuitable; timber is only harvested for salvage following catastrophic events or to achieve specific vegetation management objectives to reduce fire, disease, public safety; enhance visual quality or ensure long term maintenance of desire vegetation. Maintain quality and quantity of water to maintain recreational attraction. Do not permit extraction of common minerals and only allow limited access for other minerals. Acquire adjacent lands to increase potential recreation. Limit special use permits limited to those consistent with management of the area. Designate as an avoidance area for potential utility corridors. Rehab all roads except for the main access road, maintain trails to easy standards, and prohibit motorized vehicles on or off trail. Prescribed fire and insect and disease control is allowed if needed. Control wildfires at one-tenth acres or less per fire.

Selection of the No Action Alternative would retain three special areas that no longer contain the features or fulfill the purpose for which the special areas were established in the 1987 Plan. In addition, five proposed special areas – the Clear Creek Basalt Glades, Wispin'iitpe, Colt Killed Creek Campsite, Smoking Place, and Sing Lee Fen – would not be designated.

The action alternatives would differ from the No Action Alternative with respect to the number and acres of designated special areas. Three of the currently designated areas will not be retained as special areas under the action alternatives of the new plan. These include the grand fir and subalpine fir state record trees and the giant western white pine. The special features, which the special areas were based upon, are of uncertain location and/or are known or expected to be dead. The Elk Butte hemlock stand is not retained because the valued feature of this stand is minor compared to others on the forest. Also, exemplary forest communities are better represented as components of research natural areas than special features of special areas.

The four new special areas would be included with similar acreages in each of the action alternatives. These include the three new special areas, Clear Creek Basalt Glades, Wispin'iitpe, and Sing Lee Fen, as well as the Elk Creek Falls Recreational Area, which will change from Management Area A2 of the 1987 Plan to a special area in the revised plan. cheThe action alternatives increase the total acreage of special areas over the No Action Alternative by 1,421 acres to 2,005 acres total. Much of the addition occurs because of converting the existing Elk Creek Falls Recreational Area to a special area designation.

The effects of the action alternatives would be as described above under the Effects Common to All Action Alternatives because all special areas are included in each action alternative without variation. Benefits to special areas under the Land Management Plan would result from numerous plan components that would maintain or improve general vegetation and ecological processes across the landscape as discussed in the effects above. The 1987 Forest Plans had fewer such benefits but applied general research natural areas protections to special areas on the Clearwater National Forest. The revised Land Management Plan follows special areas policy provided in the Forest Service Manual, which is less restrictive and provides better flexibility in meeting the management needs and public use of these areas.

Cumulative Effects

The existing conditions within the designated areas reflect the contributions of past management actions and ecological processes. Management activities generally have been very limited within most special areas, restricted to management activities that have supported or have not detracted from the features for which the area was established. Some special areas have seen more substantial management in the past. Such activities could continue so long as these activities do not adversely affect the features and public use for which the special areas were established.

Management activities generally take place outside of special areas simply because the unusual habitats or features generally are areas that support manageable resources. In most cases, it is unlikely management would have an effect due to distance of the activities from the special areas and various plan components that protect soils, water, and other resource values forestwide. Exceptions may be when an action is needed to protect or preserve the unique features of the area. Examples might include treating weeds in a botanical area that may be necessary to prevent the loss of natural vegetative, rare species, or active fire suppression may be desirable to preserve a cedar grove from wildfire. Fuel treatments may occur within or adjacent to a special area to maintain special features or to reduce fuels, which could be desirable to reduce severity of potential future fires that could harm an area. In any case, where vegetative treatments may occur within a special area, site planning to incorporate the needs of the special area's resources would eliminate or adequately mitigate management conflicts. Thus, it is unlikely that any management action would alter any special areas in a harmful or undesirable manner.

Effects to Resource from Other Resources

Aquatic Ecosystems and Soil Management

Management activities related to watershed, soil, riparian, or aquatic habitat would generally not occur in special areas and there would be little to no effect related to the management of these resources. If such event occurred, it would be for the maintenance or enhancement of the features for which the special areas was designated.

Fire Management

Desired conditions within special areas are to maintain or enhance an ecosystem that primarily reflects the influence of natural processes or special features for public benefit. In some areas, fire could be a natural process suitable for this purpose; however, often wildfires would require suppression measures for the purposes of protecting values both within and outside the special areas. Cedar groves, for example, would need to be protected from wildfire to maintain the desired condition of such special areas. Prescribed fire is allowed within special areas for the purposes of maintaining natural processes and desired vegetation conditions when applicable. Impacts from fire management are expected to be low.

Timber and Vegetation Management

Special areas are generally not suitable for timber production or the commercial removal of special forest products due to the habitats present. Vegetation management, including timber harvest, may be allowed in special areas when used as a tool to maintain or restore the values for which the area was designated as a special area or do not negatively affect those values and the ability of the public to use the area. Thus, impacts from vegetation management activities are expected to be very low.

Livestock Grazing

There are few livestock allotments within most of the special areas; thus, there would be no grazing effects at these sites. Livestock do graze at the proposed Clear Creek Basalt Glades Special Area (267 acres of the Tahoe-Clear Creek Allotment), where cattle use the road into that area and adjacent flat grass and shrublands. Additionally, Lewis and Clark Grove Special area contains 58 acres of the Cedar Allotment and Séewisníme Special Area includes 163 acres of the Musselshell Allotment. This is an ongoing use of the area that contributes to an existing condition that is desirable for special areas inclusion. Negative effects would occur at limited, isolated sites and most of the area's features for which the special area is established are completely unused.

Wildlife

Activities related to wildlife management would generally not occur within special areas and there would be little to no effect. Where such activities might occur, they would generally be for the benefit of species or habitat.

Recreation and Access

Effects of recreational use and management within special areas are anticipated to be low. Hiking and other activities occur but the impacts can be expected to be minimal since they are generally of low intensity. Exceptions would include high use areas such as Elk Creek Falls, Giant Cedar, and Devoto Grove, where use is limited to well established and maintained trails. Trail maintenance work can be expected to have little impact on special areas. Developed recreation sites are unlikely, although trailhead and sanitation facilities can be expected in some recreational areas. Where these facilities are most needed, they are generally already in place. Any new developments would follow direction in the Forest Service Manual 2372.

Access and recreational uses would be limited within special areas to protect the features associated with designation. Motorized travel would only be allowed on designated routes; however, over-snow vehicle use could occur in some special areas where snow would protect the ground. This use would not interfere with the special area features or use and are identified on the over-snow vehicle use map.

Cultural, Historic, and Tribal Resource Management

Activities related to cultural, historic, and tribal resources would generally not occur in special areas and there would be little to no effect. An exception would be camas harvest at Séewisníme and potentially at Wispin’iitpe. In both cases, such use and management would be to maintain this resource for which both of these special areas are partially designated.

Minerals Management

Anticipated effects from minerals management would be low for all alternatives. Potential for leasable minerals is low across most of the Nez Perce-Clearwater and currently there are no permits or operating plans for exploration within any special areas. Although potential for locatable minerals does exist, there are no current permits or operating plans for mineral exploration within these areas.

Invasive Plant Species

Control of invasive species could occur in some special areas depending on ground conditions and control methods. Generally, most special areas consist of habitats that are of low susceptibility to weed invasion. However, the open grasslands or transitional habitats at the Clear Creek Basalt Glades, Elk Creek Falls, and Colgate Licks are more susceptible and do host some weed occurrences. In open, moist habitats, reed canary grass is an undesirable presence at Séewisníme, with some potential to inhabit Sing Lee Fen and Wispin’iitpe. Weed treatments would be expected to have a positive effect through the maintenance of the vegetative communities and features for which these areas were designated. Treatments could be mechanical, biological, or chemical and would be subject to forestwide direction and mitigations.

Summary of Consequences

Table 454 provides indicator values across the alternatives. All alternatives fulfill these indicators, with the action alternatives providing more proposed special areas, to better fulfill agency policy of public use and enjoyment (Forest Service Manual 2372). Under all action alternatives, the network of special areas would continue to contribute to the conservation of biological diversity and provide for public use, enjoyment, and educational opportunities in the plan area. The action alternatives better fulfill the purpose of special areas compared to the No Action Alternative through increased public opportunities and more diverse and appropriate designated areas. Similar designations are not known to occur on lands of private ownership, nor on state lands in the area, increasing the importance of maintaining them on National Forest System lands.

Table 454. Summary of special area indicator values by alternative (Alt)

Indicator	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Number of special areas	11	12	12	12	12	14

Indicator	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Acres special areas	584	1,673	1,673	1,673	1,673	2,005
Supports special areas direction	Yes	Yes	Yes	Yes	Yes	Yes

Conclusion

All action alternatives provide for a network of special areas across the Nez Perce-Clearwater through designation of 14 units comprising 2,005 acres that provide the public with a diverse opportunity for enjoyment and education concerning some of the more unique features of the Nez Perce-Clearwater National Forest. The 1987 Forest Plan referred to research natural area plan components that more explicitly prohibit management activities within special areas than does the revised plan, which allows for more flexibility when uses are consistent with the site establishment records and standards in Forest Service Manual 2372.

3.7 Risk Management and Safety

The focus of this analysis concerns the effects of each proposed alternative as it relates to life safety with respect to long-term management of Nez Perce-Clearwater lands. Through the lens of life safety, the analysis considers known risk to employees, communities, and visiting publics and how each alternative effects this risk. Additionally, it assumes that we will simultaneously address risk to communities and the visiting public by addressing future risk to employees. By managing for a landscape that lessens exposure to high-risk hazards in the future, we will lessen the risk to communities and the public in the long-term as well. The concept that a fire-adapted and resilient landscape equally reduces risk to employees and communities in and adjacent to National Forest System lands is congruent with the National Cohesive Fire Management Strategy and other national level plans, initiatives, and acts, such as the National Fire Plan, Healthy Forest Initiative, and Healthy Forest Restoration Act.

This analysis incorporates a blend of quantitative and qualitative data and information. It uses modeling outputs, injury and fatality records, and Incident Learning Reviews from accident investigations to develop a system to evaluate each alternative relative to life, risk, and safety. This analysis is an attempt to quantify risk in the long-term and there is an irreducible component of uncertainty that is inherent.

An unavoidable tenet of risk management is that choices made today affect all future options. Successful risk management not only minimizes unnecessary exposure but also depends on how well we can recover from or tolerate the consequences of undesirable outcomes. When applying a *Life Safety* lens of risk management to land management planning, we must recognize how the choices we make now will affect the safety of employees, wildland fire responders, forest visitors, and local communities today and into the future. Accepting increased risk today with a capacity to manage exposure is preferable to transferring risk into the future and hoping that those who inherit our decisions are adequately equipped to deal with the consequences, whatever they might be.

Latent risk associated with management of Nez Perce-Clearwater lands and resources involves the loss of life and property of individuals and communities exposed to hazard trees, hazardous fuels accumulation, wildfire and other natural events exacerbated by a landscape that has severely departed from its natural condition. In this context, risk also involves the loss of options available to land managers for restoring and maintaining fire resilient landscapes and safely and effectively responding to a variety of natural events. Managing this risk in the near term, while at the same time reducing risk in the long-term, is in and of itself full of uncertainty and in conflict.

The need to assume some level of risk now to lessen future risk regarding life safety in the management of public lands is at its core a “wicked problem.” A wicked problem is a problem that is difficult to solve because of incomplete, contradictory, and changing requirements that are often difficult to recognize. Moreover, because of interrelated and interdependent parts, the effort to solve one aspect of a wicked problem may reveal or create other problems. Fundamental to this is that land management organizations ultimately are sociotechnical systems that are complex and adaptive. Adapting to demands in one area may create unexpected outcomes in another, whether positive or negative. These systems are characterized by uncertainty, meaning it is an identifying trait of the system and is irreducible. Uncertainty in our Forest Service system cannot be eliminated (U.S. Department of Agriculture 2016d).

Risk is essentially a measure of the probability and consequence of uncertain events and always has been an inevitable element of forest and grassland management. Forest Service managers face risks created by natural phenomena, as well as risks that are introduced when actions are taken (Thompson et al. 2016). More specifically, in this analysis, risk is considered as the estimated probability that a particular proposed land management plan alternative will contribute to increased or decreased exposure of employees and communities to hazardous conditions in the long-term. The long-term is defined as twenty plus years from today.

Principles of risk management include integrating risk principles into all organizational processes and decisions and embracing an uncertain world. An understanding of probability, using the best available information, and a commitment to organizational learning is necessary to facilitate continual improvement. Risk management organizations are proactive and invest time and resources upstream in assessment and planning. As a result, employees are less susceptible to the vagaries of uncertain, time-pressured decision environments (Thompson et al. 2016).

The Forest Service has adopted a risk management approach to life safety, recognizing that hazards and associated risks are inherent in our work. There is no “zero risk” alternative to accomplishing the multitude of objectives required of Forest Service land management. This is especially true in the context of managing natural resources for multiple use, while at the same time restoring natural processes to the landscape.

The implementation of a formal risk management process will allow the Forest Service to enhance employee capacity to identify, evaluate, and mitigate risks across the full spectrum of work activities and improve the ability to accomplish objectives as safely and efficiently as possible. The following is an excerpt from the Forest Service Operational Risk Management Guide and expands upon the various levels of risk management and their application (U.S. Department of Agriculture 2019c).

- **Enterprise Risk Management (ERM):** This level begins with defining the agency mission and identifies national and agency-wide influencers affecting the ability to attain mission objectives. Enterprise Risk Management involves an assessment of system level fundamentals that affect how strategic, operational, and time-critical risk management choices are made.
- **Strategic Risk Management (SRM):** This level provides a risk management process to a long-term project or plan where resources are available to invest in significant analysis and research of available data. It is used in the long-term planning of complex operations, such as for introducing new equipment, new procedures, or new policies. Examples of projects where

Strategic Risk Management is applicable include Forest Land Management Planning, a watershed restoration project, or a long-term wildfire event.

- **Operational (Deliberate) Risk Management (ORM):** Operational Risk Management relies on clear objectives and each step should be documented. It primarily uses experience and brainstorming to identify hazards and develop controls and is most effective when done in a group. Examples of Operational Risk Management applications include planning upcoming projects to implement the Land Management Plan, developing an incident management plan, or implementing a prescribed burning plan.
- **Real-Time (Time-Critical) Risk Management:** This level incorporates an "on the run" mental or verbal review of the situation using the risk management process with or without recording the information. Employees implement the real-time process to consider risk when making intuitive decisions in a time-compressed situation. It is particularly helpful in choosing the appropriate course of action when an unplanned event occurs.

In the past, there has been little integration of a formal risk management process with the specific intent of addressing life safety in National Environmental Policy Act (NEPA) documents. Integrating risk management concepts focus on life safety at the project planning level of NEPA could be a particularly positive way to address safety concerns regarding project implementation earlier in the process. This would be an example of Operational Risk Management being applied as it is intended. Unfortunately, life safety issues are often left unaddressed until project implementation, which can lead to a multitude of problems concerning life safety and project design. Operational Risk Management has a specific goal to enhance an employee's ability to anticipate hazards and reduce the potential for loss, thereby increasing the probability of a successful outcome (U.S. Department of Agriculture 2019c) . Combined with the principles of Human and Organizational Performance Operational Risk Management represents a systems approach to Risk Management. The principles of Human and Organizational Performance were developed by Institute of Nuclear Power Operators and Department of Energy in response to managing the risk of organizational accidents in high-risk environments in the wake of the Three Mile Island Incident.

Human and Organizational Performance is a set of concepts and principles associated with a performance model that illustrates human performance in the context of the organization. The model contends that human performance is a product of organizational and individual elements that work together to produce repeatable outcomes. Human and Organizational Performance encompasses organizational factors, job-site conditions, individual behavior, and results. The system approach puts new perspective on human error; it is not a cause of failure but rather the symptom of deeper trouble in the system. Human error is not random; it is systematically connected to features of people's tools, the tasks they perform, and the operating environment in which they work (U.S. Department of Energy 2009).

The concept of high reliability organizations has been of interest to the federal wildland fire community in recent years. High reliability organizations provide real examples of organizations that operate successfully while almost never experiencing an unwanted event. By definition, high reliability organizations operate under very trying conditions all the time and yet manage to have very few accidents. Examples of high reliability organizations include aircraft carriers, air traffic controllers, power grid dispatch centers, nuclear submarines, airline cockpit crews, nuclear power plants, and offshore platforms, among others. Human and Organizational Performance is one approach toward achieving the attributes evident in high reliability organizations.

Principles of Human and Organizational Performance: Five simple statements, listed below, are referred to as the principles or underlying truths of human and organizational performance. Excellence in human performance can only be realized when individuals at all levels of the organization accept these principles and embrace concepts and practices that support them. Integrating these principles into management and leadership practices, worker practices, and the organization's processes and values will be instrumental in vectoring the organization towards a highly reliable organization (U.S. Department of Energy 2009)

- People are fallible, and even the best people make mistakes. Error is universal. No one is immune, regardless of age, experience, or educational level. The saying "to err is human" is indeed a truism. It is human nature to be imprecise—to err. Consequently, error will happen. No amount of counseling, training, or motivation can alter a person's fallibility.
- Error-likely situations are predictable, manageable, and preventable. Despite the inevitability of human error in general, specific errors are preventable. Just as we can predict that a person writing a personal check at the beginning of a new year stands a good chance of writing the previous year on the check, a similar prediction can be made within the context of work at the job site. By changing the work situation to prevent, remove, or minimize the presence of conditions that provoke error, task and individual factors at the job site can be managed to prevent, or at least minimize, the chance for error.
- Individual behavior is influenced by organizational processes and values. Organizations are goal-directed and, as such, their processes and values are developed to direct the behavior of the individuals in the organization. Work is achieved, however, within the context of the organizational processes, culture, and management planning and control systems. It is exactly these phenomena that contribute to most of the causes of human performance problems and resulting events.
- People achieve high levels of performance because of the encouragement and reinforcement received from leaders, peers, and subordinates. The organization is perfectly tuned to get the performance it receives from the workforce. All human behavior, whether good and bad, is reinforced by immediate consequences or by experience.
- Events can be avoided through an understanding of the reason mistakes occur and application of the lessons learned from past events (or errors). Traditionally, improvement in human performance has resulted from corrective actions derived from an analysis of facility events and problem reports—a method that reacts to what happened in the past. Learning from our mistakes and the mistakes of others is reactive—after the fact—but important for continuous improvement. Human performance improvement today requires a combination of both proactive and reactive approaches.

In summary, integrating the principles of Risk Management and Human and Organizational Performance into land management planning and operations establishes a system view of safety. A system view of safety can improve employee health and safety by reducing the incidence of fatalities related to underlying conditions both in the organizational and physical work environment. While there is no "zero risk" alterative, in the long-term, it is possible to further reduce risk to employees, communities, and publics in and adjacent to the Nez Perce-Clearwater by managing for a fire adapted and resilient landscape while at the same time meeting the multiple management objectives outlined in the land management plan.

3.7.1 Relevant Laws, Regulations, and Policy

Federal Laws

Occupational Safety and Health Act of 1970 (sec. 19 and 24), as amended (Title 29 U.S.C., sections 668 and 673 (29 U.S.C. 668 and 673)). This regulation states each employee shall comply with occupational safety and health standards and all rules, regulations, and orders issued pursuant to this act which are applicable to an employee's own actions and conduct.

Occupational Safety and Health Administration (OSHA) Title 29, CFR, Part 1910 (29 CFR 1910). This regulation contains occupational safety and health standards which have been found to be national consensus standards or established federal standards.

Occupational Safety and Health Standards, 29 Part 1926, Construction Standards (29 CFR 1926). This part sets forth the safety and health standards promulgated by the Secretary of Labor under Section 107 of the Contract Work Hours and Safety Standards Act.

Occupational Safety and Health Programs and Related Matters, 29 CFR Part 1960 (29 CFR 1960). This regulation provides basic program elements for federal employees. The regulation contains special provisions to assure safe and healthful working conditions for federal employees. Under this section, it is the responsibility of the head of each federal agency to establish and maintain an effective and comprehensive occupational safety and health program which is consistent with the standards promulgated under Section 6 of the Act.

Executive Order 12196, February 26, 1980. This order explains the required occupational safety and health programs for federal employees.

Healthy Forest Restoration Act of 2003 (Public Law 108–148, as amended): This act is aimed at expediting the preparation and implementation of hazardous fuels reduction projects on federal land; encouraging collaboration between federal agencies and local communities; requiring courts to balance effects of action versus no-action prior to halting implementation; and requires federal agencies to retain large trees under certain conditions.

2002 President's Healthy Forest Initiative: This initiative emphasizes administrative and legislative reforms to expedite fuels treatments and post-fire rehabilitation actions.

Policy

Forest Service Handbook 6700.11 - The Health and Safety Code Handbook. This policy is the primary source of standards for safe and healthful workplace conditions, project inspections, and operational procedures and practices in the Forest Service. The policy is in addition to the standards and regulations of the Occupational Safety and Health Administration (OSHA).

National Cohesive Wildland Fire Management Strategy 2014: The National Cohesive Wildland Fire Management Strategy is a strategic push to work collaboratively among all stakeholders and across all landscapes, using best science, to make meaningful progress towards three goals:

- Resilient Landscapes
- Fire Adapted Communities
- Safe and Effective Wildfire Response

Interagency Standards for Fire and Fire Aviation Operations (National Fire Equipment System 2724): This reference guide documents the standards for operational procedures and practices for the Forest Service fire and aviation management program.

State and Local Plans

The following plans provide guidance for sustained action taken to reduce or eliminate the long-term risk to human life and property from hazards. Mitigation activities pertaining to wildfires, hazard fuels, and zonal planning may be implemented prior to, during, or after an incident.

- Lewis County, Idaho Multi Hazard Mitigation Plan (Northwest Management 2011b)
- Clearwater County, Idaho Multi Hazard Mitigation Plan (Clearwater County 2017b)
- Idaho County, Idaho Revised Wildland Urban Interface Wildfire Mitigation Plan (Idaho County Commissioners 2009b, a)
- Latah County, Idaho Multi Hazard Mitigation Plan (Northwest Management 2011a)
- Nez Perce County, Comprehensive Plan (Nez Perce County 2018)

3.7.2 Methodology

Spatial Scale

The analysis area is those lands administered by the Nez Perce-Clearwater, as well as the land of other ownership within and adjacent to the Nez Perce-Clearwater or in which the Nez Perce-Clearwater has operational responsibility for wildfire suppression operations.

We used the Parameter-elevation Regressions on Independent Slopes Model (PRISM) and Simulating Patterns and Processes at Landscape Level Scales (SIMPPLLE) models interactively to analyze vegetation conditions. Wildfire disturbances were first modeled in SIMPPLLE. Resultant disturbance levels were then input into the PRISM model as acres of projected wildfire. The PRISM model was then run, and the outputs from PRISM were input into the SIMPPLLE model to allow for integration with the ecological processes and disturbances as modeled within SIMPPLLE for fire, insect, disease, and succession and with the spatial analysis of the change in vegetation conditions over time.

Temporal Scale

The temporal scale of this analysis is 200 years. It utilizes employee fatality data and vegetative condition modeling both forward and backward in time from present year. The selection of this temporal scale was based on documented employee fatalities and the projected time to future desired conditions modeled for each of the action alternatives. Employee fatality data from Line of Duty Deaths for the Nez Perce-Clearwater dates to 1919, 11 years after the establishment of the Nez Perce National Forest and Clearwater National Forest in 1908 and 9 years after the 1910 fires of Idaho, Montana, and Washington that prompted National Forest Land Managers, with the support of Congress, to establish an aggressive doctrine toward fire suppression and prevention on National Forest System lands.

Methods and Assumptions

Through the lens of life safety

This analysis is an attempt to quantify risk in the long-term. There is an irreducible component of uncertainty that is inherent. Risk to life safety in this analysis is the relative risk of fatality and severe life altering injury to employees, whether permanent, seasonal, volunteer, cooperator, or contractor; communities; and the visiting public that can be attributable to landscape conditions and organizational capacity to manage towards future desired conditions.

Desired conditions will result in a less hazardous environment

Fundamentally, this analysis is based on the premise that a fire adapted and resilient landscape within the natural range of vegetative condition is ultimately less hazardous to life safety than a landscape skewed in either direction from the natural range of vegetative condition. A return to natural range of vegetative condition can result in a reduction of extreme fire events moderated by more frequent intervals of fire being restored to the landscape. Mechanical fuels treatments and timber harvest that supplements natural and prescribed fire will further contribute to reaching desired conditions on the Nez Perce-Clearwater. Increased use of planned and unplanned ignitions in the action alternatives would lead to greater fuels reduction and the forest vegetation would be more resilient (Parks, Miller, Holsinger, et al. 2016). While not eliminating hazards encountered on National Forest System lands, desired conditions represent a landscape more favorable of reduced risk to employee, community, and public life safety.

Long-term versus near-term perspective

Short-term considerations of fire risk typically result in aggressive suppression, which in some contexts has led us down the wildfire paradox path of less fire today equals more severe fire in the future (Calkin et al. 2014). Through use of wildland fire to achieve land management objectives, the Nez Perce-Clearwater is well on its way to breaking the cycle of an increasingly challenging wildfire management environment and greater risk to both natural and human resources. Additionally, mechanical treatments to restore forests and vegetation to a condition of historic ranges could further address long-term risk in management areas where mechanical treatments and timber harvest are allowed.

Fatalities are most often a tragic outcome of normal work

Fatalities are outliers in the respect that they are an emergent phenomenon in normal work. The work is considered “normal” because it was routine, typical, or within the scope of the mission of the organization. Through a complex set of conditions and chance interactions within the organizational system of work, the conditions that lead to the fatality unfortunately materialized. These same conditions and interactions that lead to fatalities occur frequently but almost always lead to a successful outcome or less frequently a minor incident. It is for this reason that typical methods to prevent injuries applied “harder” hoping to prevent fatalities are limited in their efficacy.

Wildland firefighter fatalities (LODDs) can serve as a surrogate for the rest of the population

An underlying premise of this analysis is that the same type of exposures that contribute to wildland firefighter fatalities are typically the same exposures that contribute to employee, communities, and publics that are within the operational purview of the Nez Perce-Clearwater. While wildland firefighters may be exposed to particular risks for longer periods of time on a given day, the hazards to which they are exposed are not significantly different as to what any employee, community, or visitor may find themselves exposed to. For example, fire weakened, dead or diseased trees are a significant hazard to wildland firefighters engaged in wildland fire operations. In turn we have instances where other employees have suffered significant injury or death from being struck by falling trees. Wildland firefighter fatalities were chosen as a surrogate due to similar hazard exposure as other field going forest employees and because of the extensive documentation and review of wildland firefighter fatality incidents. Compilation of employee fatalities on the Nez Perce-Clearwater date back to 1919 and suggest similar trends and causes for fatalities of employees on the job as national studies on wildland firefighter fatalities suggest.

It may be possible to reduce the risk of on-the-job fatalities of all employees by addressing the issues that commonly are identified as contributors to incidences of wildland firefighter fatalities. Spending more time on “high end” influences with a systemic focus would likely have more broad scale implications to improve employee safety than consistently focusing on “low end” influences with an individual focus. This would be especially important in addressing long-term trends.

Organizations must balance resources of time and effort with being efficient or thorough and organizations typically trend towards efficiency over time

It is a basic attribute of human and organizational performance that the resources needed to do something often, if not always, are insufficient. The most frequent shortcomings are lack of time and funding but other resources, such as information, workforce, and social license to operate, may be in short supply. Nevertheless, in most cases, organizations manage to do what they should by adjusting how they do it to meet the current conditions. In practical terms they manage to establish and maintain a continuous balance between demands and resources. This is what is referred to as the Efficiency Thoroughness Tradeoff Principle (Hollnagel 2012).

This reflects the fact that organizations, as part of what they do frequently if not always, must make a trade-off between the resources, primarily time and effort, they spend on preparing and monitoring an activity and the resources, again primarily time and effort, they spend on doing it (Hollnagel 2012). If safety is the dominant concern, then a trade-off may favor thoroughness over efficiency. Conversely, if throughput and output are the dominant concerns, the trade-off may favor efficiency over thoroughness. It is a basic premise of the principle that it is impossible to maximize efficiency (production) and thoroughness (safety) at the same time. One is maximized at the expense of the other. This is where all levels of risk management come into play. The gap between efficiency and thoroughness represents the level of risk that is ultimately accepted by the organization and, as equally if not more important, the individual worker. Consequently, the organization tends to move towards efficiency over time, especially when positive outcomes reinforce the rewards of efficiency. This is also referred to as Practical Drift or what has become to be recognized in part as the Normalization of Risk.

“Efficiency” means that the resources used or needed to achieve a stated goal or objective are kept as low as possible. The resources may be expressed in terms of time (to completion), materials, money, psychological effort (workload), physical effort (fatigue), and manpower (number of people) (Hollnagel 2012).

“Thoroughness” means that an activity only is carried out if the individual or the organization has verified that the necessary and sufficient conditions are in place so that the activity will achieve its objective without creating unwanted side-effects. More formally, thoroughness means that the pre-conditions for an activity are in place, that the execution conditions (resources, tools, and competence) can be ensured, and that performance is monitored and controlled so that the outcome will be the intended one (Hollnagel 2012).

Relative Risk Matrix Development

Each alternative was analyzed using the following primary indicators:

- Trajectory towards desired conditions
- Management Flexibility
- Implementation Requirements
- Infrastructure
- Workforce Capacity

Each primary indicator includes a subset of indicators (measurements) that were used in the overall risk ranking of the primary indictors. Each measurement is described in the "Measurement Indicators" section of this report. Each measurement is assigned a risk assessment code (RAC) of either 1 = Low, 2 = Moderate, 3 = High, or 4 = Very High.

Additionally, each measurement was assigned a weighting factor relative to potential effects to life safety in the long-term. For "high-end" measurements, a weighting factor of 2 or 3 was applied, while a weighting factor of 1 was applied to "low-end" measurements. Determination of high-end or low-end measurements was determined through a combination of empirical and quantitative information.

For example: For the primary indicator of Workforce Capacity, the measurement of Acres Prescribed Fire Annually was calculated for Alternative X as:

- Formula: Risk Assessment Code x Weighting Factor = Final Risk Assessment Code
- Example: Moderate RAC (2) x High-end weighting factor (2) = Final Risk Assessment Code (4)

A Total Risk Score (TRS) for each primary indicator was calculated by summing the risk assessment codes for secondary indicators and then plotted by alternative on a radar chart creating a version of a risk assessment tool (RAT). The radar charts reflect relative risk level by alternative to life safety in the long-term. Adapted from Operational Risk Management Guide (U.S. Department of Agriculture 2019c), relative risk scoring for the RAT includes:

- Low = scores of 0-10
- Moderate = scores of 11-20
- High = scores of 21-25
- Very High = scores of 26-30.

SIMMPLLE and PRISM

The SIMPPLLE model was used in this analysis for two purposes: to calculate the natural range of variation for vegetation conditions and to project the landscape conditions of the alternatives into the future for analysis for the Final Environmental Impact Statement. SIMPPLLE takes a landscape condition at the beginning of a simulation, including past disturbances and treatments, and uses logic to grow the landscape through time while simulating processes, such as growth, fire, and insects, that might occur on that landscape, while accounting for the effects of those processes.

Out of necessity, the models simplify very complex and dynamic relationships between ecosystem processes and disturbances, such as climate, fire, and succession, and vegetation, over time and space. Although the best available information, including corroboration with actual data, and professional experience and knowledge is used to build these models, there is a high degree of variability and an element of uncertainty associated with the results because of the ecological complexity and inability to accurately predict the timing and location of future events. These models are tools that provide information useful for understanding vegetation change over time and the relative differences between alternatives. The models are not intended to be predictive or to produce precise values for vegetation conditions.

Information sources

This analysis also draws upon the best available literature citations that were found to be relevant to risk to life safety on the Nez Perce-Clearwater. Literature sources that were the most recent, peer-reviewed, and local in scope or directly applicable to the local ecosystem were selected. In addition, local studies and anecdotal information that is not peer-reviewed is included where appropriate to provide context.

Incomplete and unavailable information

Terrestrial ecosystems are highly complex and contain an enormous number of known and unknown living and non-living factors that interact with each other, often in unpredictable ways. For this reason, the Nez Perce-Clearwater acknowledges that there are gaps in available information and knowledge about ecological functioning and an inability to even evaluate what those gaps may be. These gaps in information may lessen over time as new information or methodology emerges. The Nez Perce-Clearwater’s ability to predict fire or other disturbances into the future is limited and is subject to uncertainty. The level of uncertainty depends on how predictable such factors as natural disturbances, climate change, or human-caused influences may be.

Sociotechnical systems, including the Forest Service, not only contain uncertainty but are characterized by uncertainty, meaning it is an identifying trait of the system and is irreducible. Sociotechnical systems are highly complex and contain an enormous number of known and unknown factors that interact with each other, often in unpredictable ways. For this reason, qualitative and experiential data is heavily relied upon to assess the likelihood of a range of potential outcomes. Ultimately, there are gaps in understanding which result in a failure to predict. As research into complex and adaptive systems progresses, technology may become available that enables the narrowing of these gaps.

Measurement Indicators

All measurement indicators are considered in relation to risk to life safety in the long-term, defined as 20 plus years. This is an application of Strategic Risk Management (SRM), with the assumption that near-term risks to life safety can be mitigated with the incorporation of Operational Risk Management (ORM) at the project level.

Fundamentally, this analysis is based on the premise that a fire adapted and resilient landscape within the natural range of vegetative condition (NRVC) is ultimately less hazardous to life safety than a landscape skewed in either direction from natural range of vegetative conditions. Greater emphasis on fire-resilient landscapes and communities is at the heart of the National Cohesive Strategy for Wildland Fire Management acts and initiatives that have been developed in response to extreme wildland fire incidents that have been responsible for loss of homes in communities, negative impacts to rural economies, and loss of life both in the private and public sector. Increased use of planned and unplanned ignitions and harvest activity in the action alternatives would lead to greater fuels reduction and the forest vegetation would be more resilient (Parks, Miller, Holsinger, et al. 2016).

Trajectory towards Desired Conditions

As measured by acres of restoration and maintenance treatments annually, including projected time to desired conditions by alternative.

- Rate of progress to desired conditions as measured in years by alternative.
- Prescribed fire acres annually, by alternative.
- Restoration acres through timber harvest annually by alternative.
- Restoration and maintenance of ecological role of fire projected acres by alternative.
- Soils and watershed acres improved or restored annually by alternative.

The current fire management system still relies heavily on aggressive fire suppression in all but wilderness or Idaho Roadless designated lands. Regardless of management designation, the negative re-enforcement loop of fire suppression requiring more fire suppression has contributed to an increasingly complex and hazardous environment and represents a transfer of risk into the future. Fire responders are being exposed to extremely dangerous situations, such as complex fuel conditions, climatic changes, and wildland-urban interface challenges. As they pursue multiple objectives, there is an increased exposure to hazards. The Twisp River Fire of 2016 is one example of how these increased risks resulted in fatalities (U.S. Department of Agriculture 2016e).

In addition to increased utilization of wildland fire across all lands to enhance landscape resiliency, timber harvest and mechanical fuels reduction can help move the landscape towards desired conditions. Especially where the risk of management ignited or natural ignitions managed to achieve land management plan objectives are high risk due to a departure of natural vegetative conditions, or fire return intervals, from what natural processes would maintain. However, sole reliance on timber harvest and mechanical fuels reduction projects to move the landscape to desired conditions in Management Area 3 and Management Area 2 would likely not be successful without the inclusion of wildland fire.

Management Flexibility

As measured by acres of land allocations and resources that influence the way vegetation treatments are carried out, as well as managing planned ignitions and unplanned natural ignitions.

- Recommended Wilderness Acres by alternative.
- Wild and Scenic Rivers Eligible and Suitable Acres by alternative.
- National Historic Landmark Heritage Resources as measured by land management objectives compatibility.
- Compatibility of neighboring lands and Nez Perce-Clearwater Land Management Areas with the management of fire that achieves land management plan objectives.

Specially designated management areas potentially can limit options for land managers to utilize techniques and tools otherwise available to them in other management areas. Even if available, land managers may choose not to implement or utilize other techniques and tools to accomplish objectives due to the difficulty of obtaining required authorization. In turn, this may create added exposure and increased risk to employees or communities (U.S. Department of Agriculture 2017b).

A severe injury to a wildland firefighter that occurred during the Freezeout Fire of 2014 is an example of management needing to carefully balance risks of land management strategies between specially designated management areas and adjacent lands managed with different strategies and objectives. This can be viewed as a condition of influence created by two differing land management strategies, potentially compelling land management employees to make decisions that may increase risk to employees and communities (U.S. Department of Agriculture 2014j).

Heritage resources can influence what risks managers are willing to take based on need for protection. Generally, these resources can be protected from land management activities and wildland fire without subjecting employees to high levels of risk. However, there can be challenges in specially designated management areas. Of particular concern in this analysis is the Nez Perce Trail National Historic Landmark, which lies in part on lands designated suitable for timber in the 1987 Clearwater National Forest Land Management Plan. This inadvertently creates the same conditions of influence as discussed relative to compatibility of land management strategies and objectives in the Freezeout Fire example above.

Implementation Requirements

As measured by difficulty, either real or perceived, that influence the way vegetation treatments are carried out, as well as managing planned ignitions and unplanned natural ignitions.

- Slope Restriction as measured by maximum percent slope restriction by alternative.
- Detrimental Soil Disturbance limitation as measured by alternative.
- Snag Retention and Recruitment as measured by number of snags per unit measure and diameter requirements by alternative.
- Snag Retention as measured by number of snags per measurement scale by alternative.
- Live Trees per acre as measured by alternative.
- Recommended Wilderness Acres by alternative.

At times, implementation requirements can be conditional influences that effect outcomes both in positive and negative ways. While their intent is for positive effects or protection of ecosystems and natural resources, they can inadvertently create the conditions for implementation decisions that put employees at risk. Although generally not insurmountable, implementation requirements can create misconceptions about available options and steer management activities away from vegetation treatments that would support achieving desired conditions. A recent example of this occurred during the management of the Lolo Peak Fire in 2017 on the Lolo National Forest in the following excerpt from the Lolo Peak Fire Fatality Learning Review:

The way our policy regarding specially-designated management areas is currently set up has an obvious effect on the way we manage fire: the issues associated with obtaining permissions has tainted much of the wildland fire community's desire to work in them. While utilizing mechanized equipment in a specially designated management area is not an impossible task, obtaining the required approvals can be viewed as a monumental one. Due to these challenges it becomes a task that is very often avoided, creating slides for Fire and Forest leadership that remind them there are fewer available tactical options than what truly exist (U.S. Department of Agriculture 2017b).

Implementation requirements may also create downstream effects to safety and risk in a variety of ways. Leave tree and snag retention requirements can leave snags next to prescribed fire control lines, putting prescribed fire implementation crews at risk by either having to fell the snag or taking the chance it will not cause a problem and leave it be. Either way, risk is assumed on part of the implementer that might have been possible to avoid with more flexible snag retention requirements.

Other examples of implementation requirements that create unintended risk to project implementers are as follows:

- Restrictions on the ability to treat activity slash post-harvest leads to hazardous fuels accumulations or operations that entail a higher degree of risk.
- Ability to treat along roadsides that are adjacent to or within proposed wilderness areas.
- Decommissioning of roads that provide firefighter access to initial attack, as well as decommissioning prior to all activities being completed on a project.

Infrastructure

As measured by miles of roads and trails improved, watershed acres improved or restored annually, and lease of radio communication site.

- Miles of roads maintained and improved as measured by Projected Timber Sale Quantity (per million board feet) by alternative.
- Trails maintained improved as measured by alternative.
- Communication Site (GA Pilot Knob) as retained or removed by alternative.

National Forest appropriations are allocated proportionally to the amount of timber management and recreational use on each Forest. Timber management contracts include road maintenance responsibilities on haul routes, providing additional operators to perform road maintenance on the National Forest System roads. Higher timber volumes result in more road maintenance and positive road modifications, such as curve widening, improved sight distance, and replacement of failing or undersized culverts, which would be sized to pass flows from the 100-year flood event.

Under timber stewardship sales, watershed improvements can be accomplished, such as installation of aquatic organism passage culverts, bridge improvements, additional gravel surfacing, and replacement of additional drainage structures with upsized culverts, retaining walls, landslide repairs, and forestwide road maintenance such as road blading.

Safe and well-maintained forest roads are crucial to supporting land management activities, in addition to reducing risk to visiting public and local communities that utilize forest roads for a variety of activities. Increasingly, forest roads are used as control lines for wildland fire operations. Additionally, forest roads serve as primary emergency egress routes for communities located within the Nez Perce-Clearwater. Forest Service trails also facilitate the management and protection of backcountry resources and are occasionally used as fire control lines. Retained receipts from timber harvest can be used to maintain trails to protect aquatic resources. Projected Timber Sale Quantity (per million board feet) serves as a surrogate for miles of forest roads maintained or improved.

Workforce Capacity

As measured by Projected Timber Sale Quantity (PTSQ), restoration acres through timber harvest and restoration acres through prescribed fire annually by alternative.

- Volume of timber to be sold (PTSQ) annually by alternative.
- Acres timber harvest annually, by alternative.

- Acres prescribed annually, by alternative.

As it relates to risk to life safety, workforce capacity is perhaps the most critical indicator, yet the most difficult to predict, especially with a long-term view relative to reaching desired conditions. While possible to project size and skill set of the workforce needed to comfortably execute any of the proposed alternatives, future budgets, advancements in information technology, and changes in policy create a large degree of uncertainty.

As such, each alternative was analyzed with the assumption that budgets will remain flat or reduced and that, although technological advances will become available, there will remain a gap in workforce capacity that skews the organization towards efficiency and away from thoroughness. This is a fundamental attribute of human and organizational performance where ultimately either efficiency (production) or thoroughness (safety) prevails over the other, known as the Efficiency Thoroughness Tradeoff (Hollnagel 2012).

3.7.3 Affected Environment

Existing Condition

The following information includes excerpts from the most recent *Report on Wildland Firefighter Fatalities in the United States: 2007-2016* (National Wildfire Coordinating Group 2017c). The report includes data from years prior to 2007 as far back as 1990, when the National Wildland Fire Coordinating Group first started producing such reports. The 2007 to 2016 range is the most current National Wildland Fire Coordinating Group ten-year evaluation period. The report was compiled with data from a variety of sources, such as National Wildland Fire Coordinating Group "Safety Grams," National Institute of Occupational Safety and Health (NIOSH) data, and the U.S. Fire Administration Firefighter Fatality database. Wildland firefighter fatalities in the National Wildland Fire Coordinating Group report include any firefighter that is involved in wildland fire operations, including paid municipal firefighters and volunteers with rural fire departments. Additional information on specific protocols for inclusion of firefighter fatalities into the National Wildland Fire Coordinating Group Report can be found within the report.

Between 1990 and 2016, 480 firefighters died during wildland firefighting operations in the United States (Figure 152). According to the previous wildland firefighter fatalities report, fatalities increased by 26 percent during the 1999 to 2006 period when compared with the 1990 to 1998 period. There was a 2 percent decrease in the 2007 to 2016 period, with a total of 107 fatalities.

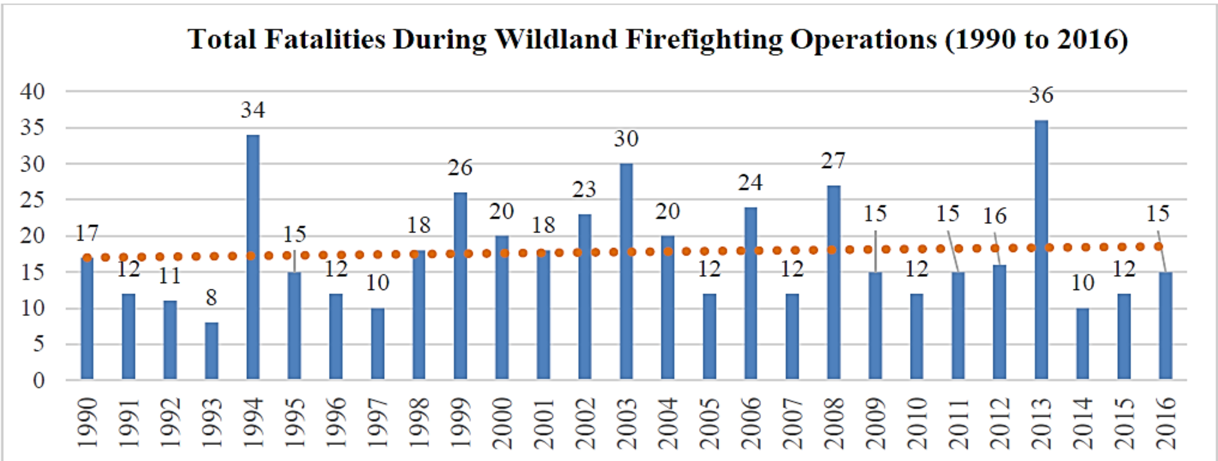

Figure 152. Total annual firefighter fatalities (all causes) during wildland fire operations between 1990 and 2016

Data Source: (National Wildfire Coordinating Group 2017c).

Causes of Death

The most common causes of death of wildland firefighters reported for the most current period between 2007 and 2016 were heart attacks (41 fatalities, 24 percent), vehicle accidents (34 fatalities, 20 percent), aircraft accidents (31 fatalities, 18 percent), and entrapments (28 fatalities, 17 percent) (Figure 153). These causes account for 79 percent of the total number of fatalities.

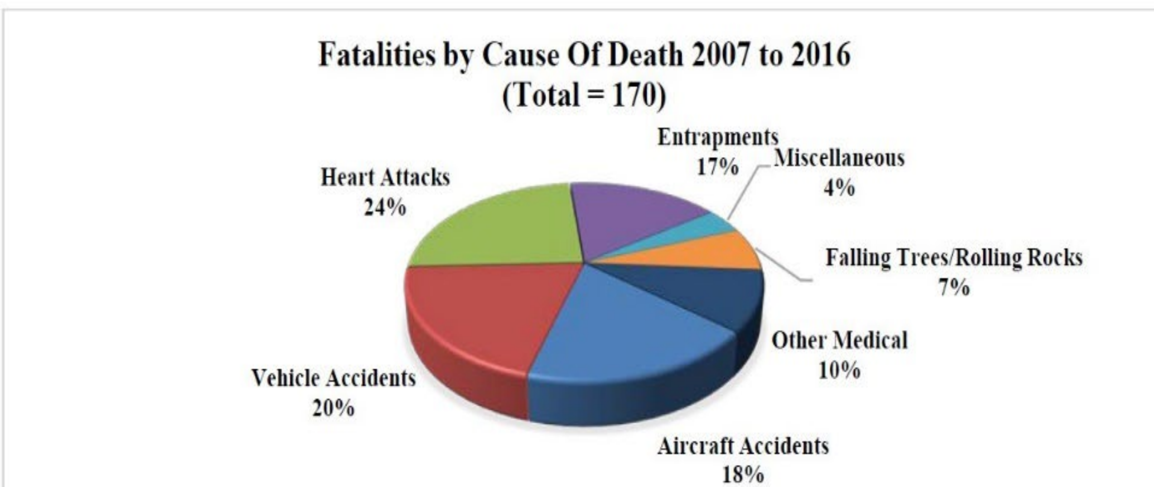

Figure 153. Wildland firefighter fatalities by cause of death from 2007 to 2016

Data Source: (National Wildfire Coordinating Group 2017c).

Federal firefighters account for a large portion of the wildland firefighter workforce, encompassing wildland firefighters from the USDA Forest Service (USFS), Bureau of Land Management (BLM), National Park Service (NPS), Bureau of Indian Affairs (BIA), and Fish and Wildlife Service (FWS), although volunteers make up the largest proportion of fire fatalities (National Wildfire Coordinating Group 2017c).

Thirty-one federal firefighters died during the most recent period (2007 to 2016). These fatalities accounted for 18 percent of all firefighter fatalities, equaling 3.1 fatalities per year. The number of federal firefighter fatalities between 2007 and 2016 was lower than for the period between 1999 and 2006. From 1999 to 2006 there were 37 fatalities, equaling 4.6 fatalities per year.

Between 2007 and 2016, vehicle accidents were the leading cause of death for federal firefighters with eight fatalities (Figure 154), followed by falling trees or rolling rocks with six fatalities (Figure 154), contrasting with volunteer deaths more often caused by heart attacks. Other causes of death for federal firefighters included four heart attacks fatalities, three aircraft accident fatalities, and three other medical caused fatalities.

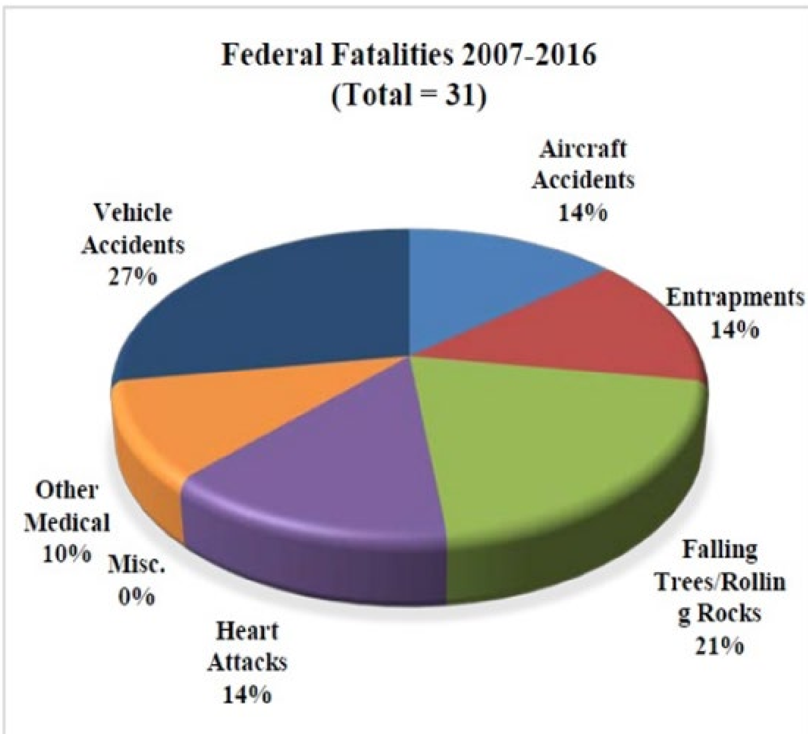

Figure 154. Federal firefighter causes of death, 2007 to 2016

Data Source: (National Wildfire Coordinating Group 2017c).

Falling Trees or Rolling Rocks

Falling trees or rolling rocks claimed the lives of 12 firefighters during the most recent period, equaling 1.2 fatalities per year, compared with 7 firefighters during the period between 1999 and 2006, equaling 0.9 fatalities per year. The total number of firefighter fatalities caused by falling trees or rolling rocks between 2007 and 2016 was equal to the combined total between 1990 and 2006. Four of the deaths during the most recent period occurred in California; two in Kentucky; and one each in Colorado, Oregon, Washington, Idaho, Nevada, and Florida.

On the Nez Perce-Clearwater, falling trees are a particularly important aspect of risk to life safety, accounting for the single largest physical threat to employees working in the field today. Often it is surmised that driving is the biggest threat to employee safety; however, fatality trends on the Nez Perce-Clearwater do not support that. Additionally, in the context of continual advancement and application of automobile safety technology, the likelihood of a person surviving a crash is much higher than ever. Falling trees, however; are different in that there are no reliable controls to protect the employee who is hit by a falling tree. The only controls available are human performance based, which is inherently unreliable.

Falling trees are the second leading contributor to employee fatalities on the Nez Perce-Clearwater over the past 100 years and are increasingly more prevalent as a leading cause of serious injury and fatalities to Forest Service wildland firefighters. In the past eight years, one fatality and two severe employee injuries related to tree strikes have occurred on the Nez Perce-Clearwater during the Steep Corner Fire in 2012 (one fatality, Figure 155), the Nut Hill Fire in 2013 (one severe injury), and the Freezeout Ridge Fire in 2014 (one severe injury).

Figure 155. Steep Corner Fire fatality site on August 12, 2012

Data Source: USDA, Serious Accident Investigation Report - Steep Corner Fire Fatality, North Fork Ranger District, Clearwater National Forest, Idaho, August 12, 2012.

The U.S. Forest Service Office of Human Performance and Innovation and Organizational Learning (HP&IOL) recently performed an internal study of Forest Service wildfire accident statistics over the ten-year period from 2007 to 2016. This study found that getting hit by a rock, log, limb, or tree was the most frequent way Forest Service firefighters were injured (Figure 156). Furthermore, getting hit by a tree was the second most frequent way Forest Service firefighters were killed (National Wildfire Coordinating Group 2018), while aviation accidents were the leading cause by nearly a three to one ratio.

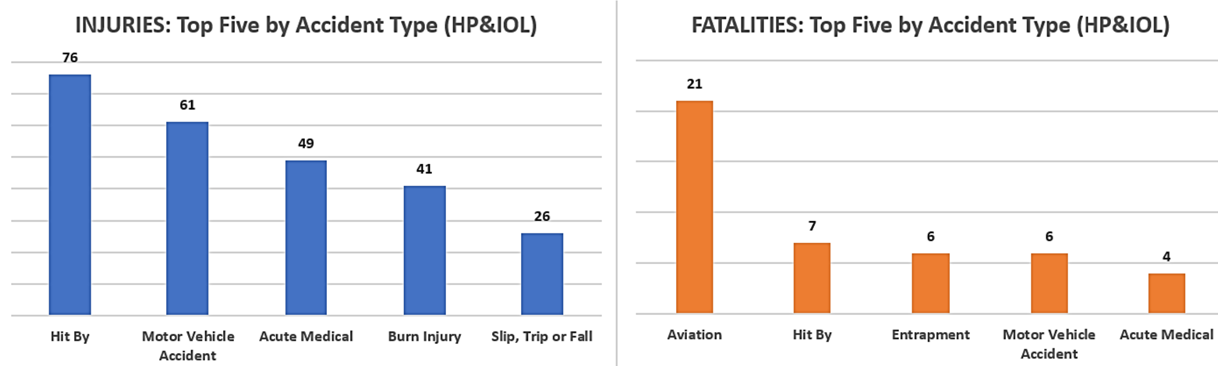

Figure 156. Top accident types for injuries and fatalities for Forest Service wildland firefighters, 2007 to 2016

Data Source: (National Wildfire Coordinating Group 2018).

Examining the Office of Human Performance and Innovation and Organizational Learning study data above, we can surmise that there are instances within each category that the accidents that lead to the injuries or fatalities are often similar in context of exposure as accidents that resulted in fatalities in all federal wildland firefighters. While not comparing "apples to apples," an interesting trend develops when comparing the Office of Human Performance and Innovation and Organizational Learning data with records of fatalities of employees on the Nez Perce-Clearwater's over the past 100 years. Aviation Accidents constitute the largest number of fatalities on the Nez Perce-Clearwater (2019-2019, Figure 157), followed by "Hit by" Tree, Heart Attack "Acute Medical," Burn-over, and Drowning and Driving, with four fatalities each. Driving includes fatalities where an employee was thrown from a horse during incidents that occurred in the 1920s prior to widespread use of motor vehicles and Forest Service roads.

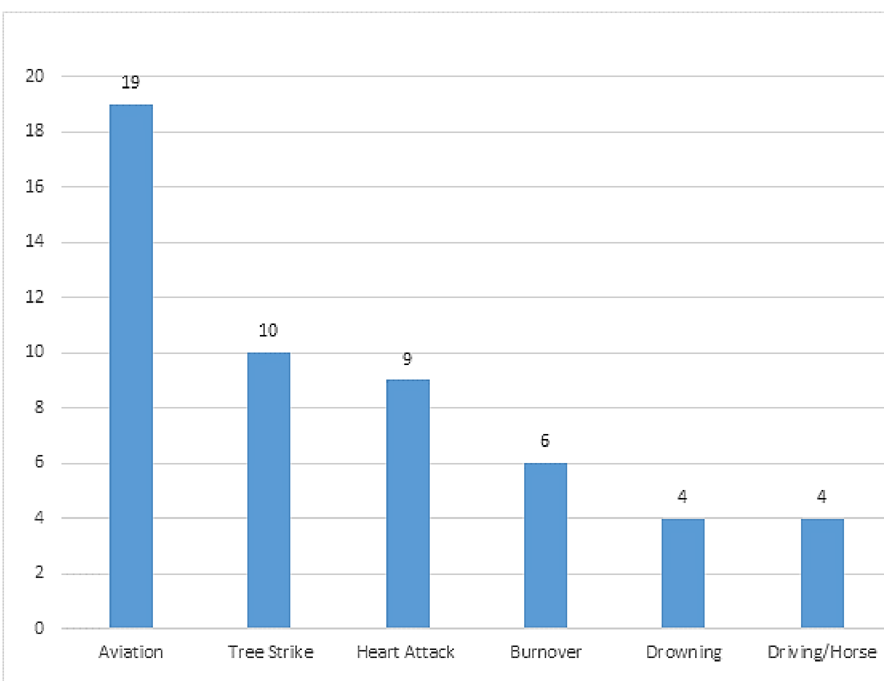

Figure 157. Deaths in line of duty for 1919 to 2019, Nez Perce-Clearwater Employees

Data Source: Adapted from Wildland Firefighter Fatalities, (Nez Perce-Clearwater Safety and Health Manager) and Employees who have lost their lives in the line of duty, Nez Perce National Forest (Schacher, 2009).

Relating the Nez Perce-Clearwater fatality data with the National Wildfire Coordinating Group data reflects the same types of fatalities, although with comparatively different rates. This is likely due to the difference in vegetation types on the Nez Perce-Clearwater (more heavily timbered), the amount of wilderness and roadless areas (aviation transport versus motor vehicle), and the high density of large rivers and streams contributing to drownings. It is important to note that each of the categories for the Nez Perce-Clearwater includes wildland firefighter fatalities.

Tragic Outcomes of Normal Work

Employee fatalities typically do not represent "super accidents" brought about by extreme errors of omission. They represent the tragic outcome of normal work due to ineffective or impossible controls in an inherently hazardous environment. High-risk work with robust controls is not risky but high-risk work that relies on the perfect human performance is extremely risky.

Fatalities are outliers in the sense that the work would have been considered a success, or otherwise normal, had there not been a fatality. The work is considered "normal" because it was routine, typical, or within the scope of the mission of the organization. Fatalities occur in a system of work that almost always produces successful results. They are therefore rare events that continually seem to defy our best efforts to eliminate them. Especially when only our "go to" methods of preventing them are applied. For example, a falling tree that injures an employee is just as deadly as the tree that kills an employee; the only difference was the outcome. In the event of a tree strike that only injures the employee, the Forest Service tends to apply the "lessons learned" of "hazard tree identification" and "maintain situational awareness" as a remedy to prevent future events. When a fatality from a tree strike occurs, traditionally managers apply these same lessons but with a stronger emphasis, including "stand-downs," "additional training," and "ad hoc committees." While well intended, this does little to address the fact that humans are fallible and perfect performance all the time is impossible. Eventually, if enough employees are exposed to hazard trees, there will be a fatality. This is not to say that traditional responses are not important or valid; it is just that they will only get us so far.

There is belief in our ability to recognize and mitigate hazards while weighing the remaining risks against the value of our intended actions. This belief assumes a high degree of control to accurately perceive and control our environment, when in fact, because of the combination of the uncertainty inherent in our system and our limitations as humans, there is much beyond our ability to control (U.S. Department of Agriculture and U.S. Department of the Interior 2011).

The following is excerpted from the Steep Corner Fire Serious Accident Investigation (SIA) report (Foster and Draeger 2013) that further emphasizes the difficulty humans have recognizing and mitigating hazards in an uncertain and dynamic working environment:

An individual's perceptual abilities (What are you looking at? What are you not hearing?) limits their capacity to identify hazards and evaluate risk, as do their notions about which risks are more significant or likely to cause harm. The day of the Steep Corner fatality, firefighters did not specifically identify the strike tree as a hazard tree. It was one potential hazard tree in a forest full of hazard trees. In a sense, everything around was a hazard.

A firefighter's choice, conscious or unconscious, to focus attention on one thing or another is governed by a number of factors. Focusing on one risk may lessen or eliminate a focus on others. People focusing on a felling operation may take a fraction of a second longer to identify and react to *a different threat. People do not "lose situational awareness" because, while conscious, they are always aware of something. In this case, they focused on a felling operation.*

By applying a long-term view, it may be possible to achieve improved life safety results by creating an environment where fires are not as frequently severe, insect and disease outbreaks in forest are moderated, watersheds are restored or protected, roads used to support land management operations are maintained or improved, and workforce capacity is commensurate with work demands.

Wildfire Trends on Nez Perce-Clearwater

Wildland fire trends on the Nez Perce-Clearwater are discussed and summarized in the Fire Management Report for the Final Environmental Impact Statement, a portion of which is excerpted below.

Since 1870, fires over 1,000 acres have been mapped to determine trends associated with climate, fire policy, and suppression success (Figure 158). On average, 314,608 acres of large fires burned per decade from 1870 to 2017. Drought years and ineffective fire suppression from 1870 to 1899 burned approximately 398,601 acres. From 1900 to 1939, fires burned approximately 2,347,828 acres. From 1940 to 1989, fires burned approximately 366,143 acres. From 1990 to present, fires have burned approximately 1,606,552 acres. This trend of increasing acres, exhibited in Figure 159, can be explained by burn cycle. Multiple influences, including fuels, weather (daily, monthly, and long term), ignition sources, and suppression efforts.

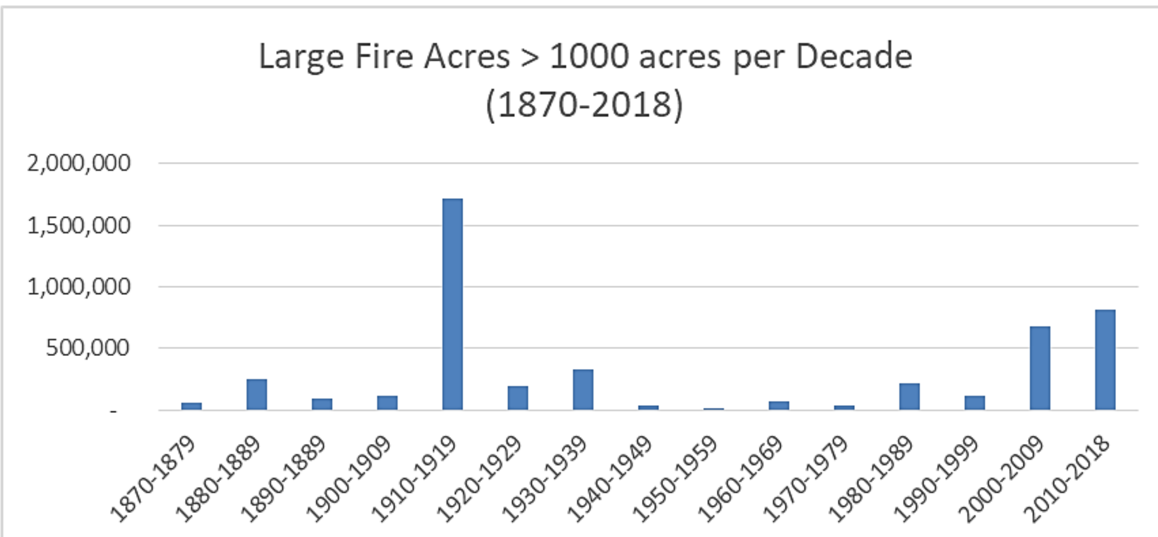

Figure 158. Large fire (>1,000 acres) acres per decade, 1870 to 2018, on the Nez Perce-Clearwater

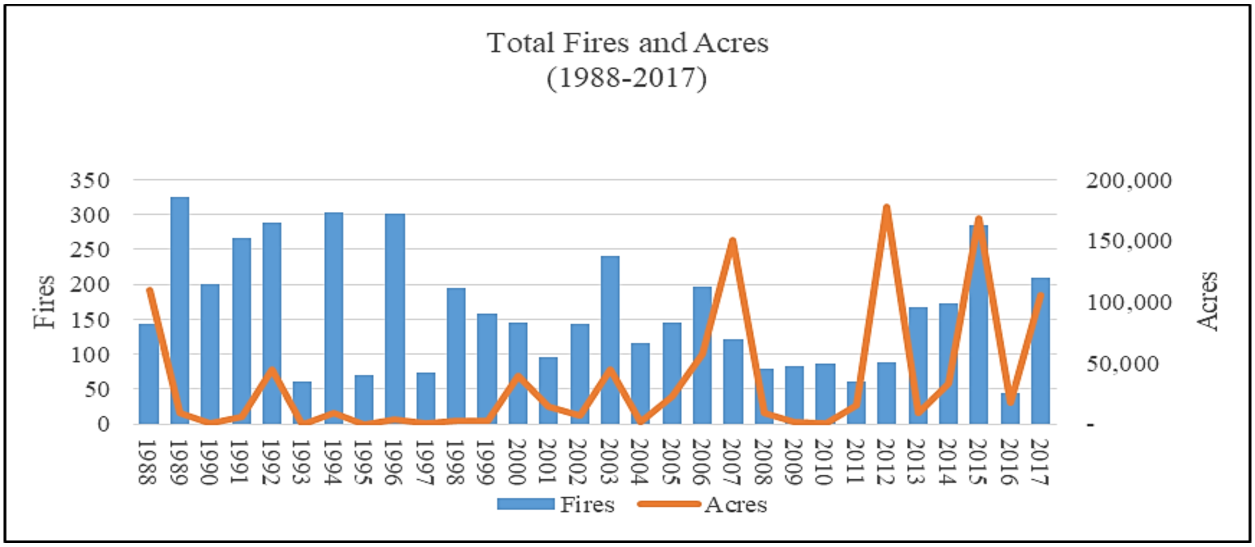

Figure 159. Number of fires per year and fire acres from 1988 to 2017 on the Nez Perce-Clearwater

Data Source: FireStat and FACTS databases

Selway-Bitterroot Wilderness

The Selway Bitterroot Wilderness is a model of a fire resilient landscape in which, to an extent, wildland fire has become self-regulated (Parks, Holsinger, et al. 2015, Wildland Fire Leadership Council 2012). This "regulatory-effect" model is of particular importance to employee and public safety in that it reflects an environment where potential exposure to environmental hazards, such as high intensity fire, a high density of snags, and insect and disease weakened trees, have been moderated by allowing a return to a more natural interval of fire on the landscape (Figure 160). Using mechanical harvest, management ignited fire, and naturally ignited fire to reduce fuels and move toward a fire resilient landscape, these same benefits to life safety can be realized across all management areas on the Nez Perce-Clearwater.

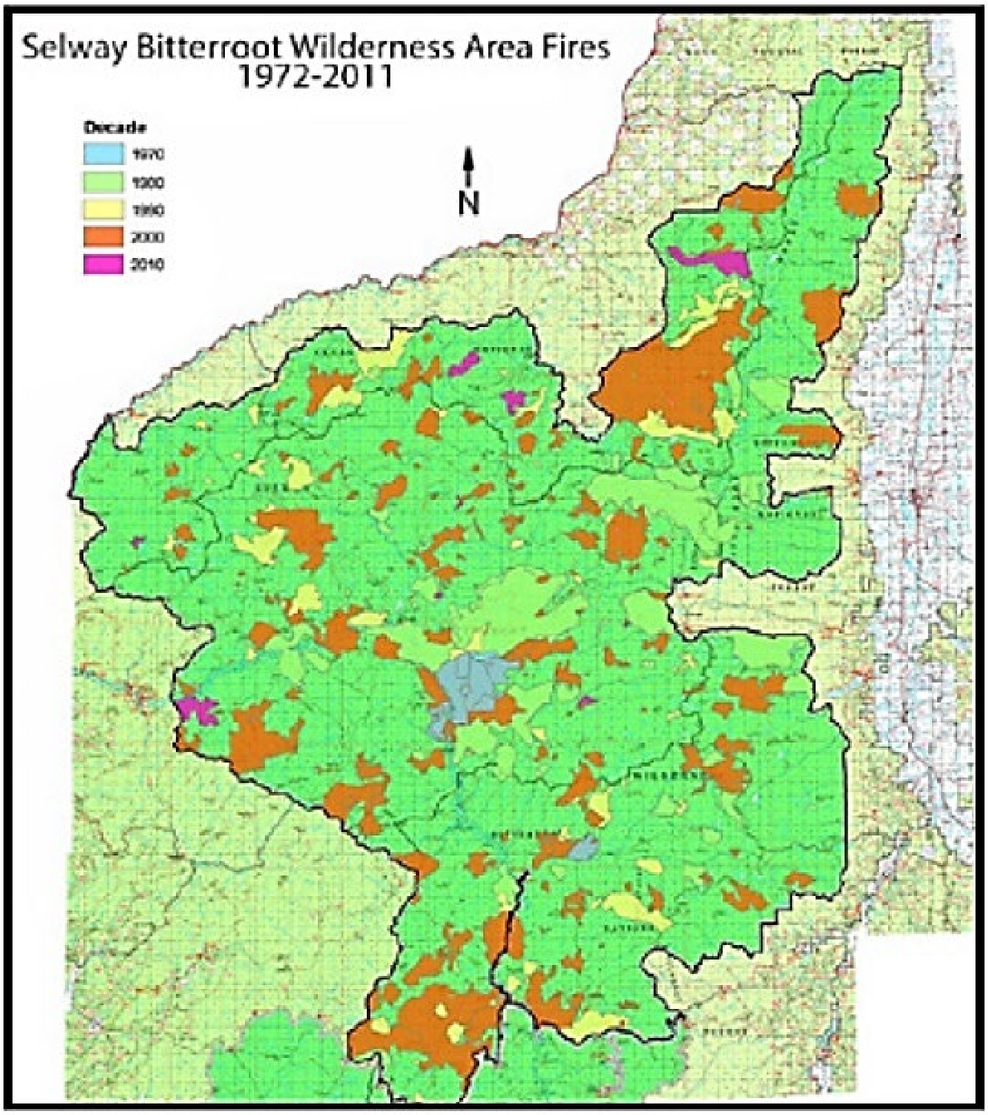

Figure 160. Map of wildland fires in the Selway Bitterroot Wilderness by decade, 1972 to 2021, illustrating the regulatory effect of prior burns through allowing fires to burn on a more natural interval

Data Source: (Wildland Fire Leadership Council 2012)

The Parks et al (2015) study reveals three important findings:

- Wildland fire clearly acts as a fuel break and is a barrier to subsequent fire spread; this effect is strongest immediately after fire and decays over time.
- The ability of wildland fire to act as a fuel break varies geographically, lasting six years in the warmest, driest study area and 14 to 18 years in the cooler, wetter study areas.
- Extreme fire-conducive weather diminishes the ability of fire to act as a fuel break. This supports the intent of the National Cohesive Wildland Fire Management Strategy with its goals of: (1) Resilient Landscapes, (2) Fire Adapted Communities, and (3) Safe and Effective Wildfire Response.

Management of fire in the Selway Bitterroot Wilderness has been a successful model that can be relied upon to meet multiple land management plan objectives by allowing fire to play its natural role on the landscape. The fire suppression paradigm is changing mainly due to the issues surrounding firefighter safety; the high costs associated with fully suppressing a fire, especially in remote, inaccessible areas; and the higher spread rates, intensities, and fire sizes that are being experienced today that have not been witnessed in the recent past (Wildland Fire Leadership Council 2012).

Wildfire has been, and will be, the greatest driver of vegetation change on the Nez Perce-Clearwater (FIRESTAT data, FACTS data) and, under all alternatives, natural unplanned wildfire would be allowed to play its ecological role. Along with prescribed fire, use of wildland fire will help in alleviating the fire deficit (Parks, Holsinger, et al. 2015, Vaillant and Reinhardt 2017), as well as providing many ecological benefits.

3.7.4 Environmental Consequences

Effects of the No Action Alternative

Resource management would continue under the current plans. Time to desired conditions would be close to a 100-year time frame. The No Action Alternative does not account for growth and succession, so is less likely to achieve desired conditions (

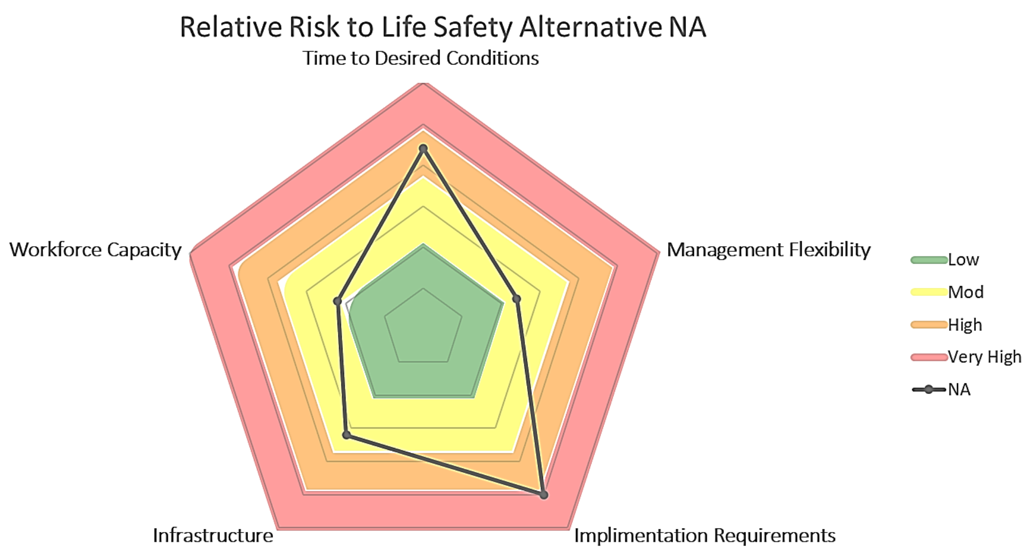

Figure 161).

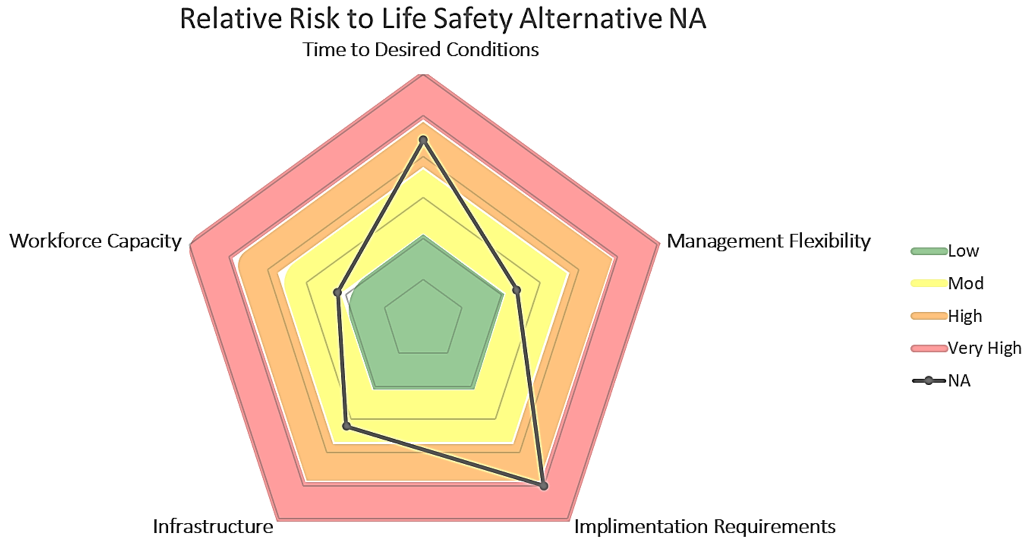

Figure 161. Relative risk to life safety under the No Action Alternative

Data Source: Nez Perce-Clearwater, Occupational Health and Safety Manager.

Alternative W

This alternative has higher levels of recommended wilderness and an increased timber output, resulting in moving vegetation toward desired conditions in 30 years. This alternative also increases the resiliency of vegetation by creating patchy landscapes by increasing the use of wildfire, prescribed fire, and mechanical fuels reduction treatments that promote native fire regimes, resulting in barriers to insect and pathogen dispersal and reduced fire severity from future wildfires.

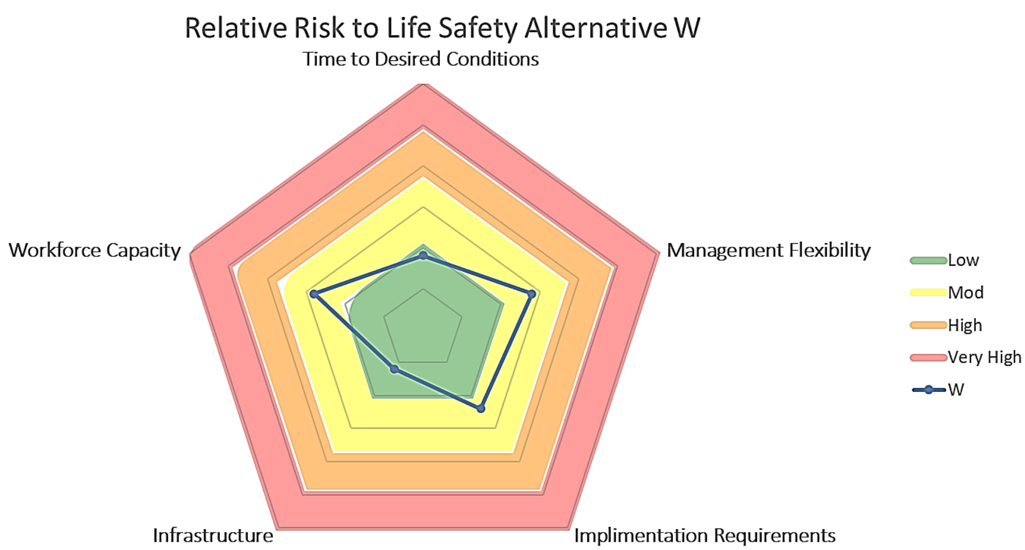

Figure 162. Relative risk to life safety under Alternative W

Data Source: Nez Perce-Clearwater, Occupational Health and Safety Manager

Alternative X

This alternative responds to the local and state plans that require fewer areas of recommended wilderness and leans heavily toward workforce capacity (Figure 163). It would move forest vegetation to the lower bounds of the desired condition within the two decades. The number of fires and acres of unplanned ignitions managed for resource objectives toward restoring and maintaining fire regimes would be like Alternative W. Outside of designated wilderness, timber harvest and prescribed fire would increase the number of fire regime acres restored or maintained within each potential vegetation type. This alternative would use more vegetation treatments and potentially fewer acres of natural wildfires than Alternative W to restore and maintain a greater number of acres of each potential vegetation type that are currently departed from the fire regime. Not renewing the lease of the Pilot Knob communication site could contribute to gaps in radio communication coverage and removes a layer of redundancy from the radio network that often relies on the ability to utilize repeaters with overlapping coverage as back-up when a repeater is down.

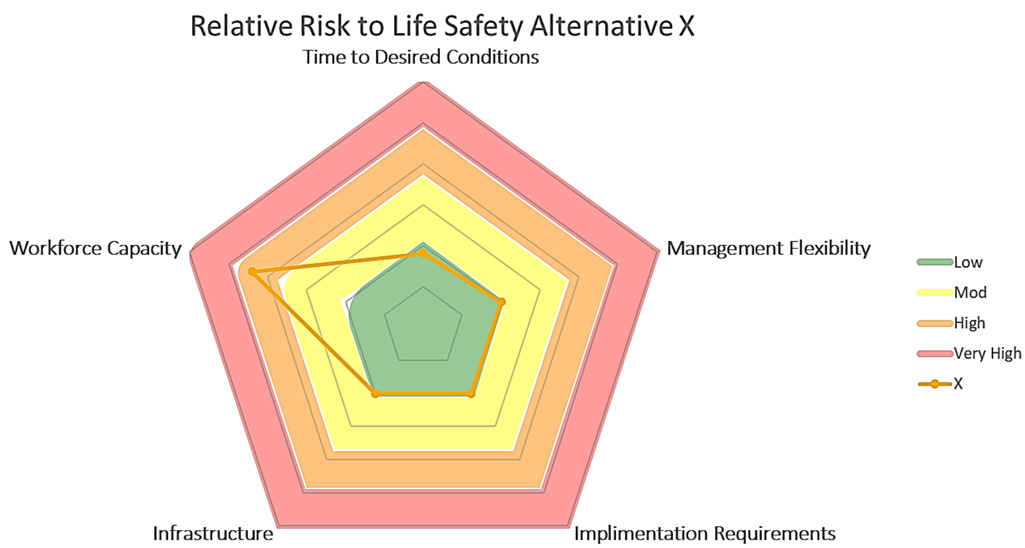

Figure 163. Relative risk to life safety under Alternative X

Data Source: Nez Perce-Clearwater, Occupational Health and Safety Manager

Alternative Y

This alternative provides for an intermediate level of recommended wilderness and moves vegetation towards forested desired conditions in 50 years (Figure 164). It also includes major rivers not designated in the Wild and Scenic Rivers Act. The period required to restore and maintain fire regimes would be greater than Alternatives W and X. This alternative would require a longer time to increase the resiliency of vegetation because of less use of prescribed fire and mechanical fuels reduction treatments.

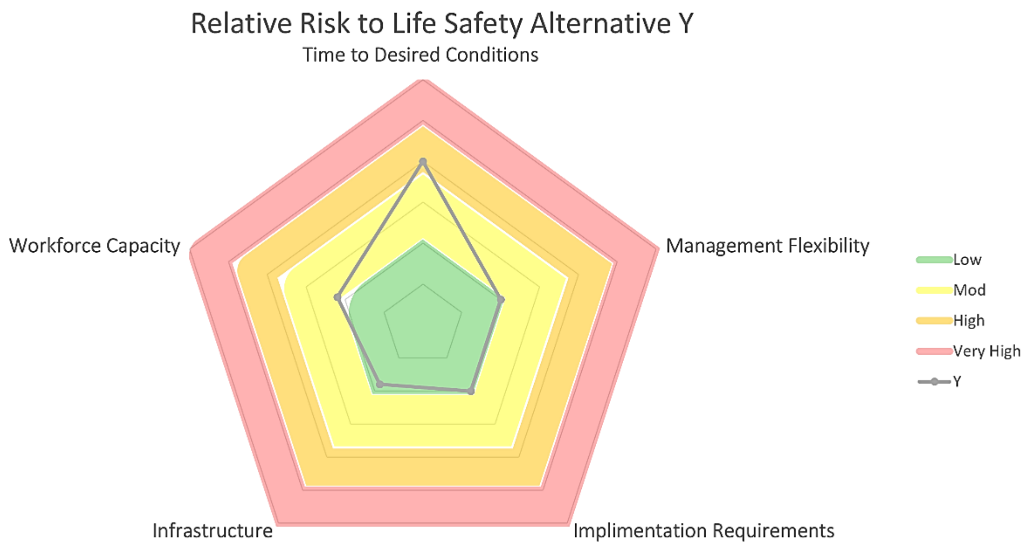

Figure 164. Relative risk to life safety under Alternative Y

Data Source: Nez Perce-Clearwater, Occupational Health and Safety Manager.

Alternative Z

This alternative promotes natural processes that dominate over anthropogenic influence (Figure 165). Reliance on natural processes would move vegetation towards desired conditions in 100 years. This alternative would require a longer time to increase the resiliency of vegetation by creating patchy landscapes because of less use of prescribed fire and mechanical fuels reduction treatments that promote native fire regimes resulting in barriers to insect and pathogen dispersal and reduced fire severity from future wildfires. Reliance on natural processes would warrant a slower movement towards forest vegetation desired conditions and is not likely to be achieved due to natural vegetative growth and succession.

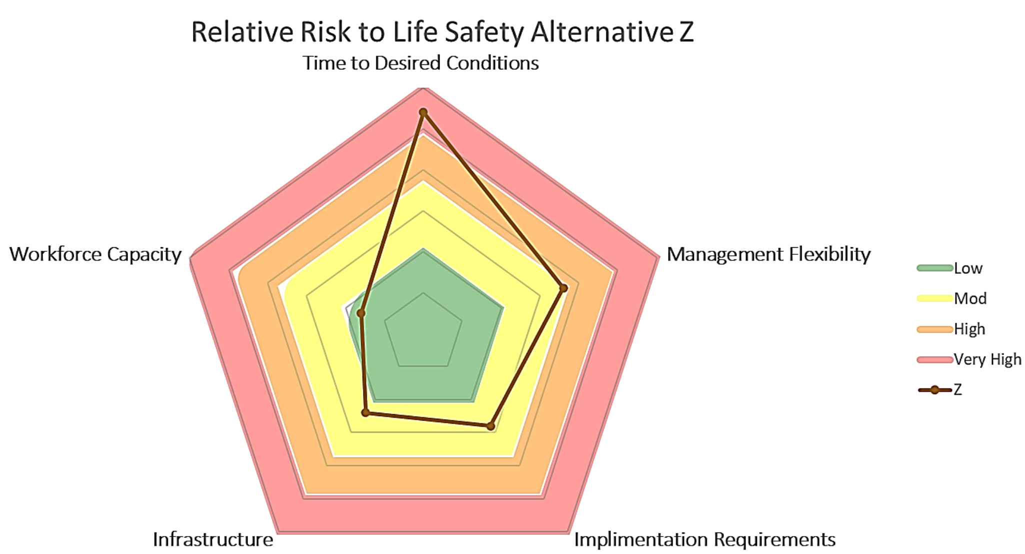

Figure 165. Relative risk to life safety under Alternative Z

Data Source: Nez Perce-Clearwater, Occupational Health and Safety Manager.

Preferred Alternative

This alternative has levels of recommended wilderness, lands available to active management , and use of a full range of fire management activities, including both prescribed and natural fire in all management areas that would allow for movement to desired conditions within 30 to 35 years. This also allows for potentially less impact on workforce capacity through utilization of opportunities for allowing fire as a restoration tool across all management areas, however active management activities will still have a sizable impact on workforce capacity. This alternative also allows for maintenance of infrastructure such as roads and administrative sites to provide safe access and egress to wildland fire responders and to communities within community protection zones, and maintenance of trails. Management flexibility is similar to alternatives X and Y, allowing for restoration of fire resilient landscapes utilizing natural and prescribed fire. It also addresses snag retention within community protection zones and egress routes, allowing snags to be removed during fuels mitigation projects within these areas. Pilot Knob communications site will be retained but phased out as suitable technology allows removal of the site.

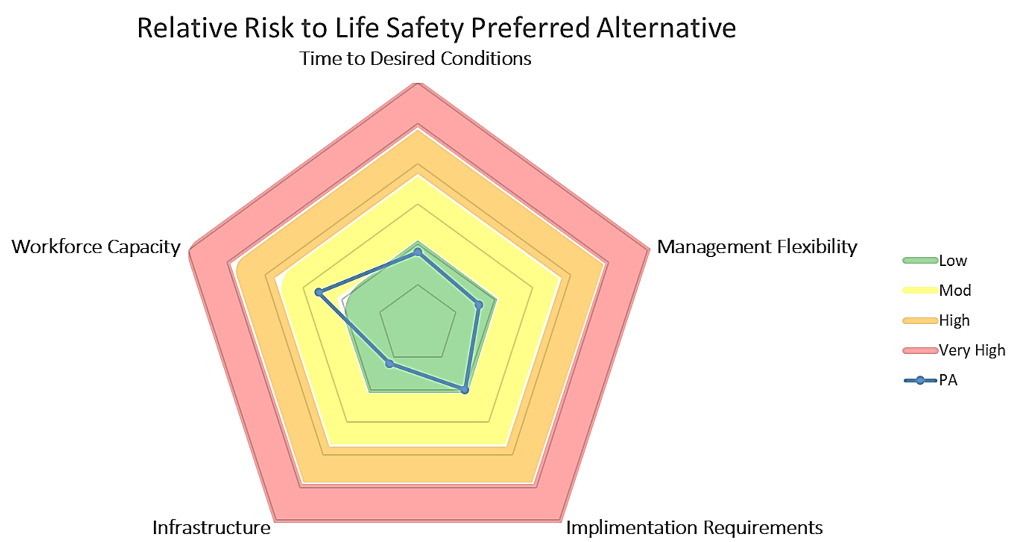

Figure 166. Relative risk to life safety under the Preferred Alternative

Data Source: Nez Perce-Clearwater, Occupational Health and Safety Manager.

Cumulative Effects

Human Population Increases and Shifts towards Wildland-Urban Interface

More human development is occurring near the boundary of lands administered by the Nez Perce-Clearwater. This trend is expected to continue in the future and is likely to have effects on forest vegetation. The need for vegetation treatments being implemented within wildland urban interface areas will increase. The wildland urban interface has become the focus of wildfire suppression resources. The future increase in the wildland urban interface will continue to challenge wildfire management during large fire events as “firefighters will likely have to protect dispersed housing over an extremely large area of fire-prone forest" (Gude et al. 2008). Relative to current levels, more wildfire in the future is expected and policies that foster adaptive resilience in the wildland urban interface are needed (Schoennagel et al. 2017).

Increased Regulation and Concern over Smoke Emissions

The ability to use fire to maintain and restore the fire-adapted ecosystems on the Nez Perce-Clearwater, or to use fire to reduce hazardous fuels in the wildland urban interface, is dependent upon air quality regulations. As air quality regulations become stricter, the ability to use fire as a management tool becomes limited. If past trends of increasing regulations and decreasing burn opportunities continue, the effects would likely result in not being able to use fire enough to make meaningful improvements to forest and fuel conditions and meet objectives.

Timber Product Manufacturing Infrastructure and Economics

The ability of the Nez Perce-Clearwater to positively affect forest vegetation is partially dependent upon the ability to sell forest products and to use harvesting processes, including the residual slash disposal activities, as a means to positively affect the forest vegetation and reduce hazardous fuels. If the forest products industry declines in areas surrounding the Nez Perce-Clearwater to the degree that it is difficult to sell forest products, or if "stumpage prices" decrease substantially, it would affect how many acres could be treated. While some treatments could be accomplished by using prescribed burning only, it is generally very risky in the wildland urban interface and expensive, leading to fewer acres treated.

Other Plans

Since they were developed, national level plans, initiatives, and acts such as the National Fire Plan, Healthy Forest Initiative, Healthy Forest Restoration Act, and National Cohesive Wildland Fire Management Strategy, have influenced the vegetation and fuel management programs on the Nez Perce-Clearwater. In general, these plans have resulted in more vegetation treatments being implemented near wildland urban interface areas with the objective of reducing hazardous fuels and fewer vegetation treatments being conducted in areas located away from communities. Not only do these plans emphasize the need to reduce hazardous fuels in the wildland urban interface, but they also stress the need to restore the natural fire regimes and forest conditions to the larger national forest landscape. These plans encourage the development of more resistant and resilient forest vegetation that would be less susceptible to large undesirable wildfires or insect outbreaks.

The Managing Fire on Lands Protected by the state of Idaho (2016) guides fire management on state lands in Idaho. The plan includes concepts that are complementary to revised plan components for the Nez Perce-Clearwater, such as state direction for suppression of wildfires. While specific desired conditions are not stated in the same terms as the Nez Perce-Clearwater, it is likely that some elements, such as providing for firefighter and public safety, would be similar. State forestlands may be actively managed to a greater degree than National Forest System lands and would likely contribute to achievement of some desired fire and fuels conditions across the landscape.

Effects to Resource from Other Resources

Effects to safety and risk from the management of other resources not specifically addressed in prior sections of this report are assumed to be "near-term" risks relative to the scope of this analysis. As such, application of Operational Risk principles may be used at the project level to reasonably mitigate risk to life safety of employees and communities.

Summary of Consequences

Table 455 provides a summary of potential effects to life safety by alternative. "Very High or High indicates a lean towards a more detrimental impact, whereas Low or Moderate would have a less detrimental impact."

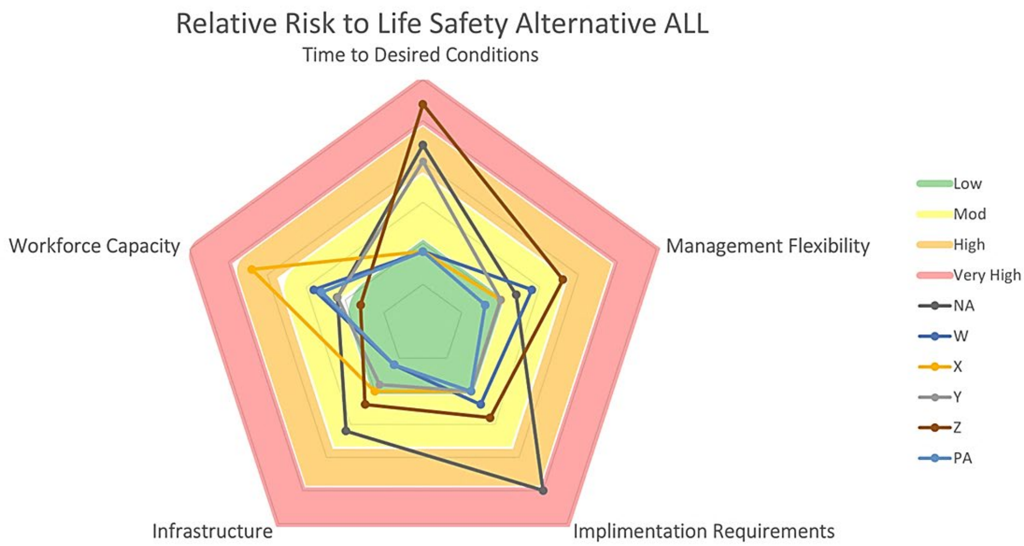

Figure 167. Summary of relative risk to life safety, by alternative
Data Source: Nez Perce-Clearwater, Occupational Health and Safety Manager

Table 455. Summary of potential effects to life safety by alternative (Alt)

Indicator	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Time to Desired Conditions	High	Low – Moderate	Low – Moderate	High	Very High	Low – Moderate
Management Flexibility	Moderate	Moderate	Low – Moderate	Low – Moderate	Moderate – High	Low
Implementation Requirements	Very High	Moderate	Low – Moderate	Low – Moderate	Moderate	Low – Moderate
Infrastructure	Moderate	Low	Low – Moderate	Low – Moderate	Moderate	Low
Workforce Capacity	Moderate	Moderate – High	High – Very High	Moderate	Low	Moderate

3.8 Economic and Social Sustainability

3.8.1 Economic Sustainability

The mission of the Forest Service is to sustain the health, diversity, and productivity of the nation's forests and grasslands to meet the needs of present and future generations. Local communities, particularly those adjacent to National Forest lands, benefit from a multitude of goods and services provided by the Nez Perce-Clearwater and the Forest Service. Some of these goods and services can be valued in a market context and have economic implications for both local and non-local communities. Relating to the key benefits described in the social sustainability report, this report will focus specifically on the direct and measurable benefits of labor income and employment contributions from these National Forest System lands and agency operations.

The 2012 Planning Rule states that plans are to guide management so that forests and grasslands contribute to economic sustainability, providing communities with ecosystem services and multiple uses that deliver a range of social, economic, and ecological benefits in the present and into the future. Specifically, plan components must include standards or guidelines to guide the Nez Perce-Clearwater's contribution to economic sustainability, considering ecosystem services, as well as multiple uses that contribute to local, regional, and national communities in a sustainable manner. Furthermore, reasonably foreseeable risks to economic benefits shall be considered when developing the land management plan.

Therefore, this section (1) describes the economic conditions of the affected environment using key indicators of economic sustainability; (2) describes how key benefits of the Nez Perce-Clearwater currently contribute to economic sustainability of beneficiaries, both locally and at a broader scale; and (3) evaluates the potential economic impacts of the proposed land management plan and alternatives on local beneficiaries and the public.

Changes between Draft and Final

The Economic Sustainability section of the Final Environmental Impact Statement has been updated to include an economic contribution analysis with additional preferred alternative and changes to total wood sale quantities estimated in the Sustained Yield Limit Tables of the Timber subchapter. Additional qualitative discussion has been included covering in greater detail topics of tribal, recreation, ecosystem services and other economic value concerns not fully represented in the quantitative economic contribution analysis. Additionally, the IMPLAN model in the Final Environmental Impact Statement includes changes to agriculture and grazing, national employment multipliers. This change, to incorporate updated methods to the model, has reduced estimated employment contributions from grazing activities on the Nez Perce-Clearwater, between the Draft Environmental Impact Statement and Final Environmental Impact Statement. This change was a nation-wide update to range management IMPLAN modeling by the National Forest System. The new model parameters are reflective of industry updates from USDA statistics, and industry practice data, and do not reflect changes made specific to this Final Environmental Impact Statement.

Relevant Laws, Regulations, and Policy

Federal Laws

The following is a select set of statutory authorities that govern the evaluation of social and economic resources on the Nez Perce-Clearwater. They are briefly identified and described below to provide context to the management and evaluation of the resource. There are multiple other laws, regulations, and policies not described below that also guide the management of this resource.

Multiple-Use Sustained Yield Act of 1960: This act identifies principles for managing the resources of National Forest System lands. The direction to manage these resources for the greatest good over time includes the use of economic and social analysis to determine management of the National Forest System.

National Environmental Policy Act of 1969: This act mandates consideration of the consequences to the quality of the human environment from proposed management actions. The agency must examine the potential impacts to physical and biological resources as well as potential socioeconomic impacts (40 CFR 1508.14).

Forest and Rangeland Renewable Resources Planning Act of 1974: As amended by the National Forest Management Act of 1976, this act requires consideration of potential economic consequences of land management planning.

Office of Management and Budget Circular A-116 (issued August 16, 1978): This act requires executive branch agencies to conduct long range planning and impact analysis associated with major initiatives.

National Forest Revenue Act (amended 1908): This act requires 25 percent of revenues generated by National Forest System lands to be paid to the states for use by the counties in which the lands are situated for the benefit of public schools and roads.

Secure Rural Schools and Community Self-Determination Act of 2000: This act was designed to stabilize annual payments to state and counties containing National Forest System lands and public domain lands managed by the Bureau of Land Management. Funds distributed under the provisions of this act are for the benefit of public schools, roads, and related purposes.

Agency Regulations

2012 National Forest System Land Management Planning Rule: The evaluations of social resources are framed within the context of sustainability because, in accordance with the 2012 National Forest System Land Management Planning Rule (36 CFR 219), land management plans are to guide management so that forests and grasslands are ecologically sustainable and contribute to social and economic sustainability. The Agency 2012 planning process leads to plans that contribute to ecological, social, and economic sustainability by protecting resources on the unit to maintain a flow of goods and services from National Forest System lands on the unit over time.

Pertaining to social resources, the 2012 Planning Rule states that the plan should:

Contribute to ecological, social, and economic sustainability by ensuring that all plans will be responsive and can adapt to issues such as the challenges of climate change; the need for forest restoration and conservation, watershed protection, and species conservation; and the sustainable use of public lands to support vibrant communities.

"Social sustainability" refers to the capability of society to support the network of relationships, traditions, culture, and activities that connect people to the land and to one another and support vibrant communities (36 CFR 219.19).

§ 219.8 Sustainability states the plan must provide for social, economic, and ecological sustainability within Forest Service authority and consistent with the inherent capability of the Nez Perce-Clearwater, as follows:

(b) Social and economic sustainability. The plan must include plan components, including standards or guidelines, to guide the Nez Perce-Clearwater's contribution to social and economic sustainability, taking into account:

4. Social, cultural, and economic conditions relevant to the area influenced by the plan.
5. Sustainable recreation; including recreation settings, opportunities, and access; and scenic character.

6. Multiple uses that contribute to local, regional, and national economies in a sustainable manner.
7. Ecosystem services.
8. Cultural and historic resources and uses.
9. Opportunities to connect people with nature.
10. Reasonably foreseeable risks to ecological, social, and economic sustainability.

The rule states that the plan must also be consistent with laws and executive orders including:

36 CFR 212 Travel Management	*36 CFR 251 Land Uses*
36 CFR 223 Special Forest Products	*36 CFR 254 Land Ownership Adjustments*
36 CFR 228 Minerals	*36 CFR 262 Law Enforcement Support Activities*
36 CFR 241 Fish & Wildlife	*36 CFR 293 Wilderness*

Methodology

Spatial Scale

The economic analysis area is defined by administrative geography. It includes counties connected to the National Forest through economic resource trade, commuting, recreation, and other economic interaction. The Socioeconomic Conditions and Trends report defines the analysis area as the five counties in north central Idaho that are adjacent to, or in the immediate vicinity of, the Nez Perce-Clearwater. These five counties are Clearwater County, Idaho County, Latah County, Lewis County, and Nez Perce County. In addition to the primary economic analysis area identified in the assessment, this analysis also considers a secondary economic analysis area defined by the most recently available data through methods detailed in the U.S. Department of Agriculture Forest Service Protocols for Delineation of Economic Impact Analysis Areas (METI Corp/Economic Insights of Colorado 2010) and further updated by the Washington Office Briefing Paper (U.S. Department of Agriculture 2018a) and additional model documentation (U.S. Department of Agriculture 2018i). It is important to note that the economic analysis area is different from the social analysis area.

This combined area is made up of 11 counties, 6 of which receive federal land payments for having Nez Perce-Clearwater lands within them (Figure 168). The counties in the secondary economic analysis area include Benewah County, Idaho; Shoshone County, Idaho; Clearwater County, Idaho; Latah County, Idaho; Missoula County, Montana; Mineral County, Montana; Nez Perce County, Idaho; Lewis County, Idaho; Idaho County, Idaho; Ravalli County, Montana; Adams County, Idaho.

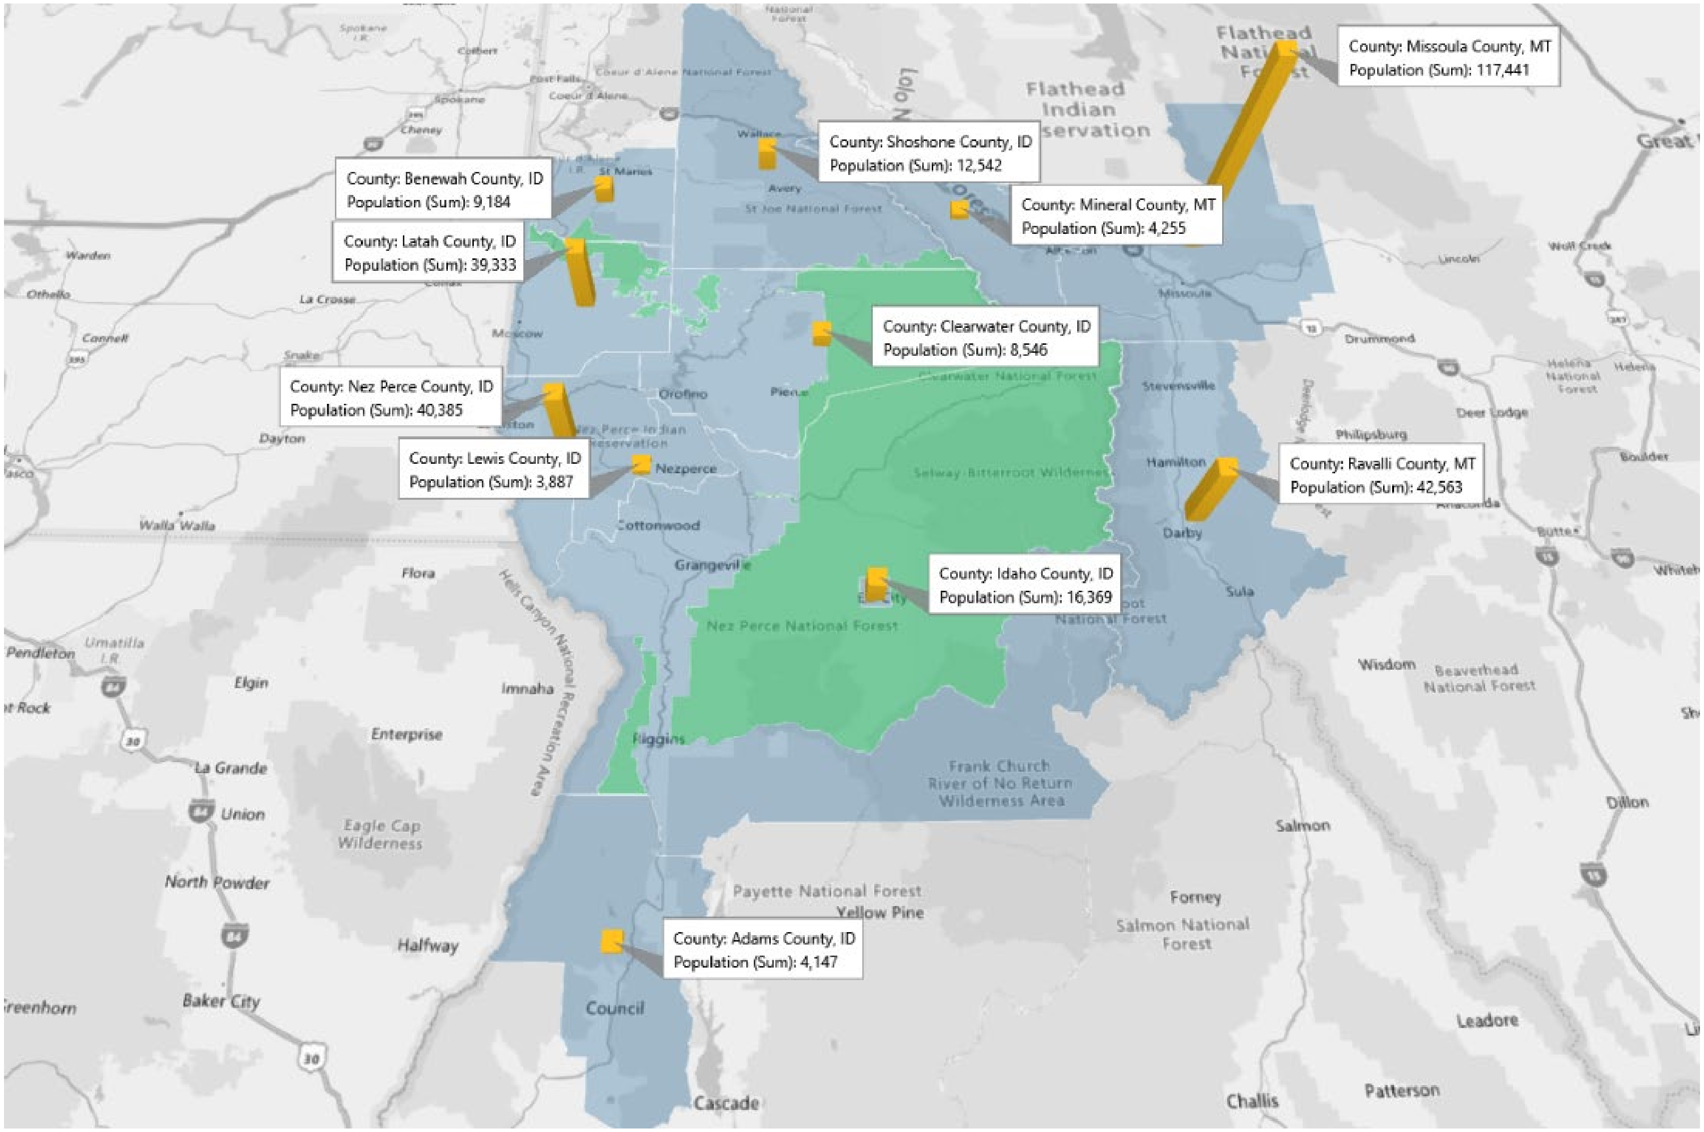

Figure 168. County Economic Analysis Area.

Data source: U.S. Census 2017; Map Source: U.S. Forest Service Northern Region 2019; Bing Maps.

Temporal Scale

The temporal scope of the analysis is the life of the plan. The analysis area for indirect effects is the same as the analysis area for cumulative effects.

Past, Present, and Future Activities used in the Analysis

The Affected Environment section below includes a synthesis of how relevant past, ongoing, and future management affect economic conditions and benefits at the county and forestwide levels.

Methods and Assumptions

The focus of this analysis is determining how the proposed plan and alternatives may affect economic conditions and economic benefits through contributions to economic sustainability.

Economic benefits of the Nez Perce-Clearwater are those that directly result from economic opportunities provided by National Forest assets including National Forest System administration.

Limited approaches exist for measuring conditions and progress towards achieving economic sustainability. In the land management planning context, an economic contribution analysis is a useful method to estimate the contribution of jobs and income from agency administration and the provision of measurable ecosystem goods and services that eventually lead to the generation of income and employment. Economic contribution analysis, however, is not suitable for analysis of all benefits from ecosystem goods and services. This is a critically important caveat when placing jobs and income into the appropriate context of the wider perspective of total economic value, where non-market benefits, or non-consumptive values (e.g., the value of a hunting experience) generated by the ecosystem and other Nez Perce-Clearwater assets may be of great, and in some cases, even greater importance to beneficiaries. For example, the delivering of fresh surface water and recharging of subsurface water supplies from the Nez Perce-Clearwater into municipal and agriculture utility systems may not directly produce income or employment but may remain critically important for social and economic sustainability. Economic contribution analysis is not a catch-all methodology for measuring total economic value.

Economic contribution analysis in this report is completed using input-output modeling methodologies available through IMPLAN software, and these model outputs are then customized into resource-level outputs using a National Forest System contribution impact analysis data processing tool called Aphelia. Aphelia is also used to generate the National Forest At-A-Glance reports. For more information regarding Aphelia and economic input and output models see the *Overview of Methods for Economic Impacts and Contributions* dated May 24, 2019 (Anderes et al. 2019), and the *At A Glance Analysis Methods Guide* from August 2018 (U.S. Department of Agriculture 2018i).

Existing condition economic data is collected and monitored through the Economic Profile System (EPS)[28] a data repository that is updated continuously as new datasets become available. The economic and population data accessed through the Economic Profile System are sourced from various federal sources including the U.S. Department of Commerce. Additional economic data is collected from IMPLAN licensed software, an aggregator of regional economic research data for

[28] Economic Profile System (EPS): https://headwaterseconomics.org/tools/economic-profile-system/about-eps

over 500 industries in the United States. Resource data is collected from the National Forest National Resource Management database (NRM).

Limits to economic data spatially, and temporally, exist. The available data for IMPLAN economic contribution analysis is the best existing source as it is the most complete and standard source for raw industry, income, employment, production, and consumption data used in economic impact modeling. The IMPLAN data sources include data managed and offered by multiple Federal sources including the U.S. Bureau of Economic Analysis, USDA, Bureau of Labor Statistics, and the U.S. Census Bureau. Current, community level economic data are not available consistently, or systematically, across economic regions of the U.S. County-level economic data is the standard level at which activities and industries can be analyzed across an economic sub-region. This is based on the nature of the collection of source data, as well as the methodology of aggregating and computing this data. Economic information pertaining to individual communities, and areas within county geography can help inform a qualitive analysis of economic values and tradeoffs pertaining to proposed plans but is not consistently available for substitution into impact analyses.

The economic analysis draws upon the best available literature citations that were found to be relevant to the economic and social conditions on the Nez Perce-Clearwater. Literature sources that were the most recent and applicable to the local economic environment were selected.

In addition to quantitative measurements of economic contributions from the proposed plan and alternatives, the analysis of effects includes qualitative analysis of economic values and tradeoffs associated with the varying alternatives. The proposed plan is programmatic and has limited direct implications with respect to definitive, measurable economic activity.

Measurement Indicators

The indicators used to assess economic sustainability are the contributions of direct, indirect, and induced jobs and labor income, as well as direct federal land payments made to local governments. National Forest System administration and National Forest assets, including natural resources as well as many other ecosystems goods and services, contribute to the economic sustainability within the area of influence.

The concept of quality of life includes economic opportunities to obtain income and employment. For the purposes of this analysis, economic factors of quality of life will be discussed separately from others labeled as social benefits.

The key economic benefits of the Nez Perce-Clearwater in the Forest Plan economic analysis area include reliable contributions to jobs and income. These benefits, as well as other social benefits were identified through interdisciplinary discussions with Nez Perce-Clearwater staff and comments from the public. Key economic benefits to society provided by the Nez Perce-Clearwater in the Forest Plan economic analysis area include:

- Income – direct, indirect, and induced income from multiple uses of National Forest assets.
- Jobs – direct, indirect, and induced jobs, including those related to providing recreation experiences, harvesting and process timber into forest products, grazing and the raising of livestock, mineral, oil and gas resources for energy, and raw material productions.

Affected Environment

Existing Economic Condition

The key indicators of economic conditions in the primary economic analysis area are summarized below. The analysis area described in this section is comprised of 11 counties, an area identified with the most recently available data through methods detailed in the *USDA Forest Service Protocols for Delineation of Economic Impact Analysis Areas* (METI Corp/Economic Insights of Colorado 2010).

This multi-county area includes the Nez Perce Tribal Reservation, a contiguous land across multiple counties in Idaho (Lewis, Nez Perce, Latah, Clearwater, and Idaho County). Tribal economic activity that is recorded by Federal sources is indirectly detailed as activity existing within each intersecting county described below. Economic values and activities not available from Federal sources are discussed further qualitatively in this and the Social Sustainability section.

The data in the Assessment was reviewed to determine which economic conditions may be relevant for analyzing the effects of the alternatives on economic sustainability. With this lens in mind, the Affected Environment section provides a more focused summation of the economic conditions in the analysis area. Relevant economic conditions, specifically income and subsequent jobs in industries closely tied to federal lands, recreation, and natural resources, are of key interest.

Total population, employment, and personal income trends since 1970 fluctuate widely across the primary analysis area counties. Table 456 shows population ranking and the population and employment trends of the 11 counties in the analysis area. Population changes since 1970 ranges from 193 percent to negative 36 percent for Ravalli County, Montana and Shoshone County, Idaho, respectively. Employment change since 1970 ranges from 333 to negative 29 percent in the same counties. Lastly, personal income changes since 1970 ranges from 516 percent to -1 percent, again, in the same counties.

Table 456. County population, employment, and personal income trends in the multi-county area (1970-2017).

County	Population 2017	Population Rank	Population % change	Employment % change	Personal Income % change
Benewah County, ID*	9,184	7	47%	110%	142%
Shoshone County, ID*	12,542	6	-36%	-29%	-1%
Clearwater County, ID*	8,546	8	-22%	-27%	13%

Adams County, ID	4,147	10	44%	75%	120%
Combined County Region	298,652	N/A	59%	129%	199%
U.S.	325,719,178	N/A	60%	115%	211%

*Counties intersecting the Nez Perce-Clearwater boundary and receiving federal land payments.

Unemployment and industry presence also fluctuate greatly across analysis area counties. Table 457 shows the 11 counties ordered by unemployment rate. Unemployment rate ranges from 7.2 percent to 2.5 percent, a measurement for Mineral County, Montana, and Latah County, Idaho, respectively. Timber industry presence in private employment is highest at 32.9 percent in Benewah County, Idaho. Mining industry presence in private employment is highest at 21.6 percent in Shoshone County, Idaho. Agriculture industry presence in private employment is highest at 12.2 percent in Adams County, Idaho. Lastly, travel and tourism industry presence in private employment is highest at 35.5 percent in Mineral County, Montana.

Table 457. Unemployment and Industry presence in private employment in primary counties.

County	Unemployment Rate, 2017	Timber % of total private industry	Mining % of total private employment	Agriculture % of total employment	Travel and Tourism % of total private employment
Benewah County, ID*	4.6%	32.9%	0.3%	6.8%	11.1%
Shoshone County, ID*	5.7%	1.7%	21.6%	0.6%	20.7%
Clearwater County, ID*	6.7%	16.2%	0.0%	6.7%	14.4%
Latah County, ID*	2.5%	4.9%	0.2%	5.1%	26.6%
Missoula County, MT	3.3%	1.1%	0.1%	0.8%	20.7%
Mineral County, MT	7.2%	22.4%	0.0%	4.4%	35.5%

U.S.	3.9%	0.6%	0.5%	1.3%	15.8%

*Counties intersecting the Nez Perce-Clearwater boundary and receiving federal land payments.

Private timber industries represent a very significant employer in many counties, including Benewah, Clearwater, Mineral, Lewis, Idaho, Nez Perce, and Adams. In these counties, where timber represents between 9 and 33 percent of all private county-level employment, the relative importance of timber resources from the Nez Perce-Clearwater are highest. Especially, timber resources and forest product manufacturing remain fundamental to economic sustainability in these counties.

Collectively, across the full extent of the economic analysis area, private timber jobs were estimated at 4,730 in 2016, down from a peak employment level of 7,669 in 1999. Figure 169 provides a 19-year trend on timber industry employment levels. Over this period, private industry timber jobs in especially saw and paper mills have declined steadily from various market forces, including increased capitalization of milling ownership, technology, and operations.

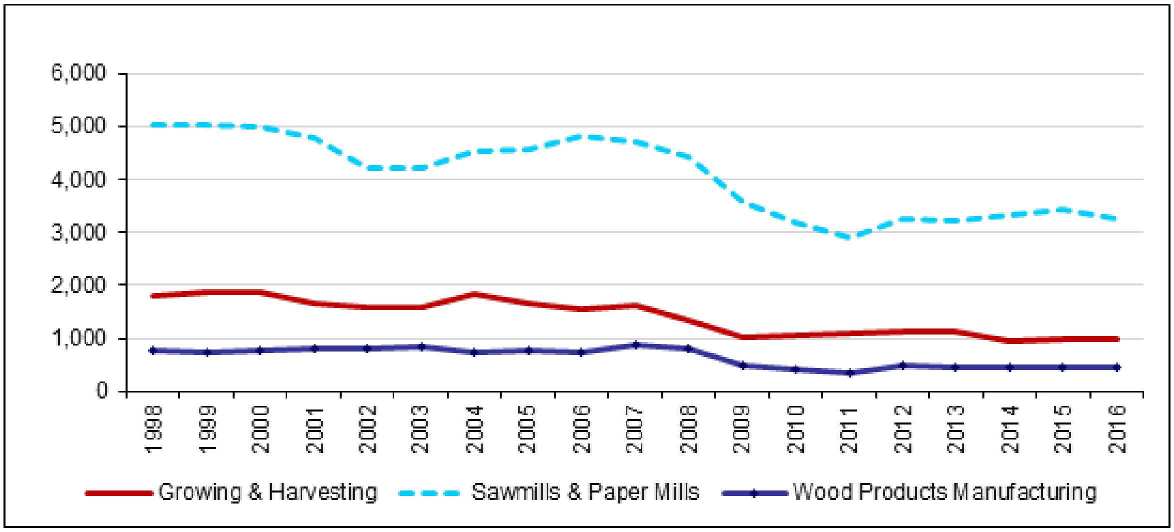

Figure 169. Jobs in timber sectors (1998-2016), eleven county analysis area.

Data Source: U.S. Department of Commerce. 2018. Census Bureau, County Business Patterns, Washington, D.C.

While timber industries remain a large stakeholder in the Nez Perce-Clearwater analysis area, the total economic value of Nez Perce-Clearwater lands and operations includes benefits to other industries including minerals and energy, agriculture and range, and travel and tourism sectors.

Across the full extent of the economic area of influence, private mineral and energy jobs were estimated at 1,212 in 2016. Figure 170 provides the same 19-year trend in mineral and energy industry employment levels. Over this period, private industry mineral and energy jobs in this multi-county region have fluctuated with the rise and fall of external market events and resource discoveries. Levels of employment in this sector have permanently declined as much as in timber sectors across the same multi-county area.

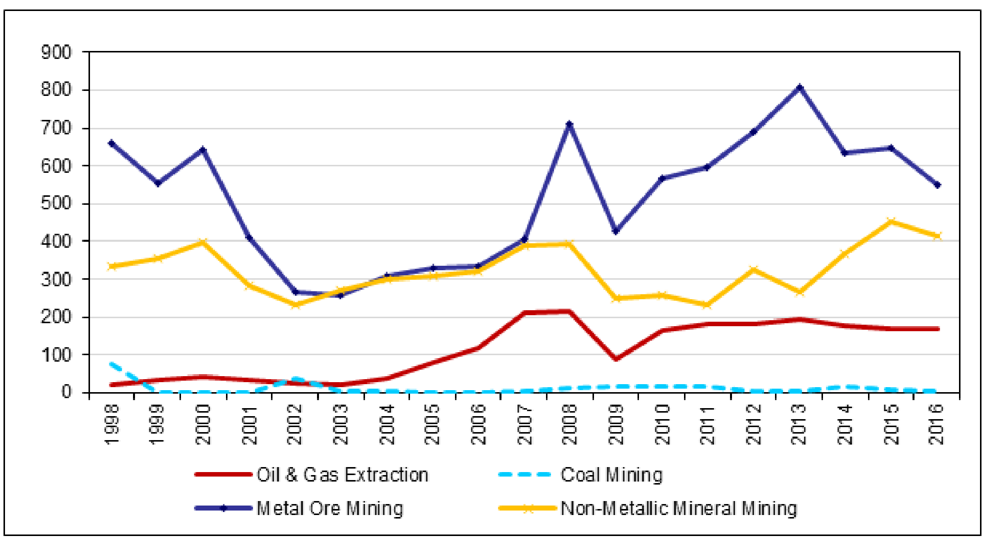

Figure 170. Jobs in mineral and energy sectors (1998-2016), eleven county analysis area.

Data Source: U.S. Department of Commerce. 2018. Census Bureau, County Business Patterns, Washington, D.C.

In additional to mineral and energy industries, agriculture and grazing industries benefit from the availability of water and rangeland delivered or provided by the Nez Perce-Clearwater (Figure 171). Total farm jobs in the analysis area have trended flat over a long period of time. From 1970 to 2016, farm jobs in this region have increased slightly from 5,040 to 5,848, but compared to non-farm jobs, have shrunk from approximately seven percent of total analysis area employment to less than one percent.

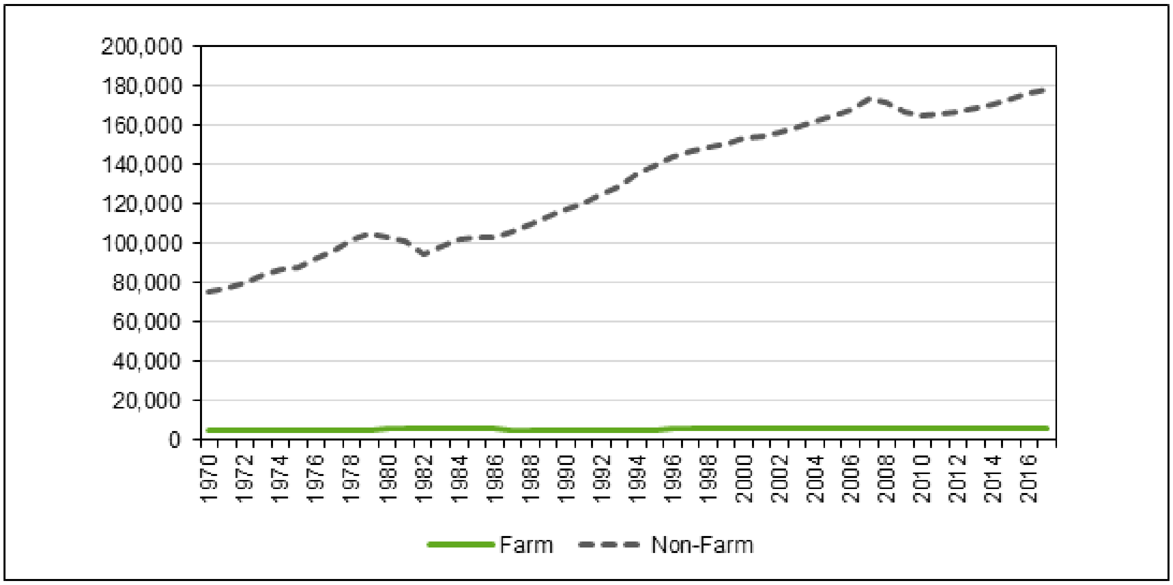

Figure 171. Jobs in farm sectors (1998-2016), eleven county analysis area.

Data Source: U.S. Department of Commerce. 2018. Census Bureau, County Business Patterns, Washington, D.C.

Finally, recreation opportunities for local and non-local Nez Perce-Clearwater visitors puts demand on goods and services from travel and tourism related industries across the analysis area (Figure 172). Collectively, jobs and income in these service subsectors are shifting and on the rise. Since 1998, jobs in retail, arts and entertainment, and accommodations and food service have been collectively on the rise from 14,632 to 19,109 in 2016. Counties with a higher proportion of travel and tourism related services include Adams, Mineral, Missoula, Latah, and Shoshone.

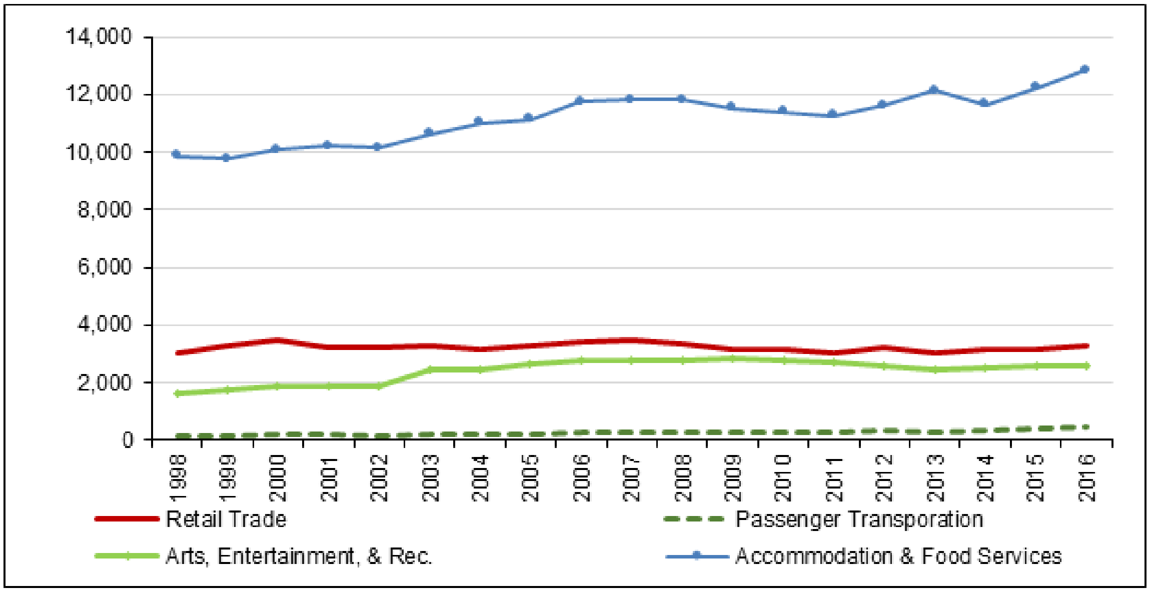

Figure 172. Jobs in recreation and related services (1998-2016), eleven county analysis area.

Data Source: U.S. Department of Commerce. 2018. Census Bureau, County Business Patterns, Washington, D.C.

The economic region described in this analysis includes other sectors and industries, however the primary industries described above represent those fundamentally closest in connection to National Forest plans and programs. There are both market activities (e.g., tribal industries not measured in Federal data) and non-market activities (e.g., economic value generated from hunting, fishing, collection of sustainable foods, or other key ecosystem service benefits) that are not reflected in the industry data provided above.

In the following section, an economic contribution analysis will look closely at the potential for the land management plan to impact jobs and income across these private industries, as well as from additional Forest Service operations.

Environmental and Economic Consequences

The land management plan provides a programmatic framework that guides site-specific actions but does not authorize, fund, or carryout any project or activity. Because the land management plan does not authorize or mandate any site-specific projects or activities, including ground-disturbing actions, there can be no direct effects. However, there may be implications or longer-term environmental and economic consequences of managing the Nez Perce-Clearwater under this programmatic framework.

The previous sections briefly assessed the economic conditions of the affected environment and industries most connected to natural resource management. The Affected Environment section provides a baseline understanding of the relative importance of industries, income, and employment in counties around the Nez Perce-Clearwater. The following section considers how the Nez Perce-Clearwater may contribute under new plan direction. Here, the potential impacts of alternative management scenarios on Nez Perce-Clearwater related market-related contributions, measured by labor income and job estimates, are considered. Not all economic benefits from the Nez Perce-Clearwater are described in this section as many benefits pass to consumers, businesses, and the public without market transactions, such as sourced municipal water or consumer surplus from recreation experiences. This section only summarizes the estimated contributions to industries, including timber and forest products, minerals and energy, agriculture and grazing, recreation travel and tourism, and government operations.

Effects Common to All Alternatives

Under all alternatives, the Nez Perce-Clearwater will continue to provide the full suite of economic benefits which currently contribute to economic sustainability, as described in the Affected Environment section. Over the life of the plan, no consequential adverse impacts are expected to the economic conditions of the primary analysis area or to any of the key industries that the Nez Perce-Clearwater currently supports.

Under all action alternatives, contributions to economic sustainability are expected to be different than under the No Action Alternative. This is due to new management direction across resource areas focused, to varying degrees, on increasing areas suitable for timber production, increasing timber volume, and increasing vegetation management. All alternatives considered provide an enhanced suite of recreation (motorized and non), wildlife, subsistence-use, forest products, and other ecosystem service-related benefits. Not all economic contributions are included and analyzed quantitatively in the contribution analysis. These economic values and contributions are captured in the intent of plan components (e.g., FW-DC-ES-01, FW-DC-ES-02, FW-GDL-ES-01) that are unchanging across alternatives.

Results of the economic contribution analysis appear in the two tables below. In Table 458, employment refers to levels of average annual jobs contributed from resource programs and agency operations. The estimate of jobs includes a mixture of full and part-time employment. In Table 459, labor income refers specifically to earned wage or proprietor income but does not include Social Security, Medicaid, dividends, or capital gains government programs or investments. These separate sources of income are defined as non-labor income sources and are not included in the contribution analysis of the Nez Perce-Clearwater.

Table 458. Employment in the analysis area (direct employment contribution, estimated number of jobs) by resource and alternative.

Resource	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Recreation: all	251	251	251	251	251	251
Wildlife and Fish Recreation: all	91	91	91	91	91	91
Grazing	56	56	56	56	56	56
Timber	839	3,096	3,347	1,954	1,088	2,461
Minerals	0	0	0	0	0	0
Payments to States/Counties	93	93	93	93	93	93
Forest Service Expenditures	1,056	1,056	1,056	1,056	1,056	1,056
Forest Total	2,387	4,643	4,894	3,502	2,635	4,008
Percent Change	14%	122%	134%	67%	26%	91%

Table 459. Labor income in the analysis area (average annual labor income, in thousands of 2016 U.S. dollars) by resource and alternative.

Resource	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Recreation: all	$7,053	$7,053	$7,053	$7,053	$7,053	$7,053

Wildlife and Fish Recreation: all	$2,628	$2,628	$2,628	$2,628	$2,628	$2,628
Grazing	$1,197	$1,197	$1,197	$1,197	$1,197	$1,197
Timber	$35,500	$130,913	$141,537	$82,648	$46,018	$104,078
Minerals	$0	$0	$0	$0	$0	$0
Payments to States/Counties	$4,474	$4,474	$4,474	$4,474	$4,474	$4,474
Forest Service Expenditures	$44,023	$44,023	$44,023	$44,023	$44,023	$44,023
Forest Total	$94,875	$190,288	$200,912	$142,023	$105,393	$163,453
Percent Change	15%	130%	143%	72%	27%	98%

Income and employment levels contributed fluctuate specifically with timber related jobs and income. As shown in the contribution tables, income and employment are different across alternatives due to changing assumptions regarding forest management activities under the timber programs. Across alternatives, total job contributions range between 2,095 and 4,894 jobs, and labor income between $82 million and $200 million (2016 US dollar currency).

Aside of changes to timber industry, that are considered across the range of possible sustain yield limits, all other quantifiable contributions remain constant. The other plan program areas are significant in their respective contribution to economic activity; however, the proposed plan and alternatives do not directly change the measured factors in estimating these contributions. The unchanged model output represents a methodological limitation in the quantitative analysis, rather than an increased focus on timber contributions. There are many other qualitative, and unmeasured tradeoffs to consider across the proposed plan and alternatives.

General recreation and wildlife related recreation specifically, are highly visible economic contributors for many communities and counties surrounding National Forests. Visitation level data are the primary input for measuring recreation related economic activity. Visitation to Nez Perce-Clearwater is not estimated to change because of plan decisions. Visitation patterns rise with public interest, population, and recreation trends. Though we consider this indirect to the land management plan, recreation benefits, economic or otherwise, are related to the aggregate level of access and opportunity provided across the national forest, which is influenced by the proposed plan and alternatives. Therefore, it is important to consider the tradeoffs between the multiple uses of a Forest that may diminish the quantity, or quality of recreation opportunities and activities. Details on recreation opportunities are provided in in both the Social Sustainability, as well as the Sustainable Recreation subsections of Chapter 3. Additionally, similar details are provided on wildlife related recreation in the Wildlife subsection of Chapter 3.

Similarly, economic value generated from ecosystem services, such as subsistence hunting and gathering are equally important to consider in the range of alternatives. Though tribal and non-tribal communities alike value these ecosystem service-related benefits, they are not accurately reflected in the quantitative economic contribution analysis. This is due to a lack of consistent, comparable community or county-level data reflecting quantified economic values for these services. Instead, these values are described and highlighted across multiple sections of the Final Environmental Impact Statement, including the Social Sustainability, Tribal Trust and Responsibilities, Wildlife, and other subsections of Chapter 3.

As discussed in the economic contribution analysis, relative to current conditions, all alternatives show a significant increase in the contributions from timber programs. This shift represents not only an increase in the sustained yield limit wood sale quantity but also the difference between actual agency operations, as compared to the highest potential for optimized, sustained yield-based sale quantities. In this sense, the action alternatives are not fully constrained estimates and cannot be compared to current forest operations without placing the future estimates in this important context.

All alternatives are estimated to produce more jobs and income over current estimated levels, with Alternative X contributing the most income and jobs. The preferred alternative is estimated to sustain a maximum of 2,461 annual jobs in timber related industries, and $104 million in labor income, annually.

Variation in employment across alternatives stems from known differences in wood quantities modeled to be sold under each alternative. Projected wood quantities represent an upper boundary to the potential economic activity within a constrained Nez Perce-Clearwater budget. These estimates do not reflect jobs and income from actual harvest levels. Instead, these estimates represent the full potential of the Nez Perce-Clearwater to contribute to resource industries under the direction of the Nez Perce-Clearwater plan and exclude factors related to private industry capacity to increase employment and productions levels.

Separate of timber programs, the economic impact model does not differentiate visitation levels, or the recreation impacts between alternatives, or the contribution from other ecosystem service-related benefits. As stated in the recreation section of the social sustainability report and pertaining to population trends, with any increase in population, recreational uses of the Nez Perce-Clearwater are expected to increase. Other economic benefits not analyzed directly, including nonmonetary benefits for Nez Perce-Clearwater stakeholders including the Nez Perce Tribe, and economic value for various recreation user groups, would vary between alternatives in parallel with ecosystem and resource availability and recreation opportunities, respectively. The best indication of these opportunities and availabilities are provided in the respective subsections of the Final Environmental Impact Statement Chapter 3.

Again, as highlighted in both tables, the greatest numerically measurable contribution to employment and income from the Nez Perce-Clearwater, as impacted by a plan, or alternative, comes by way of the levels of timber resources provided for economic gain, and the public investments that are made in agency operations.

Cumulative Effects

Many factors may influence and affect the economic environment in the future. Population growth and climate change are among the highest factors to consider in looking at cumulative effects for any resource. Population growth in the West is a trend that is expected to continue, and climate change is predicted to increase the number of hot days in the region, as well as many other environmental changing factors.

With respect to alternative selection as it is analyzed in this section, there are potential cumulative affects related to the direction and coalescing of forest product industries with long term changes to timber supply from National Forests. Industries' ability to maintain sufficient capacity to absorb supply increases from National Forests is dependent on existing infrastructure and future industry trends. Additional timber industry descriptive information is highlighted in the Timber subsection of Chapter 3.

There are also changes emerging in the recreational uses of National Forests across the West, where recreation congestion and overuse of access areas and available lands are becoming more common place. Future demands for recreation opportunities can be expected to increase on the Nez Perce-Clearwater and may be incongruent with the opportunities provided through the recreation opportunity spectrum class allocations. These trends are related to population growth locally, regionally, and nationally as well as new technologies and recreational products.

Summary of Consequences

Under the No Action Alternative through Alternative Z, including the Preferred Alternative, the Nez Perce-Clearwater would continue to provide the full suite of economic benefits which currently contribute to economic sustainability. The relative magnitude of contributions to economic sustainability vary by alternative. In this analysis, contributions to economic sustainability are made clear as hinging on choices around timber, vegetation, and designation of lands as being suitable for timber management.

Given the diversity of management preferences across both local and national stakeholder groups, it is not possible to unequivocally identify which action alternative provides the greatest overall contribution to economic sustainability for all stakeholders across all possible economic benefits, market and non-market. Within the scope of this analysis and the measured benefits identified, Alternative X provides the greatest range of opportunity to generate contributions and prioritize timber and forest product industries, as well as overall contribution to jobs and income from forest management. Conversely, the No Action Alternative has the most limiting range of opportunity under the sustain yield limit to contribute to forest product industries locally, and regionally.

The table below itemizes the relative contributions of key economic benefits by alternative. When relative contributions are expected to be similar, alternatives are listed in the same box in alphabetical order.

Table 460. Relative contributions to social and economic sustainability by alternative

Key Social Benefit	Greatest	>	>	>	>	Smallest
Income – payments in lieu of taxes, secure rural schools, labor income in various industries: recreation, timber, and grazing	Alt X	Alt W	Preferred	Alt Y	Alt Z	No Action
Jobs – including induced jobs such as recreation, timber, and grazing	Alt X	Alt W	Preferred	Alt Y	Alt Z	No Action

Data Sources

All data and methods sourced from the following:

- Headwaters Economics. Economic Profile System (EPS). Headwaters Economics. (Headwaters Economics n.d.)

Analysis Methods Guide—Job and Income at a Glance Reports: The Estimated Economic Contributions of National Forests and Grasslands. August 2018. USDA Forest Service Washington Office, National Forest System Ecosystem Management Coordination.

3.8.2 Social Sustainability

The mission of the Forest Service is to sustain the health, diversity, and productivity of the nation’s forests and grasslands to meet the needs of present and future generations. Nez Perce-Clearwater lands both influence and are influenced by local and national publics. Local communities, particularly those adjacent to national forest lands, benefit from a multitude of goods and services provided by the Nez Perce-Clearwater and the Forest Service. These social benefits are often referred to as ecosystem services, which are defined "as goods and services provided wholly or in part by ecosystems and that are of value to people" (Olander et al. 2015). The Nez Perce-Clearwater's ecosystem services, alongside infrastructure and operations, are the main ways that public lands contribute to social sustainability. Many local communities were formed based on availability of roads and ecosystem goods and services such as timber, minerals, grazing lands, and other natural resources. Historically, individuals in these communities have benefited from a host of services, such as recreation, scenery, employment, and opportunities to connect with nature. The public across the United States also benefit from the Nez Perce- Clearwater.

These same "goods and services" such as firewood or wildlife and fish for hunting and fishing are not just integral to the Nez Perce Tribe's culture, religion, health, and economy, they are legally protected rights. Social sustainability in the context of American Indians is briefly discussed in this section, and more thoroughly discussed in the Tribal Trust and Responsibilities section of this EIS.

The key benefits the Nez Perce-Clearwater and the Forest Service provide include, but are not limited to:

- clean water and water supply
- clean air
- wood products
- forage
- hunting and wildlife
- fish
- cultural values – heritage values, subsistence food gathering, spiritual and inspirational values
- aesthetics – scenery
- recreation
- flood control
- soil stabilization and landslide protection

The 2012 Planning Rule states that plans are to guide management so that forests and grasslands contribute to social sustainability, providing communities with ecosystem services and multiple uses that deliver a range of social, economic, and ecological benefits in the present and into the future. Specifically, plan components must include standards or guidelines to guide the Nez Perce-Clearwater's contribution to social sustainability, considering ecosystem services as well as multiple uses that contribute to local, regional, and national communities in a sustainable manner. Furthermore, reasonably foreseeable risks to social benefits shall be considered when developing the Land Management Plan.

This section, therefore, (1) describes the social conditions of the affected environment using key indicators of social sustainability; (2) describes how key benefits of the Nez Perce-Clearwater currently contribute to social sustainability of beneficiaries, both locally and at a broader scale; (3) evaluates the impacts of the alternatives on the benefits the Nez Perce-Clearwater provides to local beneficiaries and the public.

Changes between Draft and Final Environmental Impact Statements

The Social Sustainability section of the Final Environmental Impact Statement has been updated to include additional relevant policies and executive orders, an update to the term traditional industries to land-based livelihoods, and an analysis of the preferred alternative.

Relevant Laws, Regulations, and Policy

Federal Laws

The following is a select set of statutory authorities that govern the evaluation of the social resources in the Nez Perce-Clearwater. They are briefly identified and described below to provide context to the management and evaluation of the resource. There are multiple other laws and regulations and policies not described below that also guide the management of this resource.

Multiple-Use Sustained Yield Act of 1960: Identifies principles for managing the resources of the National Forest System. The direction to manage these resources for the greatest good over time includes the use of economic and social analysis to determine management of the National Forest System lands.

National Environmental Policy Act of 1969: Mandates consideration of the consequences to the quality of the human environment from proposed management actions. The agency must examine the potential impacts to physical and biological resources as well as potential socioeconomic impacts (40 CFR 1508.14).

Forest and Rangeland Renewable Resources Planning Act of 1974: As amended by the National Forest Management Act of 1976, requires consideration of potential social and economic consequences of land management planning.

Office of Management and Budget Circular A-116 (issued August 16, 1978): Requires executive branch agencies to conduct long range planning and impact analysis associated with major initiatives.

Secure Rural Schools and Community Self-Determination Act of 2000: Was designed to stabilize annual payments to state and counties containing National Forest System lands and public domain lands managed by the Bureau of Land Management. Funds distributed under the provisions of this act are for the benefit of public schools, roads, and related purposes.

Executive Orders

Executive Order No. 12898 on Environmental Justice (issued February 11, 1994): Mandates federal agencies to make achieving environmental justice part of their mission. This includes identification and response to disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low-income populations.

Executive Order 14008 of 2021, Tackling the Climate Crisis at Home and Abroad: This order provides direction for a government-wide approach to combat the climate crisis. The order requires a coordinated approach from planning to implementation coupled with substantive engagement by stakeholders, including state, local, and tribal governments. This order also created the Justice40 Initiative that sets the goal that 40% of covered investments will benefit disadvantaged communities and required the development of an online assessment tool to identify disadvantaged communities. Finally, the order also established the Environmental Justice Scorecard.

Executive Order 13985 - Advancing Racial Equity and Support for Underserved Communities Through the Federal Government: This order recognizes the unbearable human costs of systemic racism that arise from entrenched disparities in our laws and public policies, and in our public and private institutions that have often denied equal opportunity to individuals and communities. Consequently, this order 1) provides a definition of equity and underserved communities; 2) direct the Domestic Policy Council to coordinate efforts to embed equity principles, policies, and approaches across the Federal Government; 3) direct OMB to study methods and identify best practices for equity assessments then conduct equity assessment of agency policies, programs, and actions; 4) establish an Equitable Data Working Group; and 5) require equity action plans for each agency.

Executive Order 14096 of 2023 - Revitalize Our Nation's Commitment to Environmental Justice for All: This order revitalizes and builds on the federal government's commitment to environmental justice. It adds achieving environmental justice to the mission of each agency and recognizes communities with environmental justice concerns experience disproportionate and adverse human health or environmental burdens. This order also updates the definition of environmental justice; 2) create environmental justice strategic plans and subsequent environmental justice assessments; 3) establish an Environmental Justice Subcommittee of the National Science and Technology Council, the White House Environmental Justice Interagency Council, and the White House Office of Environmental Justice is hereby established within the Council of Environmental Quality.

Agency Regulations

2012 National Forest System Land Management Planning Rule: The evaluations of social resources are framed within the context of sustainability because, in accordance with the 2012 National Forest System Land Management Planning Rule (36 CFR 219), land management plans are to guide management so that forests and grasslands are ecologically sustainable and contribute to social and economic sustainability. The Agency 2012 planning process leads to plans that contribute to ecological, social, and economic sustainability by protecting resources on the unit to maintain a flow of goods and services from National Forest System lands on the unit over time.

Pertaining to social resources, the 2012 Planning Rule states that the plan should:

Contribute to ecological, social, and economic sustainability by ensuring that all plans will be responsive and can adapt to issues such as the challenges of climate change; the need for forest restoration and conservation, watershed protection, and species conservation; and the sustainable use of public lands to support vibrant communities.

"Social sustainability" refers to the capability of society to support the network of relationships, traditions, culture, and activities that connect people to the land and to one another and support vibrant communities (36 CFR 219.19).

§ 219.8 Sustainability states the plan must provide for social, economic, and ecological sustainability within Forest Service authority and consistent with the inherent capability of the Nez Perce-Clearwater, as follows:

(b) Social and economic sustainability. The plan must include plan components, including standards or guidelines, to guide the Nez Perce-Clearwater's contribution to social and economic sustainability, taking into account:

1. Social, cultural, and economic conditions relevant to the area influenced by the plan.
2. Sustainable recreation; including recreation settings, opportunities, access, and scenic character.
3. Multiple uses that contribute to local, regional, and national economies in a sustainable manner.
4. Ecosystem services.
5. Cultural and historic resources and uses.
6. Opportunities to connect people with nature.
7. Reasonably foreseeable risks to ecological, social, and economic sustainability.

The rule states that the plan must also be consistent with laws and executive orders including:

- *36 CFR 212 Travel Management*
- *36 CFR 223 Special Forest Products*
- *36 CFR 228 Minerals*
- *36 CFR 241 Fish & Wildlife*
- *36 CFR 251 Land Uses*
- *36 CFR 254 Land Ownership Adjustments*
- *36 CFR 262 Law Enforcement Support Activities*
- *36 CFR 293 Wilderness*

Methodology

Spatial Scale

The social analysis area is defined by both geography and social ties. The Land Management Plan Assessment, Chapter 6.0, Socioeconomic Conditions and Trends report defines the analysis area as the five counties in North Central Idaho that are adjacent to, or in the immediate vicinity of, the Nez Perce-Clearwater. These five counties are Clearwater County, Idaho County, Latah County, Lewis County, and Nez Perce County. In addition to the primary social analysis area identified in the assessment, this analysis also considers the preferences and perspectives of local stakeholders living within a secondary social analysis area. The secondary social analysis area includes all census county divisions within 50 miles of the Nez Perce-Clearwater. The 50-mile distance threshold is commonly used to approximate areas of social influence as it represents approximately a one hour's drive to the Nez Perce-Clearwater. This is a reasonable distance for one to travel on a weekly or even daily basis, either for recreation or for commuting purposes. Additionally, according to 2012-2016 National Visitor Use Monitoring Survey data, a third of visits to the Nez Perce-Clearwater were from people living within 50 miles of the Nez Perce-Clearwater.

The secondary social analysis area contains 77 county sub-divisions, spanning portions of counties in Idaho, Montana, and Washington. Figure 173 displays the primary and secondary social analysis areas.

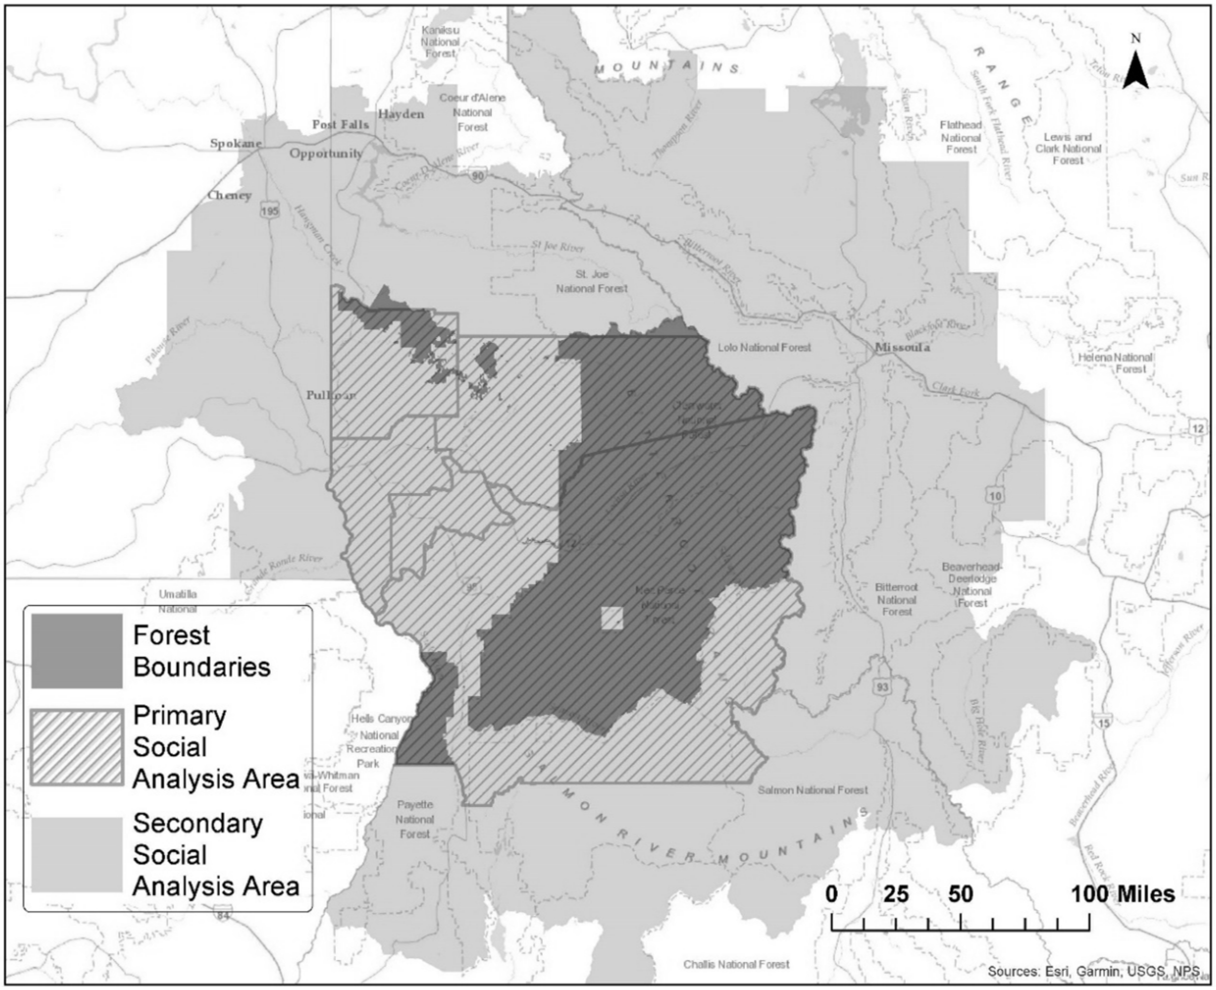

Figure 173. Primary and secondary social analysis areas

Data source: U.S. Census 2016; Map Source: U.S. Forest Service Northern Region 2019

Contributions from the Nez Perce-Clearwater to the broader landscape, including national and global stakeholders, are also considered. The scale of the broader landscape is dependent on the given benefit in question. For example, those who benefit from the existence of Wilderness, even if they never plan to visit (Kline and Mazzotta 2012), are considered when examining the cultural benefits of the Nez Perce-Clearwater. For a detailed explanation of how the primary social analysis area was selected, please see the Land Management Plan Assessment, Chapter 6.0, Socioeconomic Conditions and Trends.

Temporal Scale

The temporal scope of the analysis is the anticipated life of the plan. The analysis area for indirect effects is the same as the analysis area for cumulative effects.

Past, Present, and Future Activities used in the Analysis

The Affected Environment section below includes a synthesis of how relevant past, ongoing and future actions and processes are affecting, have affected, and may affect social conditions and benefits.

Methods and Assumptions

The focus of this analysis is determining how the alternatives may affect social conditions and social benefits, or contributions to social sustainability.

Social benefits of the Nez Perce-Clearwater are those ecosystem services, including multiple uses; infrastructure; and operations, which either directly or indirectly contribute to social sustainability, or are of value to people. This analysis focuses only on those benefits which may be affected by the alternatives.

Numerous approaches exist for measuring society's condition or progress towards achieving social sustainability. In the land management planning context, a broad ecosystem services framework, which catalogues social benefits of forests, is an ideal framework for identifying how the Nez Perce-Clearwater contributes to social sustainability.

Social benefits of the Nez Perce-Clearwater are used and valued differently by different groups and communities. The Assessment provided a brief overview of social conditions and highlighted the benefits the Nez Perce-Clearwater provides to nearby communities. In the Affected Environment section, basic social conditions of the primary social analysis are summarized. Next, the key social benefits the Nez Perce-Clearwater provides to beneficiaries that may be affected by the alternatives are described.

A primary social analysis area was identified during the Assessment phase to analyze the potential effects of the alternatives on the Nez Perce-Clearwater's contributions to social sustainability.

The social analysis is conducted in three steps. First, the key indicators of social conditions of the primary social analysis area are summarized. Next, each social benefit is briefly described, and when relevant, discussed in the context of the social conditions of the area of influence. Some social benefits are easier to quantify than others. Indicators that do not easily lend themselves to quantification, such as cultural values, are discussed qualitatively. Lastly, the alternatives are analyzed to determine how they might affect social conditions and social benefits, or contributions to social sustainability, taking relevant social conditions, risks, and stressors into account. Social benefits addressed in detail in other resource reports are only briefly addressed in this section. This section draws from other resource analysis sections.

Measurement Indicators

Social conditions

The assessment provided a comprehensive review of social conditions in the primary social analysis area. The key demographic indicators of social conditions used in this analysis are:

- population size by county, American Community Survey, five-year estimates (2012-2017).
- short-term population change by county, American Community Survey, five-year estimates (2006-2010 and 2012-2017).
- long-term population change by county, US Census population counts and American Community Survey, five-year estimates (1970 and 2012-2017).

Environmental Justice

Social conditions indicators are also used to identify whether environmental justice populations, or communities with environmental justice concerns, exist within the primary social analysis area. Environmental justice populations are defined as census tracts, a proxy for communities, with a poverty rate over 30 percent and/or a minority population of 30 percent or greater (Periman and Grinspoon 2014). The indicators of environmental justice communities used in this analysis are:

- poverty rate by census tract, or the percent of population below poverty line, American Community Survey, five-year estimates (2012-2017).
- minority population by census tract, as measured by the percent that is not categorized as non-Hispanic white population, American Community Survey, five-year estimates (2012-2017).

Environmental justice community thresholds are defined according to Periman and Grinspoon's (2014) methodology in their guide "Striving for inclusion: Environmental justice under the Forest Service 2012 planning rule." These thresholds for minority populations and poverty populations are meaningfully greater than the minority and poverty populations in Idaho and Montana. The percentage of the population that is minority, or not non-Hispanic white, in Idaho is 17.5 percent and 13.4 percent in Montana. The percentage of the population living below the poverty line in Idaho is 14.5 percent and 14.4 percent in Montana (United States Census Bureau, 2017). Environmental justice communities are, therefore, defined as areas with approximately twice the rate of poverty or minority populations as compared to the overall populations of Montana and Idaho.

Social benefits

The indicators used to assess contributions to social sustainability are the key social benefits the Nez Perce-Clearwater provides to beneficiaries that have the potential to be affected by the alternatives. The benefits are described below in the context of social conditions, where relevant. These social benefits contribute to the social sustainability of the area of influence, or the affected communities and beneficiaries, by enhancing the quality of life of the public. Quality of life is defined as the general level of wellbeing of individuals and society. The concept of quality of life encompasses all aspects of life including, but not limited to, employment, safety, and health. The key social benefits of the Nez Perce-Clearwater include ecosystem services, multiple uses, infrastructure, and operations. The key benefits were identified through interdisciplinary discussions with Nez Perce-Clearwater staff and comments from the public. Key benefits to society provided by the Nez Perce-Clearwater that have the potential to be affected by the alternatives include, but are not limited to:

- clean water and water supply
- clean air
- wood products
- forage
- hunting and wildlife
- fish
- cultural values – heritage values, subsistence food gathering, spiritual and inspirational values
- aesthetics – scenery
- recreation
- flood control
- soil stabilization and landslide protection

Additionally, the Nez Perce-Clearwater also provides additional benefits including wildfire protection, educational programs, and other ecological benefits, such as carbon sequestration and nutrient cycling. The key benefits that will be analyzed are a subset of all the benefits the Nez Perce-Clearwater provides. The planning team and the public noted these key benefits as most relevant to the planning effort, from a social perspective.

Affected Environment

Social Conditions

The key indicators of social conditions in the primary social analysis are summarized in Table 461. Population size is an indicator of community type, such as urban, suburban, or rural, and helpful in understanding how populations may relate to public lands. Urban populations are more likely to value public lands for their cultural resources, including recreation, scenery, and inspiration, while rural populations are more likely to value public lands for both cultural and economic resources such as opportunities for timber, mining, and grazing (U.S. Department of Agriculture 2014e, Van Driesche and Reardon 2014). The populations in the five-county area reside in rural, suburban, and urban areas, suggesting populations with both cultural and economic ties to the Nez Perce-Clearwater.

Table 461. Summary of key social conditions in the primary social analysis area of influence

Metric	Latah County, ID	Clearwater County, ID	Idaho County, ID	Lewis County, ID	Nez Perce County, ID	Five County Area
Population (2012-2017)	38,697	8,533	16,275	3,824	40,014	107,343
Population (2006-2010)	36,645	8,766	15,947	3,761	38,886	104,005
Short-term population % change (2010*-2017*)	5.6%	-2.7%	2.1%	1.7%	2.9%	3.2%
Long-term population % change (1970-2017)	57%	-22%	26%	-1%	33%	30%

*ACS 5-year estimates used. 2017 represents average characteristics from 2013-2017; 2010 represents 2006-2010.

Data Sources: U.S. Department of Commerce. 2018. Census Bureau, American Community Survey Office, Washington, D.C. (Headwaters Economics n.d.)

Population change is an indicator of social sustainability. Areas experiencing either rapid declines or rapid increases in population may have trouble providing adequate public services such as primary and secondary education, infrastructure maintenance, policing and public safety, and affordable housing. Long-term declines in population also indicate lower levels of social sustainability. These areas may have fewer basic social services. Long-term gains in population indicate higher levels of social sustainability.

Between 2006 to 2010 and 2012 to 2017, there have not been substantial short-term changes in county populations. Clearwater County has experienced substantial declines in population since 1970, suggesting lower levels of social sustainability. Latah, Idaho, and Nez Perce counties have experienced long-term population gains, suggesting higher levels of social sustainability.

Environmental Justice Populations

Environmental justice populations exist in the primary social analysis area and are defined as census tracts with a poverty rate over 30 percent and a minority population of 30 percent or greater. Figure 174 shows the location of environmental justice populations. The areas with greater than 30 percent of the population living in poverty are in Latah County, near Moscow. This rate is likely affected by the student population in Moscow, where the University of Idaho is located. There is one area in Nez Perce County that has an over 30 percent minority population. This is the eastern portion of Nez Perce County where the Nez Perce Reservation is located.

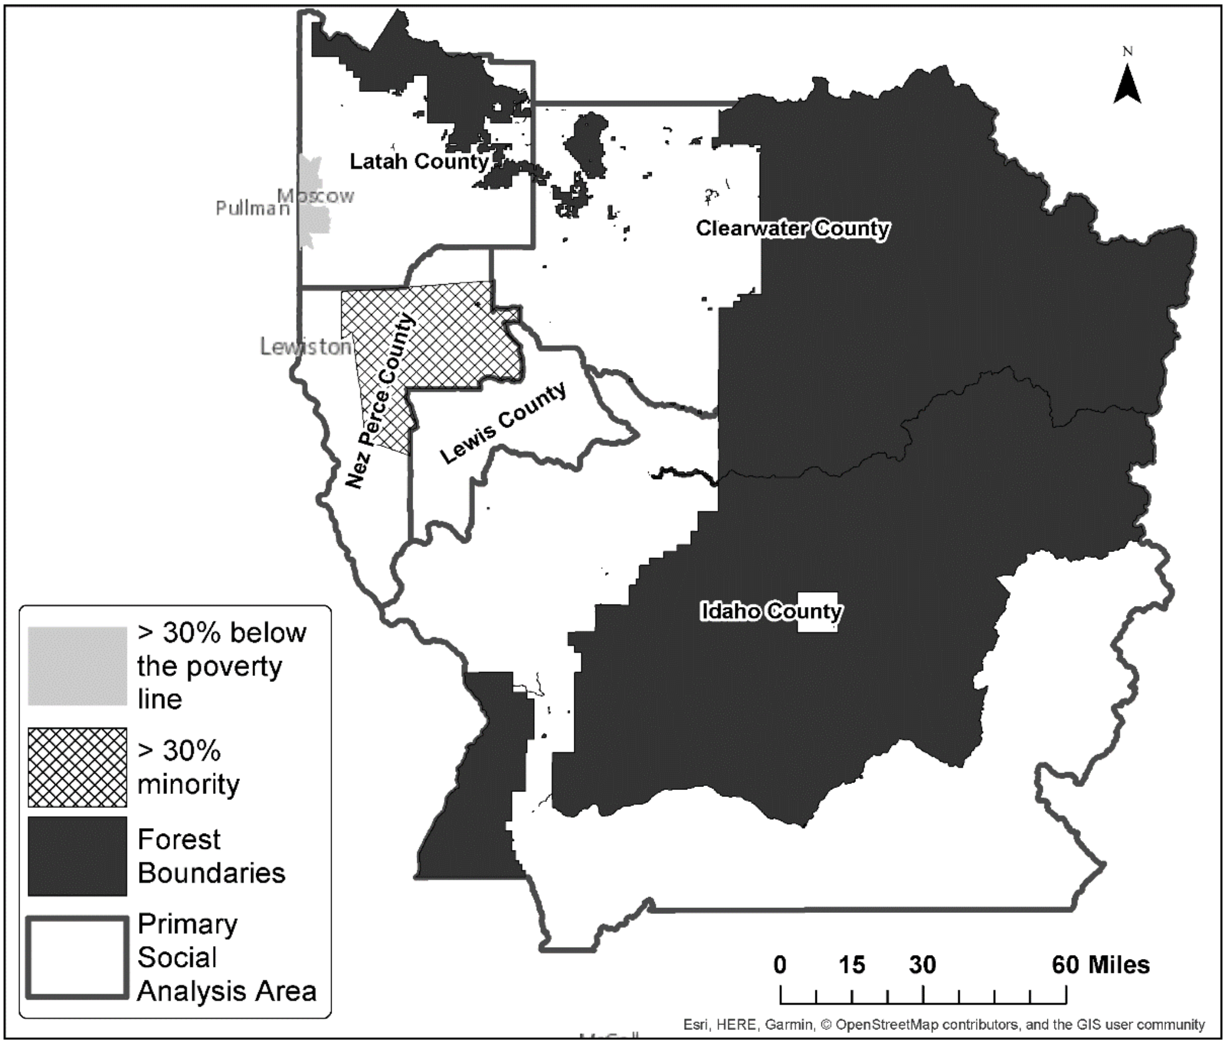

Figure 174. Environmental justice areas within the primary social analysis area

Data source: U.S. Census 2017; Map Source: U.S. Forest Service Northern Region 2019.

Social Benefits

The key benefits of the Nez Perce-Clearwater that contribute to social sustainability by enhancing quality of life are described in detail in the Assessment. These benefits include relevant multiple uses, ecosystem services, infrastructure, and operations. Below is a summary of key social benefits the Nez Perce-Clearwater provides to beneficiaries. The discussion of each benefit includes, where applicable and where data allow, a very brief description of the benefit, relevant social conditions, local stakeholder values, attitudes, and beliefs that relate to the given benefit, risks, and stressors, such as broader landscape, climate change, and conflicting benefits, that may affect how the benefit is contributing to social sustainability. Only key benefits that have the potential to impact social sustainability and have the potential to be influenced by the Nez Perce-Clearwater's management actions are addressed in detail. Local stakeholder values, attitudes, and beliefs are largely identified from the results of the Assessment's Forest Service Region 1 Social Survey (Bureau of Business and Economic Research 2018, University of Montana 2019), a review of public comments, and notes from public workshops and public meetings. Reviews of county resource plans also provided some insight. Percentages of survey data displayed are weighted responses and representative of the views of stakeholders residing in the secondary social analysis area. The confidence intervals for a proportion of 50 percent estimated from the survey is approximately plus or minus 8 percent (Bureau of Business and Economic Research 2018).

Stakeholders across the secondary social analysis area hold diverse values and preferences for management. Most survey respondents share a common vision of the most important purposes of their local, federal public lands. This vision includes protecting air and water quality, protecting wildlife habitat, protecting rare and endangered species, preserving areas for scientific study, providing scenic beauty, preserving wildlands, and providing recreational opportunities. Economic priorities, including timber, tourism, and mining, were very or extremely important to a subset of respondents, and at least moderately important to most respondents. Figure 175 shows the level of importance survey respondents assigned to various purposes of local, federal public lands. The percentages noted in the chart are weighted percentages of survey respondents located in the secondary social analysis area, defined as those living in areas within 50 miles of the Nez Perce-Clearwater boundaries.

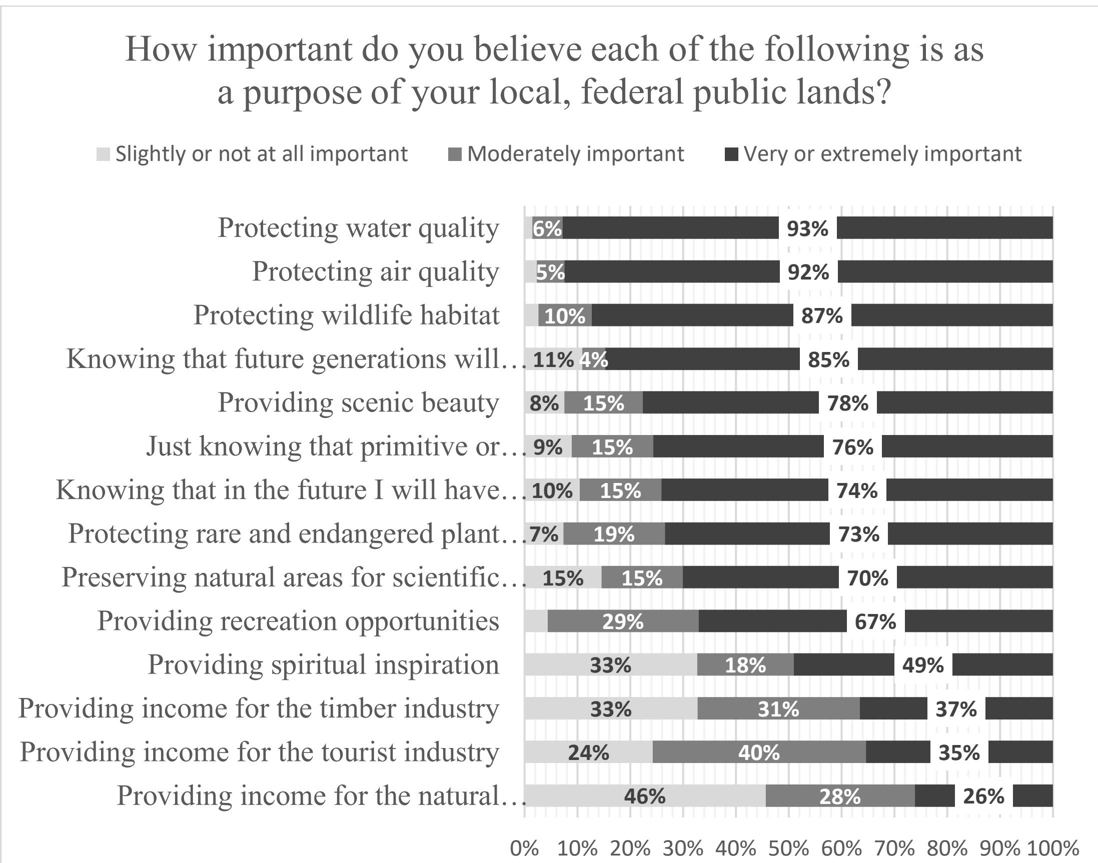

Figure 175. Local stakeholder survey respondent perspectives on the importance of federal land purposes in the local area

Data Source: (Bureau of Business and Economic Research 2018)

A review of comments received on the proposed action highlights that some stakeholders have differing, and often conflicting priorities in relation to the types of recreation opportunities, such as motorized, mechanized, and quiet; level of economic opportunity and timber harvest the Nez Perce-Clearwater should provide; and different perspectives on which areas and rivers should be recommended as Wilderness or eligible or suitable for Wild and Scenic River designations. Where relevant, these diverse perspectives are incorporated into the discussion of the benefits the Nez Perce-Clearwater currently provides. Climate change vulnerability data is taken from the Socioeconomic Climate Change Vulnerability Assessment (U.S. Department of Agriculture 2014e).

Clean Water and Water Supply

Clean water is one of the most highly valued benefits the Nez Perce-Clearwater provides. A survey of the public in the secondary social analysis area indicates that 93 percent of residents believe that protecting water quality is a very or extremely important purpose of their local, federal public lands (Bureau of Business and Economic Research 2018). Public commenters also noted the importance of clean water as an important benefit the Nez Perce-Clearwater provides. The Nez Perce-Clearwater provides benefits to towns in the region that rely on surface water for municipal use. Clean water also benefits the recreational and consumptive fishermen who fish for trout and salmon, which require relatively high-water quality to thrive. Availability of water is important not only for consumptive purposes and fishery habitats, but also for recreational activities and aesthetics, two other important benefits provided by the Nez Perce-Clearwater. Additionally, groundwater is very important (U.S. Department of Agriculture 2014e).

County resource plans highlight water quality as a key benefit and note that although many waterways are high functioning, there are streams and lakes that are impaired. The counties advocate for watersheds to be managed for a high level of water quality and suggest that federal land managers focus on restoration of impaired streams and lakes. County plans also note forest road construction, recreational activities, grazing, and timber harvest activities as potentially having negative effects on water quality.

National surveys also indicate that the majority of Americans feel that protecting water quality is a very or extremely important purpose of federal public lands, and a particularly important purpose of primitive and Wilderness areas (Cordell et al. 2005). Younger generations are most likely to identify ecosystem protection values such as protecting water quality as a very or extremely important purpose of federal, public wildlands (Rasch 2018).

Clean water and water supply were identified as highly vulnerable to climate change due to projected rising temperatures, reduced snowpack leading to lower flows in the dry seasons, and increased sedimentation due to earlier snowmelt and increases in wildfire activity. The ability of communities within the primary social analysis area to adapt to climate stressors on water supply and quality is moderate due to the high costs of water treatment and obtaining alternative sources of water in rural areas (U.S. Department of Agriculture 2014e).

The population in the primary analysis area increased by 30 percent over the past 50 years (U.S. Department of Agriculture 2014e). With any increase in population, both consumptive and non-consumptive water use is expected to increase, adding further pressure on the water supply.

Clean Air

Clean air is one of the most highly valued benefits the Nez Perce-Clearwater provides. A survey of the public in the secondary social analysis area indicates that 92 percent of residents believe that protecting air quality is a very or extremely important purpose of their local, federal public lands (Bureau of Business and Economic Research 2018). Most air quality concerns expressed by the public related to the occurrence, intensity, and frequency of wildfires in the region. Good air quality is important for public health, viewsheds, and recreational experiences (U.S. Department of Agriculture 2014e).

County plans list air quality as a key benefit and note the impacts of wildfire and prescribed burning on the ability of agricultural businesses to conduct field burning. Idaho County advocates for coordination of federal prescribed burns with the county to minimize impacts to agriculture businesses (U.S. Department of Agriculture 2014e).

Clean air was identified as moderately to highly vulnerable to climate change due to projected increases in wildfire activity and related smoke. The communities within the primary social analysis area are only moderately vulnerable, as air quality is only likely to be negatively affected by smoke in July, August, and September. Smoke from wildland fire, and agricultural burning does linger for days during the summer months and could impact recreational activities in the area (U.S. Department of Agriculture 2014e, b).

The ability of communities within the primary social analysis area to adapt to climate stressors on air quality is deemed very high. The Idaho Department of Environmental Quality and the Nez Perce Tribe regulate agricultural burning throughout the year while working with the Western Montana and North Idaho Airshed Group to coordinate projects and control potential air quality effects from each prescribed burn. The Nez Perce-Clearwater has the ability to time prescribed burns when they should have the least impact on air quality and to conduct fuel treatments designed to reduce the extent and duration of wildfires and the associated smoke (U.S. Department of Agriculture 2014e, b).

Wood products

Wood products are an important benefit for the communities surrounding the Nez Perce-Clearwater and for the timber industry in Idaho. A survey of the public in the secondary social analysis area indicates that 37 percent of residents believe that providing income to the timber industry is a very or extremely important purpose of their local, federal public lands (Bureau of Business and Economic Research 2018). Public commenters also noted the importance of wood products to local businesses and communities. The harvesting and processing of timber provide jobs and are part of the culture of the area. 60 percent of rural residents in the secondary analysis area report collecting firewood from local, federal public lands on an annual basis and 13 percent note that they harvest timber from local, federal public lands each year (University of Montana 2019).

County plans advocate for protecting traditional economic structures, including timber, and promote multiple uses of natural resources. Idaho County advocates for vegetation treatments that improve forest health, reduce wildfire risk, and provide a sustainable flow of commodities. Idaho County also advocates for harvesting dead and dying trees to recover their economic value. Latah County advocates for sustainable harvest practices and notes that unsustainable harvesting and resource conflicts could affect the long-term viability of timber harvest in the county.

Overall, wood products are viewed as being moderately vulnerable to climate change due to projected increases in wildfires, insects, and disease. Where increased temperature coincides with possible decreased precipitation, which is predicted in the Interior West where the Nez Perce-Clearwater lies, forest growth is expected to be lower (Ryan et al. 2008). Warmer winters with more sporadic freezing and thawing would likely increase erosion and landslides on forest roads and reduce access for winter harvesting (Karl et al. 2009), increasing costs and likely reducing the supply of forest products (U.S. Department of Agriculture 2014e, b).

Non-climate stressors identified were timber prices and the demand for timber, industry infrastructure, debates over logging on national forests, and conflicts with protecting other resource values. Some communities in the primary analysis area derive a relatively large percentage of their employment from timber-related industries and are highly vulnerable to both climate-related and non-climate related stressors to wood products. The ability of communities within the primary social analysis area to adapt to stressors on wood products is moderate, with some ability of the Nez Perce-Clearwater to manage for resilience to fires and insects and the potential for the industry to adapt to changing species mixes over time (U.S. Department of Agriculture 2014e, b).

Forage

Range has been, and continues to be, an important use of the Nez Perce-Clearwater. Although rangeland provides a variety of ecosystem services, such as wildlife habitat, wildlife-associated recreation, watershed functions, carbon sequestration, and biodiversity conservation, these lands have primarily been managed for forage. County plans advocate for protecting traditional economic structures, including agriculture. Idaho County recognizes the importance of productive grasslands that provide forage for deer and elk as well as for grazing domestic livestock. Commenters also noted the importance of management to address invasive weeds.

The planning team identified the vulnerability of forage to climate change as uncertain due to the uncertainty around projected precipitation changes. More precipitation can benefit forage and increase management flexibility for livestock, but a warmer, drier climate leads to reduced annual forage production and stress to riparian areas. Other stressors identified were invasive weeds and wildfires. Wildland fire can be both a stressor and a benefit. It kills in-growth of trees, so it maintains grasslands. Also, wildfires will likely kill trees in sites that have converted from rangeland to forest, causing them to revert to rangeland (U.S. Department of Agriculture 2014e, b).

Some communities in the primary analysis area derive a relatively large percentage of their employment from range-related industries, operate with limited financial resources, and are highly vulnerable to climate-related stressors to rangelands. The ability of communities within the primary social analysis area to adapt to stressors on forage was identified as uncertain due to the uncertainty around changes in precipitation.

Hunting and Wildlife

Wildlife in the Nez Perce-Clearwater provides many benefits to the public, including consumptive uses, recreational and cultural uses, and non-use values. A survey of the public in the secondary social analysis area indicates that 87 percent of residents believe that protecting wildlife habitat is a very or extremely important purpose of their local, federal public lands (Bureau of Business and Economic Research 2018). Public commenters also noted the importance of protecting wildlife habitat and providing hunting opportunities as important benefits that the Nez Perce-Clearwater provides.

County plans advocate for protection of wildlife habitat, local historical customs and culture, and traditional economic structures, and promotion of multiple uses of natural resources, including enjoyment and recreation. Idaho County also notes the importance of wildlife and hunting to local economies and subsistence and advocate for management actions to protect wildlife habitat. Latah County notes that crop predation from deer and elk is a threat to maintaining productive agricultural lands. Latah County as notes that where feasible to protect wildlife habitat, planning efforts should work to decommission forest roads, avoid placing new roads that would fragment quality habitat, and protect corridors for wildlife to promote connectivity among high value habitats (U.S. Department of Agriculture 2014e, b).

Consumptive uses include big game hunting, trapping for fur, predator harvest, and hunting and trapping by the Nez Perce Tribe. Recreational and cultural uses include sport hunting, wildlife viewing, and cultural resources for the Nez Perce Tribe. Non-use values include existence values, the value people place on knowing the species exist although they may never see or use them, and bequest values, the value people place on knowing the species will be present for future generations to enjoy (U.S. Department of Agriculture 2014e, b).

The public enjoys a wide variety of wildlife species found in the Nez Perce-Clearwater. The main game species include elk, white-tailed deer, mule deer, moose, mountain goat, bighorn sheep, cougar, black bear, forest grouse, turkey, and chukar. The main species that are trapped by the public include American marten, bobcat, and wolf. Workshop participants mentioned that people enjoy viewing many bird and wildlife species in addition to those mentioned, and that viewing wildlife was one of the top five reasons people visit the Nez Perce-Clearwater according the National Visitor Use Monitoring Survey (https://apps.fs.usda.gov/nvum/results) (U.S. Department of Agriculture 2014e, b, n).https://apps.fs.usda.gov/nvum/results) (U.S. Department of Agriculture 2014e, n, b).https://apps.fs.usda.gov/nvum/results) (U.S. Department of Agriculture 2014e, n, b).

Wildlife and hunting are viewed as being moderately to highly vulnerable to climate change. Hunting and trapping were seen as more vulnerable to the impacts of climate change, with warmer temperatures and less precipitation affecting hunter success and pelt quality. Some anticipated climate changes may benefit some species, for example, as more frequent wildfires open up grasslands for ungulate forage, or decreased snow depth allows for more winter forage and higher survival rates (U.S. Department of Agriculture 2014e, b, n) .

Wildlife viewing is less vulnerable to climate change impacts because it would most likely result in a different mix of species, as habitat types and species' ranges shift over time. So, if forest visitors enjoy viewing wildlife in general, viewing would not be impacted as much as if they wished to view only certain species (U.S. Department of Agriculture 2014e, c, n).

Non-climate stressors also varied by the type of use. For consumptive wildlife uses, fire suppression and invasive plant species were viewed as limiting big game forage and hunting opportunities. Fire suppression benefits furbearers, however. For wildlife viewing, the non-climate stressors perceived to have the greatest impact were: 1) hunting and trapping, which make animals more wary of humans and reduce viewing opportunities, 2) invasive species, which change the species composition and availability of forage for native wildlife, 3) off-highway vehicle use, which displaces wildlife that people are interested in viewing, and 4) major transportation corridors, which act as sources of mortality and barriers to dispersal. Other stressors mentioned included agriculture, grazing, pollution and poison, land use conversion, energy production, and logging (U.S. Department of Agriculture 2014e, n, c).

For communities in the primary and secondary analysis area, hunting and wildlife viewing are integrated into the culture and economy, serving as recreation, subsistence and employment for local outfitters and businesses reliant on the tourism industry. Changes to species composition, abundance, and distribution in the Nez Perce-Clearwater could have significant effects on many residents' way of life. Communities are thus highly vulnerable to climate-related stressors to wildlife and hunting opportunities. The population in the primary analysis area increased by 30 percent over past 50 years (U.S. Department of Agriculture 2014e, n, c). With any increase in population, both consumptive and non-consumptive uses of wildlife are expected to increase. The ability of communities within the primary social analysis area to adapt to stressors on wildlife is moderate, with some ability of the Nez Perce-Clearwater to improve habitat and limit negative impacts to habitat from logging, grazing and recreation (U.S. Department of Agriculture 2014e, n).

Fish

Fish are a highly valued Nez Perce-Clearwater resource, benefiting anglers, the Nez Perce tribe, and local businesses. The lakes and streams of the Nez Perce-Clearwater support many species of anadromous fish, defined as fish born in freshwater that spend time at sea and return to freshwater to spawn, and resident fish, including several species of trout, bass, and salmon, which are valued by the public for a wide variety of consumptive and non-consumptive uses. The opportunity to fish for and harvest salmon and steelhead, as well as the catch-and-release fisheries associated with the Selway River, Lochsa River, and Kelly Creek attracts anglers locally and from across the country. Fish are also an important cultural resource for the Nez Perce Tribe (U.S. Department of Agriculture 2014e, c, h).

County plans advocate for protecting fisheries and riparian habitat, protecting local historical customs and culture related to fishing, protecting traditional economic structures, opening new economic opportunities, and promoting multiple uses of natural resources, including enjoyment and recreation. Idaho County advocates for fisheries resources to be increased to 50 percent of historic levels and be managed to meet recreational needs.

Fish were viewed as very vulnerable to climate change, with the potential to be impacted by a wide variety of climate-related changes including stream temperatures, high flows and runoff, drought, snowpack depth, timing of snowmelt runoff, low instream flows, high lentic (still water) and lotic (running water) temperatures, wildfire, and ocean conditions. Fish were viewed as sensitive to the following non-climate stressors, in order of decreasing sensitivity: dams, transportation corridors, mining, logging, livestock grazing, fire suppression, and recreation. Exposure was highest for recreation, fire suppression, transportation corridors, and logging (U.S. Department of Agriculture 2014e, n).

For communities in the primary and secondary analysis area, fish are integrated into the culture and economy, serving as recreation, subsistence and employment for local outfitters, fishermen and businesses reliant on the tourism industry. Changes to species composition, abundance, and distribution of fish on the Nez Perce-Clearwater could have significant effects on many residents' way of life. Communities are thus extremely vulnerable to both climate-related and non-climate-related stressors to fish and fishing opportunities. The population in the primary analysis area increased by 30 percent over the past 50 years (U.S. Department of Agriculture 2014e, h, c). With any increase in population, both consumptive and non-consumptive uses of fish are expected to increase. The ability of communities within the primary social analysis area to adapt to climate stressors on fish is low, with some ability of the Nez Perce-Clearwater to complete stream restoration projects and limit negative impacts to habitat from mining, logging, grazing, recreation, fuels management and fire suppression (U.S. Department of Agriculture 2014e, n). For more information on fish resources, please see the 'Aquatic Ecosystems and Fisheries' analysis.

Cultural Values

Though difficult to quantify, cultural and heritage values of the Nez Perce-Clearwater are important benefits. These include an array of benefits to those living within the primary and secondary social analysis areas and those in the larger landscape. These benefits include values held by subsistence food gatherers and hunters, spiritual values held by Tribes and others religiously associated with the Nez Perce-Clearwater, recreationists seeking adventure and solitude, local people's sense of place and well-being, relationships to cultural and historic resources, and the inspiration and health benefits the Nez Perce-Clearwater provide to both visitors and those who do not visit the Nez Perce-Clearwater, but place a high value on knowing that the Nez Perce-Clearwater and its wild rivers and landscapes exist (Bowker et al. 2006, Cole 2005). For the purposes of this analysis, cultural values are discussed in three sections: inspiration and health, traditional industries, and tribal concerns.

Inspiration and Health

In both rural and more developed areas of the secondary social analysis area, residents have strong connections to the Nez Perce-Clearwater. Public commenters noted the importance of preserving certain landscapes and rivers on the Nez Perce-Clearwater to maintain their sense of place and connection to those places. Others note the importance of preserving historic properties and cultural artifacts. National and even international communities also are inspired by areas on the Nez Perce-Clearwater, especially designated areas such as Wilderness and Wild and Scenic Rivers. Other commenters noted the importance of accessing areas they value through different modes of transportation including motorized and mechanized access. Commenters held diverse perspectives on which areas should be preserved for non-motorized and mechanized access, and which areas should be open to all modes of transportation.

A survey of the public in the secondary social analysis area indicates that 85 percent of residents indicated that "knowing that future generations would have primitive or wilderness" is a very or extremely important purpose of their local, federal public lands. Seventy-six percent indicated that "knowing primitive or wilderness areas exist" is very or extremely important purpose of their local, federal public lands. Forty-nine percent noted that spiritual inspiration is a very or extremely important purpose of their local, federal public lands (Bureau of Business and Economic Research 2018). Public commenters also noted the importance of preserving primitive areas as an important benefit the Nez Perce-Clearwater provides. National surveys also indicate that the majority of Americans feel that knowing that future generations would have primitive or wilderness areas is a very or extremely important purpose of federal public lands (Cordell et al. 2005).

Connections to the Nez Perce-Clearwater also provide people with health benefits such as relaxation, stress reduction and general well-being. Forest bathing and nature therapy are acknowledged in public health literature as powerful methods for stress reduction and increasing well-being. Immersion in nature has been associated with positive effects to:

(1) the immune system function (increase in natural killer cells/cancer prevention); (2) cardiovascular system (hypertension/coronary artery disease); (3) the respiratory system (allergies and respiratory disease); (4) depression and anxiety (mood disorders and stress); (5) mental relaxation (Attention Deficit/Hyperactivity Disorder) and (6) human feelings of "awe" (increase in gratitude and selflessness). (Hansen et al. 2017).

Traditional Industries

Cultural values also include contributions to people's sense of place through participation in traditional industries and activities including mining, timber, agriculture, tourism, and recreation. In some communities, these industries contribute to people's sense of place as these activities have been part of the culture for generations (U.S. Department of Agriculture 2014e, h). County plans include principles that relate to preservation of cultural values including protecting of local historical customs and culture, protecting of traditional economic structures, maintaining rural lifestyles and character, maintaining an agrarian way of life, and promoting multiple uses of natural resources, including enjoyment and recreation. The Idaho County plan also notes the importance of mining to local community members' sense of place and connection to their heritage, as well as to local economies.

Maintaining traditional industries, providing opportunities for cultural activities, and increasing public access could be complicated by the increased stress added to forest resources from climate change and increasing demand for different, competing uses. The population in the primary analysis area increased by 30 percent over the past 50 years. Demand for cultural activities is expected to continue to increase in the future (U.S. Department of Agriculture 2014e, n, h). Visitation to Wilderness areas is expected to rise in the coming decades, particularly to areas relatively close to metropolitan areas, such as the Nez Perce-Clearwater (Rasch and Hahn 2018). This may create added stress to primitive landscapes and affect the ability of the Nez Perce-Clearwater to provide cultural values including opportunities for solitude and inspiration.

Tribal concerns

There are large Native American populations within the primary analysis area with ties to the lands and waters of the Nez Perce-Clearwater. In addition to the tribal trust responsibility of the Nez Perce-Clearwater, tribal concerns can be unique to specific tribes, including traditions and histories and, in this case, uses of Nez Perce-Clearwater resources. Examples include use of an array of wildlife species to create cultural artifacts for cultural ceremonies, interests in maintaining access to sacred spaces, protections of sacred species and honoring all treaty rights. Ecosystem services are also a concern because they contribute to traditional market and non-market economic activities that preserve and sustain the culture and tribal members and communities. For detailed information on tribal concerns, please see the Tribal Trust Responsibilities analysis.

The ability of communities within the primary social analysis area to adapt to climate stressors on cultural values was uncertain, with some ability of the Nez Perce-Clearwater to engage in restoration and conservation actions that can enhance resilience and increase the ability of the public to use and enjoy important forest resources (U.S. Department of Agriculture 2014e, n, g).

Native American communities in the area may be particularly vulnerable to climate-related shifts in opportunities to express cultural values and engage in traditional activities. This is because certain locations are sacred and cannot be substituted. Additionally, some may not have sufficient resources to travel to different areas should their local area no longer provide ample opportunities for subsistence hunting and gathering, or climate change may alter historical wildlife movements and availability of important forage species.

For more information on cultural values resources, please see the Tribal Trust Responsibilities, Human Uses of the Nez Perce-Clearwater, Production of Natural Resources, and Designated and Proposed Areas sections and analyses.

Aesthetics (Scenery)

Many areas of the Nez Perce-Clearwater are enjoyed for their scenic beauty. A survey of the public in the secondary social analysis area indicates that 78 percent of residents believe that providing scenic beauty is a very or extremely important purpose of their local, federal public lands (Bureau of Business and Economic Research 2018). Public commenters also noted that scenery was an important benefit the Nez Perce-Clearwater provides and contributes to their sense of place. Increases in forest disturbances, such as wildfires, insects, or disease can affect viewsheds – both the character of the landscape and the vantage points from which visitors experience the scenery. Scenery is vulnerable to climate change to the extent that climate change increases forest disturbances. Disturbances, such as insects, tree disease and wildfire, can impact recreation experiences, and perhaps visitation numbers. Driving for pleasure to enjoy the view is one of the top activities among visitors to the Nez Perce-Clearwater.[29] Aesthetics and the natural resource-based amenities of an area have been shown to contribute to population growth and economic development. Also, studies have found a positive effect on sales prices of homes located near National Forest lands *(Cho et al. 2009, Hand et al. 2008, Kim and Johnson 2002).* Changes in the viewsheds due to insects and disease could change the value of property in proximity to the Nez Perce-Clearwater *(U.S. Department of Agriculture 2014e, n, h).*

County plans note the importance of protecting the aesthetic values the Nez Perce-Clearwater provides. The ability of communities within the primary social analysis area to adapt to climate stressors on scenery was uncertain, with some ability of the Nez Perce-Clearwater to increase restoration efforts which have the potential to reduce negative impacts of forest disturbances on scenery (U.S. Department of Agriculture 2014e, n, h).

Recreation

Recreation on the Nez Perce-Clearwater is characterized by the vast, wild, and remote landscapes that support nature-based recreation activities that depend on water, snow, fisheries, and wildlife. A survey of the public in the secondary social analysis area indicates that 67 percent of residents believe that providing recreational opportunities is a very or extremely important purpose of their local, federal public lands (Bureau of Business and Economic Research 2018). Public commenters also noted the importance of recreation to their quality of life, well-being, local businesses, and the ability of communities to attract new businesses and residents.

Local residents in the secondary analysis area enjoy a range of recreation activities and the majority of residents participate in the following activities on an annual basis: hiking, relaxing, wildlife viewing, driving for pleasure, camping, fishing, picnicking, and foraging. Survey respondents were asked to indicate if they feel that there are "too few," an "adequate amount," "too many," or "don't know" of various types of recreational opportunities. A minority of local survey respondents in the secondary analysis area noted that the level of accessible sites, all-terrain vehicle trails, areas open to snowmobiles, and mountain bike trails are not adequate (Figure 176). Those in rural areas were more likely to note that current motorized access opportunities were not sufficient (Bureau of Business and Economic Research 2018, University of Montana 2019).

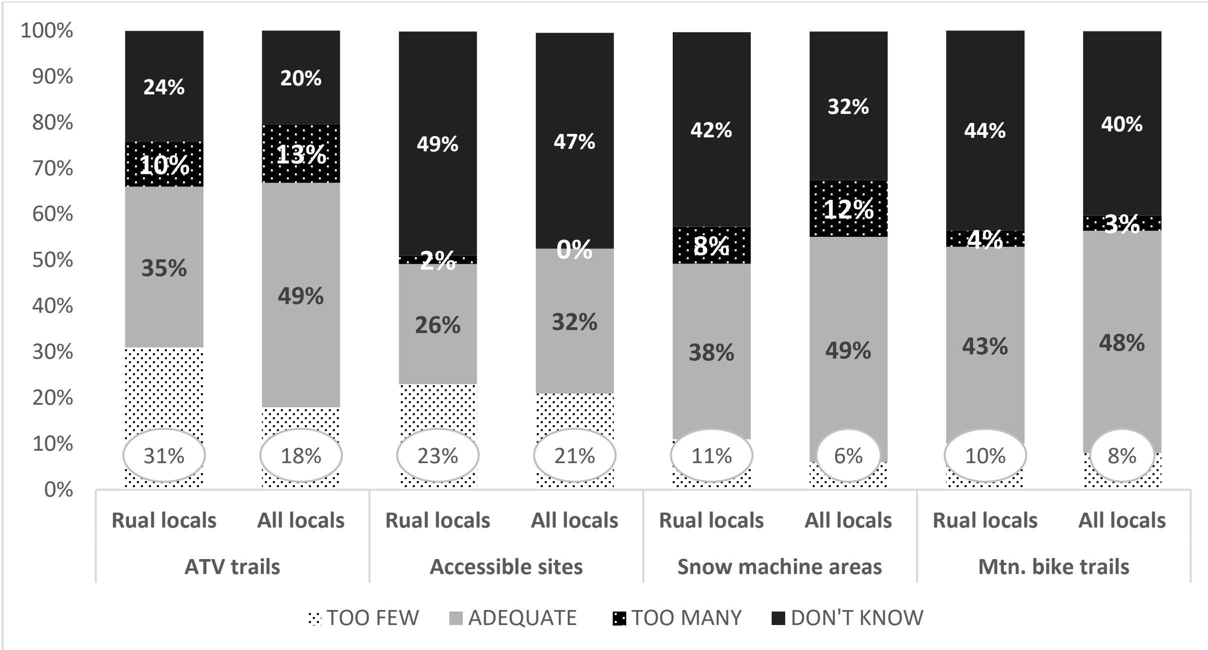

Figure 176. Residents' perceptions of the adequacy of motorized, mechanized, and wheelchair accessible facilities on federal lands in the local area

Data Source: Region 1 Social Survey, BBER, 2018; Region 1 Social Survey Year 2 only, BBER, 2019.

County plans note the importance of land and water recreation and tourism to both local economies and the well-being of residents. Idaho County also advocates for an increase in semi-primitive motorized opportunities as well as non-motorized opportunities including trails for hiking, horseback riding, mountain biking, cross-county skiing, and snowshoeing. Recreation is considered moderately vulnerable to climate change. Snow- and ice-dependent activities could be adversely affected by even small increases in temperature, especially in areas with marginal snow conditions. Snowmobiling, which depends wholly on natural snowfall and often occurs in lower-elevation areas, is vulnerable to decreases in snowfall (U.S. Department of Agriculture 2014e, n).

The desirability of nature-based activities such as hiking, river visits, and sightseeing for both scenery and wildlife viewing, may increase because of small near-term increases in temperature and the gradual development of longer warm weather seasons that may lead to longer access to natural settings and landscapes. Altered biodiversity and increases in wildfire and insect infestations, however, could adversely affect nature tourism. Viewing of wildlife, especially in critical habitat or recommended wilderness areas, and hunting opportunities could also change as animal habitats and perhaps even the viability of some species shift due to climate change (U.S. Department of Agriculture 2014e, n, h).

Lower water levels in reservoirs and rivers during the summer months could affect fishing and boating activities. However, warmer temperatures could lead to increased demand for water-related activities (Karl et al. 2009, Gamble et al. 2008) earlier in the spring and later in the fall. For communities in the primary and secondary analysis area, recreation is integrated into the culture and economy. A survey of the public in the secondary social analysis area indicates that 35 percent of residents believe that providing income to the tourism industry is a very or extremely important purpose of their local, federal public lands (Bureau of Business and Economic Research 2018).

Public commenters also noted the importance of providing recreation opportunities to support and expand recreation and tourism employment in local communities.

Changes to recreation opportunities could have significant effects on many residents' way of life and livelihoods. Communities are moderately vulnerable to climate-related stressors to recreation opportunities. The population in the primary analysis area increased by 30 percent over the past 50 years (U.S. Department of Agriculture 2014e, n). With any increase in population, recreational uses of the Nez Perce-Clearwater are expected to increase. The ability of communities within the primary social analysis area to adapt to climate stressors on recreation is moderate, with some ability of the Nez Perce-Clearwater to extend guiding and permitted water and snow-based activity seasons to coincide with changes in water flows and elevation of snow (U.S. Department of Agriculture 2014e, n, h).

Flood Control

Flood protection is an important regulating ecosystem service provided by the Nez Perce-Clearwater. Large trees break up heavy rainfall, surface duff layers encourage moisture to infiltrate the soil, soil organic matter and established root systems assist in absorbing water, and permeable soils allow surface water to soak in and recharge groundwater resources. Flood protection was viewed as important for preserving infrastructure, property, and fish habitat (U.S. Department of Agriculture 2014e, n, h).

County plans advocate for providing for the safety of county residents from flooding. Flood control was considered to have moderate vulnerability to climate change. Changes in the magnitude and frequency of extreme disturbance events are the largest factors behind future flooding frequency. Though fire suppression and dams and diversions were listed as non-climate stressors, they were identified as having positive rather than negative effects. Dams ameliorate floods by storing water. Wildfires can cause soils to be temporarily hydrophobic, or incapable of absorbing water, which leads to water collection on soil surface, increased surface runoff, and erosion in post-burn sites. Fire suppression is seen as positive since it can prevent hydrophobicity, allowing moisture to infiltrate soils and reducing runoff and erosion (U.S. Department of Agriculture 2014e, n, h).

For communities in the primary analysis area, flood control is an important benefit that the Nez Perce-Clearwater provides. Continuing urbanization and increasing construction of second homes in forested settings have expanded the area of the wildland-urban interface, causing increased concerns about protection from wildfire and potential post-fire landslides and flooding (Jones et al. 2009). Compared to other western states, the percentage of wildland-urban interface areas with homes is relatively low for the areas surrounding the Nez Perce-Clearwater – 4.7 percent contained houses in 2010. For comparison, the wildland urban interface areas occupied by houses was 12.6 percent for the state of Idaho. Although this means lower community exposure now, as populations grow and residential development in the five-county area continues to expand, exposure to floods could increase significantly (U.S. Department of Agriculture 2014e, n, h).

The ability of communities within the primary social analysis area to adapt to climate stressors on flood control was concerned low, but also highly uncertain. The Nez Perce-Clearwater may have some ability to reduce wildfire severity disturbance through restoration activities (U.S. Department of Agriculture 2014e, n, h).

Soil Stabilization and Landslide Protection

Soil stabilization and landslide protection were viewed as highly valuable benefits of the Forests Nez Perce-Clearwater that prevent damage to nature resources, property, and infrastructure. Soil stabilization and landslide protection was viewed as moderately vulnerable to climate change. Climate change would likely lead to new patterns of snow melt, runoff, soil moisture, vegetation type and wildfire that could all have adverse effects on soil stabilization and landslides. Changes in precipitation and snowpack depth were also mentioned as having a lesser impact. Non-climate stressors contributing to vulnerability include logging, transportation corridors, and livestock grazing, and to a lesser extent invasive species, recreation, and fire suppression (U.S. Department of Agriculture 2014e, n, h).

The county plans note potential for soil erosion due to residential development, logging, and road construction. County plans advocate for soil conservation practices including reducing erosion, managing to reduce noxious weeds, and providing for the safety of county residents from flooding, fires, and landslides. Continuing urbanization and increasing construction of second homes in forested settings have expanded the area of the wildland-urban interface, causing increased concerns about protection from forest disturbances such as wildfire and landslides (Jones et al. 2009). This along with the location of several communities in lower slope positions lead to a high vulnerability rating (U.S. Department of Agriculture 2014e, n, h).

The ability of communities within the primary social analysis area to adapt to stressors on soil stabilization and landslide protection was rated as low. The expense of applying best management practices or moving transportation corridors and hurdles to changing timing of land management activities were all viewed as hindering adaptive capacity. The loss of the ash cap on area soils was noted as a critical turning point after which maintaining stable soils and preventing landslides would become considerably more difficult. Along with climate impacts, there is a wide range of non-climate stressors to consider, including logging, transportation corridors, livestock grazing, invasive species, and recreation. The Nez Perce-Clearwater could act to sustain or improve soil stabilization to avoid more costly measures later. These actions would involve a mix of creating more resilience to climate-driven factors such as increased rain-on-snow events and more intense runoff patterns, and minimizing impacts of non-climate disturbance such as logging and grazing (U.S. Department of Agriculture 2014e, n, h).

Environmental Consequences

The land management plan provides a programmatic framework that guides site-specific actions but does not authorize, fund, or carryout any project or activity. Because the land management plan does not authorize or mandate any site-specific projects or activities, including ground-disturbing actions, there can be no direct effects. However, there may be implications, or longer-term environmental consequences, of managing the Nez Perce-Clearwater under this programmatic framework.

The previous sections assessed the social conditions of the Affected Environment and the social benefits the Nez Perce-Clearwater provides. The Affected Environment section provides a baseline understanding of how the Nez Perce-Clearwater currently contributes to social sustainability for local beneficiaries and the public, where applicable. The key dimensions of social sustainability assessed are how the management of the Nez Perce-Clearwater contributes to the quality of life of the public. The following section considers the potential impacts of alternative management scenarios on these contributions. This section provides a summary of the expected impacts to the key social benefits the Nez Perce-Clearwater provides, and explores how those impacts may affect contributions to social sustainability. For more details and the complete analysis of effects to specific Nez Perce-Clearwater resources, please see the relevant resource analysis.

Effects Common to All Alternatives

Under all alternatives, the Nez Perce-Clearwater will continue to provide the full suite of social benefits which currently contribute to social sustainability, as described in the Affected Environment section. Over the life of the plan, no consequential adverse impacts are expected to the social conditions of the primary analysis area or to any of the key social benefits that the Nez Perce-Clearwater currently provides. For more details on each benefit, please see the relevant resource analysis.

Under all action alternatives, contributions to social sustainability are expected to be different than under the No Action Alternative. This is due to new management direction across resource areas focused, to varying degrees, on increasing areas suitable for timber production, increasing timber volume, increasing vegetation management through fuels treatments and harvest, and increasing opportunities for motorized and mechanized recreation. The relative contributions to social sustainability for local communities, national and international publics vary by alternative and by the preferences of these diverse publics.

Effects to Social Conditions

Under all alternatives, effects to the key indicators of population size, short-term population change, and long-term population change are expected to be minimal. The main way that the alternatives could potentially impact social conditions are impacts to quality of life, including employment opportunities. If quality of life improves, populations are expected to grow. Conversely, if quality of life declines, populations may begin to decline. No significant changes to social conditions are expected under the conditions of any alternative.

However, alternative X has the largest expected change to employment opportunities and may result in a short-term increase in populations in the primary analysis area. Given that employment opportunities affected by the alternatives comprise a small fraction of overall employment in the primary analysis area, any short-term gains in populations are not expected to significantly affect quality of life in the area.

Short-term population gains do have the potential to place added stresses on local public services such as primary and secondary education, infrastructure maintenance, policing, public safety, and affordable housing. The additional timber output expected in Alternative X may help ease the financial burden on local governments as county governments receive a portion of federal timber sale revenue to use for public services. For more information on effects to local jobs and income, please see the Economic Sustainability section.

Effects to Environmental Justice Communities

Under all alternatives, effects to environmental justice communities, or communities with environmental justice concerns, are expected to be minimal. The main way that the alternatives could potentially impact these communities is to impacts to quality of life, including increasing the cost of living or employment opportunities. Under all alternatives, no significant impacts to the quality of life or employment opportunities available in environmental justice communities are expected because of alternatives. The relative contributions to the quality of life or employment opportunities available in environmental justice communities may vary across alternatives. Alternative X has the largest expected increase in employment opportunities so may result in more employment opportunities for low-income, environmental justice communities. The extent to which these communities would directly or indirectly benefit from the additional income and jobs will vary depending on where on the landscape projects occur, as well as the skill sets and desired employment types of people living in environmental justice communities. The relative contributions to the quality of life of tribal communities (minority and communities with environmental justice concerns) vary based on the unique interests and concerns of those tribal communities. For more information on how relative contributions to tribal communities vary by alternative, please see the Tribal Trust Responsibilities section.

Clean Water and Water Supply

Human populations in the primary analysis area are projected to continue to grow over the life of the plan. Therefore, demand for clean water is expected to increase. The No Action Alternative does not take climate change into account and does not incorporate as much detail and clarity regarding the conditions and management of watersheds as the action alternatives. Thus, contributions to the integrity and resilience of watersheds are expected to be less robust under the No Action Alternative, compared to action Alternatives W, X, and Y. Contributions would be highest under Alternative X, followed by Alternative W, then Y and then Z. These differences across action alternatives are mainly a function of the variations in level of proposed restoration across action alternatives. The proposed levels of watershed restoration are similar for the No Action Alternative and Alternative Z, so contributions from the No Action Alternative and Alternative Z are expected to be similar. The higher levels of expected timber harvest and motorized use under Alternative X are not expected to reduce the magnitude of the Nez Perce-Clearwater's contributions to clean water as best management practices will be implemented in road and trail construction and maintenance.

Clean Air

Clean air is an important benefit to local communities, both for the health of the local public, and for its role in facilitating a robust outdoor recreation tourism industry, which is an economic driver in some communities. While acres of expected prescribed fire vary by alternative, at the forest scale, prescribed fire is not expected to contribute to significant differences in effects to air quality across alternatives. Wildfire is expected to be the largest contributing factor to air quality across alternatives. Within recommended wilderness areas and suitable wild and scenic river corridors, wildfire is expected to be managed for resource benefit, which may result in more smoke impacts in local communities. The more acres managed as recommended wilderness and suitable wild and scenic river corridors, the greater the potential for increased smoke effects from managed wildfire. Therefore, contributions to clean air are expected to be highest under Alternative X, followed by the No Action alternative, then Alternative Y and then Alternative Z. Contributions may be lowest under Alternative W. These differences across alternatives are a function of the variation in level of recommended wilderness and suitable wild and scenic river corridors across alternatives.

Wood Products

Wood products remain an important benefit to local communities, both as an economic driver in some communities and as a contribution to sense of place and local heritage to those who may not directly benefit from economic opportunities in the wood products industries. Contributions would be highest under Alternative X, followed by Alternative W, Y, and then Z. Contributions would be lowest under the No Action Alternative. These differences across alternatives are mainly a function of the variation in level of acres suitable for harvest and the level of proposed timber harvest activities across alternatives. Opportunities for collecting firewood are not expected to vary across alternatives.

Forage

Forage remains an important benefit to local communities, both as an economic driver in some communities and as a contribution to sense of place and local heritage to those who may not directly benefit from economic opportunities in ranching industries. Contributions would be highest under Alternative X, followed by Alternative W, Y, and then Z. Contributions would be lowest under the No Action Alternative. These differences across alternatives are mainly a function of the level of active management proposed that is expected to maintain and enhance forage productivity and availability. Variations in contributions across alternatives are also a function of the levels of recommended wilderness and suitable wild and scenic rivers within active grazing allotments. These management allocations add complexity to the management of livestock and may negatively impact some grazing permittees' abilities to parsimoniously access and maintain their grazing allotments.

Hunting and Wildlife

Human populations in the primary analysis area are projected to continue to grow over the life of the plan. Therefore, demand for hunting and wildlife viewing opportunities are expected to increase. Contributions to hunting and wildlife viewing opportunities vary by alternative and by species of interest. For elk, mule deer, moose, wolf, cougar, grouse, turkey, weasel, badger, and some birds that enjoy non-forested or early seral habitats, contributions would be greatest under Alternative X, followed by Alternative W, then Alternative Y. The No Action Alternative and Alternative Z are expected to contribute the least to opportunities for hunting or viewing of these species, compared to the other alternatives. These differences across alternatives are mainly a function of the level of active management proposed that is expected to maintain and enhance species' habitats, forage availability, and prey populations.

Alternatives with higher levels of active forest management are also expected to increase forest openings, which, in turn, are expected to provide more opportunities for viewing terrestrial wildlife and birds. Contributions are expected to be similar across all alternatives for hunting, trapping, and viewing bighorn sheep, snowshoe hare, chukar, river otter, red fox, mink, skunk, raccoon, beaver, and aquatic birds as plan components across alternatives provide similar protections for their riparian and aquatic habitats. Some forest birds prefer dense, closed forests. Contributions to viewing opportunities for birds which prefer a closed forest structure would be highest under the No Action Alternative or Alternative Z, followed by Alternative Y, then Alternative W, and lowest under Alternative X. Bobcat, American marten, black bear, and mountain goat each have their own unique habitat preferences and considerations. For the relative contributions to opportunities for hunting and viewing these species, please see the summary chart in the Summary of Consequences section of this analysis.

Fish

Human populations in the primary analysis area are projected to continue to grow over the life of the plan. Therefore, demand for fish and healthy fisheries are expected to increase. The No Action Alternative does not take climate change into account and does not incorporate as much detail and clarity regarding the conditions and management of fisheries as the action alternatives. Thus, contributions to the integrity and resilience of fisheries are expected to be less robust under the No Action Alternative, compared to action Alternatives W, X, and Y. Contributions would be highest under Alternative X, followed by Alternative W, then Y and then Z. These differences across action alternatives are mainly a function of the variations in the objectives for proposed level of aquatic restoration across action alternatives. The proposed levels of restoration are similar for the No Action Alternative and Alternative Z so contributions from each are expected to be similar.

Cultural Values

Inspiration and Health

Local, national, and even international publics highly value the opportunities the Nez Perce-Clearwater provides to be inspired by nature and wild places. The health benefits of experiencing these special places, either directly through visitation, or indirectly through photography and just knowing wild places exist are well documented. Opportunities for inspiration and to enjoy the health benefits of experiencing pristine, natural environments in quiet, primitive settings vary by alternative. Contributions are expected to be greatest under the No Action Alternative, followed by Alternatives Y and Z, which are similar, then Alternative W and lowest under Alternative X.

These differences across alternatives are, in part, a function of the variation in level of proposed recommended wilderness, wild and scenic rivers, and the variation in allowable uses such as motorized uses in these areas and in Idaho Roadless Areas. For example, Alternative W allocates the most acres as recommended wilderness but also allows for a significant increase in motorized use in Idaho Roadless Areas, resulting in a net loss of primitive areas available for quiet recreation. Mechanized and motorized use in primitive areas may disturb those seeking solitude, quiet recreation settings, and opportunities for forest bathing therapies. Differences across alternatives are also due to variation in proposed level of active management. Increased timber outputs are expected to increase commercial traffic on roads, which may affect people's ability to access areas of the Nez Perce-Clearwater during harvest activities. Under Alternative W, commercial traffic is expected to quadruple, compared to the No Action Alternative. Commercial traffic is expected to more than quadruple under Alternative X and double under Alternatives Y and Z.

Historic properties are also an important benefit to local, national, and even international communities as they contribute to opportunities for inspiration, connecting to the land, preservation of heritages, and opportunities for tourism. Contributions would be highest under Alternative Z, followed by the No Action Alternative. Contributions under Alternatives W and Y would be moderate and lowest under Alternative X. These differences across alternatives are, in part, a function of the variation in level of proposed motorized use across alternatives and the resulting risk of disturbance to historic resources. These differences across alternatives are also due to variation in level of proposed timber harvest. More harvest is expected to have a positive effect on preservation of historic properties as harvest activities generally increase opportunities to formally evaluate historic resources within a project area. Harvest activities may also remove hazardous fuels, making properties more defensible in the event of a future wildland fire.

Land-based Livelihoods

Timber, grazing, mining, and recreation are part of the cultural heritage of some local communities in the primary analysis area. Opportunities for timber, grazing, mining, and recreation vary across alternatives. Timber, grazing, and recreation opportunities are described under the wood products, forage, and recreation benefit sections, respectively. The amount of land on the Nez Perce-Clearwater available for mineral entry, mineral disposal, and mineral leasing vary by alternative. Contributions to opportunities for mining are expected to be greatest under Alternative X, followed by the No Action Alternative, then Alternative Y, then Alternative Z. Alternative W is expected to provide the lowest relative contribution to mining opportunities. These differences across alternatives are, in part, a function of the variation in level of proposed recommended wilderness, suitable wild and scenic rivers, and the variation in allowable uses such as motorized and mechanized uses in these areas and in Idaho Roadless Areas. Differences are also a function of variations in plan components related to road creation, road decommissioning and restricting surface occupancy on future mineral projects.

Tribal Concerns

Contributions to tribes and tribal interests vary across alternatives and tribal communities as tribal concerns are unique to their own traditions, histories, and uses of Nez Perce-Clearwater resources. For detailed information on how the different alternatives may affect tribal concerns, please see the Tribal Trust Responsibilities section.

Aesthetics (Scenery)

Scenery is an important benefit to local communities, both as an economic driver in some communities and as a contribution to sense of place and local heritage. Scenery is important for tourism and attracting business and new residents to the area. Contributions vary by alternative. Alternative W provides the highest contributions, followed by Alternatives Y and Z, and then the No Action Alternative. Alternative X provides the lowest contribution. These differences across alternatives are mainly a function of the variation in level of proposed recommended Wilderness, suitable wild and scenic rivers, research natural areas, and significant special areas such as the Lolo Trail National Historic Landmark. Scenic integrity objectives are higher is these areas.

Recreation

Recreation is an important benefit to local communities, national publics, and even international publics. Recreation is as an economic driver in some communities that contributes to a sense of place and local heritage and provides opportunities for exercise and stress relief, which in turn contributes to human health. Recreation opportunities are also important for tourism and attracting new residents to communities within the primary analysis area. As human populations continue to grow, there will be added pressure on existing opportunities, potential for crowding, and limitations on opportunities for solitude in more popular locations.

Contributions vary depending on the type of recreation opportunities people prefer. For those most interested in motorized opportunities, Alternative X provides the highest contributions, followed by Alternatives W, Y and Z, which provide fewer opportunities compared to Alterative X. The No Action Alternative provides the least motorized opportunities. For those most interested in mechanized opportunities such as mountain biking, Alternative X provides the highest contributions, followed by the No Action Alternative and Alternative Z, which provide fewer opportunities compared to Alternative X. Alternative Y provides less that the No Action Alternative and Alternative Z and Alternative W provides the least mechanized opportunities. For those most interested in quiet recreation opportunities such as opportunities for solitude in wild places, the No Action Alternative provides the highest contributions, followed by Alternatives Y and Z, which provide fewer opportunities compared to the No Action Alternative. Alternative W provides less that Alternatives Y and Z, and Alternative X provides the least amount of quiet recreation opportunities. These differences across alternatives are mainly due to variation in level of proposed recommended Wilderness and variation in plan components which allow or do not allow different types of uses, such as mountain biking and motorized uses, in Idaho Roadless Areas and recommended Wilderness areas.

Flood Control, Soil Stabilization and Landslide Protection

Human populations in the primary analysis area are projected to continue to grow over the life of the plan. Therefore, more residential development near the Nez Perce-Clearwater and more exposure to flooding and landslides are expected. Great traffic volume is also expected as the human population increases, which can impact roads. The No Action Alternative does not take climate change into account and does not incorporate as much detail and clarity regarding the conditions and management of soils and roads as the action alternatives. Thus, contributions to the integrity, stability and resilience of soils are expected to be less robust under the No Action Alternative when compared to action Alternatives W, X and Y. Contributions would be highest under Alternative X, followed by Alternative W, then Y and then Z. These differences across action alternatives are mainly a function of the variations in level of proposed road maintenance and restoration across action alternatives. The proposed levels of restoration are similar for the No Action Alternative and Alternative Z so contributions from each are expected to be similar.

Cumulative Effects

Societal trends of population growth, urbanization, and growth in travel and tourism in the primary and secondary analysis areas may impact the Nez Perce-Clearwater's ability to contribute to social sustainability over the next 10 to 15 years. Based on the review of county plans, as referenced in the Affected Environment section, cumulative effects to the Nez Perce-Clearwater's ability to contribute to social sustainability over the next 10 to 15 years are not expected from the implementation of county natural resource and conservation plans. Minor long-term population growth within the primary analysis is likely to have minimal effects on the Nez Perce-Clearwater's ability to contribute to social sustainability. However, substantial population growth in nearby urban areas that promote an outdoor recreation-based lifestyle and culture to attract new residents, such as Missoula, Spokane, and Boise, is likely to create increasing demand for Nez Perce-Clearwater recreation opportunities and may lead to crowding and traffic in some areas, thereby affecting the quality of life of local residents. All action alternatives considered population growth, urbanization and increasing pressures from tourism, and are designed to mitigate resource impacts from these known stressors.

Summary of Consequences

Because no significant changes to social conditions are expected under any of the alternatives, including the preferred alternative, the Nez Perce-Clearwater would continue to provide the full suite of social benefits which currently contribute to social sustainability, as described in the Affected Environment section. The relative magnitude of contributions to social sustainability varies by alternative.

Given the diversity of management preferences across both local and national stakeholder groups, it is not possible to unequivocally identify which alternative provides the greatest overall contribution to social sustainability for all stakeholders. The No Action Alternative is likely to provide the greatest contributions to those who prioritize quiet recreation opportunities and inspirational and health benefits of the Nez Perce-Clearwater. Alternative X is likely to provide the greatest contributions to those who prioritize active vegetation management, motorized and mechanized recreation, timber volume, timber industry jobs, grazing opportunities, opportunities for energy and mineral extraction, and active restoration of aquatic and terrestrial habitats. Alternatives W, Y and Z provide a mix of contributions to social sustainability across all stakeholder groups. The preferred alternative will likely provide no net change in the contributions the Nez Perce-Clearwater makes to social sustainability because those that prioritize quiet recreation opportunities and inspirational and health benefits both gain and lose area they more readily affiliate with these goals and those that prioritize active vegetation management, motorized and mechanized recreation, timber volume, timber industry jobs, grazing opportunities, opportunities for energy and mineral extraction, and active restoration of aquatic and terrestrial habitats similarly gain and lose areas they more readily affiliate with these goals. In sum, there will be limited changes to social sustainability with the preferred alternative.

Table 462 summarizes potential effects to social conditions by alternative. Potential consequences to high minority environmental justice communities varies by tribal interests and community; see Tribal Trust analysis. Potential consequences to high poverty communities vary from Alternative X (highest), Alternative W, Alternative Y, Alternative Z, the Preferred action, to No Action Alternative (least).

Table 462. Summary of potential consequences to social conditions by alternative (Alt)

Measurement Indicator	No Action	Alt W	Alt X	Alt Y	Alt Z	Preferred
Population size	No effect	No effect	No effect	No effect	No effect	No effect
Short-term population change	No effect	No effect	Potential short-term population increase	No effect	No effect	No effect
Long-term population change	No effect	No effect	No effect	No effect	No effect	No effect

Chapter 4. Concluding Information and Disclosures

4.1 Unavoidable Adverse Effects

Neither the proposed Land Management Plan nor the existing Forest Plans produce unavoidable adverse effects because they do not directly implement any management activities that would result in such effects. However, the forest plans do establish management emphasis and direction for implementation of activities that may occur on National Forest System lands in the planning period. If those activities occur, the application of forestwide and management area standards and guidelines, as described in the Land Management Plan, would limit the extent and duration of any resulting environmental effects. Some unavoidable effects could still occur; however, these potential effects are described by resource area throughout Chapter 3 of this Nez Perce-Clearwater National Forests Final Environmental Impact Statement, primarily under "Environmental Consequences."

4.2 Irreversible and Irretrievable Commitments of Resources

Irreversible and irretrievable commitments of resources are defined in Forest Service Handbook 1909.15 – Environmental Policy and Procedures. Irreversible commitments of resources are those that cannot be regained, such as the extinction of a species or the removal of mined ore. Irretrievable commitments are those that are lost for a period, such as the temporary loss of timber productivity in forested areas that are kept clear for use as a powerline right-of-way or a road. The decisions made in the Land Management Plan do not represent actual irreversible and irretrievable commitments of resources. This is because forest planning identifies what kinds and levels of activities are appropriate in different parts of the forest; it does not make project decisions. Ground-disturbing activities cannot occur without further site-specific analyses, Section 7 consultation required under the Endangered Species Act, and project decision documents.

4.3 Consistency with State and Local Plans

A review of state and local plans was conducted by the interdisciplinary team comparing the stated goals and objectives of the state and local plans compared to the Land Management Plan direction. The Nez Perce-Clearwater endeavors to incorporate relevant state and local direction into the alternatives of the Land Management Plan when it is within the scope of the Land Management Plan, within the authority of the Forest Service, and in compliance with federal code, rules, regulations, and policy.

Land Management Plans attempt to provide for ecological, economic, and social sustainability. State and local plans also attempt to provide for sustainability of resources and economies. The degree to which each alternative contributes to ecological, economic, and social sustainability varies. Therefore, each alternative and each individual component of each alternative may be more consistent or less consistent with the stated purpose and specific components of each state and local plan. An individual alternative may better respond to a state or local plan than another and consistency may be realized not in any one alternative but across various alternatives. Initial results indicate consistency with some combination of the building blocks in alternatives for each state and local plan. Additional detail below summarizes the main findings of each plan.

4.3.1 Natural Resources Plans of Clearwater, Idaho, and Benewah Counties

The Idaho County Natural Resources Plan (Idaho County Commisioners 2016), the Clearwater County Natural Resource Plan (Clearwater County 2017a), and the Benewah County Natural Resources Plan (2009) were developed to assist private landowners and direct the county governments in the State of Idaho and particularly the federal government as they conduct both strategic planning and project level planning. The plans generally call for increased timber harvest, increased livestock grazing, increased mining activities, and increased motorized access and motorized recreation opportunities on federal lands. Additionally, plans generally look negatively at recommendations for designations made by the Forest Service, such as recommended wilderness and suitable wild and scenic rivers. Very specific plan components within each plan direct specific actions or decisions to be made by the Forest Service in some resource areas. An analysis of specific plan components of the county plans tied to the correlated plan components in the Land Management Plan has been conducted and is documented in the project record. Major findings are presented below.

The Idaho County and Clearwater County Natural Resources Plans generally match Alternative X. Alternative X was specifically developed to respond to county and state plans. Increases in timber harvest, mineral extraction, and motorized access are maximized in Alternative X. Additionally, Alternative X does not recommend any areas for recommended wilderness nor does it find any rivers suitable as wild and scenic rivers. Livestock grazing is held constant across all alternatives based on current allotments and grazing demand. Specific desired conditions to increase motorized recreation, in addition to finding additional areas as suitable for motorized use, are not present in the final environmental impact statement. Additionally, old growth in the Land Management Plan may still be protected in Management Area 3 to a greater extent than the county natural resource plans call for. Fire management direction in the Land Management Plan may also be less specific than the county plans call for, specifically the Land Management Plan acknowledges the benefits of wildfire, under certain conditions, in all management areas of the Nez Perce-Clearwater. County plans specify aggressive suppression of all wildfires within the lands suitable for timber production, whereas the Land Management Plan allows for greater flexibility of fire management in all management areas, including in Management Area 3 under certain conditions.

The Benewah County Natural Resource Plan calls for unrestricted suction dredge mineral extraction, increases in livestock grazing, and aggressive fire suppression for most wildfires. These items are not specifically addressed in the Land Management Plan. A detailed set of forest management policies and objectives are not specifically met but, in general, Alternative X provides for greater levels of timber harvest and maximizes the economic contribution from Nez Perce-Clearwater management similar to the policy of Benewah County but not in exact conformance. Increased motorized access and no designation or recommendation of wilderness in Benewah County is substantively similar to the Idaho and Clearwater County Natural Resource Plans.

All counties specifically desire no net decrease of lands that contribute to the taxable base of the counties. With limited private lands, particularly in Idaho and Clearwater Counties, any decrease in the taxable base, as happens when private lands transfer to public lands, significantly affects the economics of the counties. The Land Management Plan does not specifically allow or disallow such transfers of land ownership to federal agencies.

4.3.2 State Wildlife Action Plan

The Idaho State Wildlife Action Plan (Idaho Department of Fish and Game 2017b) is a 10-year comprehensive document that establishes conservation targets, identifies threats to those targets, and recommends actions to address the threats. The Idaho State Wildlife Action Plan is arranged by ecoregion, with the Bitterroot Mountains, Idaho Batholith, and Palouse Prairie ecoregions being relevant to our planning effort. There is a high degree of consistency across all alternatives with the State Wildlife Action Plan. Primary actions within the State Wildlife Action Plan that cross jurisdictions are related to habitat for wildlife species. Specific items focus on forested and non-forested vegetation being within the natural range of variability, reduction of invasive species, improving water quality and aquatic habitats, and limiting disturbance to species during vulnerable periods. The Land Management Plan shares these same overarching principles, and plan components respond to each of the overarching themes of the wildlife action plan. While some alternatives may respond to specific actions better than others, no inconsistencies between the plans have been identified at this time.

4.3.3 State Forest Action Plan

The Idaho State Forest Action Plan (Idaho Department of Lands 2020) serves to conserve, protect, and enhance forestlands within the State of Idaho. The Idaho State Forest Action Plan is broken into two documents – 1) an assessment of the condition of Idaho's forests and 2) the resource strategy. The existing condition in the environmental impact statement uses similar data sources to the State Forest Action Plan and is generally coordinated. Desired conditions in the Land Management Plan are well aligned with the resource strategy of the State Forest Action Plan. Managing forest vegetation to reduce insect and disease, prevent catastrophic wildfire, and return species compositions and densities of forest vegetation are all primary drivers of both the Land Management Plan and the State Forest Action Plan. Additionally, the State Forest Action Plan identifies at least one priority landscape area that overlaps with the Nez Perce-Clearwater – the Craig-Camas Priority Landscape Area. In this priority landscape area, threats identified are risks from insects and disease to forest health and the potential for catastrophic wildfire. Potential benefits to the area are the proximity to milling infrastructure and the high to very-high potential for diverse and abundant wildlife. These findings were also incorporated in the Land Management Plan. Overall, there is a high degree of consistency between the two plans, paving the way for shared stewardship of the cross-jurisdictional resources and an opportunity to work across administrative boundaries using an all-lands approach.

4.3.4 County Fire Plans and Community Wildfire Protection Plans

The Nez Perce-Clearwater encompasses seven counties in Idaho, five with National Forest System lands totaling 100 acres or more. All seven counties have a wildfire protection plan, a fire plan, or a community protection plan. These plans designate wildland urban interface within the counties and describe prioritized treatment areas to protect communities from wildfire. Plans also may specifically support specific or general projects planned by the Forest Service that mitigate hazardous fuels. While each plan differs, generally they call for reduced hazardous fuels, prompt response to wildfire within the wildland urban interface, and pre-planning of response agencies, communities, and local governments. The Land Management Plan supports these priorities and defers to the counties for designation of the wildland urban interface.

4.4 Other Required Disclosures

NEPA at 40 CFR 1502.25(a) directs "to the fullest extent possible, agencies shall prepare final environmental impact statements concurrently with and integrated with …other environmental review laws and executive orders."

4.4.1 Environmental Justice Act

As required by Executive Order 12898, all federal actions must consider potentially disproportionate effects on minority or low-income communities. The Land Management Plan is strategic and programmatic in nature, providing guidance and direction to future site-specific projects and activities. The Plan does not create, authorize, or execute any ground-disturbing activity, although it does provide for the consideration of certain types of activities. Site-specific activities will consider potential disproportionate effects on minority or low-income communities during project planning.

The Economic and Social Environment section of Chapter 3 did not identify any disproportionate impacts from forest management. In addition, collaboration on the plan did not identify any concerns regarding disproportionate impacts to low-income or minority populations. The Nez Perce-Clearwater also coordinated and consulted the Nez Perce Tribe. No disproportionate impacts were identified by the Tribe.

4.4.2 American Indian Religious Freedom Act

Agencies must make a good faith effort to understand how Indian religious practices may come into conflict with other forest uses and consider any adverse impacts on these practices in their decision-making practices. The Nez Perce-Clearwater consults primarily with the Nez Perce Tribe. The Nez Perce-Clearwater is wholly within the Nez Perce Tribe's homeland. Other tribes have been known to cross the Nez Perce-Clearwater. Other tribes have been notified of the Land Management Plan and final environmental impact statement.

No effects on American Indian social, economic, or subsistence rights are anticipated as a result of this Land Management Plan effort. No matter which alternative is chosen for implementation, the National Forest will be required to consult with tribes when management activities may impact treaty rights or cultural sites and cultural use. Desired conditions for American Indian Rights and Interests, for revised plan alternatives, would be that culturally significant species and the habitat necessary to support healthy, sustainable, and harvestable plant and animal populations support rights reserved by tribes in treaties; National Forest resources are available for collection by tribal members with treaty rights; and tribal members have access to sacred sites and landscapes within the Nez Perce-Clearwater for the exercise of reserved treaty rights and cultural uses.

4.4.3 Energy Requirements and Conservation Potential

Energy is consumed in the administration of natural resources from the National Forests. The main activities that consume energy are timber harvest; recreation use; road construction and reconstruction; minerals and energy exploration and development; transporting and managing livestock; and administrative activities of the Forest Service and other regulatory agencies. Energy consumption is expected to vary only slightly by alternative.

4.4.4 Prime Farmland, Rangeland, and Forestland

No prime farmland, rangeland, or forestland has been identified in the planning area. Neither the proposed Land Management Plan nor the existing Forest Plans would directly affect such lands, although implementation of the plan could have indirect effects. Regardless of the alternative selected for implementation, National Forest System lands would be managed with sensitivity to the values of any adjacent private or public lands.

4.4.5 Threatened and Endangered Species

Potential effects to species listed under the Endangered Species Act can be found in Chapter 3. The Biological Assessment and Biological Evaluation will be finalized for the final Land Management Plan and final environmental impact statement. Management direction to protect at-risk species or to provide for their habitats can be found in the Land Management Plan within forestwide and management area desired conditions, standards, and guidelines.

4.4.6 Wetlands and Floodplains

Neither the proposed Land Management Plan nor the existing Forest Plans directly implement any management activities that would result in loss of wetland or floodplains. Revised forestwide management direction provides a broad spectrum of standards and guidelines designed to protect soil, water, riparian, and aquatic resources. The goals and intent of Executive Orders 11988 (Floodplain Management) and 11990 (Protection of Wetlands) would be met through compliance with this direction. Documentation for this conclusion can be found Chapter 3 and in the Land Management Plan desired condition, standards, and guidelines.

4.4.7 Conflicts with Other Agency or Government Goals or Objectives

Contact, review, and public involvement with other federal and state agencies indicate no major conflicts between the Land Management Plan and the goals and objectives of other governmental entities. This review is documented in the project record and the cumulative effects analysis of many sections of this document.

4.4.8 Preparers and Contributors

The Nez Perce-Clearwater consulted the following individuals and cooperating agencies during the preparation of the final environmental impact statement.

Table 463. Current team members

Name	Position
Vince Archer	Regional Soil Scientist
George Bain	Recreation Planner

4.4.9 Distribution of the Environmental Impact Statement

This environmental impact statement has been made available online so that individuals who submitted substantive comments on the draft environmental impact statement may review. In addition, notifications have been made to county governments for the availability of this environmental impact statement; local governments; the State of Idaho; other federal agencies, including the Bureau of Land Management, National Marine Fisheries Service, Fish and Wildlife Service, Army Corps of Engineers, and Environmental Protection Agency; US Forest Service employees; collaborative groups; state representatives; US Congressional delegation members; the Nez Perce Tribe; and local media outlets, including print, radio, television, and web based media.
