MM-1 (PACFISH). If a Notice of Intent indicates that a mineral operation would be located in a Riparian Habitat Conservation Area, or could affect attainment of Riparian Management Objectives, or adversely affect listed anadromous fish, require a reclamation plan approved Plan of Operations (or other such governing document), and reclamation bond. For effects that cannot be avoided, such plans and bonds must address the costs of removing facilities, equipment, and materials; recontouring disturbed areas to near pre-mining topography; isolating and neutralizing or removing toxic or potentially toxic materials; salvage and replacement of topsoil; and seedbed preparation and revegetation to attain Riparian Management Objectives and avoid adverse effects on listed anadromous fish. Ensure Reclamation Plans contain measurable attainment and bod release criteria for each reclamation activity. MM-1 (INFISH). If a Notice of Intent indicates that a mineral operation would be located in a Riparian Habitat Conservation Area, consider the effects of the activity on inland native fish in the determination of significant surface disturbance pursuant to 36 CFR 228.4. For operations in a Riparian Habitat Conservation Area ensure operators take all practicable measures to maintain, protect, and rehabilitate fish and wildlife habitat which may be affected by the operations. When bonding is required, consider (in the estimation of bond amount) the cost of stabilizing, rehabilitating, and reclaiming the area of operations.	FW- GDL-AREM -04. Mineral operations should minimize adverse effects to aquatic and riparian- dependent resources in riparian management zones. Best management practices and other appropriate conservation measures should be included in plans of operations to mitigate potential mine operation effects.
MM-2. Locate structures, support facilities, and roads outside Riparian Habitat Conservation Areas. Where no alternative to siting facilities in Riparian Habitat Conservation Areas exists, locate and construct the facilities in ways that avoid impacts to Riparian Habitat Conservation Areas and streams and adverse effects on inland native fish. Where no alternative to road construction exists, keep roads to the minimum necessary for the approved mineral activity. Close, obliterate and revegetate roads no longer required for mineral or land management activities.	FW-GDL-AREM-01. To prevent adverse effects to streams, wetlands, and other riparian dependent resources, all proposed mineral operations should avoid riparian management zones. If the riparian management zone cannot be avoided, plan of operations should include practicable measures to maintain, protect, and rehabilitate water quality and habitat for fish and wildlife and other riparian-dependent resources affected by the operations. Operations should not retard or prevent attainment of aquatic and riparian desired conditions. Exceptions to this guideline include situations where the Forest Service has limited discretional authorities. In those cases, project effects should not prevent or retard attaining aquatic and riparian desired conditions to the extent possible within those authorities. FW-STD-AREM-01. Plans of Operation that propose activities in riparian management zones shall include a reclamation plan and a reclamation bond addressing the cost of removing facilities, equipment, and materials; re-contouring disturbed areas to pre-mining topography; isolating and neutralizing

PACFISH/INFISH	Land Management Plan
	or removing toxic materials; salvaging or replacing topsoil; and revegetating with trees and shrubs or native plant seed to move toward attainment of aquatic and riparian desired conditions and avoid adverse effects on native fish. FW- GDL-AREM -02. Mineral operations should reuse existing access routes and processing sites left from previous entries if they are not causing unacceptable impacts to aquatic and riparian dependent resources. Where new construction or relocation is necessary, to the maximum extent possible, construct and locate new structures, support facilities, and roads outside of riparian management zones. If new structures, support facilities, and roads cannot be constructed outside riparian management zones because of site limitations, then construct and manage them to minimize adverse effects to aquatic and riparian dependent resources. When no longer required for mineral activities, structures and support facilities should be removed and roads should be decommissioned or placed into intermittent stored service to achieve aquatic and riparian desired conditions.
MM-3. Prohibit solid and sanitary waste facilities in Riparian Habitat Conservation Areas.	FW-STD-AREM-02. Mine waste with the potential to generate hazardous material, as defined by the Comprehensive Environmental Response, Compensation, and Liability Act, shall not be authorized within riparian management zones where groundwater contamination is possible. The exception is temporary staging of waste during abandoned mine cleanup. FW-GDL-ARREC-01. To protect aquatic and riparian resources, new and reconstructed solid and sanitary waste facilities should not be located within 100 feet of water, unless no other alternative exists.
MM-4. For leasable minerals, prohibit surface occupancy within Riparian Habitat Conservation Areas for oil, gas, and geothermal exploration and development activities where contracts and leases do not already exist, unless there are no other options for location and Riparian Management Objectives can be attained and adverse effects to listed anadromous fish and inland native fish can be avoided. Adjust the operating plans of existing contracts to (1) eliminate impacts that prevent attainment of Riparian Management Objectives and (2) avoid adverse effects to listed anadromous and inland native fish. MM-6. Develop inspection, monitoring, and reporting requirements for mineral activities. Evaluate and apply the results of inspection and monitoring to modify mineral plans, leases, or permits as needed to eliminate impacts that prevent attainment of Riparian Management Objectives and avoid adverse effects on listed anadromous and inland native fish.	FW- GDL-AREM-03. To maintain water quality and to prevent biological, chemical, or industrial pollutants from being delivered to water bodies, mineral exploration, processing, and extraction projects should not have direct water flow paths to streams, lakes, or wetlands. Projects should install barriers between streams, lakes, wetlands, or groundwater dependent ecosystems and construction-related pollutant hazards, such as sumps, processing pits, fuel storage, latrines, adits, and shafts, underground workings, open pits, overburden, development rock and waste rock dumps, tailings impoundments, leach pads, mills, and process water ponds or natural pollutant hazards such as acidity, metals, sulfate, cyanide, or nitrate or a combination of the preceding.
MM-5: Permit sand and gravel mining and extraction within Riparian Habitat Conservation Areas only if no alternatives exist, if the action(s) would not retard or	FW-GDL-RMZ-09. New saleable sand and gravel mining and extraction should not occur within riparian management zones, to minimize ground disturbance

PACFISH/INFISH	Land Management Plan
prevent attainment of Riparian Management Objectives, and adverse effects to listed anadromous and inland native fish can be avoided.	and sediment inputs, and avoid adverse effects to riparian vegetation and water temperature.

Effects common to all action alternatives

The action alternatives do not differ in the level of mineral activity proposed or aquatic components. The Nez Perce-Clearwater Aquatic Ecosystems plan components provides three standards and four guidelines, as shown in Table 143, that are designed to refine the existing standards and guidelines in PACFISH and INFISH and require enhanced and strengthened consideration for aquatic resources. FW-STD-ARE&M-01 requires that the plans of operation include a reclamation plan to address any disturbance caused by activities. FW-STD-ARE&M-02 requires that mine waste with the potential to generate hazardous material shall not be authorized within the riparian management zones (RMZs). FW-STD-ARE&M-03 requires that mineral activities avoid adverse effects to aquatic threatened or endangered species and their critical habitat. FW-GDL-ARE&M-01 requires operations to prevent adverse effects to streams, wetland, and riparian dependent resources. FW-GDL-ARE&M-02 requires operations to use existing routes, or construct routes outside riparian management zones, or minimize effects to aquatic and riparian dependent resources. FW-GDL-ARE&M-03 requires barriers between biological, chemical, or industrial pollutants. Best management practices (BMPs) that apply under the No Action Alternative would also apply to activities conducted under these alternatives and are required in FW-GDL-ARE&M-04. Therefore, these alternatives are expected to result in similar or the same outcomes to riparian resources, aquatic habitat, and aquatic species as the No Action Alternative.

Recreation Activities and Recreation Facilities

No Action Alternative

PACFISH and INFISH provided three standards and guidelines for recreation management, as shown in Table 144 mainly related to relocating or constructing new developed and dispersed sites outside of riparian areas. No developed recreation sites have needed to be relocated due to adverse effects, although the continued presence of these structures results in ongoing alterations to the riparian management zones (RMZs) in which they are located. These facilities would continue to exist in RMZs and public use would continue as well. There are no known locations, however, that have resulted in pervasive and permanent degradation of aquatic habitat. These facilities would continue to exist and their public use would continue as well. Current PACFISH standards and guidelines would be expected to continue to be effective at maintaining aquatic and riparian resources.

Many dispersed and developed recreation sites are located within riparian areas and are adjacent to streams that support important spawning and early rearing habitat. Effects from repeated use of these areas include soil compaction and frequently the removal of ground vegetation. However, the Nez Perce-Clearwater has taken steps to address human use effects resulting in expansion of the footprint of these sites located in RMZs through placement of boulders. Vault toilets have been installed at heavily used dispersed sites, but less used sites do not have toilet facilities so they may have concentrations of human waste at some locations. Hazard trees have been felled for safety reasons in campgrounds and would continue to be felled for safety reasons. Once again, this impact is limited in nature, and monitoring does not show that large wood has been limited in the Nez Perce-Clearwater streams. Conversely, large wood in stream channels is one of the three PACFISH and INFISH Biological Opinion (PIBO) indicators that are contributing most to the improving trend in aquatic habitat forestwide.

The location of developed and dispersed recreation sites results in human use of these sites as most people enjoy recreating and camping next to streams and lakes. Human presence at these sites results in direct effects to aquatic species through disturbance to individual fish from fishing, swimming, and wading that probably would not, or to the degree they do if there was not an established site for parking and camping. Travel planning efforts for the Nez Perce-Clearwater attempt to address these effects through monitoring. PACFISH and INFISH include standard RM-2, which provides direction to mitigate these effects and move or close the site if they are not effective.

Table 144. PACFISH/INFISH recreation standards and guidelines crosswalk with Land Management Plan standards and guidelines

PACFISH/INFISH	Land Management Plan
RM-1. Design, construct, and operate recreation facilities, including trails and dispersed sites, in a manner that does not retard or prevent attainment of the Riparian Management Objectives and avoids adverse effects on listed anadromous and inland native fish. Complete watershed analysis prior to construction of new recreation facilities in Riparian Habitat Conservation Areas within key and priority watersheds. For existing recreation facilities inside Riparian Habitat Conservation Areas, assure that the facilities or use of the facilities would not prevent attainment of Riparian Management Objectives or adversely affect listed anadromous and inland native fish. Relocate or close recreation facilities where Riparian Management Objectives cannot be met or adverse effects on listed anadromous and inland native fish cannot be avoided. RM-2 Adjust dispersed and developed recreation practices that retard or prevent attainment of Riparian Management Objectives or adversely affect listed anadromous and Inland native fish. Where adjustment measures such as education, use limitations, traffic control devices, increased maintenance, relocation of facilities, and/or specific site closures are not effective in meeting Riparian Management Objectives and avoiding adverse effects on listed anadromous and inland native fish, eliminate the practice or occupancy. RM-3. Address attainment of Riparian Management Objectives and potential effect on listed anadromous and inland native fish in Wild and Scenic Rivers, Wilderness, and other Recreation Management plans.	FW-STD-RMZ-05. Trees felled for safety shall be retained onsite unless more than what is needed to achieve aquatic and riparian desired conditions. Trees shall be directionally felled towards or into streams, where it is safe and practical to do so. If aquatic and riparian desired conditions for wood are met at the site, surplus wood can be transported to other aquatic and riparian restoration project sites. Exceptions to this standard are allowed in developed recreation and administrative sites where needed to address concerns for human safety or infrastructure and when not practicable to leave on site. FW-GDL-ARREC-01. To protect aquatic and riparian resources, new and reconstructed solid and sanitary waste facilities should not be located within 100 feet of water, unless no other alternative exists. FW-GDL-ARREC-02. To reduce potential adverse effects to water quality and aquatic resources, construction of new facilities or infrastructure within floodplains should be avoided. Where new activities inherently must occur in riparian management zones (for example, at road and trail stream crossings, boat ramps, or docks), they should be located and designed to minimize adverse effects to floodplains and other riparian-dependent resource conditions (for example, within geologically stable areas and avoiding major spawning areas). FW-GDL-ARREC-03. To reduce the risk of sediment delivery when closing trails with physical barriers (for example, berms), drainage features should be sufficient to minimize risk to aquatic resources such as removing culverts from stream crossings. FW-GDL-ARREC-04. To reduce trail-related mass wasting and sediment delivery to watercourses, new and relocated trails should not be constructed on lands with high mass wasting potential. FW-GDL-ARREC-05. Trail construction, reconstruction, and maintenance activities should prevent concentrated water from directly entering streams, by hydrologically disconnecting the trails from delivering water, sediment, and pollutants to water bodies. FW-GDL-ARREC-06. To maintain channel stability and reduce sediment delivery to watercourses, when constructing or reconstructing trails, fords should be hardened to protect the stream bed, banks, and approaches.

Effects common to all action alternatives

The Nez Perce-Clearwater Aquatic Ecosystems plan components are designed to provide guidance for managing recreation sites within riparian management zones (RMZs). However, it is assumed that minor, localized impacts to riparian vegetation, woody debris, and water quality would still occur where recreational use and activities are allowed. Existing recreational facilities and actions within or affecting RMZs might need to be modified, discontinued, or relocated if they are identified as not fully meeting functional aquatic and riparian conditions and processes or improving impaired conditions and processes.

The Aquatic Ecosystems plan components are designed to provide guidance for managing recreation sites within RMZs. It includes FW-DC-ARREC-01 that provides expectations for recreation facilities in RMZs. It also includes FW-OBJ-ARREC-01, which includes removal or relocation of two existing recreation facilities every five years, including dispersed sites outside of RMZs, or other means if they are and degrading aquatic or riparian resources. FW-GDL-ARREC-01 and 02 address the effects of existing and new recreation facilities. Collectively, these components are expected to accomplish the same or similar outcomes as the No Action Alternative.

It is assumed that minor, localized impacts to riparian vegetation, woody debris, and water quality are still possible where recreational use and activities are allowed. Maintenance of recreation sites, including removal of hazard trees, would continue to occur. FW-STD-RMZ-05 addresses the disposition of hazard trees felled for safety reasons, including those in recreation sites. Continued monitoring of the effects of existing sites under current travel plans is expected to result in measures taken to address any effects that are unacceptable to aquatic species.

Recreation use related to roads and trails

Effects common to all (including No Action Alternative) alternatives

The Aquatic Ecosystems plan components are designed to provide guidance for managing recreation sites within riparian management zones (RMZs). However, it is assumed that minor, localized impacts to riparian vegetation, woody debris, and water quality would still occur where recreational use and activities are allowed. Existing recreation facilities and actions within or affecting RMZs might need to be modified, discontinued, or relocated if they are identified as not fully meeting functional aquatic and riparian conditions and processes or improving impaired conditions and processes. Changes in management according to the components for the action alternatives would be expected to maintain current trends in aquatic habitat condition.

Infrastructure, Including Roads, Trails, and Airstrip

Table 121 provides a summary by subbasin of the miles of roads located within RMZs, as well as the number of stream crossings. Streamside roads result in a permanent alteration of the riparian area, at least until such time as the road is decommissioned. Stream crossings result in localized changes to riparian areas at the crossing structure itself as well as the approaches. Trails and airstrips and their use can result in localized effects to riparian areas, but not to the extent of roads and their uses.

The most widespread alteration of riparian conditions, as well as stream process and function, across the Nez Perce-Clearwater is road development, particularly construction of streamside roads and roads with multiple stream crossings (U.S. Department of Agriculture 1998b, 2001b, 2003c, Ecovista 2003, U.S. Department of Agriculture 2003e, 1999). Road development has been correlated to instream conditions including substrate composition, low numbers of large wood in the stream channel, and number and quality of pools on both the Clearwater and Nez Perce National Forests

(Huntington 1998, U.S. Department of Agriculture 2003e). System roads cover an estimated 2,400 acres equaling 600 road miles within riparian management zones (RMZs) on the Nez Perce National Forest and an estimated 4,000 acres equivalent to 1,000 road miles within RMZs on the Clearwater National Forest. As long as the road prism persists on the landscape, there is little to no chance for recovery of floodplain function or condition. Routine maintenance, hydrologically disconnecting roads, storm proofing roads, and site-specific improvements, however, can be made to mitigate effects.

PACFISH and INFISH, while recognizing the significance of roads to riparian areas, aquatic habitat, and their role in potential recovery of spawning and early rearing habitat for anadromous and inland native fish, also recognized the complexity of managing a road network for access for timber harvest, fire suppression, and other human uses. Both strategies contained numerous standards and guidelines, many related to maintenance, road management, and access management. They also included requirements for Watershed Analysis, development of Road Management Plans, and prioritizing the closing, stabilization, and obliteration of roads not needed for future management activities. Among other things, they required construction of new stream crossings to accommodate 100-year floods and provide and maintain fish passage at all road crossings in known and potential fish-bearing streams.

While recognizing the correlations between existing population strongholds of at-risk salmonids and roadless and wilderness areas, PACFISH and INFISH stopped short of prohibiting new road construction in roadless areas that are known strongholds or potential strongholds, or other areas important for recovery of listed fish.

PACFISH and INFISH did not speak directly to trails, management of trails, or recreational use on trails or airstrips. They did, however, include standards and guidelines for recreational facilities, which included trails.

No Action Alternative

Under the No Action Alternative, standards and guidelines related to road management would continue to apply. Access management and motorized use on roads and trails would continue according to current travel plans. Not all standards and guidelines related to roads have been implemented to the degree directed in PACFISH and INFISH, yet construction of specified, permanent roads was de-emphasized on both the Clearwater and Nez Perce National Forests and mostly has not occurred since 1995. Rather, temporary road construction off existing roads, combined with enhanced maintenance and improvement of existing roads, has been emphasized to provide access for timber harvest. In addition, hundreds of miles of road decommissioning and road improvements have been completed, including many miles of streamside roads. In these areas, riparian process and function are expected to be restored over time.

Under the No Action Alternative, standards and guidelines in PACFISH and INFISH, as shown in Table 145, related to road management would continue to apply. Access management and motorized use on roads and trails would continue according to current travel plans. Not all standards and guidelines related to roads have been implemented to the degree directed in PACFISH and INFISH, yet construction of specified, permanent roads was de-emphasized on both the Clearwater and Nez Perce National Forests and mostly has not occurred since 1995. Rather, temporary road construction off existing roads, combined with enhanced maintenance and improvement of existing roads, has been emphasized to provide access for timber harvest. Temporary roads were decommissioned after timber harvest activities were completed. In addition, hundreds of miles of road decommissioning and road improvements have been completed, including many miles of streamside roads. In these areas, riparian process and function are expected to be restored over time.

Table 145. PACFISH/INFISH roads/infrastructure standards and guidelines crosswalk with Land Management Plan standards and guidelines

PACFISH/INFISH	Land Management Plan
RF-1. Cooperate with Federal, Tribal, State, and county agencies, and cost-share partners to achieve consistency in road design, operation, and maintenance necessary to attain Riparian Management Objectives. RF-2. For each existing or planned road, meet the Riparian Management Objectives and avoid adverse effects on listed anadromous fish and inland native fish by: completing watershed analyses prior to construction of new roads or landings in Riparian Habitat Conservation Areas and within priority watersheds.	FW-STD-ARINF-01. Road maintenance and new road construction shall be designed to minimize adverse effects to threatened, endangered, proposed, or candidate aquatic species and their habitat.
RF-2. For each existing or planned road, meet the Riparian Management Objectives and avoid adverse effects on listed anadromous fish and inland native fish by: minimizing road and landing locations in Riparian Habitat Conservation Areas	FW-GDL-RMZ-02. To reduce the likelihood of sediment input to streams, avoid new road and landing construction, including temporary roads and mechanical trail construction, in riparian management zones except where: • necessary for stream crossings, or • a road or trail relocation contributes to attainment of aquatic and riparian desired conditions, or • Forest Service authorities are limited by law or regulation (for example, General Mining Act of 1872). Temporary roads should be managed to protect aquatic and riparian desired conditions. FW-GDL-ARINF-04. To reduce road-related mass wasting and sediment delivery to watercourses, new and relocated roads, including skid trails and temporary roads, and other linear features should not be constructed on lands with high mass wasting potential. FW-GDL-ARINF-08. To avoid adverse effects to water resources, wetlands and seasonally wet meadows should be avoided when constructing new roads and landings, including temporary roads. For all roads, and where reconstruction of existing roads cannot avoid water courses and wetlands drainage features should maintain wetland functions and characteristics. FW-GDL-ARINF-09. When constructing, reconstructing, or maintaining roads, including temporary roads, road drainage should be routed away from potentially unstable channels, fills, and hillslopes, to prevent destabilization of channels and hillslopes.
RF-2. For each existing or planned road, meet the Riparian Management Objectives and avoid adverse effects on listed anadromous fish and inland native fish by: Avoiding sediment delivery to streams from the road surface,	FW-STD-ARINF-02. Best management practices shall be used during dust abatement applications on roads, and ensure chemicals are not applied directly to watercourses; water bodies such as ponds and lakes; or wetlands. FW-GDL-ARINF-02. To reduce the risk to aquatic resources when decommissioning roads, making roads impassable, or closing roads for longer

PACFISH/INFISH	Land Management Plan
Outsloping of the roadway surface is preferred, except in cases where outsloping would increase sediment delivery to streams or where outsloping is infeasible or unsafe. Route road drainage away from potentially unstable stream channels, fills, and hillslopes.	than one year, roads should be left in a hydrologically stable condition where road drainage is routed away from water resources and landslide prone areas and towards stable areas of the forest floor to provide filtering and infiltration. FW-GDL-ARINF -03. To reduce the risk of sediment delivery from gully formation or mass wasting when closing travel routes such as roads, skid trails, and temporary roads with physical barriers (for example, berms), drainage features should be left in a condition that will function without any maintenance for the planned duration of the closure.
RF-2. For each existing or planned road, meet the Riparian Management Objectives and avoid adverse effects on listed anadromous fish and inland native fish by: avoiding disruption of natural hydrologic flow paths.	FW-GDL-ARINF-01. Construction, reconstruction, and maintenance activities of roads, skid trails, temporary roads, and airstrips, should hydrologically disconnect the drainage system from delivering water, sediment, and pollutants to water bodies to prevent concentrated water from directly entering streams. FW-GDL-ARINF-10. Transportation infrastructure should be designed to maintain natural hydrologic flow paths, including surface and subsurface flow, to the extent practical. For example, streams and seeps upslope from roads should have cross-drains or relief culverts with sufficient capacity to ensure water is not routed down ditches.
RF-2. For each existing or planned road, meet the Riparian Management Objectives and avoid adverse effects on listed anadromous fish and inland native fish by: avoiding sidecasting of soils or snow on road segments within or abutting Riparian Habitat Conservation Areas in key or priority watersheds.	FW-STD-ARINF-03. To reduce or prevent sediment delivery to water, on roads other than outsloped roads, road surface and fill materials shall not be sidecast into streams during road construction or reconstruction, when occurring within or adjacent to riparian management zones. FW-GDL-ARINF-07. To reduce sediment delivery from maintenance activities, such as road blading and snow plowing, avoid sidecasting into streams. Care should be taken when plowing snow so as not to include road soil. Breaks should be incorporated in the snow berms to direct water off the plowed surface.
RF-3. Determine the influence of each road on the Riparian Management Objectives. Meet Riparian Management Objectives and avoid adverse effects on listed anadromous and inland native fish by: reconstructing road and drainage features that do not meet design criteria or operation and maintenance standards, or that have been shown to be less effective than designed for controlling sediment delivery, or that retard attainment of Riparian Management Objectives, or do not protect priority watersheds from increased sedimentation. closing and stabilizing or obliterating, and stabilizing roads not needed for future management activities. Prioritize these actions based on the current and potential damage to listed anadromous and inland native fish in key and priority watersheds, and the ecological value of the riparian resources affected.	FW-STD-ARINF-05. When constructing or reconstructing roads, incorporating woody debris into the fill portion of the road prism shall be avoided. FW-GDL-ARINF-02. To reduce the risk to aquatic resources when decommissioning roads, making roads impassable, or closing roads for longer than one year, roads should be left in a hydrologically stable condition where road drainage is routed away from water resources and landslide prone areas and towards stable areas of the forest floor to provide filtering and infiltration. FW-GDL-ARINF-06. To maintain channel stability and reduce sediment delivery to watercourses, when reconstructing roads, fords should be hardened to protect the stream bed, banks, and approaches.

PACFISH/INFISH	Land Management Plan
RF-3. Determine the influence of each road on the Riparian Management Objectives. Meet Riparian Management Objectives and avoid adverse effects on listed anadromous and inland native fish by: prioritizing reconstruction based on the current and potential damage to listed anadromous fish and their designated critical habitat and inland native fish and their priority watersheds, the ecological value of the riparian resources affected, and the feasibility of options such as helicopter logging and road relocation out of Riparian Habitat Conservation Areas.	FW-STD-ARINF-07. In the Conservation Watershed Network and HUC12 subwatersheds with Endangered Species Act critical habitat or listed aquatic species, when constructing or reconstructing roads, projects shall result in a net decrease in the hydrologic connectivity of the road system and stream channel network unless no further decreases are needed to meet desired conditions for Water and Aquatic Resources or Conservation Watershed Network. Treatment priority shall be given to roads or road segments that pose the greatest relative ecological risk to riparian and aquatic ecosystems. The net decrease is measured by project area.
RF-4. Construct new, and improve existing, culverts, bridges, and other stream crossings to accommodate a 100-year flood, including associated bedload and debris, where those improvements would/do pose a substantial risk to riparian conditions. Substantial risk improvements include those that do not meet design and operation maintenance criteria, or that have been shown to be less effective than designed for controlling erosion, or that retard attainment of Riparian Management Objectives, or that do not protect designated critical habitat and priority watersheds from increased sedimentation. Base priority for upgrading on risks in key and priority watersheds and the ecological value of the riparian resources affected. Construct and maintain crossings to prevent diversion of streamflow out of the channel and down the road in the event of crossing failure.	FW-STD-ARINF-04. New, replacement, and reconstructed stream crossing sites, such as culverts, bridges, and other permanent stream crossings, shall accommodate at least the 100-year flow, including associated bedload and debris. FW-GDL-ARINF -05. To maintain free-flowing streams, new, replacement, and reconstructed stream crossing sites, such as culverts, bridges, and other stream crossings, should be constructed to prevent diversion of stream flow out of the channels and down the road in the event the crossing is plugged or has a flow greater than the crossing was designed.
RF-5. Provide and maintain fish passage at all relevant road crossings of existing and potential fish-bearing streams.	FW-STD-ARINF-06. In fish bearing streams, construction, reconstruction, or replacement of stream crossings shall not impair passage of any life stages of native aquatic organisms, unless barriers are desired to maintain or prevent spread or invasion of non-native species in alignment with fish management agencies. FW-GDL-ARINF-11. Culverts and bridges in fish-bearing and perennial streams should allow for passage of fish and other aquatic and riparian dependent species through the establishment of banks inside or beneath the crossing structure and mimicking the natural channel features, unless precluded by site characteristics such as bedrock or high channel gradient.

Lack of new, permanent road construction combined with an emphasis on temporary road construction and road decommissioning to meet aquatic restoration goals may be the most important factor in achieving the improving trends in riparian and stream habitat evident in both PACFISH and INFISH Biological Opinion (PIBO) data and forest plan monitoring data. In addition, direction to provide for passage for aquatic species at road and stream crossings (standard RF-5 in PACFISH) reduces areas that are not accessible to fish and restores passage where currently blocked.

In addition, the Nez Perce Forest Plan Appendix A sediment yield guidelines, upward trend requirements from the 1987 Nez Perce Forest Plan, and the Clearwater's litigation settlement have contributed greatly towards reduced sediment yield since the mid-1990s. This direction, combined with sediment-reducing aquatic restoration road decommissioning projects, has undoubtedly resulted in improved sediment conditions in many streams across the Nez Perce-Clearwater. Improved sediment conditions in specific areas are evident in both PIBO and forest plan monitoring data. Since deposited sediment in streams has been identified as a primary limiting factor for both anadromous and resident salmonids in spawning and early rearing habitat, improved less sediment conditions are expected to result in improved spawning success and greater carrying capacity for juveniles.

Management of infrastructure under the No Action Alternative with this same management framework combined with additional aquatic restoration would be expected to maintain current conditions or further contribute to improving trends. These trends would be expected to result in improving conditions for aquatic species and their habitat.

Effects common to all action alternatives

Infrastructure components described in the Aquatic Ecosystems plan components, as shown in Table 145, are designed to provide additional clarification and specificity when compared to those in PACFISH and INFISH. FW-DC-ARINF-01 sets the expectation that the transportation system has minimal impacts on aquatic and riparian conditions through reduced hydrologic connectivity of roads to streams, lower sediment delivery to streams, and improved aquatic organism passage. All standards and guidelines are intended to direct achievement of this desired condition. They are similar or the same as some standards in PACFISH and INFISH but contain additional clarification and specificity for many road activities. As for the No Action Alternative, motorized travel on roads and trails would continue consistent with current travel plan direction.

While none of the Conservation Watershed Network (CWN) components prohibit new road construction, FW-DC-CWN-03 sets the expectation of minimizing risks of roads to aquatic habitat. While similar to FW-DC-ARINF-01, the expectation in the CWN is that projects that achieve this desired condition are prioritized. FW-STD-ARINF-07 requires a net decrease in hydrologic connectivity of roads to streams when planning projects in subwatersheds with Endangered Species Act critical habitat or listed aquatic species, which can be accomplished through road decommissioning or various techniques that direct runoff from roads to areas other than streams, such as installing cross drain structures. FW-OBJ-CWN-01 and FW-OBJ-CWN-2 prioritize storm-proofing roads and treatment of road segments known to be adversely affecting riparian conditions and stream habitat. FW-STD-CWN-01 directs that all activities, including those associated with roads and trails, support or initiate achievement of aquatic desired conditions. Multiscale analysis aids in providing consistency with this standard.

When comparing alternatives, it is important to note that as the level of anticipated timber harvest varies among the action alternatives when compared to the No Action Alternative and each other, the transportation system needed to access and support these changes may increase similarly depending on the specific project and its location. It is expected that the aquatic components, particularly those in the CWN, will influence the type and management of any additional infrastructure needed for access and that they will reduce or minimize effects to riparian resources.

Further, while PACFISH and INFISH and their Biological Opinions referred to "Key" and "Priority" watersheds and contained direction specific to them, the Aquatic Ecosystems plan components are designed to further expand this concept by establishing the CWN and included components intended to address potential effects, particularly from roads and infrastructure. The CWN on the Nez Perce-Clearwater includes many subwatersheds within designated wilderness and roadless areas and Management Area 3.

Sediment delivery from roads to streams is a primary limiting factor across the Nez Perce-Clearwater. Desired conditions FW-DC-WTR-05, 06, and 07 are designed to set an expectation that sediment delivered to streams is transported at natural rates and maintains reference dimensions within streams. In order to maintain or achieve these desired conditions, FW-STD-WTR-04 is designed to require that projects shall restore or not retard attainment of desired conditions. Assessment of desired conditions using the Stream Condition Indicator Assessment is described in Appendix 4. Where desired conditions are not met, potential stream and riparian restoration actions are recommended to maintain or achieve those desired conditions.

To provide for social and economic sustainability of rural communities, access to activities such as recreation, hunting, fishing, gathering, egress, and wildfire management should continue to be provided for on routes or in areas designated as open to motorized use in the summer and winter. If a route is identified as substantially impairing aquatic ecological values, rerouting and route improvement should be considered prior to closure to preserve motorized access opportunities. If a route or area needs to be closed, alternate motorized access to maintain social and economic sustainability of rural communities should be provided.

The conclusion that the action alternatives will result in outcomes that are indistinguishable from the No Action Alternative's static or improving conditions, and possibly improved conditions and fewer effects, is supported by Nez Perce-Clearwater Aquatic Ecosystems plan components.

Lands and Special Uses

Effects common to all alternatives

Effects from lands and special uses would be primarily associated with activities occurring in riparian areas from special uses. Other potential effects would be through special use permits to outfitters who have camps and conduct activities within riparian areas. Effects would be the same under all alternatives because the plan components are the same for the action alternatives and have not changed markedly from PACFISH and INFISH amendment, as shown in Table 146, with the exception of reauthorizations. The Aquatic Ecosystems plan components contain two standards and one guideline, two of which are designed to address hydropower development. Existing special-use permits were consulted on when salmon, steelhead, and bull trout were listed under the Endangered Species Act or had site-specific consultation if issued after these listings and were determined to largely be "no effect," except for some outfitter and guide permits.

Table 146. PACFISH/INFISH leases and hydroelectric facilities standards crosswalk with Land Management Plan standards and guidelines

PACFISH/INFISH	Land Management Plan
LH·1. Require instream flows and habitat conditions for hydroelectric and other surface water development proposals that maintain or restore riparian resources, favorable channel conditions, and fish passage, reproduction, and growth. Coordinate this process with the appropriate State agencies. During relicensing of hydroelectric projects, provide written and timely license conditions to the Federal Energy Regulatory Commission (FERC) that require fish passage and flows and habitat conditions that maintain/restore riparian resources and channel integrity. Coordinate relicensing projects with the appropriate State agencies.	FW-STD-ARLND-01. When authorizing new lands special uses or reauthorizing existing uses, include conditions to avoid adverse effects to fish, water, and riparian resources. If adverse effects are unavoidable to Endangered Species Act listed fish, species of conservation concern, impaired water bodies, or stream habitat conditions, authorizations shall require actions that result in the re-establishment, restoration, mitigation, or improvement of conditions and ecological processes to ensure that projects that degrade conditions also include measures to improve conditions to the extent practicable. These processes include in-stream flow regimes, physical and biological connectivity, water quality, and integrity and complexity of riparian and aquatic habitat. FW-STD-WTR-01. New stream diversions and associated ditches shall have screens placed on them to prevent capture of fish and other aquatic organisms, using criteria established by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service, when listed fish may be present. FW-STD-ARLND-03. In the Conservation Watershed Network and subwatersheds with Endangered Species Act critical habitat or listed aquatic species, hydroelectric and other surface water development authorizations shall include requirements for instream flows and habitat conditions that maintain or restore native fish and other desired aquatic species populations, riparian dependent resources, favorable channel conditions, and aquatic connectivity.
LH-3. Issue leases, permits, rights-of-way, and easements to avoid effects that would retard or prevent attainment of the Riparian Management Objectives and avoid adverse effects on listed anadromous and inland native fish. Where the authority to do so was retained, adjust existing leases, permits, rights-of-way, and easements to eliminate effects that would retard or prevent attainment of the Riparian Management Objectives or adversely affect inland native fish. If adjustments are not effective, eliminate the activity. Where the authority to adjust was not retained, negotiate to make changes in existing leases, permits, rights-of-way, and easements to eliminate effects that would prevent attainment of the Riparian Management Objectives or adversely affect inland native fish. Priority for modifying existing leases, permits, rights-of-way, and easements would be based on the current and potential adverse effects on inland native fish and the ecological value of the riparian resources affected.	
LH-2. Locate new hydroelectric ancillary facilities outside Riparian Habitat Conservation Areas. For existing ancillary facilities Inside the RHCA that are essential to proper management, provide recommendations to FERC to assure that the facilities would not prevent attainment of the Riparian Management Objectives and that adverse effects on listed anadromous and inland native fish are avoided. Where these objectives cannot be met, provide recommendations to FERC that such ancillary facilities should be relocated. Locate, operate, and maintain hydroelectric facilities that must be located in Riparian Habitat Conservation Areas to avoid effects that would retard or prevent attainment of the Riparian Management Objectives and avoid adverse effects on inland native fish.	FW-STD-ARLND-02. Locate new hydropower support facilities outside of riparian management zones to reduce effects to fish, water, and riparian resources. Support facilities include any facilities or improvements such as workshops, housing, switchyards, staging areas, or transmission lines not directly integral to its operation or necessary for the implementation of prescribed protection, mitigation, or enhancement measures. FW-GDL-ARLND-01. If existing hydropower support facilities are located within the riparian management zones at time of permit reissuance, reduce impacts on aquatic and riparian resources, such as moving support facilities outside of riparian management zones or further from water bodies where feasible. FW-STD-ARLND-04. In the Conservation Watershed Network and in subwatersheds with Endangered Species Act critical habitat or listed aquatic species, new hydroelectric facilities and water developments should not be constructed unless it can be demonstrated that there are no substantial

PACFISH/INFISH	Land Management Plan
	adverse effects to critical habitat or listed aquatic species. Exceptions to this standard include situations where Forest Service authorities are limited such as the Alaska National Interest Lands Conservation Act, 1872 Mining Law, or valid state water rights. In those cases, project effects shall not retard attainment of desired conditions for watershed function, to the extent possible within Forest Service authorities.

Other exceptions included water withdrawal structures to support private lands adjacent to Forest Service lands or inholdings. Effects from re-authorization of these special use permits are expected to be addressed by FW-STD-LSU-01.

Fire Management

Wildland fire management incorporates a spectrum of responses ranging from full suppression to managing for resource objectives. All wildland fires are managed on a continuum between meeting protection objectives and achieving resource objectives. Available data indicates riparian areas burn at a lower intensity than the surrounding uplands due to higher humidity next to streams. See Figure 35, Figure 36, and Figure 37. That does not mean, however, that riparian areas do not burn at high severity; rather, there is a lower percentage of high severity when compared to uplands. There have been notable instances when riparian areas have burned at very high severity, including the McGuire Fire in 2007 and the Sheep Fire in 2012. In these cases, as well as others, high severity of wildfire in riparian areas was included within a larger block of high severity in the uplands and there is no evidence that fuel conditions in riparian areas have contributed to higher fire severity when compared to uplands (U.S. Department of Agriculture 2019a).

Fire suppression activities can result in direct effects to riparian areas, particularly where machine firelines are constructed within riparian management zones (RMZs) and cross streams and wetlands. Much of the timber removed and sold from RMZs in the past decade is from merchantable trees removed during machine fireline construction and decked and sold after suppression actions cease. Well over 10 million board feet of timber have been sold from decked logs from fire suppression activities over the past decade, though it is not known the percentage that came from RMZs.

Fire camps, helibases, and other firefighting resources located within RMZs can result in effects as well, although these effects are often short-term.

Managing naturally ignited fires to meet land management plan resource objectives has been a tool used extensively in designated wilderness areas and some roadless areas to achieve resource benefits. Wildfires allowed to burn for resource benefits result in some level of effect to riparian areas and riparian resources, although as previously noted, riparian areas have been documented to burn at lower severities than uplands. The role of fire as a natural agent of change should be acknowledged and it should be recognized that its long-term effects are necessary to maintain and build high quality riparian and stream habitats, particularly where it burns within natural frequency intervals. In other words, wildland fire is a natural change agent to which riparian resources have evolved and it is one that is necessary to maintain and enhance riparian processes within their historic ranges.

A more detailed discussion of fire effects to riparian and stream habitat is included above and can be found in the Aquatic Ecosystems Assessment (U.S. Department of Agriculture 2019a).

No Action Alternative

Under the No Action Alternative, direction in PACFISH and INFISH, as shown in Table 147, would continue to apply to fire management on the Nez Perce-Clearwater. There are five standards and guidelines in these documents that guide this program. They provide direction for the design of fuel treatment and suppression actions; location of incident bases, camps, and helibases; avoidance of fire retardants to surface waters; design of prescribed burn projects; and development of fire rehabilitation plans. Ignition of fire within riparian habitat conservation areas has been avoided since 1995, although neither PACFISH nor INFISH includes direction to do so. Avoidance has largely been the result of project-level Endangered Species Act consultations. Fire has been allowed to burn within riparian habitat conservation areas where it has backed into them from upland areas.

Table 147. PACFISH/INFISH fire/fuels standards and guidelines crosswalk with Land Management Plan standards and guidelines

PACFISH/INFISH	Land Management Plan
FM-1. Design fuel treatment and fire suppression strategies, practices, and actions so as not to prevent attainment of Riparian Management Objectives, and to minimize disturbance of riparian ground cover and vegetation. Strategies should recognize the role of fire in ecosystem function and identify those instances where fire suppression or fuel management actions could perpetuate or be damaging to long-term ecosystem function, listed anadromous, or designated critical habitat, and inland native fish.	FW-STD-RMZ-01. Vegetation management shall only occur in riparian management zones from the edges of the active stream channel to within 150 feet within Riparian Management Zone Category 1 and to the edges of the active stream channel to 100 feet within Riparian Management Zone Category 2, 3, and 4 to restore or enhance aquatic and riparian-associated resources. Non-mechanical treatments, for example, hand fuel treatments, prescribed fire, small diameter (for example, sapling, pole) conifer thinning, may be authorized if aquatic and riparian-associated resources are maintained. Timber Harvest in this zone shall leave trees on site or use for aquatic restoration. Vegetation management may occur in the outer Riparian Management Zones to meet desired conditions for fuel loading and silvicultural desired conditions, so long as project activities retain functions of the outer Riparian Management Zone, including sediment filtering, large wood recruitment to streams, and protection of the inner Riparian Management Zone from windthrow. Vegetation management in Riparian Management Zones shall not retard attainment of aquatic and riparian desired conditions. FW-STD-RMZ-06. Direct ignition of low severity prescribed fire in riparian management zones can achieve or maintain desired conditions so long as: • direct ignition within the riparian management zone will not retard attaining water, aquatic, and riparian desired conditions. • direct ignition within the riparian management zone maintains or enhances existing stream conditions and effects to threatened or endangered species and their designated critical habitat are considered.
FM-2. Locate incident bases, camps, helibases, staging areas, helispots, and other centers for incident activities outside of Riparian Habitat Conservation Areas. If the only suitable location for such activities is within the Riparian Habitat Conservation Area, an exemption may be granted following a review and recommendation by a resource advisor. The advisor would prescribe the location, use conditions, and rehabilitation requirements, with avoidance of adverse effects to inland native fish a primary goal. Use an interdisciplinary team, including a fishery biologist, to predetermine incident base and helibase locations during pre-suppression planning.	FW-GDL-RMZ-05. To minimize adverse effects to the Endangered Species Act listed species, riparian areas, aquatic habitat, and riparian dependent species, new incident bases, camps, helibases, helispots, staging areas, and other centers for incident activities should be located outside of riparian management zones. When no practical alternative exists, measures to maintain, restore, and enhance riparian areas, stream habitat, and riparian dependent species should be used.
FM-3. Avoid delivery of chemical retardant, foam, or additives to surface waters. An exception may be warranted in situations where overriding immediate safety imperatives exist, or, following a review and recommendation by a resource advisor and a fishery	FW-GDL-RMZ-04. Aerial application of chemical retardant, foam, or other fire chemicals and petroleum should be avoided in mapped aerial

PACFISH/INFISH	Land Management Plan
biologist, when the action agency determines an escape fire would cause more long-term damage to fish habitats than chemical delivery to surface waters.	retardant avoidance areas to minimize impacts to the riparian management zones and aquatic resources.
FM-4. Design prescribed burn projects and prescriptions to contribute to the attainment of the Riparian Management Objectives.	FW-GDL-WTR-06. Firelines should be located and configured to minimize sedimentation to waterbodies, limit capture of overland and stream flows, and restrict development of unauthorized roads and trails. Firelines should be restored following suppression or prescribed fire activities. FW-GDL-RMZ-06. To minimize sediment delivery and adverse effects to stream channels, construction of machine fireline in riparian management zones should be avoided, except where needed to cross streams.
FM-5. Immediately establish an emergency team to develop a rehabilitation plan to attain RMOs and avoid adverse effects on listed anadromous fish and inland native fish whenever Riparian Habitat Conservation Areas are significantly damaged by a wildfire or a prescribed fire burning out of prescription.	FW-GDL-RMZ-07. To reduce sediment delivery to streams during or after fire suppression activities, disturbed areas in riparian management zones, such as firelines, drop-points, camps, roads, and trails, should be restored by actions such as scattering slash piles, replacing logs and boulders, scarifying soils, re-contouring terrain, and reseeding with native species.
Empty cell	FW-GDL-RMZ-08. To maintain water quality, pumping directly from a stream channel should be avoided if chemical products are to be directly mixed with water being withdrawn. When chemicals are used, pumping should be conducted from a fold-a-tank that is located outside the riparian management zones.

Fire suppression activities would continue to be implemented as they have in the past, including use of machine fireline as a primary tool, particularly where private lands and other human values are at risk from fires burning on National Forest System lands.

Managing wildland fires would continue to be used as a tool to achieve resource benefits in designated wilderness and roadless areas. While all these activities would be expected to result in site-specific, and in some cases broad, alterations of riparian vegetation and condition including potential effects aquatic species, when considered at the national forest and subbasin scale, adverse changes in riparian and stream conditions are not evident based on PACFISH and INFISH Biological Opinion (PIBO) monitoring from the early 2000s through 2019.

Effects common to all action alternatives

The Aquatic Ecosystems plan components related to fire management, as shown in Table 147, are designed to address fire management that would apply under all action alternatives. Fire management does not vary by alternative, nor do the Aquatic Ecosystems plan components. Unlike PACFISH and INFISH, direction for the conditions under which ignition of fire within riparian management zones (RMZs) could occur are included in FW-STD-RMZ-06. For prescribed fire, ignition in RMZs could result in a wider array of effects to riparian areas than not, except the conditions under which ignition would occur are stringent and would include an objective of meeting or contributing to attainment of Aquatic Ecosystems plan component desired conditions. Also, clarification on machine fireline construction in RMZs is included in FW-GDL-RMZ-06. Other components addressing fire management, as well as those more broadly addressing all activities (FW-STD-WTR-04) are similar to those in PACFISH and INFISH.

Effects from fire management activities conducted under these alternatives are largely dependent on the size, location, and extent of future wildfires and are therefore difficult to predict. In comparing their effects to the No Action Alternative, it would be expected that they would be similar or the same, as the incidence of wildfires would be same. There are, however, differences between direction in PACFISH and INFISH regarding fire management. For example, avoiding construction of machine firelines in RMZs (FW-GDL-RMZ-06) would be expected to result in fewer site-specific effects to riparian conditions than the No Action Alternative. Specific actions to reduce sediment and restore disturbed riparian areas following fire suppression (FW-GDL-RMZ-07, FW-GDL-WTR-08) may result in a greater degree of restored riparian conditions.

Allowing naturally ignited fires to play their role, particularly in wilderness areas and designated roadless, would result in long-term beneficial effects to aquatic habitat and aquatic species. This conclusion is based on many studies, including monitoring and inventory conducted on the Nez Perce-Clearwater, which have found that over various time scales the aquatic habitat resulting from disturbances caused by even high severity fire is more productive than similar habitats where the fire events were suppressed or altered by human influences (Reeves et al. 1995, Dunham et al. 2003, Rieman et al. 2003, Benda et al. 2003). In a report from monitoring conducted in the Upper Selway on the Bitterroot National Forest, Jakober (2002) found increased large woody debris, number of pools, residual pool volume, habitat complexity, and no evidence of long-term sedimentation of fish habitat. Jakober and Dentino (2003) described similar results after long-term monitoring of another fire in the Upper Selway, in addition to increased abundance of bull trout and cutthroat trout. They also documented a 35.6 to 37.4-degree Fahrenheit increase in stream temperatures but surmised this increase was not enough to preclude cold water species such as bull trout since numbers of bull trout had increased in the years following the fire.

For prescribed fire, ignition in riparian management zones (RMZs) could result in a wider array of effects to riparian areas than not, except the conditions under which ignition would occur are stringent and would include an objective of meeting or contributing to attainment of riparian and Aquatic Ecosystems plan components desired conditions.

FW-GDL-RMZ-04 addresses use of aerial fire retardants in RMZs and is expected to reduce risk of direct effects to aquatic species. FW-STD-RMZ-02, FW-GDL-RMZ-08, FW-STD-WTR-03, and FW-STD-WTR-05 address risks of direct effects to aquatic species from other firefighting activities, including use of pumps for water drafting, storage of fuel containers, staging of vehicles and equipment in RMZs, and use of screens on pumps. While some of these are also included in the No Action Alternative, the action alternatives provide more detail and specificity.

It should be recognized, however, that high severity wildfires in RMZs can result in direct and indirect mortality of fish from deleterious increases in stream temperature while the fire is burning and subsequent debris torrents in the months following the fire, and that these risks are a trade-off to the long-term benefits described above. In addition, long-term increases in stream temperature post-fire have also been documented (Sestrich et al. 2011, Mahlum et al. 2011), in some cases persisting for years after the fire (Dunham et al. 2007, Mahlum et al. 2011). As described in Rieman et al. (1997), fire may create changes in watershed processes, such as surface erosion and mass failure, that are often considered negative for fish, but the spatial and temporal nature of the disturbances are important (Reeves et al. 1995), and episodic contributions of large woody debris and coarse sediments that often occur after fires in many cases result in beneficial long-term effects and an amelioration of short or long-term negative effects, including increases in stream temperature.

Rieman et al. (1997), Rieman and Clayton (1997), Jakober (2002), Howell (2006), and others have documented increased abundance of fish years after fires, even in reaches where the fire had resulted in local extirpation of fish (Jakober 2002, Rieman et al. 1997). Sestrich et al. (2011) documented a decline in non-native brook trout over time and rapid recovery of native westslope cutthroat trout in severely burned areas in the Bitterroot River, suggesting fire may have shifted the competitive advantage in the favor of the native species.

In many cases, fire suppression actions, as well as the fact that successful suppression efforts temporarily remove fire from the landscape, may pose a greater risk to long-term process and function of streams than if the wildfire was left to burn. This could result in a decline in stream productivity for aquatic species over the long-term, depending on how successful suppression actions are. In areas where fire is utilized to meet land management plan objectives, the risks would be reduced.

In monitoring the effects to streams from a large fire that occurred in 1988 in the Lower Selway, Green and Gerhardt (1991) documented changes in stream channels and increased surface fines in 1989 and 1990 but, by 1991, surface fines were lower, indicating much of the fine sediment delivered after the fire had been moved downstream. Subsequent observations of the fire made in 2004 indicated little or no fine sediment deposition.

Therefore, the effects and outcomes related to fire management under the five action alternatives are expected to be similar to those described under the No Action Alternative. Static conditions and trends in riparian resources described by PACFISH and INFISH Biological Opinion (PIBO) monitoring that were achieved under the management described in the No Action Alternative are expected to be indistinguishable from those under the action alternatives. Action alternative aquatic components may result in fewer adverse effects at specific sites, as described above.

Summary of Consequences

Table 148 provides a summary of consequences by alternative.

Table 148. Summary of consequences to aquatic ecosystems and fisheries by alternative.

Measurement Indicator	No Action Alternative	Action Alternatives and Preferred Alternative
PIBO Indicators – condition and trend	This alternative has maintained existing stream conditions since the late 1990s and resulted in improved conditions Forestwide. Condition is static in some subbasins.	Aquatic components in Aquatic Ecosystems plan components are common to all action alternatives, except for some objectives. Alternatives expected to maintain existing stream conditions, maintain existing improving trends, and initiate improving trends in some watersheds where conditions have been static.
Effects to Aquatic Species	Effects to aquatic species mostly based on effects to aquatic habitat. PIBO data indicate habitat in managed watersheds is in worse condition than reference, when summarized at the national forest scale. While improving trends have been documented, trends in adult returns of anadromous fish (including Pacific lamprey) have been highly variable for the past 5 years. Bull trout trends have been static or improving state-wide.	Aquatic components in the Nez Perce Aquatic Ecosystems plan components are common to all action alternatives, except for some objectives. Based on addition and clarification of components designed to address direct effects (for example, water drafting, screening of pumps, redd tramping from livestock, etc.) direct effects are expected to be fewer than for No Action Alternative. Indirect and cumulative effects to aquatic habitat and trends are expected to support recovery goals for Endangered Species Act listed fish species and provide habitat conditions for long term persistence of Pacific lamprey.

Conclusions

Endangered Species Act Listed Species

The following represent the species determinations made in the Biological Assessment for Endangered Species Act (ESA) listed species, in addition to species determinations made for Species of Conservation Concern and Sensitive Species.

This section synthesizes the information in the Biological Assessment to substantiate an overall effect determination for each species and critical habitat listed by the ESA and each essential fish habitat listed by the Magnuson-Stevens Act. Consideration is given to distribution within the action area to determine how likely a species is to experience effects, baseline conditions, potential duration and magnitude of project effects, and cumulative effects to provide a comprehensive evaluation of how federally listed species might be affected by the revised forest plan.

Bull Trout and Critical Habitat

Almost all bull trout core areas in the action area have substantial portions of the watershed in either wilderness or Idaho roadless area which has kept habitat in near-reference condition and greatly reduces the risk of potential future project effects. Bull trout streams are subject to the most potential risk from future project effects, in Management Area (MA) 3 where suitability components generally do not preclude future actions that could adversely affect bull trout. Most core areas in the action area are showing either stable or increasing trends such that they are serving as strongholds within the larger Mid-

Columbia recovery unit. Only the South Fork Clearwater core area trend is inconclusive as discussed above. This trend data mirrors baseline conditions where those stable or increasing core areas are largely within MA1 or MA2 with habitat that is at or near reference condition. Conversely, PACFISH and INFISH Biological Opinion (PIBO) results indicate the South Fork Clearwater has several habitat indicators that are departed from unmanaged systems. Indirect effects of proposed programmatic actions would be mostly beneficial for bull trout, however, the proposed expansion of the motorized access suitability (10 percent increase in summer; 21 percent increase in winter) could lead to adverse effects in the future. Proposed plan components are expected to provide enough guidance that future activities would not threaten stable or increasing core areas nor hinder recovery in the South Forth Clearwater core area, but some adverse effects to individuals of the species or physical or biological features (PBFs) would likely be unavoidable. It is the combination of uncertainty about the trend in a core area, partially degraded baseline, expanded suitability for motorized use, and plan components that cannot completely prevent adverse effects to individuals that warrants a **May Affect, Likely to Adversely Affect** determination for bull trout and bull trout critical habitat (Table 149).

Snake River Steelhead Trout and Critical Habitat

Anadromous steelhead migrate in the mainstem corridors of the Snake River (up to Hells Canyon Dam) and Clearwater system rivers (up to Dworshak Dam in the North Fork Clearwater River). They spawn and rear in most subbasin tributaries where much of the production occurs in intermittent streams. This life history trait makes steelhead sensitive to management actions that could affect summer baseflows, pool formation, and floodplain inundation. As with bull trout, the risk of being affected is greatest for steelhead spawning streams in MA3. Recent biological viability assessments indicate the steelhead major population groups (MPGs) within the action area are either “maintained”, “viable”, or “highly viable.” Much of these trend data are related to habitat that is at or near reference condition (that is, MA1 and MA2); however, the South Fork Clearwater aggregated stocks appear to have a stable “viable” rating despite PACFISH and INFISH Biological Opinion (PIBO) results that indicate several habitat indicators are departed from unmanaged systems. Indirect effects of proposed programmatic actions would be mostly beneficial for steelhead except for the proposed expansion of the motorized access suitability (10 percent increase in summer; 21 percent increase in winter) which could lead to adverse effects in the future. Proposed plan components are expected to provide enough guidance that future activities would not threaten stable or viable stocks, but some adverse effects to individuals of the species or physical or biological features (PBFs) would likely be unavoidable. Despite the stable or viable trend within the action area, the combination of partially degraded baseline, expanded suitability for motorized use, and plan components that cannot completely prevent adverse effects to individuals that warrants a **May Affect, Likely to Adversely Affect** determination for Snake River steelhead trout and steelhead trout critical habitat (Table 149).

Snake River Spring/Summer Chinook Salmon, Critical Habitat, Essential Fish Habitat

Listed spring and summer Chinook salmon migrate in the mainstem corridors of the Snake River (up to Hells Canyon Dam) and Salmon River. They spawn and rear in many of the same subbasin tributaries as steelhead although not quite to the same extent; spring and summer Chinook would also have a substantial amount of exposure to management actions. A biological viability assessment reported in 2022 (Ford 2022) that the Upper Salmon and South Fork Salmon River major population groups (MPGs) have a “high” overall viability risk rating (Ford 2022). This is because despite improvements in abundance and productivity in several populations relative to the time of listing, most populations experienced sharp declines in abundance in the recent five-year period. This is thought to be related more to changing ocean conditions than from spawning or rearing habitat as PACFISH and INFISH Biological Opinion (PIBO) reports show several watersheds in the action area are near reference condition (that is, MA1 and MA2). Indirect effects of proposed programmatic actions would be mostly beneficial for spring and summer

Chinook except for the proposed expansion of the motorized access suitability (10 percent increase in summer; 21 percent increase in winter) which could lead to adverse effects in the future. Proposed plan components are expected to provide enough guidance that future activities would not hinder recovery of high-risk MPGs, but some adverse effects to individuals of the species or PBFs would likely be unavoidable. It is the combination of high-risk MPGs, partially degraded baseline, expanded suitability for motorized use, and plan components that cannot completely prevent adverse effects to individuals that warrants a **May Affect, Likely to Adversely Affect** determination for Snake River spring and summer Chinook and their critical habitat, and a **May Adversely Affect** determination for spring and summer Chinook essential fish habitat (Table 149).

Snake River Fall Chinook Salmon, Critical Habitat, Essential Fish Habitat

Fall Chinook currently spawn primarily in the mainstem Snake River (below Hells Canyon Dam), and the lower Clearwater River (below the North Fork Clearwater, largely downstream of the action area). Because most of the spawning takes place in larger mainstem rivers below and downstream of any potential forest management actions, fall Chinook are at lower risk of being affected by proposed actions than bull trout, steelhead, or spring and summer Chinook salmon, which use smaller stream habitat throughout the Nez Perce-Clearwater. The critical habitat designation is likewise located primarily at the western edge of the action area, although essential fish habitat includes entire watersheds upstream from mainstem rivers and therefore would have greater potential to be affected by the revised forest plan. Recent biological viability assessments indicate the overall status of Snake River fall Chinook salmon has improved compared to the time of listing such that the single population in the evolutionary significant unit (ESU) is currently meeting the criteria for an overall risk rating of "viable," although the entire ESU is still not meeting recovery goals. Baseline conditions in the lower Clearwater subbasin are measurably departed from reference conditions according to PACFISH and INFISH Biological Opinion (PIBO) data where median substrate size, pool tail fines, and observed versus expected aquatic macroinvertebrate were all degraded; the bank stability indicator also shows a negative trend. Indirect effects of proposed programmatic actions would be mostly neutral because fall Chinook and their critical habitat are generally restricted to mainstem rivers downstream of most forest management activities. Proposed plan components are expected to provide enough guidance that future activities would not threaten the population, but some adverse effects to individuals of the species or physical or biological features (PBFs) could be possible. Despite fall Chinook's viable trend near the action area, the combination of degraded baseline where they spawn and plan components that cannot completely prevent adverse effects to individuals warrants a **May Affect, Likely to Adversely Affect** determination for Snake River fall Chinook and fall Chinook critical habitat, and **May Adversely Affect** determination for essential fish habitat (Table 149).

Snake River Sockeye Salmon and Critical Habitat

Snake River sockeye salmon migrate from the ocean, up the Salmon River, passing through the Nez Perce-Clearwater on their way to natal, lacustrine habitats to spawn. There is no spawning or rearing habitat on the national forest and the critical habitat in the Salmon River that forms the southern boundary of the action area is used for migration only. In terms of natural production, the Snake River sockeye salmon evolutionary significant unit (ESU) remains at "extremely high risk" and the viability of ESU has likely declined since the time of the prior review so that the extinction risk category remains "high." The network of PIBO sites does not cover the Middle Salmon-Chamberlain subbasin but despite some minor degradation from isolated grazing and mining, the baseline condition is generally considered to be functioning appropriately because large portions of the watershed are either designated wilderness or roadless area. Indirect effects of proposed programmatic actions would be neutral because sockeye salmon and their critical habitat only skirt the edge of the action area. Furthermore, many of the Nez Perce-Clearwater tributaries to the Salmon River are within the Gospel-Hump and Frank Church-River of

No Return wilderness and roadless areas such that land management designations and forest plan components are expected to guide management of future activities in a manner that would not threaten the population or even allow effects to exceed beyond insignificant or discountable levels. For these reasons, the appropriate effect determination is **May Affect, Not Likely to Adversely Affect** for Snake River sockeye salmon and their critical habitat Table 149.

Coho Salmon

Coho salmon were historically present in the Clearwater basin but were officially declared extirpated in 1985. Coho have been reintroduced in some drainages on the national forest, but hatchery or reintroduced coho are not listed under the Endangered Species Act. The only federally listed entity that requires an effects determination is therefore the essential fish habitat in the Clearwater and Selway watersheds. Indirect effects of proposed programmatic actions would be mostly beneficial for coho essential fish habitat except for the proposed expansion of the motorized access suitability (10 percent increase in summer, 21 percent increase in winter) which could lead to adverse effects in the future. Proposed plan components are expected to provide enough guidance that future activities would not cause adverse habitat modification, but some negative effects to habitat elements would likely be unavoidable. For this reason, the appropriate effects determination for coho salmon essential fish habitat is **May Adversely Affect** (Table 149).

Table 149 Summary of effect determinations for individuals and critical habitat listed under the Endangered Species Act (ESA) and essential fish habitat listed under the Magnuson-Stevens Act (MSA).

Species	Listing Status	Individuals (ESA)	Critical Habitat (ESA)	Essential Fish Habitat (MSA)
Bull trout	Threatened	LAA	LAA	Not Applicable
Snake River Steelhead Trout	Threatened	LAA	LAA	Not Applicable
Snake River Spring/Summer Chinook Salmon	Threatened	LAA	LAA	MAA
Snake River Fall Chinook Salmon	Threatened	LAA	LAA	MAA
Snake River Sockeye Salmon	Endangered	NLAA	NLAA	Not Applicable
Hatchery Coho Salmon	Not Applicable	Not Applicable	Not Applicable	MAA

LAA = Likely to Adversely Affect
NLAA= Not likely to Adversely Affect
MAA= May Adversely Affect

Species of Conservation Concern

Pacific Lamprey

As research continues into the causes of population declines in Pacific lamprey, as lamprey conservation science matures, and the effectiveness of translocations and other conservation measures are evaluated, land allocation decisions and aquatic ecosystem plan components in the revised plan are designed to continue to protect suitable upriver and tributary spawning and rearing habitat for lamprey by not retarding attainment of desired conditions for aquatic habitat. Movement of stream and riparian areas toward aquatic desired conditions is expected to be beneficial for lamprey. Adult lamprey should benefit from plan components that are designed to protect spawning habitat for salmonids, because they use similar habitat for spawning. Juvenile lamprey are expected to benefit from plan components designed to protect and enhance low velocity, off stream habitat and channel complexity. Incidentally, juvenile lamprey may benefit from some fine sediment in streams on as they need fine sediment to burrow into and mature for several years before out-migrating to the ocean, so sediment effects that could be detrimental to salmonid spawning and overwintering could offer some to benefit juvenile lamprey. An individual plan component specific to lamprey (FW-GDL-WTR-07) is designed to conserve existing

Pacific lamprey populations on the Nez Perce-Clearwater, by suggesting that individuals should be re-located to an alternative site with suitable habitat prior to de-watering channel work proposed in areas containing habitat for these species. This is a continuation of a practice that currently occurs on the national forest. For areas on the national forest that are protected from land management effects by land allocation decisions, threat ratings were low, and are expected to continue to be low under the revised forest plan. For areas that did receive higher threat scores (whether warranted or not), it is expected that aquatic plan components, as well as continued habitat restoration projects will continue to protect and improve conditions for lamprey. Overall, the land management plan and especially the aquatic and riparian plan components are expected to provide the ecological conditions necessary to ensure long term persistence of Pacific lamprey within the plan area.

Other Species

Although they are not Endangered Species Act listed or included on an Species of Conservation Concern list because of ineligibility, hatchery produced Clearwater River spring Chinook and coho provide regionally important tribal and sport fisheries on the national forest, and a specific plan component (FW-GL-WLMU-02) was developed that is designed to foster cooperation and collaboration with the State of Idaho and Nez Perce Tribe for the perpetuation of those fisheries.

Conclusion

Although the material reproduced above from the Biological Assessment highlights that there may be effects to individuals on the Nez Perce-Clearwater, for National Environmental Policy Act purposes the concern is if there will be effects to populations on the national forest from various alternatives. Except for some land allocation details and some differences in risk as noted in this document, the effects on aquatic species and habitat are expected to be largely the same or similar between action alternatives, and the preferred alternative offers an improvement from the No Action Alternative. The risks associated with climate change effects including more frequent high-severity fire under the No Action Alternative outweigh the risks presented by the preferred alternative. In conclusion, most of the area that is covered by the forest plan (approximately two-thirds) is found in land allocations such as designated wilderness, proposed wilderness, Idaho Roadless Rule themes, and Wild and Scenic Rivers, that by design, offer sweeping protections from management activities. For the remaining one-third that is subject to forest management, there are strong ecosystem plan components that carry forward, clarify, and improve upon PACFISH and INFISH direction, and offer unprecedented protective measures to streams and aquatic organisms on the Nez Perce-Clearwater. Differences between action alternatives are muted by aquatic riparian buffers that are larger than adequate to protect aquatic resources. Additional benefit is expected from the strategy of integrated plan components in the revised forest plan, which is designed to move ecological conditions at the landscape scale toward a set of desired conditions developed based on analysis of natural range of variation. The combination of integrated plan components of the revised plan regarding desired conditions, as well as specific aquatic plan components are expected to continue to protect and enhance aquatic habitat on the national forest, in addition to increasing resilience of aquatic species, and these factors are expected to support recovery of Endangered Species Act (ESA) listed fishes on the national forest.

Because there are so many factors and stakeholders involved, recovery and protection of salmon, steelhead, and other native fishes on the forest can be a slow process, that requires a great deal of scientific expertise and coordination to identify and apply scientific outcomes to forest management in order to deal with continuing ecological threats. Although it began years before the latest Presidential Memorandum from the Biden Administration came out, the Forest Plan Revision process and especially the ARCS working group exemplifies the process that was directed in the White House memo:

to "pursue effective, creative, and durable solutions, informed by Indigenous Knowledge, to restore healthy and abundant salmon, steelhead, and other native fish populations in the Basin".

The forest has been doing this for over a decade, using the implementation of the forest plan revision process to pursue solutions that creatively engage with stakeholders, are that are effective and durable in the face of climate change and other threats; and the resulting revised Land Management Plan represents a durable and creative solution that was informed by collaboration and cooperation with many stakeholders including the Nez Perce Tribe.

In summary, the combination of large areas of intact high quality stream habitat protected by land allocations, the required application of U.S. Forest Service best management practices in management that occurs outside those protective land allocations, in addition to protective measures provided by aquatic ecosystem plan components, as well as the integrated nature of other forestwide plan components, and the application of results of the ESA consultation with is expected to be sufficient to protect ESA listed fishes on the national forest and to provide the conditions for recovery as it pertains to critical habitat on the national forest. The same factors are also expected to provide for continuing viable populations of Species of Conservation Concern on the national forest. The revised forest plan is thus expected to maintain the status of a select set of the ecological conditions required under § 219.9 to contribute to the recovery of federally listed threatened and endangered species, conserve proposed and candidate species, and provide long term persistence ofeach species of conservation concern.

3.2.9 Wildlife

The 2012 Planning Rule provides direction to maintain diversity of animal communities and the persistence of native species through a complementary coarse filter approach (FSH 1909.12 23.11 (1)(c)). The coarse filter components ensure that the broad habitat types and characteristics that support many native species are maintained. Fine-filter plan components can be added when additional direction is needed to support a specific species. The plan must provide the ecological conditions to maintain the diversity of plant and animal communities and support the persistence of most native species in the plan area. As described in the Planning Rule and in the Directives, plan components developed for ecosystem integrity and ecosystem diversity are expected to provide for ecological conditions necessary to maintain the persistence of most native species within the plan area (FSH 1909.12, sec 23.11).

The Wildlife section evaluates terrestrial and aquatic wildlife species, including birds, mammals, reptiles, amphibians, and some invertebrates. The analysis evaluates the sufficiency of plan components and alternatives to meet the substantive requirements of the 2012 Planning Rule under sections 219.8—Sustainability, 219.9—Diversity of plant and animal communities, and 219.10—Multiple use and associated directives as they relate to wildlife.

Section 219.8—Sustainability of the 2012 Planning Rule requires that forest plans must provide for social, economic, and ecological sustainability within Forest Service authority and consistent with the inherent capability of the plan area. Ecological sustainability is provided through ecosystem integrity, which is defined in the planning rule as:

The quality or condition of an ecosystem when its dominant ecological characteristics (for example, composition, structure, function, connectivity, and species composition and diversity) occur within the natural range of variation and can withstand and recover from most perturbations imposed by natural environmental dynamics or human influence.

An ecosystem is defined as the following (36 CFR 219.19): An ecosystem is a spatially explicit, relatively homogeneous unit of the Earth that includes all interacting organisms and elements of the abiotic environment within its boundaries. An ecosystem is commonly described in terms of its:

1. Composition. The biological elements within the different levels of biological organization, from genes and species to communities and ecosystems.
2. Structure. The organization and physical arrangement of biological elements, such as snags and coarse woody debris, vertical and horizontal distribution of vegetation, stream habitat complexity, landscape pattern, and connectivity.
3. Function. Ecological processes that sustain composition and structure, such as energy flow, nutrient cycling and retention, soil development and retention, predation and herbivory, and natural disturbances, including wind, fire, and floods.
4. Connectivity. Ecological conditions that exist at several spatial and temporal scales that provide landscape linkages that permit the exchange of flow, sediments, and nutrients; the daily and seasonal movements of animals within home ranges; the dispersal and genetic interchange between populations; and the long-distance range shifts of species, such as in response to climate change.

Ecological integrity, as described above, influences the ecological conditions for wildlife in the plan area. Ecological conditions are defined in the Planning Rule as:

The biological and physical environment that can affect the diversity of plant and animal communities, the persistence of native species, and the productive capacity of ecological systems. Ecological conditions include habitat and other influences on species and the environment. Examples of ecological conditions include the abundance and distribution of aquatic and terrestrial habitats, connectivity, roads and other structural developments, human uses, and invasive species.
Section 219.8 also requires the plan to provide for social and economic sustainability, which includes multiple uses and ecosystem services. Multiple uses and ecosystem services both have implications for how wildlife is addressed in the plan as directed under Section 219.10 of the Planning Rule.

Section 219.9 of the 2012 Planning Rule adopts a complementary ecosystem and species-specific approach to maintaining the diversity of plant and animal communities and the persistence of native species in the plan area. It does so under two parts pursuant to Section 219.8 paragraph a and paragraph b. Paragraph a is intended to provide the ecological conditions to both maintain the diversity of plant and animal communities and support the persistence of most native species in the plan area. Paragraph a requires plans to maintain or restore the diversity of ecosystems and habitat types throughout the plan area. In doing so, the plan must include plan components to maintain or restore:

- Key characteristics associated with terrestrial and aquatic ecosystem types;
- Rare aquatic and terrestrial plant and animal communities; and
- The diversity of native tree species similar to that existing in the plan area.

Ecosystem diversity is defined as “the variety and relative extent of ecosystems” (36 CFR 219.19). Habitat types are defined as “a land or aquatic unit, consisting of an aggregation of habitats having equivalent structure, function, and responses to disturbance.”

Paragraph b of Section 219.9 of the Planning Rule requires that, when ecosystem plan components do not provide the ecological conditions necessary to provide for at-risk species, then additional species-specific plan components be included in the plan to provide such ecological conditions in the plan area. The term at-risk species is used in land management planning to refer to, collectively, the federally recognized threatened, endangered, proposed, and candidate species and species of conservation concern within a plan area (1909.9 zero code).

Pursuant to these requirements, this analysis will first evaluate how the suite of plan components and alternatives provide ecological conditions for 1) ecosystem integrity as it relates to wildlife, 2) how they provide for the diversity and abundance of wildlife, and 3) how the plan components and alternatives provide for at-risk species and "contribute to the recovery of federally listed threatened and endangered species, conserve proposed and candidate species, and maintain a viable population of each species of conservation concern within the plan area." Evaluation of how the coarse filter would provide for the diversity and abundance of wildlife is found in the Diversity and Abundance of Wildlife section. Evaluation of the consequences of the proposed plan for at-risk species are in two sections: the Abundance and Diversity of Wildlife section and the Threatened, Endangered, Candidate, and Proposed Wildlife Species section.

While meeting the requirements of 219.8 and 219.9 of the Planning Rule, the plan must provide for ecosystem services and multiple uses for wildlife and fish. Section 219.10 requires the deciding official to consider habitat conditions, subject to the requirements of § 219.9 for wildlife, fish, and plants commonly enjoyed and used by the public for hunting, fishing, trapping, gathering, observing, subsistence, and other activities. Plan components for wildlife uses were developed in collaboration with the Nez Perce Tribe and the Idaho Department of Fish and Game. The suite of plan components and alternatives will be analyzed for whether they provide for habitat conditions for species commonly enjoyed and used by the public as described above. This analysis can be found in the Wildlife for Multiple Uses section.

These wildlife reports provide information on the degree to which the revised plan and alternatives provide components that will maintain the diversity of animal communities and support the persistence of most native species in the plan area. By design, this report relies in part on the coarse filter information in the Forestlands section as a key part of that analysis. The directives state "for most species, the only practical quantitative evaluation of their required ecological conditions is an assessment of habitat conditions (ecological conditions)" (FSH 1909.12 23.13). In all reports, the analysis will evaluate how plan components and alternatives provide ecological conditions for wildlife, first through a coarse filter approach and then, if needed, through fine filter plan components. The fine filter plan components provide for the needs of wildlife species that are not well captured by coarse filter components and require individual attention. Some discussion is included from other resource reports as needed, particularly the Forestlands, Soil Resource, Water Resources, and Aquatic Ecosystems and Fisheries sections, for describing additional ecological conditions relevant to evaluation of wildlife habitats.

A brief description of the habitat needs of each species known to occur in the plan area can be found in Appendix C of the Final Environmental Impact Statement. To facilitate analysis of coarse filter ecosystem plan components, all wildlife species known to occur in the plan were grouped into one of seven broad categories or groups based on their habitat preferences. Species were further divided into habitat subgroups or subcategories, which are also presented in Appendix C. Rather than analyzing the effects of the plan on individual wildlife species, the analysis evaluates the effects of the plan and alternatives on these habitat groupings or subgroupings. The habitat groups are described and analyzed in the abundance and diversity of wildlife report, and a crosswalk of ecosystem plan components with habitat groups can be found in Appendix C. At-risk species were included in these groupings and individually analyzed.

At-risk species analyzed separately include the federally listed threatened Canada lynx (*Lynx canadensis*) and grizzly bear (*Ursus arctos horribilis*), wolverine (*Gulo gulo*), and the following species of conservation concern: fisher (*Pekania pennanti*), harlequin duck (*Histrionicus histrionicus*), white-headed woodpecker (*Dryobates albolarvatus*), bighorn sheep (*Ovis canadensis*), and mountain quail (*Oreortyx pictus*). Appendix C includes an evaluation of the threats to each at-risk species using the methods described below. The analysis in the wildlife report then goes on to evaluate the threats to these species in the plan area and how those threats are addressed in plan components. A crosswalk of at-risk species back to their risks and how plan components address these risks are included in Appendix C.

Additional sections of the Final Environmental Impact Statement analyze aspects of ecosystems that contribute to wildlife habitats. The Forestlands section describes how plan components in the No Action Alternative and action alternatives would provide for ecological sustainability and ecological integrity of ecological conditions for species that rely on forest vegetation characteristics, as directed by the 2012 Planning Rule. The Forestlands section discusses the degree to which some key ecosystem characteristics, which are identified as indicators for that analysis, would be maintained or restored by each alternative. More specifically, that report provides information regarding the potential impacts of the revised plan and alternatives on a variety of ecosystems, plant communities, and vegetation characteristics. These plant communities and vegetation characteristics provide many, but not all, of the habitat components required by terrestrial animal communities and native wildlife species.

Plant communities in the Forestlands section are discussed as broad potential vegetation type (PVT) groups and analysis in that report addresses succession, dominance types, density, resilience, size class, old growth, aspen, both live and dead large diameter trees, and some non-forested types. These characteristics will support many wildlife species. Many species depend on vegetation structural characteristics as key requirements and will be evaluated under ecosystem plan components. Plant communities for non-forested vegetation and their conditions, as well as effects, are discussed in the non-forested vegetation section of the Forestlands report.

A broad variety of wildlife, both terrestrial and aquatic associated species, use aquatic habitats, riparian areas, rivers, ponds, wetlands, and lakes. Aquatic habitats are discussed in the Aquatics Ecosystem and Fisheries and the Water Resources sections. These sections describe how plan components in the No Action Alternative and action alternatives would provide for ecological sustainability and ecological integrity of aquatic habitats, as directed by the 2012 Planning Rule. The Aquatics Ecosystem and Fisheries section discusses the degree to which key ecosystem characteristics of aquatic habitats would be maintained or restored by each alternative from a mostly fisheries perspective. More specifically, that report provides information regarding the potential impacts of the alternatives on a variety of aquatic ecosystems characteristics. These aquatic communities and vegetation characteristics provide many of the habitat components required by aquatic wildlife communities and native aquatic wildlife species. While the Aquatic Ecosystem and Fisheries and the Water Resource sections focus on fisheries and water quality and quantity, the Abundance and Diversity of Wildlife section evaluates the effects of the plan on aquatic and riparian habitat from a wildlife perspective.

Terrestrial wildlife species are important as contributors to biological diversity and ecosystem integrity, as well as providing benefits to humans in the form of viewing, hunting, trapping, cultural relevance, and sense of place. Many species serve ecological roles that contribute to the function of an ecological system. For example, some wildlife species disperse seeds and play an important role in reforestation after disturbance. Other species disperse fungi, many of which form symbiotic relationships with vegetation required for nutrient exchange between plants and their environments. Several bird species forage heavily on insects, which provide important checks and balances system on insect pests. Ensuring that native wildlife species are present, abundant, diverse, and will persist over the long term in the plan area will guarantee that ecosystems function properly and safeguard that wildlife continue to be available for a variety of human uses.

The 2012 Planning Rule requires that the plan must include components, such as standards or guidelines, to maintain or restore connectivity. As it pertains to wildlife, connectivity is defined as “the ecological conditions that exist at several spatial and temporal scales that provide landscape linkages that permit the daily and seasonal movements of animals within home ranges, the dispersal, and genetic interchange between populations, and the long-distance range shifts of species, such as in response to climate change” (36 CFR 219.19). Habitat connectivity is widely recognized as a crucial component for maintaining biodiversity and managing for sustainable populations of native species (Hansen 2009, McIntyre and Ellis 2011, Parks et al. 2012, Cushman and Landguth 2012, Wade et al. 2015, Haber and Nelson 2015, McClure et al. 2016, Western Governor's Association 2008, Thomas 1979).

Relevant Laws, Regulations, and Policy

Federal Laws

The following includes the key set of statutory authorities that affect wildlife management on National Forest System lands. They are briefly identified and described below to provide context to management and the Final Environmental Impact Statement evaluation of the wildlife resource. Many other laws, regulations, executive orders, and policies not described below also guide the management of this resource.

Bald and Golden Eagle Protection Act of 1940: This act prohibits unauthorized possession of bald and golden eagles, as defined through subsequent regulations.

Endangered Species Act of 1973, as amended: This act provides requirements for federal agencies with regard to species listed as threatened, endangered, or candidate under the act. Section 2 requires all federal agencies to “seek to conserve endangered species and threatened species.” Section 5 directs the Secretary of Agriculture to "establish and implement a program to conserve fish, wildlife, and plants," including federally listed species. Section 7 requires federal agencies to ensure that actions authorized, funded, or carried out by them are not likely to jeopardize the continued existence of any threatened or endangered species or result in the destruction or adverse modification of their critical habitats.

The Federal Cave Resources Protection Act of 1988: The purpose of this act is to protect and preserve significant caves and cave resources, including animal and plant life occurring naturally in caves, on federal lands and to foster cooperation and exchange of information between governmental authorities and those who use caves for a variety of purposes. A list of significant caves is to be maintained and periodically updated and significant caves are to be “considered in the preparation or implementation of any land management plan.”

Migratory Bird Treaty Act of 1918: This act prohibits unauthorized take of migratory birds, as defined through subsequent regulations. The language of this act, as amended, is as follows “unless and except as permitted by regulations…it shall be unlawful at any time, by any means or in any manner, to pursue, hunt, take, capture, kill, attempt to take, capture, or kill…any migratory bird, any part, nest, or egg of any such bird…included in the terms of the conventions.”

National Forest Management Act of 1976: This act states that the Secretary shall “promulgate regulations” under the principles of the Multiple-Use Sustained-Yield Act of 1960 to “provide for diversity of plant and animal communities based on the suitability and capability of the specific land area to meet overall multiple-use objectives, and within the multiple-use objectives of a land management plan adopted pursuant to this section, provide, where appropriate to the degree practicable, for steps to be taken to preserve the diversity of tree species similar to that existing in the region controlled by the Plan”

(Pub. L. 94-588, Sec. 5 (g)(3)(B)). The 2012 Planning Rule was determined to be consistent with this act (77 FR 21162).

Nez Perce Treaty of 1855: This treaty retained certain rights to hunt, fish, graze, and gather on the lands ceded to the United States. These rights, retained on ceded lands, are known as “off-reservation treaty rights” or “other reserved rights.” These treaty rights include hunting, gathering, and grazing rights on federal lands within the plan area. Trust responsibility arises from the United States' unique legal and political relationship with Indian tribes. It derives from the Federal Government's consistent promise, in the treaties that it signed, to protect the safety and well-being of the Indian tribes and tribal members. The federal trust responsibility is a legally enforceable fiduciary obligation on the part of the United States to protect tribal treaty rights, lands, assets, and resources, as well as a duty to carry out the mandates of federal law with respect to all federally recognized American Indian and Alaska Native tribes and villages.

Sikes Act of 1974, as amended: This act states that Forest Service policies recognize the fact that state agencies and Indian tribes are responsible for management of animals, whereas national forests manage wildlife habitats in cooperation with those entities. The Sikes Act directs the Secretaries of Interior and Agriculture to cooperate with the states in developing comprehensive plans to plan, maintain, and coordinate the conservation and rehabilitation of wildlife, fish, and game, including but not limited to protection of species considered threatened or endangered pursuant to Section 4 of the Endangered Species Act (16 USC 1533) or considered to be threatened, rare, or endangered by the state agency.

Executive Orders

Executive Order 11644—Use of Off-Road Vehicles—1972, as amended by Executive Order 11989: This order addresses the use of off-road vehicles on public lands. It requires the Forest Service to “establish polices and provide for procedures that will ensure that the use of off-road vehicles on public lands will be controlled and directed so as to protect the resources of those lands, to promote the safety of all users of those lands, and to minimize conflicts among the various uses of those lands.” The order directs agencies to designate the “specific areas and trails on public lands on which the use of off-road vehicles may be permitted and areas in which the use of off-road vehicles may not be permitted.” The minimization criteria are identified in the final rule for Travel Management—Designated Routes and Areas for Motor Vehicle Use. This rule is commonly referred to as the 2005 Travel Management Rule and implements provisions of Executive Orders 11644 and 11989 regarding off-road use of motor vehicles on federal lands. Regulations implementing this rule are found in 36 CFR § 212. The portion of the rule pertaining to motor vehicle use is subpart B and the portion of the rule pertaining to motorized over-snow vehicle use is subpart C, which was updated in January 2015. The “minimization criteria” referenced in the 2015 circuit court opinion and district court order are in 36 CFR § 212.55(b), where specific criteria for designation of trails and areas relevant to wildlife specify that “in designating National Forest System trails and areas on National Forest System lands, the responsible official shall consider effects on the following with the objective of minimizing… (2) Harassment of wildlife and significant disruption of wildlife habitats.” The Nez Perce-Clearwater designates specific areas and trails for the use of motor vehicles, including off-road vehicles. These areas and trails are displayed on the Nez Perce-Clearwater’s motor vehicle use maps, as required by 36 CFR § 212 subpart B.

Executive Order 12898—Environmental Justice—February 11, 1994: This order directs federal agencies to identify and address the disproportionately high and adverse human health or environmental effects of their actions on minority and low-income populations to the greatest extent practicable and permitted by law.

Executive Order 13112—Invasive Species—February 3, 1999: This order called upon executive departments and agencies to take steps to prevent the introduction and spread of invasive species and to support efforts to eradicate and control invasive species that are established.

Executive Order 13186—Migratory Birds—January 10, 2001: This order was issued by President Bill Clinton in furtherance of the purposes of the Migratory Bird Treaty Act, the Bald and Golden Eagle Protection Acts, the Fish and Wildlife Coordination Act, the Endangered Species Act, and the National Environmental Policy Act. This order requires including effects of federal actions on migratory birds as part of the environmental analysis process. On January 17, 2001, the Forest Service and the Fish and Wildlife Service signed a memorandum of understanding to complement the executive order. The memorandum of understanding expired in 2017; however, other sections of the executive order, coupled with the Migratory Bird Treaty Act and Bald and Golden Eagle Act, address Forest Service avian compliance to protect migratory birds.

Policy

2001 Roadless Area Conservation Rule (36 CFR § 294 subpart B; 66 FR 3244-3273): This rule includes a prohibition on road construction and road reconstruction in inventoried roadless areas and prohibits timber cutting, sale, or removal except in certain circumstances.

2012 Planning Rule: The rule requires national forests to maintain the diversity of plant and animal communities and support the persistence of native species within the plan area. National forests are directed to use a "complementary ecosystem and species-specific approach to provide for the diversity of plant and animal communities" and to maintain species persistence in their planning.

Relative to wildlife species, the rule directs national forests to consider:

- habitat conditions for at-risk species, subject to the requirements of 36 CFR § 219.9;
- habitat conditions for wildlife, fish, and plants commonly enjoyed and used by the public for hunting, fishing, trapping, gathering, observing, subsistence, and other activities in collaboration with federally recognized Tribes, Alaska Native Corporations, other federal agencies, and state and local governments (§ 219.10 (a)(5)), subject to the requirements of § 219.9;
- dominant ecological processes, disturbance regimes, and stressors such as natural succession, wildland fire, invasive species, and climate change;
- the ability of terrestrial and aquatic ecosystems on the plan area to adapt to change (§ 219.8);
- habitat and habitat connectivity; and
- riparian areas (§ 219.10 (a)(1)).

The 2012 Planning Rule requires that forest plans use a complementary ecosystem and species-specific approach. The responsible official determines whether the plan components provide the ecological conditions necessary to contribute to the recovery of federally listed threatened and endangered species, conserve proposed and candidate species, and provide ecological conditions to maintain a viable population of each species of conservation concern within the plan area. If the responsible official determines that the ecosystem plan components are insufficient to provide such ecological conditions, then additional species-specific plan components, including standards or guidelines, must be included in the plan to provide such ecological conditions in the plan area (36 CFR § 219.9 (b)(1)). If the responsible official finds that it is beyond the authority of the Forest Service or not within the inherent capability of the plan area to maintain or restore the ecological conditions to maintain a viable population of a species of conservation concern in the plan area, then the responsible official must show that the plan includes plan components, including standards or guidelines, to maintain or restore ecological conditions within the plan area to contribute to maintaining a viable population of the species within its range.

The term "recovery" is defined in the 2012 Planning Rule as "the improvement in the status of a listed species to the point at which listing as federally endangered or threatened is no longer appropriate." The term conserve is defined as "to protect, preserve, manage, or restore natural environments and ecological communities to potentially avoid federally listing of proposed and candidate species." The term "conservation" is defined as "the protection, preservation, management, or restoration of natural environments, ecological communities, and species" (36 CFR 219.19).

2015 Final Land Management Planning Directives: These directives provide specific information regarding implementation of the 2012 Planning Rule, including identifying at-risk species and guidance for development of plan components to provide ecological sustainability for at-risk species. The directives state that plan components developed for ecosystem integrity are expected to provide conditions that will maintain the persistence or contribute to the recovery of native species within the plan area. They also state that if components for ecosystem diversity are not adequate to do that for at-risk species, then species-specific plan components should be developed.

Plan components developed for multiple uses may contribute to, or detract from, ecological conditions needed for at-risk species. For example, on some forests or grasslands a portion of the plan area may have a desired condition for undeveloped remote recreation. Such a desired condition should be taken into account when evaluating the ecological conditions for at-risk species because it may mitigate some stressors, contribute to ecological conditions, or provide refugia.

Development of plan components for proposed and candidate species should be based on the ecological conditions necessary to conserve proposed and candidate species that were identified in the assessment phase or through information brought forward during the public and governmental participation process and maintain or restore their habitats in the plan area to contribute to preventing them from being federally listed (FSH 1909.12, Ch. 10, sec. 12.55).

Additional policies specific to Wildlife include the following:

- 36 CFR 212 Travel Management
- 36 CFR 223 Special Forest Products
- 36 CFR 228 Minerals
- 36 CFR 241 Fish & Wildlife
- 36 CFR 251 Land Uses
- 36 CFR 254 Land Ownership Adjustments
- 36 CFR 262 Law Enforcement Support Activities
- 36 CFR 293 Wilderness

State and Local Policy

Title 36—Fish and Game: This policy provides the State of Idaho's comprehensive wildlife laws.

State and Local Plans

Clearwater County Natural Resources Plan: This plan establishes a framework for the county's resource management activities

Clearwater County Community Wildfire Protection Plan

Idaho County Natural Resources Plan: This plan clearly states the desires and objectives of the county regarding management of the natural resources located on public lands located within the county.

Idaho County Wildland-Urban Interface Wildfire Mitigation Plan: This plan was developed to address the National Fire Plan, consistent with Federal Emergency Management Agency requirements, at the county level and it describes the risks and potential treatments within the wildland-urban interface of Idaho County.

Benewah County Natural Resources Plan

Idaho Elk Plan: This plan functions as an action plan to provide specific goals, strategies, and performance objectives for elk management. The planning process outlines the status of hunter preferences and wildlife populations to determine goals, strategies, and performance objectives that will drive future management direction. The plan provides guidance to Idaho Department of Fish and Game's staff to manage Idaho's elk habitat and populations.

Idaho Whitetail Deer Plan: This plan provides guidance to Idaho Department of Fish and Game staff to manage Idaho's white-tailed deer habitat and populations.

Idaho Moose Plan: This plan provides guidance to Idaho Department of Fish and Game staff to manage Idaho's moose habitat and populations.

Idaho Mule Deer Plan: This plan provides guidance to Idaho Department of Fish and Game staff to manage Idaho's mule deer habitat and populations.

Idaho Bighorn Sheep Plan: This plan provides guidance to Idaho Department of Fish and Game staff to manage Idaho's bighorn sheep habitat and populations.

Idaho Mountain Goat Plan: This plan provides guidance to Idaho Department of Fish and Game staff to manage Idaho's mountain goat habitat and populations over the next six years. The plan directs Idaho Department of Fish and Game to sustain or increase mountain goat populations across the state. To accomplish this goal, Idaho Department of Fish and Game has identified statewide management direction and strategies, as well as specific strategies for each Population Management Unit (PMU).

Latah County Community Wildfire Protection Plan

Shoshone County Fire Mitigation Plan

State Wildlife Action Plan: Idaho's statewide plan for conserving and managing Idaho's diverse fish and wildlife and the habitats they depend on serves as strategic direction to implementing proactive, nonregulatory, action-based solutions to conserve fish and wildlife. The Plan provides a checklist of wildlife species in the state; provides criteria for identifying species of greatest conservation need; and provides an assessment of each species of greatest conservation need, including their extirpation risk in Idaho. The document identifies associated conservation targets, such as habitat and species assemblage, and a narrative description for each conservation target, its viability, and prioritized threats and strategies.

Methodology

Changes Between the Draft and Final Environmental Impact Statements

Many plan components underwent editing and revision between the Draft and Final Environmental Impact Statement in response to comments, feedback from cooperating agencies, internal Forest Service review, consultation with the U. S. Fish and Wildlife Service, and consultation with the Nez Perce Tribe. Changes to coarse filter ecosystem plan components occurred within several sections of the plan including the forestlands, aquatic ecosystems, and in the meadows, grasslands, and shrublands sections, for example. There were also changes to species specific plan components including for bighorn sheep related to pack goats, the fisher plan component, the plan components for multiple use wildlife including elk (*Cervus canadensis*), and the addition of plan components designed to contribute to grizzly bear recovery.

The wildlife analysis for the Final Environmental Impact Statement is far more developed than it was at the Draft Environmental Impact Statement phase. Improvements include more rigorous spatial overlays in nearly every section of the wildlife analysis to evaluate the effects of land allocations, improved vegetation modeling and queries to evaluate the effects on habitat, a more robust grizzly bear analysis, and changes in response to plan component changes. For example, there were significant improvements in the model to evaluate the trend in riparian habitat conservation areas (RHCAs) under the plan. This included improved delineation of riparian areas, improved vegetation data, and improved pathways to predict their growth patterns. They were also calibrated with our understanding of fire behavior from on the ground surveys in the plan area. A second example is that there was a more refined habitat model to evaluate the trend in fisher habitat including the development of a spatial query to evaluate how the plan would affect the spatial distribution of preferred female home ranges. In a third example, the elk query was combined with a nutrition potential model to evaluate the changes in available high-quality nutrition as a result of the plan which should support higher elk and other ungulate populations for multiple uses. There was improvement to the analysis of coarse filter ecosystem plan components to evaluate how the plan would provide for the diversity and abundance of wildlife based on key ecosystem characteristics, and effects on habitats. Appendix C provides a new crosswalk of species, their habitat, key ecosystem characteristics of habitats, and how plan components provide for those habitats. It also provides a crosswalk of how plan components address threats to at-risk species.

Spatial Scale

The spatial scale is the plan area of the Nez Perce-Clearwater. However, in some cases, the evaluation looks at the broader landscape when evaluating cumulative effects, connectivity, and wide-ranging species. The plan area was chosen because it represents nearly 4 million acres of habitats for wildlife, which is sizable enough to contain populations of most species. Furthermore, the Nez Perce-Clearwater only has control over activities and actions within the plan area.

In general, the analysis area for wildlife includes all lands managed by the Nez Perce-Clearwater; however, for the purposes of this document it may include segments outside National Forest System boundaries. In some cases, National Forest System lands may provide all, or a high percentage, of the habitat for a given species; however, in most instances, wildlife generally move from area to area without regard for boundaries. Cumulative effects analyses generally include lands within other ownerships immediately adjacent to the Nez Perce-Clearwater, although for some wide-ranging species the analysis area may have been larger and included an evaluation of connectivity between larger areas of habitat, such as connectivity for grizzly bears between recovery zones.

Temporal Scale

In most cases, the temporal scale of analysis included the life of the Land Management Plan. Some habitat analyses are evaluated over a longer timeframe. The Ecosystem Research Group report (Ecosystem Research Group 2019, 2021), for example, assessed habitat changes for the next five decades. Past actions were also considered, as they play a role in determining the existing conditions and may interact cumulatively with the effects of the Land Management Plan. In some cases, it may be appropriate to evaluate a longer time scale. Such instances include situations where a wildlife species' generation time or lifespan is longer than the life of the plan. Some habitat management may have effects that last much longer than 50 years. For example, management in mature or old forest that could occur under the selected alternative may affect habitat conditions at a site for hundreds of years. These effects would be of little consequence at a landscape scale unless they occurred at a pace that affected the proportions of those habitat types through time in the plan area. To account for these situations, the analysis used modeling for 120 years through SIMPPLLE and 120 and 150 years in PRISM. However, the farther out predictions are made the more uncertain they are. Most reporting from SIMPPLLE and PRISM modeling is for 50-year periods to limit uncertainty. The analysis recognizes that effects can last over longer time periods.

Some changes that would occur under the plan may be permanent and consequences may be permanent. The conversion of native habitats to a condition dominated by exotic vegetation could have effects that would be more or less permanent. The loss of very live old trees could be permanent from a practical standpoint given the length of time needed for trees to reach that age. Similarly, in the event the climate changes enough so that forest conditions of the past could not be maintained, the effects of some management may never return to their historic range of variability. The question then becomes whether those systems are sustainable through time. In summary, effects for most species will be the life of the plan, except in the cases described above when generation times are long, when species are dependent upon old growth or climax stage forest, or in cases where effects are more or less permanent. In those instances, the analysis used different timeframes on a case-by-case basis.

Use of Models, Maps, and Data

The Nez Perce-Clearwater relied on a variety of databases to support the development of plan components and assess the consequences of alternatives to native species. The Nez Perce-Clearwater's map-based information is stored in a geographic information system (GIS) database maintained by the Nez Perce-Clearwater's GIS specialists. GIS-based data includes layers such as forest vegetation layers, topography layers, administrative boundaries, management areas, road and travel layers, recreation sites, timber suitability layers, range, wildlife databases, wildlife habitat models, and others.

The models used are identified in the individual section for each species. Wildlife analyses relied on quantitative and spatial outputs from multiple modeling exercises, using GIS and other tools. Such models were used to evaluate:

- proportions of unique habitat types affected by permanent human developments, such as roads and other infrastructure
- amounts and types of habitat for species, such as lynx and wolverine
- important areas for wildlife habitat connectivity
- predicted changes in climate patterns and potential impacts to wildlife and habitat.

Statistician George Box famously wrote "all models are wrong, but some are useful" (Box 1979). This statement implied that models do not perfectly represent reality exactly, but models often do provide remarkably useful approximations (Box 1979). A model is a simplification or approximation of reality and will not reflect all of reality. In this analysis, it is not assumed that the models are exact representations of reality, only that they approximate reality in a useful way through the parameters they are meant to inform. It is important to understand that models have limitations. There is uncertainty with all models, including models of the natural range of variation that occurred in the past, as well as the changes predicted to occur in the future. In addition, models, maps of habitat, and numeric estimates of habitat or species populations may change over time due to changes on the ground, as technology changes to acquire better data, or as on-the-ground inventories are conducted that better inform our understanding. Inventories, models, maps, and data may be updated periodically for the implementation of projects.

A variety of sources were used to determine historic and existing vegetation conditions on the Nez Perce-Clearwater. The development of management recommendations for the Final Environmental Impact Statement to maintain or restore ecological conditions was based on the natural range of variability and desired future conditions influenced by climate change. Movement towards the desired conditions for vegetation under the Land Management Plan would provide for an array of ecological communities of sufficient size, structure, and distribution that is expected to maintain habitats for most native species that occur on the Nez Perce-Clearwater. See the Forestlands section for additional information.

The natural range of variation (NRV) reflects the ecosystem conditions that have sustained the current complement of wildlife and plant species on the Nez Perce-Clearwater and provides context for understanding the natural diversity of ecosystems and processes, such as wildfire, insects and disease, and plant succession. The NRV, current conditions, future trends, and effects of alternatives for vegetation were estimated using the SIMPPLLE and PRISM models, which use the Northern Region's Existing Vegetation Database (VMap) and Forest Inventory and Analysis (FIA) data sets for inputs and calibration of the models. SIMPPLLE estimates the NRV for vegetation composition, size class, canopy cover, density, pattern, patch size, and patch distribution (Ecosystem Research Group 2019). SIMPPLLE is a spatially interactive, dynamic landscape modeling system for projecting temporal changes in the spatial distribution of vegetation in response to insects, disease, wildland fire, and other natural and management-caused disturbances. SIMPPLLE must be calibrated with disturbance data so that predictions are good estimates of outcomes.

Vegetation outputs from SIMPPLLE simulations can be queried to estimate effects to wildlife species. The analysis used several wildlife queries to estimate outcomes of plan alternatives. Wildlife queries are composed of a set of measurable vegetation characteristics, such as size classes, canopy cover, dominance type, or tree density, that are thought to indicate habitat conditions selected by wildlife. Several wildlife queries were developed to estimate outcomes for wildlife species. Queries were developed for fisher, American marten (*Martes americana*), Ponderosa pine associated species, elk, mountain quail, Canada lynx, and others for evaluation of Land Management Plan outcomes. The Ecosystem Research Group interpreted vegetation model outputs to estimate outcomes of the plan and alternatives on a select set of wildlife species over the next 50 years. Wildlife models are derived from a query or subset of the full SIMPPLLE model outputs which represent habitat characteristics known to be selected by these species based on the best available scientific information. The model outputs estimate the trend or outcome of the alternatives on the subset of vegetation characteristics that represent the habitats used by the species.

For example, the Canada lynx habitat model was created, as described in the 2014 Threatened, Endangered, Proposed, and Candidate Species Assessment (U.S. Department of Agriculture 2014d). This model used vegetation data for broad potential vegetation types that are known to contribute to lynx habitat. The lynx habitat model was queried in SIMPPLLE to estimate the natural range of variability for lynx habitat in the plan area. A combination of PRISM and SIMPPLLE modeling was then run for lynx vegetation queries to simulate future conditions and evaluate the effects of plan components and alternatives on lynx habitat.

Although model outputs show future trends over the next 50 years, there is uncertainty regarding the timing and magnitude of trends due to the uncertainty associated with the models. SIMPPLLE simulates disturbance randomly and grows vegetation to make predicted outcomes, but disturbances simulated by the model do not represent actual events. However, events simulated in SIMPPLLE, like wildfire or insect outbreaks, are typical and common in the plan area. The amounts of these disturbances in the model are informed by a variety of data sources to ensure proper calibration. More information about SIMPPLLE modeling methods can be found in the Forestlands report.

In some cases, we relied on models that were developed by scientists, state agencies, or within the Forest Service. For example, similarly, a fisher habitat model developed by Joel Sauder (2014) was used to evaluate similar overlays of alternatives on fisher habitats. Models developed by scientists from the Intermountain Bird Observatory (Miller and Carlisle 2018) were used to identify threats within their distribution and evaluate the effects of the plan on white-headed woodpeckers and mountain quail. Such overlays lend context to effects of alternatives. Models used and how they were used are outlined as follows:

- SIMPPLLE Model was used to estimate the natural range of variation (NRV) for large landscapes and provide predictive vegetation response or outcomes resulting from following desired conditions, objectives, and alternatives. Landscape outputs were then queried to inform outcomes for a suite of habitats that provide for wildlife. Queries included dry forest or large tree associated species (Ponderosa pine associates), fisher, American marten, Canada lynx, Burned Forest associates (for example black-backed woodpecker [*Picoides arcticus*] and three-toed woodpecker [*Picoides dorsalis*]), snags and coarse woody debris associates, summer elk nutrition, mountain quail, riparian habitat associated species, and patch size.
- we employed models of wolverine habitat model (Inman 2013), to evaluate the effects of the plan on wolverine habitat. This model was used to understand the scope of effects to wolverines by overlaying them on various alternatives. The Inmann models are composed of wolverine maternal, wolverine primary, and wolverine female dispersal habitat. This model was used to understand effects to wolverines by overlaying wolverine habitat with the different alternatives for land allocations. For example, the amount of recommended wilderness was overlaid on wolverine habitat to evaluate those effects.
- Lynx habitat model as described in as described in the 2014 Threatened, Endangered, Proposed, and Candidate Species Assessment (U.S. Department of Agriculture 2014d). Used as a model input into SIMPPLLE to model effects of Northern Rockies Lynx Management Direction, and as the basis for restrictions in lynx habitat. The model was also used to evaluate the effects to lynx habitat from the alternatives for various land allocations.
- Fisher habitat model developed by (Sauder 2014). This model was used to evaluate overlays of alternatives on fisher habitats, assess threats to the species in the plan area, and to calibrate the fisher query in SIMPPLLE. An additional spatial query for SIMPPLLE was developed to evaluate how the plan components and alternatives would contribute to the distribution of fisher habitats.
- White-headed woodpecker model (Miller and Carlisle 2018). Used to evaluate threats to White-headed woodpecker and to calibrate and validate the query for dry forest or large tree species query in

SIMPPLLE. Because the Miller and Carlisle model was not forestwide, a white-headed woodpecker query based on VMap vegetation data was used to qualitatively evaluate the spatial overlap with land allocations and the effects of the alternatives.

- Mountain Quail model (Miller and Carlisle 2018). Used to evaluate threats to mountain quail and to calibrate and validate the query for dry forest or large tree species query in SIMPPLLE.
- Elk nutrition models developed within the plan area to predict existing and potential elk nutrition (Cook et al 2018). The existing and potential nutrition models were crosswalked with vegetation types and used as inputs into SIMPPLLE to predict nutritional response of desired conditions, objectives, and alternatives.
- Bighorn sheep habitat models presented in Mack et al (2017). These models were used to understand the current and potential bighorn sheep habitat, evaluate threats to bighorn sheep, evaluate the alternatives and develop plan components.
- Downscaled climate models were used to predict the effects of a changing climate. For the Final Environmental Impact Statement, the Nez Perce-Clearwater used a compilation of climate change effects published for the U.S. Forest Service Northern Region Adaptation Partnership (Halofsky, Andrews-Key, et al. 2018, Halofsky, Peterson, et al. 2018a) that summarizes climate change projections by subregions. Furthermore, McKelvey and Buotte McKelvey and Buotte (2018) provided a summary of modeled climate change effects on wildlife in the northern Rocky Mountains.

A wide variety of wildlife location data was used in conjunction with habitat models to understand the distribution of wildlife species in the plan area.

Past, Present, and Future Activities Used in the Analysis

Past and present activities have affected habitat conditions in the plan area. Activities and factors include fire suppression, past timber harvest practices, road development, exotic forest diseases, invasive plants, fuels, and mining. Before about the 1980s, timber management, coupled with fire suppression, favored dominance by shade intolerant forest species, reduced old growth, increased forest density, changed patch size, reduced patch heterogeneity, changed landscape pattern, and reduced amounts of non-forested habitats. Since the 1987 plans were signed, timber harvest has declined, but fire suppression has continued which has exacerbated some conditions like encroachment of grand fir into Ponderosa types, decreased early seral and non-forested habitats, increased mature seral stages, favored fire intolerant trees, and decreased heterogeneity across the landscape.

Roads increased throughout the Nez Perce-Clearwater, especially in the managed front country with associated timber harvest through the 1980s, but the road system has been reduced by hundreds of miles through Forest Service closures since the 1987 plans were signed. Roads were also reduced or prevented through the Idaho Roadless Rule. Still, some areas in the managed front have relatively high road densities usually on lands where timber harvest is emphasized.

Exotic and native forest disease and insects have affected forest health. For example, blister rust has caused substantial decline in two important tree species, the western white pine and the whitebark pine. Whitebark pine provides mast as a food source for a number of wildlife species. The effects of the widespread loss of western white pine are unknown for wildlife but probably could be an important change in wildlife habitat.

Mining was extensive in the days of early European settlement and several areas of the Nez Perce-Clearwater were impacted by the gold rush. Most of the impacts were to river systems where, in some cases, extensive changes to stream geomorphology occurred. Mining continues today but is much less intrusive. It is mostly constituted of small-scale operations that are conducted to minimize impacts to federally listed fish.

Several invasive plants have become established and spread. In some cases, these species have displaced native vegetation, especially in the warmer drier, non-forested habitats. These serve as important winter habitats for big game and important habitats for species that use non-forested habitats. These changes can be more or less permanent without comprehensive restoration and an integrated approach to control the spread of invasive weeds. Existing invasive weed species continue to spread and new invasive weed species continue to be introduced outside of Forest Service control. Ongoing efforts to control and prevent invasive weed species continue through cooperative weed partnerships.

These factors and conditions were considered during the development of plan components and alternatives and evaluation of the proposed Forest Plan and Preferred Alternative.

Evaluation of Threats

The Nez Perce-Clearwater adopted a framework for the evaluation of threats similar to those used by a number of conservation organizations, including The Nature Conservancy, the International Union for Conservation of Nature, and NatureServe (Salafsky et al. 2003). The general approach is to evaluate the scope and severity of threats to assign the magnitude of the threats. The NatureServe method uses a combination of the scope of the threats and the severity of the threats to assign an estimated impact. The Nez Perce-Clearwater adjusted the scale of the threats to the spatial distribution of the Nez Perce-Clearwater and used the NatureServe criteria for assigning scope and severity (Table 150). The definitions used for scope and severity in threats evaluations are presented in the following table.

Table 150. Definitions of scope for evaluation of threats to wildlife in the plan area

Threat Scope
Pervasive = Affects all or most (71-100%) of total population for a species or occurrences in plan area or affects area/percent of habitat
Large = Affects much (31-70%) of total population for a species or occurrences in plan area or affects area/percent of habitat
Restricted = Affects some (11-30%) of total population for a species or occurrences in plan area or affects area/percent of habitat
Small = Affects a small proportion (1-10%) of total population for a species or occurrences in plan area or affects area/percent of habitat
Negligible = Affects a negligible proportion (<1%) of total population or occurrences
Unknown
Does not occur = Threat does not occur within plan area

Table 151. Definitions of severity for evaluation of threats to wildlife in the plan area

Threat Severity
Within the scope, the threat is:
Extreme = Likely to destroy or eliminate occurrences or reduce population or distribution of habitat 71-100%
Serious = Likely to seriously degrade/reduce affected occurrences or habitat or reduce population 31-70%
Moderate = Likely to moderately degrade/reduce affected occurrences or habitat or reduce population 11-30%
Slight = Likely to only slightly degrade/reduce affected occurrences or habitat, or reduce population 1-10%
Negligible = Likely to have only negligible negative effects on occurrences or habitat or reduce population <1%
Neutral or Benefit Potential = Not a threat

Threat Severity
Unknown

The scope of a threat is the spatial overlap of each threat with that of the conservation target. The severity of the threat is the extent to which it will either reduce the percent area of a conservation target or reduce the population numbers, extent, or distribution of a species. The scope was informed by evaluating the distribution of the threat against either 1) the distribution of modeled habitat within the Nez Perce-Clearwater or 2) the distribution of observations within the habitat preferences of the species when habitat models were not available. The severity is the degree to which a threat is likely to destroy or eliminate populations or reduce distribution within the next 15 years. The impacts or magnitude of the threat were assigned based on a matrix that assigns a severity score based on the combination of these two factors (Salafsky et al. 2003, Master et al. 2012). Depending upon the combination of scope and severity, the method assigns a relative threat impact that ranges from very high, high, medium, and low (Table 152).

Table 152. The rule-based threat category based on a combination of scope and severity

Severity	Pervasive in Scope	Large in Scope	Restricted in Scope	Small in Scope	Unknown Scope
Extreme	Very high	High	Medium	Low	Medium
Serious	High	High	Medium	Low	Medium
Moderate	Medium	Medium	Low	Low	Low
Slight	Low	Low	Low	Low	Low
Unknown	Medium	Medium	Low	Low	N/A

The distribution of the threats was often constrained or determined by land allocations or designations, such as designated wilderness, Idaho Roadless Rule areas, wild and scenic rivers, or multiple-use lands. Because management areas by nature are spatial in extent, the analysis found it easy to evaluate the scope of threats by nesting them within management area direction. For example, designated areas, such as wilderness, prohibit many management actions. Whereas, in the general forest areas such as Management Area 3, more management actions are allowed that could be considered threats, such as timber production, motorized recreational uses, road construction, or other threats that are allowed. Therefore, the analysis could analyze the effects of the threats from the plan direction, plan components, and alternatives by evaluating the percent of overlap of a species habitat or area occupied by various land allocations. For any given threat, if that activity is not allowed under the management direction for the land designation, then it was not considered a threat for that portion of the Nez Perce-Clearwater. When a threat was present regardless of management area direction, the distribution and intensity of the threat was informed by published literature, models, or agency expertise.

Threats were evaluated in detail in this report when they were identified as medium through very high or if a threat was identified within the best available scientific information as significant threats to threatened, endangered, or candidate species. Plan components and alternatives were developed to address threats within Forest Service control to federally listed threatened, endangered, proposed, or candidate wildlife species and are evaluated below. The intended effect of plan components is to reduce the scope or severity of threats. Alternatives considering land allocation, such as those for management areas, recommended wilderness allocation, and Wild and Scenic River suitability, often altered the scope of the threats.

The unified classifications of threats (Salafsky et al. 2008) was used as the basis to identify the list or definition of threats. This classification system is a hierarchical listing of terms and associated definitions that are comprehensive and exclusive at the upper levels of the hierarchy, expandable at the lower levels, and simple, consistent, and scalable at all levels. In some cases, the analysis found it was necessary to use expanded definitions at the third level. For example, the analysis evaluated the effects of several types of practices associated with silviculture distinctly as third level threats because their effects are different. For example, regeneration harvest has different effects than thinning and the Nez Perce-Clearwater thought it useful to distinguish these. Examples of these categories include commercial and noncommercial thinning, intermediate harvest, clear cuts, site prep, and firewood gathering. Similarly, the analysis expanded recreation and evaluated more specific categories of recreation than is generally included in in the standard lexicon (Salafsky et al. 2008). To focus our analysis, some threats were eliminated altogether because they did not occur within the plan area. So, the analysis evaluated these threats only once for the whole plan area and, when the threat did not occur, the analysis did not continue using that category of threats. For example, agricultural and aquaculture do not occur within the plan area as defined. The Nez Perce-Clearwater is not aware of any oil and gas production in the plan area. The analysis considered the plan area to be absent of war, military exercises, and civil unrest as these are not threats at this time and are not likely to be threats within the life of the plan. These categories were considered but eliminated from future evaluation. Threats determinations for species of conservation concern and federally listed species can be found in Appendix C. Plan components were developed to address the threats specific to each at-risk species.

Assumptions

The Land Management Plan provides a programmatic framework that guides site-specific actions but does not authorize, fund, or carry out a project or activity, including ground-disturbing actions. As a result, it does not result in direct effects to wildlife but may result in indirect or cumulative environmental consequences under this programmatic framework. Before ground-disturbing actions take place, they must first be authorized in a site-specific environmental analysis. Therefore, none of the alternatives would cause unavoidable adverse impacts or an irreversible or irretrievable commitment of resources. The Land Management Plan's desired conditions, objectives, standards, guidelines, management area allocations, and suitability will be followed when planning or implementing new site-specific projects and activities. Laws, regulations, and policy regulations will also be followed when planning or implementing new site-specific projects and activities. Terms and conditions and reasonable and prudent measures resulting from U.S. Fish and Wildlife Service consultation on the programmatic framework of the Land Management Plan will be followed when planning or implementing new site-specific projects and activities, unless modified by site-specific consultation.

The planning rule assumes that natural systems will provide the ecological conditions for most native species in the plan area if they are operating within their natural range of variability and have ecological integrity. This framework is identified by the planning rule as the coarse filter. The coarse filter approach is much more practical from a management standpoint in providing for the diversity and abundance of wildlife, which moves away from single species management. Implementation will be subject to testing with appropriate monitoring data. See the Land Management Plan Appendix 3. Effects analyses, including some of the modeling efforts, are based on the following assumptions:

- There is some degree of uncertainty with all modeling efforts, but the models used in the effects analysis provide a reasonable approximation of past, current, and predicted future environmental conditions upon which to base assessments and form conclusions.

- Data collected at the national forest, regional, and national scale have varying levels of accuracy and completeness but provide a reasonable representation of wildlife occurrence, abundance, distribution, and habitat conditions on the Nez Perce-Clearwater.
- The natural range of variation reflects ecosystem conditions that have sustained the current complement of wildlife and habitats on the Nez Perce-Clearwater and provides the context for understanding natural diversity of ecosystems and processes, such as wildfire, insects and disease, and natural plant succession. The analysis assumes that managing habitats within their natural range of variation would provide for the diversity and abundance of wildlife in the plan area and for the ecological conditions for long-term persistence of most native species.
- Population trends of wildlife species may change as a result of effects from national forest management practices. However, due to the natural range of vegetation patterns and disturbance processes in the northern Rocky Mountains, fluctuations in wildlife populations and distribution are normal and often result from natural factors, such as predation, starvation, disease, or widescale habitat changes resulting from fire, flood, drought, and other natural disturbance processes. For migratory species, a change in population may not reflect a change in local habitat conditions but rather occur as a result of activities or conditions experienced elsewhere in the United States or even in other countries.
- Effects of permanent changes to habitat are more impactful than those that temporarily alter habitat conditions but do not result in permanent habitat loss. Permanent habitat loss includes construction of buildings, paved or permanent roads, dams, invasive plants, and some aquatic alterations. Temporary impacts result from changes to habitat that will recover through time. Examples of these types of impacts include vegetation treatments, fuels treatments, and wildfire. These impacts do not result in permanent loss of habitat.
- Effects of threats vary based on the combination of scope and severity they pose to wildlife. Threats that have wider scopes and higher severity have more impacts, while those with small scopes and lower severity have less impacts.
- Global and state species rankings are indices of species status at the relative scale but may or may not be indicative of local wildlife populations in the Nez Perce-Clearwater.
- Wildlife habitat occurs as a function of the biophysical composition of the landscape. Habitat for wildlife is a product of the vegetation, water, soils, topography, and associated both natural and human-induced ecological processes from the micro-site level to local, regional, and global extents. The wildlife analyses rely on, and often tier to, information and analysis presented in other sections of this document.

Wild animals are mobile, wary, and often actively avoid humans. Therefore, it can be difficult to locate and study individuals, let alone obtain meaningful scientific information for entire populations. Population trend information is extremely difficult to obtain because it requires data for at least a reasonable reference set of individuals over broad areas, including information on survival and reproduction rates and immigration and dispersal. Considering the large number of wildlife species inhabiting the vast expanse of the Nez Perce-Clearwater for at least part of their life cycle, there is limited scientific information on biology, ecology, and population trends for most species present that is specific to the plan area. Some species are rare or associated with remote, rugged environments or are present here for a relatively short time before moving elsewhere, making detection and observation even more difficult. Sometimes, population trends can be inferred indirectly through indices, upward trends in observations, or though trends in harvest success rates.

Habitat, on the other hand, is generally stationary and can be readily surveyed, monitored, and studied over time. However, the large geographic extent and wide range of habitat diversity within the Nez Perce-Clearwater generates considerable complexity for research and monitoring purposes. Demonstrating causality and relationships between the myriad of factors affecting wildlife habitat is not only difficult but also costly. As a result, uncertainty exists regarding the direct, indirect, and cumulative impacts of various collective management activities on individual animals, habitat, and wildlife populations. While there is an appreciable body of science on the topic and information is growing at a considerable rate, uncertainty can lead to different conclusions on not only the potential impacts to habitat but also how such impacts might affect wildlife populations.

The analysis assumes that there is variability in the abundance of different species but that the coarse filter would provide for most of these species. The analysis assumes that most species have a distinctive ecological niche that allows them to persist or thrive despite competition from other species. The competitive exclusion principle is an evolutionary theory that suggests that species evolved to avoid competition with other species and so nearly all species have differentiated niches. While many species have a distinctive niche, most habitat features that make up the niches of species are common and, in most cases, will be present without specifically describing these features in desired conditions. Therefore, the analysis assumes that, in most cases, the habitat features that make up ecological niches of common species will typically be present when habitats are functioning within their natural range of variability.

Providing for ecological integrity is an intended outcome of the Land Management Plan. It starts with a comparison of the current abundance and condition of various habitats with ecological reference conditions, including the historic range of variability, based on our knowledge of the past and on our understanding of ecological processes, such as fire, flooding, insects, and disease. This coarse filter approach to providing ecological conditions that provide for the diversity and abundance of wildlife and viable populations of the Forest Service's Species of Conservation Concern is reflected in the vegetation desired conditions in plan components and alternatives for the Land Management Plan. The coarse filter approach forms the foundation of the analysis for each species. The report by the Ecosystem Research Group (Ecosystem Research Group 2021) assessed the effects on habitats of selected species in response to plan components with the assumption that declines are not a concern unless conditions fall below the lower level of the natural range of variation.

The companion approach to the course filter of ecosystem diversity is the "fine filter" approach in which conservation strategies are used for individual species or groups of species to contribute to species diversity. The fine filter approach narrows the focus to those species that require ecological conditions that may not be provided through coarse filter plan components. This fine filter approach is reflected in the species-specific plan components for wildlife found in the Land Management Plan. Each species' assessment in this report evaluates the effects of the coarse filter, fine filter, and other components in the Land Management Plan.

A variety of sources were used to determine historic and existing vegetation conditions on the Nez Perce-Clearwater. The development of management recommendations to maintain or restore ecological conditions was based on the historic range of variability and desired future conditions influenced by climate change. Movement toward the desired conditions for vegetation under the Land Management Plan would provide for an array of ecological communities of sufficient size, structure, and distribution that is expected to maintain habitats for the vast majority of native species that occur on the Nez Perce-Clearwater. See the Forestlands section for additional information.

Measurement Indicators

Key ecosystem characteristics were identified as indicators of ecological integrity in terms of composition, structure, function, and connectivity. Some of these components are addressed in detail in other sections of the Final Environmental Impact Statement. Since wildlife habitat is largely dependent upon hydrologic and vegetative conditions, the wildlife and habitat analyses presented within this report often tiers to key indicators and measures found in the other sections. Other key indicators and measures of wildlife habitat quality vary by wildlife species and unique habitat types and are addressed in those sections that follow. Unless noted otherwise for a particular species or habitat, key indicators for indirect and cumulative effects include quantitative measures of anticipated changes to species' habitats, as well as qualitative descriptions of plan component contributions to, or potential to address, key stressors for species and their habitats.

For forested habitats, key characteristics include the percent of various size classes, the relative density, tree species composition, dominance type, the amount and size of snags, the amount and size of downed wood, the presence of large and very large live trees within many age classes, connectivity of forested habitats, and the landscape configuration and distribution of forest patches. Also important are the presence and distribution of stands of deciduous forest.

For non-forested habitats, key indicators are condition, species composition, extent, and distribution. As non-forested habitats are uncommon in the plan area, the connectivity of non-forest vegetation is an important consideration. These are discussed in conjunction with early seral conditions as many species use both.

As many species use ecotones, which are the edges between two habitats, the interface between non-forested and early seral forest and mature forest is an important feature of habitat for many species. This is best indicated by the landscape configuration and distribution of patches of non-forested and early seral forest and mature forest. The size and shape of patches influences the quality of habitats for species that use ecotones. A landscape that reflects natural disturbance patterns provides this patch heterogeneity.

For aquatic wildlife habitats, key indicators are the amount and distribution of aquatic habitats relative to management areas, the condition and types of vegetation surrounding aquatic habitats, the condition of water quality, stream geomorphology, and hydrology. The connectivity of aquatic and riparian habitats is also an important consideration.

Many species are vegetation generalists, occurring in many vegetation types and conditions. Rather than vegetation conditions, these species require features like rock outcrops, talus, cliffs, cutbanks, caves, or soils suitable for burrows, rocks, or logs for hiding. These habitats are collectively referred to as substrate habitats and the presence of wildlife that depend upon them often depends upon their presence but is not often dependent upon their condition. While these habitats are often long-term, they can be impacted by some activities that cause disturbance, loss, or alteration. Examples include mining and quarrying and road construction. Some species that use these habitats might be sensitive to recreation like rock climbing. Their presence, distribution, and threats are the key indicators for these habitats.

Some species are habitat generalists, occurring in many habitats, but are reliant upon the presence of the resources they require. Resources include mast, grain, fruiting plants, nectar, prey, and carrion. Examples include hummingbirds relying mostly upon nectar resources and predators like coyotes (*Canis latrans*) occurring wherever prey is present or turkey vultures (*Cathartes aura*) who seek out carrion. From a habitat standpoint, the species that use nectar resources would require flowering plants. Therefore, flowering plants are an indicator for some wildlife species. Species that depend upon mast require mature mast producing trees, for example.

A few species are high elevation or alpine specialists. Examples of these species are the wolverine, the grey crowned rosy finch (*Leucosticte tephrocotis*), and American pipit (*Anthus rubescens*). Their habitats have few threats, except for perhaps future climates. High elevation vegetation functioning within the natural range of variation are indicators for some of these species. Wolverines require persistent snow into spring for denning. Whitebark pine is important to Cananda jays (*Perisoreus canadensis*) as they exploit the mast resource these trees provide. Whitebark pine is another indicator for alpine habitats.

About one-third of all wildlife species in the plan area are dependent upon either snags or downed wood or both, so snags and downed wood are analyzed in their own section. Snag retention guidelines vary by alternatives and various species use different size classes and decay stages. Indicators for snags are whether they will be present and usable by a variety of wildlife based on the sizes and decay classes available under the plan components and alternatives.

Some species use or are associated with hardwood or deciduous tree habitats. Hardwood tree dominance type and presence is an important indicator for the wildlife species associated with hardwood tree habitats. Hardwood or deciduous tree habitat can dominate a stand or more commonly are a component within conifer dominated stands. Hardwood species often occur along riparian areas. Trends over time in the non-coniferous vegetation types, such as hardwood and grass and shrub plant communities, are difficult to portray through modeling. Persistent non-forested plant communities are relatively rare types on the Nez Perce-Clearwater and are naturally fragmented in nature. Therefore, model results, although helpful, should be supplemented with other information for discerning the trend and amounts of these communities over time. Since hardwood trees are largely associated with early-successional forest conditions, modeling of forest successional stages, including forest size classes, and disturbance processes and their effects on deciduous vegetation can provide insight and information for the assessment of trends in hardwood species over time.

Deciduous trees and shrubs tend to grow along streams and are typically seral components that result from fires, insects, and disease. Some tree species, like cottonwoods, are maintained by periodic flooding. Riparian vegetation was modeled in SIMPPLLE to generate an estimate of natural range of variation for the amount of deciduous vegetation occurring as a result of disturbance within riparian habitats. Outcomes of the plan for riparian vegetation were predicted by SIMPPLLE modeling to evaluate the outcomes of plan components and alternatives on riparian vegetation. The query was designed to assess the availability and relative proportions of habitats that provide shrubs and deciduous trees within riparian habitat conservation areas and riparian management zones. Current conditions for deciduous trees were assessed using a combination of Forest Inventory and Analysis (FIA) and VMap data with cover types dominated by shrubs and deciduous trees to quantify the extent of these habitats. For purposes of modeling future vegetation treatments, areas that are mapped as riparian habitat conservation areas and riparian management zones are not suitable for timber production. Future habitat was modeled as forest openings containing riparian shrubs and hardwood trees, primarily resulting from moderate- or high-severity wildfires and insects and disease within 20-years following the disturbance.

Many species of wildlife are associated with ecotones or edge habitats. In particular, some species require or prefer forested habitats adjacent to early seral or non-forested habitat. Therefore, the landscape pattern of patch size and distribution functioning within the natural range of variability is an important indicator for habitat of these species. Landscape patch and pattern within the natural range of variation is also an indicator for connectivity.

Forest density often matters for wildlife species that use mature forest habitats. Some wildlife species prefer mature forest with higher tree densities whereas other species use mature forest with lower tree densities. Therefore, tree densities operating within the natural range of variation is an indicator for wildlife species that use forested habitats.

Some wildlife species are sensitive to roads, motorized trails, or motorized uses. While the plan does not make travel management decisions on the ground, the alternatives identify areas suitable for motorized uses where new roads or motorized trails could be constructed in the future. Some land allocations also restrict or constrain the construction of new motorized routes whereas other land allocations are suitable for motorized uses. Furthermore, the plan proposes timber harvest objective and sale quantity. Timber harvest often requires infrastructure like roads to access or transport harvested trees. The plan contains plan components that direct how or where motorized uses would not be allowed in the future. Therefore, the plan indirectly influences future development of motorized uses. How the plan would influence or guide the development of future motorized uses, and where motorized uses are suitable, is an important indicator for some wildlife species.

In some cases, population trend data for wildlife species are available. For example, population and occupancy trend data is available for many migratory birds through the Intermountain Bird Observatory's Integrated Monitoring in Bird Conservation Regions, coordinated by the Bird Conservancy of the Rockies, in partnership with federal agencies. For purposes of this analysis, migratory bird trend data was reported within the Idaho Bird Conservation Region 10 in Idaho and trends are reported within habitat groups. The focus therefore is not on trends of individual species but trends within the habitat group that might indicate habitat conditions.

Additionally, the Idaho Department of Fish and Game provides information on population trends for big game. These were used as an indicator for habitat conditions for species used by people and are evaluated within the Multiple Uses Wildlife section below.

Lastly, important indicators are related to the threats identified for each at-risk species and whether the Forest Plan would contribute to or constrain such threats. Threats are specific to each at-risk species and so the indicators are often specific to those threats.

Abundance and Diversity of Wildlife

The following analyses address the effects to wildlife and their habitat from the suite of plan components and range of alternatives considered in the Land Management Plan. This section emphasizes evaluating how ecosystem plan components, also called coarse filter plan components, provide the ecological conditions to provide for the diversity and abundance of wildlife. These plan components also provide the basis for ecological conditions to provide for the long-term persistence of species of conservation concern and contribute to the recovery of federally listed species.

The diversity in habitat and topography contributes to the biodiversity of the wildlife community. The plan area is located within the Northern Rockies. Wildlife communities are typical of the Northern Rockies. The State of Idaho's Species Diversity Database represents the best available scientific information for the species that occur here and within a half mile around the administrative boundary of the plan area. The database contains observations of approximately 370 species of wildlife, including gastropods within the Nez Perce-Clearwater and lands within one-half mile of the plan area's boundary. It also contains several observations of insects like bumblebees, aquatic insects, butterflies, and more. The Idaho Species Diversity database was accessed multiple times throughout the planning process and the species list considered in planning was updated multiple times. The most recent update of the Idaho Species Diversity Database was made available to the Forest Service in July 2022.

Identifying a species list for this analysis was a distinct process from the criteria used to identify and evaluate species of conservation concern. For species of conservation concern, we limited species only to those observed within the plan area boundaries. Therefore, there were some species identified within one-half mile that were not included in the evaluation as potential species of conservation. Of note are several species of endemic gastropods that have not been documented within the plan area but have been observed within one-half mile of the plan area boundary. They were not evaluated as potential species of conservation concern because species must be known to occur in the plan area to be a species of conservation concern.

Table 153 shows the number of species of birds, mammals, reptiles, amphibians, and mollusks recorded in the plan area, as identified in the Idaho Species Diversity Database. The database query used to identify wildlife species below does not include the fish species that occur in the plan area. For additional analysis of effects on aquatic habitats and fish, see the Water Resources and Fisheries sections in the Final Environmental Impact Statement.

Table 153. Number of recorded species documented in the plan area, by assemblage

Assemblage	Number of Species
Birds	203
Mammals	70
Reptiles	11
Amphibians	11
Gastropods	70
Mussels	3
Terrestrial Insects of conservation interest	3
Total	**371**

Data Source: Idaho Species Diversity Database

There are undoubtedly thousands and perhaps tens of thousands of arthropod species that reside in the plan area, including insects, arachnids, isopods, crustaceans, and decapods, most of which are not identified in the Idaho Species Diversity Database and in some cases, likely not even described by science yet. Consider for example that in the United States, the number of described insect species alone is approximately 91,000. The undescribed species of insects in the United States, however, is estimated at some 73,000 (Smithsonian Institute 2021). It would be impossible to analyze for all these species so, in this case, it is assumed that coarse filter ecosystem components would provide for most arthropod species. Gastropods or snails and slug species are analyzed because of the unique diversity and endemic gastropod fauna present in the plan area.

There are more than 260 uniquely identified arthropods or other invertebrate species observed in the Idaho Species Diversity Database and more than 200 unique observations of arthropod taxa not identified to species. They include insects, spiders, worms, leeches, harvestmen, crustaceans, and others. Of these, 22 are of conservation interest or are identified in the Statewide Wildlife Action Plan as species of greatest conservation need. Often these species have gaps in scientific information compared to vertebrates. Most invertebrates identified as species of greatest conservation need (IDFG 2016) are aquatic insects and are evaluated in the fisheries and aquatic ecosystems section of the Final Environmental Impact Statement. Several invertebrates were also evaluated as potential species of conservation concern. Three terrestrial insects will be analyzed here because either 1) they have been found warranted for federal listing, 2) they are currently undergoing review by the U.S. Fish and Wildlife

Service for endangered species listing, or 3) they were of interest to government agencies, the Tribe, or the public. The three terrestrial insects analyzed within this section include the monarch butterfly (*Danaus plexippus*), the Gillette's checkerspot (*Euphydryas gillettii*), and the western bumble bee (*Bombus occidentalis*). The monarch butterfly was recently identified as warranted for listing but precluded and is now a candidate species under the Endangered Species Act. The Gillette's checkerspot is a butterfly that has specialized habitat needs, because of which it has long been of conservation interest. The western bumble bee was petitioned, and the U. S. Fish and Wildlife Service found that it may be warranted for listing and is currently under review. Several pollinators have received recent conservation attention and will be analyzed as a group in the Resources Habitats section below.

To evaluate whether coarse filter ecosystem plan components would provide the ecological conditions for most species in the plan area, species were grouped into habitat groupings and subgroupings. Effects of the plan on the habitat groupings were then analyzed. To group species into habitat categories, a species profile was created for each species known to occur in the plan area. The species profiles are formatted as a spreadsheet that contains habitat needs and species characteristics. For each species, the spreadsheet included the common name, scientific name, whether the species is a game species, the type of game (big game, furbearer, upland game, etc.), food habits, a brief habitat summary, their association with broad potential vegetation types, their key ecological requirements, their primary threats, whether the species uses snags, whether the species uses downed wood, any mitigation or management measure identified, and the source relied on for the species profile. Species were grouped into broad habitat grouping and habitat subgrouping based on the description of their habitats. The spreadsheet with this information is available in the project record and some information from the spreadsheets are included in the wildlife Appendix C including habitat groups and subgroups, the species habitat descriptions. The habitat summaries and key ecological characteristics were then reviewed to construct logical groupings of habitats that would facilitate analysis of coarse filter plan components. This analysis evaluates the effects of the plan on broad habitat groupings instead of on individual species and is presented in Table 154. The habitat groupings were necessarily broad to be inclusive so the species could be assigned based upon their primary habitat preferences. The eight broad habitat groupings are shown in the following table. The number of species associated with each habitat group informs the relative contribution of these habitats to species richness. The key ecosystem characteristics of the species within each habitat group were the basis to identify the key ecosystem characteristics of the broad habitat group. Similarly, the threats identified for the species within the groups helped inform the key threats to each habitat grouping. The analysis of the effects of plan components on the broad habitat groupings are based on the effects to key ecosystem characteristics and how the plan addresses the threats to the habitat groupings.

Table 154. Habitat groups used for wildlife species

Habitat Groupings	Amphibians	Birds	Mammals	Mollusks	Reptiles	Terrestrial Insects[1]	Habitat Group Total
Aquatic, wetland, water, and riparian habitats	11	59	9	22	1	0	102
Forested habitats	0	55	12	0	0	0	67
Non-forested or early seral habitats	0	45	9	0	0	0	54
Substrate habitats: rock outcrops, soils, downed wood, cliffs, talus, or caves	0	7	20	51	10	0	88

Habitat Groupings	Amphibians	Birds	Mammals	Mollusks	Reptiles	Terrestrial Insects[1]	Habitat Group Total
Resource habitats: nectar, fruit, seeds, plant forage, host plants, or prey	0	8	5	0	0	3	16
Ecotone, forest edge, or habitat grouping combinations	0	24	9	0	0	0	33
Habitat generalist	0	1	4	0	0	0	5
Alpine, boreal, or high elevation habitats	0	4	1	0	0	0	5

1 - Insects of conservation interest

Species of Conservation Concern (SCC) were identified as part of the Land Management Plan process. Forest staff identified species to be evaluated as SCC if they met the categories outlined in Forest Service Handbook 1909.12, Chapter 10, Section 12.52 and Chapter 20, Section 21.22a for identifying species of conservation concern. Forest Service Northern Region staff, in coordination with the Nez Perce-Clearwater planning team and other experts, as needed, evaluated the best available scientific information to determine which species should be recommended to be identified as species of conservation concern and which species should not be identified as species of conservation concern. Summary rationale were provided for all recommendations, including those species found not to meet the criteria. The recommendations were then provided to the regional forester for ultimate identification as species of conservation concern. For more information about identification of species of conservation concern and rational used to determine their status, see the "Process for Identifying Species of Conservation Concern" and the "Rationale (Species Evaluations) Used to Select Animal and Plant Species as Coeur d'Alene salamander for the Nez Perce-Clearwater Draft Plan and Draft Environmental Impact Statement," which can be accessed through the U.S. Forest Service's Northern Region Species of Conservation Concern website at https://www.fs.usda.gov/detail/r1/landmanagement/planning/?cid=fseprd500402. Species evaluated for potential inclusion as SCC included 6 amphibians, 36 birds, 13 mammals, 41 terrestrial invertebrates, 23 aquatic invertebrates, 4 fish species, and 82 plant species. Of these, the regional forester identified the bighorn sheep, fisher, harlequin duck, white-headed woodpecker, and mountain quail as wildlife species of conservation concern. Effects of these species are evaluated in this document below and determinations are provided as to whether the plan would provide for their long-term persistence.

There were significant improvements in the model to evaluate the trend in riparian habitat conservation areas under the plan. This included improved delineation of riparian areas, improved vegetation data, and improved pathways to predict their growth patterns. They were also calibrated with our understanding of fire behavior from on the ground surveys in the plan area.

Affected Environment

This section describes the existing condition of significant wildlife resources in the plan area.

Habitats

The Nez Perce-Clearwater consists of approximately 4 million acres of beautiful and diverse land located in northcentral Idaho. The Nez Perce-Clearwater is located largely within two ecoregions (Bailey 1995): the Idaho batholith and the Bitterroot Mountains. Areas of the Nez Perce-Clearwater south of the southern ridge above the Lochsa River lie within the Idaho Batholith Ecoregion, while those north of the ridge above the Lochsa River lie largely within the Bitterroot Mountain Ecoregion.

The Bitterroot Mountains section is part of the Canadian Rocky Mountain Ecoregion. The Bitterroot Mountains span from 984 to 7,920 feet in elevation, with the highest peaks occurring along the Idaho–Montana border within the North Bitterroot Range. Like most of the sections in north Idaho, this section is cool and temperate with an annual precipitation of 20 to 82 inches and an average annual temperature that ranges from 36.7 to 49.5 degrees Fahrenheit. Precipitation occurs mostly as snow from November to March, while summers are dry. This section has a maritime-influenced climate that delivers moisture-laden air currents in the fall, winter, and spring in the form of heavy snowfall and warmer winter temperatures. On the other hand, summers are hot and dry, with some areas reaching temperatures of around 100 degrees Fahrenheit (Idaho Department of Fish and Game 2017a).

The habitats in the Bitterroot Mountains section are influenced by soil and topography conditions, which create variation in site conditions and the dominance types of forested habitats in the plan area. The section is composed of extensive coniferous forests with comparatively little non-forested areas. Deciduous forested habitats are uncommon in the plan area. Volcanic ash soils, coupled with higher precipitation, support productive coniferous forests. These forests contain diverse stands of mixed coniferous forest at lower elevations, such as the western redcedar, grand fir, western larch, Douglas-fir, small amounts of Ponderosa pine, and western white pine. Western white pine was once abundant in this section but has succumbed to the influences of blister rust and has been replaced largely by grand fir. In some cases, stands at lower elevations can contain all these species growing together; in other cases, stands can be dominated by single species, such as grand fir. See the Terrestrial and Aquatic Ecosystems and Watersheds section of the 2014 Assessment (U.S. Department of Agriculture 2014a) for additional information about forest vegetation.

At higher elevations, the section grows western hemlock, lodgepole pine, Engelmann spruce, whitebark pine, Douglas-fir, and subalpine fir types. Whitebark pine was once more abundant but has succumbed to blister rust like western white pine. Dominance types in the Bitterroot Mountain section can contain several species in mixed stands or be dominated by a single species, such as lodgepole pine.

Although the higher elevations of the North Bitterroot and North Clearwater ranges were carved by mountain glaciers, the lower portions of the ranges were unaffected by glaciation. This preserved the steep “V-shaped” canyons at lower elevations and provided refugia for coastal species and an environment for the evolution of endemic plants. The maritime climate of this section continues to provide the mild temperatures and heavy precipitation necessary for nearly 40 species of disjunct populations of coastal plants identified in the lower canyons of the North Fork Clearwater, Selway, and Lochsa Rivers. Examples of plants characteristic of the canyon habitats include red alder, deer fern, Sierra marsh fern, North Idaho monkeyflower, and Constance’s bittercress, which is a regional endemic. These communities support several endemic species.

Several species of beetles, snails, harvestmen, aquatic insects, and earthworms are endemic to northern Idaho. The area of the lower Salmon River canyon is a hotspot for land snail diversity. Similarly, the Coeur d’Alene salamander (*Plethodon idahoensis*) is another species endemic to the ecoregion. The Northern Rocky Mountain Refugium is a term used to describe the area where this endemism occurred (Brunsfeld et al. 2001, Stagliano et al. 2007). In simplest terms, it is the mountainous, forested area along the Montana and Idaho border that was neither covered by northern ice sheets during glaciation periods nor paved with lava from the south and west (Stagliano et al. 2007).

Wildlife habitat conditions vary widely from the dry, rugged canyons of the Salmon River to the moist cedar forests of the Selway River drainage, the rolling uplands of the Palouse, and the high-elevation mountains across the Nez Perce-Clearwater.

The southern half of the Nez Perce-Clearwater has soil conditions characteristic of the Idaho batholith with a drier climate than those to the north. These conditions are conducive to more extensive drier forest types of Ponderosa pine, Douglas-fir, and grand fir at lower elevations. At higher elevations, the Nez Perce-Clearwater is composed of vast stands of lodgepole pine, Engelmann spruce, grand fir and subalpine fir, whitebark pine, western larch, and Douglas-fir, or a combination of these species. Grand fir generally diminishes in dominance as elevation increases. The prevalence of western redcedar and western white pine diminishes as one moves southward in the plan area. Larger amounts of non-forested vegetation occur in the southern half of the Nez Perce-Clearwater, which supports grazing allotments. A more complete description of forest types and tree species can be found in the Terrestrial and Aquatic Ecosystems and Watersheds section of the 2014 Assessment (U.S. Department of Agriculture 2014a) and in the Forestlands section.

The plan area contains five large rivers that are culturally, economically, and ecologically important to the region. The northern plan area drains into the North Fork of the Clearwater River. The Lochsa and Selway Rivers converge into the main stem of the Clearwater and drain the heart of the Nez Perce-Clearwater. The South Fork of the Clearwater drains much of the southern portion of the Nez Perce-Clearwater, and the Salmon River forms the southern border of the plan area. These major drainages create topographic variation that gives variety to the composition, structures, and dominance types of the Nez Perce-Clearwater. The broad potential vegetation type groups are influenced by these river drainages. This variety provides a diversity of habitats for wildlife. The amount of precipitation creates a vast web of riparian habitats and smaller streams that drain into these larger rivers. Riparian habitats are disproportionally used by wildlife species compared with their availability. The mesic climate provides seeps, springs, and ponds throughout the plan area. Many small lakes and wetlands scattered in limited areas in the plan area also provide habitats for many terrestrial wildlife species.

Habitats in the plan area have undergone various amounts of anthropogenically derived changes through time. Prior to settlement, Native Americans were present and used the land for hunting, gathering, fishing, and other uses. As part of this management, the Native Americans sometimes managed portions of the Nez Perce-Clearwater through fire use to benefit game populations and increase or maintain food plants. After settlement times, extractive uses became more prevalent. Extractive uses included timber harvest, mining, fire suppression, road development, and construction of facilities like fire towers, ranger stations, or recreation facilities.

Timber harvest resulted in changes in landscape pattern, size class, dominance types, tree composition and a reduction in large trees. When conducted with a lack of conservation measures, timber harvest resulted in soil erosion, landslides, and impacts to aquatic habitats. Save for wilderness areas, fire suppression also resulted in nearly forestwide changes in vegetation, including changes to dominance patterns, forest density, landscape pattern, insect and disease outbreaks and, more recently, changes to the size and intensity of wildfires. The spread of blister rust severely reduced the dominance of white pine and whitebark pine. The changes are undesirable for several reasons, including the restoration and maintenance of wildlife habitats. The Land Management Plan seeks to address these changes through a variety of activities, restrictions, and conservation measures designed to maintain and restore ecological conditions.

In addition to anthropogenic impacts, invasive species have altered some lower elevation habitats to the exclusion of native vegetation. Placer mining resulted in changes to stream geomorphology. Road development implemented to move timber and facilitate forest travel has impacted habitats from their footprint, increased sediment into streams, and caused changes to stream connectivity through the installation of culverts and stream crossing structures. For some species, roads have fragmented habitats. Because roads coarse along several major rivers in the plan area, roads have removed much of the riparian areas along one side the plan's major rivers, and measures to stabilize riverbanks have altered these riverbanks. For example, roads run along the Lochsa, North Fork Clearwater, Southfork Clearwater, and portions of the Selway, and Salmon River.

These impacts have occurred in some areas on the Nez Perce-Clearwater more than others, leaving varying degrees of anthropogenic impacts. Areas closer to population centers have received greater impacts than those in remote areas. These differences are manifested through existing plans and land use allocations and are also features of the Land Management Plan.

The Land Management Plan determines which uses are suitable, which lands would be allocated for various uses, and implements conservation measures designed to enable extractive uses to continue while conserving resource values. The plan does this through plan components, such as desired conditions, goals, objectives, suitability determinations, management approaches, and restrictions on what and how the Nez Perce-Clearwater would conduct activities through plan guidelines and standards. This analysis evaluates potential effects of this plan direction on wildlife habitats including species identified as species of conservation concern.

Distinctive Roles and Contributions

Fisher

The Nez Perce-Clearwater contains much of the core habitat of the fisher in the Northern Rockies (Krohner 2020). Occupancy studies conducted by Krohner (2020) presented two core areas of fisher occupancy: a large area across the Clearwater and Nez Perce National Forests in Idaho and a smaller area in the Cabinet Mountain range crossing the border between Idaho and Montana. Some fisher in the plan area were found to have a unique genetic identity found nowhere else in the fisher range indicating they survived extirpation in the early twentieth century (U.S. Department of the Interior 2017d). Genetic research by Vinkey et al. (2006) and Schwartz (2007) established that fisher survived their minimum population numbers on the Nez Perce-Clearwater, while results from Krohner (2020) from both spatial and non-spatial analyses demonstrate that fisher currently occupy this area to a greater extent than in Montana and other parts of Idaho within the Northern Rockies. Krohner (2020) also demonstrates an absence of fisher detections in large areas across the Northern Rockies of Montana and Idaho, even within predicted fisher habitat. These studies underscore the importance of the Nez Perce-Clearwater to fisher conservation in the Northern Rockies.

Bighorn Sheep

Historically, bighorn sheep were abundant and widespread throughout the mountainous regions of Idaho, including the Salmon River Canyon (Merriam and Steineger 1891, Smith 1954, Buechner 1960, Idaho Department of Fish and Game 2010). Dramatic and swift declines in abundance occurred during the mid-1800s to mid-1900s and were attributed to overharvest, habitat loss, and competition for forage and disease transmission from domestic livestock (Hornaday 1914, Honess and Frost 1942, Couey 1950, Smith 1954, Buechner 1960, Jessup 1981, Goodson 1982, Wehausen et al. 1987). Bighorn sheep herds in the Lower Salmon River Canyon were one of the few remaining herds that were not extirpated in the State of Idaho. Although bighorn sheep were not extirpated from this area, the herd represents the last remaining native population in Idaho and current population levels remain low. Bighorn sheep within the Salmon River area represent the core of Idaho's bighorn sheep populations, and this unique native genetic stock represents a heightened conservation need across federal, state, and tribal jurisdictions. This population is one of the largest native populations of Rocky Mountain bighorn sheep.

Bighorn sheep along the breaks of the Salmon River Canyon, as elsewhere across the Nez Perce Tribe's treaty territory, are a culturally significant treaty resource (Mack et al. 2017)). Based on archeological evidence and verbal histories of tribal elders, bighorn sheep were the primary game animal that sustained the Nez Perce way of life prior to European settlement (Mack et al. 2017). Bighorn sheep were used for a large variety of purposes, including food, clothing, tools, utensils, and weapons (Mack et al. 2017). Native bighorn sheep within the Salmon River drainage are of particular importance to the Tribe as native bighorn sheep represent the last genetic stock that has sustained the Tribe's subsistence lifestyle from time immemorial. The Tribe continues to work towards bighorn sheep restoration with state, federal, and other partners. Bighorn sheep are analyzed as species of social and economic value in the Multiple Uses Wildlife section.

Elk

Elk are one of Idaho's most iconic wildlife species. Elk are one of the most highly sought-after big game animals in the state. In 2002, elk hunting was estimated to generate more than $70 million annually in direct hunter expenditures like fuel, meals, and lodging (Cooper et al. 2002) and in excess of $6.15 million in license revenue annually statewide (Idaho Department of Fish and Game 2014a). The combined economic impact of elk hunting in Idaho and Clearwater counties alone was more than $27.6 million in 2007. In 2016, hunting related expenditures in Idaho totaled $1.05 billion, the majority of which was spent on big game hunting (Institute 2018). Population declines have impacted this herd previously renowned for its abundance and trophy opportunity, which used to draw hunters from all over the country. The plan area makes up most of the Lolo zone, Selway zone, and Elk City zone; a substantial portion of the Dworshak zone; and smaller portions of the Palouse and Hells Canyon zones. Each zone is comprised of one or more game management units that roughly encompass a population. In total, the plan area contains portions of 12 game management units in the State of Idaho, which is 12.3 percent of the total game management units in Idaho. These zones make up the core of elk hunting areas in North Central Idaho. The elk herds in the plan area represent a distinctive role and contribute both economically and socially. Elk habitats are analyzed in detail in the Multiple Uses Wildlife section.

Unique, Rare, or Endemic Species—Rocky Mountain Refugium

The plan area lies at the heart of the Rocky Mountain Refugium, a term used to delineate the high endemism and biodiversity of land snails, salamanders, and plants in this area. This area is essentially comprised of areas spared from glaciation nor paved by volcanic flows, which allowed some species to survive the last glacial maxima until today (Stagliano 2007). Examples of species or groups that persist today include land snail biodiversity, the Idaho giant salamander (*Dicamptodon aterrimus*), the Coeur d'Alene salamander, and coastal disjunct plant communities. This assemblage of endemics represents a distinctive role and contribution to biodiversity. For additional information regarding land snail biodiversity see the Mollusk Assemblage section below. See the Amphibian Assemblage section for more information pertaining to the Coeur d'Alene salamander. The effects on habitats of these species are analyzed within the Abundance and Diversity of Wildlife section.

Bitterroot Grizzly Bear Recovery Zone

The Selway-Bitterroot Wilderness and the Frank Church-River of No Return Wilderness areas make up the core of the Bitterroot Ecosystem Recovery Area for the federally threatened grizzly bear. These two wildernesses make up the largest contiguous block of wilderness in the contiguous United States. The Bitterroot Ecosystem is currently unoccupied by grizzly bears, but this ecosystem represents one of six grizzly bear recovery zones. Reestablishment of grizzly bear in this recovery zone is currently through natural dispersal.

Wildlife Assemblages

Bird Assemblage

Per the Idaho Department of Fish and Game's Species Diversity Database, accessed in July 2020, there are 203 species of birds that have been recorded in the plan area. Birds represent the largest taxonomic class of wildlife by species count in the plan area. The bird species are diverse in their use of habitats and are associated with habitats of many groupings. The bulk of the bird species are grouped into one of three habitats, the aquatic, forested, and non-forested or early seral habitats, followed by ecotone groupings. However, at least one bird species was grouped in every grouping (see Table 154). A few species use alpine habitat, and a few others are associated with the resource group but otherwise use a wide array of habitats. Examples of species that rely on resources but are otherwise habitat generalists include the turkey vulture, which is found in many habitats but requires carrion, and hummingbirds that are widespread and need nectar resources.

Many shorebirds and aquatic birds are found in the plan area because of the presence of large rivers, lakes, and wetlands. See Appendix C for more information on habitat descriptions of bird species and habitat groupings.

Population trends are available for birds much more than for other wildlife species. This is the result of organized efforts at the national scale to count birds, such as breeding bird surveys and Christmas bird counts, and the ease at which birds are surveyed with methods such as point counts. Their visibility, diurnal habits, and distinctive songs enable easy detection. However, it should be noted that some bird species do not lend themselves well to these types of surveys and population trends are less understood. A few examples include owls whose nocturnal habits make them difficult to count; secretive aquatic species like the Virginia rail (*Rallus limicola*); species that live naturally at low densities, such as the black backed woodpecker; and species that do not readily vocalize, such as the forest grouse.

Many bird species are migratory while others are year-round residents. Most migratory species are present in the plan area only during the summer, but a few species are here only in the winter. For example, the common goldeneye (*Bucephala clangula*) and Barrow's goldeneye duck (*Bucephala islandica*) winter on large rivers in the plan area and migrate north for the summer. Some year-round residents use different habitats in winter or migrate only a short distance from their summer habitats, which represents a change in elevation. Some bird species use the same habitats year-round. The seasonal presence and habitat use of bird species were considered when assigning bird species to habitat groups and when evaluating coarse filter plan components in the Final Environmental Impact Statement.

Threats to birds can occur from within the plan area or far away in their migratory habitats. They may be affected within their group by threats to their habitats. Birds are most affected by permanent changes in habitat that result in permanent loss. They may be affected short-term by changes in vegetation conditions or disturbance. Forest species can be affected by changes in the structure, function, and composition of forested vegetation. When forests change from a mature seral condition to an early seral condition, the bird species assemblage changes from those that use mature forest habitats to those that use early seral or non-forested habitats. Through forest growth, the bird assemblage transitions over time back to species that use mature forests. This is the natural course of changes in forested ecosystems. This progression happened naturally through fire in the past but can also occur as a result of timber harvest, mechanical treatments, or prescribed fire. Naturally, changes in forest composition or dominance, density, and structure also influence bird species assemblages. When hosting variety in seral stages, density, structure, and tree species composition, the diversity of bird species can be maximized and maintained. When anthropogenic change is extensive enough that it limits any one of these conditions, changes forest conditions permanently, or removes some key ecological features required by birds, some species become less prevalent or may even disappear. Commonly, concern arises for species that are specialized to vulnerable habitats or where habitat features take a long time to develop. For example, concern for cavity nesting species arises because trees may take hundreds of years to develop the heart rot necessary to enable excavation of nesting sites in large and very large trees. Therefore, threats to forest habitats include anthropogenic changes such that any key feature or forest condition becomes rare or non-existent. This usually happens through excessive extraction or lack of conservation practices like retention of live and dead trees, protection of riparian areas, leaving coarse woody debris, or reforestation.

Similarly, aquatic birds may be affected by threats to aquatic habitats. Changes in aquatic habitats arising from sedimentation, turbidity, eutrophication, pollution, channel alteration, flow, or temperature can cause a cascade of changes to aquatic species assemblages that support aquatic birds. Some of these changes may be permanent or ephemeral.

Birds of open habitats have generally not been the subject of conservation concern and are usually abundant and their populations stable. Birds of open or early seral habitats can be affected by threats to open habitats. The most damaging threats are those that cause permanent loss, such as developments or farming. Forest Service management rarely results in these types of changes and, when they do, they are of small scale. More commonly, management results in changes that lower habitat quality or reduce the extent of open or non-forested habitats. These include fire exclusion, excessive amounts of forest succession, changes in species composition, invasion by non-native plants, or over exploitation by livestock.

Several birds use edge habitats or the interface between forested habitats and non-forested habitats and may be affected by changes in distribution and abundance of patch size or heterogeneity. Some ground dwelling birds require different seasonal habitats within accessible proximity to utilize a landscape. Changes in landscape pattern can occur from changes to disturbance processes, such as those from fire suppression or forest harvest patterns that reduce heterogeneity of landscape patterns.

Some species may be affected by threats to critical resources, such as losses of nectar resources for hummingbirds, loss of fruiting plants through succession for frugivores, or loss of prey species for predatory species. Climate change may threaten habitat by changing precipitation and temperature gradients that support vegetation, particularly in high elevation species. Their ability to fly allows most species to disperse far and wide without connectivity concerns. A few exceptions may include ground dwelling birds, such as mountain quail, where connectivity or proximity to seasonal habitats and other subpopulations may be important.

Several species of ducks, grouse, quail, and doves are species that are commonly hunted. A wide variety of bird species are used for Native American tribes for ceremonial, religious, cultural uses, and subsistence. Birds are popular for wildlife watching and photography and enhance the enjoyment of recreation. For more information about commonly used wildlife, see the Multiple Uses Wildlife section.

National and regional data sets indicate that most bird species found in the plan area are secure with stable or increasing trends. Other species are declining nationally but are stable regionally or locally. Some have declined nationally but are still relatively abundant. Some species are naturally rare locally, but surveys indicate there is no decline, a decline is undetected, or there are few threats. Examples include black-backed woodpeckers, three-toed woodpeckers, flammulated owls (*Psiloscops flammeolus*), boreal owls (*Aegolius funereus*), Lewis's woodpecker (*Melanerpes lewis*), pygmy nuthatches (*Sitta pygmaea*), and great gray owls (*Strix nebulosa*). Only a few species are thought to have declined sharply or are uncommon and are experiencing threats or habitat loss, which indicates substantial concern for their long-term persistence. These species are identified as species of conservation concern. Three bird species are identified as species of conservation concern: the white-headed woodpecker, mountain quail, and the harlequin duck. Species previously identified as Regional Forester Sensitive Species (RFSS) include the bald eagle (*Haliaeetus leucocephalus*), the black-backed woodpecker, the flammulated owl, pygmy nuthatch, the harlequin duck, mountain quail, the peregrine falcon (*Falco peregrinus*), and the white-headed woodpecker. The bald eagle and the peregrine falcon were once federally listed but have recovered. No observations have been made within the plan area for the threatened yellow-billed cuckoo (*Coccyzus americanus*). Many of these species were evaluated in detail for inclusion as a species of conversation concern but were not found to have a substantial concern for their long-term persistence based on the criteria used to evaluate them.

Mammal Assemblage

A total of 69 mammals have been observed in the plan area. Two species were added between the draft and Final Environmental Impact Statement. At least two, and perhaps three, grizzly bears were observed in the plan area while the Draft Environmental Impact Statement was being written. Prior to that time, recent grizzly bear observations were not recorded in the Idaho Species Diversity Database. In addition, during the Draft Environmental Impact Statement phase, only the American marten was included; the Pacific marten (*Martes caurina*) was not included by accident. Pacific marten until recently was considered a subspecies of American marten. However, genetic evidence established that they are distinct species and that both species are present on the Nez Perce Clearwater National Forest. Recent genetic surveys indicate that both species concurrently occupy the Nez Perce-Clearwater (Krohner 2020). The largest number of mammals are grouped into the substrate habitat because many mammals require friable soil for burrowing, rock outcrops, or steep terrain as a key ecological feature; otherwise, this grouping would occur in a wide variety of habitats. Most of the bat species were included in this group because they occur in a broad variety of habitats from low elevation deserts to high elevation forestlands and their distribution is probably more tied to their roosting or maternity features rather than vegetation. Similarly, the key ecological characteristic for the American pika (*Ochotona princeps*) is talus, and the key feature for yellow-bellied marmots (*Marmota flaviventris*) is rock outcrops or talus.

Compared to birds, proportionally fewer mammals in the plan area are specialized for aquatic habitats, though many mammals use riparian habitats in addition to other features and are grouped in other categories. The North American river otter (*Lontra canadensis*) and the beaver (*Castor canadensis*) are specialized for aquatic and riparian habitats and are grouped there. Other prominent habitat associations for mammals are forested habitats, ecotone, or forest edge, non-forested or early seral habitats, and resource associations. Most mammals are year-round residents in the plan area but may migrate to wintering grounds or hibernate during the winter. Some bat species migrate during the winter. Unlike some birds, no mammals live here only during the winter. Some of the same factors that affect bird habitats also affect mammal habitats. See Appendix C for more information on habitat descriptions and habitat groupings.

Several mammals are used as game species or furbearers. Big game include elk, white-tailed deer (*Odocoileus virginianus*), mule deer (*Odocoileus hemionus*), moose (*Alces alces*), mountain goats (*Oreamnos americanus*), bighorn sheep, black bear (*Ursus americanus*), wolves (*Canis lupus*), and cougars (*Puma concolor*). Mountain cottontail rabbits (*Sylvilagus nuttallii*) and snowshoe hares (*Lepus americanus*) are considered upland game. Beavers, muskrats (*Ondatra zibethicus*), American and Pacific martens, mink (*Neovison vison*), coyotes, bobcats (*Lynx rufus*), badgers (*Taxidea taxus*), fox (*Vulpes vulpes*), river otters, long-tailed weasel (*Mustela frenata*), raccoons (*Procyon lotor*), short-tailed weasel (*Mustela erminea*), and skunks (*Mephitis mephitis*) are all valued for their fur. A wide variety of mammals are used by Native American tribes for ceremonial, religious, and cultural uses; clothing; and subsistence. For more information about commonly used wildlife, see the Multiple Uses Wildlife section.

There are two mammal species of conservation concern: the fisher and bighorn sheep. Two other mammal species are federally listed or recognized: the federally listed threatened Canada lynx and the threatened grizzly bear which has recently been identified as "may be present" in the plan area by the U. S. Fish and Wildlife Service. The wolverine was a proposed species until recently. On October 8, 2020, the U.S. Fish and Wildlife Service announced that the best available science indicates that the factors affecting wolverine populations are not as significant as believed in 2013 when the U.S. Fish and Wildlife Service proposed to list the wolverine found in the contiguous United States as threatened (U.S. Department of the Interior 2018b). See the "Rationale (Species Evaluations) Used to Select Animal and Plant Species as Species of Conservation Concern for the Nez Perce-Clearwater Draft Plan and Draft Environmental Impact Statement"[19] for more information on why wolverines are not identified as a species of conservation concern.

Amphibian Assemblage

The Idaho Department of Fish and Game's Species Diversity Database has current or historical records for 12 amphibians: 5 frogs, 2 toads, and 5 salamanders. A couple of these species are questionable as to their occurrence in the plan area. The rough-skinned newt (*Taricha granulosa*) only has a single observation from 1996; it has not been recorded since and the plan area is outside its known range. Similarly, the Woodhouse's toad (*Anaxyrus woodhousii*) is well outside of its known range and has only been observed once. These observations may be misidentifications and are believed to not truly occupy the plan area. The American bullfrog (*Lithobates catesbeianus*) is established but is not native.

Most of these amphibians breed in aquatic habitats, save for the Coeur d'Alene salamander, which is presumed to lay eggs in underground rock crevices. That, coupled with their moist skin, ties these species to moist environments as key habitat characteristics. The extent to which amphibians reside near water as adults varies. Western toads (*Anaxyrus boreas*) and Coeur d'Alene salamanders can be found far from water while other species usually stay close to water. Long toed salamanders (*Ambystoma macrodactylum*), Idaho giant salamanders, and western tiger salamanders (*Ambystoma mavortium*) use downed wood, leaf litter, or subterranean habitats as adults.

Amphibian species are grouped in the aquatic, wetland, water, or riparian habitat groups, as these are the key ecosystem requirements for these species. However, it should be noted that substrate habitats, such as soil, rock outcrops, cutbanks, rocks, logs, or leaf litter, are also key requirements for most of these species.

Some of these species require good water quality while others tolerate a variety of aquatic settings. For example, the Rocky Mountain tailed frog (*Ascaphus montanus*) requires streams with high water quality, whereas the non-native bullfrog can use nearly any water. Thus, key ecosystem requirements are aquatic and riparian habitats functioning within the natural range of variability.

Dispersal for amphibians could be restricted to the distribution of aquatic features, although they also disperse during rain events. Thus, connectivity of aquatic habitats is a key feature of ecosystem integrity for these species. Those species that have more terrestrial habits as adults may be limited in dispersal by the distribution of features like downed wood, rocks, and leaf litter. Some amphibians are reluctant or struggle to cross roads. As a group, they all forage on invertebrates as primary foods so invertebrate populations are important to their persistence.

[19] U.S. Forest Service's Northern Region (Region 1) Species of Conservation Concern website, available online: https://www.fs.usda.gov/detail/r1/landmanagement/planning/?cid=fseprd500402

Amphibians worldwide are thought to be declining for a variety of reasons (Stuart et al. 2004, Beebee and Griffiths 2005). Causes for the decline include habitat loss, over exploitation, and invasive species. Some declines are occurring without explanation (enigmatic declines) even in well protected areas, such as national parks (Stuart et al. 2004). The enigmatic declines are hypothesized to be caused by exotic disease; contaminants, such as pesticides; changes in the amount of solar radiation; and climate change (Collins and Storfer 2003). Many of the above threats could be operating within the plan area at various scales and intensities. Habitat changes and the effects of plan components and alternatives will be analyzed as coarse filter, ecosystem integrity evaluations.

A few species are regional endemics for which the plan area makes up a substantial portion of the species global range. The Nez Perce-Clearwater makes up a substantial portion of the Idaho giant salamander and the Coeur d'Alene salamander ranges. The Idaho giant salamander is an Idaho endemic, save for very few observations just over the Idaho-Montana border. The latitudinal extent of the Idaho giant salamander's range is only approximately 222 miles north to south, extending from central Valley County to northern Shoshone County, Idaho. A total of 243 out of 403 observations in the Idaho Species Diversity Database[20] (accessed in July 2022) were observed within the Nez Perce-Clearwater boundaries. Most of the remaining observations occur within the southern portion of the Idaho Panhandle National Forest. While endemic, it is widespread and abundant within the plan area and is not considered a species of conservation concern.

Similarly, the Coeur d'Alene salamander is a regional endemic whose distribution extends from the Selway River northward into southern British Columbia, including parts of far western Montana. Observations of the species within the plan area make up approximately one quarter of the observations recorded in the Idaho Species Diversity Database. The Coeur d'Alene salamander has been observed in the plan area 105 times; throughout the State of Idaho, there have been 422 observations. While its distribution is wider, its habitat requirements are far narrower than the Idaho giant salamander. It seeks seeps, springs, waterfall spray zones, talus, and streamside habitats in association with sharply fractured rock formations used for underground refugia. The number of sites known to contain the Coeur d'Alene salamander are relatively limited, as this combination of habitat is rare in the plan area. While uncommon or rare, the habitat for these species is relatively well protected by designated wild and scenic river management along the Lochsa and Selway Rivers and by PACFISH and INFISH measures for the protection of aquatic and riparian habitats. While recent population trend information does not exist, the data suggests that the Coeur d'Alene salamander population during this period observed 95 percent of sites occupied between 1987 to 1992 (Cassirer and Groves 1994).

Reptile Assemblage

There are 11 reptile species on the Nez Perce-Clearwater: 3 lizards, 7 snakes, and 1 turtle. Most reptiles are either carnivores or invertivores, though the painted turtle (*Chrysemys picta*) is an omnivore. In terms of distribution, some reptiles are widespread in the plan area. The ring-necked snake (*Diadophis punctatus*) is a widespread species in the United States but occurs in Idaho as a disjunct population and has only been observed in limited portions of the plan area. Nevertheless, there are few threats that would affect this secretive snake. The northern alligator lizard (*Elgaria coerulea*) is limited to the northern half of the Nez Perce-Clearwater and is distributed mostly along major rivers. The western fence lizard (*Sceloporus occidentalis*) has been observed at lower elevations only along the Salmon River. The western rattlesnake (*Crotalus viridis*) has been seen mostly at lower elevations along rivers, with one observation along the Selway River. An observation of the painted turtle was included in the Idaho Species Diversity Database between the Draft and Final Environmental Impact Statement. The painted

[20] Idaho Department of Fish and Wildlife Information System, Species Diversity Database: https://idfg.idaho.gov/species/

turtle is native to Northern Idaho and may only have limited distribution in the plan area. However, they are considered common and abundant where they occur, and their conservation status is not in question. The gopher snake (*Pituophis catenifer*) has only been recorded in and around the Rapid River but likely has a wider distribution because it is common and abundant throughout much of Idaho.

Most of these species, save for painted turtles, are found in a wide variety of habitats but require hiding cover in the form of rocks, logs, debris, burrows, or talus. Thus, most are grouped into the substrate habitat grouping. Substrate habitats are comparatively less affected by Forest Service management than other habitat groupings, such as aquatic habitat or forested habitats. Perhaps the most influenced facet of their habitat from management is the amount and size of coarse woody debris left after timber harvest, quarrying of rock outcrops, and impacts from soil compaction. The painted turtle is an aquatic species and is grouped into the aquatic, wetland, water, and riparian habitats group. By and large, they face few identified threats, save for collection from the pet trade. The rattlesnake also faces human persecution. These threats are not prevalent in the plan area and do not affect habitat.

Mollusk Assemblage

Mollusks in the plan area include mussels and snails. The plan area includes observations of three species of freshwater mussels, which are dealt with in the Aquatic Ecosystems and Fisheries section. These observations include the western pearlshell mussel (*Margaritifera falcata*), the western ridged mussel (*Gonidea angulata*), and the California floater mussel (*Anodonta californiensis*).

The plan area supports high gastropods (slugs and snails) diversity. In fact, approximately 70 species of gastropods are known to occur in the plan area, which is the result of the Northern Rocky Mountain Refugium (Brunsfeld et al. 2001, Stagliano 2007). Many species of gastropods in the plan area are regional endemic species limited to northern Idaho, western Montana, southern British Columbia, and eastern Washington. Others are Idaho endemics limited in many cases to Idaho and some are local endemics with distributions limited to parts of the Nez Perce-Clearwater and some lands just outside the plan area. The Selway forestsnail (*Allogona lombardii*), the Mission Creek Oregonian (*Cryptomastix magnidentata*), and the nimapuna disc (*Anguispira nimapuna*) are some examples of local endemic gastropods. For example, 33 of 38 observations of the Selway forestsnail and 79 of 89 observations of the nimapuna disc have been made on Nez Perce-Clearwater lands (Idaho Species Diversity Database, accessed 2019).

Similarly, the Lower Salmon River Canyon has an exceptional morphologic and taxonomic land snail diversity, which has been recognized by scientists since the 1860s (Frest and Johannes 1997). Several morphologically distinct land snails are thought to be local endemics limited to only the Lower Salmon River Canyon. Some of them are only known from small or scattered rock outcrops within the Lower Salmon River Canyon. Most of them occur outside of the plan area boundaries at lower elevations but some taxa have been observed on Nez Perce-Clearwater lands. The marbled disc (*Discus marmorensis*), the costate mountainsnail (*Oreohelix idahoensis*), the Seven Devils mountainsnail (*Oreohelix hammeri*), the striate mountainsnail (*Oreohelix strigosa goniogyra*), and boulder pile mountainsnail (*Oreohelix jugalis*) are examples of Lower Salmon River endemics observed on Nez Perce-Clearwater lands. The Seven Devils mountainsnail is a distinctive taxon known from only one site north of Rapid River on the Nez Perce-Clearwater. Seven of 19 observations of all known observations of the marbled disc occur on the Nez Perce-Clearwater and all known observations are limited to Slate Creek within the plan area and John Day Creek outside the plan area, with a global range estimated at less than 40 square miles. Dozens of other mountain snails have been collected on the Nez Perce-Clearwater, whose morphology suggests species status but have not yet been described by science (Frest and Johannes 1997, Frest 1999, Frest and Johannes 2000, Frest et al. 2001). Threats to these endemic land snails are identified in Frest (1999) which discusses road building, mining, grazing, wildfire, logging, talus and rock quarrying, weed control, and development.

Mountain snails from the genus *Oreohelix* make up some, but not all, of the land snail diversity in the Lower Salmon River and are highly morphologically variable. In some cases, individuals collected from hundreds of miles apart are morphologically similar, suggesting convergent evolution, while in other cases, closely related snails from only a few miles distance can look radically different. Recent molecular techniques did not clarify the situation because testing of three different techniques for identifying species resulted in vastly different phylogenies, wherein some techniques suggested lower numbers of species than morphological studies suggested while other techniques by the same study and author suggested many more species than morphological studies suggested (Linscott et al. 2020). Linscott and Parent (2020) suggested more genetic studies of *Oreohelix* snails, combined with distributional studies, should be employed to resolve the issue. In the meantime, Linscott and Parent (2020) recommended that conservation efforts should be employed to protect calcareous rock outcrops from alteration to conserve potentially valid taxa.

Habitats used by gastropods include aquatic, riparian, forest, and non-forested habitats. About 19 gastropod species use aquatic or riparian habitats, while 51 species use substrate habitats, such as rocks, logs, leaf litter, or rock outcrops.

The habitat descriptions of nearly all the terrestrial gastropod species include moist habitats provided under rocks, downed wood, leaf litter, duff or moist sites underneath mesic vegetation, and these habitat components probably represent key ecological requirements. These habitats occur in forested habitats, riparian areas, rocky areas, and talus. The number of snails in the substrate habitat group underscores the importance of these features in a variety of settings.

Only a few gastropod species were found to use non-forested or early seral habitats. Their soft, moist bodies seem less tolerant of drier, non-forested habitats. Mountainsnails (*Oreohelix* spp.) appear to be the most tolerant of non-forested habitats. On the Nez Perce-Clearwater, several mountainsnail species are found in dry forest types. Mountainsnails are often found associated with specific lithologies, especially rocks and soils that have a calcareous make up. It is generally thought that mountainsnail species are associated with calcareous substrates (Henderson and Daniels 1916). Threats to mountainsnails may include quarrying for road base.

Both fully aquatic and some terrestrial gastropod species are grouped into the aquatic, wetland, water, and riparian habitat group. Seven species appear to associate with riparian habitats, while 12 are fully aquatic. Aquatic gastropods are highly sensitive to changes in water quality, sedimentation, temperature change, and flow. Of the aquatic species, 4 use open water or lake habitats, 5 use riverine habitats, 2 are associated with springs or groundwater, and 1 is an aquatic generalist. Aquatic gastropods are highly susceptible to habitat loss and degradation, particularly narrow endemics restricted to a limited number of spring or short stream reaches (Johnson et al. 2013). Johnson et al. (2013) estimate that aquatic freshwater gastropods are some of the most imperiled species in the United States and Canada, with approximately 74 percent of 703 species identified as imperiled. This trend holds in the plan area as NatureServe ranks 2 species as G1 critically imperiled, 4 species as G2 imperiled, and 4 species as G3 vulnerable. An analysis for aquatic gastropods might be provided best through coarse filter aquatic components that maintain water quality and aquatic habitat characteristics.

The wildlife species were grouped into habitat groupings and then the habitats were analyzed. The effects to the habitats were analyzed under the plan alternatives, as presented below. Each habitat grouping is analyzed under its own section with subgroupings nested within the groupings.

Aquatic, Wetland, Water, and Riparian Habitats

Any species whose primary habitat needs include aquatic habitats, such as wetlands, rivers, ponds, springs, or groundwater, or that primarily use riparian vegetation as their habitat were assigned to the aquatic, wetland, water, and riparian habitat group. There were 102 species whose key ecological habitat characteristics fit within this habitat group. This represents 27 percent of the total wildlife biodiversity in the plan area. Most species, 59 out of 102 the total listed, assigned to this group are aquatic avian species, such as ducks, shorebirds, and geese.

Since aquatic habitats are so diverse and used by wildlife in so many different ways, the aquatic, wetland, water, and riparian habitat group was further subdivided into the following subgrouping: open water habitats, such as lakes, large rivers, and open water within wetlands; riverine habitats; ground water habitats, such as springs and seeps; riparian vegetation habitats; and depressional wetlands, ponds, marshes, and emergent vegetation habitats; and aquatic and forested habitats or forested wetlands. Another subgrouping called aquatic generalist was created for species that use multiple aquatic habitats.

There are some species whose habitat preferences overlap in these subgroupings, which requires explanation. The open water habitat subgrouping includes open water in a variety of settings. Many species use open water habitats, whether those open waters are within lakes, large rivers, or large wetlands. If a species primary habitat description was open water, they were assigned to this group even if many of them could also logically be assigned to other subgroupings. An example is the canvasback duck (*Aythya valisineria*), whose habitat description includes use of a wide variety of aquatic features during migration, such as ponds, lakes, or slow rivers. Based on this description, the canvasback could have been grouped in either open water or the depressional wetlands subgroup.

Species were assigned to the riverine subgroup if their primary habitat is restricted to river habitats. Species were assigned to the riparian group if their primary habitat is described as riparian habitats, whether they are dependent upon the vegetation surrounding wetlands, rivers, lakes, and other wet habitats but were not necessarily aquatic. If a species used aquatic habitats but also used cavities or trees for nesting, then they were assigned to the aquatic and forested habitats or forested wetlands subgroup. Lastly, a species was assigned to the wetland subgroup if they use depression wetlands, ponds, marsh, or emergent vegetation as their primary habitat. The number of species in each sub-habitat grouping are shown in Table 155 (Source: National Hydrography Dataset, waterbodies greater than 1-acre spatial layer).

Table 155. Number of wildlife species known to use habitat subgroups under the aquatic, wetland, water, and riparian habitat group

Habitat Subgrouping	Number
Open water habitats—lakes, open water within wetlands, open water on large rivers	15
Riverine habitats	15
Ground water habitats—springs or seeps	3
Riparian habitats	23
Wetland—depressional wetlands, ponds, marshes, emergent vegetation	30
Aquatic and Forested habitats or Forested Wetlands	7
Aquatic generalist	7
Island Habitats	2

The aquatic habitats are used by nine mammals, such as muskrat, northern river otter, Beaver, raccoon, American mink, and North American water vole (*Microtus richardsoni*).

Fifteen species of gastropods were grouped into the aquatic habitats group. This group also includes a few species that are dependent upon groundwater resources, such as the pristine pyrg (*Pristinicola hemphilli*) and the Coeur d'Alene salamander, which use springs and groundwater as key ecological characteristics. These species require aquatic and forested habitats or forested wetlands.

Other wildlife species that primarily use upland habitats often use aquatic and riparian habitats in addition to their use of other habitats. Aquatic and riparian habitats make up only a small percentage of the land base. Riparian habitats are used by both aquatic species and many terrestrial species. A good number of species assigned to the broad-leaved forest subgroup also use riparian habitats because riparian areas are often where broad-leaved forests grow in the plan area. These considerations underscore the importance of aquatic and riparian habitats for wildlife in the plan area.

Key Ecological Characteristics of Aquatic and Riparian Habitats

Key ecological requirements and indicators for species within the aquatic grouping include:

- Riparian vegetation functioning within the natural range of variation.
- Open water with low turbidity, fish, and invertebrates; well oxygenated water; and variety in the bottom substrates, such as soft soil bottoms or rocky bottoms.
- Good water quality.
- Rivers functioning within the natural range of variation, including temperature; appropriate inputs of coarse woody debris and leaf fall; abundant aquatic invertebrates; robust fish populations; natural channel morphology; and functioning riparian areas with appropriate plant composition for the site with deciduous trees and shrubs. Substrates should include gravel, cobble, and boulders.
- Sediment yield functioning within the natural range of variation.
- Wetlands extent and distribution maintained, with appropriate native aquatic, emergent, or riparian vegetation surrounded by meadows or forest, as appropriate for the site.
- Springs and ground water systems functioning within the natural range of variation that are free from alteration or excessive disturbance.

If these habitats are functioning within their natural range of variation, then they should provide the habitat needs for a little less than one-third of all wildlife on the Nez Perce-Clearwater. Each species interacts within these habitats in different ways to exploit their niche. The wildlife species interact within these habitats to contribute to the ecological integrity of these systems, including structure, function, composition, and connectivity. This analysis will focus on whether the plan components and alternatives provide ecosystem integrity to provide for the diversity and abundance with respect to wildlife in the plan area.

Key ecological characteristics of open waters can be informed by the life history or dietary requirements of open water species. These species are mostly invertivores, piscivores, or omnivores, which forage by diving for fish or invertebrates for foods. This often is facilitated by clear water. Threats to these key ecological characteristics include changes to water clarity from eutrophication, sedimentation, contaminants, human waste, pollution, human disturbances, and the invasion of exotic plants and animals. Since they are secondary consumers, some of these species have been documented to have bioaccumulation from contaminants, such as mercury, pesticides, polychlorinated diphenyl, lead, and other metals. Thus, clean water is a key ecological characteristic. As many are piscivores and invertivores, abundant fish and invertebrate populations are a key ecological characteristic of this habitat. A change in the physical and chemical components of the water or the quality of water could affect several fish or aquatic invertebrates, which then affects wildlife in the open water subgroup. However, not all species of wildlife would be affected equally by these threats.

Key ecological characteristics of riparian habitats include distinct mesic and aquatic vegetation communities, including emergent vegetation, mesic shrubs, deciduous trees, reeds, grasses, and sedges. Some species require shallow waters where emergent vegetation grows while others require gallery forming trees or deciduous shrubs. In forested riparian habitats, these features are maintained periodically by disturbances like fire, flooding, or beavers. Structure, function, composition, and diversity of riparian vegetation communities provide the foundation for ecological conditions for the high wildlife diversity found in riparian habitats. Threats to riparian habitats include fire exclusion and subsequent uncharacteristic wildfire resulting from fuel build up, chronic intensive grazing, removal of beavers, exotic invasive plant species, and human alterations of aquatic conditions or riparian vegetation.

Some species specialize in forested riparian habitats, while others require herbaceous riparian areas. The wood duck (*Aix sponsa*), bufflehead (*Bucephala albeola*), common merganser (*Mergus merganser*), and tree swallow (*Tachycineta bicolor*) all nest in tree cavities in snags or mature live trees. Snags with cavities adjacent to or within riparian areas are important for tree nesting riparian and aquatic species. The osprey (*Pandion haliaetus*) and bald eagle use forested riparian habitats and often use large snags for nest sites. The great blue heron (*Ardea herodias*) nests in gallery forming trees. The red-winged blackbird (*Agelaius phoeniceus*), the sandhill crane (*Grus canadensis*), and Lincoln's sparrow (*Melospiza lincolnii*) use non-forested riparian habitats. Some shorebird species require bare shoreline for foraging or nesting. Killdeer (*Charadrius vociferus*) often nest on sandy or rocky habitats adjacent to water. Thus, the amount and diversity of riparian habitats, both in the physical and vegetative characteristics, are a key ecological characteristic of riparian habitats. Threats or stressors to these characteristics include alteration of the physical properties or geomorphology of aquatic habitats and changes to vegetation communities. Changes to physical properties of aquatic and riparian habitats generally result from human alteration of wetlands, river channels, sedimentation, and flow characteristics. Changes to riparian vegetation communities can be caused by alteration of flow; dams; vegetation management; and changes to natural disturbances, such as fire, uncharacteristic wildfire, loss of ecosystem engineers like beavers, and grazing.

Species that use riparian habitats vary in their diet, and riparian habitats provide a diverse foraging environment. The rich plant community supports abundant foraging opportunities, and each species has adapted to exploit these resources. Many riparian species are herbivories that forage on mesic or aquatic vegetation. Examples include moose, beaver, and several duck species. Fruits make up a major portion of the diet of many passerine birds in the fall, and many species of fruiting plants grow within riparian areas. The yellow-breasted chat (*Icteria virens*), yellow-rumped warbler (*Setophaga coronata*), Townsend's solitaire (*Myadestes townsendi*), bohemian waxwing (*Bombycilla garrulus*), western tanager (*Piranga ludoviciana*), Swainson's thrush (*Catharus ustulatus*), and song sparrow (*Melospiza melodia*) forage on invertebrates in the spring and fruits in the fall. Threats to fruit resources and riparian vegetation forage can be caused by vegetation management, forest succession because of fire suppression, reduction through human exploitation, grazing, uncharacteristic fires, and invasion by exotic plant species that can displace fruiting plants.

Rich invertebrate communities, both aquatic and terrestrial, provide forage for dozens of wildlife species. These include songbirds, ducks, shorebirds, most amphibians, small mammals, and bats. Foraging strategies are diverse for capturing these invertebrate foods—some species capture flying aquatic insects in the air, others forage on the ground under shrubby vegetation, others dive or wade to capture their food, and some obtain their invertebrate foods under debris and duff. Thus, healthy insect and invertebrate communities are key characteristics of riparian habitats. Insect communities can be reduced or lowered in diversity from changes to water quality; water abundance; temperature; substrates; inputs, such as detritus or coarse woody debris; and changes to the vegetation community within riparian habitats. The cause of these changes can be forest management, sedimentation from roads, channelization, dredging, water diversions, dams, invasive plants and animals, wetland alteration or draining, pollution from human waste, changes to geomorphology, removal of beavers, and possibly climate change. These activities and their effects are like those that affect fish and were analyzed in detail within the Aquatic Ecosystem and Fisheries section.

Several species are piscivores dependent upon robust fisheries for food. Species, such as the bald eagle, common merganser, northern river otter, American mink, belted kingfisher (*Megaceryle alcyon*), great blue heron, osprey, and western grebe (*Aechmophorus occidentalis*) are piscivores or omnivores where fish make up a substantial portion of their diet. Species like the harlequin duck and the common merganser consume fish eggs as a portion of their diet. Robust fish communities are a key ecological characteristic of riparian and aquatic habitats. Fish communities can be affected by changes in water quality, quantity, temperature, uncharacteristic sedimentation, changes to aquatic geomorphology, and contaminants. These factors are analyzed in depth in the aquatic and Aquatic Ecosystem and Fisheries section.

Diversity and abundance of wildlife are key benefits for carnivorous riparian species. Factors that affect the forage base of plants, fisheries, and invertebrates can reduce the abundance and diversity of wildlife used as prey. The changes to the key ecological characteristics mentioned above are key threats to these carnivorous species. Trapping within riparian areas can also affect carnivores, as many of them are furbearers.

Some population trends of birds that were grouped into aquatic habitats are available from the Intermountain Bird Observatory data accessed on March 24, 2023. From this database, the Idaho BCR10 stratum was queried. There are population trends for 21 birds assigned to the Aquatic, Wetland, Water, and Riparian Habitats group of which 10 are declining and 11 are increasing. Those declining in order from strongest decline to the weakest decline include the osprey, tree swallow, ring-billed gull, red-winged blackbird, spotted sandpiper, Canada goose (*Branta canadensis*), double crested cormorant (*Phalacrocorax auritus*), belted kingfisher, willow flycatcher (*Empidonax traillii*), and song sparrow. The declines in these species range from 52 percent to 1.2 percent annually over the 13-year dataset. Some declining trends have large variation in the data which should be viewed with discretion. Declining species that have large variations in the trends include the osprey (-52 percent decline), ring-billed gull (-39 percent decline), red-winged blackbird (-42.7 percent decline), and bank swallow (*Riparia riparia*) (-33.8 percent decline). The other species have sufficient data for reliable trend inferences. The declines occur in a variety of aquatic subgroups so cause of declines do not appear to be common among the species from a habitat standpoint.

River Habitats

Many species use river habitats in addition to other aquatic habitat. Examples of species that use river habitats include bald eagle, great blue heron, common merganser, Canada goose, harlequin duck, beaver, muskrat, mallard duck (*Anas platyrhynchos*), Columbia spotted frog (*Rana luteiventris*), Idaho giant salamander, and common garter snake (*Thamnophis sirtalis*). The harlequin duck was identified as a species of conservation concern for the plan area. Many species that use open water sources also use rivers, especially large rivers like those in the plan area. Examples of species that tend to use open water include canvasbacks, double-crested cormorants, western grebes, lesser scaups (*Aythya affinis*), and ring-necked ducks (*Aythya collaris*).

While all amphibians use aquatic habitats, the Rocky Mountain tailed frog is the only amphibian on the Nez Perce-Clearwater that specializes in riverine habitats, especially those that run through mature forest. Avian species that primarily or exclusively use river habitats are American dipper (*Cinclus mexicanus*), belted kingfisher, and harlequin duck. Five aquatic gastropods were identified specifically as riverine species and are of conservation interest. These include the ashy pebblesnail (*Fluminicola fuscus*), Nez Perce pebblesnail (*Fluminicola gustafsoni*), rustic pondsnail (*Stagnicola hinkleyi*), the shortfaced lanx (*Fisherola nuttallii*), and shortspire pondsnail (*Stagnicola idahoensis*). These species are highly susceptible to changes in water quality, temperature, and sedimentation.

The only mammal identified as primarily using river habitats is the North American river otter, which uses large rivers at lower elevations and depends on fish for food. The Terrestrial and Aquatic Ecosystems and Watersheds section of the Forest Plan Assessment (U.S. Department of Agriculture 2014a) evaluated aquatic habitats with a primary focus on river and riparian habitat. The focus of the Assessment revolved around fish, specifically the quality of habitat conditions for anadromous fish and inland salmonids. The Assessment identified threats to these systems by watershed and identified roads, mining, grazing, timber management in riparian zones, uncharacteristic wildfire or altered fire regime, landslides, loss of connectivity due to culverts, establishment of invasive non-native vegetation, streamside trails, dispersed campsites, and climate change as threats to these systems. More localized threats identified in the Assessment include campground facilities, administrative sites, dispersed recreation adjacent to streams, and trail use and construction.

Collectively, these threats have changed sediment loading, stream channel morphology, cobble embeddedness, temperature, water quality, changes to width depth ratios, inputs of woody vegetation, and loss or removal of large organic debris and caused a shift in benthic macroinvertebrate assemblages, all of which is indicative of degraded stream conditions (U.S. Department of Agriculture 2014a).

The Assessment used the watershed condition framework to evaluate river conditions within the plan area. The watershed condition framework identified watersheds as either Condition Class 1, 2, or 3, where Condition Class 1 is considered functioning in good condition, Condition Class 2 is operating at risk, and Condition Class 3 is functioning in poor condition. Watershed condition class is based upon a variety of factors, such as the condition of aquatic physical, aquatic biological, terrestrial physical, and terrestrial biological. Watershed findings are generally consistent with land management allocation where wilderness and Idaho Roadless Rule areas generally are operating in watershed Condition Class 1 while the roaded front, or Management Area 3, is generally operating in watershed Condition Class 2 or Condition Class 3. Management in the roaded front has historically been used for extractive uses, such as timber production, mining, and grazing. These findings are indicative of the landscape scale effects that can be influenced by management area direction and the effects they can have on aquatic systems, especially rivers.

PACFISH and INFISH amended forest plans in the Columbia River Basin as interim guidance to protect habitats for federally listed steelhead trout (*Oncorhynchus mykiss*) and bull trout (*Salvelinus confluentus*). The intent of PACFISH and INFISH were to protect existing quality anadromous and inland fish habitat and arrest habitat degradation, allowing restoration of aquatic and riparian ecosystems to occur at natural rates. At a minimum, PACFISH and INFISH were intended to hold the line on habitat degradation over the short-term until the long-term ecosystem-based restoration strategies could be developed to protect and restore anadromous fish-producing waters on lands within the Columbia River Basin. PACFISH and INFISH established standards and guidelines in the 1987 plans that protect river habitats and implemented the PACFISH and INFISH Biological Opinion Monitoring Program (PIBO). This direction has since helped protect and restore these habitats in the plan area. PIBO has shown that managed watersheds are generally in poorer condition than reference watersheds. It also indicated a trend in management watersheds towards improvements in some water quality metrics, while other metrics have remained degraded compared to reference watersheds (Saunders et al. 2019b). For background information regarding the amending of forest plans in the Interior Columbia River Basin with PACFISH and INFISH refer to the following website: www.fs.usda.gov/detail/r6/landmanagement/resourcemanagement/?cid=fsbdev2_027084.

Both the Nez Perce and Clearwater National Forests implemented various watershed improvement activities beginning in the mid-to-late 1980s. These activities included direct stream improvements, as well as activities designed to reduce sediment such as road decommissioning. Currently, aquatic improvement activities generally include stream crossing upgrades, road decommissioning, road drainage improvements, and direct stream channel improvements in areas that were historically dredge mined. Fencing of riparian corridors and wet meadows has also been implemented to exclude cattle from riparian areas. Collectively, these activities have improved aquatic conditions in the plan area.

The most important threats to river wildlife in the plan area include historic grazing, energy production and mining, roads and motorized trails, logging and wood harvest, human intrusion and disturbance, road decommissioning, wildfire and fire suppression, channelization and bank alteration, invasive animal or plant species, landslides, and climate change.

Riparian Habitats

Riparian ecosystem areas represent some of the most dynamic and ecologically diverse areas across the landscape. Most riparian areas are obvious because of abundant water and unique vegetation and soil characteristics. Ecological drivers, such as geology, climate, glaciations, and stream gradient, all influence the type, complexity, quantity, and distribution of these ecosystems, and there is great variability in the size and complexity of riparian areas across the Nez Perce-Clearwater. Wetlands, such as swamps, bogs, fens, marshes, and wet meadows, are also considered riparian areas. Wetlands occur in sites with seasonally or permanently high-water tables, as well as on the margins of ponds and lakes, and commonly support characteristic plant or animal communities, which require those unique conditions for survival. Although riparian ecosystems cover a relatively small proportion of the Nez Perce-Clearwater, their ecological significance within the landscape exceeds their limited distribution. Riparian ecosystems can be highly responsive to both natural and human disturbances, although they may respond to restoration activities more quickly than other habitats due to the dynamic interaction between water, vegetation, and soils.

Riparian habitats provide ecological conditions for a suite of species. They provide an interface between terrestrial and aquatic habitats and both aquatic and terrestrial species use these habitats. Riparian habitats occur along rivers, around wetlands and lakes, and near other aquatic features. Nearly all wildlife species in the plan area use riparian areas. Some use them peripherally, while others can use them as a primary habitat. All species grouped in the aquatic, wetland, water, and riparian habitat grouping use riparian habitats. Of that group, 17 species were grouped into the riparian habitat subgroup because they specialize in riparian habitats. Many more species in the ecotone or habitat combination grouping and the forested species groupings can be found in riparian habitats in addition to other upland habitats. Of the forested habitats grouping, those in the broad-leaved subgroup will readily use riparian habitat. The broad-leaved subgroup includes 11 plus species that will readily use riparian areas. On the Nez Perce-Clearwater National Forest, broadleaved deciduous forest or vegetation grows in both the uplands but particularly grows in riparian areas especially after disturbance. Like much of the upland, riparian areas have experienced a lower amount of disturbance from fire than has historically occurred because of exclusion. Because several species specialize in broadleaf or deciduous habitat and many others also use habitats with these features, the plan contains FW-DC-TE-05 which states "Riparian vegetation includes native assemblages of hardwood trees, deciduous shrubs, conifers, and, where appropriate, unique coastal disjunct species." It also includes FW-DC-GS-04 as a desired condition to include hardwood species in riparian and upland areas. The plan contains objective FW-OBJ-TE-01 which aims to treat riparian habitats to restore hardwood overstory on 3,000 to 4,200 acres every five years to provide habitat diversity within riparian habitats. Additionally, FW-OBJ-RMZ-01 seeks to restore 300 to 700 acres of riparian habitat every five years including hardwood restoration. Most other species in the forest subgroupings also use riparian areas when they provide structural or compositional ecological requirements. As mentioned in the riverine habitat analysis, riparian areas provide connectivity across the Nez Perce-Clearwater.

Species that use riparian habitats include the northern waterthrush (*Parkesia noveboracensis*), willow flycatcher, North American water vole, and northern raccoon. Examples of bird species that use both deciduous forest habitat and riparian areas include the American redstart (*Setophaga ruticilla*), red-eyed vireo (*Vireo olivaceus*), warbling vireo (*Vireo gilvus*), ruffed grouse (*Bonasa umbellus*), and Bullock's oriole (*Icterus bullockii*). All amphibians in the plan area use riparian habitats, such as the Sierran tree frog (*Pseudacris sierra*), the western toad, and the long-toed salamander. Many amphibians require aquatic habitats for breeding, yet in their adult life cycle they use primarily terrestrial habitats under rocks, logs, litter, and leaves. These features are present in properly functioning riparian habitats. Thus, dead and downed wood are an important component of the structure and composition of riparian habitats.

Species that are currently identified as Regional Forester Sensitive Species (RFSS) and that rely on aquatic, wetland, or riparian habitats for at least part of their life include the bald eagle, the harlequin duck, the Coeur d'Alene salamander, mountain quail, and the western toad. Bald eagles forage and nest near rivers and lakes; harlequin ducks breed on fast-moving, low-gradient mountain streams. RFSS that are known to sometimes use riparian areas also include the fisher, the long-eared myotis (*Myotis evotis*), the long-legged myotis (*Myotis volans*), and the Townsend's big-eared bat (*Corynorhinus townsendii*).

Wetland—Depressional Wetlands, Ponds, Marshes, Emergent Vegetation

The suite of species that use riparian habitats around still water marshes, lakes, and wetlands are different than those that use riparian areas around moving water. Shore birds, wading birds, many ducks, and some passerine bird species may be more suited to riparian areas around standing water than along rivers. These habitats are often composed of wet meadows, emergent vegetation, submerged vegetation, wading habitats, and shoreline habitats. Examples of species that use these habitats on the Nez Perce-Clearwater include American avocet (*Recurvirostra americana*), greater yellowlegs (*Tringa melanoleuca*), red-winged blackbird, yellow-headed blackbird (*Xanthocephalus xanthocephalus*), swamp sparrow (*Melospiza georgiana*), Virginia rail, Wilson's snipe (*Gallinago delicata*), American coot (*Fulica americana*), and the solitary sandpiper (*Tringa solitaria*). Ducks associated with these types of habitats include northern shoveler (*Spatula clypeata*), northern pintail (*Anas acuta*), gadwall (*Mareca strepera*), green-winged teal (*Anas creccca*), blue winged teal (*Anas discors*), American wigeon (*Mareca americana*), and cinnamon teal (*Spatula cyanoptera*). Many amphibians use standing water riparian habitat, and some species appear to use wetland and pond habitat more than others. Those that tend to use more wetland habitats include the northern leopard frog (*Lithobates pipiens*), the Sierran tree frog, the western toad, and the Columbian spotted frog. These species can also sometimes be found along riverine riparian habitats. The non-native American bullfrog could be considered a stressor in these habitats because of its predatory nature. Wetland areas are lost through draining, development, and changes to hydrology.

Open Water Habitats and Wetlands

Several species use open water as their primary habitat. Open waters include lakes, large wetlands, and large rivers. The amount of these habitats is comparatively small (Table 156), and their distribution is uneven on the Nez Perce-Clearwater. Table 156 below shows the number of water bodies larger than one acre which includes the lakes in the plan area.

Table 156. Number, percent, and acres of lakes (water bodies larger than one acre) within designated wilderness, Idaho Roadless Rule areas, and general forest areas (Source: National Hydrography Dataset water bodies greater than one-acre spatial layer overlaid on Management Area spatial layer)

Area	Count	Percent of Count by Management Area	Acres	Percent of Acres by Management Area
Wilderness	371	54	3003	18
Idaho Roadless Rule Areas	151	22	1828	11
General Forest	163	24	12,211	72
Total	**685**	**-**	**17,042**	**-**

Large rivers make up the bulk of open water habitats in the plan area. Lake and wetland habitats are much less common and unevenly distributed in the plan area. In terms of numbers, most of them occur at higher elevations in glacier formations in wilderness areas. However, because of Dworshak Reservoir, the acres of open water habitats are larger than in general forest management areas.

Species were included into this grouping if open water is their primary habitat requirement resulting in 15 species in the open water habitat grouping. They are composed largely of aquatic birds and some fully aquatic gastropods that typically occur in either lentic water or large rivers. The western grebe, mallard, greater scaup (*Aythya marila*), common loon (*Gavia immer*), red-breasted merganser (*Mergus serrator*), and eared grebe (*Podiceps nigricollis*) are representatives of avian species that use open waters. The Artemesian ramshorn (*Vorticifex effusa*), twisted physa (*Physella lordi*), and rotund physa (*Physella columbiana*) are gastropods that use open waters or large rivers. Like other aquatic and riparian habitats, several other species also use open waters; however, they were placed in different groups based on other key ecological features or their habitat description. Examples of species in other habitat groupings which may also use open waters could include those in the depression wetland group and those in the aquatic generalist group. Most ducks use open waters for some portion of their life cycle. Many of these species can be found on open waters at various times of the year, particularly during migration. Some of the species were grouped in open water habitats because they only occur during migration and their migratory habitats are open waters. Breeding habitats outside of the plan area may be different. Some of the open water species may prefer to use still water only, while others may prefer to use large rivers. Some readily use both and are more generalist. For example, the Canada goose uses just about any water.

Ground Water, Spring, and Seep Habitats

Springs and seeps provide habitat for fewer species than other types of aquatic or riparian areas. However, the species that use these habitats are often specialized to exist within the narrow and consistent temperature and physical characteristics of groundwater habitats or spring habitats. Species that use spring habitats are uniquely adapted to these habitats and often live within a very limited or scattered distribution with few populations. Changes to spring habitats can wipe out the populations of these types of organisms and result in the loss of distribution or even extinction. Key ecological features of springs, ground water, and seeps include water quality, cold temperatures, and a stable environment.

There are only three species grouped into the springs, seeps, and ground water habitat group. They include the pristine pyrg, the Green River pebblesnail (*Fluminicola coloradoensis*), and the Coeur d'Alene salamander. The pristine pyrg was analyzed in the Aquatic Ecosystem and Fisheries section. The Coeur d'Alene salamander is associated with springs, seeps, and waterfall spray zones and seems to be associated with specific rock formations. Thus, they are not wholly reliant on ground water habitats. The Coeur d'Alene salamander is a species of public interest because it is a regional endemic with a limited range and specific habitat requirements.

The largest threats to springs, seeps, and groundwater habitats are those that change water flow, temperature, or water quality of springs. Diversions for livestock water developments and livestock use of springs is probably the most widespread impact to these habitats. Under the No Action Alternative, springs are managed as riparian habitat conservation areas which is similar to riparian management zone (RMZ) delineations in the action alternatives. Additionally, aquatics plan components for springs in the action alternatives include several components addressing protection of springs, seeps, and groundwater. Since springs and seeps are considered Category 4 RMZs, their width is 100 feet and all RMZ components would apply. These plan components are focused on restricting activities within RMZs that are known to have impacts to aquatic resources. Examples of these activities are timber harvest, aquatic and riparian habitat alteration, application of fire retardant in aquatic habitats and more.

Plan components that directly address springs include FW-DC-WTR-08, FW-GDL-WTR-05, FW-DC-TT-04 and FW-GDL-ARGRZ-03. These plan components provide guidance to maintain quality and quantity of water flows, and persist in size, seasonal and annual timing, exhibit water table elevations within the natural range of variability and sustain the function of surface and subsurface aquatic ecosystems.

Since the primary source of management effects to spring dependent species is probably livestock grazing, aquatics and riparian livestock grazing plan components include measures designed to protect aquatic habitats. Plan components that address impacts from livestock grazing to include those in the Livestock Grazing (Aquatics and Riparian) and Livestock Grazing sections of the plan. These plan components address many impacts livestock grazing has on aquatic resources. For example, these plan components require conservation measures to protect aquatic resources be included in reauthorizations for grazing permits, impose stubble height minimums, locate actions like trailing or salting outside of riparian areas, and prevent redd trampling. However, they do not prohibit spring development like spring boxes or water developments. Such activities would be evaluated and decided in site specific project analysis.

Collectively plan components are expected to result in few differences in effects to spring and groundwater associated species when compared to the No Action Alternative. The plan components should be adequate to provide for spring and groundwater associated species, except when water developments like spring boxes or spring diversions, cause changes in the ecological conditions that support spring- and groundwater-dependent species.

Aquatic, wetland, and riparian habitats are inherently limited in the plan area. Estimates vary depending on the data source used. To estimate the area of riparian habitats, the National Hydrography Dataset (NHD) was used to delineate and estimate riparian habitats in the plan area. These estimates include the riparian management zone outlined in FW-STD-RMZ-01, FW-STD-RMZ-02, FW-STD-RMZ-04, FW-STD-RMZ-06, and FW-STD-RMZ-07. The acres of riparian habitat found around rivers in the plan area are difficult to estimate but make up only a fraction of the plan area. The NHD-named streams layer and the water bodies greater than 1-acre layers were buffered by the RMZ distances in ArcGIS to estimate the area protected by the RMZ plan components. In total, these areas are estimated at about 548,284 acres, or about 13.9 percent, of the plan area, including those around rivers, lakes, and wetlands using this method. To get a more concise estimate of actual riparian area, we delineated riparian areas based on the floodplain surrounding NHDs and found the area to be approximately 295,000 acres. The miles of rivers that occur within different land allocations within the national forest were calculated by overlaying the NHD-named streams layer with the Nez Perce-Clearwater's management areas layer. It is estimated that about 66.6 percent of river miles in the plan area flow through designated wilderness and Idaho Roadless Rule areas so more than half of the riparian areas around these rivers receive some level of protection through management area allocation and their associated suitability plan components. Management area direction in the plan reduces or eliminates many of the threats described below because some activities that could impact riparian habitats are not suitable in roadless and wilderness.

The National Hydrography Dataset (NHD) waterbodies greater than 1 acre were buffered by 150 feet to estimate the amount of riparian areas around wetlands. The area around the NHD waterbodies greater than 1 acre is about 9,181 acres, which is less than 1 percent of the total land base of the Nez Perce-Clearwater. Thus, riparian habitats around water bodies like wetlands and lakes make up about 1 percent of the plan area, which underscores the importance of their contribution to biodiversity. The implication is that less than 14 percent of the plan area is required for approximately 27 percent of diversity for all species in the plan area. Most riparian habitats occur surrounding river habitats, while those from standing water are much less abundant. These numbers likely underestimate the number of riparian habitats because small scale wet areas would be considered riparian habitats but are too small to show up on those datasets.

Threats and Stressors to Aquatic and Riparian Habitats

Threats and stressors to riparian habitats come from sediment from roads, road construction, grazing animals, invasive species, vegetation management, climate change, drought, mining, draining, channelization, changes to flow patterns, contaminants, and uncharacteristic wildfire. Stressors to these systems that can be influenced by Forest Service management actions include livestock grazing, non-native invasive plant and animal species, pattern, and timing of motor vehicle use, draining or diversion, administrative or recreational facility development, and harvest of adjacent timber outside of riparian areas. Not all these processes or actions are stressors to all species using these habitats. Threats to these systems that are not under control of Forest Service management include drought, climate change, alterations to hydrology occurring on adjoining non-National Forest System lands, and alterations to water chemistry resulting from pollution, sedimentation, beaver removal, or other inputs originating outside of Forest Service control.

Climate change could affect aquatic habitats. Most of the effects of climate change would not be within Forest Service control, though some actions by the Forest Service may help these systems be more resilient to effects. Scientists and land managers from the Forest Service authored the *Climate Change Vulnerability and Adaptation in the Northern Rocky Mountains in 2018* (Halofsky, Peterson, et al. 2018a, b).

In that assessment, predicted effects to aquatic resources were evaluated and found the following:

Decreasing snowpack and declining summer flows will alter timing and availability of water supply, affecting agricultural, municipal, and public uses in and downstream from national forests and affecting other forest uses, such as livestock, wildlife, recreation, firefighting, road maintenance, and instream fishery flows. Declining summer low flows will affect water availability during late summer, the period of peak demand (e.g., for irrigation and power supply). Increased magnitude of peak stream flows will damage roads near perennial streams, ranging from minor erosion to extensive damage, thus affecting public safety, access for resource management, water quality, and aquatic habitat (ii).

Primary strategies that were recommended included changing hydrology in the Northern Rockies to restore the function of watersheds, connect floodplains, reduce drainage efficiency, maximize valley storage, and reduce hazardous fuels. Tactics include adding wood to streams, restoring beaver populations, modifying livestock management, and reducing surface fuels and forest stand densities. Primary strategies for infrastructure include increasing the resilience of stream crossings, culverts, and bridges to higher peak flows and facilitating response to higher peak flows by reducing the road system and disconnecting roads from streams. Tactics include completing geospatial databases of infrastructure and drainage components, installing higher capacity culverts, and decommissioning roads or converting them to alternative uses. It will be important to map aquifers and alluvial deposits, improve monitoring to provide feedback on water dynamics, and understand the physical and legal availability of water for aquifer recharge. Erosion potential to protect water quality can be addressed by reducing hazardous fuels in dry forests, reducing non-fire disturbances, and using road management practices that prevent erosion (Halofsky, Peterson, et al. 2018a, b). Plan direction and alternatives do not directly address climate change. However, aquatics and terrestrial ecosystems plan components would implement many of the strategies recommended in Halofsky et al. (2018a, b).

Modeling Riparian Vegetation

Riparian areas were modeled in SIMPPLLE to generate a natural range of variation for these areas, to identify where the Nez Perce-Clearwater riparian habitat conservation areas (RHCAs) are in relation to the natural range of variation (NRV), and to project future outcomes of the Land Management Plan under the alternatives. RHCAs typically represent a small percentage of forest acres.

Models of the NRV suggest that today's conditions have less of the RHCA in an early seral condition than under natural disturbance. The effects of this condition are that fewer acres potentially support hardwood vegetation and are more encroached by conifer dominated conditions than they were under natural disturbance. This could affect some species, such as those in the riparian and broad-leaved forest groups, that prefer deciduous forest and shrubs as habitats. These include beavers and several migratory songbirds. It should be noted that not all early seral habitats in the RHCAs result in a deciduous vegetation response. In some cases, these habitats regenerate as conifer naturally.

In the mountainous West, riparian shrub and deciduous tree communities are disturbance dependent. On wide, low gradient drainages, periodic flooding maintains a very highly convoluted pattern of meanders, sloughs, and oxbow lakes. Because this pattern is changing constantly due to periodic flooding, cottonwoods and shrubs are the predominant vegetation, whereas conifers are patchier and somewhat episodic since they only become established in the intervals between flooding events. Beaver activity also helps to maintain cottonwood and shrub communities and compliments the effects of flooding.

Unlike low gradient streams, moderate and high gradient streams (that is, tributaries to the Salmon and Selway rivers) tend to be bedrock controlled. Flooding generally has little effect on the amount of sinuosity. Conversely, wildfires, insect outbreaks, or disease reduce conifer cover and allow dense communities of riparian shrubs to occupy riparian zones. Beavers occur within moderate and steep gradient streams, however, their influence upon the shrub community is much less than within low gradient streams. In the absence of disturbance, conifers will quickly re-occupy upland riparian zones and to varying degrees will shade out riparian shrubs.

Two human activities affecting natural disturbances in moderate and steep gradient streams include fire suppression and riparian management zone (RMZ) protective measures. Wildfire history data suggests wildfire-burned acreages in the 20th century declined during the mid-1900s until the 1980s, when fuel accumulations and warmer and drier weather began a trend of increasing acreage and severity of wildfires.

Because most streams in the Planning Unit are moderate and high gradient streams, the query is designed to model those riparian deciduous communities that are maintained by disturbances such as wildfires, insects, and disease. The query is designed to assess the availability of habitats that provide shrubs and deciduous trees within RMZ. For time step zero, a GIS layer including the locations of all VMap polygons with cover types dominated by shrubs and deciduous trees was used, including VMap DOM mid-40 shrub, aspen dominated (MX-POTR5), and cottonwood dominated (MX-POPUL). For purposes of modeling future vegetation treatments, there were minimal treatments in landscape areas mapped as RMZ because these areas are not suitable for timber production. Transitional forests resulting from moderate or high severity wildfires and insect or disease within 20 years following disturbance were used to model future forest openings containing riparian shrubs and hardwood trees. Since the VMap cover class 0–14.9 percent may be lacking in trees but contain dense shrubs, it was included in the model. On the Planning Unit, once mixed conifer stands in upland riparian areas reach an average of 5 inches diameter at breast height (DBH), the presence of deciduous trees and shrubs has often been greatly reduced or eliminated due to conifer competition and shading, so these forests were not included for purposes of future modelling of highly suitable habitat for species associated with riparian shrubs and deciduous trees.

The U.S. Fish and Wildlife Service's National Wetlands Inventory dataset (NWI) was used to identify vegetation characteristics associated with "riparian" sites on the Nez Perce-Clearwater. Spatial extent was reviewed both for coverage across the State of Idaho, and in relation to stream features mapped by the National Hydrography Dataset (NHD).

After validating the availability and full coverage of the Nez Perce-Clearwater study area, an assessment was conducted to determine that NHD and NWI were in good agreement and generally represented the presence and composition of wetland and riparian sites. Considering the NWI as best available suitable for the detection of wetland and riparian conditions, it was used in a spatial intersection to select associated polygons in the spatially explicit VMap.

Since the NWI ID_Wetlands theme is considered the authoritative source for wetland and riparian delineation, and matches the extent of NHD features, it was used to define "riparian" sites and was intersected with the Nez Perce-Clearwater VMap database polygons. The output from this operation selected all VMap that were interested (touched to any extent) by NWI features, and yielded summaries of the total acres and relative distributions of vegetation types occurring at the intersection of wetland and riverine features, referred to as riparian sites, and vegetation polygons across the Nez Perce-Clearwater National Forest.

Focusing on the DOM_MID_40 attribute, the total acres and relative abundance of vegetation types was quantified for all polygons that were intersected by the NWI dataset across the Nez Perce-Clearwater. At nearly 37 percent, grand fir dominated stands is by far the most abundant stand type. It is followed in decreasing order of abundance by Douglas-fir and Engelmann spruce, with 8.7 percent and 8.4 percent, respectively. Ponderosa and lodgepole pine represent 7.7 percent and 7.4 percent abundance. Cedar and hemlock together represent around 5 percent, and deciduous stands represent less than half of one percent of all vegetation types intersected by NWI across the Nez Perce-Clearwater, as described by the VMap database.

The foundation for vegetation data is the VMap. The attributes of this dataset were translated to attributes that are used in the SIMPPLLE model, which includes information about potential vegetation types

(PVT), habitat type groups (HT_GRP), and species composition (SPECIES) of stands. The SIMPPLLE dataset represents vegetation across the landscape as a network of points. Riparian sites were defined by the NWI dataset, which represents wetland and riverine features as a network of polygons.

To gain an understanding of the distribution of vegetation types found within proximities that resemble riparian management zones (150 ft and 300 ft) across the Nez Perce-Clearwater, data from the SIMPPLLE dataset that were within 164 and 328 ft of NWI features were spatially selected and their attributes were summarized individually and in combination. Each of these sets of points were analyzed for PVT, HT_GRP, and SPECIES composition and abundance.

- The potential vegetation type (PVT) attribute was summarized for SIMPPLLE vegetation points within 164 and 328 ft from NWI wetland and riverine features.
    - ♦ Both sets of points have nearly identical distribution patterns and suggest similar vegetation is mapped within 164 and 328 ft of riparian sites. In both cases, “abgr3”, “thpl2”, and “abgr2” are the three most abundant potential vegetation types.
- The habitat type group (HT_GRP) attribute was summarized for SIMPPLLE vegetation points within 164 and 328 ft from NWI wetland and riverine features.
    - ♦ Both sets of points have nearly identical distribution patterns, and suggests similar vegetation is mapped within 164 and 328 ft of riparian sites. In both cases “D1”, “C2”, and “C1B” are the three most abundant habitat type groups.
- The VMap-SIMPPLLE translated species composition attribute was summarized for SIMPPLLE vegetation points within 164 and 328 ft from NWI wetland and riverine features.
    - ♦ Both sets of points have nearly identical distribution patterns, and suggests similar vegetation is mapped within 164 and 328 ft of riparian sites. In both cases “GF”, “GF-C-L”, “PP-DF”, and “LP” are the four most abundant species combinations.

The PVT, HT_GRP, and SPECIES attributes were combined and assessed. The combination of these attributes is referred to as the COMBO attribute. There are 291 unique combinations of PVT | HT_GRP | SPECIES labels. Of those, only 32 have a relative abundance greater than 1 percent. The riparian habitat query will use this hybrid data layer for analysis.

The query design for riparian species associated with shrubs and deciduous (hardwood) tree communities that are not maintained by flooding includes the following layers:

- Cell containing perennial water from NWI/NHD dataset.
- Habitat groups:
    - ♦ All that occur within the NWI/NHD layer
- Tree size class less than 5-inch DBH including:
    - ♦ 0–4.9-inch DBH
    - ♦ 5–9.9-inch DBH
    - ♦ 10–14.9-inch DBH
- Stands all canopy cover including:
    - ♦ 0–14.9 percent
    - ♦ 15–39.9 percent

- 40–69.9 percent
- 70–100 percent

The amount of acreage in seedling sapling-dominated riparian zones doubles during the five decades (Figure 56). Because the model limited mechanical treatments within riparian management zones, most of the disturbance is from wildfire or prescribed fires in the model. The change can be attributed to more wildfire on the landscape under all alternatives. Following wildfires, eco-burns, which are common to all alternatives at differing magnitudes, also likely provide habitat improvement since human-ignited fires are allowed to creep into riparian zones. It is anticipated that the riparian habitats trend towards the natural range of variation for disturbance within riparian areas. Disturbance in these habitats is anticipated to result in an increase in deciduous shrubs and hardwood tree species in many riparian areas and a reduction in conifer cover. The projected increase in early seral conditions in riparian habitats is expected to benefit riparian associated wildlife species that use hardwood or deciduous vegetation.

The outcomes of the alternatives are all relatively similar with differences of less than 5,000 acres in the fifth decade. The No Action Alternative has the lowest acres of disturbance while Alternative Y has the most. The Preferred Alternative is intermediate to these two alternatives.

While the amount of disturbance increases over time the total amount of disturbance remains modest compared to the amount of riparian habitat forestwide. For example, the amount of early seral conditions in riparian habitat increases from just over 10,000 acres to around 26,000 acres which represents about 8 percent of the riparian habitat forestwide. From that perspective, even though riparian habitat trends towards the desired condition, there will probably not be enough disturbance within riparian areas to restore hardwood and deciduous shrub communities to the level they were under natural disturbances. However, the modeling suggests that these disturbances would provide diversity in riparian habitat conditions and reduce conifer dominance to provide for a wide range of wildlife that use riparian habitats. Some of the future disturbances from wildfire within the riparian areas could potentially be uncharacteristically more intense than they were in the past because of a buildup of fuels and warmer drier conditions under climate change. Active management of these habitats would allow for more controlled disturbance intensity with fewer impacts than wildfire disturbance. Note that the vegetation desired condition is the same for all alternatives including the No Action Alternative, so the trend or response of the riparian habitats have a similar outcome. Also note that most of the disturbance in riparian areas is a result of natural disturbances like wildfire.

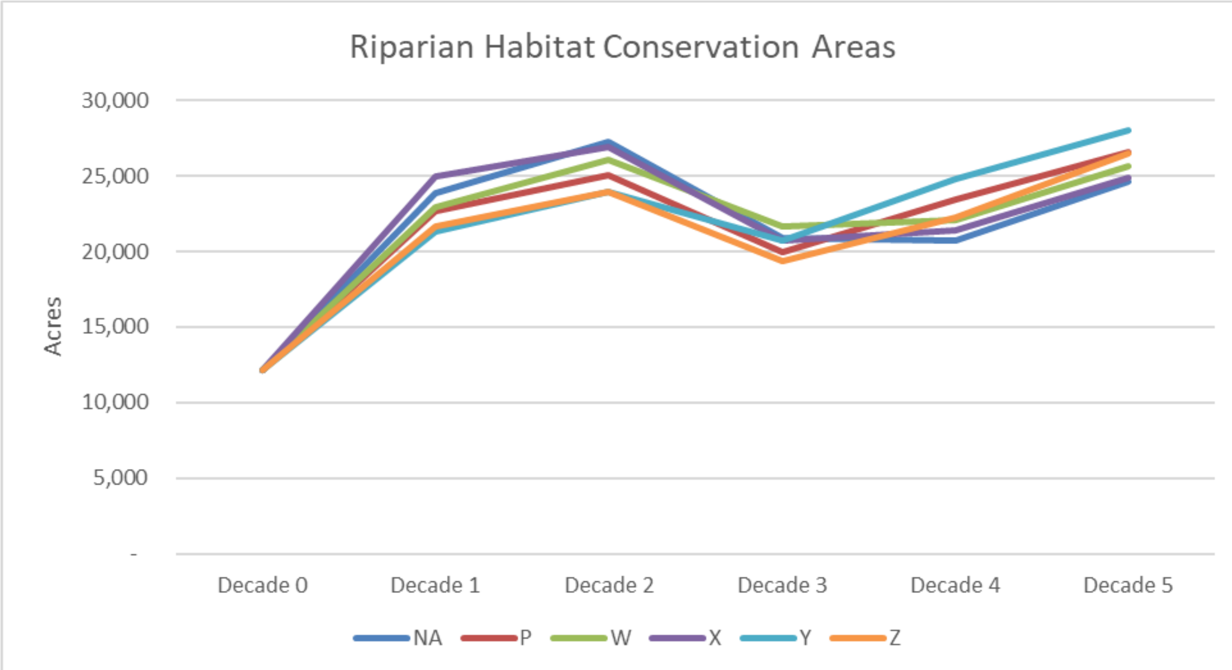

Figure 56. Trend in seedling and sapling stand conditions in riparian habitat conservation areas due to disturbance

Consequences to Open Water Habitats

Under the plan alternatives, the number and acres of open water habitats within recommended wilderness varies. Similarly, the amount of river miles that are considered for wild and scenic river suitability varies by alternative. The amount of designated wilderness or designated wild and scenic rivers does not change by alternative. Alternative W has the most open water habitats proposed within recommended wilderness, while Alternative X has the least.

Alternative Z has the most river habitats proposed as suitable wild and scenic rivers, while Alternative X has none. While most of the open water species were not selected as outstandingly remarkable values for wild and scenic rivers, many of these species would have their key ecological characteristics maintained if these rivers were found suitable. Designated wilderness and designated wild and scenic rivers currently protect many open water habitats in the plan area and do not change under the alternatives. Most smaller lakes and wetlands would be protected under any of the alternatives. While the plan components do not change under the alternatives, objectives to enhance or restore aquatic habitats do vary by alternative.

Plan Direction for the Protection and Enhancement of Aquatic, Riparian, and Wetland Habitats

Plan direction for the protection of aquatic and riparian wildlife habitats is robust and comprehensive. It can be found in the Aquatic Ecosystems section of the Land Management Plan. Aquatics plan components address threats or prevent or mitigate activities that could impact aquatic and riparian wildlife habitats. They contribute to the ecological integrity of river systems in the plan area because they mitigate or prevent activities that can adversely affect aquatic wildlife habitats. Under all action alternatives, plan components describing specific desired conditions for aquatic, wetland, and riparian habitats would improve the likelihood of maintaining their integrity, resiliency, and connectivity of river habitats. These apply forestwide and do not vary by alternatives. Plan components for water, conservation watersheds, riparian management zones, infrastructure, energy and minerals, livestock grazing, recreation, and forestlands will provide for aquatic habitats in the plan area. These components address threats in the plan area and greatly reduce the impacts from extractive uses that have adversely affected these habitats in the past.

Aquatics plan components contain measures to reduce or prevent sedimentation, decrease, or prevent many contaminants, and protect riparian areas that contribute to forage species. These plan components apply forestwide and do not vary by alternative. In addition, aquatics plan components restrict pesticide use in riparian areas, prevent fire retardants from entering waterways, implement measures to reduce contamination from dust abatement on roads, incorporate guidelines to prevent contaminants from mining, guide placement of sanitary facilities, and offer direction on human recreation sites. Not all threats to these habitats affect open water wildlife or affect them equally.

All action alternatives include direction to establish riparian management zones intended to protect the integrity and function of those areas. Impacts to riparian areas can have adverse effects on aquatic and riparian habitats and the species that use them.

Although vegetation management, livestock grazing, or other activities could occur within riparian habitats, these activities would be constrained by plan components designed to protect watershed integrity, riparian vegetation, and hydrologic function. Management direction for riparian management zones would contribute to connectivity for riparian species and protection of plant species and animal communities associated with rivers. Refer to the Aquatic Ecosystems section of the Final Environmental Impact Statement for a more detailed discussion of specific plan components. Livestock grazing is permitted only in a portion of the Nez Perce-Clearwater where there are active allotments. Active allotments are distributed mostly in Management Area 3. They occur on the Island along the western portion of the Nez Perce-Clearwater from the Clearwater River south to the Salmon River, on the Palouse district, in a few areas westward in the Nez Perce-Clearwater around Lolo Creek and the Musselshell area. These range allotments make up 612,766 acres in the plan area. Thus, impacts to grazing will only occur within these active allotments. Plan components that direct grazing in riparian areas will help lessen the impacts from grazing. See Appendix A for a distribution map of the active allotments on the Nez Perce-Clearwater.

Some riparian habitats suffer from forest succession. Plan components in the desired vegetation conditions include measures to restore forests back to their historic structure, function, composition, and connectivity under the natural range of variability. This will require restoring these systems back towards the conditions under natural fire regimes. There are limited allowable activities found in the plan to restore successional conditions, which may enhance deciduous vegetation important to many wildlife species. These actions will reduce uncharacteristic wildfire and address that threat to riparian habitats as well.

Aquatics plan components include objectives for riparian and river habitat restoration. These objectives vary by alternative and are based upon the duration that it would take to restore degraded riparian habitats in the plan area. These objectives range from restoring between 200 and 750 miles of river riparian habitats every five years, improving between 2,000 and 8,800 acres of soil restoration, stormproofing roads to prevent sedimentation, decommissioning roads, and monitoring miles of roads for their condition. Detailed descriptions of these alternatives, including the amounts and rate at which they will be achieved, can be found in the Aquatic Ecosystems and Fisheries plan components. These will serve to restore degraded conditions in riparian and river habitats and move them towards desired conditions. These objectives focus on restoring habitats in rivers and riparian areas.

There are currently no measures to reduce human disturbance to wildlife that use river habitats on the Nez Perce-Clearwater's popular large rivers. Some river species, including the Species of Conservation

Concern harlequin duck, are potentially sensitive to disturbance from recreation. Wild and scenic river plan components guide towards protection of the outstandingly remarkable values. A crosswalk of aquatic, wetland, water, and riparian habitats, including key habitat attributes with plan direction that protects or enhances these habitats, is included in Appendix C of the Final Environmental Impact Statement.

While the plan components do not change under the alternatives, objectives to enhance or restore aquatic habitats do vary by alternative. Aquatics plan components for infrastructure vary with respect to how many miles of roads would be maintained or restored. The alternatives also vary how much aquatic restoration would be conducted. Alternatives that have more of these activities would benefit aquatic wildlife more than those with less. These include objectives to improve conservation watersheds and improvements to soil and watershed conditions. These will serve to restore degraded conditions in riparian and river habitats and move them towards desired conditions. This direction towards restoration could have short-term consequences at the project scale but would benefit the ecological integrity of rivers long-term. Refer to Section 2.2.4 of the Land Management Plan for additional information.

Some aquatic habitats in Idaho have been affected by changes in aquatic vegetation due to aquatic invasive species. The State of Idaho currently identifies 16 aquatic plants as invasive species. If introduced, these aquatic invasive species generate ecological impacts that propagate along the food web. Invasive plants can substantially change the hydrology, sedimentation, clarity, and nutrient state of lakes, reducing the habitat available for other species positioned higher in the trophic web, such as invertebrates and fish (Gallardo et al. 2016). Based upon a meta-analysis of 151 publications, Gallardo (2016) found that invasive species cause a strong decrease in the overall diversity of aquatic communities and generally cause a decrease in the diversity and abundance of resident species.

Invasive plant species known to occur in riparian areas are shown in Table 157. Aquatic invasive plants can be capable of changing the environmental conditions of their surroundings through the production of detritus and sediment capture. Fierke and Kauffman (2006) studied the effects of invasive plants, in particular reed canary grass and Himalayan blackberry, on riparian habitats in Oregon. They found that invasive plant species are affecting plant composition, species richness, understory, and structural diversity of these riparian stands to the point that this influence may be greater than that of stand age. It also appears that presence and abundance of these invasive plant species are causing changes in successional patterns that may be irreversible at a riverscape level.

Table 157. Invasive plant species occurring within the plan's riparian areas

Scientific name	Common name
Iris pseudacorus	Yellow flag iris
Polygonum cuspidatum	Japanese knotweed
Phalaris arundinacea	reed canary grass
Polygonum sachalinense	Giant knotweed
Lepidium latifolium	Perennial pepperweed
Polygonum bohemicum	bohemian knotweed

These invasive species have the capability of forming dense homogenous cover, inhibiting germination, and establishment of native plant species, and possibly initiating an alternate successional pathway, which could replace historical pioneer trees species with late-successional tree species (Fierke and Kauffman 2006). These types of effects could trickle down to wildlife using riparian areas. Invasive plants often exploit disturbance to become established. Plan components reducing impacts to riparian habitat should result in less disturbances that could leave these habitats vulnerable to disturbances.

Aquatics plan components provide several desired conditions, standards, and guidelines that will provide for wildlife that use riparian habitats. Plan components for riparian management zones provide specific desired conditions to allow riparian habitats to function within their natural range of variability and to be protected by standards and guidelines that reduce threats to these systems. Aquatics plan components targeted at recreation would prevent or reduce threats from changes to water quality through pollution, disturbance, and degradation of riparian habitat. Approximately 67 percent of riparian areas are protected from many threats by designated wilderness and Idaho Roadless Rule area direction. See Sections 2.2 of the Land Management Plan for plan components that pertain to aquatics and riparian areas.

Aquatic, Wetland, Water and Riparian Habitats

Factors that vary by alternative include those for recommended wilderness, suitability of uses within recommended wilderness, suitable wild and scenic rivers, the recreation opportunity spectrum, fire and fuels treatments, access, acres of vegetation restoration, acres of timber harvest, and the maximum size of regeneration harvest units.

This analysis assumes that the river habitat in Management Areas 1 and 2 will function in their natural range of variability while those in Management Area 3 will operate in a degraded state that should improve over time under the aquatics plan components. Management area direction has the most widespread influence on the conservation of aquatic habitats because they dictate how broad areas of the Nez Perce-Clearwater are used and which activities would be allowed. Many of the factors that can adversely affect aquatic habitats are influenced by management area restrictions or allowances. Many activities and threats that have impacted rivers are not allowed, are restricted, or are allowed only under specific conditions or circumstances within Management Areas 1 and 2. Thus, about 66.6 percent of the river habitats are relatively well protected from many threats. Specifically, activities such as road building and timber production would be restricted, controlled, or disallowed in Management Areas 1 and 2. Management Area 1 prohibits new mining claims and limits current mineral extraction. After land allocations, plan direction for aquatic and riparian habitat provide direction to govern the management of a variety of activities to ensure that aquatic and riparian habitat continue to provide the structure, function, composition, and connectivity to provide for ecosystem integrity. They essentially provide a buffer of protection around aquatic resources, and address and guide many activities such that they protect these habitats.

Fire suppression activities are reduced in Management Area 1, which should prevent an uncharacteristic buildup of fuels and reduce uncharacteristic wildfires. In the past, management area direction in Management Area 3 has reduced the effects to aquatic wildlife habitats through PACFISH and INFISH measures. An analysis of PIBO monitoring suggests these measures are largely effective or are trending in a positive direction (Saunders et al. 2019b). Most of the plan area, and the amount of aquatic wildlife habitat, falls within Management Areas 1 and 2 and is protected from many threats. Essentially, under all alternatives, approximately 66.6 percent of the rivers in the plan area fall within Management Areas 1 and 2 and approximately 31 percent of the rivers fall within Management Area 3. Therefore, the majority of river habitat will be protected by Management Area 1 and 2 direction and the aquatics plan components. Aquatics plan components should help maintain or restore river habitats in Management Area 3 over time.

The amount and distribution of recommended wilderness areas varies by alternative. Recommended wilderness is managed to prevent degradation of wilderness character. Management for recommended wilderness is very similar to management for designated wilderness. Many threats to rivers from management activities are not allowed in recommended wilderness. From a wildlife perspective, there are virtually no differences in effects to river habitats when comparing recommended wilderness to designated wilderness. Plan components for recommended wilderness vary by alternative. Differences in plan components by alternative have virtually no differences in the effects on aquatic wildlife habitats because recommended wilderness management is very similar to Idaho Roadless Rule management. All recommended wilderness areas are derived from Idaho Roadless Rule areas. Alternative W has the most river miles by alternative and about 21.5 percent of all rivers in the plan area would fall within recommended wilderness under this alternative. About 7 percent of river miles would fall within recommended wilderness in Alternative Y and about 11.4 percent of rivers would fall within recommended wilderness under Alternative Z. No miles of river would fall within recommended wilderness under Alternative X. The Preferred Alternative is most similar to Alternative Y but has modified boundaries for the Mallard Larkin, Hoodoo, and Meadow Creek areas.

Similar proportions of other aquatic habitats are protected by these alternatives. Alternative W has the most open water habitats proposed under recommended wilderness, while Alternative X has the least. Most smaller lakes and wetlands would be protected under any of the alternatives.

The amount of Idaho Roadless Rule area does not change by alternative. Management in recommended wilderness would most resemble management under the wildland recreation theme under the Idaho Roadless Rule. The Idaho Roadless Rule restricts building new roads, prohibits timber production, and limits timber harvest to only be conducted under certain circumstances. The purposes for which vegetation management may be implemented varies by roadless rule theme, with backcountry restoration being the most permissive and backcountry recreation the most restrictive. In backcountry restoration areas, vegetation may be managed in the wildland urban interface for restoring structure, function, composition, and connectivity of forest vegetation. Vegetation management would be allowed only as far as it is allowed under the Idaho Roadless Rule. The roadless rule allows motorized trails to be constructed, whereas recommended wilderness does not. Mining and new mineral leases are restricted in both areas. In terms of impacts to aquatic wildlife habitats, these differences are minor or negligible. Perhaps the biggest difference for rivers is that motorized trails are allowed within Idaho Roadless Rule areas, which may impact river habitats at crossings and may result in some degradation of riparian and river habitats and increased sedimentation.

Some activities that can have minor consequences to aquatic wildlife habitats are generally allowed within recommended wilderness and Idaho Roadless Rule areas. Grazing, hiking trails, dispersed recreation, dams, and planned ignitions are activities allowed within wilderness, generally with restrictions. Some environmental factors can occur within wilderness areas. For example, climate change, the spread of invasive or non-native plant or animal species, natural landslides, wildfires, drought, habitat shifting, extreme temperatures, insect infestations, disease, and atmospheric depositions can all occur and are generally beyond Forest Service control. Management towards forestwide desired conditions address many of these threats. For example, aquatic plan components require stubble heights for vegetation that helps lessen the effects that livestock have on riparian areas. Desired conditions for vegetation would direct management towards a more resilient condition to address some factors like climate change.

Management Direction in Designated Wild and Scenic Rivers

The amount of designated wild and scenic rivers does not change by alternative. Designated wilderness and designated wild and scenic rivers currently protect many open water habitats in the plan area, and do not change under the alternatives.

Wild and Scenic River Eligibility and Suitability

The amount of river miles and acres that are considered for either wild and scenic river suitability or eligibility varies by alternative (Table 158 and Table 159). The tables below show the miles of rivers and acres of river corridor of eligible and suitable wild and scenic rivers.

Table 158. Miles of rivers eligible or suitable for inclusion into the Wild and Scenic River system by alternative

	Recreational Miles	Scenic Miles	Wild Miles	Total
No Action Eligible	241	32	329	602
No Action Suitable	0	0	0	0
Preferred Alternative Suitable	15	89	106	210
Preferred Alternative Eligible	23	4	0	27
Alternative W Suitable	37	81	115	233
Alternative W Eligible	0	0	0	0
Alternative Y Suitable	143	80	123	346
Alternative Y Eligible	0	0	0	0
Alternative Z Suitable	61	107	356	524
Alternative Z Eligible	0	0	0	0

Table 159. Acres within eligible or suitable river corridors by alternative

	Eligible Acres	Suitable Acres	Total
No Action Alternative	155,477	0	155,477
Preferred Alternative	3,899	61,849	65,748
Alternative W	0	64,587	64,587
Alternative Y	0	99,120	99,120
Alternative Z	0	145,984	145,984
Alternative X	0	0	0

Wildlife outstandingly remarkable values were identified following direction in the Final Directives and the process for identifying rivers that had wildlife outstandingly remarkable values can be found in Appendix F. They are summarized in Table 159. These rivers were selected as having outstandingly remarkable values for wildlife if they had populations of river dependent wildlife that are either rare, unique, or regionally or nationally significant or they are Species of Conservation Concern (SCC) or federally listed species. Only a few wildlife species were found to fit both criteria, and rivers were identified as eligible if they had observations of these species. These river segments were selected because they provide habitat for populations of river dependent wildlife species that are unique or rare or regionally or nationally significant. Species identified include the harlequin duck, which is an SCC, and several rare or endemic river dependent snails. Plan direction for wild and scenic rivers will protect many other river dependent wildlife and species not identified as outstandingly remarkable values that use riparian areas. Several rivers identified as eligible for wild and scenic river consideration include outstandingly remarkable values for wildlife. While most of the aquatic wildlife species were not selected as outstandingly remarkable values for wild and scenic river eligibility, many of these species would have their key ecological characteristics maintained if these rivers were found suitable.

Table 160. Species included as outstanding remarkable values for wild and scenic suitability

Species Found Eligible	Alternative W	Alternative X	Alternative Y	Alternative Z	Preferred Alternative
Ashy Pebblesnail (*Fluminicola fucus*)	Yes	No	Yes	Yes	Yes
Boulder Pile Mountainsnail (*Oreohelix jugalis*)	Yes	No	Yes	Yes	Yes
Harlequin Duck (*Histrionicus histrionicus*)	Yes	No	Yes	Yes	Yes
Marbled Disc (*Discus marmorensis*)	No	No	No	No	No
Nez Perce Pebblesnail (*Fluminicola gustafsoni*)	No	No	No	No	No
Rotund Physa (*Physella columbiana*)	Yes	No	Yes	Yes	Yes
Selway Forestsnail (*Allogona lombardii*)	Yes	No	Yes	Yes	Yes
Short-Faced Lanx (*Fisherola nuttallii*)	Yes	No	Yes	Yes	Yes

Plan direction for suitable wild and scenic rivers requires protection or enhancement of the outstandingly remarkable values of suitable rivers, which include outstandingly remarkable values for wildlife. Desired conditions for suitable rivers would direct management to prevent changes in free flow characteristics, degradation of water quality, and development and protect outstandingly remarkable values. Outstandingly remarkable values for many rivers in the plan area include those for fish and wildlife. Suitable rivers are a subset of rivers eligible. Generally, rivers and their outstandingly remarkable values would be more protected if they are managed as suitable or eligible as wild and scenic rivers in the plan. The No Action Alternative only had eligible rivers and not suitable rivers. Some eligible rivers would not be identified as suitable in the Preferred Alternative. In these cases, management would no longer need to follow wild and scenic interim direction of eligible rivers for the protection of outstandingly remarkable values. However, all rivers are protected by aquatic ecosystem plan components.

Wild and scenic rivers are designated as either wild or scenic. Whether a suitable river is recreational, scenic, or wild is determined by criteria under the Directives. Direction under these different classes vary in how they provide ecological conditions because they vary in direction on which activities or infrastructure they allow. Wild rivers are the most restrictive and recreational rivers are the least restrictive. Land Management Plan standards for wild rivers do not allow new road construction and govern the way trails are built to protect remarkable values. Plan guidelines for scenic and recreational rivers allow roads and trails so long as free flowing characteristics and remarkable values are protected. Land Management Plan guidelines protect wild rivers from vegetation management and developed recreation. Scenic river vegetation management can protect or enhance the outstandingly remarkable values and free flow characteristics. Land Management Plan guidelines also restrict recreational development and guide livestock grazing to protect outstandingly remarkable values. Land Management Plan guidelines require mining on suitable wild scenic rivers and recreational rivers be conducted in a manner so as not to impact free flowing characteristics, water quality, and outstandingly remarkable values. Furthermore, the Wild and Scenic Rivers Act restricts the building of dams and changes to free flow characteristics. Any eligible wildlife and scenic rivers identified as suitable would not allow dam building, diversions, and development of hydropower facilities. These protections apply to the river itself and the river corridor within a quarter mile of the river. While plan direction for wild rivers provides better protection than scenic or recreational rivers, all types of wild and scenic river designations greatly protect the wildlife that use rivers. See the suitability table in the Eligible and Suitable Wild and Scenic Rivers section of the Land Management Plan for information on actions that are suitable within various suitable wild and scenic river types.

Under the action alternatives, Alternative Z provides the most total miles of suitable rivers, with 160 more miles protected. Alternative Z also provides the most protection for suitable wild rivers, providing 265 more miles. Alternative Z proposes 38 more miles as wild compared to the No Action Alternative. Wild rivers, because of their unaltered characteristics, probably provide the highest amount of ecological integrity to river habitats out of the eligible rivers when compared to recreational and scenic. Alternative X selects no rivers as suitable wild and scenic rivers. The Preferred Alternative identified Cayuse Creek, Fish Creek, Hungery Creek, Weitas Creek, Kelly Creek, North Fork Kelly Creek, Middle Fork Kelly Creek, South Fork Kelly Creek, Colt Killed Creek, and Meadow Creek. The Preferred Alternative maintains two rivers as eligible for wild and scenic river designation and includes the Little North Fork and the Salmon River. A detailed analysis of the effects to all outstandingly remarkable values is provided in Appendix F.

Under the No Action Alternative, all rivers that had outstandingly remarkable values would be managed as eligible, and management would protect the outstandingly remarkable values. There were many rivers found eligible because they had a variety of outstandingly remarkable values. Management to maintain or improve outstandingly remarkable values on eligible rivers, even when they were found eligible based on non-wildlife outstandingly remarkable values, would help ensure that rivers continue to provide ecological conditions to provide for river and riparian wildlife. For example, rivers eligible for fisheries, scenery, recreation, cultural resources, and water quality would also provide ecological conditions for many wildlife species. Thus, the most river miles that would receive management to protect or enhance outstandingly remarkable values would be under the No Action Alternative.

The amount of river miles proposed as suitable by alternative differs for each wildlife outstandingly remarkable value. Alternative Y protects the most miles of rivers that had wildlife outstandingly remarkable values, which would protect 41.8 more miles than Alternative Z, the next lower alternative. Alternative Z would protect 59 more miles of river with wildlife outstandingly remarkable values than Alternative W.

No rivers that contain populations of the marbled disc and the Nez Perce pebblesnail were found suitable in any alternative. Populations of marbled disc are only known from Slate Creek in the plan area. The global distribution of this species is less than about 40 square miles, which includes Slate Creek and Johns Creek. The Nez Perce pebblesnail is a newly described species of aquatic snail that has been found in only a few reaches so far. It has only been reported to occur within the Clearwater River, Salmon River, and South Fork Clearwater but may have wider distribution as more areas are surveyed. While wild and scenic suitability would enhance protections for aquatic wildlife, forestwide plan components for protection of rivers would continue to provide for wildlife that use rivers.

Land Suitability

Decisions on suitability can have consequences for river habitats. Suitability is determined for the summer and winter recreation opportunity spectrum (ROS), timber suitability, grazing, and other uses. Suitability sets the conditions where these activities could occur. Determinations for suitability vary by alternative. Those that vary by alternative directly are the summer and winter ROS and activities that would be found suitable under the plan alternatives in various management area types. For example, suitability of uses varies by alternative within recommended wilderness. Consequences for such decisions vary depending upon the resource and type of use.

Timber suitability does not vary by alternative. There are three types of timber suitability: suitable for timber production, suitable for timber harvest for resource reason other than timber production, and areas not suitable for timber harvest nor timber production. Forestwide, river and riparian habitats are not suitable for timber production. This is particularly important in Management Area 3 where timber production is generally allowed. Timber harvest within riparian habitats is restricted unless it is needed to restore riparian habitats by aquatics plan components. Similarly, landslide prone areas are not suitable for timber production. Timber production in landslide prone areas can leave them susceptible to landslides, which affect river integrity.

The alternatives vary where motorized uses are suitable via ROS settings. Suitability of motorized uses could have impacts on aquatic wildlife habitats. Suitability of motorized uses is determined by the summer and winter ROS. The most impactful is summer motorized uses. Suitability does not make travel management decisions; instead, it identifies areas that are suitable for those uses in the future where travel management decisions could be made. There are three motorized settings and two non-motorized settings. Table 161 shows the acres of riparian habitats suitable for summer motorized uses by alternative. Maps of the alternatives for the summer ROS can be found in Appendix A. Increased amounts of riparian areas suitable for motorized uses could potentially lead to increased impacts to aquatic wildlife habitats in the future. These actions would undergo site specific analysis of the effects prior to authorizing any new travel management decisions. New motorized developments would be prevented altogether in areas not suitable for motorized uses. Therefore, alternatives with less motorized suitability would protect aquatic habitats better than those with more motorized suitability. Effects of motorized routes and route maintenance on aquatic and riparian habitats include changes in sediment delivery, delivery of contaminants, stream bank stabilization measures such rip rap, pesticide use, and some culverts can block aquatic connectivity. However, even where motorized uses are suitable, aquatic ecosystem plan components would be effective in reducing or minimizing consequences of motorized suitability. Specifically, FW-DC-WTR-06, FW-DC-WTR-02, FW-DC-WTR-05, FW-STD-WTR-04, FW-STD-WTR-06, FW-STD-RMZ-02, FW-STD-RMZ-03, FW-GDL-RMZ-02, FW-DC-CWN-03, FW-OBJ-CWN-01, FW-OBJ-CWN-02, FW-STD-CWN-01, FW-DC-ARINF-01, FW-STD-ARINF-01, FW-STD-ARINF-02, FW- STD-ARINF-03, FW-STD-ARINF-04, FW-STD-ARINF-05, FW-STD-ARINF-06, FW-STD-ARINF-07, FW-GDL-ARINF-01, FW-GDL-ARINF-02, FW-GDL-ARINF-03, FW-GDL-ARINF-04, FW-GDL-ARINF-05, FW-GDL-ARINF-06, FW-GDL-ARINF-07, FW-GDL-ARINF-08, FW-GDL-ARINF-09, FW-GDL-ARINF-10, and FW-GDL-ARINF-11. Each of these plan components addresses one or more of the threats or consequences of motorized uses and motorized suitability.

Table 161. Acres and percent of riparian, wetland, and aquatic wildlife habitats with summer recreation opportunity spectrum (ROS) by alternative

Recreation Opportunity Spectrum Settings	Primitive	%	Simi-Primitive Non-Motorized	%	Semi-Primitive Motorized	%	Roaded Natural	%	Rural	%
No Action Alternative	105,555	19.3	191,605	34.9	120,468	22.0	129,236	23.6	1,421	0.3
Alternative W	142,720	26.0	141,195	25.8	125,877	23.0	117,889	21.5	20,603	3.8
Alternative X	142,720	26.0	73,882	13.5	180,540	32.9	130,539	23.8	20,603	3.8
Alternative Y	144,741	26.4	153,101	27.9	104,108	19.0	125,731	22.9	20,603	3.8
Alternative Z	144,741	26.4	161,747	29.5	98,326	17.9	122,866	22.4	20,603	3.8
Preferred Alternative	139,361	25.4	93,840	17.1	137,219	25.0	161,066	29.4	16,799	3.1

Table 162 shows the amount of aquatic and riparian areas that would be motorized or non-motorized by alternative. The Preferred Alternative has more motorized uses than all action alternatives except Alternative X. Plan direction in the Aquatic Ecosystem's Infrastructure (aquatics and riparian) section in the Land Management Plan would help prevent impacts from new authorized travel decisions in the future.

Table 162. Acres of aquatic, riparian, or wetland habitat within motorized and non-motorized settings by alternative

	No Action Alternative	Alternative W	Alternative X	Alternative Y	Alternative Z	Preferred Alternative
Motorized Settings	251,125	264,369	331,682	250,442	241,796	315,083
Non-Motorized Settings	297,159	283,915	216,602	297,842	306,488	233,201

Activities vary by alternative within recommended wilderness areas. See the Recommended Wilderness section of the Land Management Plan for details. None of the activities that vary would have much effect on aquatic and riparian habitats. Livestock grazing is allowed and could have some impacts to aquatic wildlife habitat, but plan direction reduces these impacts. Timber harvest and mining activities are suitable within recommended wilderness only as allowed in the Idaho Roadless Rule.

Management Area Direction

Management area direction and aquatics plan components provide for the protection of open water habitats in the plan area. Threats that affect water clarity and sedimentation are restricted by management within wilderness or Idaho Roadless Rule areas. The largest percent of lakes and open water occurs in wilderness, followed by Idaho Roadless Rule areas. Like the effects in many sections of the document, this analysis finds that lakes and open waters are more protected under designated wilderness, recommended wilderness, and Idaho Roadless Rule areas than those in the general forest areas. Most smaller lakes and wetlands would be protected under any of the alternatives because most of them fall within protected lands. The threat of human waste is not addressed in the plan and these effects could still be caused in wilderness areas.

Exotic trout were planted in the past by the Idaho Department of Fish and Game. Species strains, such as brook trout (*Salvelinus fontinalis*) and non-native rainbow trout (*Oncorhynchus mykiss*), continue to occupy these habitats and may affect some native species. Stocking of non-native fish is no longer conducted by the Idaho Department of Fish and Game. Other exotic species that may be inadvertently introduced include species such as zebra mussels (*Dreissena polymorpha*) but have a low probability in lakes since this species is spread by motorboats and most of the lakes are remote without road access.

Effects to Aquatic, Riparian, and Wetland Habitats from Other Resources

Research Natural Areas

Plan components for research natural areas provide direction to manage these areas to provide ecological sustainability and are managed through natural processes. Despite their small scope, they provide protection for rivers because of this direction. Plan component direction for research natural areas include maintaining a representation of natural systems as a baseline for research, monitoring, and education by the agency. These areas are small relative to the plan area. This direction would have no consequences or beneficial consequences to aquatic habitats for wildlife.

Carbon Storage and Sequestration

There would be no effects from plan direction related to carbon storage.

Cultural or Heritage

Plan components and alternatives for cultural and heritage would either not affect or provide, maintain, or improve ecological conditions for aquatic wildlife resources.

Designated Wild and Scenic River Management

Effects from direction under wild and scenic management maintain and enhance the outstandingly remarkable values of rivers. Usually, management of wild and scenic rivers provides beneficial outcomes for wildlife. The primary exception is that wild and scenic designation often draws attention and increased recreation to these resources, which can have some effects on some wildlife species. Of note would be the effects of recreation disturbance on harlequin ducks that could displace them from preferred areas.

Eligible Wild and Scenic River Management

Effects from direction under eligible and suitable wild and scenic rivers is to maintain and enhance the outstandingly remarkable values of rivers until they are designated. Usually, management of wild and scenic rivers provides beneficial outcomes for wildlife. Wild and scenic rivers would provide few or no benefits to other aquatic habitats except when they fall within a river corridor.

Minerals

Plan direction for minerals is composed of desired conditions that generally state that minerals and energy development are available. Mineral exploration and extraction have adversely affected aquatic habitats in the past. Aquatics plan direction for minerals would help reduce or minimize impacts allowable under the law from mineral exploration, extraction, and energy development. See Section 2.2.5 of the Land Management Plan for plan components that pertain to aquatics and riparian areas.

The Forest Service cannot recommend, authorize, or consent to road construction, road reconstruction, or surface occupancy associated with mineral leases in Idaho Roadless Areas designated as Wild Land Recreation, Special Areas of Historic or Tribal Significance, or Primitive themes. For mineral leases, contracts, permits, and other associated activities authorized after the effective date of the Idaho Roadless Rule, the Forest Service will not recommend, authorize, or consent to road construction or road reconstruction associated with mineral leases in Idaho Roadless Areas designated as Backcountry/Restoration. Surface use or occupancy without road construction or reconstruction is permissible for all mineral leasing unless prohibited in the applicable land management plan.

After October 16, 2008, the Forest Service was able to authorize the use or sale of common variety mineral materials and associated road construction or reconstruction to access these mineral materials in Idaho Roadless Rule areas designated as Backcountry/Restoration only if the use of these mineral materials was incidental to an activity otherwise permissible in Backcountry/Restoration. Collectively these restrictions would help minimize the environmental consequences of mining, mineral extraction, and energy extraction in some areas.

The Aquatics Ecosystem and Fisheries section contains plan direction for Aquatic and Riparian Energy and Minerals that will help minimize the impact to aquatic wildlife habitats from mining and energy activities. However, these activities are allowable by law without much discretion by the Forest Service and may still have some impacts.

At-Risk Plants

Management direction for at-risk plants would have no consequences to aquatic habitats nor would it have beneficial consequences to these resources because they would not adversely impact these habitats or would prevent some activities that could have consequences from occurring where present.

Recommended Wilderness

Direction in the Recommended Wilderness section of the Land Management Plan would have beneficial consequences for aquatic and riparian wildlife habitats. This direction would prevent or restrict many known threats to these habitats from occurring. This direction would apply to those habitats already located within Idaho Roadless Rule areas and would be similar or slightly more protective of these resources than Idaho Roadless Rule direction.

Roadless Areas

Idaho Roadless Rule areas guide management on large areas of the Nez Perce-Clearwater, including many aquatic habitats. Direction under the Roadless Rule would restrict or prevent many of the threats to aquatic resources. Restoring the natural ecological process, natural disturbances, and wildland fire are the primary forces affecting the composition, structure, and pattern of vegetation. These activities have fewer consequences for aquatic resources than activities like timber harvest. Road construction or reconstruction is limited to specific circumstances allowed under the Idaho Roadless Rule. These restrictions would largely prevent or have beneficial consequences for aquatic habitats.

Timber cutting is prohibited in wildland recreation and is restricted in special areas of historic or tribal significance as follows:

- To improve threatened, endangered, proposed, or sensitive species habitat;
- To maintain or restore the characteristics of ecosystem composition, structure, and processes;
- To reduce the risk of uncharacteristic wildland fire effects to an at-risk community or municipal water supply system;
- For personal or administrative use, as provided for in 36 CFR part 223; or
- Where such cutting, sale, or removal is incidental to the implementation of a management activity not otherwise prohibited by this subpart.

The cutting, sale, or removal of timber is permissible in Idaho Roadless Areas designated as Backcountry/Restoration only:

- To reduce hazardous fuel conditions within the community protection zone if, in the responsible official’s judgment, the project generally retains large trees as appropriate for the Nez Perce-

Clearwater type and is consistent with land management plan components as provided for in §294. 28(d).

- To reduce hazardous fuel conditions outside the community protection zone where there is significant risk that a wildland fire disturbance event could adversely affect an at-risk community or municipal water supply system. A significant risk exists where the history of fire occurrence and fire hazard and risk indicate a serious likelihood that a wildland fire disturbance event would present a high risk of threat to an at-risk community or municipal water supply system.
- To improve threatened, endangered, proposed, or sensitive species habitat.
- To maintain or restore the characteristics of ecosystem composition, structure, and processes.
- To reduce the risk of uncharacteristic wildland fire effects.
- For personal or administrative use, as provided for in 36 CFR part 223: Where incidental to the implementation of a management activity not otherwise prohibited by this subpart; or…in a portion of an Idaho Roadless Area designated as Backcountry/Restoration that has been substantially altered due to the construction of a forest road and subsequent timber cutting. Both the road construction and subsequent timber cutting must have occurred prior to October 16, 2008.

Any action authorized pursuant to paragraphs §294. 24(c)(1)(ii) through (v) shall be approved by the regional forester and limited to situations that, in the regional forester's judgment, (i) Maintains or improves one or more of the roadless characteristics over the long-term; (ii) Maximizes the retention of large trees as appropriate for the forest type to the extent the trees promote fire-resilient stands; and (iii) Is consistent with land management plan components as provided for in §294.28(d). The activities in paragraph §294.24(c)(1) may use any forest roads or temporary roads, including those authorized under §294.23(b)(2 and 3) until decommissioned.

The Idaho Roadless Rule restricts mining activities as described in the mineral's evaluation of this document. These restrictions, as stated above, provide protection from these activities to many aquatic wildlife habitats in Idaho Roadless Rule areas. This includes effects from erosion, sedimentation, and stream channel alterations from roads.

Scenery

Scenery management would have no consequences or would have beneficial consequences on aquatic and riparian wildlife habitats.

Range management

The No Action Alternative would continue management of the grazing program under direction in the 1987 Forest Plans, as amended by PACFISH and INFISH. Current direction in PACFISH specific to grazing includes four standards and guidelines, three of which are relevant to the Nez Perce-Clearwater. They require modification of grazing practices that retard or prevent attainment of riparian management objectives or are likely to adversely affect listed anadromous fish. They also require that new livestock handling facilities be located outside of riparian habitat conservation areas and that livestock trailing, bedding, watering, salting, loading, and other handling efforts be limited to areas and times where they will not retard or prevent attainment of riparian management objectives. See Sections 2.2.6 and 5.3 of the Land Management Plan for plan components.

When assessed at broad scales, PIBO data has suggested that similar measures found in PACFISH have maintained conditions within rivers, which has shown that stream bank stabilization has not declined since PACFISH was implemented.

The action alternatives do not vary in terms of the level of grazing activity in each alternative or the aquatic components that address their potential effects. The outcome of grazing, as proposed in these alternatives, is expected to be the same or similar as the No Action Alternative with better clarified direction to address any site-specific adverse effects to riparian condition or where grazing is preventing attainment of aquatic desired conditions. Plan direction in the livestock grazing and the aquatic and riparian livestock grazing sections of the Land Management Plan would provide adequate measure to reduce impacts from grazing to acceptable levels.

Soils

Plan direction for soil management would have few consequences or would have beneficial consequences on aquatic and riparian wildlife habitats. Objectives for restoration of soils may have some short-term consequences for soil erosion in limited circumstances.

Sustainable Recreation

Dispersed recreation can have effects on aquatic habitat if sites are located close to aquatic resources. Many dispersed and developed recreation sites are located within riparian areas and are adjacent to streams. Effects could include trampling riparian vegetation, compaction of soils, pollution from litter, waste and spilled contaminants, and human waste. These impacts are localized to specific areas where dispersed recreation has been ongoing. Plan direction in the sustainable recreation and aquatic and riparian recreation sections of the Land Management Plan is adequate to provide protection for aquatic wildlife habitats.

Recreation can also displace wildlife through disturbance. Correlative evidence suggests that disturbance from recreation has reduced reproductive success of harlequin ducks (Wiggins 2005). Wiggins (2005) suggested that harlequin ducks are likely to abandon sites that receive heavy human disturbance based upon a variety of anecdotal observations of harlequin ducks being affected by disturbances. The plan has no specific plan component for disturbances to harlequin ducks.

Recreation and Access Management

The 2012 Planning Rule requires plans to develop components for multiple uses for sustainable recreation, including recreation settings, opportunities, and access. The Land Management Plan will set the summer and winter recreation opportunity spectrum (ROS) for both the Nez Perce and Clearwater National Forests. The ROS was developed following guidance from the Final Directives for the 2012 Planning Rule (FSH 1902. 12_20, section 23. 23a). While the ROS will not make decisions about recreation development levels, it will provide the framework under which recreational opportunities, such as winter and summer motorized recreation activities, could be allowed during future travel or recreation planning. The ROS categorizes recreational settings into six distinct classes as the recreational settings. Each setting provides opportunities to engage in activities, such as motorized, non-motorized, developed, or dispersed, on land, water, and in the air. The ROS sets where activities, such as over the snow motor vehicle use and motorized recreation, are allowed and include urban, rural, roaded natural, and semi-primitive motorized settings.

Under the 1987 Plans, the recreation opportunity spectrum allows winter motorized travel in all settings except wilderness and recommended wilderness. Motorized summer recreation is generally not allowed in the primitive and semi-primitive non-motorized settings. Summer ROS settings have the most potential for consequences to aquatic and riparian wildlife habitats because motorized travel can cause sedimentation, spread invasive species seeds, and impact river and stream turbidity and morphology in limited areas. Stream crossings result in localized changes to riparian areas at the crossing structure itself, as well as the approaches. Winter ROS settings probably have little to no consequences for aquatic and riparian wildlife habitats. Winter motorized recreation does not typically cause any of the threats identified above to these habitats.

The most widespread alteration of riparian conditions, as well as stream process and function, across the Nez Perce-Clearwater includes road development, particularly construction of streamside roads and roads with multiple stream crossings (Ecovista 2003). Road development has been correlated to instream conditions, including substrate composition, low numbers of large wood in the stream channel, and number and quality of pools on both the Clearwater and Nez Perce National Forests (Huntington 1995). System roads cover an estimated 2,400 acres, or 600 road miles, within riparian management zones on the Nez Perce National Forest and an estimated 4,000 acres, or 1,000 road miles, within riparian management zones on the Clearwater National Forest. Recovery potential is limited if the road prism continues to exist on the landscape, although site specific improvements can be made to reduce effects, particularly those associated with streamside roads and stream crossings.

Infrastructure components described in the aquatics plan components provide additional clarification and specificity when compared to those in PACFISH and INFISH. All standards and guidelines are intended to direct achievement of this desired condition. They are similar or the same as some standards in PACFISH and INFISH but contain additional clarification and specificity for many road activities. As for the No Action Alternative, motorized travel on roads and trails would continue consistent with current travel plan direction. See Section 2.2.4 of the Land Management Plan for plan components.

Further, while PACFISH and INFISH and their biological opinions referred to "Key" and "Priority" watersheds and contained direction specific to them, the aquatics plan components further expanded this concept by establishing the Conservation Watershed Network and included components to address potential effects, particularly from roads and infrastructure. The Conservation Watershed Network on the Nez Perce-Clearwater is extensive and includes many subwatersheds within designated wilderness and roadless areas, as well as a large percent of Management Area 3. See Section 2.2 of the Land Management Plan for plan components that pertain to aquatics and riparian areas.

When comparing alternatives, it is important to note that, as the level of anticipated timber harvest varies among the action alternatives when compared to the No Action Alternative and each other, the transportation system needed to access and support these changes may increase similarly, depending on the specific project and its location. It is expected that the aquatic components, particularly those in the Conservation Watershed Network, will influence the type and management of any additional infrastructure needed for access and that they will reduce or minimize effects to riparian and aquatic wildlife habitats. Thus, the conclusion that the action alternatives will result in outcomes to riparian resources that are indistinguishable from the No Action Alternative is based on this assumption.

Timber and Silviculture Management

Timber management will occur most intensively within the general forest areas of the Nez Perce-Clearwater, typically referred to as Management Area 3. While timber management is technically allowed in Idaho Roadless Rule areas, it is identified as low suitability and only allowed under limited circumstances. Aquatics plan direction would largely provide ecological conditions for aquatic and riparian wildlife habitats. Components intended to address potential effects from harvest activities in riparian management zones are included, particularly increases in sediment delivery from soil disturbance. See Sections 2.2 of the Land Management Plan for plan components that pertain to aquatics and riparian areas.

Aquatics plan component measures would help reduce or eliminate most or all of the primary impacts to aquatic and riparian wildlife habitats, though there would likely still be some impacts from these activities in the short term. Some of the impacts could be intensified based upon how quickly objectives in forested habitats are accomplished. The rate at which desired conditions for forest restoration are achieved vary by alternative. In Alternative Z, desired conditions are achieved at the slowest rate. Forest desired conditions are restored at the fastest rate under Alternative X. Objectives also vary under the alternatives by management area and potential vegetation type group. See the Forestlands plan components for the proposed acres under the alternatives. Naturally, alternatives with the highest objectives could see the most widespread impacts from these objectives in aquatic habitats. The Preferred Alternative seeks to use timber harvest and prescribed burning such that attainment of desired conditions in Management Area 2 and Management Area 3 are designed to take between 35 and 40 years to achieve desired vegetation conditions and is less than Alternative X but more than alternatives Z, Y, and W. Alternatives with quicker pace to meeting desired conditions results in earlier seral habitat more quickly.

Watershed

A suite of plan components directed at the management of watersheds would provide the ecological conditions beneficial to aquatic wildlife and their habitats. They are extensive and protective of all aquatic habitats. These plan components would direct management towards the conservation of aquatic and riparian wildlife habitats.

Tribal Trust

Plan components guiding tribal trust have no adverse consequences or beneficial consequences to aquatic and riparian wildlife habitats.

Wildlife

Plan components directed towards at-risk species would have no adverse consequences for aquatic and riparian wildlife habitat. These plan components do not vary by alternative. Management for elk would direct the location of some of the treatments from vegetation and timber management towards areas predicted to have higher nutrition for elk. These vary by alternative because the amounts of treatments for vegetation vary by alternative. These activities could be achieved through vegetation management or prescribed fire and could have some adverse consequences on aquatic and riparian resources. The consequences are not different than those under timber and silvicultural management, as described above, when timber management is used as a tool to complete these objectives. Plan direction for elk would require travel management decisions to provide, in some cases, guidance to strategically reduce open roads at broad scales to improve predicted elk fat accumulation. This direction would be beneficial to aquatic and riparian habitats because it would reduce motorized use in many areas to provide forage for elk away from motorized travel.

Conclusion

Under all alternatives, plan direction protects aquatic and riparian habitats from many activities and threats that could adversely affect ecological conditions for aquatic wildlife. Some alternatives provide more protection than others because they offer larger amounts of suitable wild and scenic rivers, less motorized suitability, and more recommended wilderness. Differing amounts of recommended wilderness would provide slightly more protection than if they were in Idaho Roadless Rule areas.

Alternative Z has the most miles of suitable wild and scenic rivers and would protect more miles of rivers, followed by Alternative Y, then Alternative W. Alternative X has no rivers identified as suitable as wild and scenic rivers. The No Action Alternative would manage rivers with outstandingly remarkable values as eligible. The amount managed as eligible would be more miles than any of the action alternatives. Each alternative for wild and scenic rivers will protect these rivers from dam building and changes to free-flowing character. Although the chances of dam building in the plan area is slim in the future, these would still represent substantial protections for these rivers.

The Preferred Alternative strikes a balance in the amounts of recommended wilderness, summer recreation opportunity spectrum (ROS) and motorized suitability, winter ROS and motorized suitability, eligible and suitable wild and scenic rivers, and timber suitability. The Preferred Alternative takes a relatively rapid pace towards achieving desired vegetation conditions. However, the pace is within the modeled range of disturbance the land experienced from natural disturbances during warmer-dryer periods in the SIMPPLLE model and so should be within the natural range of variability.

While land allocations differ, the outcomes or potential effects from future actions to aquatic and riparian habitat are mostly controlled by the aquatic ecosystem plan components. Aquatics plan components would greatly protect and restore habitats for aquatic and riparian wildlife in the plan area. Objectives for restoring river habitats would restore many degraded rivers, particularly in Management Area 3. These activities would restore the structure, function, composition, and connectivity of aquatic and riparian habitats. These restoration practices and protections would provide for species in the plan area that use aquatic and riparian habitats.

Terrestrial Habitats

Terrestrial wildlife habitat was grouped into habitat groupings that were based upon the habitat descriptions of wildlife species in the plan area. A description of each species' preferred habitat and the habitat groups each species is associated with can be found in Appendix C. Terrestrial wildlife broad habitat groupings and sub-groupings include the following:

- Alpine, boreal, or high elevation habitats
  - Alpine or high elevation, remote areas, or persistent snow
  - Boreal, subalpine, or high elevation forest; cold or cool moist potential vegetation type
- Ecotone, forest edge, or habitat combinations
  - Forested and non-forested habitats interface, forest edges, open habitats with scattered trees, or open woodland
- Forested habitats
  - Broad-leaved deciduous, mixed conifer and broad-leaved deciduous forest, and deciduous riparian habitats
  - Burned forest
  - Closed forest—higher density late seral or old forest or large tree habitat with closed canopy
  - Open forest—low density, late seral or old forest, or large tree habitat with open canopy
- Habitat Generalists
  - Species found in a wide variety of habitat conditions
- Non-forested and early seral habitats
  - Meadow, grassland, forbland, and shrubland
  - Shrubland, thickets, woodlands, and early seral forests
  - Sparse, barren, or bare ground habitats
- Resource habitats
  - Carrion or prey populations

    - ♦ Flowering plants
    - ♦ Fruit resources
    - ♦ Seeds, mast, and grain resources
- Substrate habitats—Rock outcrop, soil, downed wood, cliffs, talus, or cave habitats
    - ♦ Habitats under rocks, logs, downed wood, or leaf litter
    - ♦ Roosting habitats—rock outcrops, caves, crevices, sloughing bark, talus, cavities in trees
    - ♦ Soil or burrowing habitat
    - ♦ Steep terrain

The broad categories and subcategories were analyzed to determine if the Land Management Plan has ecosystem integrity for wildlife species and whether the plan will provide for most native species.

Forested Habitats

Several species found on the Nez Perce-Clearwater primarily use forested habitats. Forest species, whether conifer or broadleaf forests, were assigned to the forested habitats group. Sixty-seven species were assigned to this group, including 55 birds and 11 mammals. An additional 31 species require forested habitats in combination with non-forested or early seral habitat forest edges. Forest birds include songbirds (passerines), forest grouse, woodpeckers, owls, and a few corvids (crows, ravens, and jays). Forest mammals are represented by species like the red squirrel (*Tamiasciurus hudsonicus*), flying squirrel, fisher, Pacific and American marten, black bear, snowshoe hare, and southern red-backed vole (*Myodes gapperi*).

Forested habitats were further subdivided into subgroups that are based on wildlife habitat descriptions:

- Broad-leaved forest—mixed conifer and broad-leaved deciduous forest and deciduous riparian habitats
- Closed forest—higher density late seral, old forest, or large tree habitat with closed canopy
- Open forest—low density, mid-to-late seral, old forest, or large tree habitat with open canopy
- Forest habitat generalists—use multiple habitats like forested, riparian, and non-forested

The number of species identified into the forested habitat subgroup are shown in Table 163.

Table 163. Number of wildlife species recorded by forested habitat subgroup

Habitat Subgroup	Number of Species
Broad-leaved forest	11
Closed Mature forest	31
Open Mature forest	23
Burned forest	2

An additional 147 species can also be found in forested habitats but were grouped into other habitat groupings and subgroupings, as shown in Table 164. In total, about 230 species can be found in forested habitats. However, many of the species depend on key characteristics or habitat types that better fit into other habitat categories analyzed in other sections of the document. They are noted here to recognize the importance of forested habitat to the diversity and abundance of wildlife.

Table 164. Number of species reported by habitat group, with habitat subgroups, and section of the Final Environmental Impact Statement containing their analyses

Habitat Group	Habitat Subgroup	Number	Section with Analysis
Ecotone, forest edge, or habitat combinations	Forested and non-forested habitats interface, forest edges, open habitats with scattered trees, or open woodland	33	Ecotone, Forest Edge, or Forest Mosaic
Aquatic, wetland, water, and riparian habitats	Riparian habitats	23	Aquatic, Wetland, Water, and Riparian Habitats
Aquatic, wetland, water, and riparian habitats	Aquatic and forested habitats or forested wetlands	7	Aquatic, Wetland, Water, and Riparian Habitats
Substrate habitats—rock outcrop, soil, downed wood, cliffs, talus, or cave habitats	Rock outcrops, talus, cliffs, or cutbanks	26	Substrate Habitats
Substrate habitats—rock outcrop, soil, downed wood, cliffs, talus, or cave habitats	Roosting habitats—rock outcrops, caves, crevices, sloughing bark, talus, cavities in trees, etc.	8	Substrate Habitats
Substrate habitats—rock outcrop, soil, downed wood, cliffs, talus, or cave habitats	Habitats under rocks, logs, downed wood, or leaf litter	49	Substrate Habitats
Substrate habitats—rock outcrop, soil, downed wood, cliffs, talus, or cave habitats	Soil or burrowing habitats	3	Substrate Habitats
Substrate habitats—rock outcrop, soil, downed wood, cliffs, talus, or cave habitats	Steep terrain	2	Substrate Habitats
Resource habitats—nectar, fruit, seeds, plant forage, or prey	Flowering plants or nectar resources	4	Resource Habitats
Resource habitats—nectar, fruit, seeds, plant forage, or prey	Fruit resources	1	Resource Habitats
Resource habitats—nectar, fruit, seeds, plant forage, or prey	Carrion or prey populations	6	Resource Habitats
Resource habitats—nectar, fruit, seeds, plant forage, or prey	Seeds or mast	3	Forested Habitats
Non-forested or early seral habitats	Shrubland, thickets, woodlands, and early seral forest	22	Non-Forested or Early Seral Terrestrial Habitats
Non-forested or early seral habitats	Meadow, grassland, forbland, and shrubland	29	Non-Forested or Early Seral Terrestrial Habitats
Non-forested or early seral habitats	Sparse, barren, or bare ground habitats	3	Non-Forested or Early Seral Terrestrial Habitats

Habitat Group	Habitat Subgroup	Number	Section with Analysis
Habitat generalist	None	5	Not Analyzed

Some key ecological attributes of forested habitat were not captured well in the habitat groupings. Large and very large trees, as well as snags and downed wood, are key ecological attributes of forested habitats that were analyzed after the habitat groupings were analyzed. Appendix C contains a list of the species and a brief description of their habitat preferences, the habitat groupings that species associate with, and a crosswalk of plan direction that provides for these habitat groupings.

Some population trends of birds that were grouped into forested habitats are available from the Intermountain Bird Observatory data accessed on March 23, 2023. The stratum queried was the Idaho BCR10 stratum. There are population trends for 51 birds assigned to Forested habitats group, of which 16 are declining and 35 are increasing. Some declining trends have large variation in the data which should be viewed with discretion. Two declining species have large variations in the data such that the trends are less reliable and include the barred owl (*Strix varia*) and sharp-shinned hawk (*Accipiter striatus*). All other species have sufficient data for reliable trend inferences. The national forest habitat subgroups with the highest proportion of species declining and the subgroups with the biggest declines are those that are created or maintained by disturbance such as burned forest and broad-leaved forests (Table 165).

Table 165. Number of species and number of species declining in each habitat subgroup on the Nez Perce-Clearwater

Habitat Subgroup	Number of Species in Subgroup	Number of Species Declining within the habitat subgroup
Burned Forest	2	2
Broad-leaved forest	9	4
Closed Mature forest	20	4
Open Mature Forest	20	6

Forest Density and Structure

Wildlife species are adapted to a variety of stand ages and densities. Collectively, biodiversity depends on species adapted to a wide variety of habitat conditions, including understory vegetation, size classes, or seral stages, and differences in tree density. Scientific studies evaluating biodiversity and forest settings often use species richness and species evenness to describe biodiversity. Species richness is the number of species present, and species evenness is the relative abundance of species. The health of ecosystems is described as the combination of species richness and evenness, a term referred to as biodiversity. Studies that evaluate the effects of forest condition on wildlife communities describe changes in both species' evenness and species' richness because of changes in forest density and age class. These types of studies evaluate guilds of species grouped by their life history or characteristics and habitat use.

Wildlife species were characterized by their use of age class and density where possible. Of the species identified as using mature to old forest age classes, there were some identified as open forest and closed forest species. If the habitat description for species identified open forest, the species was grouped into that habitat subgroup. Conversely, if a species habitat description was mature or old growth forest with high canopy cover, it was grouped into closed forest habitat group.

Several structural characteristics of forest stands correlate with the composition of breeding bird communities in grand fir forests in the Blue Mountains (Sallabanks et al. 2006). Sallabanks et al. (2006) showed that bird communities in grand fir respond more strongly to within stand structure, but some metrics of landscape configuration influenced the presence of some birds like the Townsend's warbler (*Setophaga townsendii*) and Swainson's thrush. Habitat factors influencing bird species richness ranged from a gradient of closed canopy forests with little understory and large trees to a gradient with low canopy cover and a well-developed understory. Several species selected for higher canopy cover gradients while other species selected for low canopy and developed understory (Sallabanks et al. 2006). Within stand characteristics that determined abundance included canopy cover, shrub understory, and the volume of large downed wood. Understory was composed of herbaceous ground cover, regenerating conifers, and shrub cover. The presence of a large tree component 200 years old versus younger managed stands 70 to 100 years old in the Blue Mountains was important for the golden-crowned kinglet (*Regulus satrapa*). However, Sallabanks (2006) found the kinglet to be relatively abundant in several structural classes of non-old growth forest given the presence of larger trees. Ground-nesting species, such as the orange-crowned warbler (*Vermivora celata*) and the dark-eyed junco (*Junco hyemalis*), were more abundant where herbaceous ground cover was substantial.

Key Ecological Attributes of Forested Habitats

Large and Very large Trees

A key component of forests for many species includes the presence of large and very large trees. The plan alternatives all include desired conditions for increased numbers of large trees and the distribution of large forest size classes, plus old growth forest, that is maintained or increased relative to existing conditions. Associated guidelines limit the types of management actions allowed in old growth forests; specify the number, size, and conditions for snags to be retained within treatment areas; and stipulate how vegetation management should retain and promote the recruitment of large size class trees. Additional guidelines specify the amount of coarse woody debris that should be left as ground cover after vegetation management projects. Further, the revised plan alternatives contain desired conditions for coniferous forest habitats to be managed within the natural range of variation for tree species' composition, structure, size class, density, and landscape pattern. These components would provide specific habitat elements required by each species associated with mature and old growth forest structure, as well as a wide range of conditions to support the variety of habitat needs for more the generalist species.

The availability of old growth forests and very large trees varies greatly over time and across the landscape. Unlike some of the forests on the Northwest Coast, very little of the coniferous forests in the northern Rocky Mountains go for hundreds of years without wildfire. Tree species in the northern Rocky Mountains have adaptations to survive and persist in areas where natural disturbance regimes are characterized by periodic stand-replacing wildfire or old growth is maintained by periodic low intensity-non-stand replacing wildfire in some dominance types. As a result, many of the northern Rocky Mountain wildlife species associated with old growth forest are also associated with mature forest as well as individual components of old or large trees within all forest size classes, such as very large live, decayed, dead, and large fallen trees, occurring in forest stands that have predominantly younger age classes. Very large trees have wildlife value even when the surrounding area has been burned or logged (Henjum 1996) and can serve as reservoirs of genetic diversity. Very large remnant trees enrich the subsequent forest stand structure by providing a source of large snags and coarse woody debris and improving the connectivity of the forest landscape for many wildlife species. In western forests, where fire is a dominant disturbance process, maintaining a large and very large diameter cohort of trees in perpetuity may be an appropriate method to achieve the objectives for wildlife and fire resiliency (Habeck 1990, Franklin et al. 1997). The plan includes specific plan components to provide not only stands of large and very large trees, but also for the inclusion of desired conditions for live legacy trees to be provided in stands of all ages (for example, for warm dry potential vegetation type [PVT], plan desired conditions include FW-DC-FOR-04, FW-DC-FOR-05, MA3-DC-FOR-02. Similar plan components are included for Warm moist, cool moist, and cold PVTs).

Snags and Downed Wood

Snags, decayed living trees, and hollow trees are key characteristic for several wildlife species. Species that use snags span many other terrestrial habitat groupings. A snag is defined as a standing dead tree in some stage of decay that may have biological and structural attributes usable by wildlife. Many wildlife species depend upon dead or dying trees as key ecological characteristics. Dead and dying trees provide a range of features used by different species. Natural processes that produce snags include within stand competition, a variety of tree diseases, insect infestations, cracks in sapwood, fire, and senescence (growing old). Factors that determine their use by wildlife include size; the presence of invertebrate prey; decay stage; the presence of sloughing bark, tree type, broken tops, cavities, hollow limbs, or trunks; and the presence of heart rot. Wildlife use snags for cavity nesting or denning, nesting on broken tops, finding shelter in sloughing bark, foraging for invertebrates, and as thermal refuge. Decayed trees and snags function similarly as habitat for wildlife. Decayed trees are living trees with some of these same attributes, and hollow trees form as a result of fungi, especially those that cause heart rot (Bull et al. 1997). A dead tree, from the time it dies until it is fully decomposed, contributes to many ecological processes as a standing snag and fallen woody material lying on, and in, the soil (Brown et al. 2003). Downed wood or coarse woody debris are snags or live trees that have fallen or have been retained following timber management.

Some tree species that develop heart rot are particularly useful to wildlife because heart rot hollows out the center of susceptible tree species. Heart rot facilitates excavation and cavitation inside the tree, which then serves as dens and nest sites for wildlife. Tree species susceptible to heart rot include grand fir, western redcedar, Ponderosa pine, hemlock, Engelmann spruce, subalpine fir, and hardwoods like aspen and cottonwood. Snags of these species have more relative value to wildlife. Heart rot is less common at higher elevations than in lower elevations. Species resistant to heart rot include larch, western white pine, and lodgepole pine.

Based upon an analysis of the habitat requirements of wildlife species that occur in the plan area, 70 wildlife species use snags or decayed or hollow trees for denning or nesting as a key habitat requirement. A total of 92 species use downed wood as a key requirement, and 17 species use both snags and downed wood. Combined, 145 wildlife species rely upon either snags or downed wood, or both, which accounts for about 39.1 percent of the wildlife species diversity within the plan area. Snags, decayed trees, or hollow trees are used by 46 bird species, 21 mammal species, and 3 reptiles. Downed wood is used by 8 amphibian species, 6 bird species, 42 gastropod species, 26 mammal species, and 10 reptiles. Most species that use downed wood usually use the space under or in the downed wood itself. These numbers do not count the ants, bees, wasps, spiders, beetles, flies, crickets, isopods, decapods, worms, and other invertebrates that use snags or downed wood. This also does not count the species that eat these invertebrates or eat the fungi that grows on snags and downed trees. These numbers underscore the importance of snags and downed wood habitat to the diversity and abundance of wildlife species in the plan area.

Wildlife within several habitat groupings rely on the use of snags and downed wood (Table 166). This suggests that dead or dying tree habitats, both snags and downed wood, are an important resource within a wide variety of habitats, whether in forested habitats, aquatic or riparian habitats, ecotone or edge habitats, or non-forested habitats. For some species, such as those in the substrate habitats grouping, downed tree habitat can be the primary key ecological requirement for these species. Dead and dying trees are important habitat features for wildlife that use open forest, closed forest, and ecotones between forested and non-forested habitats and both deciduous and coniferous forest. The two habitat groupings that have the most species using snags or downed wood are the substrate habitat group, the forested habitat group, and the aquatic group.

Table 166. Number of species that use snags, downed wood, or both, by habitat group

Habitat group	Number Requiring Decayed Trees and Snags	Number Requiring Downed Wood	Number that Uses Both Downed Wood and Snags	Total by Habitat Group
Aquatic, wetland, water, and riparian habitats	11	17	1	29
Ecotone, forest edge, or habitat combinations	7	5	0	12
Substrate habitats—rock outcrop, soil, downed wood, cliffs, talus, or cave habitats	7	48	4	59
Forested habitats	25	3	9	37
Non-forested or early seral habitats	3	1	0	4
Resource habitats—nectar, fruit, seeds, plant forage, or prey	0	1	2	3
Habitat Generalists	0	0	1	1
Total By type of snag or downed wood	53	75	17	145

Snags and Wildlife

Alternatives vary whether plan components require retention of snags +10-inch or snags 15-inch or larger. Woodpeckers are primary excavators and the cavities excavated by woodpeckers serve as habitat for a variety of other species. Species that excavate snags or decayed trees include woodpeckers, cavity nesting ducks, songbirds, several owls, many migratory songbird species, arboreal mammals, and bat species. Woodpeckers include the northern flicker (*Colaptes auratus*), pileated woodpecker (*Dryocopus pileatus*), black-backed woodpecker, three-toed woodpecker, downy woodpecker (*Dryobates pubescens*), hairy woodpecker (*Leuconotopicus villosus*), Lewis's woodpecker, Williamson's sapsucker (*Sphyrapicus thyroideus*), red-naped sapsucker (*Sphyrapicus nuchalis*), and white-headed woodpecker. The white-headed woodpecker is a species of conservation concern and a Regional Forester Sensitive Species (RFSS). Nuthatches, such as the white-breasted nuthatch (*Sitta carolinensis*), red-breasted nuthatch (*Sitta canadensis*), pygmy nuthatch, and brown creeper (*Certhia americana*), also use snags both for foraging and nesting.

Individual species of primary excavators select different tree sizes to excavate, while others prefer various stages of decay. Primary excavators hollow out nest and roost sites for themselves that are then used by close to 60 other species on the Nez Perce-Clearwater, some of which are incapable of excavating their own cavity. For example, brown creepers are known to nest in cavities made by pileated woodpeckers or northern flickers or beneath the bark of decaying live trees (Hillis et al. 2002). Migratory songbirds and arboreal mammals often rely upon primary excavators to provide denning or nesting tree cavities. RFSS that use dead and decayed trees include the flammulated owl, black-backed woodpecker, long-legged myotis, long-eared myotis, fringed myotis (*Myotis thysanodes*), fisher, pygmy nuthatch, and bald eagle.

Cavity nesting ducks include the common merganser, wood duck, and hooded merganser (*Lophodytes cucullatus*). Some owl species use cavities, including the western screech owl (*Megascops kennicottii*), boreal owl, northern saw-whet owl (*Aegolius acadicus*), barred owl, and northern pygmy owl (*Glaucidium californicum*). Nearly every species of bat present in the plan area uses snags or decayed trees in some way. Small mammals that rely on snags and decayed trees include the northern flying squirrel (*Glaucomys sabrinus*), Douglas squirrel (*Tamiasciurus douglasii*), short-tailed weasel, Pacific marten, and American marten.

Hollow trees are used by black bears for dens and for hibernation. Bats use hollow trees and sloughing bark for roosting, rearing of young, and, in some cases, hibernation. White pine snags often have sloughing bark.

Birds that nest in snags prefer various tree species, minimum diameters, minimum snag heights, and a variety in types of snag decay (Thomas 1979). Thomas (1979) evaluated snag dependent wildlife species in the Blue Mountains of Washington and Oregon for the minimum diameter of nesting trees. Black-capped chickadees (*Poecile atricapillus*) and mountain chickadees (*Poecile gambeli*) were reported using snags as small as 4 inches diameter at breast height (DBH). Downy woodpeckers used snags as small as 6 inches DBH. Yellow-bellied sapsuckers (*Sphyrapicus varius*), hairy woodpeckers, and yellow pine chipmunks (*Tamias amoenus*) used snags as small as 10 inches DBH. American kestrels (*Falco sparverius*) and western screech owls used snags as small as 12 inches DBH. Additional studies concur with these findings and, furthermore, suggest that there may be a preferred diameter, as not all species use or select larger snags. For example, sites selected by hairy woodpeckers average 10 inches DBH (Conner et al. 1975); downy woodpecker nest trees average 12.5 inches DBH (Conner et al. 1975); red-naped sapsuckers prefer snags between 10 and 13 inches DBH in British Columbia (Harestad and Keisker 1989); red-breasted nuthatches selected snags between 8 and 14 inches and averaged 10.23 inches DBH (Harestad and Keisker 1989); western bluebirds (*Sialia mexicana*), in Idaho, averaged 13.7 inches DBH (Saab et al. 2002); black-capped chickadee nest in trees averaging 10.4 inches DBH (Hill and Lein 1989); and western screech owls select snags starting at larger than 10 inches (Cannings et al. 2017).

Some species select the very largest snags for nesting. For example, the white-headed woodpecker selected snags 25.5 inches DBH in the Sierra Nevada and central Oregon (Raphael and White 1984, Dixon 1995a) and 31.5 inches DBH in southcentral Oregon (Dixon 1995b). Thomas (1979) reported minimum sizes of bufflehead ducks and common mergansers as 15 inches DBH and wood duck and common goldeneye at 20 inches DBH. The study by Thomas (1979) listed wildlife species also known to occur on the Nez Perce-Clearwater as requiring snags and broken-topped live trees with a minimum DBH of 20 inches for nesting or denning. These wildlife species include the pileated woodpecker, barred owl, fisher, and Vaux's swift (*Chaetura vauxi*). Of the species requiring trees greater than 20 inches DBH, only one, the pileated woodpecker, is a primary excavator. Bate (1995) studied the effects of forest vegetation characteristics on woodpeckers in the warm-dry forests of central Oregon. Bate (1995) found that woodpecker density increased as the density of large, live trees greater than 20 inches DBH and hard snags greater than 10 inches DBH increased, excluding lodgepole pine; however, Bate (1995) was not able to detect a threshold where woodpecker abundance dramatically changed. As a result, Bate (1995) did not recommend a minimum number of live trees or snags per acre to support woodpeckers. Although minimum snag diameters are known for many species, there may be a high level of uncertainty with respect to minimum snag densities.

There appears to be a selection towards preferred tree species, which differs by wildlife species. Heartwood decay was the most important factor in nest tree selection by primary cavity-nesting birds in the Interior Douglas-fir Biogeoclimatic Zone of British Columbia. Therefore, a variety of species, sizes, densities, and conditions of snags is needed to provide for the needs of the wide variety of wildlife species that use them.

Tree decay is an important ecological process affecting wildlife habitat. Once begun, the decay process can take hundreds of years as a tree dies, falls to the ground, and decomposes into the forest floor. As it decays, the tree supports many different wildlife groups that use it for foraging substrate, for nesting, and for shelter (Bull et al. 1997). Bull (1997) identified qualitative and quantitative information on five distinct structures—living trees with decay, such as internal decay; hollow trees; trees with brooms, or misshapen branches; dead trees, referred to as snags; and downed wood, or logs. Living trees with an internal core or pockets of decay, top dieback, broken tops, or wounds all can serve as wildlife habitat.

With a few exceptions, studies of cavity nesting birds have shown that the abundance of snags correlates with the abundance and presence of these birds (Thomas 1979, Tobalske et al. 1991, Newton 1994, Hagar et al. 1996, Hitchcox 1996, Saab 1996). Tree cavities have been demonstrated to be the limiting factor for many cavity nesting birds, particularly in secondary cavity nesters (Newton 1994). Similarly, several studies show that use by cavity nesting birds diminishes or ceases when snags are not retained during timber management; however, use is maintained when snags are retained during timber harvest activities.

Downed Wood

Downed wood is derived from snags, as well as from live trees or parts of trees that fall to the ground. This material provides habitat structures for a variety of wildlife species, plant species, and invertebrates. Downed wood also contributes to important ecosystem functions, such as nutrient cycling, moisture retention, microsites for tree regeneration, and substrate for soil microorganisms. Long, larger diameter pieces of downed wood are more valuable because they can be used by a greater range of species, provide a stable and persistent structure, and provide better protection from weather extremes. Downed wood is highly variable in the amount, size, species, and stages of decay, due in part to the irregular distribution of disturbances which create snags and add dead wood to the landscape. Recent fires and the mountain pine beetle have increased the number of snags in many areas. As these snags fall, there will be a period when downed wood is elevated in these areas. Decomposition will reduce this component over time. In some cases, wildfire reburns previously burned areas, which reduces the presence of snags.

Snags and dead wood play an important role in protecting the soil, enhancing soil development, and maintaining soil productivity over the long-term. Although all dead wood has value, large downed wood, or “coarse woody debris,” is of particular importance. Downed wood provides hiding cover, forage, refuge from desiccation, and shelter. For many of the species in the substrate species group, it is the primary habitat feature these species require. Larger sized coarse woody debris is more persistent and of greater value to these species. Downed trees with heart rot provide denning habitats for some of these species.

Benefits to People

Some snags provide a direct economic benefit to people when they are removed and used. This may occur with commercial timber sales and salvage projects or when dead trees are removed as wood for fuel under firewood permits. Snags and downed wood retained on the landscape are not specifically listed as key ecosystem services. However, these components also indirectly provide benefits to people. Snags and downed wood provide both terrestrial and aquatic wildlife habitat and create opportunities for wildlife interactions that people value, including, but not limited to, bird viewing and fishing. Dead wood contributes to watershed function and helps contribute to other key ecosystem services, such as clean air and water. Dead wood contributes to site productivity, which in turn supports desired vegetation that may be used for products, such as timber, as well as contribute to the intrinsic enjoyment of the natural landscape. In addition, plan components that describe the appropriate levels of dead wood are important to potential impacts of fires to at-risk values, which include private property, as well as other values that people possess, such as a desire to recreate in green forests.

Threats and Stressors to Snag Habitats

Studies in the Pacific Northwest show snag abundances are lower in areas of timber management and areas with more human access than areas with less or no timber harvest (Wisdom and Bate 2008). Wisdom and Bate (2008) showed stands with no history of timber harvest had three times the density of snags as stands selectively harvested and 19 times the density as stands having undergone complete harvest. Stands not adjacent to roads had almost three times the density of snags as stands adjacent to roads.

Permitted firewood harvest is responsible for the lower amounts of snags adjacent to roads. The preference for firewood differs by tree species, as those with higher British thermal units (Btu) are preferred over those with lower Btu. Desired species with higher Btu include, in descending order, larch, Douglas-fir, lodgepole pine, and Ponderosa pine. Other species are less desirable as firewood. Firewood harvest is also more acute on the uphill side of roads than on the downhill side as most people avoid moving firewood uphill. Firewood gathering is facilitated by road access and firewood collection usually does not occur very far from road access. Therefore, snags may not be as available for wildlife near roads. The desired condition FW-DC-SFP-02 addresses this service to the public. Higher snag densities are expected farther from roads as a result.

Existing Condition and Trends

The source of data for existing snags and woody debris are statistically based measurements collected on spatially balanced Forest Inventory and Analysis (FIA) plots. The work of Bollenbacher et al. (2009) is the best available science for describing the conditions of snags in the Forest Service Northern Region. This work provides snag quantity and distribution estimates for all national forests in northern Idaho by snag analysis groups and size classes. The data used for analysis represents the latest available. The effects of more recent disturbances, including the fires of 2017, are not portrayed by this data.

Bollenbacher et al. (2009) provided an estimate of the number of snags currently existing throughout the forested portion of the Nez Perce-Clearwater from FIA data. The analysis compared the number of snags presently occurring in wilderness and roadless areas versus outside wilderness and roadless areas. Bollenbacher (2009) found that there was no statistical difference between the numbers of snags in designated wilderness and managed forests in northern Idaho. In other words, the number of snags outside of wilderness and roadless areas, which represents natural snag abundance, is not very different than the number of snags outside of wilderness and roadless areas. The snag densities within wilderness and roadless areas provide insight into natural snag abundance and distribution, and this can be compared to areas outside of wilderness and roadless areas (Bollenbacher et al. 2009a).

Snags are usually irregularly distributed and often occur in clumps or patches (Bollenbacher et al. 2009a). They can be ephemeral or persist for long periods of time depending upon the tree species, cause of death, decay stage, and site conditions. Snags created because of fire are ephemeral. Bollenbacher et al. (2009) found that, in north Idaho, many FIA plots do not have snags present. However, some trends were apparent. As seral stage increased, the percent of plots and number of snags increased. Dry forests had fewer snags, while low and mid moist elevation and subalpine systems had a higher percentage with snags. Larger snags were less common than smaller snags (Bollenbacher et al. 2009a). Large snags tend to occur in the cool moist broad potential vegetation group. While snags are often reported with statistics, such as average number of snags per acre, it should be recognized that, because many areas do not have snags, areas with snags can have much higher numbers than the average.

The analysis area for snags is forestwide by snag analysis group. Snag analysis groups are consistent with Forest Service Northern Region broad potential vegetation type (PVT) groups, except that areas dominated by lodgepole pine are addressed separately. This is important for the snag analysis because lodgepole pine is relatively short lived, generally smaller in diameter than other species, and subject to stand replacing disturbances, which result in unique snag conditions and dynamics. Downed woody debris is analyzed using broad PVT groups to be consistent with the best available information to inform the desired condition.

In areas dominated by lodgepole pine, early seral stands have the most snags due to a greater proportion of stand-replacing fires and species intolerance to fire. The warm dry broad PVT group has fewer snags with a more even distribution into later seral stages because of a more frequent, low severity fire regime. All broad PVT groups show fewer mid-seral stage snags as snags transition to downed wood. Snags occur in a clumpy manner. The larger the snag, the less common it is in all groups. This is due to: 1) fewer trees living to an old age; 2) as trees age, they grow slower, never reaching large diameters; and 3) the inability of systems to contain large old trees and snags due to various types of disturbances (Bollenbacher et al. 2009a).

The creation and persistence of snags applies at a temporal scale, as well. Snag recruitment is dependent on the pattern and frequency of fire, disease, insects, and other disturbances, including human activities, as well as variation in forest composition and size classes. High snag densities, or "pulses," are often the result of high severity wildfires or insect outbreaks, which vary widely in time and space. Low densities of snags also occur under natural disturbance regimes, such as where low severity fires occur frequently, where fire has been excluded, and in areas with greater human access where snags can be removed through activities such as firewood cutting.

The trends and distribution of snags in the plan area is probably departed from historic conditions in a few important ways. First, snag abundance in some areas was probably reduced through intensive timber management through the 1980s and snag retention guidelines were incorporated into the 1987 plans. Timber management since that time has retained some snags during harvest according to plan direction. Through a combination of fire exclusion and timber management practices, Nez Perce-Clearwater tree species composition and dominance types were converted from fire tolerant species to fire intolerant species, as reported in the 2014 Forest Plan Assessment (U.S. Department of Agriculture 2014k). With that change, there was a proportionate change in the way snags are formed and which species provide snags. Naturally higher abundances of dominance types result in more snags from those species. In the plan area, increases in grand fir and redcedar have also likely increased the proportion of those snag species. Large white pine snags have virtually disappeared from the landscape because of blister rust. At higher elevations, there are probably more Engelmann spruce and subalpine fir snags because these species have dominated some former lodgepole pine dominance types. Larch, hardwood species, and Ponderosa pine dominance types have decreased and resulted in fewer snags of those species.

Shifts in species composition comes with differences in disease susceptibility. For example, root rot affects grand fir and Douglas-fir forest more than other species, resulting in potentially more snags of these types than occurred historically. Across the west, large outbreaks of insects have produced abundant snags. Bark beetles have attacked pine and spruce budworm has attacked Engelmann spruce. These outbreaks have resulted in abundant snags in some forest types. These snags may not have the heart rot sought by many species. There has been a recent uptick in fire activity in the plan area with more fires creating large areas of dead trees (U.S. Department of Agriculture 2014a), however the amount and intensity is consistent with historical observations of amount and intensity (see fire management section above). Overall, more snags are present in older age classes (Bollenbacher et al. 2009a) and the large amounts of mid seral size classes likely result in more abundant medium sized snags than historically available.

The Forest Inventory and Analysis data query results are presented in Table 167. Numbers of each size class are similar when compared across management areas by size class.

Table 167. Number of snags by size class and management area (MA)

Broad Potential Vegetation Type (PVT)	MA 1 Snags >10"	MA 1 Snags >15"	MA 1 Snags >20"	MA 2 Snags >10"	MA 2 Snags >15"	MA 2 Snags >20"	MA 3 Snags >10"	MA 3 Snags >15"	MA 3 Snags >20"
Cold PVT	16	4	1	16	4	1	19	1	0
Cool Moist PVT	20	7	1	16	5	2	16	4	2
Warm Moist PVT	22	7	2	13	8	5	11	5	2
Warm Dry PVT	9	5	2	15	5	1	17	6	3

Since the implementation of PACFISH and INFISH, riparian zones have been protected from disturbance including snag removal so there has likely been a maintained or increasing trend in snags within riparian areas. More information is needed to understand the implications of these departures for wildlife.

Snag and Downed Wood by Alternative

Alternative Z would provide more snags and coarse woody debris when conducting vegetation management. Some species, especially those that select smaller snags, would benefit more from this direction. Alternative Z would maintain these species' presence better after vegetation management. This would better promote the diversity and abundance of wildlife after timber management by ensuring that snags and downed wood are present. Snags and downed wood are particularly important for 145 species, or approximately 39 percent, of all species present on the Nez Perce-Clearwater. This alternative would better provide for those species that select or require smaller snags after timber harvest. This includes a broad variety of smaller species, such as red-breasted nuthatches, black-capped chickadees, mountain chickadees, red-naped sapsuckers, hairy woodpeckers, yellow-bellied sapsuckers, American kestrels, western screech owls, yellow pine chipmunks, and many more, especially for the species that select for smaller snags. Downed wood greater than 10 inches diameter at breast height (DBH) is sufficient for many species that use downed wood as a key habitat feature. All alternatives have coarse woody debris retention guidelines that require retention of 3 inches DBH or greater. While larger coarse woody debris would be better for wildlife, this would provide some features for species that use substrate habitats under rocks, downed wood, or debris. While the minimum is 3 inches DBH, nothing in the plan would prevent retention of larger diameter coarse woody debris.

Plan Direction

The scale of the analysis and plan components related to snags and coarse woody debris is forestwide by broad potential vegetation type. The key indicators used in this analysis include:

- Snags per acre by size class—medium 10 to 14.9 inch, large 15 to 19.9 inch, and very large 20 inch plus
- Snag distribution—percent of area that has snags by size class
- Tons per acre coarse woody debris greater than 3-inch diameter

All alternatives contain plan components that require retention of snags during vegetation treatments. The action alternatives address this through a guideline that expresses minimum snag numbers or replacement trees to be left across the project areas with values that are based on the best available science relevant to the plan area (Bollenbacher et al. 2009a). The No Action Alternative also provides snag retention standards. Snags currently present in wilderness and roadless areas provide the basis for the desired condition because they reflect a more natural condition because human management is limited, although fire suppression has occurred. At least 50 years of active wildfire management has been contributing to these more natural conditions in Management Areas 7, 10, 12 through 15, 17, and 19 through 23.

Desired conditions for snags are shown in the Forestlands section and are designed to reflect the conditions that occur as averages reported by Bollenbacher et al. (2009). Desired conditions for each broad potential vegetation type (PVT) group contain a description that snags and living remnant trees are present in all age classes for wildlife habitat and future snag retention. The plan also has desired conditions about the distribution of snags. Management direction in the Idaho Roadless Rule restricts timber production, and timber harvest is allowed for restoration only. Wildland fire might be the most prevalent tool to achieve restoration in Management Area 2, which should retain snags naturally.

In addition to guidelines specific to snags, guidelines for broad PVTs that describe within stand conditions define a desired condition to have live legacy trees persist into the next generation, even in smaller age classes. This condition would recruit more large snags and coarse woody debris over time because some of these legacy trees would die and become snags and then later fall to provide coarse woody debris. Similarly, desired conditions and associated guidelines for old growth would provide habitat conditions in some areas of the Nez Perce-Clearwater to promote larger snags. See Sections 2.1.3.4 and 2.1.6 of the Land Management Plan for plan components that pertain to snags.

Plan guidelines require minimum snag densities under all alternatives but differ by the size of snags required to retain. Alternatives W, X, and Y would require snags be retained from 15 inches with some proportion of those snags being greater than 20 inches diameter at breast height (DBH) and larger. Alternative Z, in addition to requirements in other alternatives, requires retention of snags 10 inches DBH and larger, with some proportion of those snags required to be 15 inches and larger and some 20 inches and larger. Under Alternative Z, the number of snags would be from between 2.5 to 14, depending upon PVT. The preferred is the same as Alternatives W, X, and Y. See MA2 and MA3-GDL-FOR-05 for snag guidelines, depending upon PVT. All alternatives require these snags be retained at the project scale but not necessarily within harvest units. The numbers for snags in the guideline are based upon the average number of snags reported by broad PVT in northern Idaho per Bollenbacher et al. (2009). These numbers are scaled up from Bollenbacher et al. (2009) so that they are represented as number of snags per 100 acres to give flexibility in distribution and grouping at the project level.

The desired condition for downed wood is to maintain the amounts that contribute to forest structural diversity, soil ecological function, and habitat, focusing on coarse woody debris because larger downed wood is more valuable to ecosystem function than smaller debris. Coarse woody debris is defined as pieces that are 3 inches in diameter and greater based on the best available information to describe natural and desired conditions (Brown et al. 2003). The plan contains guidelines for the amounts of coarse woody debris to be retained during timber harvest. See Section 2.1.3.4 of the Land Management Plan for coarse woody debris plan components.

Modeling Results

Snags and downed wood were modeled to estimate the trend in snag abundances under the Land Management Plan (Ecosystem Research Group 2021). The presence of large (15-inch DBH) and very large (greater than 20-inch DBH) trees largely predict the current and future potential availability of large snags and coarse, woody debris. The effects of canopy cover classes greater than 15 percent were not modeled for the following reason: high canopy cover (that is, greater than 70 percent) in combination with large or very large trees suggests that given stands will potentially produce higher future levels of snags or coarse, woody debris than low canopy cover classes (that is, 15 to 40 percent). Existing high levels of snags or coarse, woody debris, however, are more likely to occur in stands that have experienced disturbances and as a result have low canopy closure. To avoid confusion between future and existing levels of snags and coarse, woody debris potential, the query is limited to future potential based on the presence of large and very large trees:

- A2, warm and dry
- B1, warm and dry
- B2, warm and dry
- C1A, warm and dry
- C1B, warm and dry
- C2, warm and moist
- C3, warm and moist
- D1, warm and moist
- E1, warm and moist
- D3, cool and moist
- E2, cool and moist
- F1, cool and moist
- F2, cool and moist
- G1, cold
- G2, cold
- Tree size class
- Greater than 15-inch DBH
    - ♦ 15–19.9-inch DBH
    - ♦ greater than or equal to 20-inch DBH
    - ♦ Canopy cover
- Greater than 15 percent:
    - ♦ 15-39.9 percent
    - ♦ 40–69.9 percent
    - ♦ 70–100 percent

Analyses were based on the following assumptions: The SIMPPLLE model is dependent upon stand-level data (Northern Region VMap) and thus is unable to incorporate snag densities. The query design uses Forest Inventory and Analysis (FIA) data to identify the range of large snags per acre in the greater than 15-inch DBH size class within stands greater than15-inch DBH. The query also uses FIA data to identify the range of coarse woody debris tonnage per acre within stands greater than15-inch DBH.

The following snag summary tables were generated from the Northern Region Hybrid 2015 FIA data set. Table 168 shows the number of snags per acre by diameter class for each broad potential vegetation type (PVT) group. Table 169 lists the snags per acre by broad PVT group within each management area.

Table 168. Trees per acre (TPA) by diameter class and broad potential vegetation type (PVT) group

Northern Region Broad PVT Group	TPA Snags ≥ 10" DBH	TPA Snags ≥ 15" DBH	TPA Snags ≥ 20" DBH
Cold	24	4	1
Cool Moist	23	7	2
Warm Dry	15	5	2
Warm Moist	16	9	4

Management Area 2 Potential Vegetation Type	Management Area 2 Forestwide Existing Condition (tons/acre)	Management Area 2 Forestwide Desired Condition (tons/acre)
Warm Dry	8	7-15
Warm Moist	14	17-33
Cool Moist	11	9-18
Cold	10	7-24

Management Area 3 Potential Vegetation Type	Management Area 3 Forestwide Existing Condition (tons/acre)	Management Area 3 Forestwide Desired Condition (tons/acre)
Warm Dry	13	7-15
Warm Moist	19	17-33
Cool Moist	17	9-18
Cold	13	7-24

Habitat for snag dependent species is available at both ends of stand succession, including late succession mature forest and early succession grass and forb and shrub and seedling communities. The vegetation data for this analysis is based on Northern Region VMap data, which cannot detect snag densities. Forest Inventory and Analysis data indicates late seral forests typically contain high densities of snags. Therefore, this analysis compares late succession forest acres by alternative, management area, and timestep as a surrogate for snag habitat. Because of this, the analysis ignores snags in early seral forest habitat, including snags left after high severity wildfires and insect outbreaks or snags and reserve trees retained following logging operations.

The following three figures (Figure 57, Figure 58, and Figure 59) compare percentages of snag dependent habitat by management area, alternative, and timestep. Only large and very large trees are considered for this query. According to the SIMPPLLE model, snag densities decline in Management Area 3 below natural range of variation (NRV) in the Preferred Alternative, and alternatives W, X, and Y. They remain above NRV in the No Action Alternative and Alternative Z. The Preferred Alternative shows snags decline from approximately 50 percent down to approximately 28 percent. Snag levels remain relatively stable within Management Area 2 and remain within NRV ranges. Snags increase in Management Area 1 over the five-decade period but remain below NRV.

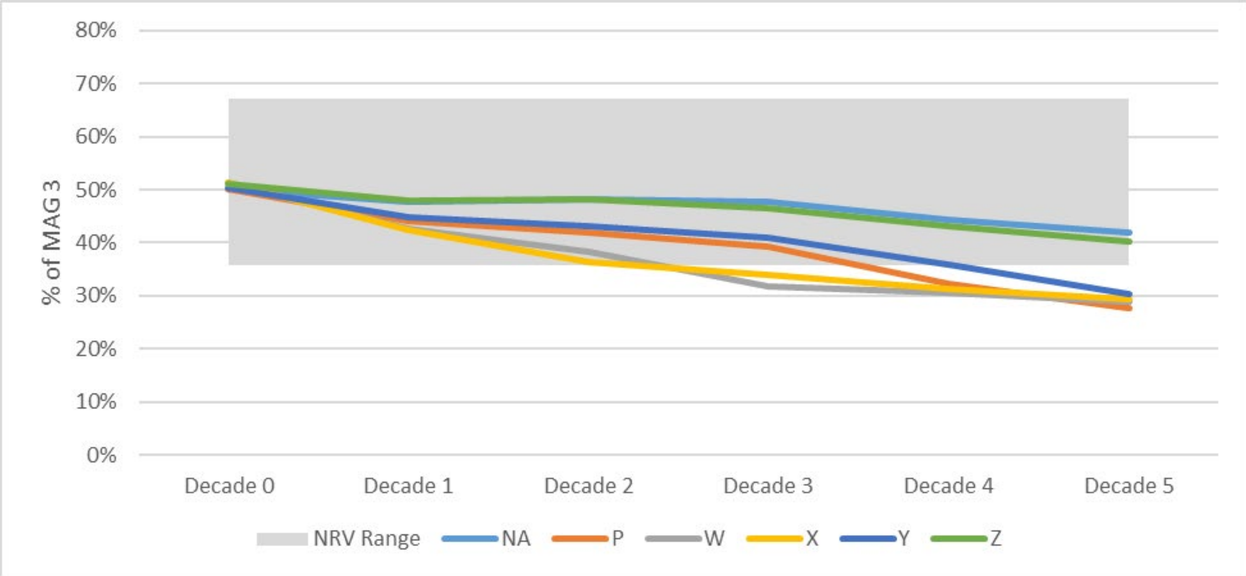

Figure 57. Snag dependent habitat by alternative and decade for Management Area 3

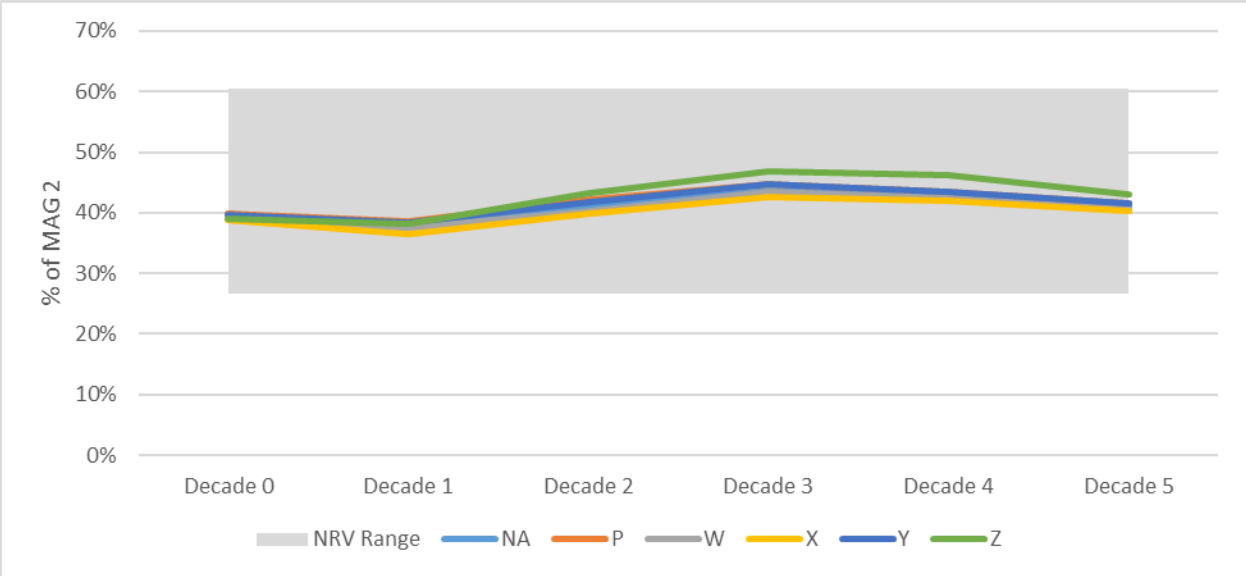

Figure 58. Snag dependent habitat by alternative and decade for Inventory Roadless areas

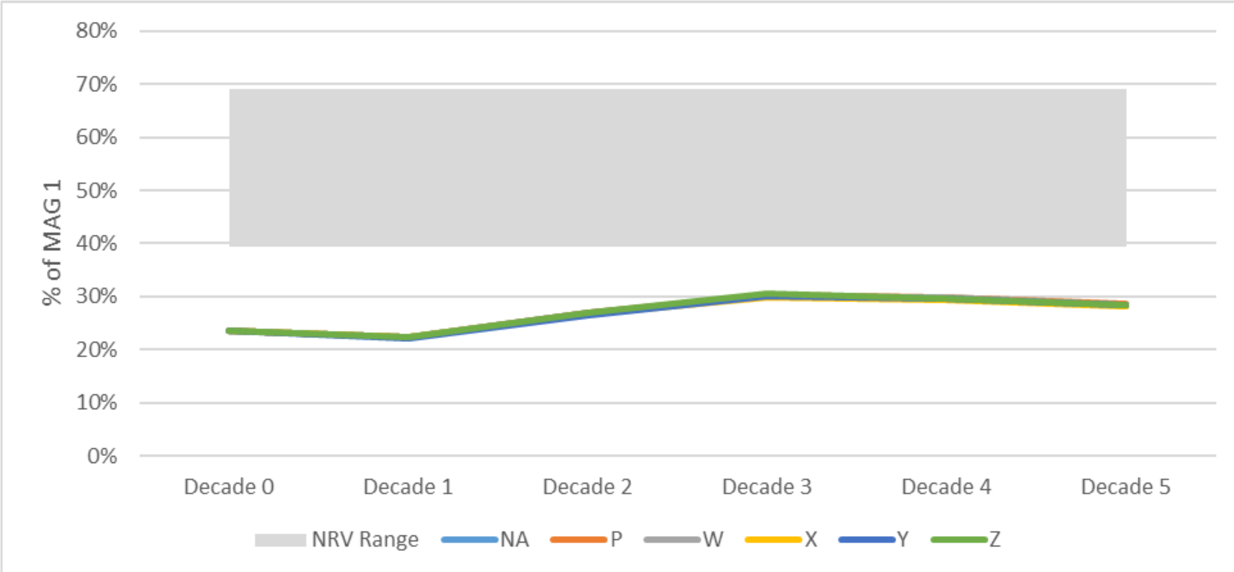

Figure 59. Snag dependent habitat by alternative and decade for wilderness areas

The Forest Inventory and Analysis (FIA) data suggests the SIMPPLLE-modeled outputs are conservative. As Table 172 suggests, snag densities based on the FIA summary data are relatively high. This result is not surprising, given the recent increase in insect outbreaks, wildfires, and root disease on the Nez Perce-Clearwater, which has resulted in tree mortality. The SIMPPLLE model concludes that the availability of medium, large, and very large size classes across all potential vegetation types (PVTs) will remain relatively stable over five decades. Snag densities in medium, large, and very large sized stands should persist at relatively high levels, based on the FIA data. Snags available following high severity wildfires and prescribed fire, and snags retained following logging operations via Forest Plan components are ignored in this analysis. The distribution of large and very large tree size classes remains substantial over five decades. FIA data show conclusively that snags are abundant within those size classes. In addition, increasing levels of wildfire and ecosystem management burns will recruit snags forestwide.

Table 172. Percent snags per acre in Forest Inventory and Analysis plots in stands greater than 15-inch diameter at breast heigh (Source: Forest Inventory and Analysis Data)

Snags per Acre	% Snags >10"	% Snags >15"	% Snags >20"
0	23.65%	35.27%	54.77%
1-11	30.29%	38.17%	34.02%
11-21	24.07%	16.18%	9.96%
21-31	14.11%	8.30%	1.24%
31-41	3.32%	1.24%	-
41-51	2.90%	0.83%	-
52+	1.66%	-	-

Effects Common to All Alternatives

Snags and downed wood are dependent on the pattern of natural and human disturbances. Under all alternatives, snag and downed wood conditions would be dynamic, highly variable, and unevenly distributed across time and space. Dead wood would be created by fire, insect, disease, and successional processes. Decomposition and fire are the primary ecological processes that remove dead wood from the ecosystem in Idaho Roadless Rule areas and wilderness areas, which make up the majority of the Nez

Perce-Clearwater. In all alternatives, most National Forest System lands are in areas where human management is limited, and natural ecological processes and disturbances would be the primary ecosystem drivers affecting snag and downed wood.

Natural disturbances, such as wildfire, are projected to occur at a similar degree in all alternatives and are the predominant disturbance, as indicated by the SIMPPLLE modeling. These disturbances influence the abundance, distribution, and condition of snags and coarse woody debris. The highest amounts of dead wood would be present where fire or insect and disease outbreaks occur or in stands of larger size classes. Snags would fall to the ground to become part of the downed wood component where they decompose and eventually become part of the soil. Wildfires can have a wide range of effects by creating snags, especially of smaller size classes, and causing some snags to fall and be consumed. Similarly, the effects to coarse woody debris can be variable, as fires may consume material on the forest floor and create snags and future downed wood. Meanwhile, insect infestations create snags, often of large size classes, and contribute to future large woody debris.

Recent fire, root rot, and insect outbreaks on the Nez Perce-Clearwater have created snag pulses which are converted to downed woody material. Regardless of the selected alternative, snags would be abundant in the short-term. In the long-term, this pulse of snags will be lost to natural attrition and the material will accumulate on the forest floor as woody debris. The timing of when dead trees fall varies by species, the cause of mortality, and site conditions. Studies suggest that the range of when most trees fall is usually between 3 and 15 years after death (Lyon 1977, Mitchell and Preisler 1998, Graham and Jain 2007, Wisdom and Bate 2008, Bollenbacher et al. 2009a). Any factor that increases tree mortality will also increase snags. This includes the effects of a changing climate on tree stress, wildfires, and insects.

To some degree, fire exclusion would continue to affect the landscape under all alternatives, due in part to continued fire suppression activities. Fire exclusion can limit snag creation in areas that would otherwise have burned. Conversely, over the long-term, fire exclusion can increase fuel loadings and stand densities that predispose areas to large stand-replacing events that create snag pulses. The creation of large and very large snags is dependent upon the development of large live trees. Large snags are not abundant because tree growth is often disease limited on the Nez Perce-Clearwater. Further, high stand densities that may develop due to fire suppression or other factors limit the potential for individual large tree growth. Homogenous landscapes yield snag pulses followed by periods with few snags. Because of pulse events, snags may not always be well-distributed spatially or temporally. Nevertheless, the snags and downed woody debris within the Nez Perce-Clearwater should be sufficient to provide for wildlife under all alternatives, though Alternative Z would provide more snags and coarse woody debris when conducting vegetation management. Some species, especially those that select smaller snags, would benefit more from this direction. Alternative Z would maintain the presence of these species better after vegetation management.

Lands where active vegetation management would occur, such as lands suitable for timber production, cover the same amount of the Nez Perce-Clearwater under all alternatives. The amount of land within Management Area 3 varies only a little under the alternatives. Many of the forests in areas suitable for timber production and within wildland urban interface areas would be managed to maintain vigorous trees and limit losses due to insects, disease, and fire where possible. This would tend to result in less tree mortality and a potentially lower density of snags and downed wood over time, as compared to areas less influenced by human actions. On the other hand, active vegetation management provides the opportunity to manage for species and larger size classes that would contribute to larger snags and downed wood. Lower amounts of snags and downed wood would tend to occur in developed sites, in areas where concern for fire hazard is elevated, and in areas closer to communities and accessible to firewood cutting.

All alternatives have standards and guidelines that direct management of snags and downed wood in timber project areas. These are designed to address the unequal distribution of snags and downed wood across the Nez Perce-Clearwater that may be the result of timber management and supports the active role that is more likely to be needed to achieve desired conditions within actively managed landscapes. Plan components for all alternatives require a normalized average of snags per acre that applies to the amounts of snags greater than 15 inches and greater than 20 inches DBH. These are required to be retained in the project area but not necessarily within the harvest units. If managers choose not to retain snags in the harvest units, some treated areas will not have snags after treatment. Plan components for Alternative Z require an additional number of snags greater than 10 inches DBH.

All management areas and broad potential vegetation type groups (PVTs) currently meet the desired conditions for the minimum number of snags per acre except the cold PVT group in Management Area 3. This is likely due to the combination of species composition and growth rates associated with the cold potential vegetation type group.

Broad-leaved Habitats

Broad-leaved forests, also called deciduous forests, are important contributors of wildlife diversity. Within the plan area, 11 species are grouped into species that seek or require broad-leaved forests as a key characteristic of their habitat. Numerous bird species use riparian and deciduous forests even though these habitats make up a very small percent of all land area in the Northern Region (Hutto and Young 1999). Species specializing in or requiring deciduous forests include the American redstart, Bullock's oriole, red-eyed vireo, downy woodpecker, western screech owl, and ruffed grouse. Some of these species are only found in deciduous forests and riparian areas. Many other wildlife species can be found in broad-leaved or deciduous forests, as well as coniferous forests. For example, many of the riparian species and those in the open and closed forest grouping can be found in deciduous forests. Habitat descriptions for 12 forest generalists, 10 open forest species, and 12 closed forest species specifically mention deciduous or mixed forests as used habitats; however, these species are more tied to the density or structure of forests rather than forest type. In addition, several bat species preferentially roost in hardwood trees, including the little brown bat (*Myotis lucifugus*) and the silver-haired bat (*Lasionycteris noctivagans*). Mammals, such as the fisher, black bear, flying squirrel, and red squirrel, are known to nest, den, or rest in very large cottonwood trees where available (Bunnell et al. 2002).

Although deciduous trees usually make up less than 10 percent of forest cover in western forests, they are highly preferred as nesting and foraging sites for birds, insectivorous mammals, and amphibians and as a preferred substrate for many invertebrates (Bunnell et al. 2002). In seven of nine Pacific Northwest studies compiled by Bunnell et al. (2002), upland hardwood communities had significantly greater bird species' richness than upland conifer communities, especially those forest communities containing quaking aspen or cottonwood trees.

Deciduous forests are uncommon to rare in the plan area because the landscape is so dominated by coniferous forests. From the Forests Vegetation geospatial layer of the VMap data, the amount of deciduous vegetation dominance types identified as hardwood mix occur on about 2,180 acres, which is less than 1 percent of the Nez Perce-Clearwater. The average size of the stands dominated by hardwood mix types are about 3.8 acres and the largest stand is about 16 acres. These stands are distributed along the Lochsa, Selway, and Salmon rivers and tributaries; Rapid River and other tributaries in the Island portion of the Nez Perce-Clearwater; the Lower Southfork of the Clearwater; and limited areas of the Potlatch Ranger District. Species of broad-leaved or hardwood forests include aspen, paper birch, red alder, and black cottonwood.

The Forest Inventory and Analysis (FIA) data suggests deciduous trees occur in riparian as well as upland areas. Deciduous trees rarely dominate on the Nez Perce-Clearwater. According to the FIA data, the hardwood tree dominance type covers a low percent of the Nez Perce-Clearwater. These are areas where aspen, cottonwood, red alder, or paper birch are the dominant species, though there may be conifer trees present as well. More commonly, they do not dominate but are present as components of coniferous forest types, usually as a minor component of conifer-dominated forests. Aspen is estimated at less than 1 percent, paper birch is present on an estimated 1 percent, and black cottonwood is present on an estimated 2 percent of the Nez Perce-Clearwater, according to the FIA data. Paper birch is estimated to be present on between 1 to 5 percent of the Nez Perce-Clearwater. To sustain hardwood tree communities, Bunnell et al. (2002) recommend encouraging upland patches of hardwoods, avoiding the conversion of riparian areas to conifer communities, and controlling domestic grazing in riparian areas.

Given their rarity on the Nez Perce-Clearwater and the fact that they support higher biodiversity among the vegetation types, deciduous forests contribute disproportionately to wildlife species diversity. Examples of key ecosystem characteristics for many species associated with this habitat include soft, decayed, or hollow trunks with heart rot, fruit production, and branching structure that provides nesting sites. Paper birch is known for loose bark that provides shelter, as well as sap and catkins that provide food. For some species, the key ecological attribute identified is deciduous vegetation itself.

In the mountainous west, hardwood tree communities are disturbance dependent. The 2014 Forest Plan Assessment did not evaluate deciduous forests or evaluate departures for these species. However, since they are dependent upon disturbance, it could reasonably be assumed that they probably occurred over a larger extent and were more commonly components of stands during pre-Columbian times than they are presently due to fire suppression and lack of disturbance. Some forestry practices probably give competitive advantages to conifer species. Planting coniferous species and spraying herbicide after timber harvest might provide an advantage for coniferous species over deciduous species. More impactful are factors such as fire suppression and lack of disturbance in riparian areas.

Aspen historically relies on fire or disease to remove the overstory, kill encroaching conifers, and stimulate suckers from the existing clone root system (Shepperd 1990a). Without periodic self-regeneration, aspen stands become decadent and deteriorate as root systems decline; mature clones can also decline due to repeated animal herbivory (Shepperd 1990a). Aspen may coexist with conifers for decades after a disturbance, but aspen gradually declines as conifers become more numerous and denser and are replaced by conifer forest.

On the Nez Perce-Clearwater, cottonwood is confined to riparian areas with fluctuating water tables and is more common on private lands outside of the national forest boundary. While present in limited areas, it is poorly represented by available data. It is desirable to maintain and promote this species where it exists, but no quantitative desired condition was developed because it is absent from available data sources in all management areas.

Forestwide, the natural range of variation (NRV) analysis indicates that the aspen and hardwood cover type is generally within its natural range for abundance, although it is at the low end or slightly below its natural range in all management areas. The modeling also indicated that aspen species distribution is below its natural abundance at the forestwide scale and in the warm dry and cool moist broad potential vegetation groups. Aspen is below the desired condition in all management areas. The desired condition ranges reflect a desired trend of maintaining and increasing aspen. The highest levels of aspen correlated with past warm and dry climate periods.

Between Draft and Final Environmental Impact Statements, the plan components for riparian areas and broad-leaved habitats in FW-DC-TE-05 and FW-OBJ-TE-01 were adjusted to restore hardwood species within riparian areas as found in the Terrestrial Ecosystems section of the Land Management Plan. The plan also includes FW-OBJ-RMZ-01 in the riparian management zones section of the plan, which also seeks to restore hardwoods within riparian areas. Additionally, FW-DC-GS-04 is a desired condition that describes riparian and hardwood habitats. These plan components are designed to provide for these habitat features. The plan also contains a desired condition and objectives to increase aspen forest types in the plan area. The objectives in the plan area for aspen vary by alternative with Alternative W restoring 925 acres, Alternative X restoring 1400 acres, Alternative Y restoring 550 acres, and Alternative Z restoring 275 acres annually. The Preferred Alternative seeks to restore 680 acres of aspen annually. Some have questioned whether these acres could be reasonably achieved given the low amounts of riparian and hardwood vegetation in the plan area. However, it should be realized that this could be achieved by restoring hardwood components as a component of stands in addition to increasing the dominance of these types. Additional disturbance, including increased wildland fire use, prescribed fire and timber harvest would promote hardwood presence in upland forest habitats.

Modeling Results

The Land Management Plan interdisciplinary team requested that the Ecosystem Research Group query the SIMPPLLE model for predictions on how deciduous forest would respond to the plan and alternatives. This was a challenge for the Ecosystem Research Group to accomplish because there are so few stands that are dominated by deciduous vegetation and most of these are smaller than the 5-acre pixel size that SIMPPLLE uses in simulations. The second challenge was that pathways for the responses of deciduous forest succession were not well developed in SIMPPLLE. Between the Draft and Final Environmental Impact Statements, the query was adjusted to better estimate the trends and outcomes of deciduous hardwoods. Since many deciduous shrublands and hardwood vegetation frequents riparian areas and are limited in the uplands, modeling to represent broad-leaved forests were combined in the riparian vegetation query in SIMPPLLE. Figure 56 shows the predicted outcome of riparian and hardwood vegetation.

Modeling did not identify a natural range of variation for these habitats, but it is assumed that they are at the low end of the NRV. Acres of riparian habitat in an early-successional condition would increase from wildfire disturbance and prescribed fires that is allowed to back into riparian areas in the model. The results under the alternatives are all similar in magnitude and trend with broad-leaved vegetation and early seral riparian vegetation increasing positively over time. These positive trends are positive for broad-leaved and riparian associated species. Some species that depend upon more mature forest conditions in riparian areas or forested wetlands will likely be adversely affected by disturbance in riparian habitats locally when these disturbances occur. However, mature riparian habitat appears to be abundant.

Closed Mature Forest Habitats

A total of 22 wildlife species were identified as being associated with mature closed canopy habitats and several other species also use mature closed forests. Examples of species that use closed mature forests include the brown creeper, Southern red-backed vole (*Myodes californicus*), fisher, Vaux's swift, white-breasted nuthatch, American marten, boreal owl, golden-crowned kinglet, varied thrush (*Ixoreus naevius*), pileated woodpecker, Swainson's thrush, blue-headed vireo (*Vireo solitarius*), and Cordilleran flycatcher (*Empidonax difficilis*). Few wildlife species in this group are thought to require old growth, but most are found to use a range from mid-seral and late seral to old forest. The species in this group can sometimes be found to use other habitats, but these species were grouped here because this is the best fit for their habitat description. This section is to address species that use closed mid seral to old forests. Like other habitat groups, other species are often found in closed mature and old forests as well. These include the species grouped as forest generalists, forest understory species, habitat generalists, broad-leaved or deciduous forests group, riparian habitat subgroup, and ecotone habitat groups.

Many of these species use multiple dominance forest types, while others are associated with dominance types typically found within certain broad potential vegetation types. Townsend's warbler and red-breasted nuthatch, for example, use many mature forest dominance types. Golden-crowned warbler (*Basileuterus culicivorus*) and boreal owls typically reside in cool moist and cold potential vegetation types (PVTs) in mature forests. Vaux's swift, varied thrush, and fishers typically occurs in warm moist or warm dry PVTs.

Key characteristics of mature closed canopy forests for wildlife include large live trees with periodic very large trees, increased amounts of snags, higher amounts downed wood, closed or connected canopies, higher amounts of fungi, a mix of tree species present, and a variety in vertical structure. Mast production from mast producing tree species is important for some species and larger mature trees produce more mast than younger trees. A disproportionate number of species in this habitat grouping use snags or downed wood as key habitat features. Of the species that were grouped into the closed mature forest type, 64 percent use or require snags, downed wood, or both. Of the total species in this group, 58 percent rely on snags and 32.2 percent rely on downed wood, while 25.8 percent rely on both snags and downed wood. Therefore, snags and downed wood are key habitat features of mature closed canopy forests. The southern red-backed vole is prey for several species and is highly dependent on higher amounts of coarse woody debris. While understory often declines with canopy closures, understory vegetation is important to some species. Mature forests that lack the features mentioned above may not function to provide for some of these species. A table showing the habitat groupings and a description of their habitats are found in Appendix C of this Final Environmental Impact Statement.

Many species in this group are insectivores, some are carnivores, and fewer are omnivores and herbivories. Thus, insect populations are important features of these habitats and are assumed to be present in these forest types. Properly functioning mature forest with the key characteristics mentioned above are assumed to provide these resources. Carnivores dependent upon prey species and properly functioning mature forest with the key characteristics mentioned above are assumed to provide prey populations. Key indicators for closed canopy mature forests include the amount and trend of closed canopy mature forests and the proportion of size classes. These were modeled in PRISM and SIMPPLLE models.

Existing Condition

Habitat conditions in the plan area are a result of changes in the disturbance patterns compared to pre-Columbian times and forestry practices since European settlement. Additional changes were made because of forest diseases that impacted white pine and whitebark pine. These changes have resulted in an increase in fire intolerant species and increases in density and older age class. Past timber practices that preferentially cut fire tolerant species and old growth and the susceptibility of fire intolerant tree species to diseases have resulted in less old forests. Therefore, while there is an overabundance of mature closed forest, the amount of old forest is lower than occurred under natural disturbance regimes.

Fire exclusion has resulted in higher canopy densities across all potential vegetation type (PVT) groups, which would otherwise have been maintained at more open densities by frequent low and mixed severity fire. Many forests on the cool moist sites also had low to medium density, which were likely forests in their early and mid-successional stages or older forests where disturbances removed trees and opened the canopy. In all types, the shift toward higher densities reflects the impacts of fire exclusion and the increased abundance of shade tolerant species. Low to medium density forests were at the higher end of their natural ranges during warm and dry periods, whereas medium-high and high-density forests were at the lowest end.

Fire acted like a thinning agent in some broad PVTs. Thinning would allow young trees to grow among larger trees, creating a multistory structure. Single-storied forests are more common than they were historically while multi-storied forests are less common, especially in the warm dry and cold broad PVTs. The medium to high tree canopy cover class represents a more fully stocked forest, a condition which is common in more moist forests of shade tolerant species often found on the cool moist and warm moist broad potential vegetation groups. Examples of forests with this density could include mature single-storied lodgepole pine or spruce and fir multi-storied stands. Dry forests may also be in this density class, particularly where fire has been excluded and understory layers have developed.

The high canopy cover class includes forests with a relatively closed canopy, most often on productive sites on the cool moist broad PVT. This density class is common in stands with a spruce and fir component in a multi-storied condition. This condition also arises in single-storied lodgepole pine and sometimes Douglas-fir that regenerate to extremely high densities after fire. High tree density can limit tree growth, as well as sunlight to the understory, limiting vegetation in the understory. This condition may also occur in dry forests that have missed natural fire entries and developed layers in the understory. Evaluating canopy cover classes predicted by modeled natural range of variation (NRV) suggests that higher density forest conditions are much higher in extent than they were under natural disturbance regimes. Additional information about these habitat conditions can be found in the Forestlands section.

Most of the wildlife species in the mature closed forest habitat group can use a variety of dominance types and it is unclear what effects the change in dominance types has had on wildlife distribution and abundance. There is a lack of studies providing information on the wildlife communities supported by western white pine dominated forests and the effects that the loss of this forest type had. The loss of whitebark pine and probably western white pine is thought to affect many wildlife species that rely on mast. Stands dominated by white pine likely provide a distinct structure that some wildlife species probably preferred. The effects of blister rust go far beyond the loss of individual trees. There is a cascading effect on associated plant and animal communities throughout affected ecosystems. Natural regeneration and intermediate age classes have been rapidly killed by blister rust, resulting in dramatic changes to normal successional pathways (Samman et al. 2003). Western white pine has been replaced by grand fir, Douglas-fir, and hemlock species that are more susceptible to diseases, such as root rot, that can prevent these species from achieving old growth conditions as defined in Green et al. (2008). Actions to restore to mature closed canopy forest would potentially take centuries, which is complicated by blister rust susceptibility. Restoration efforts would require regeneration followed by planting to properly restore these forest stands.

Given the trend and existing conditions of mature closed forest, habitats for species that use mature closed forest are overrepresented compared to forests operating within the NRV in terms of extent, density, and dominance types. Closed mature forests should decline to return to the NRV. A decline in mature closed forests is an expected and desired outcome of the revised plan. The decline should not be considered a concern if the amount and distribution of closed mature forest drops below the NRV that occurred under past disturbance regimes. It should be noted that not all wildlife species use mature closed canopy forests. Many species in the early seral or non-forested vegetation habitat grouping avoid mature closed canopy forests. Similarly, some species that use open mature forests avoid or select against dense forests. Some species may use mature closed canopy forest for resting, nesting, hiding, or thermal cover but require open habitats for foraging. Some species may use mature forest but are more abundant in other habitats.

Thus, the appropriate mix of different size classes and densities should also be provided for the diversity and abundance of wildlife.

An important characteristic of mature forests for some species is whether these conditions occur in a contiguous and connected condition across landscape scales. Fisher, for example, exhibit a preference at the landscape scale for large areas of mature closed canopy forest conditions in a contiguous and connected pattern (Sauder and Rachlow 2014). The landscape pattern of mature forests was modeled in SIMPPLLE and PRISM to determine the NRV of these patterns in mature and closed canopy forests. If model simulations estimate past conditions as believed, these conditions occur naturally within the forest types in the plan area. However, these conditions over long time periods were dynamic across space and time under natural disturbance. They tended to ebb and flow with moisture and temperature conditions across time. During moist periods, they increased in extent and distribution, while in drier periods they were reduced through wildfire disturbance. While present consistently through time somewhere in the plan area, the stochastic nature of fire moved where these conditions occurred across decades or even centuries, creating a dynamic patchwork of mature forests that changed locations as stands were regenerated by wildfire and again regrew to mature conditions. These conditions operate at scales larger than the management areas under the Land Management Plan.

Threats and Stressors to Mature Closed Canopy Forests

Modeling results from SIMPPLLE suggest that this habitat condition declines as a result of fire and management under the plan. This habitat condition is prone to burning and insects and disease and is of interest for timber harvest. The effects from each of these disturbances differ from each other and can be variable depending upon dominance type. Fire under a warmer and drier climate, and with a buildup of fuels, may burn more often and more intensively than under past climate. Fire is more unpredictable than timber harvest in that it is a stochastic process and will be operative more in Management Areas 1 and 2 than in Management Area 3. While it is less predictable, it also operates with greater variability, which is beneficial to wildlife species. Susceptibility to insect and disease develops because of stand age and distribution of this condition. Timber harvest would affect mature closed forests in Management Area 3 more than other management areas, but the modeling indicates that these habitats should continue to persist in the plan area and not fall below the natural range of variation (NRV) for these systems as long as forests are managed towards desired conditions and follow appropriate standards and guidelines. In most broad potential vegetation types (PVTs), medium, large, and very large size classes remain within the NRV but not in others. Changes to fire behavior or improper harvest patterns can affect the dynamics of the landscape pattern of the contiguous mature forests required for some species, such as fisher. Improper harvest patterns are defined as those that do not replicate natural disturbance patterns at the landscape scale. Departure in landscape patterns for mature closed canopy forests arises because of fire suppression, followed by uncharacteristic wildfire. Departure in patch size also arises due to restrictions in the size of timber harvest units that do not allow a pattern more representative of the natural disturbance. They also could arise by changes in fire start patterns due to human interference, improper timber rotations, and over exploitation of timber resources. The plan has direction to address these stressors, which can be found in the Forestlands section of the Land Management Plan.

Plan Direction

The plan includes extensive direction for the management of forested habitats. The plan direction for forested lands was designed to provide for ecosystem integrity by including desired conditions, objectives, standards, and guidelines to provide the structure, function, composition, and connectivity to meet requirements of the 2012 Planning Rule and were designed to provide the key ecosystem characteristics needed by most wildlife in the plan area (U.S. Department of Agriculture 2012c). In most cases the plan component parameters were aligned with the estimated natural range of variability (NRV).

The plan direction for forestlands is organized by broad potential vegetation types (PVT) and within each broad PVT, they differ slightly within the three primary management areas. The plan provides direction for each broad PVT on the composition of forest dominance types, within stand conditions, stand density, stand size class distribution, and landscape pattern. Each of the desired condition above differ slightly within the three different management areas. Plan components for composition include desired conditions for the distribution of these forests also provide direction as to their pattern on the landscape (for example, MA1 and MA2-DC-FOR-06, MA3-DC-FOR-02, MA1 and MA2-DC-FOR-07, MA3-DC-FOR-04, MA1 and MA2-DC-FOR-08, MA3-DC-FOR-06, MA1 and MA2-DC-FOR-05, and MA3-DC-FOR-09). Even after harvest, desired conditions, standards, and guidelines provide measures for green tree retention and retention of snags and downed wood, to allow some of these species to continue using these areas after harvest. The plan also has a more flexible framework for dealing with wildfire that encourages the use of fire to achieve land management plan objectives more than the No Action Alternative has. While these changes will impact some of the species that use these habitats, many of them are common and abundant and are not of conservation concern at this time. Objectives include those targeting the restoration of white pine. The proposed plan components include measures to conserve old growth and protect some old growth types. The monitoring plan includes metrics to track the forestwide changes in size classes to achieve desired vegetation conditions. Objectives to restore vegetation conditions include measures to treat fuels and restore vegetation desired conditions that would help reduce susceptibility to uncharacteristic wildfire.

The plan provides plan components that ensure that mature closed forests will be present on the landscape. These plan components include FW-DC-FOR-05, FW-DC-FOR-08, FW-DC-FOR-11, FW-DC-FOR-12 which provide for 15- to 19.9-inch diameter at breast height (DBH) and 20-inch plus DBH size classes that would meet the needs of most species that use mature closed forest. Additionally, the plan contains components to ensure old growth is provided with MA3-STD-FOR-01, and MA2 and MA3-GDL-FOR-01.

Modeling Results

Modeling results from SIMPPLLE predict an overall decline in mature closed forest stands. This decline occurs in all alternatives. The source of that decline is complicated and includes changes occurring by dominance type, size class, density and by broad potential vegetation type (PVT), in which mature closed forest in some of these categories increase while others decline.

The modeling results from SIMPPLLE indicate a decline in dense mature forests for all size classes in the warm dry PVT. These systems are currently too dense relative to the natural range of variation (NRV) for this potential vegetation type. The largest decline is in grand fir closed mature dominance types as desired dominance types for these PVTs are lower than current conditions and treatments are expected to change grand fir dominance types into other dominance types over time. Declines also occur in closed mature forest in Ponderosa and Douglas-fir dominance types because these types would be managed for lower stand densities than they currently are and a change from higher density stands to open mature forest conditions is the expected outcome for these dominance types. Again, this trend is similar under all alternatives.

A decline is also predicted by the model in the warm moist potential vegetation type (PVT). This decline happens in the Douglas-fir, larch, white pine, grand fir, and grand fir and redcedar dominance types. Only Douglas-fir and larch and Engelmann spruce and subalpine fir dominance types increase. Perhaps the biggest driver of these changes is that they are converting to open stands according to the model. The main exception is in grand fir, where it appears that the open structure forest in this dominance type also declines. This may be because they are also converting to smaller size class stands and converting to other dominance types. The change in size class is influencing the change in closed mature forest.

The large size class and the very large size class appear to be increasing in this PVT. Many of the large mature closed forests appear to be maturing into very large mature forest classes. The medium size class of closed canopy forest declines because some trees mature into large and very large size classes while others could be converting from grand fir to another type. The decline is also influenced by dominance types where grand fir and redcedar dominance types are predicted by this SIMPPLLE model to decline.

In the cool moist PVT, the model results suggest an increase in closed canopy forest. Douglas-fir, Douglas-fir and larch, larch, and Engelmann spruce and subalpine fir mature to closed canopy forests. Two dominance types of closed mature forest decline in this PVT—the lodgepole pine and grand fir dominance types. The model predicts an increase in large and very large size classes of closed forests and a decrease in pole and medium sized closed forests as they mature in this PVT group. Overall, the trend is upward in this forest type. There is a concurrent shift away from open mature forests in these types within this PVT group. While there are slight differences, all alternatives predict a similar pattern.

In the cold PVT, the amount of closed forest overall decreases. Mature closed forests dominated by Douglas-fir increase slightly. Those dominated by lodgepole pine decrease heavily, while those dominated by Engelmann spruce and subalpine fir increase dramatically and whitebark pine decreases. These are influenced by a shift to open forest conditions. There is also a change in size class of closed forest in the cold PVT group. The decrease is greatest in the pole and medium size classes with increases in the amount of large and very large size classes of enclosed forests within these PVTs. For more information, analysis, and trends of these habitats, see the Forestlands section.

In the warm dry PVT, medium, large, and very large size classes of mature closed forests fall below the natural range of variation (NRV) in some alternatives. In particular, the medium size class falls well below NRV ranges in all alternatives, though some grow into large size classes while others experience disturbance and become early seral size classes. The large size class in the warm dry broad PVT falls below NRV in alternatives Y, X, W, and the No Action Alternative, but it stays within the NRV ranges in Alternative Z and the Preferred Alternative. The very large size class in the warm dry PVT increases in all alternatives from its current state below NRV. It increases to just below the lower boundary of NRV in alternatives X, Y, and W. Very large size classes in warm dry PVT increases to just above NRV in Alternative Z and the Preferred Alternative. See figures for warm dry PVT for medium, large, and very large size classes in Appendix B of this Final Environmental Impact Statement.

Several factors cause the trends in the warm dry PVT in the mature closed forest modeling environment. Factors include the warmer-drier climate conditions in the model, resultant increase in wildfire, an increase in projected root disease, tree succession growing into the next size class, the rapid increase in the amount of pole and seed-sapling size classes, and the conversion of some dominance types into other dominance types as a result of plan desired conditions. For example, current conditions for grand fir are higher than desired conditions in the warm dry, cool moist and warm moist PVTs so the model uses a variety of actions to convert grand fir types to other dominance types. The grand fir dominance types decline sharply in the Preferred Alternative forestwide and in the warm dry, warm moist, and cool moist PVTs. Grand fir dominance would be replaced by a combination of dominance types that include Ponderosa pine, larch, grand fir and cedar, and Douglas-fir and larch. As habitats change, the amount and distribution of wildlife species would change until mature forest regrows.

The effects, if the above predictions were to happen, is that habitats for species that use mature, closed canopy forests would decline forestwide. Species that might experience this decline include the Vaux's swift, the varied thrush, the piliated woodpecker, and the fisher. Habitat for these species would decline to near or slightly below the low end of NRV levels in the warm dry PVT type.

In terms of density, the model shows that forestwide mature closed forest stands stay relatively stable though the 5-decade timesteps. It increases slightly in the cold, and cool moist, but declines slightly in the warm moist and warm dry. Density trends are inconsequential for wildlife.

Open Mature Forest Habitats

Open mature forest habitats are mature forests that have lower tree densities providing open structure, that allows enough light to support the understory. Open mature forest conditions can occur in any of the broad potential vegetation types (PVTs) and each broad PVT can support species that tend to use open mature forest conditions. The factors that provide open mature forest differ between the broad PVTs. However, open mature forest is more common in some broad PVTs than others. Open forests are found in dry forest types at all stages of succession, particularly in the warm dry broad PVT group, where site conditions or disturbances maintain lower tree density. Open mature forest structure is a naturally occurring condition maintained by low intensity fire in some of the warm dry PVTs like Ponderosa pine. Cool moist or cold forests may also be found in this condition, particularly when impacted by disturbances, such as mountain pine beetle infestations or wildfire. They can also be in this condition where variation in site conditions is less than optimal resulting in lower density stands. Open conditions in warm moist types result from mixed severity fire or insects and disease. In the warm moist and cool moist broad PVTs, insects and disease or mixed severity fire promote lower tree density. Broad-leaved habitats can also result in open forest structures including in riparian areas where periodic or seasonal flooding acts as a disturbance agent lowering tree density. Other than where trees grow in naturally lower site potential, many lower density forests are the result of disturbance processes, and thus disturbance is an important factor in the production of open forest structure.

Some wildlife species often select structural characteristics, such as age class or density, rather than dominance types, species composition, or broad PVTs. Open mature forest habitats support high biodiversity, and some wildlife species are uniquely adapted or require these conditions. The preferred habitats for several species were described as open forests or open stands. These often-included descriptions of the use of a wide variety of conifer or mixed deciduous and coniferous forests. Thus, these species were grouped into the open forest habitat group, which referred to open mid seral to old forest with an open or lower density structure. Thinning treatments have been shown to increase wildlife biodiversity after treatments in the Northwest depending on thinning intensity (Verschuyl et al. 2011).

Wildlife species grouped into the open forest habitat group includes 22 species that specialize in this habitat. Examples include the white-headed woodpecker, Nashville warbler (*Leiothlypis ruficapilla*), western wood pewee (*Contopus sordidulus*), pine grosbeak (*Pinicola enucleator*), pine siskin (*Spinus pinus*), Cassin's vireo (*Vireo cassinii*), Lewis's woodpecker, violet-green swallow (*Tachycineta thalassina*), flammulated owl, pygmy nuthatch, Williamson's sapsucker, western tanager, western heather vole (*Phenacomys intermedius*), and Townsend's solitaire. The fringed myotis was also grouped into this habitat grouping because of the habitats where it occurs in the plan area, which is within Ponderosa pine forest. However, it should be recognized that this species could have been placed in other groupings as well, as it has a wide range of habitat both within and outside of the plan area. Other wildlife, as described below, also use open forest habitats conditions.

The number of species in the open mature habitat groupings suggest that open mature forests are important within several broad potential vegetation types (PVTs) and that managing for lower density mature forests in many PVTs may be an important management goal to provide for the diversity and abundance of wildlife. These results suggest that departures in density are an important source of departure for a wide range of broad PVTs and dominance types. Key characteristics of mature open canopy forests for wildlife include open structures with the presence of large live trees with periodic very large trees and snags, diverse and abundant understory, fruiting plants, a mix of tree species present in some types, abundant insect populations, and various amounts of vertical structure, depending upon the last disturbance event. Mast production from mast producing tree species is important for some species and larger mature trees produce more mast than younger trees. Mature open forests are assumed to produce these features naturally. However, stands that lack the features mentioned above, such as snags with cavities, trees with heart rot, periodic large and very large trees, and diverse understories, may not function to provide for some of these species. Of these species about 43.4 percent of those assigned to this group use snags and only about 8.6 percent use downed wood. Four species are associated with mast or seeds.

Warm dry broad PVTs dominated by Ponderosa pine occur within many places on the Nez Perce-Clearwater and are more prevalent in the southern half of the national forest than the northern half. They occupy drier sites in the large river canyons of the Salmon, South Fork Clearwater, Middle Fork Clearwater, Lochsa, and Selway rivers. They are also present on ridgetops forestwide. In pre-Columbian times, they were maintained by frequent low intensity fire that acted as a thinning agent and achieved open stand conditions with large trees that persisted through repeated disturbance events in many places. The 2014 Forest Plan Assessment found these habitats had been reduced through fire suppression. Early logging practices targeted the large Ponderosa pines as a lumber resource and these large trees are less common than they once were. The stands of Ponderosa have since been encroached by other tree species, the most prevalent of which is grand fir, leaving them susceptible to stand replacing events which were less common in pre-Columbian times. The 2014 Assessment evaluated these under biophysical settings rather than broad PVTs. The conclusions in the report suggest that encroachment increases as they move north and upward in elevation on these Ponderosa habitat types.

The Ponderosa pine systems support a unique suite of wildlife that are uniquely adapted to those systems, several of which have received conservation attention over time because of the trends of these habitats and because these species occur at low abundance naturally in some cases. Examples of species on the Regional Forester Sensitive Species (RFSS) list include the flammulated owl, white-headed woodpecker, pygmy nuthatch, fringed myotis, and mountain quail. The white-headed woodpecker and mountain quail are analyzed as species of conservation concern in this analysis. For many of these species, warm dry forests functioning with ecosystem integrity, that is when its dominant ecological characteristics, such as composition, structure, function, connectivity, and diversity, occur within the natural range of variation and would be sufficient to provide for these species.

Open forest conditions often support higher biodiversity because the open crown facilitates understory growth that is selected by many species. Because understory plants are often composed of deciduous shrubs and trees, deciduous species also use these types. Open forest conditions are sometimes used by species that use ecotones between open and forested habitats. So long as there are snags available, many mature closed forest species can also use these habitats. Open forest conditions are more likely to produce multi-storied stand structures because sunlight can penetrate the forest floor, allowing younger trees and later successional tree species to better grow in the understory. This complexity in habitats allows many species to thrive in these habitats. Open forests can provide for wildlife species in other habitat groupings as well, such as those grouped into the forest generalist, ecotones, substrate, riparian, and deciduous forest habitats; those that seek resources; and some in the non-forested or early seral groups. This increased diversity is apparent from studies evaluating the effects of wildlife diversity in response to thinning (Verschuyl et al. 2011).

Verschuyl et al. (2011) conducted a meta-analysis on 33 studies that evaluated the effects of thinning on wildlife diversity. A meta-analysis applies statistics to evaluate the effect size, or magnitude, combining data from multiple scientific studies. When the treatment effect or effect size is consistent from one study to the next, meta-analysis can be used to identify this common effect. The finding from Verschuyl et al. (2011) was that forest thinning treatments had generally positive or neutral effects on diversity and abundance across all taxa, although thinning intensity and the type of thinning conducted may at least partially drive the magnitude of response. Thinning produces a variety of short- and long-term changes to forest structure, the most obvious of which is a decrease in tree density and increase in forest canopy gaps and abundance and diversity of mid-story trees. The increased diversity may also be because of the development of more complex understory vegetation due to increased light availability below the canopy. Thinning can cause a more rapid return to conditions simulating older seral stages which can increase the number of species using the diversified habitat. These results included studies from the Pacific Northwest and represented a variety of forest types like lodgepole, aspen, coastal hemlock and fir, interior hemlock and cedar, and mixed conifer (Verschuyl et al. 2011).

Existing Condition

The current conditions across the Nez Perce-Clearwater indicate a trend away from open stand conditions because of wildfire exclusion, forest succession, management towards old growth conditions, even aged timber harvest, and avoidance of management to conserve some wildlife species, such as lynx, goshawks, and fisher.

Threats and Stressors to open Canopy Forests

Key threats to these habitats include forest succession; fire suppression, especially when followed by subsequent stand replacing fire; even aged forestry practices; invasive plant species displacing understory vegetation; and practices that result in a reduction of snags. Some reforestation practices, such as replanting at high densities after harvest, can create denser stands that may result in future closed forest stands that are denser than occurred under natural disturbances. Grazing may impact understories depending upon intensity.

Restoration Activities

Actions that can restore these habitats include thinning treatments with snag retention, wildland fire (for example, prescribed fire or wildfire managed for resource benefit), a combination of thinning and fire, weed treatment to maintain understory, uneven aged management, green tree retention during harvest, and variable retention harvest.

Plan Direction

The plan provides a description of desired conditions for densities in various broad potential vegetation types (PVTs), the presence of large and very large trees in all age classes, and a description of features like snags and downed wood desired to be present. The desired conditions also describe the landscape patterns of these habitats. Desired conditions address the landscape proportions of size classes by PVT in the plan area, which should ensure that some open forests occur in a variety of size classes. Forests functioning within the natural range of variation (NRV) will have variation in stand densities, with some stands in an open condition. The plan also includes language in the Forestlands section that stand density reflects historic fire regimes. Objectives include those targeting restoration of forest systems. The proposed plan components include measures to conserve old growth and protect some old growth types. Desired forest conditions, specifically for the warm dry PVT group, emphasize managing these systems towards functioning within the NRV for these types. The plan provides plan components that ensure that mature open forests will be present on the landscape. These plan components include those for size classes like FW-DC-FOR-05, FW-DC-FOR-08, FW-DC-FOR-11, FW-DC-FOR-12 which provide for 15- to 19.9-inch diameter at breast height (DBH) and 20-inch plus DBH size classes that would meet the needs of most species that use open forest. Additionally, the plan contains components to ensure old growth is provided with MA3-STD-FOR-01 and MA2 and MA3-GDL-FOR-01. Specific plan components addressing warm dry Ponderosa pine forest includes FW-DC-FOR-02 (structure and function), FW-DC-FOR-03 (composition), FW-DC-FOR-04, MA1-DC-FOR-01, MA2-DC-FOR-01, MA3-DC-FOR-01 (density), FW-DC-FOR-05 (structure, composition, function), and MA1 and MA2-DC-FOR-06/MA3-DC-FOR-02 (landscape pattern, composition, connectivity). A crosswalk of plan direction with open forest types, their key ecological attributes, and threats is provided in Appendix C.

Modeling Results

Between the Draft and Final Environmental Impact Statements, adjustments were made to SIMPPLLE model assumptions and pathways that resulted in a different model prediction of habitat conditions of dry forest-associated species. The updated modeling results suggest that stands of mature open structured forest are predicted to decline overall. The decline is most apparent in the cold and cool moist broad PVTs. The warm moist and warm dry broad PVTs dips then recover by the end of the fifth decadal timestep. These outcomes were derived from the full model outputs in all dominance types (Ecosystem Research Group 2021).

In the warm moist PVT, the pattern is a slight increase overall in open mature forest. The model predicts an increase in mature open forest in Ponderosa pine, Douglas-fir and larch, larch, and white pine and a large increase in open mature grand fir. It also predicts a decline in open mature Douglas-fir, grand fir and redcedar, and lodgepole pine and a large drop in Engelmann spruce and subalpine open mature forest types. As noted above, some of these forest dominant types are converting to mature closed forest while others are converting to early seral size classes.

In the cool moist broad PVT, open mature forests decline in Douglas-fir, Douglas-fir and larch, and grand fir; drop drastically in lodgepole pine; and decline in Engelmann spruce and subalpine fir. This once again appears to be the result of forest succession changing mature open forest for mature closed forest and large and very large size classes into small size classes. In this PVT, the large and very large size class are predicted to decline while lodgepole pine is expected to increase.

In the cold PVT, the amount of open mature forest is expected to decline. Declines occur in Douglas-fir and Engelmann spruce and subalpine fir but are expected to increase in lodgepole pine and whitebark pine. Some forest dominant types increase in density from open mature to closed mature forest. In other cases, the stands convert to smaller size classes and other dominance types. For more information about these trends see the Forestlands section.

The Ecosystem Research Group conducted a wildlife specific query for the warm dry Ponderosa pine systems, specifically for Ponderosa pine associated species. This query might also provide some habitat for the fringed myotis. As there is much overlap in the habitats for these species, the Ecosystem Research Group combined the SIMPPLLE query to predict future conditions in the Nez Perce-Clearwater by alternatives into one query expanded over a range of size classes to represent all of these dry forest associated species. This query was meant to evaluate habitat parameters for the white-headed woodpecker, flammulated owl, Lewis's woodpecker, and pygmy nuthatch, as these species were identified as potential species of conservation concern in the 2014 Assessment (U.S. Department of Agriculture 2014k).

The 2014 Assessment evaluated the natural range of variation (NRV) for several Ponderosa associated species and nearly all of them were near or below the lower boundaries of the NRV (U.S. Department of Agriculture 2014k). Current conditions for white-headed woodpecker and Lewis's woodpecker habitats were both below their NRV, while the flammulated owl and pygmy nuthatch was at the low end of their NRV.

We modeled a subset of the warm dry broad potential vegetation type (PVT) to predict the change in large diameter Ponderosa pine dominated dry forest habitat because of concerns for the white-headed woodpecker and several other species receiving conservation attention associated with the park-like open structure of Ponderosa pine forest that is maintained by periodic low intensity fire. A description of the query and the model outcome are described in detail in (Ecosystem Research Group 2021).

The query for dry forest associated species assumes that highly suitable nesting and foraging habitat is limited to forested stands with an average of greater than 15 inches diameter at breast height (DBH). To address the nesting habitat needs of flammulated owls (open forest), the nesting and foraging needs of white-headed woodpeckers (open and closed forest), and the nesting needs of pygmy nuthatches (closed forest), the model tracks the availability of large diameter stands in both open (less than 40 percent canopy closure) and closed (greater than 40 percent canopy closure) forest conditions. Based upon Forest Inventory and Analysis (FIA) data, forests with an average diameter greater than 15 inches DBH contain sufficient snags to provide habitat for the species that excavate nesting cavities. SIMPPLLE logic pathways show that dense stands of potential habitat (stands greater than 40 percent canopy closure) will convert to highly suitable habitat (stands less than 40 percent crown closure) if treated by under-burning, are burned by low-to-moderate severity wildfire, are attacked by Douglas-fir beetles, or are harvested or commercially thinned to remove understory and mid-story trees. At a home range scale, timing of treatments would be designed to create a mosaic consisting of mature forest and dense understory patches of small trees, shrubs, and openings.

The query design for dry forest associated species habitat includes the following layers:

Cover types: all cover types within the following habitat groups that include either Ponderosa pine or Douglas-fir including mixed stands that contain large Ponderosa pine and Douglas-fir.

- A2, warm and very dry Ponderosa pine/Douglas-fir
- B1, warm and dry Ponderosa pine/Douglas-fir
- B2, moderately warm and dry Ponderosa pine/Douglas-fir/grand fir
- C1A, moderately warm and moderately moist Douglas-fir/grand fir

Tree size class: greater than 15-inch DBH including Break-out by diameter class and dominance type.

- 15–19.9-inch DBH—All dominance types
- 15-19.9-inch DBH—Ponderosa pine dominance type
- 20+ inch DBH—All dominance types
- 20+ inch DBH—Ponderosa pine dominance type

Canopy cover (tracked separately as open or closed):

- Stands of 15–39.9 percent canopy cover
- stands of greater than 40 percent canopy cover

There are 628,584 acres of Ponderosa pine dominated dry forest habitat (all size classes) on the Nez Perce-Clearwater National Forest. Habitat for dry forest-associated species, stands containing large and very large size classes, currently totals 179,179 acres, representing 29 percent of potential habitat on the national forest. Under the Preferred Alternative, Ponderosa pine dominated habitats increase strongly in the warm dry potential vegetation type (PVT) as well as other broad PVTs. Ponderosa pine dominated habitats increase in Management Areas 1,2, and 3 as well. The overall increase should benefit species associated with Ponderosa pine habitats.

Stands with mature trees in an open structure are a key ecological attribute for species associated with Ponderosa pine dominated forests. The plan includes proactive measures to increase the amount of lower density, mature Ponderosa pine habitats (for example, FW-DC-FOR-03, FW-DC-FOR-05 and MA3-OBJ-FOR-01). Despite these measures, the model predicts a decline in mature open warm dry Ponderosa pine dominated forests. There would be a decrease in open dry forest habitat under all alternatives over the five decades.

Over the five decades modeled, there would be an increase in closed dry forest habitat (Ponderosa pine/Douglas-fir/grand fir) under the No Action Alternative and Alternatives X and Z and a decrease in this forest type under Alternatives P, W, and Y. The modest shift from closed to open forest under Alternatives P, W, and Y suggests that vegetation management activities are contributing positively to this shift in stand structures and suggests that long-term habitat sustainability is improving. These modeled outcomes suggest that habitat for dry forest-associated species such as the flammulated owl, white-headed woodpecker, and pygmy nuthatch is not being placed at risk by these management alternatives. Keep in mind that the query measures open and closed canopy closure rather than stem density, and as forests mature, the canopy naturally closes as crowns branch out, even when the stem densities are lower. The model does not represent an absolute decline in open Ponderosa pine mature structure, simply a closing of the canopy as trees expand their crowns. Note that large and very large size classes in the warm dry broad PVT are expected to remain within the natural range of variation (NRV) (see Appendix B for large and very large size classes within the warm dry Broad Potential Vegetation Type), and that plan components in the warm dry suggest more Ponderosa pine and a desire to have an increase in larger and very large diameter size classes (FW-DC-FOR-03 and FW-DC-FOR-05).

The SIMPPLLE modeling results predicted that open forest habitats for these species continue to decline over the five-decade period modeled for Ponderosa pine dominated dry open forest and closed dry forest types. The declines vary slightly by alternative, as shown in Table 173. These results seem counter-intuitive since all alternatives emphasize restoring large, open stands of Ponderosa pine. Declines in habitat are likely due to much higher levels of high severity wildfire, attributable to 70 years of accumulating fuels from successful past wildfire suppression. While the modeled decline of this habitat is alarming, the fact that the decline within wilderness and inventoried roadless areas is no less that that within National Forest-Other Management Areas suggests that the decline is both inevitable and unavoidable due to long-term fuel accumulations resulting from fire suppression. This is consistent with thinking within the scientific literature that these habitats are vulnerable (Wisdom et al. 2000a;b;c). Another source of the change in the model is that early seral size classes increase across the warm dry PVT and that affects the amount of mature open and closed forest (See Appendix B Figure 39).

The time horizon of the model is not long enough to show the long-term outcomes of the plan on dry Ponderosa pine forest. Essentially, the model attempts to increase Ponderosa pine dominance and that does occur, but the time horizon that it takes to grow mature Ponderosa pine trees is longer than the 50-year analysis window presented and even longer than the 150-year future projection. Furthermore, the range of treatments available in the modeling environment and the way those treatments were applied in the model do not match the range of conditions on the ground, and the treatment options available to practitioners in reality. For example, the model bases its decisions for treatment on dominance type but is not sophisticated enough to recognize the complexity of stand composition. In the model for example, a stand might be identified as grand fir dominant and the prescription in the model was to treat grand fir with a regeneration treatment to change the dominance type which results in an early seral condition in the model. In reality, practitioners might recognize Ponderosa pine as a component in the stand and apply a treatment to remove the grand fir but leave the Ponderosa pine resulting in a stand that is open in structure and dominated by mature Ponderosa pine trees.

Data Source: SIMPPLLE modeling

Modeling results substantiate findings within published wildlife research which suggest that the Ponderosa pine ecosystems have been and continue to have a declining trend (Wisdom et al. 2000c, a, b) due to activities such as suppression of wildfire and timber practices. Wisdom et al. (2000c, a, 2000d) suggested that low elevation old forests were changed from low density forests maintained by low intensity fire into more dense stands invaded by species such as Douglas-fir and grand fir because of fire suppression. Timber harvest practices changed these systems to mid-seral age classes. In its current condition, these habitats are more susceptible to stand-replacing fires and increasingly vulnerable to insect and disease related tree mortality (Wisdom et al. 2000b, c, a). Wisdom et al. (2000b, c, 2000d) estimated that source habitats for low elevation old forest had declined in 70 percent of watersheds within the Columbia River Basin between the historical and current periods, including a decline in watersheds in the plan area. Under all alternatives, the modeling predicts another 25 to 39 percent decline in these habitats, which is a trend against the potential long-term persistence of Ponderosa pine associated species.

These conditions and trends may require active management to restore more desirable forest structure and composition. These results may indicate the actions modeled are not progressive enough or do not take the appropriate actions to increase or maintain open mature forests in this broad potential vegetation type (PVT). The model represents a simplification of a complex process and could be based upon questionable assumptions. The modeling represents change on the Nez Perce-Clearwater under a warmer drier scenario with an assumed greater amount of wildfire. The model is using a combination of wildfire, prescribed fire, and silvicultural prescriptions to change dominance types and increase the amount of early seral habitats. Keep in mind, the outcomes are a result of the fact that the model used wildfire or prescribed fire and disease in Management Areas 1 and 2 to trend back towards the natural range of variation (NRV). If the assumptions about how these systems burn are correct, then this may represent a useful estimate of future trends. In areas where timber harvest is allowed, stands may need to be thinned or thinned and burned to decrease grand fir while retaining Ponderosa pine instead of using even aged management to convert dominance types.

Burned, Diseased, and Insect Infested Forested Habitats

Only two species were grouped into this habitat subgrouping. They include the black-backed woodpecker and American three-toed woodpecker. Both species have been the subject of conservation interest. The black-backed woodpecker is a Regional Forester Sensitive Species (RFSS) in the Northern Region, while the American three-toed woodpecker is a RFSS in the Intermountain Region. Burned and insect infested trees are the primary habitat of the black-backed woodpecker and the American three-toed woodpecker. These two species seek out and exploit these disturbed areas for insects. While uncommon except in disturbed areas, there is no significant decline in the populations of these two species according to the Intermountain Bird Conservatory long-term trend monitoring of bird populations.

Since these habitats are ephemeral, they require periodic fires and disease or insect outbreaks to persist. A number of snag dependent species could have also been included in this group but better fit in other habitat groupings. Snags are analyzed as a key ecological characteristic of forested habitats.

The key indicators for these species include the amount of disturbance from fire, insects, and disease under the plan. There are no species-specific plan components designed for these species. However, a couple factors contribute to habitat for these species. Natural amounts of root rot, insect outbreaks, and fire all contribute to habitat for these two species. Fire suppression is perhaps the biggest threat to this habitat group.

Existing Conditions and Trends

Several large fires, insect outbreaks, and disease events have affected much of the conifer forest on the Nez Perce-Clearwater. These disturbance events have created large areas of disturbed habitat that have provided habitat for species in this subgrouping. The trends of these conditions are dependent upon the weather and moisture conditions. Under a future climate, which is projected to be warmer and drier, there should be increased incidences of wildfire, insect outbreaks, and disease. Therefore, the trend is upward. Compared to conditions in the past, current conditions in the plan area for disease and insect infestations are more prevalent than they were under natural disturbance because the dominance types have shifted towards species more susceptible to disease and climatic conditions have facilitated infestations of bark beetles and other tree damaging pests. Burned forests are probably less abundant than they were historically because of fire suppression.

Threats and Stressors

Burned, diseased, and insect infested habitats are modified through forest activities, such as salvage logging and treatments to reduce root rot. Other factors that affect the amount of these habitats include fire suppression. These habitats otherwise have few threats.

Restoration Activities

There are no restoration activities to enhance insect and disease habitats. Usually, projects seeking to restore forests are designed to reduce these habitat types or harvest lost timber. However, prescribed fire can create habitats used by species that use burned forests.

Plan Direction

The plan does not have species specific components for these species. In general, the goal of the plan is to increase fire disturbance, change dominance types, and make the national forest less prone to disease and insect outbreaks. Plan components in the Forestlands section include measures to restore size class distribution, within stand characteristics, density, and landscape patch and pattern. This includes plan direction to increase the amount of young size classes while, at the same time, increasing stands of large and very large size classes. Combined plan direction will aim to reduce susceptibility to insects and disease but increase burned forest.

Another overarching goal of the plan is to restore fire adapted ecosystems. The plan contains objectives for burning to restore structure, function, composition, and connectivity of forests. Plan components in the Fire Management section seek to facilitate the use of wildland fire to restore natural disturbance.

The plan does not contain components prohibiting or restricting salvage harvest. See the Land Management Plan for plan components that pertain to the soils resource and timber. These plan components are meant to facilitate the Nez Perce-Clearwater's ability to respond to abundant insects and disease outbreaks and timber lost to fire. Insect and diseased forests and burned forest will still be present on the landscape despite these measures because salvage harvest is often not possible because the terrain is too steep and landslide prone and because of delicate soil conditions. Many burned areas of the Nez Perce-Clearwater will occur in wilderness and Idaho Roadless Rule areas. These activities are either prohibited within wilderness and some Idaho Roadless Rule area themes or not accessible from existing roads in Idaho Roadless Rule areas where this activity is allowed.

Modeling Results

The SIMPPLLE model was used to model trends in burned forests for species such as three-toed woodpeckers and black-backed woodpeckers. Fire assumptions and calibration were adjusted between the Draft and Final Environmental Impact Statements. The query design for burned forest-associated species considers only recent burns less than 10 years old and included the following:

Habitat Type Groups: all habitat groups (excluding high elevation alpine cover types WB, WB-ES-AF, and AL-WB-AF) including:

- A2, warm and dry
- B1, warm and dry
- B2, warm and dry
- C1A, warm and dry
- C1B, warm and dry
- C2, warm and moist
- C3, warm and moist
- D1, warm and moist
- E1, warm and moist
- D3, cool and moist

Pre-disturbance tree size class greater than 10-inch diameter at breast height (DBH) including:

- 10–14.9-inch DBH
- 15–19.9-inch DBH
- greater than 20-inch DBH

Pre-disturbance canopy cover greater than 15 percent including:

- less than 15 percent
- 15–39.9 percent
- 40–69.9 percent
- 70–100 percent

The query for this species guild was limited to burned forest of medium, large, and very large forest for only 10 years following the burn. That short timeframe was incorporated to address the needs of the black-backed woodpecker. This substantially limited the number of acres meeting those criteria. For other fire associated species like mountain bluebirds (*Sialia currucoides*) or olive-sided flycatchers (*Contopus cooperi*), which use burned areas for longer periods, the acres modeled in this analysis must be considered very conservative. Differences between alternatives and management areas are not significant.

It is difficult to compare burned acres against natural range of variation (NRV) for several reasons:

1. Fire Return Intervals (FRIs) vary across the Nez Perce-Clearwater from very short in the warm dry potential vegetation type (PVT) to very long in the cold PVT. Simplistically, if we assumed a 50-year forestwide average FRI, recognizing the Nez Perce-Clearwater's predominance of warm dry, warm moist, and cool moist PVTs, that might suggest that 20 percent or roughly 600,000 acres would be available per decade for black-backed woodpeckers and other fire-associated species.
2. Warm dry and warm moist PVTs tend to burn at low or mixed severities. Those lower severity wildfires typically do not provide habitat for fire-associated species. Consequently, the aforementioned 20 percent NRV estimate is unrealistically high.

3. Moderate and high severity wildfires only provide black-backed woodpecker habitat within stands 10 inches diameter or greater. Thus, fires burning in seedling and sapling or pole-sized stands, or double burns that occur within previously burned stands contribute no habitat for that particular species further suggesting the aforementioned 20 percent estimate is too high.

Considering all those factors, the range of habitat provided by the alternatives over five decades may not be much below mean NRV. More importantly, from a species viability standpoint, moderate and high severity wildfires are clearly increasing due to a combination of accumulating fuels resulting from wildfire suppression and warmer, drier weather. As discussed in Chapter 2, fire-associated species like the black-backed woodpecker occur at high densities in recent burns, despite the habitat bottleneck that was generated by the absence of wildfires in the years from 1930 to 2000. SIMPPLLE-modeled vegetation outcomes suggest that medium, large, and very large size classes will remain abundant, albeit at more open stand structures. Consequently, there will be no interruption of potential burned forest habitat on the Nez Perce-Clearwater. The amount of burned forest remains relatively stable over the five decadal timesteps (Figure 60).

Modeling in SIMPPLLE indicates that the Nez Perce-Clearwater will undergo sufficient fire and disease episodes over the next 50 years. The trend from the specific query for burned forests suggests that burned forest will increase across the five-decade period. The model predicts, based upon its assumptions and parameters, that many acres will be burned in the first decade and that the amount of burned forests increases dramatically. In the following decades, the amount of burned forests declines through time after the first decade. The trends in all alternatives are similar. So, while susceptibility to insects and disease declines, the amount of burned forests available for these species will increase. These trends should allow species that rely on burned forests to persist long-term. Trend in burned forest acres by alternative.

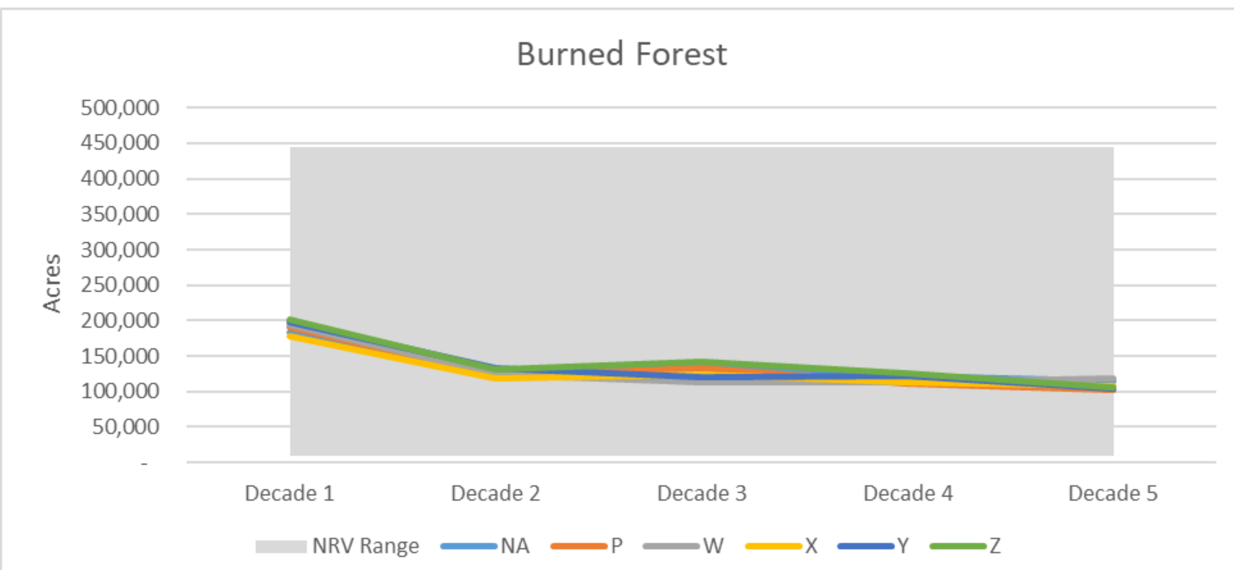

Figure 60. Trend in burned forest acres by alternative

Summary of Environmental Consequences to Forested Wildlife Habitats from Plan Components of Other Resources

Table 176 provides a summary of environmental consequences by resource area, whether there are adverse environmental consequences, and explanation of effects.

Table 176. Environmental consequences to forested wildlife habitats from plan direction

Resource Area	Adverse Environmental Consequences	Explanation
Terrestrial Ecosystems	No	No effect
Biophysical Features	No	No effect
Forested Lands	Yes	Larger size classes of mature forest, both open and closed, expected to decline. Early seral forest expected to increase. However, large and very large trees should increase across the plan area. Some timber management practices may reduce snags in some areas.
Carbon Storage and Sequestration	No	No effect
Meadow, Grassland, and Shrubland	No	No effect
Fire Management	Yes	Fires will still be suppressed, especially in Management Area 3. Plan components should provide for more management of wildlife fires for resource benefit compared to the 1987 Plans. Wildfire is the biggest source of disturbance according to the models. The Nez Perce-Clearwater may burn more under additional fuel and warmer climates. This would shift some forests to younger age classes despite management towards mature and old forests and towards very large and large trees. Fires are needed to trend towards the natural range of variability. Some areas around structures and roadways may lack snags as a result of plan direction.
Invasive Species	No	No effect
Soil Resources	Yes	Plan direction may prevent some forest habitats from being restored by some methods because of soil protections. The emphasis in protecting the soils is critical for future forest conditions.
Aquatic Ecosystems	Yes	Some management activities to restore forest ecosystems would be prevented by plan direction.
Water and Aquatic Resources	Yes	Some management activities to restore forest ecosystems would be prevented by plan direction.
Conservation Watershed Network	Yes	Some management activities to restore forest ecosystems would be prevented by plan direction.
Riparian Management Zones	Yes	Some management activities to restore forest ecosystems would be prevented by plan direction.
Infrastructure	No	No consequences
Lands and Special Uses	Yes	Plan direction may shift special uses, such as utility lines and infrastructure, upland into forested habitats.
Recreation	Yes	Plan direction may shift recreation trails and facilities upland into forested habitats.
Wildlife	Yes	Plan direction for Canada lynx would make management towards the natural range of variation more difficult in cool moist and cold potential vegetation type groups. This would result in further departures and potentially uncharacteristic fire. Plan direction for fisher would require consideration of landscape configuration.
Multiple Use Wildlife	No	No consequences
Multiple Use Elk	Yes	Some management would be directed towards improving elk habitat in areas with higher site potential. Some of these forests

Resource Area	Adverse Environmental Consequences	Explanation
		would shift towards early seral conditions, which may reduce mature forest.
Air Quality	Yes	Plan components for air quality may sometimes restrict the use of prescribed burning to achieve forest restoration.
Tribal Trust	No	No consequences
Cultural Resources	No	No consequences
Municipal Watersheds	No	No consequences
Sustainable Recreation	Yes	Some recreation may disturb wildlife habitats and spread invasive plant species, and motorized roads and trails may fragment forest habitats.
Scenery	Yes	Management direction in scenery may alter some projects designed to restore forest habitats.
Public Information, Interpretation, and Education	No	No consequences
Land Ownership and Land Uses	Yes	Plan may facilitate infrastructure development in the plan area.
Suitability	Yes	Some types of management towards achieving forest desired conditions may be prevented in some areas labeled as not suitable.
Timber	Yes	Timber management has the potential to reduce snags, coarse woody debris, and mature open and closed forest while increasing early seral habitats. Guidelines for snags and downed wood in the Forestlands section should retain some snags. Timber management direction allows liberal salvage operations, which could have impacts to burned forest. This could reduce some burned forest and dead tree habitat but not all. Reforestation practices can result in denser stands, which may decrease the chances for open mature forest structure. Fire would not be a preferred tool in areas suitable for timber production. These effects would be most apparent in Management Area 3.
Energy and Minerals	Yes	Mineral and energy activities under the plan may impact or fragment forest habitats for wildlife.
Livestock Grazing	Yes	Direction for grazing may affect some early seral habitats. Effects should be temporary and minor.
Special Forest and Botanical Products	Yes	Plan direction facilitates collection of firewood along roadways. These activities can reduce downed wood and snags important for forest wildlife.
Designated Wilderness	Yes	Plan direction for wilderness would facilitate wildfire to change forest habitats.
Wild and Scenic Rivers	No	Plan direction for wild and scenic rivers provides some restrictions on vegetation management. Some projects may be altered or prevented due to restrictions within wild and scenic rivers.
Lolo Trail National Landmark	Yes	Plan direction would direct management to be achieved through prescribed fire or wildland fire use.
Recommended Wilderness	Yes	Identification of recommended wilderness would convert some lands into more restricted Idaho Roadless Rule area themes, which would restrict the ability or means to achieve a trend towards the natural range of variation. Wildland fire use would be required to achieve desired conditions in recommended wilderness.

Resource Area	Adverse Environmental Consequences	Explanation
Idaho Roadless Rule Areas	Yes	Management direction in some Idaho Roadless Rule themes would restrict the means to achieve desired conditions and the purposes for why it is proposed.
Research Natural Areas	No	No consequences
Geographic Areas	No	No consequences
Gospel-Hump	No	No consequences
Lower Salmon	No	No consequences
Pilot Knob	No	No consequences
Special Interest Areas	No	No consequences

Forest Understory Habitats

Some species are associated with understory habitat conditions. These are key characteristics of forested habitats. Understory habitats are important in all forested habitat groups. These species include the snowshoe hare, Swainson's thrush, common yellowthroat (*Geothlypis trichas*), western heather vole, and blue-headed vireo. Snowshoe hares have been associated with horizontal cover, which in many cases measures forest understory. The heather vole is associated with evergreen ground cover. Swainson's thrush habitat could be described as mature forest, but understory vegetation is emphasized as important. The common yellowthroat occurs in many habitats, but the common thread is that it requires dense growth of low vegetation. It could be said that forest understory is probably important for many species in the deciduous forests, the open forests, and the closed forests. Forest understory tends to be associated with site conditions and understory dominant plants are often associated with habitat type groups. The condition or abundance of understory can be affected by the amount of light penetrating to the forest floor. Understory vegetation can decline or change through time as the canopy closes. Thus, the quality or abundance of understory habitats in many cases are dependent upon lack of overstory canopy. Thus, they are often disturbance dependent. Duguid and Ashton (2000b) evaluated a meta-analysis on the effects of forest management on understory vegetation. Across 96 studies, they found no consistent effects on understory species' richness from forest management for timber. Thinning or uneven aged management increased understory diversity. Where regeneration harvest showed no effect on species' richness, stands in later successional stages showed a decrease in understory species richness compared to unlogged stands. Their research suggested that site characteristics had more influence than timber management. Forests with better site characteristics have more abundant and diverse understories. Forest understory vegetation is usually more abundant along forest edges with non-forested habitats and in early seral forests. Understory plants do well along riparian areas and in disturbed forests.

Ecotone, Forest Edge, or Forest Mosaic

It has long been known that many wildlife species prefer to use ecotones. An ecotone is a transitional area of vegetation between two different plant communities, such as forest and grassland. In examining the descriptions of habitats preferred by the species that occur on the Nez Perce-Clearwater, it became clear that many species select ecotones as key habitat features. The species were grouped into the ecotone, forest edges, or habitat combinations habitat grouping if the description of their habitats included features such as both open and forested habitats, if they required trees for breeding but open habitats for other phases of their life cycle, or if they preferentially use forest edges as selected habitats. A total of thirty-one species were grouped into this habitat grouping and analyzed with respect to how the plan provides for these species. A list of species and their habitat descriptions can be found within Appendix C. Examples of species in this group include wild turkeys (*Meleagris gallopavo*), black-billed magpies (*Pica hudsonia*), mourning doves (*Zenaida macroura*), the short-tailed weasel, the northern flicker, northern saw-wet owl, olive-sided flycatcher, and ungulates like elk, deer, and moose. While they might have variation in their habitat needs, the common feature they all use are ecotones.

Ecotones have a higher biological diversity because species that use either habitat type can occur along with species that select ecotones as preferred habitat and species that require both adjacent habitat types within their home range. The presence of species from non-forested vegetation, early seral habitats, and forest species can therefore all be present near or on edges.

Ecotones can be natural or created by disturbances. In limited places on the Nez Perce-Clearwater, natural meadows form a natural mosaic with forests that provides ecotones, but these situations are less common because conifer forests dominate across wide areas of the Nez Perce-Clearwater. More commonly, ecotones are created through disturbances that create early seral conditions next to older age classes. Thus they are disturbance dependent habitats. Under natural disturbance, these situations are created through wildfire; insects and disease; and windthrow. The size, shape, and configuration of ecotones were influenced by the configuration of biophysical features, such as slope, aspect, and topographic position and the size, shape, distribution, and intensity of fires burning under varying conditions. Natural fires started burning under cool or wetter conditions, burned at low intensity, and remained small. These types of burns were frequent and common. When conditions became warmer or drier and weather conditions favored fire, fire starts burned hotter and larger. Yet, even when this happened, many areas of the Nez Perce-Clearwater burned in low or mixed severity fires.

Fires can burn at a variety of intensities, creating variable sized patches with irregular edges, feathered edges, completely burned areas, or patches of unburned trees and thinned forest, all of which produce a variable landscape. Furthermore, some tree species are capable of surviving fire well and patches often contain large and very large trees, even when in an early seral stage (Hessburg et al. 2015). Over time and wider spatial scales, this disturbance pattern created heterogeneous forest conditions with many forest edges of various age classes and dominance types influenced by topography. These characteristics should be considered key characteristics of patch dynamics at the landscape scale.

After European settlement, fire suppression and timber management changed this pattern at the landscape scale. Small fires were quickly put out and larger fires were contained. Over time, this changed the pattern at which these disturbances occur. Furthermore, timber harvest altered the size distributions, shapes, and spatial arrangements of successional patches (Hessburg et al. 2015). In cool, mesic mixed-conifer forests, where dispersed clear cuts were emphasized, successional patches were bisected by plantations, which were often smaller than natural disturbance events by order of magnitude.

Timber management in drier types removed fire tolerant tree species and the subsequent growth resulted in more homogenous stands and subsequent regeneration and release of shade-tolerant conifers, which increased the patch size and abundance of dense, multistory forest conditions (Hessburg et al. 2015). In many areas, livestock grazing removed fine fuels and reduced fire frequency, further contributing to fire exclusion. The pattern observed in modern-day managed pine and mixed conifer landscapes is largely the result of stand management, roads, livestock grazing, and fire exclusion, which is now being altered by wildfires that often defy suppression efforts during extreme weather conditions (Hessburg et al. 2015). These conditions drive forest patch and patterns into larger and more severe disturbances.

Natural meadows, grasslands, and persistent shrub areas contribute to habitat ecotones. These features exist today like they did prior to European settlement but their boundaries have been encroached by trees and smaller openings have disappeared (Hessburg et al. 2015). This change has been the result of a lack of disturbance in these locations. Some areas of the Nez Perce-Clearwater have mollisol soils, which form under prairie or grasslands over long time periods. Many of these mollisols are currently forested, but the presence of mollisols is an indicator that was not always the case.

Of species in the ecotone, forest edge, or mosaic habitat group, seven use snags or dead parts of live trees and four use downed wood as habitats. The species that use snags include the olive sided flycatcher, mountain bluebird, northern saw-wet owl, hoary bat (*Lasiurus cinereus*), northern flicker, great gray owl, and western blue bird. Those species that use downed wood include a different suite of species, including the red-tailed chipmunk (*Neotamias ruficaudus*), short-tailed weasel, American pygmy shrew (*Sorex hoyi*), and dusky or montane shrew (*Sorex monticolus*). This underscores the importance of these features along edges. From an ecological perspective, in many cases, snags are sometimes more abundant near ecotones for a couple reasons. First, fires kill and leave trees standing on the edges of patches or trees are left alive but die later due to damage. Secondly, where natural persistent meadows occur, the soils and ecological conditions are often less optimal for tree growth and habitats are often in the margins when trees grow in these habitats and trees tend to be less healthy growing here.

Some population trends of birds that were grouped into the Ecotone, Forest edge, or Forest Mosaic habitat group are available from the Intermountain Bird Observatory data accessed on March 24, 2023. The stratum queried was the Idaho BCR10 regional stratum. There are population trends for 21 birds that use ecotone habitat of which 14 are declining and 6 are increasing. Some declining trends have large variation in the data which should be viewed with discretion. Four declining species have large variations in the data such that the trends are less reliable and include the lark sparrow (*Chondestes grammacus*), western kingbird (*Tyrannus verticalis*), ring-necked pheasant (*Phasianus colchicus*), and the merlin (*Falco columbarius*). The lark sparrow, ring-necked pheasant, and merlin are uncommon birds on National Forest System lands which accounts for the wide variation in the trend data. That leaves 11 species with sufficient data for reliable trend inferences. Of those with reliable data, five species have declined by more than 20 percent annually, one has declined by 16 percent, and five have declined less than 5 percent per year over 13 years of data collection. In general, these are stronger declines than those in the forested habitat groups. Ecotone habitats rely in part on disturbance to create or maintain edge or ecotone habitats and the higher rate of decline regionally may indicate a decline in the quality or abundance of forest edge or ecotone habitats.

Hessburg et al. (2015) recommended seven principles to restore the fire prone landscapes of the Pacific Northwest. Five of the recommended principles speak to landscape pattern and patches as follows:

- **Principle 1:** Regional landscapes function as multi-level, cross-connected, patchwork hierarchies.
    - ♦ Implication: Conduct planning and management at appropriate scales to effectively restore multi-level landscape patterns, processes, and dynamics.
- **Principle 2:** Topography provides a natural template for vegetation and disturbance patterns at local landscape, successional patch, and tree neighborhood scales.
    - ♦ **Implication:** Use topography to guide restoration of successional and habitat patchworks.
- **Principle 3:** Disturbance and succession drive ecosystem change.
    - ♦ Implication: Move toward restoring natural fire regimes and the variation in successional patterns that supported them so that other processes may follow.
- **Principle 4:** Predictable patch size distributions historically emerged from linked climate-disturbance-topography-vegetation interactions.

- ♦ Implication: Move toward restoring size distributions of historical successional patches and allow changing climate and disturbance regimes to adapt them.

- **Principle 5:** Successional patches are "landscapes within landscapes."
  - ♦ Implication: In dry pine and dry to mesic mixed-conifer forests, restore characteristic tree clump and gap variation within patches.

Changes in landscape pattern are an important source of departures from the natural range of variability. Landscape patterns of patches and disturbances influence the abundance and distribution of species that use ecotones. They may also influence the connectivity of habitats for some species. For example, a homogenous landscape of mature forest might influence connectivity for land-based species that use early or non-forested habitats.

It should be noted that not all wildlife species benefit from ecotones. Some species that use interior forests can be adversely affected by an increased forest edge. Similarly, some studies have shown that brood parasitism increases in songbird nests along edges for the brown-headed cowbird (*Molothrus ater*). Highly fragmented landscapes can reduce overall wildlife diversity. Therefore, it is appropriate to have the size and shape of habitat patches configured similarly to how they were under natural conditions.

Existing Condition

Conditions in the plan area for landscape patch and pattern are departed from historical conditions like the departures described by Hessburg et al. (2015) above. Some areas of the Nez Perce-Clearwater are more departed than others when it comes to patch size and pattern. Wilderness areas have been allowed to burn more naturally since it was created, and these areas are more similar to the natural range of variation than the rest of the national forest. Many small fires burn frequently with periodic larger fires that overlap in extent with previous fires driving conditions back towards a more natural patch pattern. The managed front in Management Area 3 is the most departed because it has been managed to reduce the loss of timber resources from fire and timber harvest practices have favored more homogeneity and larger patches. Idaho Roadless Rule areas are departed at an extent somewhere between wilderness and managed front areas.

Restoration Activities

Restoration activities may include wildland fire (prescribed fire; wildland fire use); mechanical treatments and fire surrogates; and timber harvest. There are no objectives specific to restoring patch and pattern per se, but restoration following the desired conditions should lead managers to design projects that should help restore the landscape patch and pattern to provide for a variety of wildlife.

Plan Direction

To address this important aspect of departure in the plan, plan components for terrestrial vegetation contain language attempting to incorporate some of the principles outlined by Hessburg et al. (2015). See Sections 2.1.1, 2.1.3, and 5.1 of the Land Management Plan for plan components that pertain to terrestrial ecosystems, forestlands, and timber. More information is available in the Forestlands section about patch size. Desired conditions for proportions of size classes, along with those for landscape patch and pattern and maximum allowed size of regeneration harvest, should provide for a variety of wildlife species, including those associated with forest edges. Plan direction for patch and pattern and ecotones does not vary by alternative but the tools available, such as timber harvest, prescribed fire, and wildfire managed to achieve land management plan objectives, differ by land allocation where some tools cannot be used in some land types or are emphasized differently by land type. For example, timber harvest is the preferred tool in Management Area 3, whereas natural disturbance is generally the only tool allowed within wilderness.

Modeling Results and Predicted Outcomes

Patch size and distribution was modeled twice, first by Ecosystem Research Group with a simplified query, and second analysis was conducted by the Forest Service in conjunction with researchers from Rocky Mountain Research Station to produce a more robust and intensive analysis of patch size and distribution. The purpose of the two queries were different. The purpose of the Forest Service's query was to understand the natural range of variation (NRV) for patch size and distribution and understand the appropriate scale at which to manage for patches. The purpose of the Ecosystem Research Group query was to estimate and understand the future trend in patch size.

Patch size estimates are influenced by the pixel size in the model, and the grain size of the unit. In this case the smallest unit in the model was 5.56 acres and so the lack of smaller sized openings brings the average down. Therefore, the outputs are best interpreted as general trends or estimates and not as precise estimates.

SIMPPLLE outputs, in conjunction with a fragstats or a spatial query, can provide inferences about landscape patch and pattern under the NRV and the alternatives. Ecosystem Research Group used SIMPPLLE model outputs and a patch query to describe the future landscape patch and pattern outcome under the plan.

The Forest Service's query estimated the NRV for patch size. The spatially interactive model SIMPPLLE was used to consider the effects of forest growth and disturbance for a period of approximately 1,000 years before present. Empirical data, expert knowledge, and relevant scientific studies were used as a basis for the model information and assumptions. Thirty independent stochastic model runs were used to estimate the approximate average patch size for transitional or seedling-sapling forest, or openings, that existed historically. Results were quantified to show the range of sizes that occurred historically as well as the acreage amounts in size class ranges. Metrics include average patch size, area weighted mean patch size, and patch sizes classified with the Jenks Natural Breaks algorithm. This effort better addressed many of the challenges in modeling patch size and distribution. The Forest Service effort included careful evaluation of the effect of grain size, pixel adjacency and used distribution analysis to more fully understand patch size, pattern and distribution. The purpose of the Forest Service effort was not to project future change in patch size but to understand the distribution of patch sizes under natural disturbance, estimate the NRV for patch size to inform the proper scale of management.

The results revealed that the area weighted mean today is much smaller than modeled estimates of the natural range of variation (NRV) both forestwide and within broad potential vegetation types (PVTs). Similarly, the average patch size was also smaller today than the average patch size under modeled NRV. The limit on harvest opening size over the past 30 years imposed by National Forest Management Act (NFMA) is partially responsible for the trend in smaller patch sizes. Stand-replacing fire is the largest driver of historical openings and their size distribution on the Nez Perce-Clearwater National Forest. Changes to management strategies around opening creation events such as fire and timber harvesting can potentially help restore some of this pattern. The study recommended concentrating mechanically created opening sizes towards the average size within the second Jenks break, which is larger than the NFMA limit, but also relying on natural processes such as wildfire to create the larger openings. The Forest Plan employs such a strategy, which should trend the Nez Perce-Clearwater more towards the NRV of larger average and larger area weighted average patch size conditions. It does so with the 207-acre minimum patch size standard (FW-STD-TBR-06) prior to requiring regional forester's approval, and through plan direction that suggests a landscape pattern consistent with the NRV (for example, MA1 and MA2-DC-FOR-06, MA3-DC-FOR-02, MA1 and MA2-DC-FOR-07, MA3-DC-FOR-04, MA1 and MA2-DC-FOR-

08, MA3-DC-FOR-06, MA1 and MA2-DC-FOR-05, and MA3-DC-FOR-09). The modeling suggests that there will be a range of patch sizes to provide for species that use early seral and edge habitats.

Ecosystem Research Group analyzed patch size performed using the Forest Service-developed SIMPPLLE Output and Analytic Processor (SOAP). Patch statistics were performed on SIMPPLLE outputs and the following metrics were generated: total area of patches, average patch size, and average weighted mean. The patch query focused on seedling and sapling stands greater than one modeling cell (5.56 acre), so the smallest patches analyzed would be at least three modeling cells, or 17 acres (Table 177).

Results from Ecosystem Research Group's patch size analysis suggested that the size and total area of patches increase through time under all alternatives and within each of the three management areas. By timestep five, the average patch sizes are the largest in wilderness areas, smaller in Management Area 2, and smallest in Management Area 3. The modeled increase in patch size and number of larger patches can be attributed to an increase in large moderate and high severity wildfires, which is common to all alternatives. Because of the emphasis on landscape pattern, and larger patch size in the plan and because of the projected increase in fires, the plan will produce a landscape with more habitat edges, and a more complex forest mosaic to provide for species that use ecotones. The management under the plan components would benefit species that use ecotone habitats.

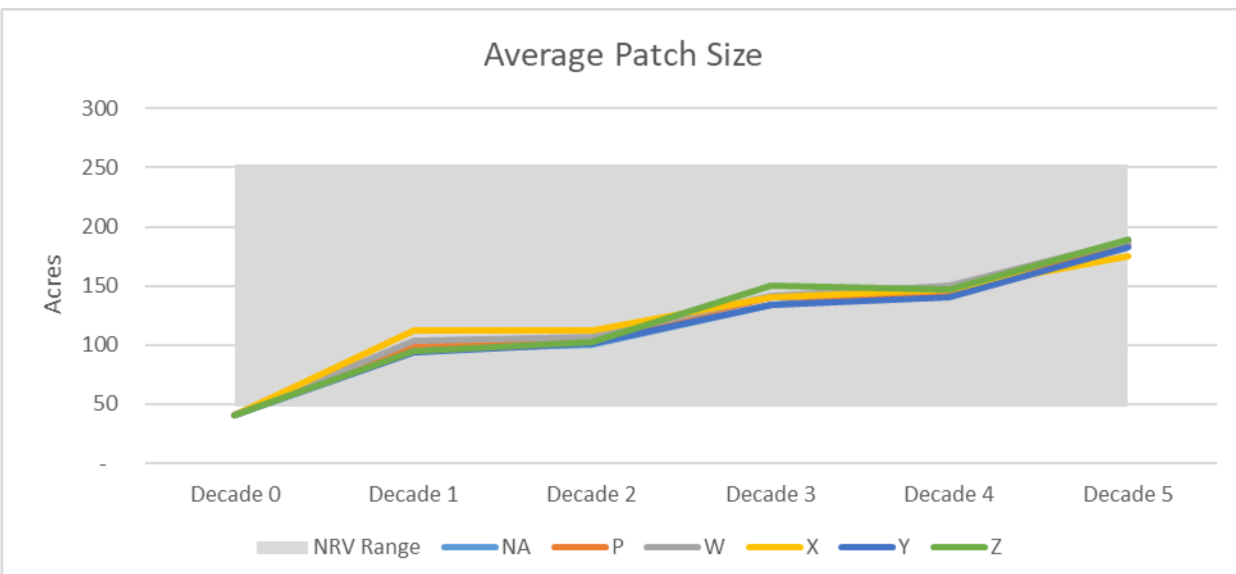

Figure 61. Average patch size by alternative. NA = No Action Alternative

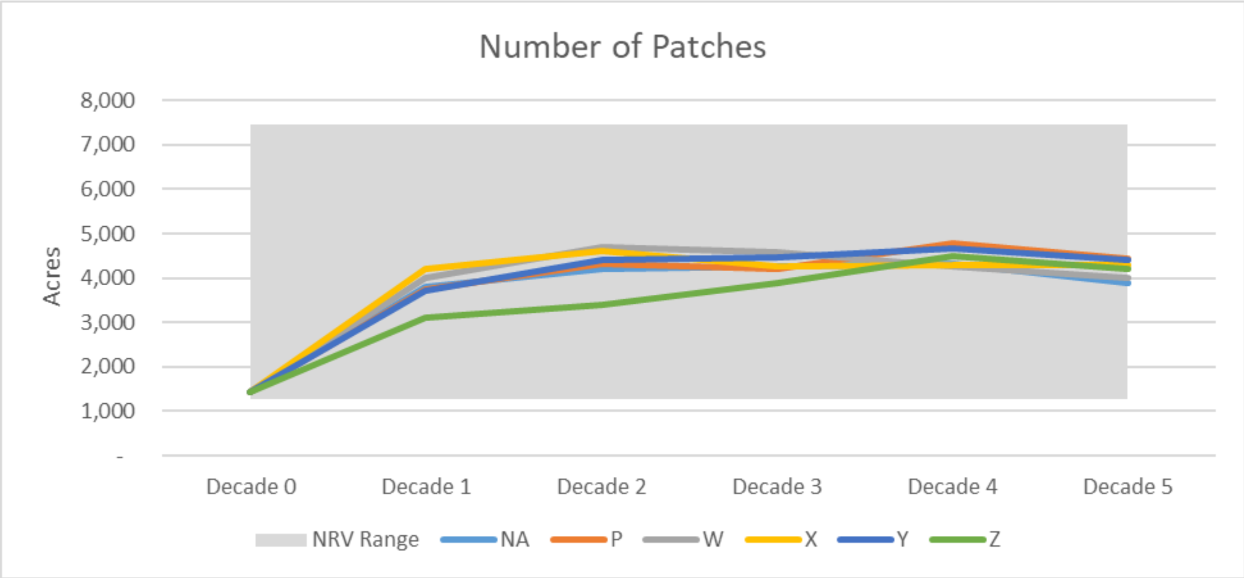

Figure 62. Change in patches over five decades by alternative. NA = No Action Alternative

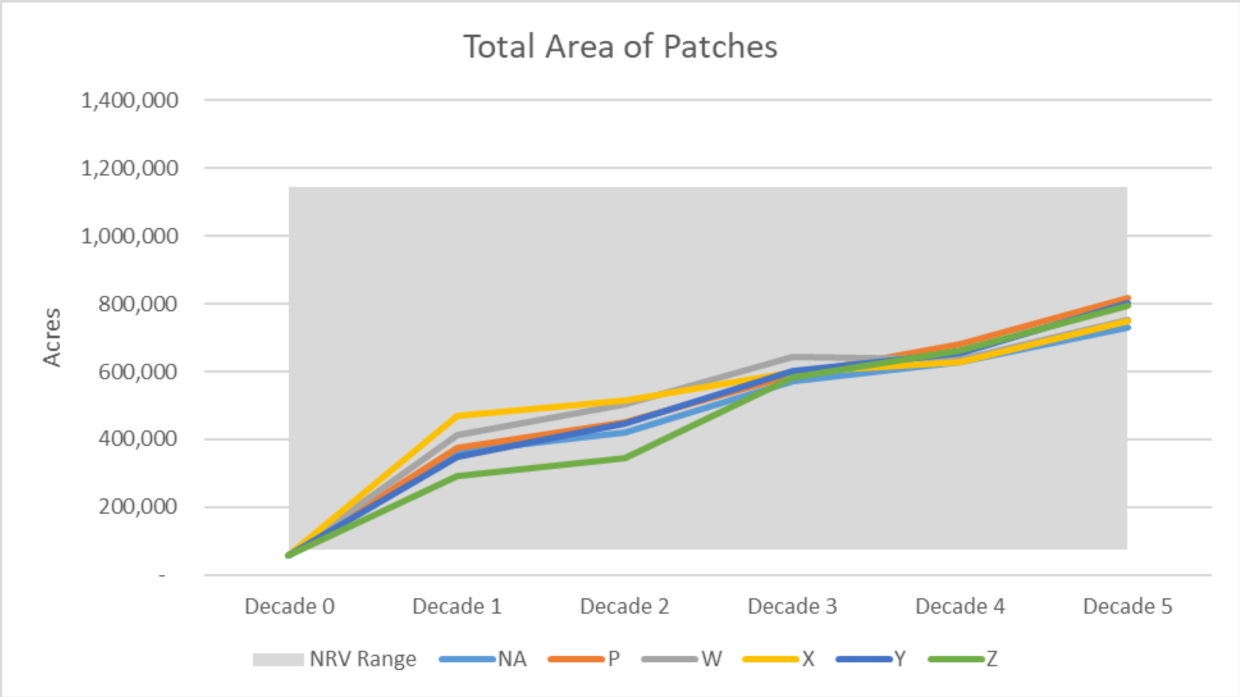

Figure 63. Total area of patches by alternative. NA = No Action Alternative

Environmental Consequences

Land allocations influence patch size distribution because of differences in how fires would be managed. Wilderness and recommended wilderness are managed with limited suppression efforts so patch sizes trend larger. The alternatives with more wilderness will provide more areas with larger patch sizes, while those with less wilderness will provide less or no areas with larger patch sizes. Management Area 2 direction and management (mostly Idaho Roadless Rule areas) should promote larger patch sizes than previously occurred because of the emphasis on fire as a disturbance driver, but fire suppression activities will likely still occur more often in Management Area 2 than in wilderness and recommended wilderness.

Nevertheless, the patch size, and amount of edge habitats will increase in the plan area under all alternatives, which is consistent with the natural range of variability for patch size distribution.

Table 179 summarizes environmental consequences to ecotone, forest edge, or forest mosaic from plan direction.

Table 179. Environmental consequences to ecotone, forest edge, or forest mosaic from plan direction

Resource Area	Environmental Consequences	Explanation
Terrestrial Ecosystems	No	No consequences or beneficial consequences on patch size, forest edge and ecotone habitats.
Biophysical Features	No	No consequences
Forested Lands	Yes	These plan components emphasize managing landscape patterns similar to patterns under the natural range of variability. Plan components should direct management to improve landscape patch and pattern. These plan components will promote habitats for species that use edges. These plan components would increase the average patch size to trend towards the natural range of variability for patch size. These plan components contain plan desired conditions to manage the landscape pattern similar to those under natural disturbances.
Carbon Storage and Sequestration	No	No consequences
Meadow, Grassland, and Shrubland	Yes	Management direction should improve non-forested habitats.
Fire Management	Yes	Fire management can change the landscape pattern. The direction under the Land Management Plan should facilitate an improved patch and pattern. Though some management may still suppress fires, which would continue to cause departures from historic patch and pattern. Plan direction provides the flexibility and emphasis to improve fire management for resource benefits.
Invasive Species	No	No consequences
Soil Resources	No	No consequences
Aquatic Ecosystems	Yes	Some management activities to restore forest ecosystems would be prevented by plan direction especially in riparian areas. Overall these effects should be minor in scope and impact for species that use ecotones.
Water and Aquatic Resources	Yes	Some management activities to restore forest ecosystems would be prevented by plan direction.
Conservation Watershed Network	Yes	Some management activities to restore forest ecosystems would be prevented by plan direction.
Riparian Management Zones	No	No consequences
Lands and Special Uses	No	No consequences
Recreation	No	No consequences
Wildlife	No	No consequences
Multiple Use Wildlife	No	No consequences
Air Quality	Yes	Air quality measures in the plan, as well as those required by each individual state, may sometimes prevent, hinder, or reduce prescribed burn windows.
Tribal Trust	No	No consequences

Resource Area	Environmental Consequences	Explanation
Cultural Resources	No	No consequences
Municipal Watersheds	Yes	Some management activities to restore forest ecosystems would be prevented or restricted by plan direction in some areas.
Sustainable Recreation	Yes	May facilitate disturbance of these habitats by recreationists. Motorized roads and trails have the potential to fragment habitat.
Scenery	No	No consequences
Public Information, Interpretation, and Education	No	No consequences
Infrastructure	No	No consequences
Land Ownership and Land Uses	No	No consequences
Suitability	Yes	Some types of management towards achieving forest desired conditions may be prevented in some areas as not suitable.
Timber	Yes	Timber management has the potential to continue departures in patch size and distribution. It may also serve to improve patch size and pattern and increase early seral habitats. Reforestation practices can result in denser stands and shorter lived early seral habitats, which may decrease the longevity of edges. Fire would not be a preferred tool in areas suitable for timber production, which naturally increases habitat heterogeneity. These effects would be most apparent in Management Area 3.
Energy and Minerals	Yes	Plan direction may facilitate fragmentation and impacts to patch configurations.
Livestock Grazing	Yes	May facilitate impacts from grazing within the open or early seral forest. Should have minor consequences because of the utilization plan direction of 35 to 55 percent.
Special Forest and Botanical Products	No	No consequences
Designated Wilderness	No	No consequences
Wild and Scenic Rivers	No	No consequences
Lolo Trail National Landmark	No	No consequences
Recommended Wilderness	Yes	Would remove some means and reasons for achieving desired conditions for patch and pattern. Fire would be the primary tool.
Idaho Roadless Rule Areas	Yes	Would remove some means and reasons for achieving desired conditions for patch and pattern. Fire would be the primary tool.
Research Natural Areas	No	No consequences
Geographic Areas	No	No consequences
Gospel-Hump	No	No consequences
Lower Salmon	No	No consequences
Pilot Knob	No	No consequences
Special Interest Areas	No	No consequences

Non-Forested or Early Seral Terrestrial Habitats

A total of 54 species were grouped into the non-forested or early seral habitats group. In many cases, these species can be found in either non-forested habitats or in forestlands in an early seral condition. Therefore, this grouping combines both together as a logical grouping.

This broad grouping contains three habitat subgroups:

- meadow, grassland, forbland, and shrubland
- shrubland, thickets, woodlands, and early seral forests
- sparse, barren, or bare ground habitats

As a group, these species make up 14.5 percent of the species on the Nez Perce-Clearwater. The scientific literature was not always clear, nor consistent, in describing habitats for some of these species. Specifically, habitat descriptions often conflated grasslands, shrublands, thickets, and woodlands for some of these species. Some species in this group were identified as preferring grassland, meadow, forbland, and shrubland, while other species were identified as using shrubland, thicket, woodland, and early seral habitats. Seemingly, habitats like grasslands seemed perhaps like they would be functionally different than habitats like shrublands or woodlands. Where possible, these species were placed into subgroups that reflect these differences, but it should be recognized that there is a lot of overlap with some species within these habitat groups, while other species seem more limited to grasslands, for example.

Many other species in other habitat groups also use these habitats. For example, many species in the ecotone habitat grouping, habitat generalists' group, resources habitat groups, substrate habitats grouping, broad-leaved vegetation habitat group, and open forest groups can also be found in non-forested habitats. Taken together, the number of species that use non-forested or early seral habitats represent a large portion of the wildlife biodiversity of the Nez Perce-Clearwater. For example, broad-leaved shrubs often occur within early seral forest conditions and are used by some of the species in the broad-leaved habitat group. Similarly, many species are grouped into substrate habitat groups because they rely on features like cliffs, burrows in cutbanks, or habitats under rocks but some of these species prefer these features within non-forested areas. Appendix C contains a table showing the habitat descriptions of species and shows the habitat groups in which they were assigned.

The first habitat subgroup is the meadow, grassland, forbland, and shrubland habitat subgroup, which includes 27 species. Species assigned into this habitat subgroup include the Brewer's blackbird (*Euphagus cyanocephalus*), American badger, American goldfinch (*Spinus tristis*), northern harrier (*Circus hudsonius*), Savannah sparrow (*Passerculus sandwichensis*), mountain cottontail, American kestrel, western meadowlark (*Sturnella neglecta*), Say's phoebe (*Sayornis saya*), vesper sparrow (*Pooecetes gramineus*), northern pocket gopher (*Thomomys talpoides*), montane vole (*Microtus montanus*), brown-headed cowbird, and meadow vole (*Microtus pennsylvanicus*). This grouping also includes non-native species like the European starling (*Sturnus vulgaris*), Eurasian collared dove (*Streptopelia decaocto*), house sparrow (*Passer domesticus*), grey partridge (*Perdix perdix*), and rock pigeon (*Columba livia*). Most of these species are herbivores or granivores, and predators usually feed on rodents or birds. Key ecological characteristics include grass and herbaceous vegetation; seeds or grains for some species; loose friable soil for burrowing; and robust prey populations for predatory species. Fire can act to maintain grassland and shrubland habitats. These habitats are prone to invasion by invasive plants. Only two of the species in this group use snags—the American kestrel and the European starling.

The next habitat subgroup is the shrublands, thickets, woodlands, and early seral forests subgroup. These species include herbivores, granivores, insectivores, frugivores, browsers, and nectar feeders. This subgroup includes species like mountain quail, Brewer’s sparrow (*Spizella breweri*), calliope hummingbird (*Selasphorus calliope*), dusky flycatcher (*Empidonax oberholseri*), fox sparrow (*Passerella iliaca*), spotted towhee (*Pipilo maculatus*), lesser goldfinch (*Spinus psaltria*), yellow-breasted chat, MacGillivray's warbler (*Geothlypis tolmiei*), Bewick's wren (*Thryomanes bewickii*), white-crowned sparrow (*Zonotrichia leucophrys*), gray catbird (*Dumetella carolinensis*), spruce grouse (*Falcipennis canadensis*), and mule deer. Most of these species seek shrublands, thickets, or early seral forested habitats. A couple non-native species occupy these habitats as well, such as the house finch (*Haemorhous mexicanus*) and California quail (*Callipepla californica*). Key ecological characteristics for these habitats include deciduous shrubs or small trees, thickets, fruiting plants, nectar resources, browse, and insect populations. Only one of these species, the Bewick’s wren, uses snags or downed wood. Only yellow-pine chipmunk uses downed wood. Both prescribed and wildfire are key characteristics to maintain or create these habitats. Most of these features are assumed to be present when functioning in the natural range of variability.

A much smaller subgrouping includes those species that rely on sparse, barren, or bare ground habitats. Species included in this group include the killdeer, horned lark (*Eremophila alpestris*), and kit fox (*Vulpes macrotis*). The kit fox may not actually occur in the plan area but was included because there is one observation listed in the species diversity database for Idaho. Kit foxes usually inhabit deserts, and their range only extends north near Boise, so that identification was likely erroneous.

Population trends of birds that were grouped into the non-forested or early seral habitat group are available from the Intermountain Bird Observatory data accessed on March 24, 2023. The stratum queried was the Idaho BCR10 regional stratum. There are population trends for 42 birds of which 34 are declining while 8 are increasing. Some declining trends have large variation in the data which should be viewed with discretion. Eight declining species have large variations in the data such that the trends are less reliable and include the killdeer, barn swallow (*Hirundo rustica*), Swainson’s hawk, California quail, Eurasian collared dove, yellow-breasted chat, sage thrasher (*Oreoscoptes montanus*), and house finch. These birds are either uncommon or are patchily distributed which account for the wide variation in the trend data. That leaves 26 species with sufficient data for reliable trend inferences. Of those with reliable data, 13 species have declined by more than 20 percent annually, 2 have declined between 10 to 20 percent, and 11 have declined less than 10 percent per year over 13 years of data collection. In general, these are stronger declines than those in the forested habitat groups. Early seral or non-forested habitats rely in part on disturbance to create or maintain edge or ecotone habitats and the high rate of decline regionally by these species may indicate a decline in the quality or abundance of early seral or non-forested habitats regionally.

Distribution and Trend in the Plan Area

The meadow, grassland, forbland, and shrubland habitat subgroup includes persistent mountain meadows at higher elevations, bogs or peatlands, and lower montane foothills distributed along the Salmon River and South Fork Clearwater, on the Island, and at lower elevations or mid elevation ridge tops, especially on the Nez Perce portion of the national forest. They can also occur at high elevation ridgelines, particularly in alpine meadows and persistent shrublands. There are substantial quantities of these habitats along the North Fork Clearwater River as well.

Natural or persistent grassland and forbland habitats are relatively uncommon in the plan area because of the heavy dominance by coniferous forests. More common are grass shrub seral stages of forestlands, which can be either ephemeral or persistent. Grasslands and shrublands commonly occur after fire, timber harvest, or other disturbances. Persistent shrublands can occur after repeated burns on forested habitats.

The modeling suggests that these habitats are less abundant than they were under natural disturbance, as fires maintained these habitats. Some mesic meadows have shrunk at the margins and smaller meadows have likely disappeared altogether through conifer encroachment Hessburg et al. (2015).

Modeling of the natural range of variability suggests that these habitats have declined in the plan area. Small size classes in the 0- to 4.9-inch class and the grass shrub stage appear to be less abundant currently than they were under natural disturbance as the result of fire exclusion and subsequent succession.

Key Threats

The key threats are similar for these two subgroupings. The primary threat to both includes forest succession and fire suppression. Invasive plants pose a serious threat to the meadow, grassland, forbland, and shrubland habitat subgrouping because they are prone to invasion and can be dominated by these species. Common invaders include yellow star thistle, cheatgrass, Medusa head, bulbous bluegrass, and spotted nap weed. Invasive plants may also occur in the shrublands, thickets, woodlands, and early seral forests subgroup and could degrade the habitat for some species. However, in these subgroups, shrubby or woody vegetation can compete with invasive plants better than in grassland habitats. Grazing could impact these habitats at higher intensities. Silviculture practices to replant trees and control competition from shrubs could alter these habitats or shorten their duration once created through timber harvest. In some cases, over browsing by big game or livestock has impacted the condition of some of these habitats.

Natural grasslands and persistent shrublands were exploited heavily after European settlement by unregulated livestock grazing. These uses could have affected species' composition and the condition that may persist today. Intensive sheep grazing probably reduced the amount of shrub dominated habitats, which may take decades to recover. Grazing intensities today are much less than they were historically and have less impact.

Restoration Activities

Depending upon site conditions and desired outcomes, restoration activities include mechanical removal of trees through timber harvest but also lop and scatter; cut, pile, and burn; mastication; chaining; and girdling. Wildland fire may be particularly effective. Restoration may include the control of invasive plant species or planting native vegetation. All these activities are designed to setback succession and reduce conifer or invasive weed encroachment.

Plan Direction

Plan direction for these habitats includes desired conditions to restore size class distribution in all of the potential vegetation types, particularly those for the seral grass or shrub and 0- to 4.9-inch size class. Direction to help inform the pattern of these habitats is included within the forested plan components regarding landscape patch and pattern. Objectives to restore size class and dominance types will benefit species that use non-forested and early seral habitats.

Additional direction is found in the meadow, grassland, and shrubland plan components. These components describe a desire to have less encroachment by conifer trees and describe the desired species compositions by type. Direction in the Fire Management section will serve to promote wildland fire to restore fire prone landscapes.

Plan direction to prevent or control invasive plant species are relevant to conserving and restoring these habitats.

Plan direction for sustainable grazing includes measures to ensure sustainable use of these habitats by livestock. While livestock can be a stressor to these habitats at higher intensities, lower and moderate intensities can usually be sustained with no, less, or beneficial impacts. Livestock grazing plan components are particularly relevant and should allow sustainable use by livestock while maintaining the health of non-forested and early seral habitats.

Plan direction under tribal trust and responsibilities may have implications for early seral, meadow, grassland, or shrubland habitats. See the Land Management Plan for plan components that would have implications for the conservation or use of these habitats.

Under the wildlife section of the Land Management Plan, plan components provide for or direct the management of non-forested or early seral habitats. Under the multiple uses' wildlife section, plan components have implications for habitat conditions or the amounts in non-forested early seral habitats.

Plan direction for designated and recommended wilderness emphasizes a management system through natural processes. This direction should maintain or increase non-forested vegetation and early seral habitats. A crosswalk of plan components with early seral and non-forested vegetation is provided in Appendix C.

Modeling Results

The SIMPPLLE model projects disturbance and forest vegetation response. It was not configured to model naturally occurring non-forested habitats. It does model the amount of early seral habitats. In all alternatives, early seral habitats increase through the 50-year period.

Environmental Consequences

Table 180 summarizes the environmental consequences to non-forested or early seral terrestrial habitats from plan direction.

Table 180. Environmental consequences to non-forested or early seral terrestrial habitats from plan direction

Resource Area	Environmental Consequences	Explanation
Terrestrial Ecosystems	No	No consequences or consequences beneficial to early seral or non-forested habitats.
Cave and Karst Features	No	No consequences
Forestlands	Yes	Plan components should direct management to increase and restore early seral habitats.
Carbon Storage and Climate Change	No	No consequences
Meadow, Grassland, and Shrubland	Yes	Management direction should improve and increase non-forested and early seral habitats.
Fire Management	Yes	Fire management can change the amount and quality of early seral habitats. The direction under the Land Management Plan should facilitate an increase in these habitats.
Invasive Species	Yes	Invasive species management would help conserve early seral and non-forested habitats and limit the spread of invasive species.
Soil Resources	No	No consequences
Aquatic Ecosystems	Yes	Some management activities to increase non-forested or early seral forests would be prevented by plan direction.
Water and Aquatic Resources	Yes	Some management activities to restore forest ecosystems would be prevented by plan direction.
Riparian Management Zones	Yes	Some constraints within the direction for riparian management zones might prevent or reduce efforts to restore or treat early seral or non-forested habitats. However, the plan does contain direction to treat

Resource Area	Environmental Consequences	Explanation
		riparian areas and mesic non-forested habitats to maintain or restore non-forested habitats.
Conservation Watershed Network	Yes	Some management activities to restore early seral or non-forested conditions would be prevented by this plan direction.
Infrastructure (Aquatics and Riparian)	No	No consequences
Energy and Minerals (Aquatic and Riparian)	No	No consequences
Livestock Grazing (Aquatics and Riparian)	No	No consequences
Lands and Special Uses (Aquatics and Riparian)	No	No consequences
Recreation (Aquatics and Riparian)	No	No consequences
Wildlife	No	No consequences
Multiple Use Wildlife	No	No consequences
Air Quality	Yes	Some prescribed fires would be prevented through air quality regulations.
Tribal Trust	No	No consequences
Cultural Resources	No	No consequences
Municipal Watersheds	Yes	Some management activities to restore forest ecosystems would be prevented or restricted by plan direction within within municipal watersheds which are limited in scope.
Sustainable Recreation	Yes	May facilitate disturbance of these habitats by recreationists. Motorized roads and trails have the potential to fragment habitat. Recreation opportunity spectrum is the primary mechanism used in the plan to establish the suitability of motorized uses. These plan components identify where motorized uses are suitable. Areas identified as suitable for motorized uses can set the stage for future development of motorize routes which could impact nonforested and early seral habitats.
Scenery	Yes	May alter some projects designed to increase these habitats.
Public Information, Interpretation, and Education	No	No consequences
Infrastructure	Yes	Infrastructure management primarily focuses on maintanence and presence of infrastructure like roads and buildings. They emphasize responsibility and good maintanence practices for these features. The direction in infrastructure might have some minor site specific impacts to early seral or non-forested habitats.
Land ownership and Land Uses	No	No consequences
Ecosystem Services	Yes	Ecosystem services plan direction emphasizes the use of ecosystem services, some of which could create indirect impacts to non-forested habitats. Examples include snag or downed wood removal from non-forested habitats, or impacts to non-forested habitats from recreation. Restrictions in closing motorized access found in FW-GDL-ES-01 could potentially result in retaining or relocation motorized routes in non-forested habitats.

Resource Area	Environmental Consequences	Explanation
Timber	Yes	Timber management would increase these habitats. Reforestation practices can result in denser stands and shorter lived early seral habitats, which may decrease the longevity of early seral habitats. Fire would not be a preferred tool in areas suitable for timber production, which naturally increases habitat heterogeneity. These effects would be most apparent in Management Area 3.
Energy and Minerals	Yes	Plan direction may facilitate fragmentation and impacts to patch configurations.
Livestock Grazing	Yes	May facilitate impacts from grazing within the open or early seral forest. Should have minor consequences because of the utilization plan direction of 45 percent.
Special Forest and Botanical Products	No	No consequences
Designated Wilderness	No	No consequences
Wild and Scenic Rivers	No	No consequences
Recommended Wilderness	Yes	Would remove some means and reasons for achieving desired conditions for early seral and non-forested habitats. Fire would be the primary tool. In general, early seral habitat would increase in extent because of recommended wilderness management.
Eligible and Suitable Wild and Scenic Rivers	Yes	Direction in Eligible and Suitable Wild and Scenic Rivers are protective or constraining, but this direction might prevent some activities to create or maintain early seral or non-forested habitats within river cooridors because of the emphasis on protecting or enhancing Outstandingly Remarkable Values.
Idaho Roadless Rule Areas	Yes	Would remove some means and reasons for achieving desired conditions for early seral and non-forested habitats. Fire would be the primary tool.
Research Natural Areas	No	No consequences
Geographic Areas	No	No consequences
Gospel-Hump Geographic Area	No	No consequences
Lower Salmon Geographic Area	No	No consequences
Pilot Knob Geographic Area	No	No consequences
Lolo Trail National Historic Landmark Geographic Area	Yes	Would constrain some activities typically used to create or maintain early seral or non-forested habitats. However, they emphasize natural disturbance to managed these habitats. Consequences are minor because the Landmark is limited in area and this plan direction otherwise has no detrimental consequences.
Special Areas	No	No consequences
Suitability	Yes	Some types of management towards achieving forest desired conditions may be prevented in some areas listed as not suitable. Suitability plan components are associated with land allocations and are consistent with the emphasis management in those areas. While mechanical treatments are constrained in some land allocations other tools are emphasized such as wildfire, which should trend towards larger openings sizes and greater amounts of early seral habitats. Motorized suitability sets the stage for future motorized route

Resource Area	Environmental Consequences	Explanation
		development and could lead indirectly to impacts of roads and some early seral or nonforested habitats.

Connectivity

The Nez Perce-Clearwater National Forest consists of a large contiguous block of public land with few obstructions to disrupt connectivity and animal movements. Most of its boundary is bordered by other national forests save for the western boundary, parts of the Palouse Ranger District, and the area between the Salmon and Snake River commonly referred to as the Island. Landownership on lands west of the Nez Perce-Clearwater boundary is made up of a combination of private lands managed for timber, state lands managed for timber, and privately owned lands used for agriculture or development. Terrestrial habitats are well connected throughout the interior of the plan area. The primary manmade barriers are Highway 12 and Highway 64. The plan also contains natural barriers like large rivers such as the North Fork of the Clearwater, the Lochsa River, the Selway River, the middle Fork of the Clearwater River, and the Salmon River.

The plan contains desired conditions that were designed to provide connectivity for wildlife. Plan components designed to provide connectivity include FW-DC-WL-03, FW-DC-WL-06, FW-DC-WL-09. Plan direction for landscape pattern also was intended to provide connectivity. These include MA1 and MA2-DC-FOR-06, MA3-DC-FOR-02, MA1 and MA2-DC-FOR-07, MA3-DC-FOR-04, MA1 and MA2-DC-FOR-08, MA3-DC-FOR-06, MA1 and MA2-DC-FOR-05, and MA3-DC-FOR-09.

The most prominent barriers to connectivity are human made features like high-speed highways, cities, or reservoirs. The land allocations and associated suitability plan components provide the ecological conditions to provide connectivity because they prevent or constrain many activities that would disrupt connectivity. For example, the Idaho Roadless Rule prohibits construction or reconstruction of roads in wilderness management prohibits construction of roads, buildings, and most other activities. Designated wild and scenic rivers prohibit dam building. Approximately two thirds of the National Forest System lands in the planning area are either Idaho Roadless Rule or wilderness areas. Essentially, connectivity is well provided on the Nez Perce-Clearwater National Forest. Land allocations and their associated suitability plan components can conserve large blocks of land for connectivity. Land allocations vary by alternative in how they provide for connectivity. Of greatest conservation value related to connectivity are recommended wilderness, but to a lesser extent suitable and eligible wild and scenic rivers, and research natural areas. Alternative W provides the most recommended wilderness while Alternative X provides the least with zero recommended wilderness. The No Action Alternative, Alternative Y, and Alternative Z provide intermediate levels of recommended wilderness. The Preferred Alternative strikes a balance the amount of recommended wilderness provided and provides recommended wilderness in locations important to connectivity such as in the Mallard Larkins, the Hoodoo, and Meadow Creek recommended wilderness areas. It should be noted that all proposed recommended wilderness in all alternatives is derived from Idaho Roadless Rule areas that already receive protective management by the Idaho Roadless Rule. Recommended wilderness allocations would provide additional protection to already protected lands. Namely, prohibitions on motorized and mechanized uses under the Preferred Alternative. The area along the Idaho-Montana border has been identified as an important area for North and South movements for wide ranging wildlife like wolverines (Carroll et al. 2020) and grizzly bears (Peck et al. 2017). The majority of the area along the Idaho-Montana border are included in either designated wilderness, recommended wilderness, or Idaho Roadless Rule areas.

Suitability plan components and plan direction for existing land designations can also contribute to connectivity because they restrict activities that disrupt connectivity. For example, plan direction and suitability plan components for Idaho Roadless Rule Areas, designated wilderness, and designated wild and scenic rivers all constrain or prohibit many activities that disrupt connectivity, such as road building, and construction of buildings. Suitability plan components within Idaho Roadless Rule areas find road building unsuitable in most Idaho Roadless Rule areas. Suitability plan components in designated wilderness areas find timber production, timber harvest road construction, most mineral activities, construction of new buildings, motorized travel, and mechanized travel as unsuitable. Activities such as livestock grazing and mineral extraction are conditionally suitable according to designating legislation and wilderness management plans.

Collectively, land allocations in the Nez Perce-Clearwater, especially those in designated wilderness, designated wild and scenic rivers, suitable wild and scenic rivers, Idaho Roadless Rule areas, Research Natural Areas, and the National Historic Landmark are managed with restrictions on the suitability of uses. As such they will provide for large tracts of lands with high connectivity value that have few barriers and management that restricts the creation of new barriers. These lands combined account for approximately two thirds of the nearly 4 million acres within the plan area. Connectivity is well provided and not a concern on the Nez Perce-Clearwater National Forest under the revised plan.

Habitat Generalists

Several species are found so widely and in so many habitats that they did not fit within the other habitat groupings. These include species like the North American deer mouse (*Peromyscus maniculatus*), porcupine (*Erethizon dorsatum*), common raven (*Corvus corax*), and long-tailed vole (*Microtus longicaudus*). These species are found in a diverse range of habitats and will likely be present within many areas of the Nez Perce-Clearwater. These species will not be evaluated further.

Resource Habitats

Some species are reliant on available resources rather than specific habitat types or structure. These species can occur in any habitat so long as their specific resource needs are met. Some examples include predators that can persist in a wide range of habitats so long as they have prey or hummingbirds that rely on nectar resources but can otherwise occur within a wide variety of habitats. Species in this group can be found in many habitats, from deserts to grasslands to forests. This grouping came about because these species did not fit into other habitat groupings because of the variability of the habitats in which they are found. In total, there were 16 species grouped into these habitat groupings, but it should be recognized that some of these species are found in forested, non-forested, ecotone, or edge habitats.

Examples of species in the resource habitat grouping include carnivores and scavengers, such as the red fox, bobcats, coyotes, mountain lions, wolves, long tailed weasels, and turkey vultures. It also includes bird species that rely on mast, such as the red crossbill (*Loxia curvirostra*), white-winged crossbill (*Loxia leucoptera*), and Clark's nutcracker (*Nucifraga columbiana*). Similarly, fruiting plants are the main drivers of waxwing habitat selection and include both the bohemian waxwing and cedar waxwing (*Bombycilla cedrorum*). The last group of species that use resource habitats include hummingbirds, such as the rufous hummingbird (*Selasphorus rufus*) and black-chinned hummingbird (*Archilochus alexandri*), that are reliant on nectar resources.

Most species are reliant upon resources available in their respective niches, though. Several other wildlife species could have also been grouped into this habitat grouping as well but were a better fit in other groupings based upon their habitat descriptions. Examples include pine siskin, calliope hummingbird, pygmy nuthatch, red squirrel, and flying squirrel. Many migratory bird species are insectivorous in the spring and frugivores, or fruit eaters, in the fall.

Some bird population trends of species grouped into the resource habitat group are available from the Intermountain Bird Observatory data accessed on March 24, 2023. The stratum queried was the Idaho BCR10 regional stratum. There are population trends for seven birds of which three are declining and four are increasing. The declining species includes the cedar waxwing, the rufous hummingbird, and the black-chinned hummingbird. Of note also, is that the calliope hummingbird is also declining but was placed in the non-forested or early seral habitat group. The species that declined were those that rely on nectar resources or fruit. The black-chinned hummingbird is the species with a declining trend but has large variation in the data which should be viewed with discretion, but it declined by 39 percent annually. The rufous hummingbird declined by 14.1 percent and the cedar waxwing declined by 24.9 percent each year over the 13-year sample period. The calliope hummingbird declined by 26.3 percent per year. The resource habitat species that rely on seeds or mast did not decline. Nectar and fruit producing vegetation rely in part on disturbance to create or maintain habitats and the higher rate of decline regionally may indicate a decline in the quality or abundance of these resource habitats.

The resources these species rely on could be considered key ecological characteristics of habitats rather than distinct habitats. Prey, nectar resources, and mast are expected to be provided by habitats that have ecosystem integrity. Mast or tree seeds are provided by conifer trees like whitebark pine, western white pine, Ponderosa pine, spruce, and Douglas-fir. Larger trees produce more mast than younger trees of the same species. Shifts towards a dominance type from those that produce mast to those that do not, for example conversion to grand fir from Ponderosa pine, has reduced some mast trees in some areas. Western white pine and whitebark pine both produce cones that produce mast. Exotic forest diseases, such as blister rust, have reduced some mast producing trees as well.

Nectar resources are provided by forbs and deciduous shrubs and trees. Fruits are provided by these same features. Nectar resources and fruiting plants are more abundant in early seral, non-forested, and riparian habitats and open forests than in closed canopy forests (Hanula et al. 2016). Bees and butterflies generally favor open forest habitats regardless of forest type, geographic region, or the method used to create these habitats. Dense shrub layers of native or nonnative species beneath forest canopies negatively impact herbaceous plant cover, diversity, and pollinators (Hanula et al. 2016). Fruiting plants include many deciduous trees, shrubs, and forbs. Some notable species include huckleberry, chokecherry, raspberry, strawberry, blackberry, thimbleberry, and elderberry. Threats to nectar resources and fruiting plants include fire suppression, forest succession, grazing, habitat fragmentation, pesticides, and invasive plant species. Many broad-leaved, deciduous trees and shrubs produce fruit and nectar resources. Plan components that favor early seral forests, non-forested habitat, and deciduous or broad-leaved forests would produce nectar and fruit resources for many wildlife species. These plan components include FW-DC-FOR-05, FW-DC-FOR-08, FW-DC-FOR-11, FW-DC-FOR-12 especially in seral grass or shrub, and 0- to 4.9-inch size classes. For nectar or pollination resources, the plan includes FW-DC-TE-03. FW-DC-TE-05 and FW-OBJ-TE-01 that encourage resources for pollinators and species that use deciduous, fruit producing vegetation.

Restoration activities for mast producing trees include the conversion of dominance types toward mast producers like Ponderosa pine, western white pine, and whitebark pine. Restoration of nectar resources includes any activities that open canopies or disturb non-forested habitat, such as thinning, timber harvest, wildland fire, and plantings. Treatment of invasive plant species could restore some native nectar sources, though invasive plant species often have flowers.

Plan direction for these activities is found within the forestland; meadow, grassland, and shrubland; and riparian plan components. Objectives include restoring some dominance types of mast producing trees, such as white pine and whitebark pine; increasing the dominance of Ponderosa pine; increasing early seral forests; and restoring camas and huckleberry. Plan components included those for dominance types such as FW-DC-FOR-03, FW-DC-FOR-06, FW-DC-FOR-09, FW-DC-FOR-13 and provide direction to provide a variety of tree species that produce mast important for wildlife, especially when composed of larger size classes. See the Land Management Plan for plan components that pertain to terrestrial ecosystems. A crosswalk of plan direction with resource habitats can be found in Appendix C.

Substrate Habitats

Many species of wildlife in the plan area use or depend on soils, rock, cliff, talus, caves, or non-vegetative characteristics, in part or exclusively, for their habitat requirements. This report refers to those habitat features as substrate habitats, which include soil conditions, spaces under rocks or debris, rock outcrops, talus, cliffs, caves, mines, cervices, cut banks, or other geological features. For example, many species depend on the ability to burrow into soils for dens and hiding habitats but are otherwise generalists in regards to vegetation. Other species are specialized to both vegetation and also require burrowing habitats. A suite of species is reliant upon rock outcrops, talus, or cliff habitats. The effects to substrate habitats are analyzed under the assumption that, if these habitats are provided, then these species would contribute to the diversity and abundance of wildlife. Analysis for soil resources can be found in the soil specialist report.

Many species were grouped into the substrate habitats grouping. Substrate habitats are features such as cliffs, soil, rock outcrops, caves, mines, steep terrain, habitat under rocks or logs, or other non-vegetated features. Wildlife species in this group often occur in a wide array of habitats if there is the presence of their preferred substrate features. Substrate habitat subgroupings include species that use habitats under rocks, logs, or leaf litter; rock outcrops, talus, cliffs, or cutbanks; caves, crevices, or mines; steep terrain; roosting habitats; and substrate or soil and non-forested habitats. A total of 88 species were grouped into this habitat grouping.

The subgroup habitat under rocks, logs, or leaf litter includes ground dwelling species like reptiles, amphibians, mollusks, and some small mammals. The western terrestrial garter snake (*Thamnophis elegans*), ring-necked snake, rubber boa (*Charina bottae*), Selway forestsnail, nimapuna disc, vagrant shrew (*Sorex vagrans*), and masked shrew (*Sorex cinereus*) are examples.

The subgrouping rock outcrops, talus, cliffs, or cutbanks habitat supports birds, small mammals, and some mollusks. Examples of these species include the American pika, peregrine falcon, cliff swallow (*Petrochelidon pyrrhonota*), bushy-tailed woodrat (*Neotoma cinerea*), white-throated swift (*Aeronautes saxatalis*), salmon coil (*Helicodiscus salmonaceus*), and Seven Devils mountainsnail. These species mostly use these features in non-forested habitats. Twenty-two species were included in this subgrouping.

Bat distribution and habitat use is highly variable, as most bat species use a wide variety of habitats from forests and grasslands to deserts. The main driver of their distribution is based upon the availability of their preferred roosting habitats. Their roosting habitats can be snags, talus, mines, caves, cliffs, crevices, hollow trees, trees with sloughing bark, or buildings. Therefore, a subgrouping was created as roosting habitats that fit this pattern of use. Bats that occur in the Nez Perce-Clearwater include the little brown bat, silver-haired bats, big brown bats (*Eptesicus fuscus*), long-legged myotis, long-eared myotis, Townsend's big-eared bat, California myotis (*Myotis californicus*), and western small-footed myotis (*Myotis ciliolabrum*). Species like the Townsend's big eared bat are wholly reliant on caves and mines, whereas other species sometimes use caves but can be found in other features. Hollow trees and snags are important for some bat species in both winter and summer. This subgrouping includes eight species of bats. Some other bat species were grouped into other groups based on habitat descriptions, but most could have been placed here as well.

Only two species are included in the steep terrain subgroup—mountain goats and bighorn sheep. Steep terrain features are the selected habitat feature for these two species. These habitats must also have vegetation as forage. They use these habitats to escape predation.

Three species occur in a wide range of habitats but require burrowable soils as a key feature. These include golden-mantled ground squirrel (*Callospermophilus lateralis*), Columbian ground squirrel (*Urocitellus columbianus*), and Great Basin pocket mouse (*Perognathus parvus*). Other species in other habitat groups could also have been placed here but were a better fit in other groupings. Similarly, some might argue that these species could have been placed in other habitat groupings.

There is a suite of species that require substrate habitats in conjunction with open or non-forested habitats. These species were grouped into the substrate and non-forested habitat subgroup and include golden eagles (*Aquila chrysaetos*), which require cliffs with non-forested habitats for foraging, and barn swallows that need some substrate to attach their nest and non-forested habitats for foraging. The yellow-bellied marmot uses non-forested habitats along with rock outcrops. The northern rough-winged swallow (*Stelgidopteryx serripennis*) uses cliffs or rock cuts in roads and forages over non-forested habitats. In total, six species were grouped with this habitat grouping.

Some population trends of birds that were grouped into the substrate habitat group are are available from the Intermountain Bird Observatory data accessed on March 24, 2023. The stratum queried was the Idaho BCR10 regional stratum. There are population trends for seven birds of which four are declining and four are increasing. Three of the four declining species have large variation in the data which should be viewed with discretion. The species with large variations in the include the bank swallow, canyon wren (*Catherpes mexicanus*), and cliff swallow. The uneven distribution of these species accounts for the wide variation in the trend data. The rock wren (*Salpinctes obsoletus*) has sufficient data to provide reliable estimates of population trends and declines within the stratum are estimated at -9.7 percent. While the trend is declining, this species is relatively abundant. The rock wren is closely associated with relatively open habitats nearly anywhere there is exposed rock and associated crevices, and open habitats are often maintained or created by disturbance.

The plan area contains many either regional or Idaho-endemic mollusk species that use substrate habitats. Many of these species have been identified as G1 and G2 by NatureServe because of their restricted ranges and limited distribution. Most of these rare mollusks are dependent upon substrate habitats. Some, like the Selway forestsnail, occur in mesic forested habitats in the Selway and Lochsa River corridors and use habitats like rocks, logs, and leaf litter often found in riparian habitats. Other species with similar conservation status and attributes include the nimapuna disc, marbled jumping slug (*Hemphillia danielsi*), thin-lipped tightcoil (*Pristiloma idahoense*), lyre mantleslug (*Udosarx lyrata*), and humped coin (*Polygyrella polygyrella*). Many unique, rare, or endemic mountain snails and Oregonians occur in the lower Salmon River canyon or the Lochsa and Selway River canyons and are associated with specific rock outcrops or rocks with calcareous lithologies. These include the lyrate mountainsnail (*Oreohelix haydeni*), boulder pile mountainsnail, marbled disc, and Seven Devils mountainsnail.

There are a few things to note about the above-mentioned species. Taxonomy is difficult with these species leading to problematic taxonomic classification even by experts. Recent genetic studies were unable to sort out some of the taxonomic relationships (Linscott et al. 2020). These species tend to be understudied as well. Some recent studies in northern Idaho have found that snail and slug species, which were previously thought rare or limited in distribution, are common and more widespread (Baumgardt and Sauder 2012, Lucid et al. 2016).

It is possible that some of the G-ranked species will be found more common than currently thought. While the species mentioned above have been detected in the plan area, some others included in the list of species have not actually been detected in the plan area but were within a half mile of the boundary and were included. Some of the rare land snails may not actually occur within the boundaries of the Nez Perce-Clearwater. A list of species, their habitat descriptions, and the habitat group they were assigned to can be found in Appendix C.

Threats and Stressors

Substrate habitats in the plan area have little that affects them. However, there are some activities that can affect them. Some rock outcrops and cliff habitats are quarried by the public or by the Forest Service for road-base in support of timber harvest. Rock quarrying within the Lower Salmon River area can impact many endemic and rare snail species. The Nez Perce-Clearwater has only a few known caves. Papoose Cave is identified as a nationally significant cave and is gated for protection of the feature that made it recognized. Use is allowed through a permit system and only people who have vertical caving skills can effectively explore it because of vertical passages. There are few visits made each year.

Habitats under rocks are quite stable and persistent and largely unaffected by management, except in the case of road building. However, the amount of downed wood can be influenced by forest and fuels management. The Nez Perce-Clearwater has abundant downed wood and the 1987 Plans, as well as the Land Management Plan, have measures to retain downed woody debris after timber harvest. Cliff and rock outcrops can be affected by rock climbing recreation, but this is not prevalent on this forest. Burrowing habitats can be impacted by soil impairment, usually because of timber harvest or wildfire suppression efforts. Roosting habitats can include a wide variety of features that are not often impacted; however, impacts can include mine closures, rock climbing, loss of snags, and quarrying. Mines are a man-made feature that poses hazards to both humans and bats. While it is important to protect these populations, human safety concerns must also be considered. Some of the substrate habitats, especially those in non-forested settings, could be vulnerable to invasive plant species. Some of these species may be affected by invasive plant species while others may not.

Existing Conditions

These habitats are largely intact in the plan area. Some rock quarries have affected some rock outcrops. Downed wood is largely unmanaged in wilderness and roadless areas, which make up most of the Nez Perce-Clearwater. Rock climbing is uncommon in the plan area. Invasive plant species are prevalent on dry sites, such as in the Lower Salmon River canyon, and substrate habitats may be affected there. High elevation talus and cliff habitat is abundant in roadless and wilderness areas.

Restoration activities

There are no restoration activities for substrate habitats. However, retaining downed wood as a forestry practice can ensure these features remain after timber harvest. Soils can be repaired to functioning condition after ground disturbing activities. Treating invasive plant species can restore some adjacent habitats.

Plan Direction

The plan contains direction for the conservation of substrate habitats aimed at conserving rare snails. See the Land Management Plan for plan components that pertain to terrestrial ecosystems. Many biophysical features plan components support substrate habitats, including caves and rock outcrops. FW-GDL-WL-02 addresses closures of mines to prevent harm to bats. In the Salmon River Geographic Area, GA-DC-SR-

03 is a desired condition that habitat for endemic terrestrial snails is available. This section also includes a prohibition on the impact to these resources if they have species rated as globally imperiled by NatureServe. The plan contains desired condition FW-DC-TE-02 and standard FW-GDL-TE-01 to protect these habitats and species.

Forestlands plan direction the Land Management Plan will help maintain or provide for species that use habitats under rocks, logs, or litter. FW-DC-GS-06 provides habitats for burrowing soils for some wildlife.

Invasive species plan components the Land Management Plan will help reduce the impact from invasive plant species for species that use substrate habitats. Soils Resources plan components will provide for, maintain, or restore soil resources species that many species in the substrate habitat group use.

FW-DC-WL-05 addresses bighorn sheep habitat, which is identified as areas of native, high protein grass and forbs near rugged escape cover. In general, we assume that substrate habitats will be present and provide habitat for wildlife as a natural component of the landscape. Threats to some substrate habitats are few so they are not in danger of impacts in most cases. Impacts to substrate habitats can occur from mineral extraction, forestry activities that do not retain snags or downed wood or are disturbed by recreational activities such as caving or rock climbing. Overall, however, there is little evidence that substate habitats are limiting in most cases. Plan components that provide for substrate habitats include those in the Cave and Karst section of the plan, the Forestlands section that addresses coarse woody debris, and snags, and those in the across the landscape section of the plan. Plan components in the Soils Resources section of the plan provide for the conservation of soils. Plan components for substrate habitats include FW-DC-TE-01, FW-DC-TE-02, FW-GDL-TE-01, FW-DC-CAVE-01, FW-DC-CAVE-04, FW-STD-CAVE-01, FW-GDL-CAVE-01, MA2 and MA3-GDL-FOR-01, MA2 and MA3-GDL-FOR-02, MA2 and MA3-GDL-FOR-05, MA3-GDL-FOR-06, MA3-GDL-FOR-07, FW-DC-SOIL-01, FW-DC-SOIL-02, FW-STD-SOIL-01, FW-STD-SOIL-02, FW-GDL-SOIL-02, MA2 and MA3-GDL-SOIL-02, and FW-GDL-WL-02. A list of species, their habitat descriptions, and the habitat group they were assigned to can be found in Appendix C. Also See Appendix C for a crosswalk of plan components that contribute to substrate habitats.

Environmental Consequences

Environmental consequences to substrate habitats from plan direction are summarized in Table 181.

Table 181. Environmental consequences to substrate habitats from plan direction

Resource Area	Environmental Consequences	Explanation
Terrestrial Ecosystems	No	No consequences
Cave and Karst Features	Yes	Plan direction in this section addresses impacts to caves and other substrate habitats.
Forestlands	Yes	Plan direction for forested lands requires retaining coarse woody debris which could provide substrate habitats for species that use downed wood as shelter. Additionally, the forestland plan components include measures to retain snags which can fall and provide shelter for species that use substrate habitats. These plan components mitigate impacts to substrate habitats from activities like timber harvest.
Carbon Storage and Sequestration	No	No consequences

Resource Area	Environmental Consequences	Explanation
Meadow, Grassland, and Shrubland	No	No consequences
Fire Management	No	No consequences
Invasive Species	Yes	Invasive species can affect the vegetation characteristics around substrate habitats. Plan direction should help address this threat.
Soil Resources	Yes	Plan direction could facilitate management of soil resources which could prevent impacts and restore habitats for soil dwelling wildlife.
Aquatic Ecosystems	No	No consequences
Water and Aquatic Resources	No	No consequences
Conservation Watershed Network	No	No consequences
Infrastructure (Aquatics and Riparian)	No	No consequences or beneficial consequences.
Riparian Management Zones	No	No consequences
Lands and Special Uses (Aquatics and Riparian)	No	No consequences
Energy and Minerals (Aquatic and Riparian)	No	No consequences
Livestock Grazing (Aquatics and Riparian)	No	No consequences
Recreation (Aquatics and Riparian)	No	No consequences
Recreation	No	No consequences
Wildlife	No	No consequences
Multiple Use Wildlife	No	No consequences
Air Quality	No	No consequences
Tribal Trust	No	No consequences
Cultural Resources	No	No consequences
Municipal Watersheds	No	No consequences
Sustainable Recreation	No	No consequences
Scenery	No	No consequences
Public Information, Interpretation, and Education	No	No consequences
Infrastructure	Yes	Quarrying for road base is one of the primary threats to rock outcrops used by many rare and endemic snails. Plan direction provides guidance on the management of gravel pits that are generally permissive. Plan direction for infrastructure, especially road maintenance, requires the use of locally sourced gravel. Desired conditions such as FW-DC-INF-01 and FW-OBJ-INF-02 would encourage a high level of maintenance activities which might facilitate an increase in the number of gravel pits or their footprint. However, FW-DC-TE-01 and FW-GDL-TE-01 should prevent these plan components from impacting important

Resource Area	Environmental Consequences	Explanation
		habitats for rare or uncommon species that rely upon substrate habitats.
Land Ownership and Land Uses	No	No consequences
Timber	Yes	This activity may compact soils and result in loss of woody debris and snags which serves as habitat for species that use substrate habitats. However, plan components such as MA2 and MA3-GDL-FOR-01 should in most cases require leaving downed wood to provide for species that use substrate habitats.
Energy and Minerals	Yes	This plan direction may facilitate impacts to substrate habitats from these activities. Mining and quarrying have the potential to affect rock outcrops.
Livestock Grazing	Yes	Livestock grazing around rock outcrop features can impact vegetation required by species that use substrate habitats.
Special Forest and Botanical Products	No	No consequences
Designated Wilderness	No	No consequences
Wild and Scenic Rivers	No	No consequences
Lolo Trail National Landmark	No	No consequences
Recommended Wilderness	No	No consequences
Idaho Roadless Rule Areas	No	No consequences
Research Natural Areas	No	No consequences
Geographic Areas	No	No consequences
Gospel-Hump	No	No consequences
Lower Salmon	No	No consequences
Pilot Knob	No	No consequences
Special Interest Areas	No	No consequences
Suitability	Yes	Suitability plan components identify areas where different uses are suitable or not. Including timber production, timber harvest, road construction, prescribed fire, livestock grazing, the different types of mineral extraction, construction of buildings, motorized travel, mechanized travel, and use of airstrips. Many of these activities can affect the amount and distribution of substrate habitats. Activities such as road construction or road maintenance can facilitate extraction of gravel which may impact substrate habitats. Activities such as mineral extraction can also impact substrate habitats. Identifying lands suitable for these activities can cause localized impacts to some substrate habitats. However, in most cases substrate habitats are common and widespread such that impacts to some of these habitats are inconsequential to the status of the species in the plan area. Furthermore, plan components such as, FW-DC-TE-01 and FW-GDL-TE-01 should prevent these plan components from impacting important uncommon habitat elements of rare or uncommon species that rely upon substrate habitats.

Effects Common to All Alternatives

Habitat restoration is one of the main outcomes of the direction in the Land Management Plan and provides for the restoration of habitat for native wildlife species. The Land Management Plan provides more flexibility in the tools available to accomplish this habitat restoration in the long-term. This is particularly true regarding fire and natural disturbance processes. Under the Land Management Plan there is more emphasis and flexibility to utilize wildland fire and natural disturbance processes to trend the habitat towards the desired conditions for vegetation. Those desired conditions account for both historic conditions and potential warmer-drier climate conditions, both of which consider natural disturbance. By allowing natural disturbance to function nearer to historic conditions, the approximate quantity, quality, and pattern of wildlife habitat across the Nez Perce-Clearwater would be nearer to what the native species evolved with in this part of their range. By moving towards the conditions, they evolved with, ecological conditions to provide species viability would be maintained. Active restoration through mechanical treatments can help in moving towards the desired conditions. The tool that has the best chance of success is wildland fire and natural disturbance, including both active and passive restoration. Natural disturbance has a greater influence over the rate at which the Nez Perce-Clearwater trends towards the desired conditions. However, the plan provides for ample opportunity to affect change with tools like timber harvest, prescribed wildland fire, and mechanical treatments.

Cumulative Effects on the Diversity and Abundance of Wildlife

The current Forest Plans are generally consistent with Idaho Department of Fish and Game's management plans and will serve to increase populations of many species of interest to the public for hunting. The current Forest Plans conserve habitat for a broad variety of wildlife, generally consistent with the Idaho Statewide Wildlife Action Plan, which emphasizes the conservation of habitats as a primary goal for conserving species. The plan is also consistent with the plans for the management of natural resources produced by local counties.

Conclusions: Abundance and Diversity of Wildlife

The plan was designed to provide for a variety of habitat conditions to support the broad diversity of wildlife species that occur within the plan area. Furthermore, the plan's desired conditions were designed to provide ecological integrity, a basic requirement of the 2012 Planning Rule. The alternatives do not vary the plan's desired conditions, rather they vary the pace at which the plan achieves the desired conditions. Instead, the plan designed the desired conditions based upon the natural range of variation to provide for ecosystem integrity. Therefore, the effects of the alternatives are similar to each other, and the modeled outcomes are similar between the alternatives. The prevailing theme of the plan is an increase in disturbance that would reduce, but not eliminate late seral forested habitats, and increase habitats dependent upon disturbance. A variety of habitats and wildlife species depend in part or wholly on disturbance. Habitat groups that rely on disturbance include burned forest, broad-leaved or deciduous forest, open forest, and non-forested and early seral habitats. Disturbance also provides variety in aquatic and riparian habitats. Regional trends of migratory bird populations substantiate the importance of disturbance, as many species within disturbance dependent habitats have declined over the past 13 years of data collected by the Integrated Monitoring in Bird Conservation Region bird surveys. Yet, species that use mature open or closed forest show largely stable population trends. The plan will shift the balance of habitats more towards those maintained or created by disturbance, and away from mature or undisturbed forests. The change will happen over time as a result of plan direction and the response of Forest Service management to direction in the plan. While the trend in the plan's projected outcome is towards early seral and disturbance dependent habitats, the plan's desired conditions also provide for adequate conditions for species that use mature forest habitats. Thus, the **plan by will provide for the diversity and abundance of wildlife in the plan area by providing for ecosystem integrity and diversity in habitat conditions through plan components based on the natural range of variation. The plan will**

provide for the diversity and abundance of wildlife under all alternatives including the Preferred Alternative. While managing for a broad diversity in habitat conditions will provide for most species in the plan area, some individual species may require additional analysis and consideration to ensure that the plan provides for at-risk species. While at risk species were also evaluated within the diversity and abundance of wildlife, additional analysis is provided below to ensure that the plan provides the ecological conditions to contribute to recovery, provide for long term persistence, or conservation of at-risk species.

Species of Conservation Concern

Identification of Species of Conservation Concern

The Nez Perce-Clearwater began the Land Management Plan process and conducted the assessment prior to the finalization of the Final Directives for the 2012 Planning Rule. Prior to that, the Nez Perce-Clearwater had prepared the 2014 Assessment (U.S. Department of Agriculture 2014k) and the regional forester had issued a letter identifying Species of Conservation Concern (SCC). Upon release of the Final Directives, the identification of SCC needed an update to be consistent with the Final Directives. The first shortcoming was that the 2014 Assessment did not properly document a thorough review of all species that, according to the directives, should be considered. More specifically, the assessment documented rational for adding several species but did not explain why other species were not included. Second, the criteria for determining SCC may not have been applied as directed by the Final Directives. Third, the 2014 Assessment relied upon the Idaho Statewide Wildlife Action Plan as the best available scientific information to draw conclusions. In 2017, the State of Idaho released their revised Statewide Wildlife Action Plan (Idaho Department of Fish and Game 2017b), which contained updates to the conservation status of many species, leaving the first SCC list reliant upon outdated science.

To update the SCC list, the Land Management Plan interdisciplinary team used the Idaho Species Conservation Database to screen all species present in the plan area according to the categories of species to consider, as outlined in the final planning directives in Forest Service Handbook 1909.12, Chapter 10, Section 12.52, thereby removing some common species that did not fit the criteria. From there, the regional forester, in coordination with the Nez Perce-Clearwater, evaluated each of the remaining species for consideration as SCC in accordance to the directives. As part of the process, the regional forester reviewed a species list recommended by the Nez Perce Tribe as SCC. In order to facilitate plan development and analysis, the Regional Office staff provided a preliminary SCC list, with the intent to provide a fully documented evaluation of potential SCC to be provided at the release of the Final Environmental Impact Statement. For further information, see the Northern Region's website for information regarding the process used to identify SCC.

At-Risk Species Evaluation and Plan Development

In order to develop plan components, the species of conservation concern (SCC) identified in the 2014 Assessment (U.S. Department of Agriculture 2014k) and species identified through the updated efforts were evaluated for key ecological requirements, key ecosystem characteristics, and habitats. Threats and stressors were evaluated through the NatureServe method, as described below, for identifying threats. Plan components were then developed to address these threats and stressors. When ecological conditions were insufficient to provide for the long-term persistence of SCC, the Land Management Plan interdisciplinary team identified and developed species-specific plan components, as appropriate. The plan components included consideration of desired conditions, goals, objectives, suitability, management area specific direction, standards, and guidelines. The evaluation of threats and stressors to these species can be found in Appendix C.

In many cases, coarse filter ecosystem plan components were all that were needed to provide for Species of Conservation Concern (SCC). Examples of ecosystem plan components include, but are not limited to, those for Ponderosa pine systems associated with SCC, such as the white-headed woodpecker; mesic mixed conifer forests used by fisher; forests in cool moist and cold potential vegetation types for lynx; lower elevation riparian habitats in the Lower Salmon River for mountain quail; and snags and leave tree measures for many species. Species specific plan components were developed for some species when coarse filter ecosystem plan components were thought to be insufficient to provide for the long-term persistence of at-risk species. Examples include measures to reduce disease transmission to bighorn sheep, adopting the Northern Rockies Lynx Management Direction for lynx, and species-specific desired conditions for fisher that describe how fisher select habitat at multiple scales.

Bighorn Sheep

An in-depth evaluation of bighorn sheep was provided in the Multiple Use and Ecosystem Services portion of the 2014 Assessment (U.S. Department of Agriculture 2014k). The Assessment also outlined the economic and social contributions of bighorn sheep. A summary is provided here, as well as new information about this species. The Assessment outlines bighorn sheep populations, distribution, trends, biology, and threats. In Idaho, bighorn sheep exist in both small, isolated populations and in interconnected metapopulations. The largest native population of Rocky Mountain bighorn sheep in Idaho resides in the Salmon River drainage within the Salmon River breaklands and is shared with the Payette National Forest. Bighorn sheep habitat on the Nez Perce-Clearwater is generally associated with the Idaho Batholith breaklands in the Salmon and Selway River basins. Bighorn sheep also occur within the Snake River canyon and may be found in the plan area between the Snake River over from Hells Canyon and the lower Salmon River canyon, though most sheep there tend to remain on the Wallowa-Whitman administered lands. No other portions of the Nez Perce-Clearwater are known to have bighorn sheep populations at this time. However, modeled habitat produced by the Payette National Forest (O'Brien et al. 2014, Carpenter et al. 2014) indicates that other portions of the national forest contains habitat similar to that used by bighorn sheep that is unoccupied.

Bighorn sheep are analyzed below in the multiple use wildlife section. This species is both a game species and a SCC. The most important factors for the persistence of bighorn sheep include the threat from disease transmission from domestic sheep, lesser impacts to habitat from invasive plant species invasion, and forest succession. The Land Management Plan eliminates the only remaining sheep allotment, names the allotment unsuitable for sheep grazing in the plan area and provides active management to restore habitats for bighorn sheep lost through succession. The Land Management Plan clarifies that pack goat use is not restricted as a use by the public in the plan area, including within bighorn sheep habitats, because, while there is some risk, the probability of pathogen transmission from pack goats to bighorn sheep is likely lower than from sheep grazing. The risk is reduced for multiple reasons having to do with differences in how pack goats are handled and cared for and because the numbers of pack goat users is low. In addition, some evidence suggests pathogens from goats may not be as dangerous to bighorn sheep compared to those from domestic sheep. However, there are examples where goat pathogens were identified as responsible for die-offs within the Hells Canyon herd, a herd from which some individuals that use the plan area originated. While the risk is low or even very low, the potential consequences could be high. A contact between pack goats and sheep could occur in the event a pack goat escapes from ownership control. Goats, including pack goats, have the potential to carry pathogens that are known to affect bighorn sheep. Such a contact has the potential to cause transmission of pathogens that cause pneumonia in bighorn sheep, which could potentially impact a large portion of the herd, causing long term chronic effects on the population growth. The conclusion was that the bighorn sheep would persist long-term on the Nez Perce-Clearwater because the plan would find the last sheep grazing allotment unsuitable for sheep grazing in combination with a standard that prohibits any authorization of new sheep allotments within 16 miles of the bighorn sheep core herd home range.

The analysis on the coarse filter components above placed sheep in the substrate habitat group and identified steep terrain as the subgrouping because the key requirement of bighorn sheep is steep country for refuge from predators. These habitats have been affected by forest succession and invasive plant species invasion. Few other factors threaten their habitats. Therefore, the plan area provides the ecological conditions to provide for the long-term persistence of bighorn sheep.

Bighorn sheep typically inhabit rugged, rocky grasslands and open forests from low elevation river canyons to alpine areas. Although elevational migrations are generally common with bighorn sheep, most bighorns in the planning area remain in the river canyons year-round, except for the bighorns in the Selway drainage. The primary limiting factor for Rocky Mountain bighorn sheep in the plan area is disease. Domestic sheep, goats, and other exotic relatives of bighorn sheep can carry pathogens that can be lethal to bighorns and can have lasting effects on population performance through lower lamb survival. Bighorn sheep in the Salmon River and Hells Canyon population management units experienced high rates of mortality in pneumonia outbreaks in the 1980s and 1990s, likely originating from contact with domestic sheep. Those populations have not recovered to previous population levels, and bighorn populations are currently limited by low lamb survival primarily due to pneumonia-caused mortality (Idaho Department of Fish and Game 2010). Disease transmission to bighorn sheep can be controlled by maintaining separation between bighorn sheep and domestic sheep and goats. Additional discussion and cited literature are presented below.

Although disease is currently thought to be the primary reason for low bighorn sheep numbers, other factors may contribute, including vegetation changes caused by fire suppression and increases in noxious weeds. Frequent fires have had beneficial effects by reducing conifer encroachment and rejuvenating grasses and forbs; however, fire and other disturbances may also have the negative impact of facilitating the invasion of noxious weeds. Other than the threat of disease transmission, the largest threat to bighorn sheep are invasive plans which act as habitat agent of habitat change for bighorn sheep populations in the plan area, though the effects of noxious weeds on bighorns have not been well studied. Bighorn sheep are discussed as a potential Species of Conservation Concern in the 2014 Assessment (U.S. Department of Agriculture 2014k), with the primary concern being pathogen transmission.

Between 2007 and 2013, bighorn sheep in the lower Salmon River canyon were studied using radio telemetry to assess the population status of bighorn sheep along the Salmon River in central Idaho (Mack et al. 2017). The conclusions of this study follow. First, the study found that the Salmon River bighorn sheep populations have undergone previous assumed pneumonia-caused die-offs and are thought to be disease limited. Habitat modeling identified continuous bighorn sheep habitat within the project area and the larger Salmon River drainage, which provides well for habitat connectivity. Habitat distribution was dendritic, closely associated with the rugged canyon breaks of the Salmon River and its main tributaries. Lesser amounts of more fragmented potential habitat were identified at higher elevations associated with mountain and ridge tops. Bighorn sheep within the Lower Salmon River population were distributed within an estimated 990 square kilometer population range encompassing an 84-kilometer reach of the main stem Salmon River and the lower 21-kilometer reach of the South Fork Salmon River. Bighorn sheep appear to use the same locations throughout the year but may make elevational changes during winter. Reductions in bighorn sheep connectivity within the plan area is not a concern because the occupied bighorn sheep areas on the Nez Perce-Clearwater are generally within protected areas, such as wilderness, wild and scenic river corridors, or roadless rule areas.

The population consisted of five female and four male social groups. Female groups used discrete use areas that were distributed sequentially and continuously along the Salmon River main stem and South Fork Salmon and either shared or slightly overlapped adjacent group boundaries. Female groups did not display seasonal space use, such as summer versus winter or lambing versus non-lambing and used the same general area year-round. Female and male groups displayed strong site and group fidelity. Male groups were also distributed sequentially and continuously within the project area. Male use areas were discrete and disjunct during the non-rut season but overlapped extensively during the rut season. Spatial analysis and probability modeling established a high level of connectivity among main stem groups, primarily through male movements during the rut season. During the rut season, males along the main stem abandoned site and group fidelity and traveled long distances in search of female groups, resulting in a high level of connectivity as they interacted with multiple female and male groups.

The proximity of domestic sheep in the western portion of the project area, coupled with a high degree of connectivity among bighorn sheep groups, raised concerns over potential pathogen transmission throughout the population. Summer lamb survival and recruitment were low but increasing trends in these parameters and population counts provided evidence for a growing population during the term of the project. Adult survival and annual female reproductive rates remained consistent through the project period and were within the ranges reported for stable to declining populations. The annual summer lamb survival rate was low, indicative of a pneumonic population. Recruitment rates were low from biological years 2000 to 2012 and were in line with those estimated for declining populations. Pneumonia was manifested through lamb mortality. Population counts accounted for substantially more bighorn sheep (250 percent) than previously estimated. The maximum count of 347 bighorn sheep should provide for a greater degree of resiliency against demographic and environmental stochasticity than previously thought.

The project evaluated the risk of contact with domestic sheep both before and after the decision prior to the 2010 Forest Plan amendment of the Payette National Forest and estimated bighorn sheep in the Lower Salmon River population had a high probability (100 percent) of annual contact with active allotments and a high probability (37 to 100 percent) of extirpation. The evaluation was based upon models or the risk of contact from forays and risk of disease transmission coupled with estimated habitat (Carpenter et al. 2014, O'Brien et al. 2014). The 2010 Record of Decision (U.S. Department of Agriculture 2010d) finalized the Forest Plan amendment for the Payette National Forest and implemented new management direction for domestic sheep grazing. The Payette National Forest projected their new management direction would decrease the risk of contact to 4 percent and the probability of extirpation between 2 to 29 percent. The Nez Perce National Forest has potential for contact and disease transmission from one (currently vacant) sheep allotment located within the Lower Salmon River within the core home range of this bighorn sheep herd. This sheep allotment has been vacant for several years at this point. This sheep allotment would be unsuitable for domestic sheep use in the Land Management Plan by Standard FW-STD-WL-02. The current threat of new disease transmission at this point originates mostly from private sheep and goat operations off of federal lands and outside of Forest Service authority. The risk of contact model-based risk of contact solely on movements of bighorn sheep contacting domestic sheep but did not account for movements of stray domestic sheep coming into contact with bighorn sheep (Mack et al. 2017). However, the herds in the Salmon River are carriers of pathogens from previous exposures and which still affect lamb survival.

The science is clear from pen comingling studies and empirical evidence in the field that pathogens transmitted from domesticated sheep to bighorn sheep results in pneumonia that has a high lethality rate to bighorn sheep. The Payette National Forest concluded the Lower Salmon River population would have a low probability of persistence without a regional effort to address the risk of contact across Bureau of Land Management (BLM), Nez Perce-Clearwater, and Payette National Forest administered allotments.

The BLM Cottonwood, Idaho office conducted a similar analysis while amending their management plan. Under grazing management conditions prior to the amendment process, their analysis predicted a high chance of annual contact between bighorn sheep on at least one of four BLM allotments analyzed, primarily due to the close proximity between the occupied bighorn sheep range and the Partridge Creek allotment. The amended management plan was adopted in 2017, which resulted in an extremely low probability of contact from livestock grazing on the subject BLM lands because of the closure of domestic sheep allotments.

In addition to the infectious risk from domestic sheep mentioned above, bighorn sheep are susceptible to infections from pathogens carried by domestic goats. Pneumonic infections in bighorn sheep are polymicrobial, meaning that more than one pathogen results in the expression of symptoms. Several bacteria have been implicated as the causative agent of pneumonic outbreaks in bighorn sheep and often multiple pathogens are present in pneumonic sheep. *Mycoplasma ovipneumoniae* is the primary pathogen thought to initiate the disease in bighorn sheep (Besser et al. 2012, Besser et al. 2008, Besser et al. 2013). It is not well understood how these different bacterial complexes interact, but they appear to contribute to, or are present, during pneumonic outbreaks.

The scientific literature often discusses the effects of pathogens on sheep and goats together without considering them separately. However, there appears to be some scientific evidence that suggests the effects may differ. It has been demonstrated that domesticated goats can be carriers of *M. ovipneumoniae* and can transmit it to bighorn sheep. A controlled experiment where *M. ovipneumoniae* naïve bighorn sheep were penned with *M. ovipneumoniae* positive domestic goats demonstrated transmission from domestic goats to bighorn sheep (Besser et al. 2017). It should be noted that the study showed the transmission of a milder strain of the bacterium than seen in previous experiments conducted with domestic sheep, leading to sub-lethal pneumonic symptoms.

In another example, Foreyt et al. (1994) conducted a study where penned bighorn sheep were exposed to llamas, domestic goats, mountain goats, cattle, and mouflon sheep. Foreyt (1994) found that bighorn sheep remained clinically healthy during and after contact with llamas, cattle, mountain goats, and domestic goats, but all bighorn sheep died from acute bronchopneumonia after contact with domestic sheep and mouflon sheep.

There have been two reports of pathogen transmission between goats and bighorn sheep in Hells Canyon (Rudolph et al. 2003, Cassirer et al. 2017). Rudolph et al. (2003) document that a feral goat was observed within a herd of bighorn sheep near the Snake River. The goat, a bighorn ram, and a bighorn ewe were seen broken off from the main group, with the ewe showing signs of pneumonia. The goat and two bighorn sheep were euthanized and tested for pathogens, and it was found that the three shared strains of *Pasteurella* species. While Pasteurella is not thought to be the primary causative agent, it has often been found concurrently in lung tissues of pneumonic sheep and has been suspected to contribute to morbidity. The author states:

"Because samples were not obtained from the animals prior to contact, the direction of transmission could not be ascertained with certainty. The fact that identical strains of Pasteurella, particularly biovariant 1 P. haemolytica, were isolated from both goats and bighorn sheep is suggestive of transmission of the organisms from goats to bighorn sheep. However, because both the biovariant 1 and ToxA 1 organisms were limited to the three animals shot on 29 November 1995 and were not isolated from any of the other bighorn sheep in groups A and B, there is no evidence that those organisms were associated with subsequent disease or deaths. Although we know of no other information regarding transfer of potentially lethal Pasteurella spp. between domestic goats and free-ranging bighorn sheep, we believe that goats can serve as a reservoir. Thus, interactions

between the two species should be avoided to prevent Pasteurella transmission that could negatively impact the health of bighorn sheep populations. Pack goats have gained popularity for use on public and private lands. We recommend that individuals with pack goats have total control of their animals when in or near bighorn sheep habitat, both while on the trail and at the campsite. Likewise, we recommend that any bighorn sheep should be driven away from goats to prevent nose-to-nose contact and that any bighorn sheep that does come into direct contact should be removed from the herd to prevent potential transmission of disease-causing organisms to other bighorn sheep."

Phylogenetic analysis of a *M. ovipneumoniae* strain that recently caused 33 percent mortality in adult bighorn sheep within the Hells Canyon region indicated this strain was most likely of domestic goat origin (Cassirer et al. 2017). This suggests that some domestic goats could carry more serious strains of *M. ovipneumoniae* than captive commingling studies have indicated to date.

Evidence from the Hells Canyon population suggests that infection from one strain of *Mycoplasma ovipneumoniae* does not appear to provide immunity from other strains (Cassirer et al. 2017). This study found that introduction of a new genotype (strain) of *M. ovipneumoniae* into a chronically infected bighorn sheep population in the Hells Canyon region of Washington and Oregon was accompanied by adult morbidity (100 percent) and pneumonia-induced mortality (33 percent), similar to that reported in epizootics following exposure of naive bighorn sheep. This suggests an immune mismatch occurred that led to ineffective cross-strain protection. Phylogenetic analysis showed that the strain associated with the outbreak observed in Hells Canyon was likely of domestic goat origin, whereas strains from other recent disease outbreaks probably originated in domestic sheep. Cassirer et al. (2017) concluded that the lack of cross-strain immunity in the face of recurrent spillovers from reservoir hosts may account for a significant proportion of the disease outbreaks in bighorn sheep that continue to happen regularly despite a century of exposure to domestic sheep and goats. Pneumonic disease mortality is high across all age classes. Bighorn sheep lamb mortality is demonstrably higher, causing failure of herd recovery following a pneumonia die off event. "The presence of domestic sheep and goats within and adjacent to bighorn sheep ranges presents a constant and substantial risk of another major epizootic" (Washington Department of Fish and Wildife 2014).

There is currently a dearth of studies directly demonstrating the effects of incidental contact between pack goats and bighorn sheep leading to a pneumonia outbreak. There has also not been an incident reported in the literature demonstrating transmission from pack goats to bighorn sheep. Rising recreational uses of pack goats into rugged, remote areas such as those used by bighorn sheep may increase contact between pack goats and bighorn sheep that would otherwise be isolated from domestic goat herds. When examined from a risk assessment perspective, there would be an unlikely to rare probability of disease transmission coupled with potentially serious to catastrophic consequences to bighorn sheep populations in the area in the event of a contact. Demonstrated connectivity of bighorn sheep groups can exacerbate the risk to the greater population due to incidental exposure from goats (Mack et al. 2017). Many studies have shown that domestic sheep and goats can carry pneumonia pathogens without being sick or showing symptoms of pneumonia, making it difficult to determine the potential for infection prior to an epizootic outbreak (Besser et al. 2019, Heinse et al. 2016).

There are some characteristics of pack goat use that could present a lower risk of contact to bighorn sheep populations. First, pack goat users typically keep close tabs on their goats. Pack goat users often tie their animals to pack strings while traveling, and pack goats naturally tend to follow their owners because of herding behavior. The distribution of bighorn sheep is limited within the plan area and vast areas of the Nez Perce-Clearwater could be used safely without risk of contact. However, pack goat use within bighorn sheep core herd home ranges would present some risk of contact in the event a pack goat is separated from its owner. Perhaps the biggest risk is at night, where pack goats could get spooked by predators and become separated from their owners. Most owners are aware of this possibility and take measures to prevent that by tying their goats up at night rather than allowing them to range freely. In the event they become separated, owners would likely try to find and retrieve their animals, which could help reduce the risk of contact with bighorns. Pack goats tend to try to return to their owners in the event they become separated and pack goat users suggest that pack goats tend to seek humans out rather than to gravitate towards other animals when lost. While the practice is growing, current pack goat recreational use is conducted by relatively few forest visitors. For example, The North American Pack Goat Association, which is the largest organization associated with pack goat use, currently has only 289 members total in all North America. It is estimated that only a proportion of these members live near and use the Nez Perce-Clearwater. Less extensive surveys of domestic goats reported 37.5–88 percent of flocks to be Polymerase Chain Reaction positive on nasal swabs, and larger flocks were more likely to be positive for carriage (Heinse et al. 2016). In contrast, pack goat owners usually keep small flocks with greater attention to goat health so the risk for positive carriage could be lower. However there are no published studies evaluating pathogens in pack goats specifically.

Within the Nez Perce-Clearwater Land Management Plan, two actions were proposed to address the threats to the lower Salmon River bighorn sheep populations. First, the Nez Perce-Clearwater only has one remaining sheep allotment (the Allison-Berg allotment) across the whole planning area, which is located within the heart of the Lower Salmon River bighorn sheep home range area where separation from domestic sheep and bighorn sheep is not possible. This allotment is vacated currently. This allotment is proposed to be unsuitable for sheep grazing and would be closed under the plan after site specific decisions on range authorizations. Second, in the event that any new sheep allotments are initiated within the Nez Perce-Clearwater under the plan, a standard was adopted to disallow domestic sheep grazing within 16 miles of core herd home ranges, which is the same distance to those identified in the 2010 Payette National Forest's decision to maintain a low risk of contact (U.S. Department of Agriculture 2010d). Associated scientific publications were produced in conjuction with the Payette National forest that describes the models and evaluation(Carpenter et al. 2014, O'Brien et al. 2014). This distance was determined based on the Payette analysis to present a low risk of contact, though there is still some risk, while still allowing sheep grazing. In addition, this distance is thought sufficient because the last sheep allotement in the plan area would be identified as unsuitable for sheep grazing in the plan. Therefore this distance should present a low risk of contact when considering new sheep allotments. These measures should reduce the chances that new disease transmission events will occur from Forest Service allotments.

The effects of finding the Allison-Berg allotment not suitable for sheep grazing would be to eliminate all existing sources of pathogen transmission between bighorn sheep and domestic sheep from authorized sheep within the Forest Service authority. Additionally, any new sheep authorizations within the plan area would undergo a site-specific, detailed analysis and determination of effects to bighorn sheep before authorization. While new sheep allotments are possible under the plan, no new sheep allotments are anticipated in the future at this time. Sheep grazing operations exist outside of Nez Perce-Clearwater lands and may continue to pose a threat of disease transmission to the bighorn sheep populations within the plan area. These operations are outside of the Forest Service's control.

Bighorn sheep in the plan area are provided for through plan components for ungulates. FW-DC-WLMU-03 emphasizes that the habitats in the plan area provide for ungulate species that meets their life history requirements in both summer and winter. As noxious weeds are a challenge throughout the west and in the plan area, FW-DC-WLMU-03 has language desiring that big game habitats are composed of native vegetation. Plan components in the invasive section of the document also serve to provide for bighorn sheep habitats. Fire plan components and those for forested vegetation would also help increase disturbance that would decrease encroachment of forested habitats into bighorn sheep habitats. FW-GDL-WLMU-03 restricts disturbing activities on winter ranges, which will serve to protect these species during this challenging time.

As pathogens are the primary concern for bighorn sheep, FW-STD-WL-02 addresses the need for separation of domestic sheep, goats, and bighorn sheep. The distance identified in this standard was based upon the extensive analysis completed on the Payette National Forest under their Forest Plan amendment, which shares the same herd in the Lower Salmon River as the Nez Perce-Clearwater(U.S. Department of Agriculture 2010d land and resource management plan). In the Payette Forest Plan amendment decision, it was determined that 16 miles of separation was an adequate distance to reduce the risk of contact and thus pathogen transmission to an acceptable level. This analysis relies on the risk of contact modeling that the Payette National Forest conducted to identify the distance at which sheep grazing would not be suitable on the Nez Perce-Clearwater. Furthermore, since there is only one sheep allotment within the plan area which would be found unsuitable for sheep grazing in the Land Management Plan this would not be consistent with FW-STD-WL-02 and could not be reauthorized for grazing. This distance would be adequate to protect bighorn sheep long-term. The assumption is that this distance is adequate to reduce the risk of contact in the event that a new allotment for sheep grazing is authorized in the future under the plan. However, there are no current plans to authorize any new sheep allotments in the future and any new allotment would require site-specific analysis that would be analyzed for adequate separation.

Pack goats within bighorn sheep occupied core herd home ranges are specifically excluded from FW-STD-WL-02. This would allow pack goat use forestwide, including within bighorn sheep areas. The modification was made after considering the risks posed to bighorn sheep from potential contact and pathogen transmission. While there does appear to be some risks of goat to bighorn sheep pathogen transmission, the risk was considered low because the controlled circumstances under which pack goats are used reduces the probability that a pack goat would come into contact with bighorn sheep. While the risk is low, there is still a risk of contact between pack goats and bighorn that could result in a pneumonic event that could affect a substantial proportion of the herd and lower population recovery long term. FW-GL-WL-03 serves to minimize this risk through education about best management practices for pack goat owners. FW-DGL-WL-04 ensures that permits for goat packing include provisions to minimize the risk of disease transmission.

The bighorn sheep herds in the Salmon River Canyon mostly falls within the designated Gospel-Hump, Frank Church-River of No Return, and Selway Bitterroot wilderness areas and as such is protected by plan components that emphasize managing lands consistent with their designation. Suitability plan components associated with designated wildernss management found in the Land Management Plan identifies those lands as unsuitable for timber harvest, timber production, road construction, motorized travel, construction of buildings, and mechanized travel and not suitable within wilderness areas. Therefore these activities would not be allowed. Livestock grazing and mineral extraction activities are only suitable provided they are consistent with enabling legislation or wilderness plans, which essentially was only those existing prior to designation. Therefore additional or new livestock or mineral leases would not be allowed. These constraints will protect much of the bighorn sheep habitat in the plan area from alteration and disturbance.

Additionally, much of the Salmon River is designated as a wild and scenic river while other portions are included as a suitable wild and scenic river in the Preferred Alternative. Plan direction for wild and scenic rivers would be applied to the river and the one-quarter mile river cooridor which includes bighorn sheep habitat areas. These plan components emphasize managing free-flowing condition, water quality, and the outstandingly remarkable values for which the river was designated. Suitability plan components found in

Table 28 of the Land Management Plan identifies the activities that are and are not suitable within the different classifications of designated wild and scenic rivers. The Salmon River is designated as a wild classification which is more constrainging than scenic or recreational rivers. Designated wild and scenic rivers within the wild classification, except for allowences within enabling legislation, Wild and Scenic River Act or Wild and Scenic River Plan, are not suitable for timber production, timber harvest, road construction, mineral activities, motorized travel, and mechanized travel. These activities would not be suitable within the river cooridor providing protections for bighorn sheep habitats that occur there.

Similar suitability plan components found in Table 32 of the Land Management Plan apply to suitable wild and scenic rivers evaluated in the alternatives. The Salmon River outside of the designated wild and scenic river area would be suitable for inclusion in the wild and scenic river system and would be managed as a Recreational class river. Suitability plan components constrain timber production hydroelectric power facilities, and utility lines and facilities. Activites like vegetation management and timber harvest, road construction and reconstruction, mineral extraction activities, water resource protection construction, building construction, recreational vehicle travel are conditionally suitable if those activities are consistent with Forest Service Handbook direction and provided they are also consistent with standards and guidelines in the Eligible and Suitable Wild and Scenic River section of the Land Management Plan. While this direction is less constraining than in Wild segments, they still provide constraints that will ensure these activities are conducted in a manner that would protect the river and its resources. These suitability plan components would constrain or limit such activities to help protect bighorn sheep habitat within the lower Salmon River Canyon within the river cooridor in the 23 miles of river outside of designated wilderness areas and designated wild and scenic rivers.

Collectively, the plan will provide for the long-term persistence of bighorn sheep because it contains measures to reduce threats and protect habitat of bighorn sheep. Species-specific plan components would limit the exposure to pathogens carried by livestock, which is the primary threat to bighorn sheep in the plan area. It would conserve habitat because plan components to address the threat of invasive species would help limit the spread of weeds in bighorn sheep habitat and seek to reduce existing invasions. Lastly, the plan would provide land allocations and associated management that would constrain or prohibit many human activities and development from altering bighorn sheep habitat.

Fisher

Fisher are a medium-sized mesocarnivore in the weasel family (*Mustelidae*). A generalist predator, fisher hunt along the forest floor as well as within the canopy (Spahr et al. 1991). Noted for eating porcupines, prey includes snowshoe hare, other small mammals, reptiles, amphibians, bird eggs, fish, fruit, and carrion (Heinemeyer and Jones 1994, Roy 1991, Ruggiero et al. 1994b).

Fishers are limited to North America and are broadly distributed across the boreal forests of Canada with disjunct populations in the Pacific Northwest south into California, New England and the Mid-Atlantic, the Great Lakes Region, and the Northern Rockies. Fishers in the Southern Sierra Nevada of California are federally listed as threatened. In the northern Rockies fisher occur on at least eight forests in the Forest Service Northern Region (Cushman et al. 2008, Olson et al. 2014, Sauder and Rachlow 2014, Schwartz 2007, Schwartz et al. 2013, Krohner 2020), with the plan area providing a substantial portion of the available habitat (Olson et al. 2014) and known occupancy (Sauder and Rachlow 2014, Krohner 2020).

Distribution

The fisher was once found throughout northern forests of North America south into the Appalachian Mountains in the Eastern United States and along the Cascade Mountains into the Sierra Nevada

Mountains of California in the west. Fishers declined or were extirpated in most of the United States and much of Canada between 1800 and 1940 because of over trapping and habitat alteration via timber extraction. Fishers declined down to 43 percent of their historic range but recovered to occupy 68 percent of their former range primarily through reintroductions, but also after trapping seasons closed, and habitat recovery programs were implemented. (Powell and Zielinski 1994). Fishers were re-established through 38 translocations in the United States and Canada.

In the Northern Rockies, the situation was similar. Fishers were erroneously presumed extirpated in the Northern Rockies by the 1930s. (Powell and Zielinski 1994). For example, the Idaho Species Diversity Database (accessed January 2023) does not contain fisher observations between 1916 and 1970. Five translocations in the Northern Rockies were conducted from 1959 to 1991 (Lucid et al. 2019).

Genetic studies of fishers in the Northern Rockies indicate that a remanent population of fishers escaped extirpation. These studies indicate that fisher genetics in the Northern Rockies include individuals with genetics matching types from translocation sources such as British Columbia and the Midwest, but also from a native source. Genetic testing in the Northern Rockies identified a unique genetic haplotype found nowhere else in the fisher range which matched the genetics of fisher specimens collected in Idaho in the late 1800s, indicating that remanent population escaped extirpation (Vinkey 2003, Vinkey et al. 2006, Schwartz 2007) (U.S. Department of the Interior 2017d). The unique genetic signature of this Northern Rockies population also likely indicates that fishers were isolated from populations outside the region by distance, small population number, or both, for some time before the influences that led to the presumed extirpation in the early 20th century (Vinkey 2003). The U. S. Fish and Wildlife Service determined that the population of fisher in the Northern Rockies fit the criteria as distinct population segment because they have markedly different genetic characteristics relative to the rest of the taxon, and because they are isolated from populations in Canada, the eastern United States, and those in the Cascades and Sierra Nevada Mountains (U.S. Department of the Interior 2011a). The implications are that the Northern Rockies population of the fisher could be evaluated for federal listing if it meets the definition of threatened or endangered based on the five factor criteria outlined in the Endangered Species Act regardless of the status of other fisher populations in North America.

As a result of reintroductions, fishers have dispersed and reoccupied areas across North Idaho, North Central Idaho, and Western Montana (Vinkey 2003, Vinkey et al. 2006, Schwartz 2007, U.S. Department of the Interior 2017d, Krohner et al. 2022). Contemporary fisher observations have been made on the Lolo, Bitterroot, Idaho Panhandle, Kootanai, Beaverhead Deerlodge, Payette, Salmon-Chalis, Flathead and throughout the Nez Perce-Clearwater National Forest (U.S. Department of the Interior 2017d).

While fishers have distributed widely in the Northern Rockies, occupancy and genetic studies suggest that the Nez Perce-Clearwater provides much of the high-quality fisher habitat regionally (Sauder 2014, Idaho Department of Fish and Game 2017b, Krohner et al. 2022). Furthermore, the Nez Perce-Clearwater contains most of the areas with the highest occupancy rates of fishers in the Northern Rockies with habitats in much of Montana but other parts of Idaho having low occupancy rates (Krohner et al. 2022). Save for the Cabinet Mountains, the probability of occupancy in Montana and other parts of Idaho south of the Salmon River are less than or equal to half that of those on Nez Perce-Clearwater. For example, probability of occupancy rates of 7.5 km^2 cells across the Northern Rockies was 0.14 overall, with most of dryer forest in western Montana estimated at less than 0.10, but within the Nez Perce-Clearwater, the probability of occupancy was estimated between 0.3 to 0.5 (Krohner et al. 2022). Even in high quality habitat within Idaho, the species occurs at very low densities of approximately one female per 20 square miles (Idaho Department of Fish and Game 2017b). Covariate analysis found that fisher occupancy was higher in wet forest stratum versus dry forests across the region, with dry forests negatively associated with fisher occupancy. Generally speaking, wet forest stratum occurs in Idaho north of the Salmon River, whereas dry forest stratum occurs in limited parts of Montana and in Idaho in areas north of the Salmon River (Krohner et al. 2022).

Habitat models display the distribution of fisher habitats in the plan area (See Sauder and Olson Models in Appendix A of this Final Environmental Impact Statement). Unlike other at-risk species analyzed in the plan whose habitats are located eastward in the plan area at higher elevation, fisher habitats tend to be at lower elevations in mesic habitats. These models suggest fisher habitat is concentrated in the western portions of the Nez Perce-Clearwater. Furthermore, fisher habitat is more contiguous in the western portion of the national forest and more fragmented within the eastern portion of the national forest. Furthermore, the amount and distribution of Sauder's "high quality habitat" is concentrated within the western portion of the plan area. Also, within the eastern portions of the plan area, fisher habitats exist mostly at lower elevations within river canyons. The distribution of fisher habitat has implications for land allocations and uses. A substantial portion of fisher habitats occur within areas proposed for multiple uses management, where they would be subject to more intensive land use, including timber production, vegetation restoration to meet desired conditions, and fuels treatments compared to Idaho Roadless Rule Areas, Wilderness Areas, and Recommended Wilderness Areas that compose the eastern portions of the Nez Perce-Clearwater. Fisher habitats farther west outside of the plan area are composed mostly of lands managed for industrial timber harvest on private and state lands, wherein a higher percentage of the land is in early seral conditions.

Conservation Status

Fishers have garnered conservation attention in many areas in the western United States. NatureServe identifies fishers as G5 globally secure but S2 imperiled in Idaho and S3 vulnerable in Montana. Fishers are identified as a species of greatest conservation need by the states of Idaho and Montana. They are identified as an Oregon Conservation Strategy Species by the Oregon Department of Fish and Wildlife. The fisher is listed as endangered by the State of Washington but is not federally listed there. Fishers are a Regional Forester Sensitive Species (RFSS) in several national forests in the west in the Northern Region, the Pacific Northwest Region, the Intermountain Region, and the Pacific Southwest Region of the Forest Service. Fishers are federally listed as endangered in the Southern Sierra Nevada distinct population in California, but not in Northern California. The species was identified as a Species of Conservation Concern for the Nez Perce-Clearwater National Forest.

There have been limited population estimates for the population of fisher in the Northern Rockies (Lucid et al. 2019). Lucid et al. (2019) studied fisher populations in the Idaho within the Selkirk, Purcell, West Cabinet, and St. Joe and Coeur D'Alene areas and estimated population size through genetic testing. Lucid et al. (2019) found that fishers appear to have been effectively extirpated from both the Selkirk and Purcell Mountain Ranges, while populations in the St. Joe and Coeur D'Alene were small and suffer from inbreeding. Lucid et al. (2019) also found a slightly larger population in the West Cabinets which is isolated from other populations with minimal genetic evidence of migration. Population estimates range from 52–300 fisher in the West Cabinets and 13–88 fisher in the St. Joe and Coeur D'Alene mountains for a total estimate of 65–388 fisher in the North Idaho study area (Lucid et al. 2019). Coltrane and Inman (2021) studied fishers on the Montana side of the Cabinet Mountains and found they exist there in very low abundance and all detections were male fishers. No reliable population estimates have been made for the Nez Perce-Clearwater portion of Idaho.

The fisher was petitioned for listing under the Endangered Species Act in 2013 and in 2016. The U.S. Fish and Wildlife Service published a 90-day finding that announced there was substantial information that listing the Northern Rocky Mountain fisher may be warranted. Based on the best scientific and commercial information available, the U.S. Fish and Wildlife Service found that the Northern Rocky Mountain fisher is genetically different from other fisher populations and qualifies as a distinct population segment under the Endangered Species Act. On October 5, 2017, the U.S Fish and Wildlife Service published a 12-month finding which determined the Northern Rocky Mountain fisher is not in danger of extinction and does not need protection under the Endangered Species Act.

The following reasons form the basis for the finding:

- That the distribution of the Northern Rocky Mountain fisher includes forested areas of western Montana, north-central Idaho, and possibly northeastern Washington.
- The Northern Rocky Mountain fisher was found across most of its historic range.
- Distribution and quantity of modeled habitat across the Northern Rocky Mountains appears adequate to support the Northern Rocky Mountain fisher and is resistant to localized fire and drought.
- The potential stressors of climate change, development, forestry, fire, trapping, poisoning, and predation were evaluated, with no evidence of significant impacts to the Northern Rocky Mountain fisher.

Habitat

The fisher generally occur in areas with wetter, milder climates that limit snow accumulation, and topography in the form of drainages or valleys (Olson et al. 2014, Jones 1991b, Raine 1983, Arthur et al. 1989, Krohn et al. 1995, Krohn et al. 1997, Aubry and Houston 1992, Heinemeyer 1993, Ruggiero et al. 1994b). Throughout their range, fisher are associated with forested habitats with high canopy closure, complex vertical and horizontal structure, plentiful snags, and an abundant prey base (Heinemeyer and Jones 1994, Powell and Zielinski 1994, Raley et al. 2012, Aubry et al. 2013, Schwartz et al. 2013, Olson et al. 2014, Ruggiero et al. 1994a).

Fishers are found in a variety of forest types and use a variety of age classes if adequate canopy cover, large structures for denning and resting are present, vertical and horizontal cover, and prey is present. Fishers avoided drier forest types such as Ponderosa pine, Douglas-fir, and lodgepole pine (Jones 1991b, Schwartz et al. 2013). Modeled fisher habitat in the plan area occurs within the more mesic types within the warm-dry, the mesic cool moist types, and most prominently within the warm moist broad potential vegetation types.

Den sites are often located within the largest trees. In the Northern Rockies, fisher occupancy is closely tied to mature stands of mesic forest types (Olson et al. 2014, Krohner 2020, Schwartz et al. 2013, Sauder and Rachlow 2014) and riparian areas with sufficient cover (Vinkey 2003, Jones 1991b, Raley et al. 2012). Moist forested habitats with continuous overhead cover and riparian zones are frequently used (Vinkey 2003) and stream courses may be used as travel corridors (Jones 1991b).

Lofroth et al. (2010) compared fisher habitat across multiple studies. The strongest and most consistent habitat association observed across many fisher studies is the use of cavities in live and dead trees by reproductive females with kits. Fisher kits are born during late winter to early spring when weather conditions are still cold and wet and are completely vulnerable until weaned at about 10 weeks of age. Tree cavities provide both thermal insulation and security from potential predators. Kits are still vulnerable after weaning and dependent on their mother until they can hunt on their own.

Trees used by reproductive females for denning are typically large to very large in size. The average diameter at breast from a meta-analysis of fisher habitat across multiple studies was 36 inches, with a range of averages reported of between 18 and 72 inches (Lofroth et al. 2010). In all studies that analyzed den tree selection, den trees were on average 1.7 to 2.8 times the diameter of other available trees within the vicinity of the den. The relatively large size of trees and snags used for denning is most likely related to tree age and the time required for heartwood decay to develop and form cavities and the size of cavities needed to accommodate an adult female and kits (Lofroth et al. 2010). These features represent key ecological features for fisher habitats.

Fishers select habitat characteristics at multiple scales for different activities or purposes including selection for home ranges, habitat characteristics within home ranges, and specific resources within those habitats (Raley et al. 2012, Lofroth et al. 2011, Powell and Zielinski 1994). (Sauder and Rachlow 2014, Weir and Corbould 2010).

When selecting home ranges, fishers select areas with a higher proportion of high canopy cover, higher amounts of mature forest, and a lower percentage of open areas. Home ranges are characterized by a mosaic of seral stages, including young forests (8.5- to 13.5-inch diameter at breast height as defined by Jones 1991 and Jones and Garton "year") which appear to provide important winter habitat (Jones and Garton 1994, Jones 1991b, Roy 1991), but in general, fisher tend to occupy areas with a high proportion of mid- to late-seral forest and little open or non-forested habitat (Raley et al. 2012, Schwartz et al. 2013, Sauder and Rachlow 2014, Sauder 2014, Sauder and Rachlow 2015, Jones 1991b, Weir and Corbould 2010, Lewis et al. 2016, Zielinski et al. 2004b).

Within home ranges, the mosaic of forest conditions that typify fisher habitat provides the vegetative and structural heterogeneity necessary to support fisher, including high canopy cover, large diameter trees and snags for dens, multilayered canopies to protect against predation, downed wood for denning and resting, and coarse woody debris that supports prey (Jones 1991b, Heinemeyer 1993 habitat use, activity, and spacing of reintroduced fishers in northwestern Montana, Powell and Zielinski 1994, Jones and Garton 1994, Ruggiero et al. 1994a, Weir and Harestad 2003, Weir et al. 2011, Sauder and Rachlow 2015, Schwartz et al. 2013, Lofroth et al. 2010, U.S. Department of the Interior 2010). Fishers are known to hunt in both mature and younger forests but are widely reported to avoid non-forested areas and pole-sapling forest (Jones and Garton 1994, Raley et al. 2012, Weir and Corbould 2010, Zielinski et al. 2004a, Self and Kerns 2001) (Aubry and Raley 2006) Although fisher appear adaptable to a variety of forest structural conditions, they are less likely to use areas with limited cover (Buskirk and Powell 1994, Sauder and Rachlow 2014, Sauder 2014, Sauder and Rachlow 2015), which may limit occupancy and dispersal in fragmented landscapes (Carroll et al. 2001, Zielinski et al. 2013).

Within their home ranges, they rest and den in mature and old stands. Female fisher use large diameter live trees and snags with cavities for denning and rearing of young and have been reported to use a wide variety of tree species (Raley et al. 2012). A key feature of these trees is that they are large diameter dead or partially dead trees often reported to have cavities and heart rot, suggesting that damage and decay play critical roles in the suitability of habitat for reproduction. Thus, retaining and promoting ecological processes that result in the recruitment of trees with these features is important to the conservation of reproductive habitat for fisher (Raley et al. 2012). Fishers selects areas with higher amounts of coarse woody debris, large downed trees, and standing large diameter live trees or snags with cavities which are used for resting, denning, refuge from predators, and thermal regulation, (Jones 1991b, Heinemeyer 1993, Jones and Garton 1994, Weir and Harestad 2003, Weir et al. 2011)(Raley et al. 2012). Several studies have suggested that the abundance of these structures to potentially be a limiting factor for fishers (Zielinski et al. 2004b, Powell and Zielinski 1994, U.S. Department of the Interior 2011a, Spencer et al. 2008). Even when using younger forests in winter, studies note the importance and use of large diameter trees, snags, and downed wood (Jones and Garton 1994). Fishers forage in both mature and younger forests and are more tolerant of early seral conditions while foraging but are widely reported to avoid openings. Moist forested habitats with continuous overhead cover and riparian zones are frequently used (Vinkey 2003) and stream courses may be used as travel corridors (Jones 1991b).

Home Range and Space Use

Home ranges for fishers in the Northern Rockies are among the largest in their range. Home ranges are large, with males having larger home ranges than females and male home ranges overlap one or more female home ranges. However, fishers maintain relatively exclusive intra-sexual home ranges which contributes to low densities. Fisher home ranges vary in size across North America and range from 16 to 122 square kilometers (4.7 to 36 square miles) for males and from 4 to 53 square kilometers (1.2 to 15.5 square miles) for females. Within the plan area average "year-long" estimates of intra-sexually exclusive home range size were 40.8 and 82.6 square kilometers for females and males, respectively (Jones 1991a). Sauder and Rachlow reported average home ranges of 98.4 km^2 for males and 49.3 km^2 for females. The large home ranges and exclusive inter-sexual home ranges contribute to the low densities of the species. These homerange characteristics informed queries to model outcomes of the Forest Plan as described below. In addition to home ranges, researchers have also reported core use areas that are smaller than fisher home ranges. Sauder reported core use areas were estimated at 6,795 acres (or 27.5 km^2) for males, while female core use areas were 4,596 acres (or 18.6 km^2). Sauder (2014) suggested female home ranges overlapped by 21.3 percent, and female core areas overlapped by 8.1 percent. Male home ranges overlapped 15.3 percent, and male core areas overlapped by about 3.3 percent.

Natural Processes that Contribute to Fisher Habitat

Several natural ecological processes contribute to habitat conditions that support fishers including forest succession, fire, and tree diseases. As stands age, trees become larger, and factors that affect tree health become more prevalent. These conditions contribute to the development of larger trees with cavities that provide denning habitat. Insects and diseases affect forest health conditions and the amount of denning and resting structures present. Insects and disease include mountain pine beetles, Douglas-fir beetle, spruce beetle, fir engraver, balsam woolly adelgid, western hemlock looper, western spruce budworm, root diseases like armillaria, laminated root rot, annosus root disease, schweinitzii root and butt rot, Indian paint fungus and White pine blister rust. Generally speaking, these pests and pathogens affect mature trees more readily than younger trees. Root disease is the leading cause of tree mortality on the Nez Perce National Forest. Insects and disease can affect stand densities, proportion of live and dead trees, tree condition, and stand composition. Insects and tree diseases and subsequent excavation by woodpeckers create the conditions in mature forests that support fisher denning, resting and thermal cover such as tree trunks with hollow cavities in live and dead trees. Female fishers are among the largest obligate-tree cavity users in North America, and trees used as dens need to be large enough to provide a cavity that has an inside diameter of nearly 12 inches or larger. Once dead trees fall to the forest floor, they create woody debris that support fisher habitat and their prey. While most insect and diseases are endemic, trends and projections suggest that many of these insects and diseases are currently operating at higher than endemic levels and trending higher through time as a result of increases in forest age, climate conditions, and increased dominance of tree species that are susceptible to these pathogens. Forest insect and diseases are important processes that contribute to structural diversity that wildlife like fishers depend on. These are disturbance factors that operate within a natural range of variability to support important features for wildlife. An in-depth discussion about insects and diseases is provided in the Forestlands section of this Final Environmental Impact Statement.

An especially important process that contributes to fisher denning and resting structure is heart rot. Indian paint fungus causes decayed heartwood and hollow stems in living small-size and larger true fir and hemlock trees. Hollow stems are created during advanced stages of decay, when cylinders of rotted heartwood detach from surrounding sapwood and collapse, causing formation of a hollow chamber.

Heartwood weakened by this fungus provides a substrate suitable for cavity excavation, while hollow stems provide ready-made cavities for nesting, roosting, resting, and denning. Decayed and hollow stems also provide areas of weakness where stem breakage may occur. Broken tops may provide points of entry to hollow stems, or, in conjunction with green limbs remaining near breaks, may provide structures useful for denning. Stem breakage contributes to the formation of canopy gaps, increasing structural diversity, and adds decayed wood elements to the forest floor.

Windborne Indian paint spores infect new host trees, usually when the trees are small and growing in the understory, through tiny (less than 2 mm) dead branchlet stubs. Spores germinate and mycelia grow within the branchlet until it is overgrown by healthy tissue. The fungus then enters a dormant phase as a resting spore, surviving for 50 years or more until activated by a tree wounding injury that allows air into the trunk interior near the resting spore. Once activated, decay develops rapidly in the heartwood. Fruiting bodies (conks) form on the tree bole after extensive decay has developed and typically produce spores for several years. Suppressed, slow-growing trees are more likely to be infected by Indian paint fungus than fast growing trees, because they tend to have more shade-killed branchlets and to overgrow dead branchlet stubs more slowly, providing increased opportunities for infection. Thus, Indian paint fungus is most common in stands that developed from dense, suppressed, trees growing under infected overstories, especially on sites where tree vigor is low. Cool, moist sites such as those found near water, on north aspects, on lower slopes, and under dense shade, as well as uneven-aged stand structures favor spread and infection by this fungus. Wounds that activate dormant infections are commonly caused by mechanical injuries to the tree bole, frost cracks, or the breaking of a large-diameter branch close to the tree bole. Stands containing host trees, especially grand fir or white fir, that are managed on long rotations of 120 years or longer are likely to develop decay that provides useful structures for wildlife sheltering, nesting and denning.

Several forest types used by fishers burn with a mixed severity fire regime. Mixed fire regimes naturally result in fire mosaics that consist of a mix of fire severities including low burn severity, unburned fire skips, and live trees within burned areas that live into the next stand generation. A critical outcome of this heterogeneity is the formation of fire refugia—unburned or lightly burned areas in the burned matrix that are functionally unaltered by fire. The variable nature of mixed fire regimes results in older and larger diameter trees, and islands of large trees present within a burn perimeter that later grow to provide denning and resting habitat for fishers. Many factors influence burn severity, including fuel characteristics, climate, weather conditions, topography, vegetation characteristics, and elevation. Fuel conditions can affect the rate of spread, shift fire behavior from surface fire to crown fire and influence fire severity. High severity fire has been reported to be avoided by fishers and has the capacity to destroy large swaths of suitable habitat, but areas that burned at low and medium intensity or were left unburned maintain fisher use, and forest structural characteristics predictive of den presence were found in areas that burned at low to moderate severity. Uncharacteristic high intensity fire has been identified as a threat to fishers in the Southern Sierra Nevada Mountains and contributed to federal listing of the Sierra Nevada population. Wildfire has been, and will be, the greatest driver of vegetation change on the Nez Perce-Clearwater. Efforts to promote a sustainable low- to mixed-severity fire regime that creates habitat heterogeneity and forest resiliency can support fisher conservation and facilitate habitat connectivity for fishers.

During timber harvest, Jones and Garton (1994) emphasized retaining an abundance of cull grand fir for future dens, retaining 54 but no more than 109 metric tons of large diameter logs, and retaining decks of cull logs and a few slash piles would recover fisher habitat faster after clearcutting. They also maintained that uneven harvest management would better maintain fisher habitat at the stand level. They suggested that fisher habitat management may require a landscape-based approach to maintain the integrity of ecological systems. Applying such an approach would require land managers to adopt long-term, large-scale plans that would mimic natural landscape patterns and processes. Such an approach would keep a certain proportion of forests in various successional stages, together with a specific frequency distribution of various patch size and linkage areas across the landscape. Such an approach would help ensure the viability of fisher populations within a managed landscape (Jones and Garton 1994).

Harris (1984) suggested that fisher habitat management must involve management of a system of mature forests, as opposed to management of individual stands. Sauder and Rachlow (2015) published two studies on fisher from data they collected from radio collared individuals within the plan area and on adjacent lands. Sauder and Rachlow (2015) found that fisher selected habitat at different scales and identified key ecological features of fisher habitat. Landscapes, defined as 50 to 100 square kilometers that had greater than or equal to 55.8 percent mature forests arranged in connected complex shapes with few isolated patches and open areas comprising less than 5 percent of the landscape characterized a forest pattern selected by fisher. Mature forests, identified as trees 25 to 50 meters tall, were important to fisher ecology at the landscape scale. Open canopy cover was defined by Sauder and Rachlow (2014) as the percent of the of landscape with canopy cover less than 10 percent and canopy height categories were defined as nonforested or open, 0–4.9 m, 5–9.9 m, 10–24.9 m, and 25–50 m. Per a personal conservation with Joel Sauder on September 11, 2019, tall forests were a surrogate for characteristics that contribute to fisher habitat such as snags live trees with heart rot, or large diameter trees, but some younger stands can reach 25 to 50 meters tall yet lack some of the characteristics that provide for fisher, such as snags, live trees with heart rot, and larger diameter trees. The top model included a landscape configuration and a landscape composition metric. The configuration metric was the proximity among mature forest patches representing the connectedness of mature forest patches within a landscape and the composition metric included the percentage of the landscape classified as open area. The proximity index distinguishes sparse distributions of small habitat patches from configurations where the habitat forms a complex cluster of larger patches. The proximity index among mature forest patches was the most supported habitat variable influencing habitat selection by fishers for home ranges at the landscape level and was 40 times more plausible than the amount of open area as best explaining landscape-level habitat selection by fishers. The percentage of the landscape with open areas was selected against by fishers. Landscapes with greater than five percent open area display pronounced decreases in the probability of use. With 10 percent open area on the landscape, the probability of occupancy drops 39 percent when compared to the 5 percent area mentioned previously (Sauder 2014). The rapid falloff of occupancy probability is indicative of the fisher's high degree of sensitivity to open areas on the landscape. Thus, the connectivity of mature forest is a key ecosystem characteristic of landscapes selected by fishers as home ranges.

Sauder and Rachlow (2014) compared areas with different management histories in relation to how they would provide for fisher habitat. Based on these findings, Sauder and Rachlow (2014) concluded that landscapes managed primarily for industrial timber production and lands managed as roadless and wilderness had significantly more open areas, less mature forest, and a reduced proximity of mature forest patches than occupied fisher home ranges. Sauder and Rachlow (2014) defined industrial forest (that is, state, corporate, and privately owned forested lands managed primarily for timber production), roadless forest (that is, federally owned and designated roadless or wilderness areas), and multiple use forest (that is, the remainder of federally owned lands). This seemingly suggests that the amount of disturbance in the multiple use forest areas prior to 2014 supports fisher occupancy at higher levels than industrial or roadless forest.

Similarly, Weir and Corbould (2010) examined factors affecting the probability of a potential home range being occupied in British Colombia with data from 10 radio tagged resident fisher in the Sub-Boreal Spruce bio geoclimatic zone between 1996 and 2000. They reported that the percentage of a home range in open areas, defined as wetlands and recently logged areas within the past 12 years, best predicted the likelihood of occupancy by fishers. The probability of a home range area being occupied by a resident fisher decreased with increasing amounts of wetlands and recent logging present in the area. They estimated that a 5 percent increase in open areas decreased the relative probability of occupancy of a potential home range by 50 percent. Logging 5 percent of their area equated to approximately 591 acres within a female home range of 11,786 acres in a 12-year period.

Two researchers have developed habitat models for fisher on the Nez Perce-Clearwater:

- Olson et al. (Olson et al. 2014) modeled fisher habitat based upon using a suite of vegetative, topographic, and climatic variables. Olson found the probability of current fisher occurrence was highest given the presence of mesic forest types with tall trees, high annual precipitation, and mid-range winter temperatures. From this study, Olson produced a model across the Northern Rockies that predicts the probability of occurrence. Olson's model suggests that the Nez Perce-Clearwater contains much of the core fisher habitat in the Northern Rockies. The Olson model suggests that the warm moist potential vegetation type group composes most of the fisher habitat in the plan area.
- Sauder (2014) refined the Olson model by including landscape scale variables for connectivity of mature forest and the amount of open habitat. The Sauder model is a probability surface that combines the climate only model of fisher habitat from Olson et al. (2014) with two other published models of fisher habitat at the landscape (Sauder 2014) and home range (Sauder and Rachlow 2015) scales. Sauder's model is more specific for the Nez Perce-Clearwater for fisher because it was developed from radio-collared fishers on the Nez Perce National Forest and represents the habitat preferences of fishers. The model displays relative probabilities of occurrence, but not absolute probabilities of occurrence. The model applies a threshold to the continuous probabilities to define "probable and not probable" fisher habitat that maximizes the sensitivity (that is, correctly predicting fisher presence) and specificity (that is, correctly predicting fisher absence) of the habitat model. This approach puts equal importance on correctly predicting presence and absence. Thresholds used for probable habitat are at minimum specificity levels of 80 percent and 95 percent, meaning that the probability of incorrectly predicting fisher habitat to be present when it was less than or equal to 20 percent or less than or equal to 5 percent, respectively. Sauder (2014) used these levels to identify "probable" and "high quality" habitat. For this analysis we applied the threshold for "probable" habitat because it is inclusive of high-quality habitat and also includes many areas that are likely occupied by fishers. Sauder's model is the best available scientific information for fisher habitat in the plan area. The analysis of the effects of management area allocation on fisher is informed by the distribution of Sauder's probable fisher habitat.

See Appendix A for maps of the Olson and Sauder fisher habitat models.

Essentially both the Olson model and the Sauder model suggest that the core of fisher habitat in the Northern Rockies habitat exists within the Nez Perce-Clearwater and the Cabinet Mountain range. They also showed that fisher habitat was more fragmented and of lesser amounts in other areas of Idaho and Montana.

Key Threats and Stressors

Threats were assessed using the NatureServe method for threat identification. The method uses a combination of the scope and severity of threats to derive the overall impact. The threats assessment for fisher using this method can be found within Appendix C. The threats assessment identified several medium level threats, but no high or severe threats. According to the threats assessment, threats include past livestock grazing, illegal harvest (such as incidental trapping), past timber management, regeneration harvest, pathogens, fire suppression, uncharacteristic wildfire, habitat shifting, and alteration as a result of climate change. Some of these threats are identified as medium level threats because the severity, scope or both are unknown, such as for past livestock grazing or introduced genetic material, and the method treats uncertainty with caution by increasing the resulting threat level. However, these are indirect threats that could have altered habitat, but are not likely to affect habitat in the future, and effects are likely to diminish with time. Therefore, they are not analyzed in detail. Threats that could alter fisher habitat or populations in the future are discussed in more detail below.

Stressors to this species group that are outside the control of Forest Service management may include:

- Global warming—Increased and prolonged summer temperatures and drought conditions, and the increased risk of fire, duration of fire, or increased intensity of burning that may impact forest cover and downed wood. May also result in a northward shift in habitat, changes in tree species composition, and habitat fragmentation.
- Private land development—Developments to support increased human populations that may impact suitable forest cover on non-public lands and impact connectivity between public lands.
- Over-harvesting by trappers—Incidental trapping may be an important source of mortality, particularly where populations are small and fragmented. Idaho prohibits trapping of fisher so all mortality of fishers from trapping is through incidental captures in pursuit of other species or illegal trapping.
- Habitat loss and degradation—Loss of forested habitat, particularly late-successional forests, to fire and timber harvest results in the reduction and fragmentation of suitable habitat. Loss of habitat cover and structure near streams and loss of downed woody material near streams.
- Small, isolated populations—May lose genetic diversity and have a higher probability of extinction. It is unknown if a sufficient number of individuals exist to sustain the populations across the full range of environmental and demographic stochasticity (Vinkey 2003). Stressors may cause loss of habitat, displacement, or mortality. Genetic diversity in the Northern Rockies may be higher than other areas within the fisher's distribution because populations here are composed of individuals with native genetics and individuals from populations in the Midwest and British Columbia.

The following Forest Service management activities may have direct or indirect effects on forested and riparian habitats:

- Timber Harvest and Vegetation Treatments—Changes in mature and late-successional forest stand composition and structure affecting canopy cover, large and very large live and dead trees, hollow trees, downed trees, and forest composition. In addition to timber harvest, this category includes prescribed fire, fuels treatments, habitat restoration, wildlife habitat treatments (for big game for example), and other vegetation treatments. The magnitude of this threat depends upon the scale, intensity, and manner of timber and vegetation management activities.
- Wildfire patterns—This would include fire patterns that are either lacking due to fire exclusion or are more intense and larger in scale than was typical historically, resulting in widespread habitat changes and landscape patterns. This category includes fire exclusion, uncharacteristic wildfire, and the interaction of wildfire and climate change.

For fisher, as with all wildlife on the Nez Perce-Clearwater in general, wildfire, insects and disease, in-growth, and stand succession largely determine the amount and pattern of habitat on the Nez Perce-Clearwater for this species rather than management activities (Ecosystem Research Group 2019).

However, forest management could be in part additive to natural disturbance, and climate change could alter the intensity, timing, and frequency of disturbances, and the distribution and condition of habitat.

Methodology

The analysis focused on the Plan Area, except for cumulative effects, which were considered at larger spatial scales to reflect activities occurring on non-National Forest System lands. The analysis at a minimum considered the anticipated life of the plan (15 years), but changes in vegetation were considered over longer periods to reflect the effects treatments have on forest conditions. The alternatives were designed to achieve desired conditions at different rates (No Action Alternative at the current pace of management, Alternative W within 20 years, Alternative X within 30 years, Alternative Y within 50 years, Alternative Z within 100 years, and the Preferred Alternative within 40 years), and thus were compared at 10-year timesteps to highlight the effects of different rates of implementation. The No Action Alternative was set to achieve the desired conditions at the current pace of vegetation management. However, all alternatives, including the No Action Alternative, are moving towards a common set of desired conditions that do not vary. Each alternative is expected to achieve results at different rates relative to forest cover type, size class, and density distributions. All alternatives, including the No Action Alternative, are expected to have different trajectories and effects related to the pace of achieving desired conditions.

In addition to the coarse filter ecosystem analysis for mature closed forest habitats analyzed above, the analysis of the effects of the Land Management Plan specific to fishers involves two parts:

1. A spatial analysis of fisher habitat overlaid with Land Management Plan alternatives for land allocations to evaluate how much fisher habitat would be subject to, or protected from, a variety of potential land uses as a result of suitability plan components;
2. the vegetation modeling outcomes for fisher habitat using the SIMPPLLE model that implements the plan's integrated plan components. Plan direction influences the trend and condition of fisher habitats. Fisher were analyzed with coarse filter ecosystem components in mind. The analysis of vegetation conditions and the effects of coarse filter ecosystem plan components were modeled in SIMPPLLE to determine the outcomes for fisher habitat under the alternatives. See the Forestlands section for more information on vegetation modeling.

Spatial Overlays

The spatial overlays use the Sauder model of probable fisher habitat overlaid with land allocation alternatives. Variations between the alternatives that could affect fisher habitat include the amount of fisher habitat within management areas, recommended wilderness, suitable and eligible wild and scenic rivers, the recreation opportunity spectrum, timber suitability, and geographic areas. The various land allocations and their associated suitability plan components would determine where and which types of activities would potentially occur within those lands.

In addition, suitability plan components in designated land allocations provide protections as well which includes designated wilderness, Idaho Roadless Rule Areas, designated wild and scenic rivers, the Lolo Trail National Historic Landmark, and designated research natural areas. A variety of activities that could affect fisher are not suitable or are conditionally suitable within these land allocation types and so would not be subject to unsuitable activities and would have limited amounts of these activities when conditionally suitable within these lands. For example, these land allocations constrain vegetation management and timber harvest, which could be detrimental to fisher habitat. Instead, they include the use of wildland fire to trend towards land management plan desired conditions and objectives, which provide natural ecosystem processes that promote diversity in habitat structure that fisher require. The Idaho Roadless Rule constrains timber harvest, road building, and mining activities to various extents depending on the Roadless Rule theme and directs the purposes for which vegetation treatments may be conducted. Idaho Roadless Rule areas allow vegetation treatments but must be conducted based on the allowances within Idaho Roadless Rule themes.

The most widespread influence on fisher habitat is land use allocations, such as those for wilderness, Idaho Roadless Rule, or multiple use areas (see Effects Alternatives of Land Allocations). Important decisions made in Forest Plans are the allocation of lands proposed for designation, their different uses, and their broad management direction. Examples of land allocation decisions that will be made in this plan are management areas; the summer and winter recreation opportunity spectrum classifications which identify areas suitable for motorized uses; areas suitable for timber; areas recommended as wilderness; rivers eligible or suitable for inclusion into the wild and scenic river system; and areas proposed for research natural areas. In addition, the plan sets prevailing direction for the different land allocations. Furthermore, the plan's land management area allocations and associated suitability plan components will determine which activities are suitable to occur on those lands. Fisher habitat within the various land allocations will be managed under the direction established by the plan's desired conditions. Furthermore, uses suitable within the different land allocations would potentially occur within fisher habitat on those lands.

Important decisions made in Forest Plans are the allocation of lands proposed for designation, their different uses, and their broad management direction (Table 186). Table 182 shows the amount and percent of fisher habitat within the different types of designated and multiple use land allocations types. These land allocations combined make up the majority of the national forest's land allocations. Designated Wilderness, designated wild and scenic rivers, the national historic landmark, and Idaho Roadless Rule areas are lands designated by congress or were established by rule by the Idaho Roadless Rule. General multiple use lands are areas of the national forest not already designated.

Table 182. Acres and percent of fisher habitat by land allocation type in the No Action Alternative

Management Area	Acres	Percent
Designated Wilderness	232,914	11.7
Idaho Roadless Rule	799,152	40.1
General Multiple Use Forest	900,846	45.2
Lolo Trail National Historic Landmark	26,858	1.3
Designated Wild and Scenic Rivers	34,468	1.7
Grand Total	**1,994,238**	**100**

Management in designated wilderness emphasizes maintaining wilderness character and prohibits actions like road building, building structures, timber harvest, and mechanized travel. Fires from natural ignitions are generally allowed to burn if they do not threaten any critical values at risk near towns and communities. Grazing and mineral activities that existed before designation of wilderness areas were allowed to continue, but new grazing and mineral activities were withdrawn. The management paradigm in wilderness is protective of fisher habitat except for the limited exceptions and all allowed activities must be consistent with maintaining wilderness character. Natural fire ignitions within designated wilderness are generally allowed to burn, which could affect fisher habitat.

Designated Wild and Scenic Rivers are focused on the protection of the rivers, but management constraints apply to uplands within one-quarter mile of the river corridor. While these areas make up limited amounts of fisher habitat (see Table 182 for acres and percent), actions within these river corridors must protect or enhance the river's free-flowing character, water quality, and outstandingly remarkable values. The Middle Fork Clearwater River provides 33,889 acres, the Rapid River offers 255 acres, and the Saint Joe River includes 2 acres of fisher habitat. Generally speaking, wild rivers allow fewer activities than recreational or scenic rivers. These lands are generally protective of fisher habitat but with exceptions that must follow the river management plan, Forest Service Manual policy, the Wild and Scenic Rivers Act, designating legislation, or mining laws. Suitability of uses depends on whether the river is wild or recreational, with wild rivers having more restrictions than recreational rivers. The suitability of uses within wild and scenic rivers can be found in the Designated Wild and Scenic Rivers section of the plan. While only a low percent of habitat occurs within these areas (Table 183), they contribute to fisher conservation because riparian habitats are known to be used by fisher.

Table 183. Sauder model fisher habitat by designated wild and scenic river theme

Designated Wild and Scenic River Theme	Acres	Percent
Recreational	29451	1.5
Wild	5016	Less than 1

Data Source: Sauder model overlaid with designated wild and scenic river spatial layers representing a one-quarter mile river corridor.

The Lolo Trail National Historic Landmark contains a relatively small percentage of fisher habitat, but timber harvest and timber production are both unsuitable. Natural processes like wildfire are encouraged, and activities within the landmark should maintain National Register integrity. These lands are generally protective of fisher habitat.

Designated and Idaho Roadless Rule lands do not change as a result of the Forest Plan. Only the broad direction for these lands and suitability plan components are influenced by the Forest Plan. Combined, designated wilderness, designated wild and scenic rivers, and Idaho Roadless Rule Areas constrain or prohibit activities like timber harvest that alter fisher habitat. Thus, approximately 54.8 percent of fisher habitat is protected from these activities. Wildland fire is the primary agents of habitat change for fisher on these lands. Prescribed fire is usually conducted with lower severity burns that recovery faster from disturbance and could still be used by fishers.

A number of recommended land allocations vary by alternative and decisions in the Forest Plan. They include eligible and suitable wild and scenic rivers, recommended wilderness, and proposed research natural areas. These land allocations establish the variation in area within the three broad management areas shown in Table 186. In most cases, recommended areas overlap either Management Area 1 or 2 lands. In addition, the plan makes decisions about the suitability of motorized uses via the winter and summer Recreation Opportunity Spectrum and identifies timber suitability for the different land allocations. These are analyzed in more detail below. In many cases, these would direct where forest management activities occur or are restricted. Designated wilderness areas are the most restrictive, Idaho Roadless Rule Areas are intermediate, and multiple use areas are the least restrictive for management activities. They direct where and for what reasons timber harvest or production are allowed, how fires are managed, and how much motorized access there is generally. The most permissive are the multiple use areas, which would undergo the most timber production, and fuels treatments and would have the most motorized access. The least permissive are wilderness areas (Table 184), recommended wilderness is slightly less restrictive, and depending roadless rule areas constrain road building, timber harvest, and some mineral uses depending on roadless rule theme. The overlays provide a quantitative evaluation of the amount and percent of total fisher habitat that would potentially be subject to the types of activities that would occur under the plan. Thus, spatial analysis provides an indication of the distribution and scope of potential activities that could occur. Results and analysis are presented below.

Table 184. Acres and percent of fisher habitat in designated wilderness areas

Designated Wilderness Area	Acres	Percent
Frank Church-River of No Return Wilderness	11,487	0.6
Gospel-Hump Wilderness	23,685	1.2
Non-Wilderness	1,761,323	88.3
Selway-Bitterroot Wilderness	197,742	9.9

Vegetation modeling

See the Forestlands section for more information on vegetation modeling.

SIMPPLLE was used to estimate the natural range of variability of fisher habitat by modeling vegetation conditions backwards into the past for 100 decadal time steps simulating vegetation conditions over a thousand-year period. The natural range of variation (NRV) simulations incorporated climate models to simulate how variation in climate conditions changes in fisher habitat over time. Climate models simulate both warmer-drier and cooler-moister periods which in turn affect the amount of disturbance forests experience in the model and ultimately determine the condition of fisher habitat in outputs. Simulations are run 30 times and the NRV ranges are the averages of the simulations. Future projected outcomes of the alternatives are evaluated relative to the lower and upper ranges of the NRV, with the assumption that fishers have persisted in habitat conditions that operated within that variation. See the Forestlands section for more information on vegetation modeling. The natural range of variation provides a frame of reference for ecological integrity and resilience. It reflects the conditions that have sustained the current complement of wildlife and plant species and provides context for understanding the natural diversity of vegetation and the processes that sustain it. Since the mid-1800s, human presence and activities have increased dramatically in the plan area. The NRV estimates provide a reference to conditions that might have occurred prior to these impacts.

The analysis of the NRV was a primary element that informed desired conditions, but desired conditions depart from the NRV in some cases, recognizing that future climates necessitates changes to forests to ensure resiliency. The intent of using the NRV to inform desired conditions is not to return precisely to conditions that occurred at a single point in time but to understand the full range of conditions that were supported prior to substantial human influence. Desired conditions are framed within the variability associated with the natural range of variation to provide context for management objectives.

The analysis focused on key threats and stressors that may affect the ecological conditions necessary to maintain a viable population of fisher within the plan area. The analysis included a qualitative assessment based on the best available science and information, and when available and appropriate, additional quantitative analyses were added to further elucidate the relationships between stressors and the ecological conditions that support fisher populations. Specifically, the analysis included two quantitative models to estimate the effects of the alternatives on 1) the availability of fisher habitat (that is, acres of mature, mesic forest) and 2) the suitability of available fisher habitat to support a preferred fisher home range based the spatial arrangement of preferred fisher home ranges (proportion of mature, mesic forests and open or sparse vegetation).

Fisher Habitat Availability Model

The availability of suitable habitat can limit the distribution of species, including fisher (Olson et al. 2014). For fisher, the presence of mature, mesic forests is one of the primary predictors of occupancy and distribution (Krohner 2020, Jones 1991a, Jones 1991b, Jones and Garton 1994, Sauder and Rachlow 2014, Sauder 2014, Sauder and Rachlow 2015, Schwartz et al. 2013, Olson et al. 2014). The availability of mature, mesic forests was modeled using the SIMulating Patterns and Processes at Landscape scaLEs (SIMPPLLE) model and compared among alternatives and against the estimated natural range of variation (NRV) to identify major departures from historic conditions (see Timber section for NRV methodology). The alternatives were modeled to meet the desired conditions for forest composition and size classes, as described in the revised Forest Plan. The alternatives were constrained by other resource factors (for example, riparian area direction, Northern Rockies Lynx Direction), known operational or logistical limitations, and management area direction. Outside of such constraints, treatments were assigned randomly with respect to their distribution. Based on the best available science, a query within the SIMPPLLE model was created to approximate the mature, mesic forest types that fisher tend to occupy.

A query was created to estimate fisher habitat for SIMPPLLE modeling. We reviewed published literature to identify habitat types to include in the model which included Jones (1991), Jones (1994), Schwartz 2013, Olson 2014, Sauder and Rachlow (2014 and 2015). Aspects of the fisher habitat informed by these publications were size classes, canopy cover, and habitat types. To identify broad potential vegetation types (PVT) to include as fisher habitat, the modeling compared broad potential vegetation with fisher observation data. To more closely compare to a locally derived fisher-habitat model (Sauder 2014), the query was adjusted between the draft and final analysis to include additional warm dry forests habitat types that fisher may occupy (Krohner 2020); however, Ponderosa and lodgepole pine habitat types were excluded as they are largely unused by fisher (Schwartz et al. 2013). The updated query also added forest types in some of the cool-moist broad PVTs, most notably some of the mesic, spruce-fir habitat types (Jones 1991b, Jones 1991a, Jones and Garton 1994). Finally, assumptions regarding fire intensity and scale were modified to better replicate the Nez Perce-Clearwater historic fire patterns more closely.

These habitat preferences led to the identification of the query below and suggest that fisher habitats align with those in the warm moist, some warm dry, and some cool moist broad PVTs. The habitat query included separate queries for denning habitat and foraging habitat. Denning and foraging habitat used the same cover types, but denning habitat was trees at least 15-inch diameter at breast height (DBH) while foraging habitat was trees at least 10-inch DBH. Details on the modeling parameters are available in the project record.

Denning Habitat

- Mature—qualifies as part of the 55.8 percent within a home range
- Cover type: Unless specified below, all cover types are included
    - Habitat groups and cover types:
        - A2—all cover types except pure Ponderosa pine
        - B2—all cover types except pure Ponderosa pine
        - C1A—all covertypes except pure lodgepole pine, Ponderosa pine, Engelmann spruce, lodgepole pine-grand fir
        - C1B—all covertypes except Ponderosa pine
        - C2—all covertypes except Ponderosa pine
        - C3—all covertypes

  - D1—all covertypes
  - D3—all covertypes except lodgepole pine, Engelmann spruce, subalpine fir, Engelmann spruce-subalpine fir, subalpine fir-Engelmann spruce-mountain hemlock, lodgepole pine-subalpine fir
  - E1—all covertypes, including Engelmann spruce, subalpine fir, Engelmann spruce-alpine fir
  - E2—all covertypes except Engelmann spruce, alpine fir, Engelmann spruce-subalpine fir-lodgepole pine; lodgepole pine IS included
- Habitat 15 inches and larger is denning habitat while habitat 10 inches and larger is foraging habitat. Foraging habitat includes denning habitat.
  - 10-14.9 inches
  - 15–19.9-inches
  - greater than 20-inches
- Fisher habitat was identified as canopy cover greater than 10 percent and includes:
  - 10-39 percent
  - 40–69.9 percent
  - 70–100 percent

Modeling for both the natural range of variation and the future outcomes are run forestwide 30 times with all forest stands receiving a treatments schedule in PRISM while natural disturbances are simulated by SIMPPLLE. Each run produces an estimate of the outcome, and the 30 runs are each averaged together to produce the outputs presented below. The fisher query, as informed by the best available scientific information, is a subset of the forestwide vegetation outcomes from the query above which is a set of criteria that are indicative of fisher habitat. The SIMPPLLE model query for fisher habitat identifies the relative amounts of the denning and foraging habitat by alternative over time and allows for a comparison between alternatives.

The final queries approximate fisher habitat, but they are not based on actual fisher occupancy data. Rather the queries represent general vegetation characteristics indicative of fisher habitat as derived from published literature (Krohner 2020, Jones 1991a, Jones 1991b, Jones and Garton 1994, Sauder and Rachlow 2014, Sauder 2014, Sauder and Rachlow 2015, Schwartz et al. 2013, Olson et al. 2014). See the description of the query below for additional information.

While the query has similarities to those of Sauder and Rachlow (2014), there are some distinctive differences that must be understood. First, the data that Sauder and Rachlow (2014) used was Landfire data, which used 30-meter pixels and included tree height data. SIMPPLLE modeling used a broad potential vegetation type layer and the Northern Region VMap product as the vegetation layers. Neither of these layers contain tree height data, but tree height and tree diameter are correlated. Landfire did not have diameters, so tree height is correlated with both canopy cover and diameter. A threshold of 10 inches diameter at breast height (DBH) was determined to be the diameter that corresponds best to trees greater than or equal to 25 meters within the size class breaks of VMap data and within the vegetation types queries in the model. Furthermore, 10 inches DBH was the size class within our habitat breaks that corresponded to habitats described by Jones 1991 and Jones and Garton (1994) as “young forest,” which they describe as 8.5-to-13.5-inch DBH, conditions that showed habitat use in summer and preferred use in winter. VMap is a vegetation map derived mainly from remotely sensed data calibrated with on-the-ground sample data. Forest Inventory and Analysis (FIA) data was used to corroborate the VMap assignments and to help add vertical structure to stands according to cover type and size. This layer contains the dominance type, size, and density information needed by the SIMPPLLE model. The size of the pixels for this analysis was 150 meters.

While every effort was made to ensure the model would be as accurate as possible, uncertainty associated with the fit of the fisher species-habitat relationships in the literature to those used in the SIMPPLLE model may affect the absolute accuracy of the resulting outputs (that is, acres of habitat); however, as the assumptions were consistent across all model runs, any inherent errors or biases were also likely consistent. Thus, while there should be some caution when considering the effects generated by the modeling exercise (that is, acres of habitat created or lost), comparisons among alternatives can provide some insight into the relative effects and overall trends of fisher habitat.

Ecosystem Research Group analysis (2022) compiled and presented SIMPPLLE and PRISM model outputs projecting future vegetation changes projected over the next 50 years as a result of managing towards desired conditions. All alternatives are projected for 50 years. The context for comparison of alternative outcomes is the natural range of variation of fisher habitat under natural disturbance. PRISM analysis models were run for 150 years to assess the stability of vegetation communities following proposed silviculture treatments and natural disturbance regimes. PRISM selects the appropriate set of treatments to achieve the desired conditions while SIMPPLLE concurrently simulates natural disturbances like fire and insects and diseases. The results are presented below.

The No Action Alternative represents the amount of treatments currently conducted under the 1987 Forest Plans as the “current pace of treatment” scenario. However, an important note is that the model is still trying to achieve the desired vegetation conditions proposed in the revised plan. This was done for comparison purposes and to put management under the 1987 Forest Plans into context. The action alternatives represent a treatment schedule needed to produce vegetation conditions to achieve the common set of desired vegetation conditions, with Alternative W within 20 years, Alternative X within 30 years, Alternative Y within 50 years, Alternative Z within 100 years, and the Preferred Alternative within 40 years.

Modeling considered a warmer, drier climate over the next five decades to anticipate the effects of the plan under future climates. Model outcomes were conducted with the assumption of warmer, drier climate conditions that were estimated from a subset of the full natural range of variation range that included only the warmest and driest decades. These scenarios also considered that the current level of fire suppression would continue, and the acres burned over time due to a warmer, drier climate and increased fuel loads would increase in the future.

Fisher Home Range Habitat Suitability Model or Spatial Model

In addition to the absolute availability of habitat, the relative degree of habitat fragmentation may also act to limit habitat suitability (Fahrig 2003). Although the presence of mature, mesic forests is one of the strongest and most consistent predictors of fisher habitat suitability (Raley et al. 2012), the juxtaposition of different vegetative communities ultimately affects fisher distribution (Olson et al. 2014, Krohner 2020) and habitat use (Sauder and Rachlow 2014, Sauder 2014, Sauder and Rachlow 2015). Heterogeneous forest conditions likely provide access to a greater diversity and abundance of prey species while still retaining access to habitat features that are important to reproduction and thermoregulation (Raley et al. 2012). Despite being associated with a diverse vegetative community, fisher tend not to use areas of open or sparse vegetation (Sauder and Rachlow 2014, Sauder 2014, Sauder and Rachlow 2015, Buskirk and Powell 1994, Powell and Zielinski 1994, Weir and Corbould 2010, Zielinski et al. 2004a) , with potential consequences for occupancy and dispersal (Olson et al. 2014, Krohner 2020). Regeneration harvests, for example, may significantly reduce fisher use of an area until trees of sufficient size are regrown (Jones and Garton 1994). Similarly, fisher are also less likely to use areas that experience high intensity wildfire, although fisher continue to use areas that experience less intensive fires where the structural characteristics that fisher prefer are often retained (Jones and Garton 1994, Sweitzer et al. 2016, Blomdahl et al. 2019).

Sauder (2014) reported that occupied fisher home ranges contained a median of 55.8 percent mature forest with an interquartile range of 39.5 to 64.8 percent and a median of 5.4 percent open with an interquartile range of 4.5 to 8.2 percent. Areas with these characteristics were found to have a high probability of occupancy (estimated at 0.7) (Suader and Rachlow 2014). To address the potential for the spatial relationships of vegetative communities, including fragmentation, to affect fisher home ranges, outputs from the SIMPPLLE model were further evaluated using a spatially explicit moving windows analysis that considered the effect of areas of both the composition of mature and open or sparse vegetation on the likelihood that an area may provide the components that support a female fisher home range. Using a window of 49.3 square kilometers, a size representative of an average female fisher home range (Jones and Garton 1994, Sauder and Rachlow 2014), individual pixels (of 5 acres) were categorized as supporting a female fisher home range if the surrounding window exceeded two habitat thresholds. First, the window must include at least 55.8 percent mature forest using the same definition of as outlined above (that is, mesic forest with greater than 40 percent canopy cover for trees 10 inches dbh or greater). Second, the area of open or sparse vegetation (that is, areas with less than 10 percent canopy cover or trees less than 4.5 inches in DBH) would be less than or equal to 10 percent of the window. The 10 percent threshold was selected because it is a level at which there was a reasonable probability that that an area would be occupied (Weir and Corbould 2010, Sauder and Rachlow 2014). The threshold of 10 percent open (or sparse vegetation) is the point at which the probability of occupancy is estimated at roughly to 0.40 or higher. Amounts of open (or sparse habitat) higher than 10 percent correspond to a lower probability of occupancy by fishers as estimated in Sauder and Rachlow (2014) but could still be occupied at lower occupancy rates. The spatial query essentially asks, how much of the fisher habitat has the characteristics of a female fisher home range with a probability of occupancy of 0.40 or higher at each time step. The spatial query was run into the past over a 100 time steps to estimate the natural range of variability for the spatial pattern of fisher habitat and for the future projections to determine the effects of the alternatives. The resulting spatial query is presented below:

- Habitat type groups same as fisher foraging habitat presented above.
- Mature was defined as tree size classes at least 10-inch DBH and canopy cover greater than 10 percent
- Open Habitat is defined as habitat with less than or equal to 10 percent canopy cover as well as all non-forested habitats, and forested habitats in grass, shrub, and seedling stage or 0- to 4.9-inch sapling size.

During the development of the methodology, thresholds of 5.3 and 10 percent were tested. Thresholds of 5.3 percent resulted in erratic disparities in the natural range of variation (NRV) outcomes for spatially relevant fisher habitat. The 10 percent threshold in the model was selected because this is a level at which fisher still have a reasonable probability of occupancy (Sauder and Rachlow 2014) and better reflects the percent of open habitats under natural disturbance. Furthermore, a 5.3 percent threshold was also not selected because of the erratic behavior the model at this level. Habitats with 10 percent or less include habitats that meet the 5.3 percent threshold identified by Sauder and Rachlow (2014). Ultimately, the outputs generated a spatially relevant NRV for fisher habitat from both a spatial and non-spatial standpoint, the results of which are analyzed below. The planning team worked with Joel Sauder and researchers from the Rocky Mountain Research Station in the development of the model.

As with the analysis of mature, mesic forest availability, the moving windows analysis approximates selected fisher home ranges as reported in Sauder and Rachlow (2014) but are not based on actual fisher occupancy data. While size of the moving window was determined by the average size of fisher home ranges as published in literature, it is important to recognize that there is a distribution of home range sizes around the average, with some being larger and some being smaller than the average. Like the findings from the trend of total fisher habitat, the findings from the spatial analysis have value in understanding the relative effects of the various alternatives on fisher habitat suitability, but it is important to consider the findings in the context of the uncertainty inherent to the models. The spatial query estimates the spatial arrangement of mature and open forests which could indicate the suitability of habitat to support an occupied female home range.

Affected Environment

Of the Nez Perce-Clearwater's approximately 3.9 million acres, 1.99 million acres, or a little over half, is considered probable fisher habitat based on the Sauder Model. Table 182 displays the amounts of fisher habitat in the different land allocation types. Combined, Idaho Roadless Rule areas and designated wilderness areas contain about 54.8 percent of the fisher habitat within the plan area compared to 46 percent in general multiple use forest (see Table 182).

There have been broad scale changes in forest composition in the plan area since the late 1800s. Historically, western white pine was a more widespread dominance type in northern Idaho, occupying the region's cooler moister sites in elevations between 2,000 and 5,500 feet (Haig 1932) which today make up a substantial portion of fisher habitats. White pine dominance has declined greatly as a result of historic harvest, blister rust, and lack of disturbance. Instead, shade tolerant species like grand fir, Douglas-fir, and Western hemlock have supplanted western white pine (Fins et al. 2001). Site specific observations in the project area verify these general observations made by Fins et al. (2001). In the stands proposed for vegetation management, the most abundant species are shade tolerant species rather than long-lived early seral species, such as western white pine, Ponderosa pine, or western larch. Grand fir and western red cedar are important species for fisher. It is assumed that white pine was also an important species for fisher because of its prevalence historically and because it attained a large size capable of providing habitat features used by fishers. Furthermore, western white pine was often dominant or codominant with grand fir on white pine habitat types, and western redcedar and Englemann spruce was often present in white pine stands. As such, it was a prevalent species within areas occupied by fishers today. However, these assumptions have not been tested in the science due to lack of existing mature western white pines currently due to blister rust. Restoration of western white pine is emphasized in the plan at various intensities within the alternatives. Changing grand fir types back into white pine dominance types may impact fisher habitat over in the short term, at least until white pine stands provide large tree structure usable by fisher.

The warm moist group includes some of the most productive forest sites on the Nez Perce-Clearwater. The warm moist group is nearly fully contained within the Sauder probable fisher habitat model. Grand fir types within the warm dry type also have substantial overlap with the Sauder model. On drier sites, grand fir is the dominant climax species north of the Northfork Clearwater River. Western hemlock dominates the wetter end of this group, with western redcedar dominating on cooler and wetter sites south of the Northfork Clearwater River. This setting occurs on mid-to-high elevation sites across all aspects. Historically, western white pine is the most common seral species dominant within the warm moist group, along with grand fir, western larch, and Douglas-fir. An important part of the productivity of the plan area that is extremely relevant to fishers is the capability to grow very large trees that provide large cavities for denning. All of these tree species mentioned are capable of providing cavities large enough to support denning fisher.

The cool moist group comprises the most productive subalpine fir and Engelmann spruce sites on the Nez Perce-Clearwater. Moist mountain hemlock and lodgepole pine habitat types are in this group, along with subalpine fir and spruce habitat types. This setting occurs on mid-to-high elevation sites across all aspects. Lodgepole pine and Engelmann spruce are the most common seral species. Engelmann spruce was reported by Jones and Garton (1994) to provide for fisher denning habitat. However, lodgepole pine has been identified as avoided by fishers. The Nez Perce-Clearwater has undergone ongoing disturbance through time. Disturbance like wildfire, insects and diseases, and other disturbances are a natural part of forest ecosystems. In addition, timber harvest is also part of the current management regime and influenced the habitat conditions seen today. The amount of disturbance in fisher habitat through time provides context for the analysis below.

To quantify the amount of human disturbance, an overlay of Sauder's probable fisher habitat with the Forest Service's Facts Activities spatial layer (accessed 8-30-2023) was conducted to evaluate how much fisher habitat has been treated in the past 80 years. Since it is assumed that forest stands become preferred fisher habitat at about 80 years or more, and because records of timber activities in the Facts Activities layer become less reliable as you go back in time, we evaluated the amount of timber harvest over the past 80 years or since 1943.

According to the overlay, there are 2,030,514 acres of fisher probable habitat including on private inholdings (36,277 acres) within the administrative boundary. Excluding private inholdings, we estimate there are 1,994,237 acres of fisher probable habitat within lands controlled by the Nez Perce-Clearwater.

Modeled fisher habitat has experienced approximately 361,312 acres of footprint treated with timber activities as recorded within the Facts Activities layer since 1943, which represents approximately 18.1 percent of modeled fisher habitat treated. There are approximately 1,621,856 acres of modeled habitat that has not been treated since 1943. Over that time, treatments in modeled fisher habitat averaged 5,667 acres per year or about 0.28 percent of fisher habitat per year. There is variation in how much was actually treated in a given year as demonstrated by the following graph (Figure 64). Note that the year 2024 represents acres planned but not yet implemented and those acres will likely be implemented over multiple years. Also note that these numbers only display the amount of timber activities within fisher habitat and does not include timber activities outside of modeled fisher habitat.

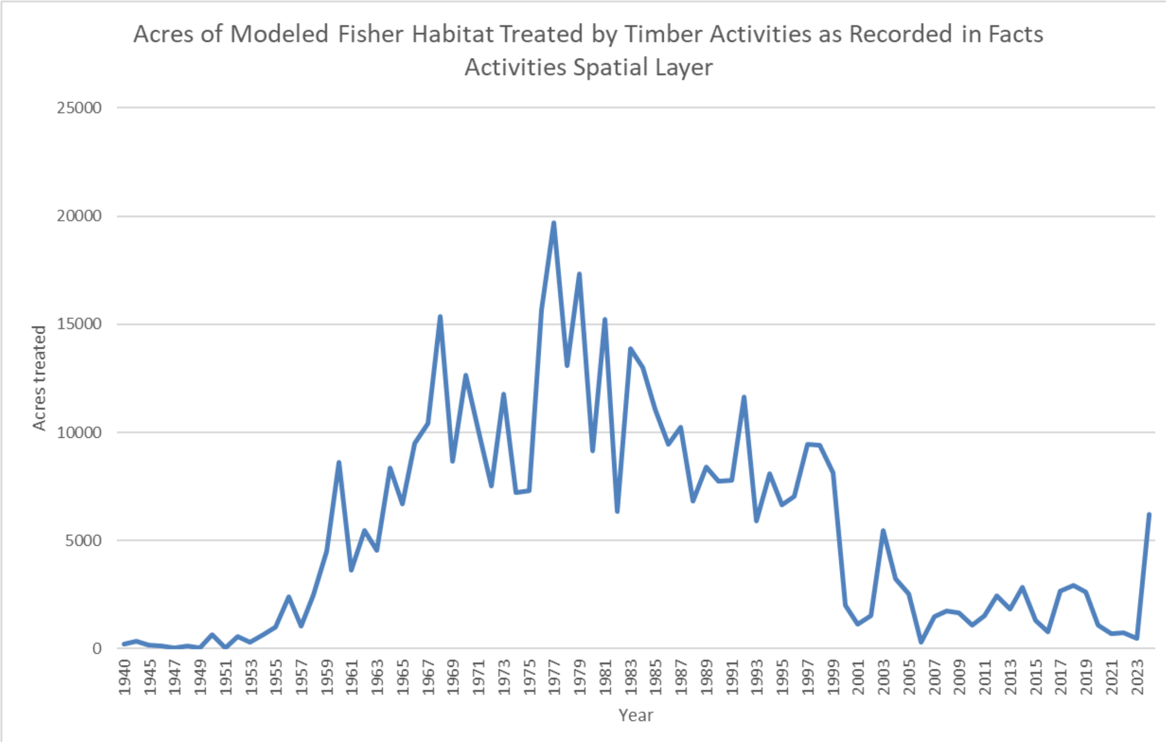

Figure 64. Acres of modeled fisher habitat treated by timber activities as recorded in Facts Activities Spatial Layer. Note that acres for 2024 are acres planned but will probably be implemented over multiple years.

The average amount of fisher habitat acres treated per decade is presented below in Figure 65. These were calculated by averaging the amounts within each decade. For example, the average for the 1970s was the average calculated from the amounts of timber harvest from 1970 to 1979 in fisher habitat. The most intensive decades of treatments were recorded in the 1960s to the 1990s. As the Sauder Model is in part a condition-based model that takes into account the connectivity of mature forest and the amounts of open habitat, it takes into account areas treated within the model's distribution as inclusive of fisher habitat, which suggests fisher habitat has been sustained over time under these levels of timber harvest. The alternatives explore the effects of the pace of restoration or acres of treatment needed to achieve desired conditions. The average amount of timber harvest per decade within probable fisher habitat in the past is comparable to the amounts of total timber harvest explored in the alternatives.

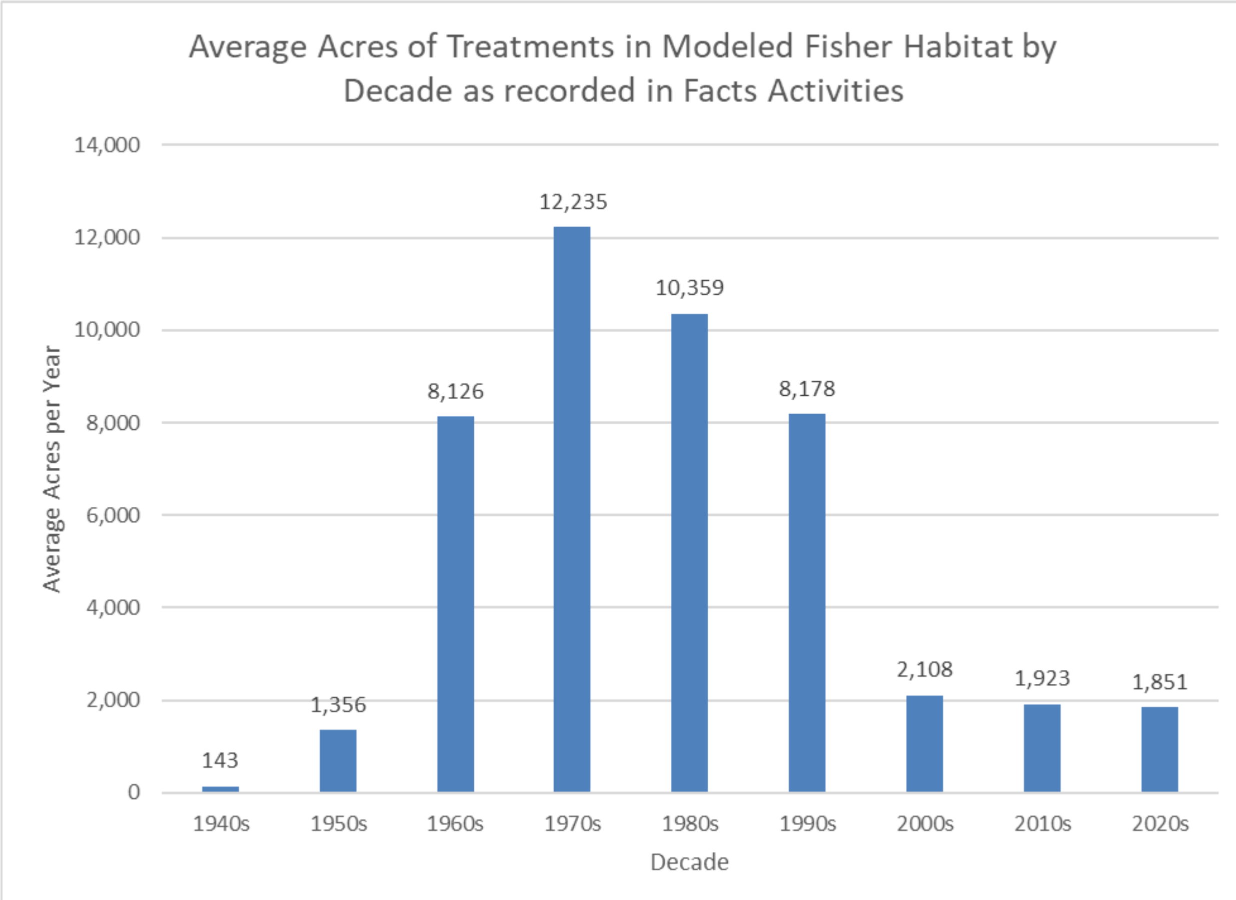

Figure 65. The average acres treated with timber activities per year by decade within probable fisher habitat. Note that 2020s data includes actual treated acres and acres of planned timber activities

The treatment types that occurred in the past in modeled fisher habitat are presented in Table 185 below. Note that this table contains more treatments than the total acres treated identified above because some of the treatments were multiple entries. The alternatives propose treatment schedules and types of treatments needed to achieve the desired vegetation conditions, which might differ substantially from the treatments used in the past. The different types of timber activities have potential to result in different effects on fisher habitat. For example, even-aged harvests result in a regenerating stand that would lack denning structures until the stand is in advanced seral stages. By contrast, two-aged treatments allow legacy features like live trees that survive long into the next generation and would allow older trees that potentially provide denning structures to remain within younger, regenerating stand. Thinning treatments result in short-term simplification of stand structure but increase tree vigor and growth rate that over time promotes larger trees that are preferred by fishers in shorter time periods. Uneven aged treatments promote stand age diversity, creating a multi-age and multi-size class stand at finer scales, but also requires a more intensive road network for timber access. Different treatment types can be used to favor different tree species, change species composition, affect density, and affect size class distribution. A detailed description of the timber harvest systems, and resulting outcomes is presented in the Forestlands section of the Final Environmental Impact Statement and specific amounts of the types of timber harvest systems needed to achieve desired conditions are presented in Appendix B.

To make the treatments easier to understand, the treatments have been condensed into categories that better describe whether the treatment is an intermediate treatment like thinning, an even-aged treatment, an uneven-aged treatment, or a two-aged treatment. The amounts of each category are shown below in (Figure 66).

Table 185. The types of timber harvest treatments within modeled fisher habitat, the category of treatments, acres of treatment since, and the percent of the total acres of treatment since 1943

Type of Timber Management Activity	Category of Treatment	Acres Since 1943	Percent of total treatment
Commercial Thin	Intermediate	21,276	4.7%
Group Selection Cut (UA/RH/FH)	Uneven Aged System	3,199	0.7%
Harvest Without Restocking	Even Aged	3,141	0.7%
Improvement Cut	Intermediate	14,182	3.1%
Liberation Cut	Intermediate	17,345	3.8%
Natural Changes (excludes fire)	Natural Change	6,725	1.5%
Overstory Removal Cut (from advanced regeneration) (EA/RH/FH)	Even Aged	75	0.0%
Patch Clearcut (EA/RH/FH)	Even Aged	3,969	0.9%
Patch Clearcut (w/ leave trees) (EA/RH/FH)	Two Aged	17	0.0%
Permanent Land Clearing	Non-Forest	261	0.1%
Salvage Cut (intermediate treatment, not regeneration)	Intermediate	95,724	21.0%
Sanitation Cut	Intermediate	96	0.0%
Seed-tree Final Cut (EA/NRH/FH)	Even Aged	7,906	1.7%
Seed-tree Preparatory Cut (EA/NRH/NFH)	Even Aged	512	0.1%
Seed-tree Removal Cut (w/ leave trees) (EA/NRH/FH)	Two Aged	2,565	0.6%
Seed-tree Seed Cut (with and without leave trees) (EA/RH/NFH)	Even Aged	37,087	8.1%
Shelterwood Establishment Cut (with or without leave trees) (EA/RH/NFH)	Even Aged	42,481	9.3%
Shelterwood Preparatory Cut (EA/NRH/NFH)	Even Aged	3,640	0.8%
Shelterwood Removal Cut (EA/NRH/FH)	Even Aged	8,623	1.9%
Shelterwood Staged Removal Cut (EA/NRH/NFH)	Even Aged	5,373	1.2%
Single-tree Selection Cut (UA/RH/FH)	Uneven Aged System	12,875	2.8%
Special Products Removal	Non-Silvicultural	634	0.1%
Stand Clearcut (EA/RH/FH)	Even Aged	132,250	29.0%
Stand Clearcut (w/ leave trees) (EA/RH/FH)	Two Aged	23,425	5.1%
Two-aged Coppice Cut (w/res) (2A/RH/FH)	Two Aged	661	0.1%
Two-aged Preparatory Cut (w/res) (2A/NRH/NFH)	Two Aged	7	0.0%
Two-aged Seed-tree Seed and Removal Cut (w/res) (2A/RH/FH)	Two Aged	4,171	0.9%
Two-aged Shelterwood Establishment and Removal Cut (w/ res) (2A/RH/FH)	Two Aged	2,348	0.5%
Two-aged Shelterwood Establishment Cut (w/res) (2A/RH/NFH)	Two Aged	230	0.1%
Two-aged Shelterwood Final Removal Cut (w/res) (2A/NRH/FH)	Two Aged	3,596	0.8%

Type of Timber Management Activity	Category of Treatment	Acres Since 1943	Percent of total treatment
Two-aged Stand Clearcut (w/res) (2A/RH/FH)	Two Aged	1,156	0.3%

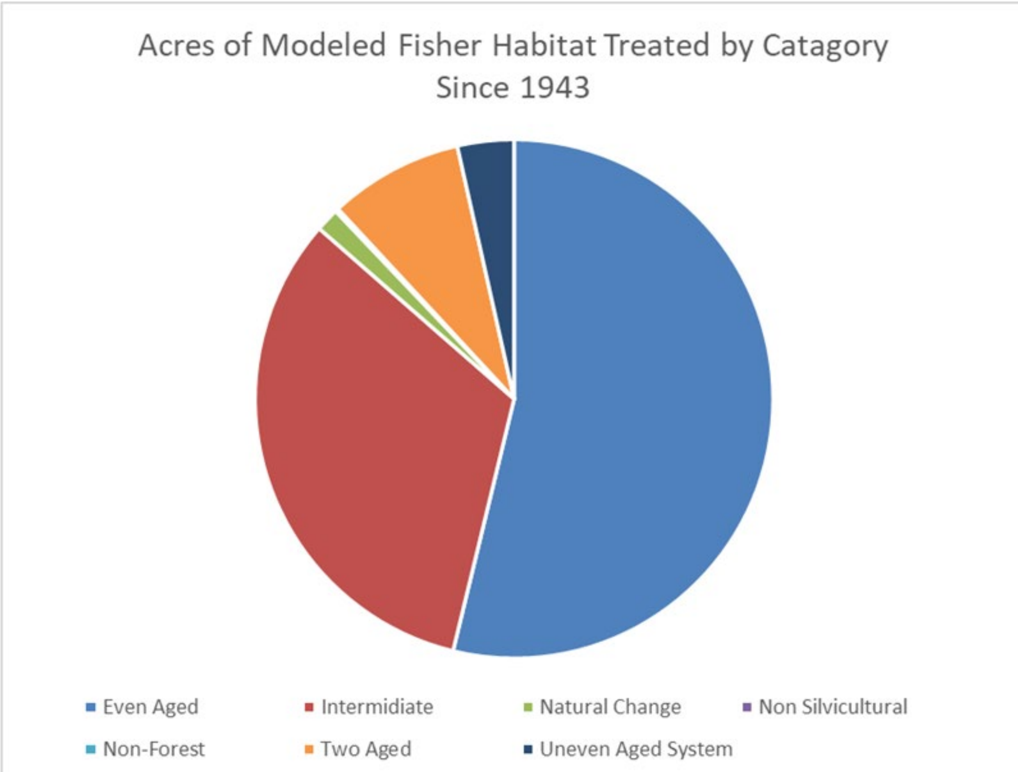

Figure 66. The categories of timber treatments within modeled fisher habitat

Fisher habitat has also experienced fire disturbance through time as an agent of change. Disturbance from fire in the past was estimated by overlaying the Forest Service's fire perimeters layer with modeled fisher probable habitat. Once again, we used an 80-year threshold for evaluating effects of past fire disturbance because this age is assumed to be long enough for stands to grow into habitat used by fishers. Also, fire data are less reliable the farther back in time they are. Note that the fire perimeter layers do not record fires that were less than 10 acres. Also, keep in mind that fires burn at various intensities with a fire perimeter, so some areas experience no or light intensity fire, other areas burning at moderate intensities, and other areas burning at high intensity. The Wildfire History and Recent Trends subsection of the Final Environmental Impact Statement describes the variation in fire burn intensity within different potential vegetation types (PVTs).

Fire intensity influences the effects on fisher habitat, and the majority of fire that burns fisher habitat operates at as a mixed and low severity intensities. Fire severity has often been described in categories as high, mixed, or low severity. Low severity fire burns at ground level and does not typically kill most trees. High fire severity or stand replacing fire is characterized by mortality of most or all the vegetation. Mixed severity fires are a highly complex disturbance regime that produces unique patch dynamics and ecosystem responses. Characteristics of mixed-severity fire include widely varying fire intervals and combinations of surface, torching, and crown fire behavior both within and between fires, resulting in intermixed patches of live and dead understory and overstory vegetation. A majority of fisher habitat is in the warm moist PVT group, and fire regime group III makes up approximately 82 percent the warm moist broad PVT. Some fisher habitat is also present within some cool moist broad PVTs. The cool moist PVT group is composed of only 28 percent of Fire Regime Group III which included white pine dominated sites that are now dominated by mixed conifer, grand fir, or Douglas-fir. Thus, a substantial portion of fisher habitat is within Fire Regime Group III, which is characterized as a mixed and low severity fire regime.

The total acres of fisher habitat within fire perimeters over the last 80 years (since 1943) was 323,583 acres which represents approximately 16.2 percent of fisher habitat that has burned. This is a very low amount of fire compared to estimates of fire under natural disturbance patterns and fires recorded in 1910s and 1920s. Lawler et al. (2012) found that moderate to high frequencies of low- and moderate-severity fire create and maintain snags and coarse woody debris over the long term. Note that fires smaller than 10 acres are not recorded in the fire perimeters spatial data. Fire suppression efforts to protect the timber resources in the managed front contribute to the relatively lower amounts of fire over time. The long-term lack of fire as a natural disturbance process, combined with historical selective removal of large, fire-resistant trees, have led to increased fuel loads so fisher habitat could be prone to more high intensity fires.

Fire and timber treatments overlap spatially in some cases. For example, some timber harvests later burned, while some burned areas received subsequent treatments. Therefore, the total amount of disturbance cannot be derived from adding the fire and timber treatments. As the fisher habitat model is in part a condition-based model, this amount and intensity of fire has sustained fisher probable habitat through time.

This information provides the context to the amount of disturbance that has occurred through time for the fisher analysis. Disturbance from timber harvest, fire, insects and disease, and forest growth or succession is dynamic and overlaps through time. Therefore, not all the disturbance factors can be quantified through overlays like this. The SIMPPLLE model takes into account these factors and simulates disturbance and tree growth to project future trends in fisher habitat through time as a result of Forest Plan alternatives, objectives, and desired conditions.

Environmental Consequences

Land Allocations

General forest management is the most permissive land type which allows most activities so long as they are consistent with the Forest Plan. These lands are suitable for timber production, road building, motorized recreation, livestock grazing, mechanized travel, and more. Within these lands, fisher habitat could potentially be subjected to these activities. These areas make up Management Area 3.

Management Area 2 consists of lands composed of backcountry areas with moderately restrictive management because they are either proposed for designation, roadless areas, or were set aside legislatively as restrictive land management types. Management Area 2 consists of Idaho Roadless Rule Areas; proposed areas such as recommended wilderness or rivers proposed as suitable or eligible for congressional consideration as wild and scenic rivers; designated and proposed Research Natural Areas, and the Gospel-Hump Multi-Purpose area. The Gospel-Hump Multi-Purpose Area was established by legislation for specific management when the Gospel-Hump Wilderness was established. Management Area 2 is composed mostly of lands within Idaho Roadless Areas, but depending upon alternative, also includes significant acreage of recommended wilderness areas, and smaller amounts of eligible and suitable wild and scenic rivers, proposed and designated research natural areas, and the Gospel-Hump Geographic Area.

Management Area 2 is made up of relatively large areas, generally without roads, few motorized trails, and provides a variety of recreation opportunities. A variety of different constraints apply to these lands depending upon allocation. Revised Forest Plan direction for Management Area 2 would apply to projects within any and all land allocation types they occurred in. In many areas, more than one set of set of plan direction would apply. For example, if a project fell within a sub-management area that had Idaho Roadless Rule areas, suitable Wild and Scenic river corridor, and established Research Natural Area, then all of the plan direction including suitability from each sub-management area would apply to that project. In recommended wilderness, both Idaho Roadless Rule area restrictions apply, and recommended wilderness area restrictions apply. If conflicting plan guidance is discovered, or a project is located within more than one overlapping land allocation, the direction from the more restrictive management area would apply. Idaho Roadless Rule areas constrains, or allow under only limited conditions, timber production, timber harvest, some mineral activities and road building. This management protects or reduces the impacts on fisher habitat from these activities. Other activities would be suitable, such as grazing, prescribed fire, motorized recreation.

Management Area 1 is composed of three areas designated by congress for specific uses and that have restrictions or special management direction prescribed by law. These include designated wilderness, designated wild and scenic rivers, and the congressionally designated Lolo Trail National Historic Landmark. These designations offer high levels of land protections against developments. Plan components or direction specific to these areas in the plan are labeled with MA1. Management direction for these lands do not vary by alternative.

The largest land allocation types are the three broad Management Areas. The three Management areas are composed of lands with similar management profiles. Management area 1 is composed of designated areas, Management area 2 is composed of areas proposed for designation as well as Idaho Roadless Rule Areas, and Management area 3 is composed of areas managed as general forest managed for multiple uses. The Forest Plan groups these different land allocations into three broad management areas which vary by alternative as shown in Table 186.

Table 186. Acres and percent of fisher habitat by management area (MA) and alternative

Management Area	No Action Alternative	Alternative W	Alternative X	Alternative Y	Alternative Z	Preferred Alternative
	Acres %	Acres %	Acres %	Acres %	Acres %	Acres %
MA1	294,459 15	294,459 15	294,459 15	294,459 15	294,459 15	294,459 15
MA2	798,932 40	783,378 39	781,377 39	798,809 40	787,043 39	782,041 39
MA3	900,846 45	916,401 46	918,402 46	900,969 45	912,736 46	917,737 46

General forest management is the most permissive land type which allows most activities so long as they are consistent with the Forest Plan. These lands are suitable for timber production, road building, motorized recreation, livestock grazing, mechanized travel and more. Within these lands fisher habitat could potentially be subjected to these activities. These areas make up Management Area 3.

Management Area 2 consists of lands composed of backcountry areas with moderately restrictive management because they are either proposed for designation, roadless areas, or were set aside legislatively as restrictive land management types. Management Area 2 consists of Idaho Roadless Rule Areas; proposed areas such as recommended wilderness, or rivers proposed as suitable or eligible for congressional consideration as wild and scenic rivers; designated and proposed Research Natural Areas, and the Gospel-Hump Multi-Purpose area. The Gospel-Hump Multi-Purpose Area was established by legislation for specific management when the Gospel-Hump Wilderness was established. Management Area 2 is composed mostly of lands within Idaho Roadless Areas, but depending upon alternative, also includes significant acreage of recommended wilderness areas, and smaller amounts of eligible and suitable wild and scenic rivers, proposed and designated research natural areas, and the Gospel-Hump Geographic Area.

Management Area 2 is made up of relatively large areas, generally without roads, few motorized trails, and provides a variety of recreation opportunities. A variety of different constraints apply to these lands depending upon allocation. Revised Forest Plan direction for Management Area 2 would apply to project within any and all land allocation types they occurred in. In many areas, more than one set of set of plan direction would apply. For example, if a project fell within a sub-management area that had Idaho Roadless Rule areas, suitable Wild and Scenic river corridor, and established Research Natural Area, then all of the plan direction including suitability from each sub-management area would apply to that project. In recommended wilderness, both Idaho Roadless Rule Area restrictions apply, and recommended wilderness area restrictions apply. If conflicting plan guidance is discovered, or a project is located within more than one overlapping land allocation, the direction from the more restrictive management area would apply. Idaho Roadless Rule areas constrains, or allow under only limited conditions, timber production, timber harvest, some mineral activities and road building. This management protects or reduces the impacts on fisher habitat from these activities. Other activities would be suitable, such as grazing, prescribed fire, motorized recreation.

Management Area 1 is composed of three areas designated by congress for specific uses and that have restrictions or special management direction prescribed by law. These include designated wilderness, designated wild and scenic rivers, and the congressionally designated Lolo Trail National Historic Landmark. These designations offer high levels of land protections against developments. Plan components or direction specific to these areas in the plan are labeled with MA1. Management direction for these lands do not vary by alternative.

Recommended Wilderness

The alternatives propose different amounts of recommended wilderness which captures different amounts of fisher habitat. Alternatives with more recommended wilderness generally capture more fisher habitat. Alternative W has the most fisher habitat, with Alternative X having none. The No Action Alternative has the second least amount of fisher habitat and the Preferred Alternative captures the second least, with 94,290 acres of fisher habitat or about 94,270 acres. These lands are generally protective of fisher habitat and are not suitable for timber production, and timber harvest is very constrained.

The primary consideration with recommended wilderness is that natural ignitions would generally not be suppressed. The benefit of wilderness management to fisher has been questioned because fire management within wilderness or recommended wilderness is thought to create higher amounts of open area resulting in a lower probability of occupancy (Sauder 2014). However, wilderness areas and recommended wilderness areas are among the most protected areas from timber harvest, and they are unsuitable for timber production. They allow prescribed burning and wildfire to achieve land management plan objectives. The amount of fisher habitat by alternative is shown in Table 187. The most protective alternatives for fisher habitat are the alternatives that include more recommended wilderness and occur in the following order with Alternative W being highest, and Alternative Z, Alternative Y, the Preferred Alternative, and the No Action Alternative having the lowest amount.

Table 187. Acres of fisher habitat within recommended wilderness by alternative

Recommended Wilderness	No Action Alternative	Alternative W	Alternative X[1]	Alternative Y	Alternative Z	Preferred Alternative
Bighorn—Weitas	n/a[2]	166,890.4	n/a	n/a	n/a	n/a

Grand Total	45,880.8	430,485.2	n/a	107,579.8	227,675.1	94,290.0

1 - Alternative X has no recommended wilderness.
2 - n/a = not applicable

Recreation Opportunity Spectrum

The recreation opportunity spectrum (ROS) identifies the expected recreational experience users should expect to experience in different areas of the Nez Perce-Clearwater. The Forest Plan also uses ROS as a mechanism to identify areas suitable for motorized uses as a land allocation. Settings suitable for motorized uses include Rural, Roaded Natural, and Semi-primitive Motorized. Settings not suitable for motorized uses include Primitive and Semi-primitive Non-motorized. The amount of fisher habitat within the various ROS classes is shown in Table 188 and Table 189. The descriptions of the ROS categories can be found in the Sustainable Recreation section of the Final Environmental Impact Statement.

Vehicle strikes have been identified as a source of mortality for fishers and linear features like highways have been identified as potentially affecting connectivity in California (USFWS 2016, USFWS 2019). In areas suitable for motorized uses, future motorized routes could be constructed after a site-specific analysis which could lead to a loss of habitat from the footprint of the road, or habitat fragmentation could occur. Otherwise, roads or motorized route concerns are not prevalent within scientific publications on fishers suggesting that roads and motorized routes are not a concern from a fisher conservation standpoint.

Effects of winter recreation on fishers has not been studied, however oversnow motorized vehicle use does not typically occur in the dense forest habitats preferred by fisher. The ROS classes could influence where new development of motorized areas could occur in the future and the level of future recreational developments. These could impact some fisher habitat if roads are constructed in motorized settings in the future by loss of habitat as a result of the footprint of new roads. Winter motorized travel could disturb fisher and could influence where trapping might be more likely to occur, although trapping of fisher is currently not allowed by the Idaho Department of Fish and Game. It should be noted that the 1987 plans did not apply ROS as suitability for motorized uses. The No Action numbers in these comparisons were contrived from policy direction that provided guidance as to how to identify the different recreational settings. The existing condition was that prior to travel planning in the Clearwater portion of the national forest was open to motorized travel unless closed by a site-specific decision. The Nez Perce national forest has not yet undergone travel planning, so it is currently open to motorized uses unless areas are closed by a specific closure order. There were different mechanisms in the 1987 plans and a variety of other factors that influenced decisions on the travel system such as elk habitat effectiveness, management area emphasis, and other considerations. The proposed plan and all alternatives will newly establish the ROS settings as a suitability plan component in the plan.

The amount of impacts to fisher habitat from motorized uses and the different levels of recreation experience are described from the amount of habitat within the different spectrum settings, with the assumption that more habitat in non-motorized settings would be more beneficial to fishers than habitats in motorize settings. Alternatives that would have the most fisher habitat in non-motorized settings are listed from the highest amount to the lowest amount in the following order: Alternative Z would have 41 percent in non-motorized, followed by Alternative Y with 39 percent, Alternative W with 36 percent, the Preferred Alternative with 27 percent and last Alternative X with 23 percent.

Table 188. Acres and percent of fisher habitat by summer recreation opportunity spectrum (ROS) class and alternative

Summer ROS Class	No Action Alternative		Alternative W		Alternative X		Alternative Y		Alternative Z		Preferred Alternative	
	Acres	%	Acres	%	Acres	%	Acres	%	Acres	%	Acres	%
Rural	3,531	0	112,833	6	112,833	6	112,833	6	112,833	6	98,751	5
RN	623,175	31	560,615	28	604,979	30	590,983	30	581,781	29	785,026	39
SPM	523,024	26	594,447	30	813,614	41	505,587	25	481,086	24	577,805	29

ROS = recreation opportunity spectrum; SPNM = semi-primitive non-motorized; SPM = semi-primitive motorized; RN = roaded natural. ROS classes listed in order of least to most restrictive.

Eligible and Suitable Wild and Scenic Rivers

Designated wild and scenic rivers are designated by Congress and will not be changing in the Land Management Plan. However, the plan identifies rivers suitable or eligible for inclusion within the wild and scenic river system as part of the alternatives. Table 190 shows the amount of fisher habitat within the different classifications of eligible or suitable wild and scenic rivers considered in the alternatives. Table 191 shows the acres of fisher habitat for each river considered as eligible or suitable for inclusion into the wild and scenic river system.

The number of rivers and river corridors as suitable or eligible wild and scenic rivers varies by alternative. The total acres of fisher habitat within a quarter mile of suitable wild and scenic rivers by alternative and classification are shown in Table 190 below. Also, some rivers contain more fisher habitat than others as shown in Table 191.

Table 190 The acres of modeled fisher habitat within the one-quarter mile river corridor of suitable or eligible wild and scenic rivers by alternative

Type	Classification	No Action Alternative	Alternative P	Alternative W	Alternative Y	Alternative Z
Eligible	Recreational	33,431	0	0	0	0
Eligible	Scenic	9,175	657	0	0	0
Eligible	Wild	56,265	0	0	0	0
Suitable	Recreational	0	2,275	2,275	28,827	6,590
Suitable	Scenic	0	21,083	17,996	17,953	22,433

Grand Total	98,872	46,730	47,413	76,349	88,656

Those alternatives with more probable fisher habitat within the quarter mile river corridors would benefit fisher more than the alternatives with less. The No Action Alternative does not include any suitable rivers and only contains eligible rivers. The Preferred Alternative would include 46,730 acres of fisher habitat in suitable wild and scenic rivers, which is the second lowest of any alternative and about half of what was identified as eligible under the No Action Alternative. The No Action Alternative has the highest amount of eligible wild and scenic rivers (and comparably more acres of habitat identified for inclusion to the wild and scenic river system), followed relatively by Alternative Z and Y. Alternative W has slightly more than the Preferred Alternative. In terms of benefits to fishers, the alternatives with higher amounts of fisher habitat within suitable (or eligible) river corridors would be better because they would be managed with more constraints on alteration of fisher habitat.

Timber Suitability

Timber suitability under the plan falls into three classes: areas suitable for timber production, areas not suitable for production but suitable for harvest to meet other resource objectives, and areas not suitable for harvest nor production. Timber suitability does not authorize any activities. Instead, it identifies where such uses are suitable after site-specific National Environmental Policy Act analysis and consultation. While timber suitability does not authorize specific actions, it identifies the types of suitable activities that could be expected to occur. Suitability plan components act as a constraint on activities on lands where they are unsuitable.

The distribution of the different timber suitability types was influenced by alternatives for other land allocations. For example, designated wilderness, recommended wilderness, and the Lolo Trail National Historic Landmark are not suitable for timber production nor timber harvest. Idaho Roadless Rule Areas are not suitable for timber production, but some limited areas are suitable for timber harvest, typically only along roads where timber could be accessed and within the appropriate Idaho Roadless Rule Theme. However, when conducting timber harvest activities, Idaho Roadless Rule provisions outlined in 36 CFR 294.24(a) and (b) would need to be followed. Many other Idaho Roadless Rule areas are not suitable for timber production nor harvest. Both designated and suitable Wild and Scenic Rivers are not suitable for timber production, and neither timber harvest nor timber production are suitable within the wild classification, but timber harvest to meet other resource objectives is suitable within recreational and scenic rivers. Riparian areas are not suitable for timber production but are suitable for timber harvest to meet other resource objectives.

Management Area 3 is primarily an area suitable for timber production. However, there are areas within Management Area 3 that are not suitable for timber production. Some portions of riparian areas for example are suitable for harvest but not production. While the land allocations influenced the identification of timber suitability classes, the timber suitability layer establishes where timber activities are or are not suitable.

The timber suitability allocation also identifies where different types of activities would be suitable. Timber production activities are timber activities where the primary goal is to produce marketable timber. Timber production activities include commercial and pre-commercial thinning, and a variety of timber cuts designed to produce lumber. These activities often require roads for access and transportation of the lumber. Infrastructure associated with timber production should be expected within areas suitable for timber production. Harvests typically include reforestation efforts.

Areas suitable for timber harvest to meet other resource objectives would be suitable for activities that may or may not produce marketable timber, but where the purpose of the project is to meet other resource objectives like vegetation desired conditions, wildlife habitat objectives, hazardous fuel reduction, habitat restoration, riparian area restoration, and more. Areas that are suitable for timber harvest to meet other resource objectives are typically within access distance to existing motorized routes, so they would not be associated with transportation developments in most cases. In some cases, the actions to treat vegetation would be similar to those for timber production, but in other cases, the actions would use other methods that might result in more retained legacy features, be more variable in distribution, or be actions that do not produce marketable timber. These treatments may or may not include reforestation depending upon the objectives.

Areas not suitable for timber harvest are areas where timber harvest treatments are not suitable uses of the lands. Timber harvest would not be allowed in these areas. Projects designed to meet vegetation desired conditions will rely mostly on natural or prescribed fire or mechanical treatments that do not result in lumber. Areas not suitable for harvest nor production would serve to protect fisher habitat from timber harvest and production activities. However, it would not protect habitat from wildfire loss.

Generally speaking, timber harvest or production activities may alter fisher habitat. Within stands at smaller scales, timber activities can alter seral stages, stand densities, tree species composition, amount of overhead canopy, reduce habitat complexity, reduce den structures, change understory conditions, and change amounts of coarse woody debris. As fishers mostly use mature forest with high canopy cover, the changes affect fisher habitat use until stands regrow to the point where they provide foraging conditions or resting or denning structures.

At larger scales, timber activities can change landscape patterns that can influence fisher use. The changes in landscape patterns can both increase habitat heterogeneity and diversity (defined by Sauder and Rachlow (2014) as intermediate abundances of high canopy forest and landscape edge density) selected for within home ranges by fishers. Similarly, timber activities can also create conditions that result in a lower probability of a fisher establishing a home range if the amount of open habitat is too high at the landscape scale.

The duration and intensity of effects depend on how timber activities are conducted. Timber activities that result in a complete regeneration without retention of legacy trees, snags, or downed wood result in effects that last longer and are more severe. Fishers typically avoid areas with low canopy cover, large forest openings, clearcuts, and other cleared areas (Buck et al. 1983, Arthur et al. 1989b, Powell 1993, Buskirk and Powell 1994, Jones and Garton 1994, Weir 1995). Regenerated stands are avoided until they regrow sufficiently. Early and mid-successional even-aged forests likely do not provide the same prey resources, rest sites, and den sites as more mature forests (Powell and Zielinski 1994). Early seral stages like 4.9- to 10-inch size classes, might be used for foraging, travel or connectivity. Regenerating stands may be used in winter or for foraging once they become 8.5 to 13.38 inches in diameter (young forest as defined by Jones 1991, and Jones and Garton 1994). Because denning structures can take more than 100 years to develop, regeneration cuts without reserves, or retained legacy features result in an even aged stand without denning structures until the trees grow to large diameter and become infected with tree diseases that result in hollow trunks (heart rot), cavities, snags, and coarse woody debris. Jones and Garton (1994) provided an estimate of the timeline for habitat recovery following regeneration harvest. They suggested that fisher would avoid regeneration harvest for at least 50 years, use them occasionally for another 60 to 100 years, and likely would not preferentially select them until trees were 120 to 160 years in mixed conifer forest (Jones and Garton 1994).

On the other hand, timber activities that result in two-aged or uneven-aged harvest systems, or that reserve live trees, result in stands that have size class diversity, and retain or develop characteristics of denning structures earlier in their regrowth. In these cases, younger aged stands contain or develop denning structures over time.

Intermediate treatment, such as thinning, reduces the density and complexity of the stand in the short-term but recover more quickly and may still be used by fisher soon after treatment. Intermediate treatments can reduce wildfire risk and increase the growth rate and vigor of remaining trees so that they reach larger sizes sooner to provide large tree habitat. Thinning also releases the understory vegetation to the benefit of fisher prey. Smith (2021) concluded that fishers would use recently thinned habitat as long as sufficient overhead cover (at least 50 percent) and high-valued resources (for example, den sites) were retained within their home range.

A number of measures can reduce the effects timber harvest has on fisher habitat, such as retention of legacy features like snags, live trees, and coarse woody debris. Weir and Harestad (2003) and Zeilinsky

(2004) suggested that the maintenance of large structural elements at small scales may mitigate for the negative effects of large-scale alterations of forests. Jones and Garton (1994) recommended retaining equal to or greater than 5 grand fir trees per acre for future dens with the objective to have these trees to be at least 18 inches DBH that would begin to fall 80 to 100 years after logging.

Measures to retain coarse woody debris can help maintain habitat features important to fisher after timber activities have occurred. Jones and Garton (1994) recommended retaining between 21 and 44 tons per acres of large diameter logs to provide for fisher prey and retain decks of cull logs and a few slash piles for potential fisher resting sites. Plan direction for retention of live trees is three per acre and requirements to retain downed woody debris requires logs 3 inches and greater and preferably 12 inches in diameter. The amount varies by broad potential vegetation type (PVT) and includes 7 to 15 tons per acres in the warm dry, 17 to 33 tons per acre in the warm moist, and 9 to 18 tons per acre in the cool moist, by comparison. The plan does provide plan components to retain these features in a limited way when conducting timber harvest. MA2 and MA3-GDL-FOR-01 establishing minimum amounts of coarse woody debris retainment within the warm moist broad PVT mostly overlaps Jones and Garton's recommendation, though on the low side, whereas the cool moist amount is wholly below the recommendation. The amount of coarse woody debris affects ground dwelling prey species availability, which are a portion of the fisher's diet, and used as denning and resting sites by fishers.

However, vegetation treatments like timber harvest or production provides the diversity of stand conditions that provide for fisher prey. Evidence suggests fishers select home ranges that include a diverse array of forest conditions resulting in access to a greater diversity and abundance of prey species while still attaining habitat features important for reproduction and thermoregulation. Sauder and Rachlow (2014) suggested a variety of habitat patches within a matrix of well-connected mature forest was a forest pattern favored by fishers. Light harvests, or small patch cuts, may increase habitat diversity thus prey diversity and have little negative impact on fishers where adequate late-successional forest are available (Arthur et al. 1989b, Jones and Garton 1994).

Lands managed for timber have been documented to support fisher populations. Fishers in southwestern Oregon are found in in uneven-aged, intensively managed forests containing many roads and selectively harvested stands but snags, logs, and cavity trees were relatively abundant (Mathew and Stinton 1998). Powell (2019) documented reproduction and consistent population growth from reintroduced fishers from and to lands managed for timber production in California. Powell (2019) noted that reproduction and survival appear not to be limited by logging and other forest management activities. Fishers tolerate some clearcuts in their home ranges, though the mean proportion tends to be below 25 percent of their home-range area (Powell et al. 2019). Niblett (2017) documented fishers denning habitat occurring on mostly industrial timberland in Northern California. Niblett (2017) observed denning in areas where as much as 24 percent of the area near the den sites is in openings. In addition, female fishers selected areas that contain large trees, even when the landscape is not a continuous canopy covered mature to late seral forest, and the density of such stands is high enough to support movement between suitable denning sites. Fishers continue to persist in actively managed landscapes in California and Oregon on Green Diamond Resource Company owned lands. Mathews (2013) documented fisher denning within the 89,400-acre Hoopa Valley Indian Reservation where timber is actively managed. Mathew (2013) emphasized the importance of retention of legacy features such as green tree and snag retention to retain breeding habitat for fishers. They recommended conserving patches of existing mature forest, maintaining larger numbers and a diversity of structural elements in project areas, and promote tree growth, damage (for example, low-intensity surface fires), disease, and decay that recruit fisher reproductive habitat. The U.S. Fish and Wildlife Service after reviewing several studies of fishers on lands managed for timber production on industrial timber lands concluded that fishers occupy managed landscapes and stands where timber harvest and other vegetation management activities occur and the degree to which fishers tend to be found in these areas often depends on a multitude of factors, including the scale, intensity, and rate of activities; the composition and configuration of suitable habitat; and the amount and type of retained legacy structures (USFWS 2020). Each of these studies emphasized that logging activities in these areas retained legacy features like live trees, snags, and downed wood, to ensure that regenerated stands exist over time that have a number of suitable denning and resting structures.

Timber management is likely to continue on non-National Forest Service lands. If done in moist forest types with dense canopies, then fisher habitat may be altered. Snags, large trees, and downed wood may be reduced, particularly on private lands. The focus on private lands may not be on restoration, historic conditions, and creating resilient stands but on monetary factors.

The prevailing method to manage vegetation in areas not suitable for production nor harvest, would be managed primarily through prescribed fire or wildfire. Jones 1991 suggested that while fishers used young stands (4.9- to 13.5-inch DBH) more in winter, these stands had regenerated following fire and had a higher availability of large diameter trees, snags, and downed wood present. It should be noted that stands regenerated after fire usually retain structural characteristics that allow fisher use, such as a few residual large diameter live trees, snags, and downed wood or logs (Jones and Garton 1994). While wildfire leaves a more variable pattern of biological legacies, it can also be unpredictable and burn large amounts of fisher habitat in a single disturbance resulting in habitat loss. Like timber activities, these effects last until vegetation regrows into used or preferred fisher habitat. Prescribed fire is typically conducted within a burn window where weather conditions promote lower fire intensities and results in less change to fisher habitat compared to wildfire. Compared to timber harvest, prescribed fire and wildfire managed for resource benefits can be more challenging to conduct because it requires a burn window and requires complicated logistics to organize the personnel required to conduct a prescribed fire. These factors might result in fewer opportunities to pull off burns, a delay that might risk a higher intensity fire event where more fisher habitat is lost. Thus, long term areas not suitable for timber production nor harvest are more likely to change as a result of wildfire.

The amount of fisher habitat within the three different timber suitability types varies by alternative. Table 192 provides the acres and percent of fisher habitat suitable for the various timber suitability types under the plan alternatives. The amount of fisher habitat suitable for timber production is roughly the same across all alternatives, only varying by less than 1 percent. Areas suitable for harvest for other resource objectives and areas not suitable vary more by alternative, mostly due to variations in the areas identified as recommended wilderness or wild and scenic river eligibility or suitability. The Preferred Alternative would have 38.4 percent of fisher habitat in the plan area suitable for timber production, 18 percent not suitable for production but suitable for harvest to reach other resource objectives, and 43 percent would be not suitable. This essentially would allow 56.8 percent of fisher habitat in the plan area to be suitable for either harvest or production, while 43 percent would not be suitable. The most beneficial alternative for fisher habitat would be Alternative W because it has the most habitat in areas not suitable and less habitat suitable for harvest for other resource objectives compared to the other alternatives. Alternative X would include the most fisher habitat within one of the suitable categories, with approximately 57.3 percent of fisher habitat in either suitable for production or suitable for harvest for other resource objectives. More areas suitable for timber harvest and production could result in more impacts to fisher habitats under the plan. While these are suitable uses, it does not mean that these activities would occur on all acres, only that those acres would be suitable for that use. Suitable uses would only be conducted after a site-specific analysis to evaluate the effects of a potential project.

Table 192. Acres and precent of fisher habitat by timber suitability type and alternative

Timber Type Suitability	No Action Alternative	Alternative W	Alternative X	Alternative Y	Alternative Z	Preferred Alternative
Not suitable for harvest nor production	931,027 acres 47%	994,527 acres 50%	850,676 acres 43%	871,553 acres 44%	896,336 acres 45%	862,427 acres 43%
Suitable for timber harvest for other resource objectives	308,654 acres 16%	235,820 acres 12%	378,396 acres 19%	367,998 acres 19%	336,615 acres 17%	366,996 acres 18%
Suitable for Timber Production	754,556 acres 38%	763,892 acres 38%	765,166 acres 38%	754,687 acres 38%	761,286 acres 38%	764,815 acres 38%

Fishers evolved in habitats that are dynamic and experience disturbance. Timber suitability delineates the areas where timber activities are suitable or could occur. In addition to timber activities, fisher habitat is also likely to be altered by natural disturbances like insects and tree disease, wildfire, and fuel reduction activities. Past timber harvest, fuels reduction, and fire have intermixed to result in the amount and pattern of fisher habitat on National Forest System lands today. Ultimately the overall impacts from these factors will depend on the pace, scale and distribution of habitat alterations which will determine the overall amount distribution, and trend of fisher habitat long term in the future under the plan. Of more importance than timber suitability is the overall pace of treatments, coupled with natural disturbances which will ultimately result in the landscape scale effects to fisher habitat conditions over the long term. The pace the alternatives for the rate at which desired conditions are achieved vary by alternative as well and determine the amount of change fisher habitats would undergo. The amount of timber production and the number of treatments to restore vegetation are shown in Chapter 2 of the Final Environmental Impact Statement. To determine the overall long-term trend fisher habitat was modeled in SIMPPLLE to take into account the pace of restoration, simulate natural disturbance, and tree growth and are analyzed below. These represent both short- and long-term impacts.

Snag Retention

Fishers are dependent upon hollow trees and snags for reproduction, protection from predators, and shelter. They are known to prefer areas with more large trees, increased snags, and more downed wood. The Forest Plan provides plan components for retention of snags which vary by alternative. MA2 and MA3-GDL-FOR-05 identify the amount and distribution of snags required to be retained when managing forested habitats. The amount of snags differs by broad potential vegetation type (PVT) as specified by size and overall number of snags retained. Snags are required to be retained within the project area but not necessarily within the treatment units. If existing snags are not sufficient, then additional live leave trees are required. The guideline is informed by average number of snags found in Forest Inventory and Analysis data as published in Bolenbacher (2009).

MA3-GDL-FOR-05 varies by alternative in that Alternative Z requires retention of snags at least 10 inches as specified by Bolenbacher (2009). The other alternatives require snag retention of snags at least 15 inches but does not require retention of snags smaller than this size. The average number of snags at least 10 inches is much higher than the number of snags at least 15 inches. For example, in the warm moist broad PVT, the number of snags 15 inches and greater including snags 20 inches and more totals 19 combined, whereas if snags at least 10 inches were required to be retained in addition, it would add 16 additional snags per acre. These additional snags would better provide for more potential denning sites and coarse woody debris to support fisher habitat after timber activities than alternatives that the require only retention of snags 15 inches or greater. Retention of snags and live retention trees are a factor in the effects that timber activities have on fisher habitat and the speed at which these habitats recover and whether an area harvested by timber activities continue to support fisher habitat use as described above for effects of Timber Suitability. The Preferred Alternative does not require retention of snags 10 inches and greater. Desired conditions for snags are focused on managing the current and future snag pool to promote snag retention by considering spatial distribution, snag density, size class distribution, snag species, and safety. The targets for snag retention for each broad PVT group are intended to be applied at the project level. Individual stand level snag densities may contribute to project level targets. The intent is not to normalize snag retention and recruitment at the per acre level but to achieve a project level target which reflects natural disturbance patterns. In addition, the plan has desired conditions that encourage large diameter living trees be present, such as MA3-DC-FOR-02, FW-DC-FOR-08, MA3-DC-FOR-04, MA3-DC-FOR-06, that encourage live tree retention and can contribute to future snags. Alternatives that retain more snags would be better for fisher than those with less, but all alternatives should retain snags at the project level at levels similar to the averages found within each broad potential vegetation type (Bolenbacher 2009). The retention of snags, live leave trees, and downed wood would help provide for fisher habitat in project areas managed by timber activities.

Suitability of Uses Within Recommended Wilderness

The alternatives vary by which activities are suitable within recommended wilderness. If actions are unsuitable, they would not be allowed. The actions that vary include whether motorized travel in winter would be a suitable use, whether mechanized travel would be suitable, whether public use of motorized and mechanized tools would be suitable, whether administrative use of motorized and mechanized tools would be suitable, whether recreational aircraft landing would be suitable, and whether aircraft landings for administrative uses would be suitable. Additionally, there are other suitability plan components for recommended wilderness that do not vary by alternative. This section analyzes only the effects of the suitability that vary by alternative.

Alternatives that include administrative use of mechanized and motorized tools in recommended wilderness would have minor consequences because they are expected to be limited in extent and relatively infrequent. Furthermore, they would mostly be used to maintain trails. These plan components and alternatives would have at most, minor consequences to fisher habitat in most circumstances. While these activities could occur and could remove some features like downed wood or live or dead trees, they would not likely impact fisher habitat to an extent and severity to reduce fisher use of an area. Motorized and mechanized tools used by the public would be similar but less regulated. The Preferred Alternative does not allow motorized tool use by the public but would allow administrative use of motorized and mechanized tools.

Winter motorized uses would bring motorized oversnow travel into fisher habitat, which might have disturbance effects. However, fishers primarily use forested habitats consisting of older or larger trees with high canopy cover and larger amounts of coarse woody debris and snags. While Jones (1991) and Jones and Garton (1994) described fishers using “young forests,” they defined those as trees 8.5- to 13.5-inch diameter at breast height with higher tree density, which are conditions where winter motorized users avoid. So, there is a lack of overlap in space use between fisher and the preferences of winter motorized users. Some new types of oversnow vehicles like snow bikes can navigate forested habitats but these users are mostly passing through forests to open areas suited for winter motorized uses. The most likely consequence could be in some additional access by trappers, which could expose some individual fisher to incidental trapping while trapping for other species. Incidental non-target trapping of fisher is uncommon, and the Idaho Department of Fish and Game currently does not allow trapping of fisher currently under law. Winter motorized uses do not alter fisher habitat directly, and forestwide, only 4.7

percent of modeled fisher habitat occurs within recommended wilderness under the Preferred Alternative. The Preferred Alternative does not allow winter motorized use in recommended wilderness.

Mechanized travel, for example on bicycles, would have disturbance effects. The amount distribution of this disturbance would be limited to where existing or future trails would occur. Fisher response to mechanized travel is not studied but potentially could result in disturbance or displacement. The trails needed to support mechanized travel could cross through fisher habitat. Fisher habitat would not be altered more than the required trail system. In general infrastructure development represents a minimal threat to fisher because the development of roads or trails typically occurs at relatively small spatial scales in forested areas, and vehicular related mortalities are rare (Naney et al. 2012). Fisher do prefer areas that have limited human development and use (Kordosky et al. 2021), but fisher occupancy is largely insensitive to the presence of roads (Carroll et al. 2001), and presumably human activity in and around roads. The differences in overall effects to fisher are likely minimal if allowed. The Preferred Alternative does not allow mechanized travel in recommended wilderness.

Alternatives that find these activities suitable in recommended wilderness are slightly better for fisher than those that allow these activities, but either way the difference is not generally impactful such that it would cause a population decline or significant change in distribution.

Modeling Results

Total Fisher Habitat Availability

The most influential factor that determines the trend in fisher habitat is the rate or pace of combined disturbance over time (both natural and human produced), while taking into account tree growth. Examples of disturbance include the amount of timber production, vegetation treatments for restoration, fuels treatments, wildfire, and insects and diseases. The treatments, fires, and insects and disease can overlap in space over time and interact with each and trees regrow after disturbance. The best way to evaluate the alternatives under such complexity is through computer modeling that simulates forest growth, treatments schedules and stochastic events like fire or insects and disease. The context of the comparison is whether the amount and distribution of treatments operates within or similar to the natural range of variation. Both were estimated within the SIMPPLLE and PRISM model as described above.

The alternatives propose variation in the pace of disturbance to achieve a common set of desired vegetation conditions. The common set of desired vegetation conditions are based on the range of conditions present when climatic conditions were at the warmer-drier range of the natural range of variability (NRV). Natural range of variation modeling indicates that fisher habitat trends lower when climatic conditions in the model are within the warmer-drier range of the NRV because these conditions result in an increase in the amount and frequency of disturbance like wildfire and insects and disease. Over time, warmer-drier conditions tend to result in a lower proportion of larger tree sizes, more early seral size classes, and can shift dominance types towards shade intolerant or fire tolerant tree species such as western larch, Ponderosa pine, lodgepole pine, Douglas-fir, or white pine rather than shade tolerant or fire intolerant tree species such as grand fir, subalpine fir, or western redcedar. The modeling for future trends in fisher habitat was conducted using assumptions of a warmer-drier climate condition representing anticipated future climates. Since the common set of desired conditions are targeting vegetation conditions representative of the warmer drier range of NRV and using the warmer-drier climate assumptions in the model, the expected outcome would naturally be a lower amount of fisher habitat overall. Keep this in mind when interpreting the results below.

The predicted outcome of the alternatives on denning habitat is shown in Figure 67. The amount of fisher denning habitat based on the model query is currently estimated at 985,110 acres and is predicted to decline due to a combination of natural and human-caused disturbance. Since all the alternatives were subject to the same natural disturbance regimes and had the same desired conditions, the predicted outcome of denning habitat for the alternatives all had a similar downward trend after 50 years. Although the desired conditions were the same, differences in treatment rates lead to notable differences in the outcome of fisher habitat changes among alternatives. Alternatives with a faster pace of achieving desired conditions had more decline than those with slower rates. The differences in alternatives differed by about 127,173 acres (between 803,200 in Alternative Z to 676,027 in Alternative X). All alternatives except Alternative X remain above the NRV low which is estimated at 680,522, while Alternative X declines below that level slightly. The Preferred Alternative is predicted to experience about a 30 percent decrease down to 686,983, which is near the lower NRV range (See Figure 67 below).

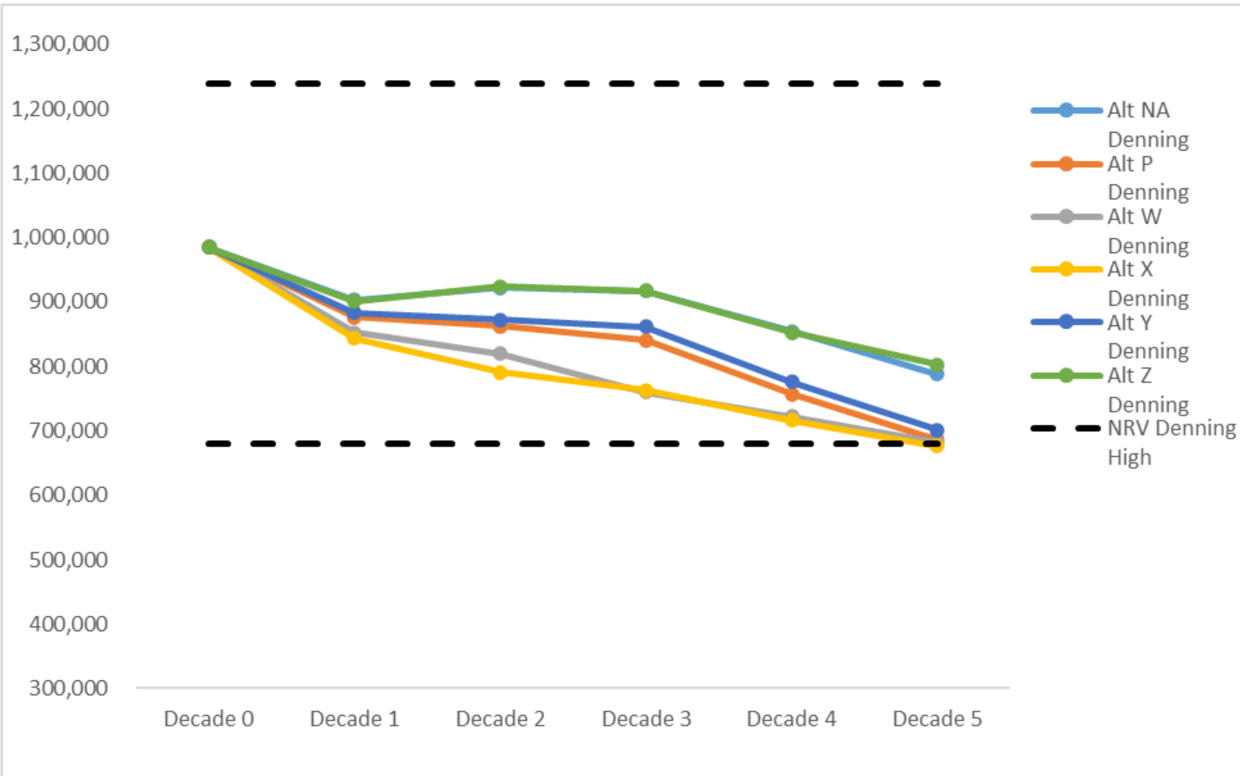

Figure 67. Trend of fish denning habitat by alternative and decadal time step as estimated through the SIMPPLLE and PRISM models for the fisher denning query. The black dashed lines represent the upper and lower Natural Range of Variability ranges. The colored lines represent the differences in denning habitat for each alternative. The Preferred Alternative is shown in orange.

Similar to denning habitat, the amount of total fisher habitat (both denning and foraging) declines under all alternatives as shown in Figure 68. The amount of total fisher habitat is currently estimated at 1,649,930 acres according to the fisher query, and due to natural and anthropogenic sources of disturbance, is predicted to decline. Again, since all the alternatives were subject to the same natural disturbance regimes and had the same desired conditions, the predicted availability of fisher habitat after 50 years differed little among alternatives (between 1,235,586 and 1,336,605 acres), with the Preferred Alternative predicting a percent decline of 24.3 percent to 1,247,842 acres Figure 68). Although the desired conditions were the same, alternatives did differ in treatment rates, leading to notable differences in the relative rate of fisher habitat loss among alternatives (Figure 68). Like with denning habitat, alternatives that achieved the desired conditions faster (that is, higher treatment rate) resulted in progressively faster rates of habitat loss for total habitat. For example, for the most intensive alternative, Alternative X, modeled fisher habitat declines from 1,649,930 acres to 1,399,871 by the first decade, drops to 1,194,021 by Decade 3 before recovering to 1,312,094 acres by 50 years. In contrast, for Alternative Z, modeled fisher habitat declines from 1,658,721 acres to 1,336,605 acres but not until Decade 5. Despite difference among alternatives, the availability of fisher habitat is projected to remain within the natural range of variation (NRV) for all alternatives, although Alternatives W and X do temporarily fall outside of this range before recovering above the NRV low by the fifth decade (Figure 68).

The overarching trend of all alternatives in both denning and total fisher habitat is driven by three factors:

1. The model's climate conditions are assumed to operate under a warmer-drier climate which were conditions under which fisher habitat was at the lower end of NRV. SIMPPLLE generates natural disturbances like lightning ignitions and then the model's fire logic determines the rate of spread based on climate condition
2. The model is managing towards the desired conditions which are based on warmer-drier periods of the NRV range, conditions in which fisher habitat was at the lower end of NRV. PRISM prescribes a treatment schedule and types of treatments to meet desired condition, such as forest composition and size classes.
3. Today's current conditions are ripe for disturbance according to the model assumptions. For instance, a dry climate might stress mature trees of a certain species and make them susceptible to insect infestation in the model assumptions. Another example, the fire spread logic in the model environment is influenced by the time since the last disturbance, and the probability of spread is increased under warm dry conditions. Each start is given the opportunity to grow. The size the fire grows to is dependent on the surrounding vegetation, as well as the historic probability that it will end with a weather event, or, if simulating fire suppression, whether or not there are enough resources to put the fire out. The type of fire that spreads (lethal, semi-lethal, or non-lethal) is dependent on the vegetation conditions of the site, including past disturbance or treatment, the climate assumption for the timestep, its elevational position relative to the burning fire (uphill, downhill, etc.), and whether it is downwind or not. The speed at which a fire grows in a certain direction is dependent on the slope of the landscape and the wind speed and direction. Again, the fire process will stop according to the probability of a weather-ending event, successful fire suppression, or perhaps running up against a natural barrier, such as the treeline or a lake. SIMPPLLE will then determine the effect of the fire by considering whether there are trees present capable of reseeding or resprouting the site (in the case of a lethal fire), whether the stand's fuel conditions have been reduced (for semi- or non-lethal fires), and whether there has been a change in size or species on the site.

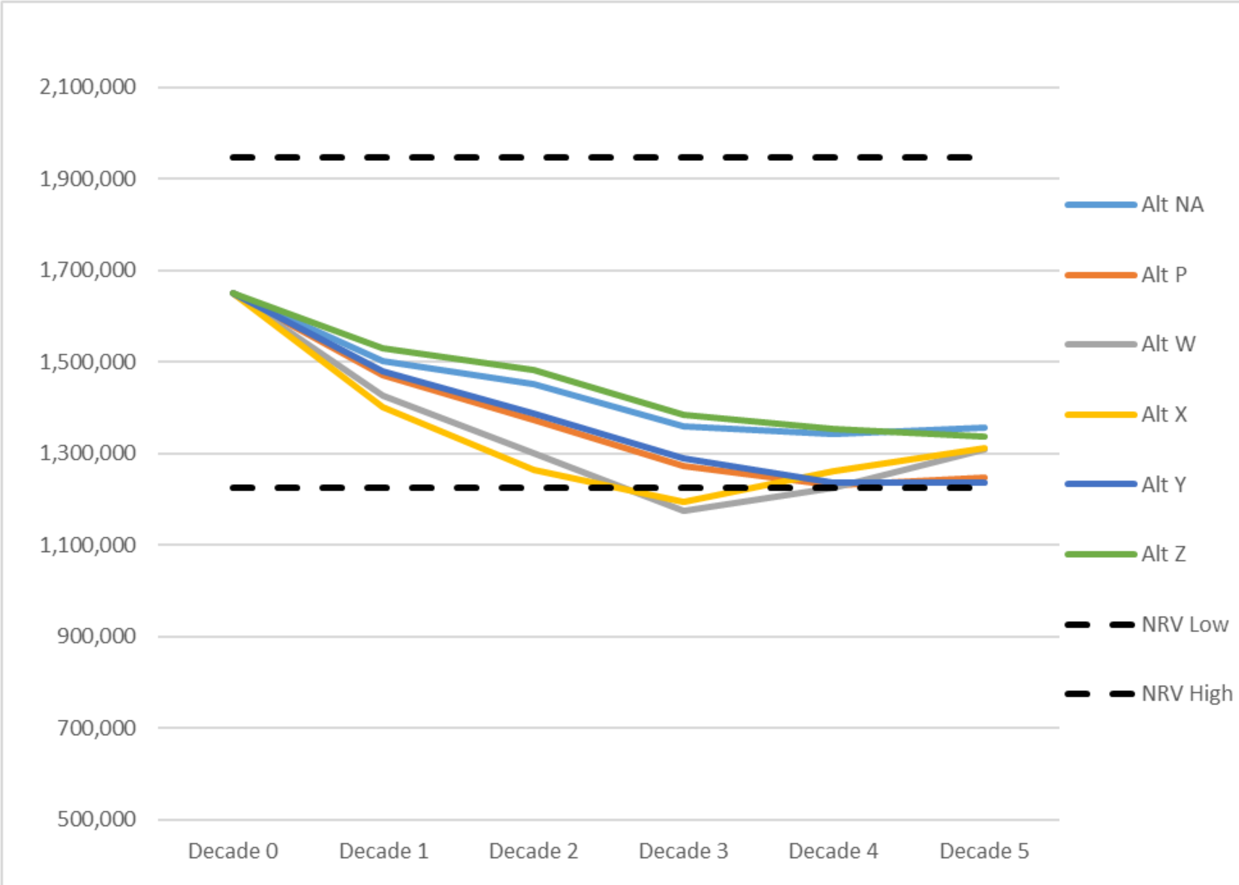

Figure 68. The projected amounts of fisher total habitat (foraging plus denning) by alternative and decadal time step as estimated through the SIMPPLLE and PRISM models. The black dashed lines represent the upper 95 percent and lower 5 percent Natural Range of Variability ranges. The colored lines represent the differences for each alternative. The Preferred Alternative is shown in orange.

Y-axis units in decades. X-axis units in acres. NRV=Natural range of variation.
Data from simulated PRISM and SIMPPLLE model. The colored lines represent alternatives. The black dotted line shows the natural range of variation (high and low range).

The amount of habitat decline within the three management areas is shown in Table 193, while the trend in fisher habitat within the three broad management areas is shown in Table 194. While decline happens in all management areas, the decrease within Management Area 1 and 2 is relatively consistent among alternatives. In contrast, the variability in the reduction in fisher habitat after 50 years between the alternatives is greatest within Management Area 3. Thus, the differences in outcome between the alternatives are mostly manifested in differences in habitat change within Management Area 3. This is largely because of constraints in the model imposed by land management direction found in the plan or regulations such as wilderness managment, limitations on timber harvest in Idaho Roadless Rule Areas, and constraints within lynx habitat imposed by the Northern Rockies Lynx Direction as examples. The model constrains timber harvest in these areas and uses natural disturbances there. In addition, it tends to direct harvest treatments to Management Area 3 to trend forest vegetation towards the desired vegetation conditions.

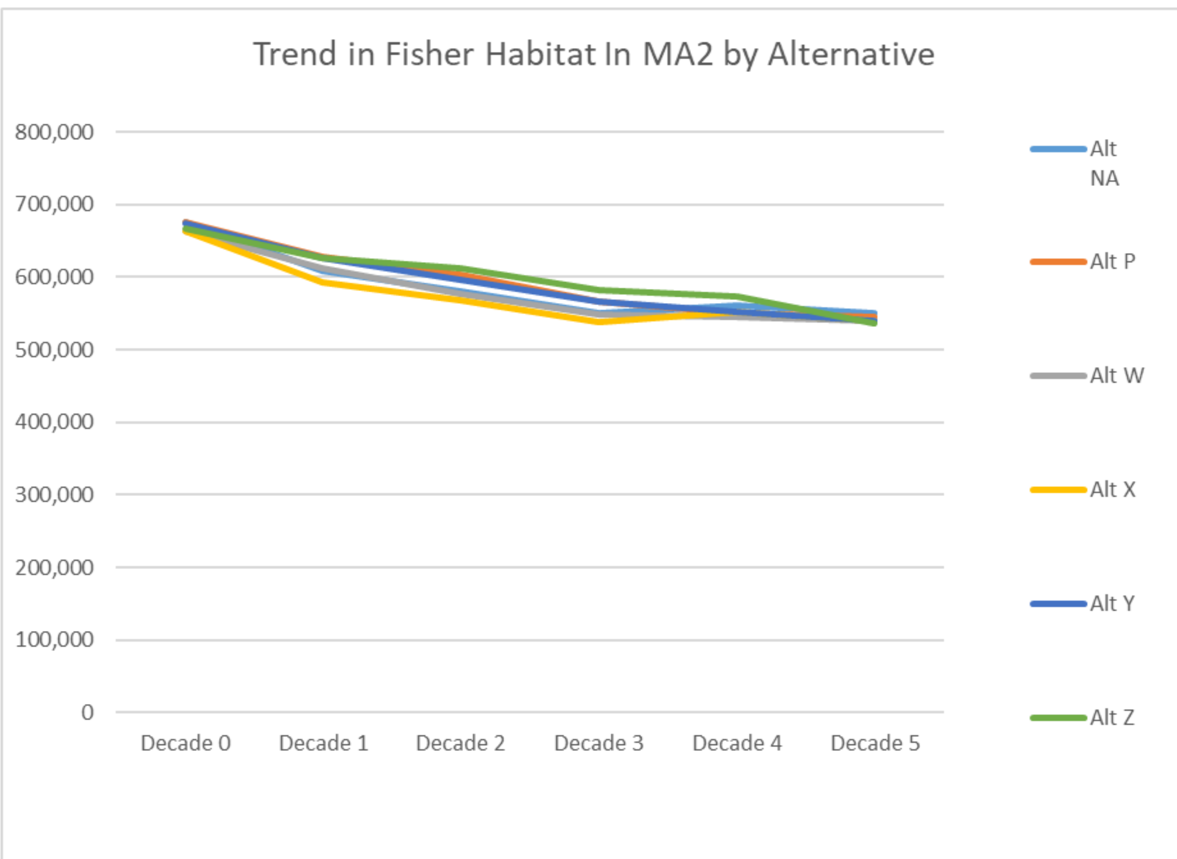

Figure 70. The trend in fisher habitat within Management Area 2 by alternative within the 50-year time horizon projected by the SIMPPLLE Model

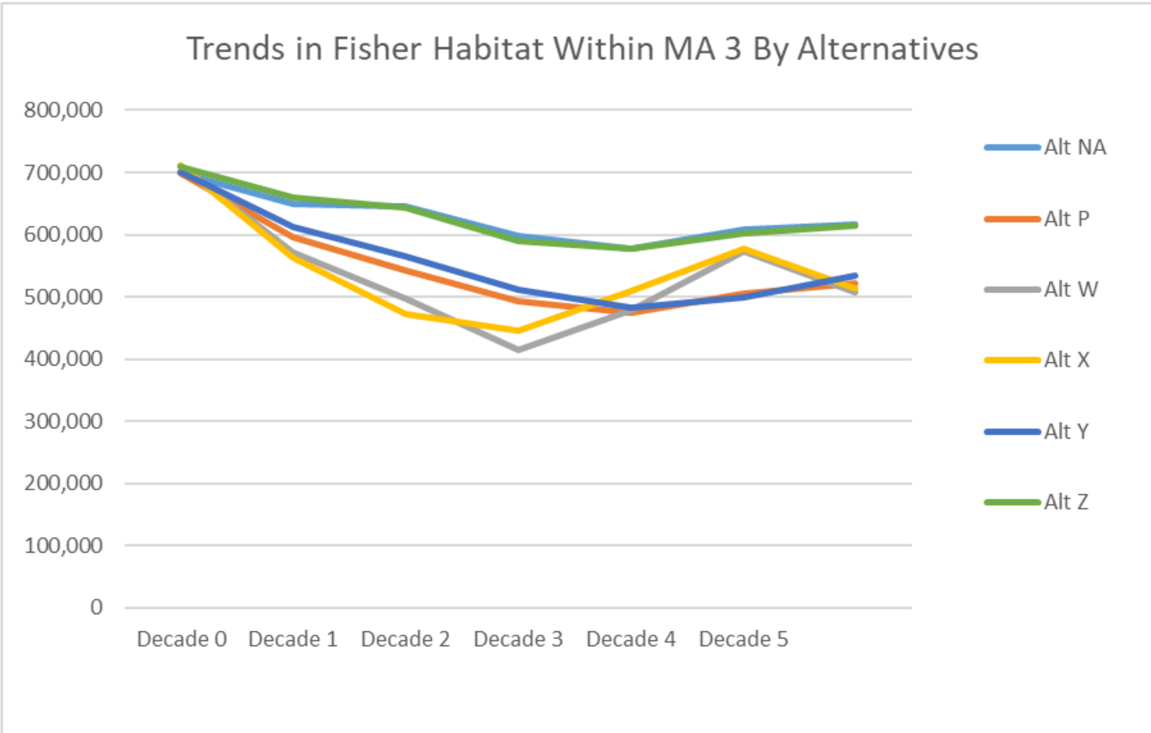

Figure 71. The trend in fisher habitat within Management Area 3 by Alternative as projected in the 50-year time horizon in the SIMPPLLE model

Table 193. Change in acres and percent decline in fisher habitat after 50 years, by management area and alternative

Management Area	Alternative	Change in Acres in total Acres in Decade 5	Percent Decrease
Management Area 3	No Action Alternative	121,873	17
Management Area 3	Alternative W	232,972	33
Management Area 3	Alternative X	203,500	29
Management Area 3	Alternative Y	218,658	31
Management Area 3	Alternative Z	131,155	19
Management Area 3	Preferred Alternative	224,235	32
Management Area 2	No Action Alternative	115,134	17
Management Area 2	Alternative W	119,107	18
Management Area 2	Alternative X	110,816	17
Management Area 2	Alternative Y	122,922	18
Management Area 2	Alternative Z	93,423	14
Management Area 2	Preferred Alternative	125,806	19
Management Area 1	No Action Alternative	71,812	26
Management Area 1	Alternative W	71,788	26
Management Area 1	Alternative X	73,894	27
Management Area 1	Alternative Y	72,623	26

Management Area	Alternative	Change in Acres in total Acres in Decade 5	Percent Decrease
Management Area 1	Alternative Z	72,545	26
Management Area 1	Preferred Alternative	70,690	26

The amounts of different types of total disturbance projected in the model under the Preferred Alternative across the 50-year time horizon broken out by management area is shown in Table 194 below. The average annual amount of disturbance as a percent of the total forest area is about 1.58 percent annually, which is a relatively modest amount. The amount of total disturbance acres is at the high end of the desired disturbance amounts for all alternatives except the No Action Alternative and overall is within the amount of disturbance needed on average per year to keep the Nez Perce-Clearwater within the average fire return interval according to the distribution of fire regime groups on the national forest (see Fire Management section of the Final Environmental Impact Statement). At 62,419 average annual acres, the amount is on the high end of the range identified in the alternatives which were between 53,000 and 64,500 and respresents a worst case scenario within that range. Table 194 shows the amount of timber harvest and total fire forestwide, and as a percentage of Management Area 3 under the Preferred Alternative. These are the disturbances that influence the trends in total fisher habitat. Note that timber harvest is concentrated within Management Area 3, and that timber harvest makes up a substantiative portion of the disturbance in that management area. Forestwide, the amount of fisher habitat disturbed by timber harvest is approximately 33 percent over the 50-year time horizon of the plan forestwide. Timber harvest is concentrated in Management Area 3 which supports a substantiative amount of fisher habitat forestwide. Timber harvest is projected to be the dominant disturbance regime in Management Area 3 making up approximately 49 percent of the disturbance in that management area. Timber harvest will be a minimal part of Management Area 2 and non-existent in Management Area 1.

Forestwide, fire is expected to make up 63 percent of all disturbance forestwide and is expected to disturb an amount of approximately 50 percent of the total forest area. Note, however, that some fire is expected to reburn the same area within the time horizon of the model. Fire is expected to operate in Management Area 3 at lower levels than at the forestwide amount and makes up approximately approximately 38 percent of the total disturbance in Management Area 3, which is expected to disturb approximately 39 percent of Management Area 3. Note again that fires are likley overlap timber harvests during the 50-year period so the disturbance is not always additive.

The amount of timber harvest projected by the model in the first decade is modest, representing only approximately 12 percent of the total disturbance or about 89,039 acres total in the first decade. The amount represents about 8,904 acres annually forestwide, an average annual amount of timber harvest sustained in the 1960s to the 1990s that sustained fisher habitat Figure 64 and Figure 65. As a percentage of the total area of the national forest, this amount of harvest represents approximately 2.26 percent of the total forest area per decade and less than 1 percent as an annual average.

Table 195 shows the proportional distribution of disturbance by management area under the Preferred Alternative, and the proportion of the total area of the national forest made-up of each management area. This table suggests that Management Area 3 receives a greater proportion of the total disturbance compared to the other management areas.

Table 194. The acres of disturbance types broken out by management area (MA) and forestwide total over the 50-year time horizon under the Preferred Alternative

Type of Disturbance	MA 3	MA 2	MA 1	Total Forestwide Disturbance by Type	Annual Average Acres per year (Total Forestwide Disturbance by Type ÷ 50 years)	Average annual acres of disturbance as a percent of the total area of the national forest (3,939,056 acres)
Disease	128,677	141,732	36,421	306,830	6,137	0.16%
Insects	33,454	75,279	73,929	182,662	3,653	0.09%
Intermediate Treatments	207,767	0	0	207,767	4,155	0.11%
Light Severity Fire	110,713	105,486	113,879	330,078	6,602	0.17%
Mixed Severity Fire	189,713	249,647	298,784	738,144	14,763	0.37%
Stand Replacing Fire	134,616	262,140	260,062	656,818	13,136	0.33%

Regeneration Harvest	420,448	28,039	0	448,487	8,969	0.23%
Total	1,273,165	1,064,722	783,075	3,120,962	62,419	1.58%

Table 195. The acres in each management area, the total disturbance projected by the SIMPPLLE model in each management area, the proportion of the national forest made up of each management area, and proportion of the total disturbance occurring in each management area under the Preferred Alternative according to the model. Note that disturbances often overlap in space through time so the overall footprint of the disturbance will be smaller than the total acres.

Management Area	Area	The Management Area's proportion of the total plan area	Total Acres of Disturbance	Total Disturbance in Each Management Area as a percent total disturbance	Total Disturbance as a Percent of Area
Management Area 1	1,231,638	31.3%	783,075	25%	64%
Management Area 2	1,467,078	37.2%	1,064,722	34%	73%
Management Area 3	1,240,340	31.5%	1,273,165	41%	103%
Total	3,939,056	100%	3,120,962	79%	79%

Table 196. The amounts of timber harvest and fire forestwide and within Management Area 3 over the 50-year time horizon projected by SIMPPLLE model

Disturbance event	Acres or percent
Total Timber harvest (Intermediate plus regeneration harvest)	656,254
Timber Harvest as a Percent of Total Disturbance over 50 Years	21.03%
Timber Harvest as a Percent of Total Plan Area over 50 Years	16.66%
Total Timber Harvest in MA3 (Acres of Intermediate + Regeneration)	628,215
Total Timber Harvest as a percent of disturbance in MA3	49.34%

Disturbance event	Acres or percent
Total Harvest as a Percentage of Area in MA3	50.65%
Total Timber Harvest as a percent of Total Forestwide Fisher Habitat (1,994,238 acres)[1] over 50 years	32.91%
Timber harvest in MA3 as a percent of fisher habitat in MA3 (917,737 acres)[2]	68.45%
Total Fire (Light Severity +Mixed Severity+Stand Replacing Fire+Prescribed Fire)	1,975,216
Total Fire as a Percent of total Disturbance Forestwide	63.29%
Total Fire as a Percent of Total Forest Area (3,939,056 acres)	50.14%
Total Fire within Management Area 3 (Light Severity +Mixed Severity+Stand Replacing Fire+Prescribed Fire)[3]	482,819
Fire as a percent of total disturbance within Management Area 3	37.92%
Fire in Management Area 3 as a total percent of the Management Area 3 (1,240,340 acres)	38.93%

1. Note that not all timber harvest at the Forestwide scale will be in fisher habitat.
2. Note that most but not all timber harvest in Management Area 3 will be in fisher habitat.
3. Fire is expected to burn some areas treated for timber harvest and re-burn some areas more than once.

Several studies have described the conditions under which fishers have persisted on lands managed for timber production including on industrial timber lands (Sauder and Rachlow 2014, Sauder and Rachlow 2015, Niblett 2017, Mathews 2013, Green et al 2022, Higley and Mathews 2009, USFWS 2017). Many of these studies described the past management for the study area, some of which had undergone relatively intensive management on industrial timber lands. The descriptions of the management in these areas are inadequately described to comprehensively compare to the combined disturbance and regrowth being evaluated for the plan and alternatives because they do not report the amounts of natural disturbances, timber harvest, and tree regrowth combined. However, many of these studies emphasize the retention of legacy features like live trees, snags, and downed wood as conservation measures (Mathews 2013, Green 2022, USFWS 2017).

Green et al. 2022 reintroduced and studied fishers to evaluate whether fishers can persist in lands managed for timber production. Green (2022) described the treatment history their landscape as follows:

"By 1902, about 31% of the forested area in and around Stirling had been logged commercially using selective-logging practices that extracted approximately 50% of the available timber. Between 1903 and 1992, logging on Stirling continued using selective-logging practices by Diamond Match Company. Selective logging during this period left approximately 20% canopy closure in logged areas of Stirling. Sierra Pacific Industries acquired Stirling in 1992 and began logging using even-age management in 1999. Sierra Pacific Industries logged approximately 600 ha (1483 acres) annually using even-aged management during the study period. Logging units were <8 ha in size and included retention of wildlife trees, snags, legacy trees, mast-producing hardwoods, and large downed wood. Units also included at least 2% of the original stand as retention islands. These retention standards were applied to all logging units in Stirling during the study period as per a 2008 Candidate Conservation Agreement with Assurances for fisher on Stirling between Sierra Pacific Industries and the U.S. Fish and Wildlife Service. In 2008, a majority of Stirling (59%) was in a small-tree or moderately-dense-forest condition. The remainder of Stirling was in an early-seral condition (6%) or older age classes (35%)."

Green et al. (2022)reported population growth and fisher densities comparable to other fisher populations. The amount of treatment in their study area was more intensive than proposed on the Nez Perce-

Clearwater with higher amounts of small trees and less older age classes than the plan's desired vegetation condition. Green et al. (2022) emphasized the importance of biological legacies in their management as an important factor for fishers.

Higley and Mathews (2009) and Mathews (2013) documented fisher denning within the 89,400-acre Hoopa Valley Indian Reservation where timber is actively managed. They captured 179 individual fishers from 2004 to 2011 for their study. They described the management of the reservation's timber resources as follows (with units converted from hectares to acres):

Past and current timber harvests created a mix of mature old growth and early seral forests. Prior to 1990, clear-cuts averaged 30–49 acres, although cuts up to 682 acres occurred. From 1960 to 1980, 30% of Hoopa was harvested, averaging over 1236 acres cut/year across multiple clear-cuts averaging 46 acres. Between 1994 and 2010, under the direction of the Hoopa Tribe's Forest Management Plan, tribal forest managers harvested 23,196 m3 (9.83 million board feet) annually on approximately 371 acres, precommercially thinned approximately 408 acres, early-released 247–432 acres, and burned for cultural resource management 15–99 acres. Harvest was implemented using regeneration methods with green tree (12 trees/ha 50 cm diameter at breast height) and snag (all that do not pose a safety hazard) retention in small, 24.7 acre stands. A minor amount of commercial thinning and single-tree and group selection was also employed.

Between 1994 and 2010, the amount of disturbance described above would be between 2,082 and 2,613 acres annually representing between approximately 2.3 and 2.9 percent per year and a total disturbance of between 37.2 to 46.7 percent of the reservation in 16 years. Fishers there are apparently recovering as Mathews (2013) reported catching 179 fishers from 2004 to 2007 and documented good reproduction but expressed concerns over recruitment and dispersal. Mathews (2013) reported a prior apparent 73 percent fisher population decline in Hoopa between 1998 and 2005, citing clear cut logging on Hoopa and on adjacent lands prior to 1990, which left no biological legacies. The amounts of treatment on Hoopa Valley are more than the total annual disturbance proposed in the plan at a forestwide scale (1.58 percent annually) and less than the amount within Management Area 3.

Zeilinski (2013) studied fisher tolerance to the rate and variety of managed forests. They documented that fishers consistently occupy, at the highest rate of use, places where an average of 2.6 percent of the area has been disturbed per year. The disturbance in these areas was described as restorative, which they identified as mostly thinning or intermediate treatments. They reported a rate of an average of 47.1 acres of disturbance per year per square mile. At those rates, fisher habitat at a forestwide level could sustain 129,933 acres per year in fisher habitat at a forestwide level or 59,796 acres in Management Area 3 if the treatments were mostly restorative and still maintain high rates of fisher use. They also describe fisher habitat use at medium use levels as having undergone 93.4 acres per year per square mile which were also identified as restorative treatments. This would equal approximately 291,034 acres of fisher habitat disturbed annually within the total fisher habitat of the Nez Perce-Clearwater if the disturbance was restorative. They reported low levels of fisher use when 121.8 acres of treatment per year per square mile of mostly extractive timber harvest activities had occurred, which would represent 379,529 acres of mostly extractive treatments annually, an amount far higher than the Nez Perce-Clearwater's proposed 53,000 to 64,500 acres average annual disturbance.

Sweitzer (2016) studied fisher habitat occupancy and persistence rates in response to restorative fuels treatments and wildfire. Sweitzer (2016) described their study area as undergoing 2.4 percent of the study area disturbed per year with restorative fuels reductions, which were defined as thinning, masticating, and up to 3.5 percent total disturbance annually with fires and prescribed fires included. Sweitzer (2016) documented fisher use was at higher levels in areas where annual disturbance rates from restorative fuels treatments were 2.6 percent per year but documented, a decline of 24 percent when disturbance rates were 3.2 percent annually. These numbers were comparable to those reported by Zeilinski (2013). These amounts are fewer than both the annual rate of treatment within Management Area 3 which is projected to be around 1 percent annually and the forestwide amount of disturbance which is around 1.58 percent annually. It should be noted that the scale at which percent disturbance was measured was within 1 square kilometer cells rather than at larger landscapes as measured by our model.

The indication is that the model's decline towards natural range of variation lows is consistent with fisher persistence, and that the amount of total disturbance proposed in the Preferred Alternative is less than has been documented to sustain fisher use in other areas of the fisher's range. It is important to note however, that the disturbance occurring at higher annual percents described in those landscapes represented restorative fuels reductions such as thinnings, or understory reductions rather than clear cut timber harvest proposed in this plan. It is also important to note that in these the landscapes managed for timber production, had a commitment to retaining legacy features to allow habitat use of younger aged forest stands. The Nez Perce-Clearwater National Forest has plan components to leave such features as part of their desired conditions and guidelines.

Fisher Home Range Habitat Suitability

With forest wildlife, the area of habitat available to a species is a subset of the habitat within the envelope of biophysical conditions that could potentially provide habitat. Forest conditions change through time as disturbance occurs and forests regrow as a natural part of system dynamics. At any given time, some proportion of forest habitats are in a state that does not provide for a given species as a result of forest condition. For example, if the species relies on mature forests, early seres would not provide potential habitat for the species until forests regrow. Changes in forest conditions over long periods of time result in variation in the amount of total available habitat for a species and define the natural range of variation in forest conditions. The fisher total habitat suitability model presented above is an example of the total habitat available to fishers.

Most wildlife habitat selection studies examine the characteristics of used or selected habitat compared to the total available habitats across the area of comparison, such as a home range or characteristics within a home range. Selected habitats are identified as those that have proportionally more use compared to total available habitats because of habitat characteristics or condition. The condition of forested habitats can determine the selection of habitats by a species. The fisher home range habitat suitability query identifies the amount of selected or preferred habitat out of the total available through time based on a set of criteria thought or assumed to be representative of selected habitats in contrast to total habitat. Naturally, selected habitats are a subset of total available habitat. Figure 72 shows the relationship between the total amount of fisher habitat and the amount of habitat out of the total that has the spatial characteristics of selected fisher home ranges for the natural range of variability. Habitat with characteristics of selected home ranges is estimated for both for the natural range of variation and for the future habitat simulations, so the results are comparable to each other.

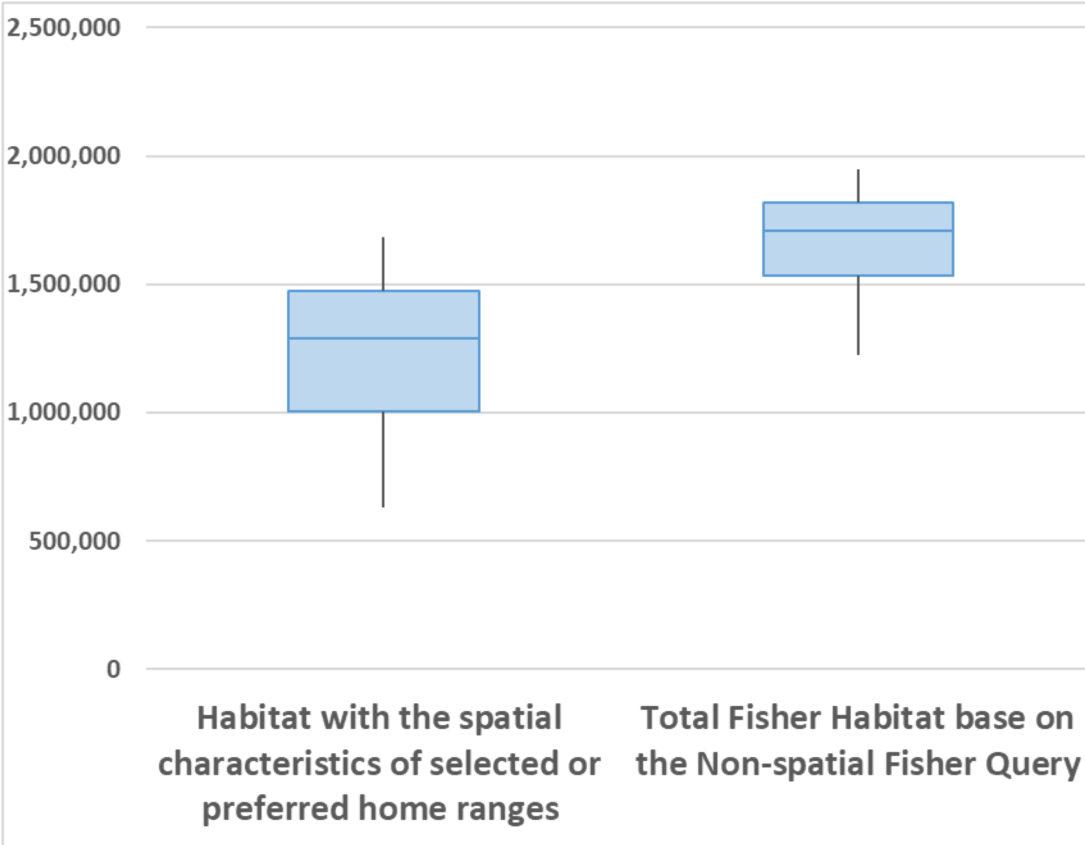

Figure 72. A comparison of the box plots of the natural range of variation of total fisher habitat compared to habitat with the spatial characteristics of preferred fisher home ranges. The box plot on the left represents the natural range of variation for habitats that have the spatial characteristics of preferred home ranges, while the box plot on the right represents the natural range of variation for total fisher habitat based on fisher habitat query. The line in the middle represents the median amount of fisher habitat across all time steps. The boxes show the 25th and 75th quartile and the whiskers show the full natural range of variation. Note that the lower whiskers on the box plot are longer than the ones on the upper whiskers, and that the median line is closer towards the top of the boxes, indicating a slightly skewed distribution towards the higher end of NRV. This suggests that fisher habitat was at higher end of NRV more often than it was towards the lower end. The skewed distribution is an artifact of the behavior of the trend lines during NRV runs. The periods when climate conditions trended fisher habitat rapidly towards the lower end of NRV, while fisher habitat trended upwards over longer periods of time in the model environment.

Under the natural range of variation (NRV) within the model, habitat with the spatial characteristics of selected home ranges fluctuated from between a low of about 631,124 acres and a high of about 1,683,374 acres with a difference of about 462,750 acres between the NRV high and low. The average through time was about 1,229,249 acres. This compares to the amount of total habitat without the spatial criteria under the natural range of variation (NRV) of 1,224,385 at the low end and 1,947,284 acres at the high end, with difference of 722,899 and an average of about 1,658,721 across all time steps. Note that the amount of habitat that has the spatial characteristics of preferred home ranges is always less than the total amount of fisher habitat and that selected habitats are a subset of total available habitat.

One important source of departure from the NRV is the landscape pattern disturbance. During NRV runs, the spatial distribution of fisher habitat was dynamic over time in the model, shifting around the landscape through time in response to large scale disturbance and regrowth. At any given point in time, there was a portion of the total amount of fisher habitat that was in a state that would have low probability of fisher use. The pattern of disturbance suggested that large areas of fisher habitat were impacted by fire leaving other large areas with low amounts of open habitats. The dynamic nature of fisher habitat with its patchy distribution at the landscape scale explains how the NRV for the amount of disturbance in warm moist and cool moist broad potential vegetation types (PVTs) can be higher overall than those tolerated by fisher at the home range scale. To illustrate, the NRV for the percent of the landscape in the warm moist broad PVT in the grass-forb-shrub seral stage is between 2 and 17 percent, a total higher than the 5.3 percent open habitat fishers reportedly prefer for home ranges Sauder and Rachlow (2014). While disturbances occur at these higher percents at the landscape scale, they occurred mostly in large patches resulting from wildfire disturbances and so are not evenly distributed across the landscape. To put it another way, fires burned off large blocks of habitat, while in other areas, fisher habitat had low amounts of open habitat. In contrast, forest management has resulted in small, scattered treatments, 40 acres or smaller, evenly distributed across the landscape and often at lower amounts overall than within the NRV. While timber harvest treatments mostly occur in forests of larger size classes, wildfire can burn forests of all ages. This facet of fisher habitat underscores the importance of understanding the patch dynamics and application of the proper distribution and amount habitats in these conditions at the landscape scale.

The difference between preferred habitat and total habitat is not even across the NRV indicating that, as the habitat trends down towards the low end of the natural range of variation, it becomes more fragmented, resulting in a proportionally lower amount of preferred habitat. In other words, as a greater amount of the total habitat is disturbed, it becomes proportionally more fragmented such that preferred fisher habitat becomes proportionally less available. Figure 73 presents the difference between total fisher habitat and preferred fisher habitat under the NRV. Note that the space between the blue line (NRV of total habitat) and orange line (NRV of fisher habitat with the spatial characteristics of preferred home ranges) increases as they get closer to the NRV low (Figure 73). It basically means that fisher habitat is naturally more fragmented when at the NRV low. These are the expected natural or endemic amounts of fragmentation during NRV runs that existed under natural disturbance. These may be compared as a reference of the relative amounts of fragmentation compared the alternative outcomes.

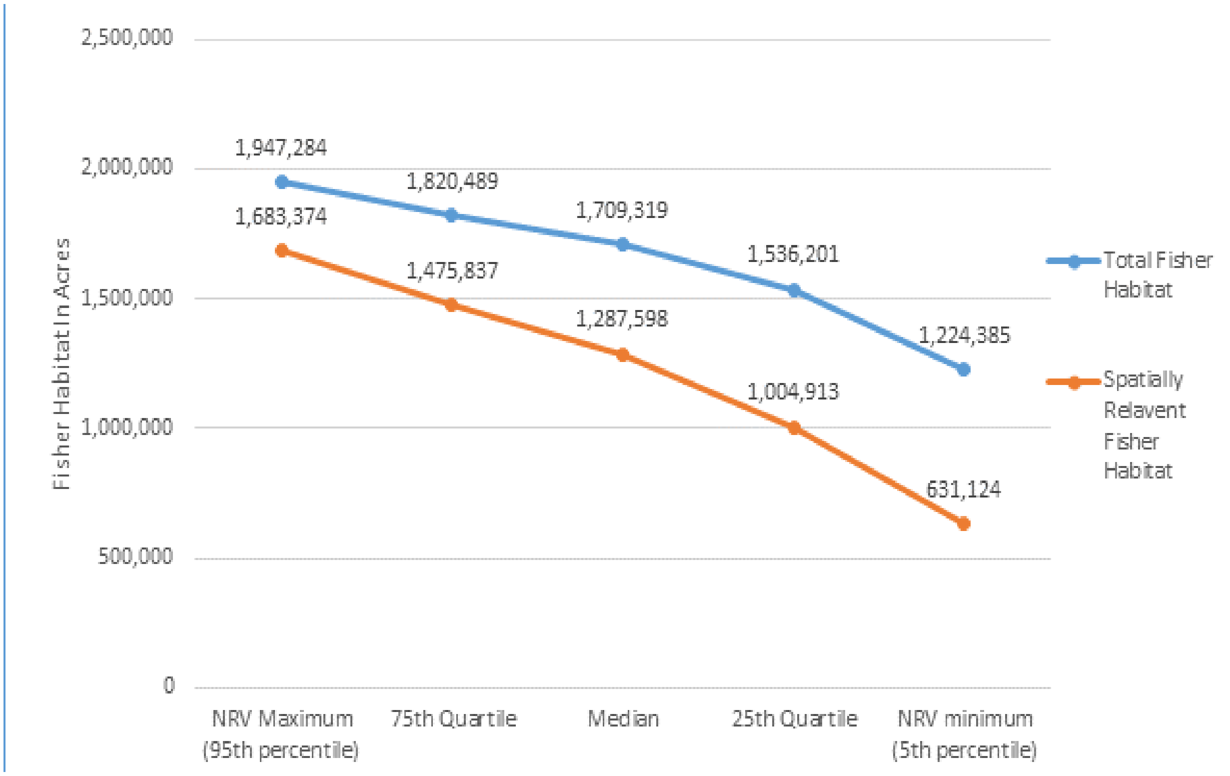

Figure 73. Differences in fisher habitat between the habitat availability model and the spatially explicit moving windows analysis across the Natural Range of Variability. In addition to an absolute difference in acres of predicted fisher habitat, the models also predict more fragmented habitat at the NRV low. Note that the space between the blue line (habitat availability model) and the orange line (moving windows analysis) increase when total habitat is at the NRV low compared to when total fisher habitat is at the NRV high.

A comparison of the trends of the spatial fisher habitat model under the alternatives is presented in Figure 74. When comparing model outcomes, there are differences. Both models estimate the same acres of mature, mesic forests and the same acres of open or sparse vegetation because both models rely on the SIMPPLEE model queries. The difference between models in what is available versus what is suitable fisher habitat reflects how the available mature, mesic forest is arranged on the landscape. By setting spatial thresholds for preferred forest conditions within the landscape, the analysis explores questions of connectivity (area of mature, mesic forest) and fragmentation (area of open or sparse vegetation) for a specified probability of fisher occupancy threshold of 0.4. The difference between the two models, thus, represents the modeled effects of connectivity and fragmentation on the suitability of fisher habitat to support a home range.

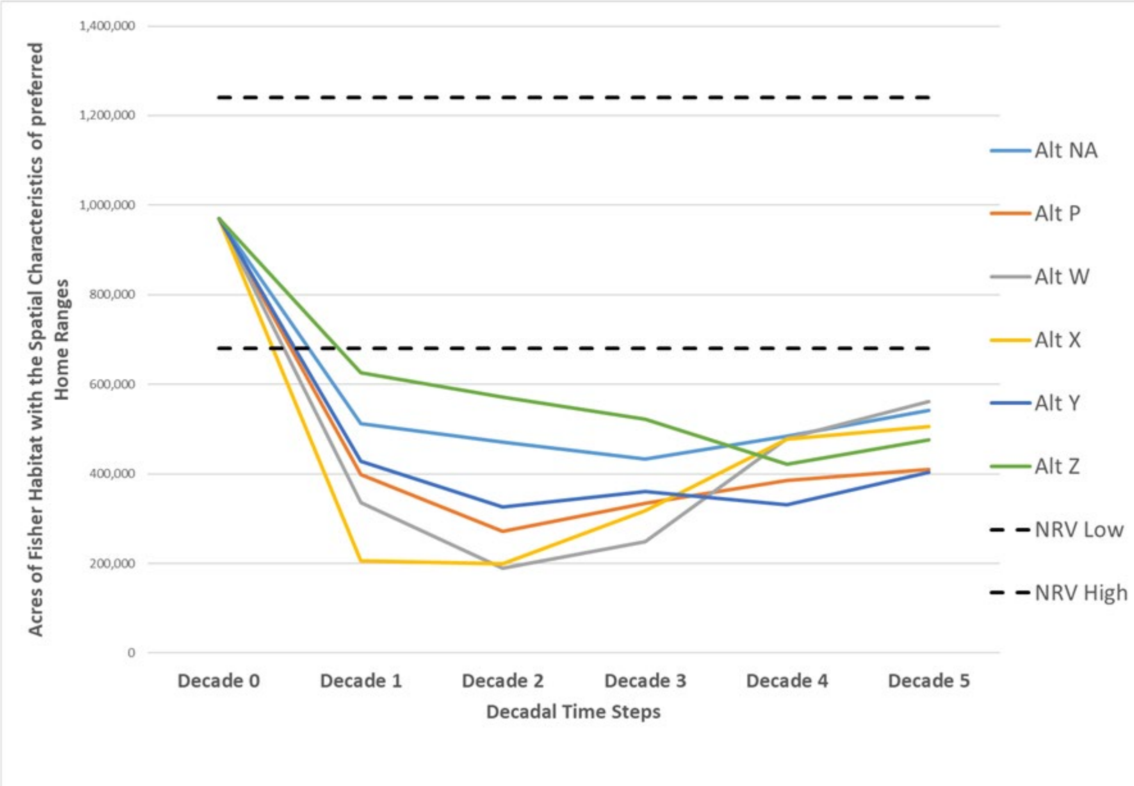

Figure 74. Predicted trend in the amount of fisher habitat in acres that have the spatial characteristics of female home ranges at a specified probability of occupancy of 0.4 by decade and alternative. Time steps represent decades, data was generated from a query of in SIMPPLLE and PRISM outputs that represent fisher habitat and an algorithm that identifies areas with greater than or equal to 55.8 percent mature and less than or equal to 10 percent open. For the query mature is defined as trees 10" D.B.H. or greater, while open is defined as all non-forested habitats, and forested habitats in grass, shrub, and seedling stage or 0-4.9" sapling size.

Like the total fisher habitat availability model, the Fisher Home Range Habitat Suitability model estimated the current acreage of fisher habitat that is suitable to support home range to be well within the natural range of variation (NRV) at about 970,265 acres (Figure 74). Again, since all the alternatives were subject to the same natural disturbance regimes and had the same desired conditions, the predicted acres of habitat suitable to support a fisher home range differed little among alternatives (Figure 74), although the difference were greater than those for total fisher habitat availability (Figure 68). Like the previous model, the rate of change depended largely on the rate of treatment, with the most intensive vegetation management alternatives resulting in a faster rate of change (Figure 74). Applying the spatial criteria via a moving window analysis to future predictions of fisher habitat suggests an increase in fragmentation in fisher habitat through time. The percent decline in spatially relevant fisher habitat is presented in Table 197. The decline in habitat through fragmentation occurs within all alternatives.

Model results of the spatial query are primarily a reflection of the landscape pattern of disturbance and resulting landscape pattern of fisher habitat in the modeling environment. So as modeled, the resulting landscape from natural disturbance like wildfire, and insects and disease, differs from the landscape pattern that result from the combination of natural disturbances, and vegetation treatments like timber and fuels treatments. The outcome in the SIMPPLLE model was the result of how SIMPPLLE and PRISM prioritized the distribution, size, and priority of disturbances through time. The pattern of landscape disturbance modeled in SIMPPLLE and PRISM do not necessarily replicate the spatial pattern of the proximity index used by Sauder and Rachlow (2015) which showed that fishers selected landscapes that had large patches of mature forest that were arranged in complex, highly connected patterns.

Table 197. The percent decline of habitat with the spatial characteristics of preferred home ranges at the end of 50 years

Alternative	Percent Decline
No Action Alternative	44%
Alternative W	42%
Alternative X	48%
Alternative Y	58%
Alternative Z	51%
Preferred Alternative	58%

Also like the fisher total habitat availability model, some alternatives decline faster but then recover some before the 5th decade, which is observed in Alternative W and Alternative X, reflecting a faster recovery back into fisher habitat compared to other alternatives. The time horizon projected in the model is too short to understand the longer-term trends. Under the Preferred Alternative, the availability of fisher habitat that is suitable to support a home range drops by nearly 66 percent after the second decade to about 385,339 acres before rebounding and ultimately resulting in a nearly 58 percent decline, to roughly 410,126 acres, by the end of the fifth decade. None of the alternatives, however, fall outside of the natural range of variation for total acres of open or sparse vegetation (Figure 75) a reasonable proxy for total disturbance.

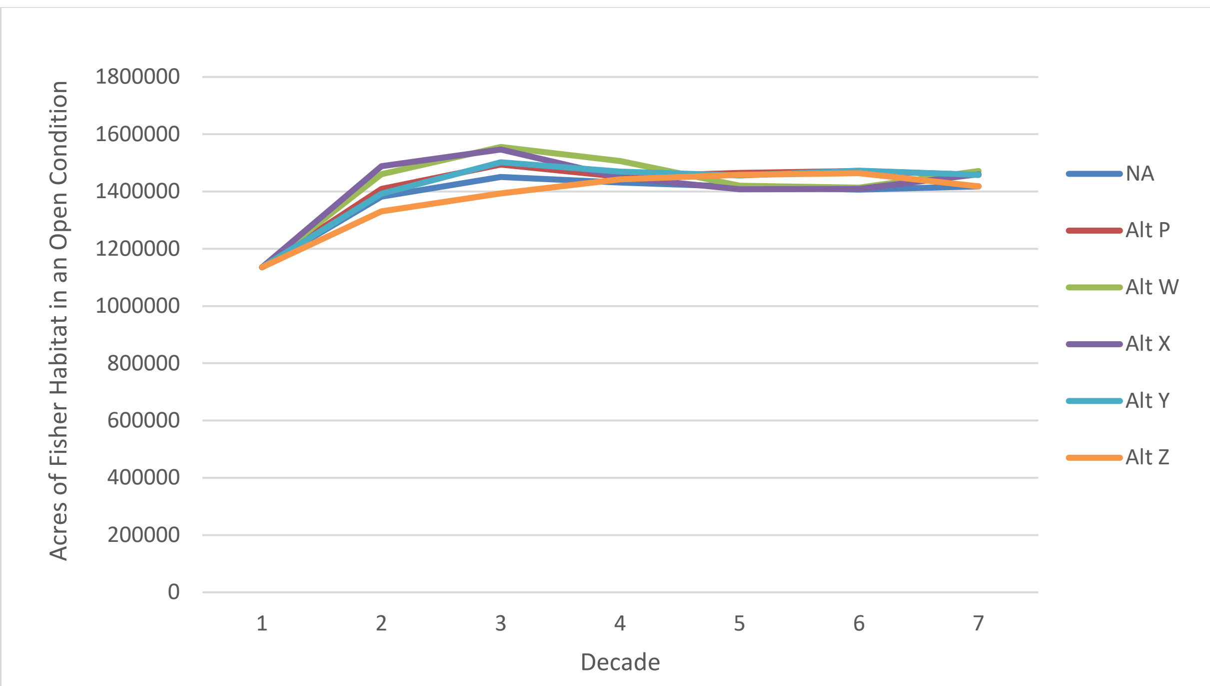

Figure 75. Predicted trend in open condition within fisher habitat by alternative

It is not the total acres of disturbance that primarily differentiates the effects documented by the moving windows analysis, but rather the size and distribution of individual disturbance events. Historical sources of disturbance largely resulted in large, concentrated areas of open or sparse vegetation; however, management actions are smaller and often more dispersed across the landscape. The outcome is that although all the alternatives fell within the natural range of variation for total acres disturbance, the patch size and distribution did not. Ultimately, this departure from historic landscape patterns is the primary driver of the decline in habitat suitable to support a fisher home range.

Like the fisher total habitat model, the variation between the alternatives was mostly manifested within Management Area 3, whereas the trend within Management Areas 1 and 2 remain relatively consistent among alternatives (Figure 76, Figure 77, and Figure 78).

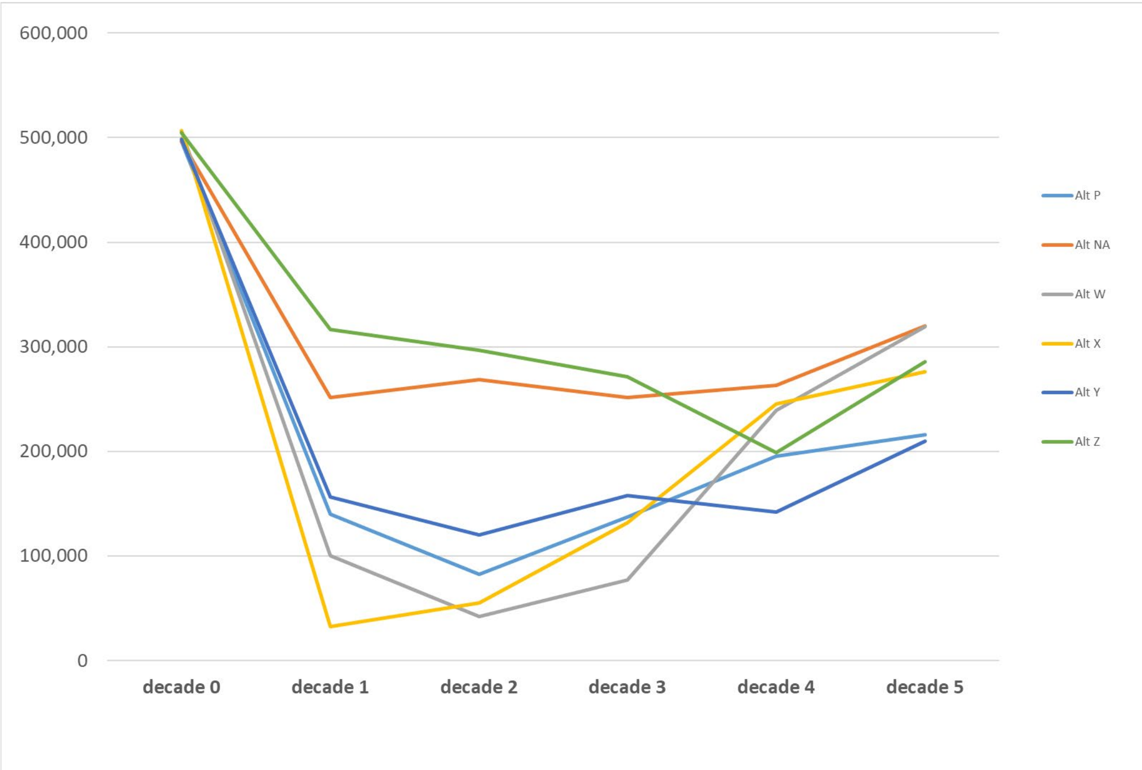

Figure 76. The trends of fisher habitat with the spatial characteristics of preferred female home ranges by alternative within Management Area 3

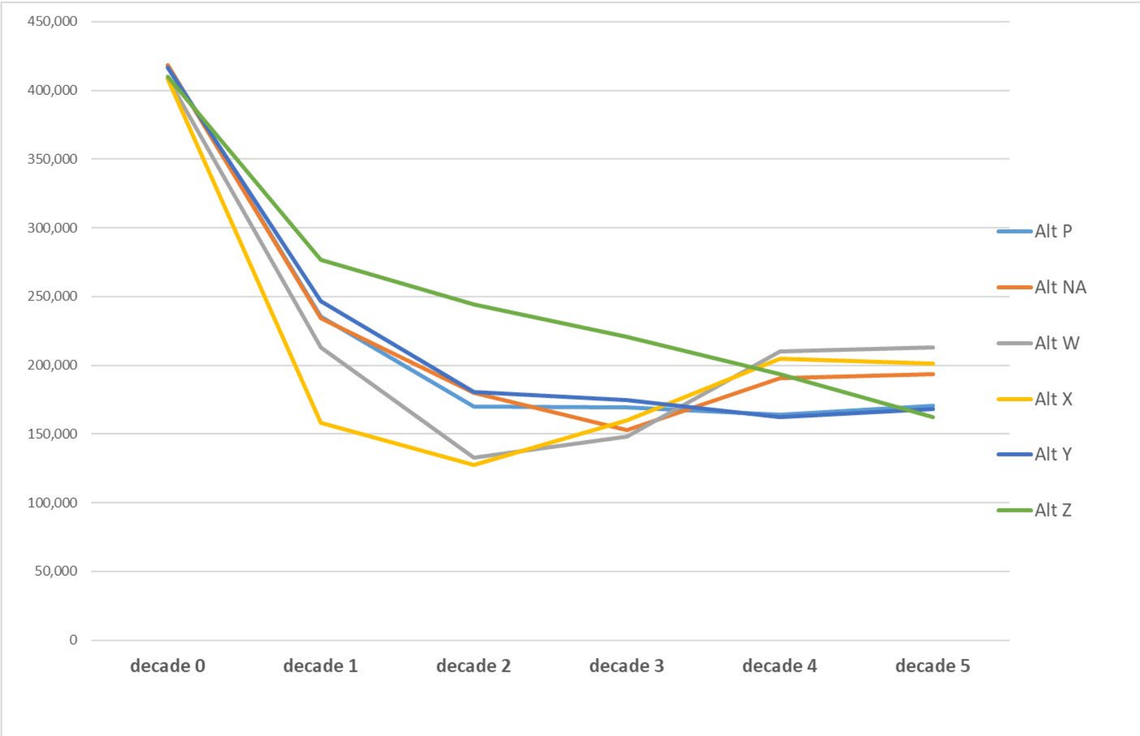

Figure 77. The trends of fisher habitat with the spatial characteristics of preferred female home ranges by alternative within Management Area 2

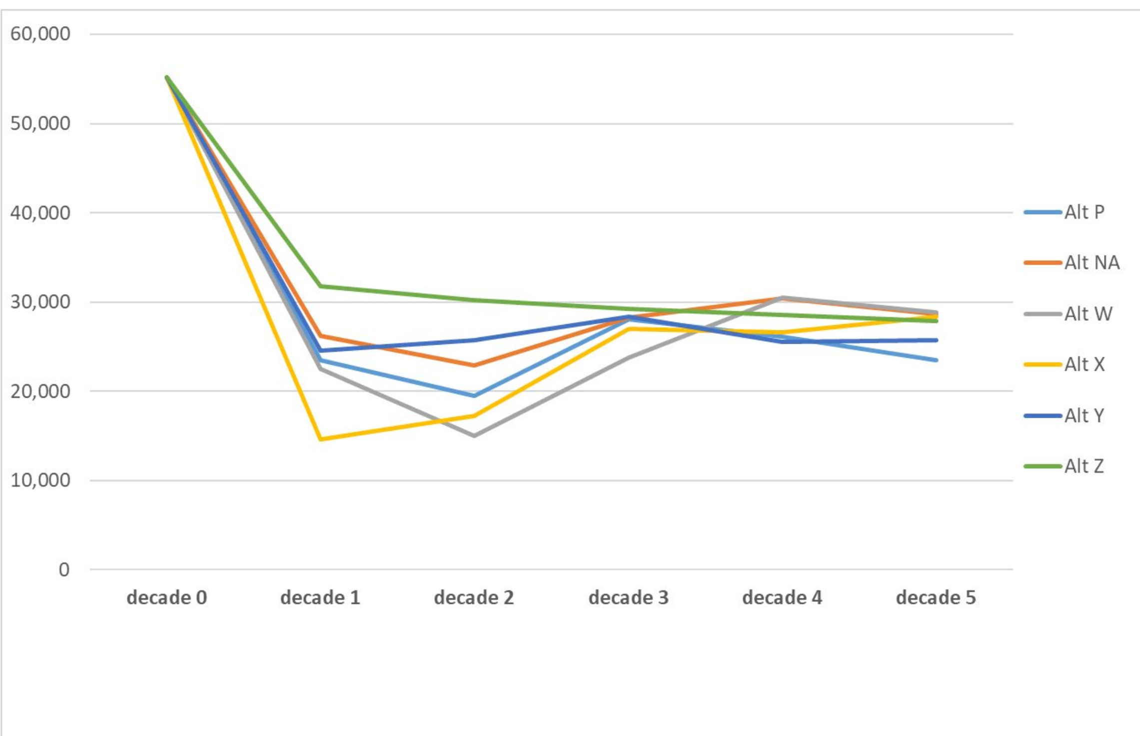

Figure 78. The trends of fisher habitat with the spatial characteristics of preferred female home ranges by alternative within Management Area 1

Model Discussion

One thing to note is that in all alternatives, the moving windows analysis results in the greatest rate of change in habitat within the first decade (Table 198). Further examination of the proposed treatment schedule in the model revealed that total disturbance of fires, prescribed fire, timber harvest, and insects and disease exceeded the plan's annual disturbance acres of Disturbance/Restoration annually to be within natural range of variation in the first decade by modest amount but not thereafter. For example, the plan proposes between 53,000 and 64,500 acres of total disturbance annually to meet desired conditions. Within the first decade in the model, the amount of total disturbance averages 76,917 acres annually. The amounts of disturbance in the first decade in the model are about 12,417 acres annually. The amount of disturbance in the model averages 65,291 acres annually over the 50-year period, which is on the high end of the proposed range of desired disturbance amounts in the plan. The model results represent a worst-case scenario under the Preferred Alternative. Examination of the types and amounts of disturbance indicate that approximately 423,463 acres of disturbance or 55 percent of total disturbance is wildfire of some type, with 20 percent stand replacing fire, 23 percent mixed severity fire, and 12 percent light severity fire. Including prescribed fire, the disturbance from fire in the first decade makes up the majority of total disturbance (63 percent). Another factor might be that the model could have identified non-habitat when the spatial criteria could not be met within the moving window when it ran up against the boundary edge of the modeled landscape.

Table 198. The types and acres of disturbance types in the first decade under the Preferred Alternative

Disturbance Type	Acres of Disturbance in Decade 1 -Preferred Alternative	Percent of the Total for Each Disturbance Type	Percent of the Total Forest Area (3,939,056 acres)
Disease	14,598	2%	0.37%
Insects	48,522	6%	1.23%
Intermediate	27,562	4%	0.70%
Planting	97,115	13%	2.47%
Prescribed Fire	68,618	9%	1.74%
Regeneration Treatment	89,039	12%	2.26%
LIGHT-SEVERITY-FIRE	90,574	12%	2.30%
MIXED-SEVERITY-FIRE	179,015	23%	4.54%
STAND-REPLACING-FIRE	153,874	20%	3.91%
Total Disturbance	768,917	100%	19.52%

The model projects additional disturbance because existing vegetation conditions on the ground today are conditions that are prone to increased amounts of natural disturbance like wildfire, insects, and disease according to the model assumptions. Additionally, the model is using assumptions of a warmer-drier climate which tends to produce more disturbance in the model. These factors combined suggest that forest conditions in fisher habitat today are prone to disturbances like wildfire.

While the effects of fire on fisher habitat have not been studied within the Northern Rockies, some recent studies have been published on the effects of fire on the Sierra Nevada population of fishers that could be useful in the interpretation of the effects of fire disturbance in the model (Hansen 2015, Swietzer 2016, Lewis 2016, Blohmdahl 2019, Thompson 2019, Thompson 2021). The general consensus and key findings from these studies are that while fishers appear to avoid high severity fire, fishers have been documented to use and persist in burned areas including managed burns especially if the fires were low and mixed severity burns. Fisher use of postfire landscapes may center on low severity or unburned islands (fire refugia or fire skips) (Hansen 2015, Thompson 2019, Blohmdahl 2019, Thompson 2021). Second, while fisher population might decline after fire, they were found to persist albeit at lower numbers (Thompson 2021). Third, areas that burned at low or moderate severity fire had forest structural characteristics predictive of den presence within burned areas and the presence of den structures are not necessarily dependent on time since fire (Swietzer 2016, Blohmdahl 2019). Sweitzer (2016) found fishers using previously burned areas, including areas that had been subjected to managed burns. Within fire perimeters, the distribution of burn severity is heterogeneous. Fire mosaics consist of myriad burn severities, including areas that experienced little or no burning. A critical outcome of this heterogeneity is the formation of fire refugia—unburned or lightly burned areas in the burned matrix that are functionally unaltered by fire (Blohmdahl 2019). Areas predictive of denning habitat can occur even in areas burned with high severity fire especially if they contained some large-diameter trees capable of surviving higher severity fire (Blohmdahl 2019). As fire refugia or fire skips age, they often contain remnant old-growth patches, an abundance of residual large woody structures, and legacy old-growth trees that survived the fire and contribute to fisher denning habitat (Lewis 2016, Jones 1991, Jones and Garton 1994). Fisher studies from the Northern Rockies (Jones 1991, Jones and Garton 1994) documented fisher use of areas previously burned by wildfires that retained scattered large trees and structures important for denning, security, or thermoregulation. A landscape mosaic created and supported by a mixed-severity fire regime could provide a diversity of habitat and prey while protecting against large habitat losses associated with large or uncharacteristically severe disturbances. Efforts to promote a sustainable low- to mixed-severity fire regime that creates habitat heterogeneity and forest resiliency can support fisher conservation (Thompson 2021).

Prescribed fire makes up approximately 9 percent of total disturbance or about 68,618 acres per decade or an average of about 6,862 acres per year. This amount of treatment makes up about 1.7 percent per decade and less than 1 percent annually forestwide. Prescribed fires are typically conducted under conditions that result in light or moderate severity burns.

The fire outcomes in the model do not fully incorporate the highly complex and variable nature of fire, especially within the fire regime groups that burn with mixed severity fire, which make up most of the fisher's habitat envelope. It only partially accounts for mixed-severity fire. The disturbance algorithm calculates changes to stand density and canopy cover by dominance type as a function of disturbance severity. If a pixel burned with mixed severity, then the stand density is reduced by 50 to 75 percent depending on dominance type and associated species. For example, if a stand was 50 percent grand fir and 50 percent western larch, then all grand fir is removed, the stand converts to a western larch dominant stand at lower density. In reality there is high variability in mixed burn severity, and lots of residual legacy features that research above suggests allows continued fisher use after burning. Furthermore, the model operates with a minimum pixel size of 5 acres which is not fine enough resolution to capture the variability of mixed severity fire that occurs at fine scales. Small fires (under 5 acres) are the dominant disturbance scale in terms of number of fires.

The spatial algorithm to identify habitat with the spatial characteristics of fisher home ranges possibly treated many burned pixels as non-fisher habitat if the canopy cover thresholds if the model classified them as below query thresholds. In reality, research suggests that at least some of these burned areas will likely maintain habitat use (Hansen 2015, Swietzer 2016, Lewis 2016, Blohmdahl 2019, Thompson 2019, Thompson 2021). Model outcomes should be viewed with caution because it might inappropriately overestimate the impacts to fisher habitat from natural disturbance.

Several studies have evaluated the tradeoffs of maintaining fisher habitat while using fuels treatments designed to reduce the threats of high severity fire. Fuel reduction efforts can reduce wildfire intensity, limit extent, and protect critical structures used by fishers for resting and reproduction; however, at the same time, these activities come with short-term reductions in habitat quality (Thompson 2011, Scheller et al. 2011, Truex and Zielinski 2013, Zielinski et al 2013, Hanson 2015, Sweitzer et al. 2016, Thompson 2019). The overarching findings are that while fuel treatments can reduce probability of occupancy or habitat use short term over smaller scales, fuels treatments can reduce the loss of fisher habitat to large scale high severity fires long term. Furthermore, these studies suggest that patterns of occupancy indicated that fishers remained in the vicinity of fuel reduction projects as long as they were able to move around fuels treatments and thinned areas. Furthermore, fisher occupancy or habitat use recovers from fuels or restorative treatments within a shorter period of time, whereas recovery from high severity fire takes longer and represents larger losses of habitat. Finally, even though restorative fuel reduction reduced occupancy, fishers would continue to maintain occupancy and persistence rates at lower levels (Thompson 2011, Thompson 2019, Thompson 2021, Sweitzer 2016, Hanson 2015). Model results should be interpreted as potentially lowering probability of occupancy rather than complete loss of fisher habitat use and loss of persistence.

SIMPPLLE model testing suggested that active management, including forestry treatments and prescribed fire, do decrease the risk of fisher habitat loss to wildfire. To test this, we ran the model without forestry and prescribed fire treatments and compared the amount of fisher habitat that would have burned without treatments to the amount that would burn in the presence of forestry and prescribed fire treatments under the Preferred Alternative. The results indicate that forestry and prescribed fire treatments reduced the projected amount of fisher habitat burned by wildfire by approximately 33 percent overall (Figure 79).

Our results for fire are similar to those found by Thompson et al. (2011) who used landscape trajectory analysis to evaluate the long-term outcome of fisher habitat when considering different management options in Sierran fisher habitats. They simulated the effects of both no action and forest thinning, with and without an unplanned fire, on vegetation characteristics over a 45-year period. Under the no action scenario, landscapes remained similar to the reference conditions for approximately 30 years until forest succession resulted in a loss of landscape heterogeneity. Comparatively, fuel treatment resulted in the reduction of certain forest elements below those found in female fisher home ranges, yet little overall change in habitat suitability. Adding a wildfire to both scenarios resulted in divergence from the reference conditions, though in the no action scenario the divergence was four times greater, and the landscape did not recover within the 45-year timeframe. Therefore, a schedule of treatments like those in the Preferred Alternative may represent a tradeoff of timber harvest effects in exchange for preventing greater wildfire losses of fisher habitat.

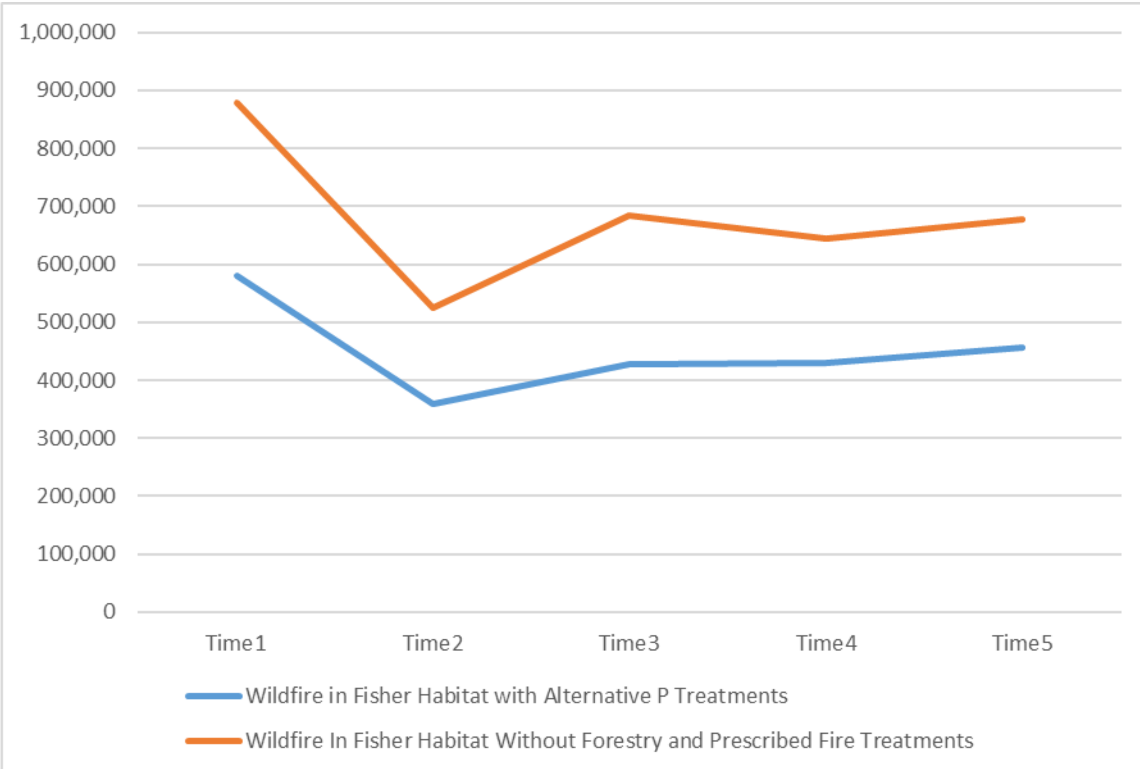

Figure 79. A comparison of the amount of fisher habitat burned by wildfire without prescribed fire nor forestry treatments compared to the amount of fisher habitat burned by wildlife with prescribed fire and forestry treatments of the Preferred Alternative by decade. The orange line represents acres burned in wildfire without forestry and prescribed fire treatments while the blue line indicates the amount of fisher habitat burned by wildfire when forestry and prescribed fire treatments are implemented according to the Preferred Alternative.

Olson (2014) modeled the response of fisher habitat to climate change in the Northern Rockies. Climate change modeling predicted an increase in fisher habitats under two scenarios but also found that fisher habitat would become more fragmented as well. Olson (2014) found a large contrast in the results when minimum patch size and species dispersal capabilities were considered. Their distribution model with full dispersal and no limits on patch size predicted a 24.5 percent increase in fisher habitat by 2090, whereas a dispersal limit of 1 kilometer through non-habitat, such as agricultural fields and urban zones, and a minimum patch size yielded a loss of 25.8 percent of fisher habitat under this same scenario. Varying dispersal appears to limit habitat availability more than minimum patch size under most scenarios. Fisher habitat was associated with mesic forest and the model found no support for fisher selection for dry forests. The Olson (2014) model suggested that locations within the study area in the Rocky Mountains with the greatest fisher abundance is the Clearwater River subbasin in Idaho. Climate change modeling by Olson (2014) also predicted that the contiguous habitat in the Clearwater Mountains in Idaho become less suitable and more fragmented, resulting in a large loss of contiguous habitat as climate changes. The fragmentation and decline of fisher habitat under the warmer-drier climate conditions in our model within the clearwater basin was consistent with findings by Olson (2014).

Not much information is available in the scientific literature to inform on how much open areas female fishers can tolerate. Additionally, different researchers define open habitats differently and do not report home range composition nor its effects on probability of use though some studies are useful. The following paragraph examines scientific literature that might inform the resilience of fishers to landscape disturbance and for context in interpreting model results.

Core areas of females and males on the Olympic Peninsula comprised about 12 percent and 26 percent natural forest openings, respectively (Lewis 2016), which were considerably higher than 5–10 percent reported for females and males in northwestern California (Zielinski et al., 2004), and higher than open habitats in female home ranges of 5.3 percent reported by Sauder and Rachlow (2014). The 12 percent amount in female home ranges on the Olympic Peninsula is slightly higher than the threshold we used in the fisher spatial query for female home ranges in our model. Lewis (2016) defined natural open habitats as low amounts of open-canopied habitat, and the metric evaluated was percent of pixels that are classified as natural open area. Lewis (2016) also suggested the probability of use of an acre for a female fisher core area diminished as the amount of open habitat increased. Nonetheless, their findings support the broad consensus that female fishers generally avoid non-forested cover types and noted that the bulk of the mid-seral forest used by females occurred in areas protected from logging (Lewis 2016). Nibblett (2017) studied fishers on industrial timber grounds in Northern California and described the area as having 24 percent open habitats defined open habitat as canopy closure 25 to 39 percent, which is how Zelinski (2004) defined open. Weir and Corbold (year) defined open as water or logged areas and stated that at a home range with 25 percent open would equate to zero probability of occupancy. Kordosky (2020) defined open as low canopy cover less than 40 percent found that female home ranges averaged 8.4 percent plus or minus 7.36 open in their core use areas and 13.8 percent plus or minus 9.42 in their home range. Green (2022) studied fishers on industrial timber lands in Northern California and described early seral conditions as trees less than 5.9 inches and open as canopy cover less than 40 percent, which they reported early seral as making up 6 percent of the forest and open as making up 12 percent which would equate to a total of 18 percent open according to our query criteria. Green (2022) however, did not report the composition of female home ranges or distinguish between used and unused areas. Higley and Mathews (2009) studied fishers on the Hoopa Valley Indian Reservation managed for timber production, and identified seedling, non-forest, and sapling as occurring at 3.8 percent, 2.6 percent, and 10.2 percent respectively. Combined, these amounts would represent approximately 16.6 percent open according to our query criteria. Higley and Mathews (2009) found that home ranges generally included less non-forested or open seedling stand types, and these types were approximately 10 percent or less within female home ranges. They recommended management avoid 20- to 40-acre clearcuts because such landscapes do not mimic any natural disturbance and would ensure that huge areas are unsuitable for fishers because of predators Higley and Mathers (2009). Higley and Mathews (2009) recommended managing for larger openings up to 1,235 acres that better mimic natural disturbances and reduce fragmentation. Sauder and Rachlow (2014) provides the best information for our area and suggests that fisher probability of occupancy declines as the amount of open increases, where at 15 percent open the probability of occupancy would be a little more than 0.2 while at 20 percent open the probability of occupancy near 0.1. Sauder and Rachlow (2014) did capture some fishers on industrial timber lands where open habitats averaged 17 percent and ranged between 10.3 and 25.5 percent.

The moving windows analysis relies on specific thresholds in vegetation composition to categorize a location as fisher habitat. The choice of a high proportion of mature, mesic forest and a low proportion of open or sparse vegetation is intuitive; however even small changes in a threshold can significantly alter the magnitude of the effects in the moving windows analysis. The process of creating a threshold takes a continuous probability (that is, 0 to 1) and recategorizes that probability as habitat or not (that is, 0 or 1), yet fisher may still use areas categorized as non-habitat. For example, although the moving windows analysis categorizes an area that includes 15 percent open or sparse vegetation as non-habitat, there is still a 20 percent chance that the area would be occupied (based on Figure 2 on Page 80 of (Sauder and Rachlow 2014). As the proportion of open or sparse vegetation considered in the moving windows analysis was in many cases only slightly over the 10 percent threshold, the magnitude of the fragmentation effects may be considerably less if those small differences do not lead to the precipitous drop in the probability of use required by creating a categorical threshold. Moreover, the models did not classify dry forest, such as lodgepole pine and Ponderosa pine, as suitable fisher habitat. Although, fisher tend to avoid dry forests, fisher have been documented using them (Krohner 2020) suggesting that dry forests may contribute to landscape connectivity and help mitigate the effects of fragmentation. The spatial fisher query in our model represents the amount of habitat with the spatial characteristics preferred by fisher home ranges at specified probability of occupancy of approximately 0.4 based roughly on Sauder and Rachlow (2014) but does not indicate absolute loss of habitat. Fishers continue to use areas that exceed the 10 percent open thresholds we used in our query at lower probability of occupancy. The spatial query outcomes should be interpreted as only a reduction in probability of occupancy, but not as a complete loss of habitat use or occupancy.

The spatial query for fisher home ranges is based on two criteria that must both be met. The amount of mature forest required at least 55.8 percent, and the amount of open was required to have 10 percent or less open. We conducted model testing to determine which factor was more influential. Testing revealed that the criteria for open habitat was responsible for a greater proportion of habitat being identified as non-preferred fisher habitat. In contrast, the amount of mature forest above 55 percent was present across much of the national forest in most time steps in 50-year projections. In some area the amount of mature dropped down to between 40 and 55 percent, which are amounts of that are known to support fisher home ranges or where landscape composition on industrial timber lands contains low amounts of older age classes (Green 2022, Nibblett 2017, Mathews 2013, Kordosky 2020, Sauder and Rachlow 2014). For example, Sauder and Rachlow (2014) identified a range of mature forest between 39.5 percent and 64.8 percent in occupied fisher home ranges. An example of a future decadal projection map generated in SIMPPLLE is shown in Figure 80. It shows that most of the landscape remains above at least 40 percent mature, and substantial percentages remain above the 55 percent threshold over much of the landscape area. The amount of area with high canopy cover is widely identified as preferred fisher habitat in many studies (Jones and Garton 1994, Powell and Zeilinski 2004, Raley 2012). The evaluation of the model suggested that the amount of open habitat, in many cases, was only slightly over the 10 percent threshold. Model testing at different thresholds for percent open revealed how sensitive the model is to the threshold used for identifying fisher habitat. The 10 percent threshold used is higher than that identified by Sauder and Rachlow (2014) at less than 5.3 percent in the best fisher habitats. It should be noted, however, that the two criteria often interacted with each other to increase the amount the model identified as non-preferred habitat, perhaps excessively.

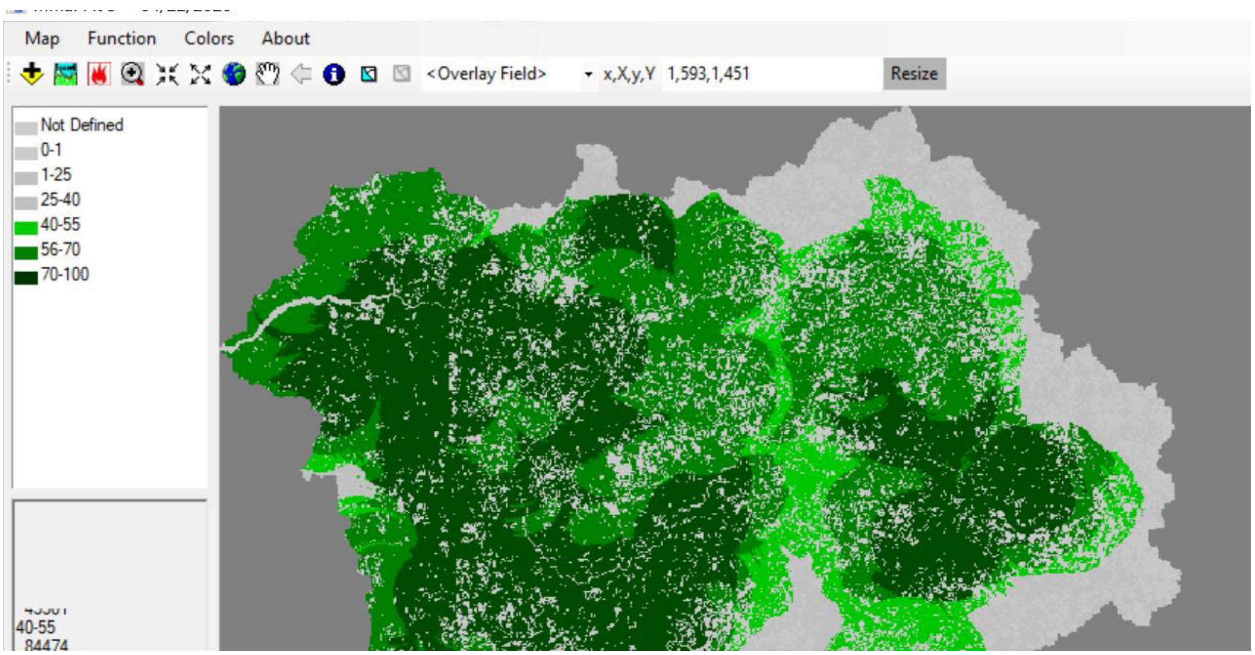

Figure 80. A map generated from a decadal timestep for a future model outcome for the North Fork landscape showing pixels where the moving window indicated the outcome for the mature forest criteria in the spatial query. Areas colored gray have less than 40 percent mature, areas colored light green indicate lands with between 40 to 55 percent mature, darker green indicates mature forest cover between 56 to 70 percent, and the darkest green color indicates pixels with between 70 to 100 percent canopy cover.

One of the most important contributions made by Sauder and Rachlow (2014) was that the proximity index of mature forest was more indicative of fisher habitat than the amount of area with high canopy cover. The proximity index of mature forest is an indicator of the size of and distance among all patches of a habitat type within a landscape to distinguish between landscapes with sparse distributions of small habitat patches and landscapes comprised of complex clusters of larger patches indicative of mature forest arranged in complex, highly connected patterns (Sauder and Rachlow 2014). Thus, the proximity index applied to fisher habitat is an index of the connectivity of fisher habitats. The proximity index was 40 times more plausible than the amount of open area at best explaining landscape level selection by fishers (Sauder and Rachlow 2014). We did not use the proximity index in our model (as recommended by Joel Sauder) because the interpretation of the results are less intuitive and we wanted decision makers, practitioners, and the public to be able to understand and implement the plan in a way that continues to support fisher habitat. Therefore, we use the percent of mature forest in conjunction with the amount of open habitat because it is likely correlated to the proximity index of mature forest and was the third most supported model in Sauder and Rachlow (2014). It may be possible to manage the landscape distribution of patches to maintain the connectivity of mature forest while simultaneously managing the system for timber production, even when the landscape distribution of such management is different than the landscape pattern under natural disturbance. The plan has several plan components that will contribute to the connectivity of mature forests including those for riparian protections which are abundant and well distributed, those that address landscape pattern within the Forestlands section, the maximum patch size limit of 207 acres, and the species-specific desired condition for fisher habitat as examples. It is well established that fisher have large home ranges that are predominantly composed of mature, mesic forests with few areas of open or sparse vegetation, but it is the specifics of these relationships that ultimately drive the model outcomes. For example, the moving windows analysis assumes an average home range of 49.3 square kilometers as an analysis window. Fisher home ranges in the Northern Rockies are among the largest known across their distribution, but even in the Northern Rockies there is considerable variation in home range size both among individuals and locations (Sauder and Rachlow 2014, Sauder 2014, Jones 1991b, Schwartz et al. 2013). While we used the average size, approximately half the home ranges were larger and half were smaller. Also, our home ranges were perfect circles rather than variable in shape like true home ranges. Species-habitat relationships are very sensitive to the spatial scale at which they are considered (Stuber and Fontaine 2017, Mirochnitchenko et al. 2021), thus changing the size of the window in a moving windows analysis can lead to significant changes in predicted relationships. A smaller window might have been appropriate if we had used the smaller, core use areas, which is an area of concentrated fisher use within home ranges, and if so, the size of the moving window would have been smaller. Because there is a high degree of variation in fisher home range size, there is subsequently greater uncertainty in the model outcomes associated with the choice of a single 49.3 square kilometers as an analysis window. For example, the use of a smaller analysis window may reduce the magnitude of the fragmentation effects if the disturbances are separated enough to allow individual windows to fall between disturbance locations. Alternatively, because the thresholds are based on a proportion, using a smaller window may increase the magnitude of the fragmentation effects because a smaller area of disturbance will be more likely to exceed the proportional threshold. Similarly, the analysis also assumes that the average size of a fisher home range constrains the acreage of disturbance that is acceptable for occupancy, but home range size reflects the availability and distribution of resources. As such, when mature, mesic forest is abundant and openings few, home ranges are more like to be small, but when mature forest is rare and openings more abundant, home range size is likely to increase. Across such a range of variation in home range size, the relative proportion of each vegetation community may be similar (for example, 10 percent open), but the absolute acres of each vegetation community may be quite different. While we tested different aspects of the model, our timeframes and budgetary constraints did not allow testing of the outcomes of different window sizes and science is lacking the information to better inform the best scale and method at which to evaluate fisher habitat distribution at the home range scale. The point is that this is a source of uncertainty in the model.

The model's selection of treatments is driven by the desired condition ranges for dominance types (Figure 81) and size classes. The desired conditions ranges were based on the dry end of natural range of variation (NRV) runs with a few exceptions shown in Table 199 where the desired conditions differ substantially from the dry NRV range. The plan does this for a few reasons including to promote more resilient forest conditions by converting dominance types to tree species more resilient to insects, disease, or resistant to fire. A second reason is to restore species like western white pine to its former dominance type. A third reason is because the climate is expected to be warmer and drier, and some species are more resilient to warmer-drier conditions.

In order to simulate the desired outcome, the PRISM model selects a treatment schedule and type of treatment to achieve the desired condition ranges. The selected treatments are based on actions that would need to achieve the conversion of dominance types in reality. For example, a clear cut with replanting would be required to convert grand fir to a different dominance type like western white pine or Ponderosa pine. The outcome in the model is a shift towards the dominance types specified in the desired conditions. A substantial portion of fisher habitat is made up of the dominance types shown in Table 199. Fishers are not tied to a particular dominance type as demonstrated by many scientific publications showing broad variety in tree types used (Raley 2012), so changing tree types is not necessarily problematic. However, a substantial proportion of fisher habitat is composed of grand fir and a small portion is composed of subalpine fir and spruce mix, and these dominance types are prioritized for treatment to convert dominance types to meet desired condition ranges. Furthermore, a disproportionate amount of the plan area is composed of these two dominance types. Therefore, the PRISM model prioritizes a schedule of treatments appropriate to achieve conversion, which are mostly clear cuts. The result is that a disproportionate amount of treatments prescribed in the PRISM model is scheduled within fisher habitat, which rapidly reduces grand fir in model outcomes as demonstrated in Figure 81. Figure 81 shows that grand fir dominance types declines by nearly 400,000 acres by decade 5, an amount commensurate with the loss of total fisher habitat Figure 68) and denning habitat (Figure 67). Grand fir dominance is projected to decline by 40 to 50 percent for the same 50-year comparative period. Grand fir composition is reduced to a greater extent in the warm dry than in the warm moist broad potential vegetation type (PVT) groups across all alternatives. The amount of Ponderosa pine, western white pine, and other dominance types concurrently increase in the model outcomes and are counted as young regenerating forests after treatment. In the case of white pine and western larch, the change is moving from one dominance type assumed to be preferred by fisher to another dominance type that is preferred by fisher. However, the time it takes to regrow into a mature habitat used by fishers and longer to develop the decadent characteristics used as denning habitat, large diameter dead or live trees with hollow trunks, downed wood, and cavities. Fisher habitat, and especially denning habitat, takes a long time to grow back, approximately 30 to 40 years, to reach the young forest size class of 8.5 to13.5 inches identified by Jones and Garton (1994) used by fishers in winter, and substantially longer than the time required to provide decadent and decay that provide denning habitat. Fisher habitat begins to recover towards the end of the 50-year time horizon in the model, which is why the alternatives with faster rate of disturbance recovers some by the 50-year mark (Figure 68 and Figure 74). Because the conversion requires regeneration harvest to achieve dominance type conversion, the treatment schedule and constraints on opening size, PRISM creates many small openings across the landscape that contribute to the trends seen in the spatial query of preferred fisher home ranges. As such it is not surprising that all the alternatives result in grand fir dominance being projected to decline by 40 to 50 percent over the 50-year timeline.

Even changes from grand fir to other dominance types that are representative of fisher habitat, such as western white pine or western larch, may have immediate negative effects if the habitat conditions indicative of mature, mesic forests are lost at a pace faster than they are replaced (Schwartz et al. 2013). For example, the desired condition for western white pine dominance is 25 to 40 percent in Management Area 3 but currently is less than 2 percent (see Forestlands section). Restoration of western white pine, which may often require regeneration harvest (FW-GDL-TBR-02, FW-STD-TBR-08), may result in reduced fisher habitat, because despite plan direction to ensure restocking happens rapidly (FW-STD-TBR-03), young white pine stands may not have the necessary structural diversity (Schwartz et al. 2013). Threats to western white pine restoration from blister rust may further delay the development of mature forests, because no cultivars are completely resistant to blister rust. Ultimately, all the alternatives explored would result in a reduction in fisher habitat availability at least in the short-term; however, in the long-term, conditions may improve due to increased heterogeneity and diversity in the landscape. Indeed, the increase in the availability of fisher habitat toward the end of the 50-year timeframe may suggest such an outcome and is a result of regrowth of the treatments in the first decade.

Schwartz et al. (2013) studied fisher in in the Clearwater River sub-basin and eastern slope of the Bitterroot-Selway ecosystem in Idaho and Montana. This included fisher captured and studied along the Lochsa River over Lolo Pass. Schwartz et al. (2013) used radio-telemetry locations from collared fisher to document fisher habitat use. Fisher disproportionately used both stand sites and regional landscapes characterized by large diameter trees and avoided areas with Ponderosa and lodgepole pine. Selection for large diameter trees in the Rocky Mountains occurs at multiple scales. These results highlight the importance of mature or late-successional forests and the importance of both stand- and landscape-level factors when directing forest management of fisher habitat in the U.S. Rocky Mountains. Fisher selected sites with larger diameter trees in landscapes with large trees, while avoiding stands of primarily xeric species composition. Specifically, this study revealed selection for large maximum tree diameter at breast height, a higher proportion of large trees at the landscape scale, and avoidance of stands with Ponderosa and lodgepole pine. Among tree species, the most preferred species was grand fir, as well as stand complexity characteristics of large logs and the presence of tree cavities. Schwartz (2013) noted that the abundance of western redcedar and grand fir may be higher now than in historical times when western white pine dominated moist, mid-elevation forests. Schwartz (2013) noted that current management to restore western white pine ecosystems may have significant ramifications for fisher given their findings, as young white pine stands may not have the structural diversity in the understory and be too open at maturity. Schwartz (2013) recommended that silvicultural treatments of stands not only consider the retention of large trees but also consider the larger landscape when managing for fisher and recommended retention of large decadent trees and snags within areas with a higher proportion of large trees to provide denning habitat for female fisher.

Western white pine conversion has a lower probability of success because even resistant strains are still susceptible to loss from blister rust. The susceptibility of western white pine to loss can reduce success rates in reestablishing white pine and provides justification for attempting to plant white pine at rates higher than the natural range of variation to compensate. Therefore, there is risk that western white pine restoration would not take hold to provide for future fisher habitat. These stands would take decades to begin to be used by fisher and would take longer to provide for fisher denning habitat with the abundant large snags, hollow trees, and downed wood that fisher prefer.

Jones and Garton (1994) provided an estimate of the timeline for habitat recovery following regeneration harvest. They suggested that fisher would avoid regeneration harvest for at least 50 years, use them occasionally for another 60 to 100 years, and likely not preferentially select them until trees were 120 to 160 years in mixed conifer forest (Jones and Garton 1994). Fisher may not find hollow trees in these stands for denning until trees reach an age where they are infected by heart rot and hollow out, a process that can take a very long time. The change away from grand fir would potentially change the abundance of trees with cavities large enough for fisher denning. This is because old, large grand fir, along with western redcedar, provide the hollow tree structure required by fisher for denning. Denning trees might be the most important factor for fisher habitat use and reproductive success. The change in the number and extent of hollow trees for denning would be extensive and would potentially take centuries to recover. While regeneration harvest generally follows a natural recovery pattern, the pace at which forests are converted must carefully be considered. Objectives vary by alternative, but all of them occur at a pace that would sharply reduce fisher habitat.

Reproductive females require tree cavities in large-diameter live trees and snags for birthing and rearing kits until weaning. Tree cavities are critical components of fisher habitat that provide protection from predators and cold. In most cases, the cavities used as dens for reproduction are created by heartwood decay caused by heart-rot fungi (Aubry and Raley 2006, Raley et al. 2012, Weir and Corbould 2008). Den trees used for reproduction are typically among the largest trees available and are 1.7 to 2.8 times larger in diameter than other trees in the vicinity of the den. Den trees also tend to be old. Estimated average age of den trees in British Columbia averaged 372 years for Douglas-fir, 177 years for lodgepole pine, and 96 years for trembling aspen (Davis 2009). Older, larger trees tend to have more heartwood decay than younger trees. Available evidence indicates that the incidence of heartwood decay and cavity development is more important to fisher for denning than is the tree species (Raley et al. 2012) (Raley et al. 2012). However, there is differential susceptibility to heart rot among the trees that occur within the Nez Perce-Clearwater. Trees that readily form heart rot that progresses into hollow trees in the Interior Columbia Basin include grand fir, western redcedar, western larch, black cottonwood, quaking aspen, and paper birch (Davis 2009) (Bull et al. 1997). Internal decay in grand fir, subalpine fir, and mountain hemlock often is indicated by conks of the Indian paint fungus, which decay can involve the entire tree trunk (Bull et al. 1997). A hollow tree is created when heart rot fungi invade the heartwood of a living tree and decay progresses to the point that the cylinder of decayed heartwood eventually detaches from the sapwood and slumps downward, leaving a hollow chamber. This process begins only in a living tree and can take many decades to produce a chamber large enough for wildlife to use. Although lodgepole pine, Douglas-fir, subalpine fir, Engelmann spruce, and western white pine are subject to heart rot, they seldom form a hollow chamber. In northeastern Oregon, grand fir and western larch make up most of the hollow trees used by wildlife (Bull et al. 1997). Hollow chambers may be common in old western redcedar in the Interior Columbia River Basin because hollows caused by heart rot in old western redcedar trees are used by pileated woodpeckers for roosting in western Washington. Conversion of grand fir to other types may result in less future hollow trees, both from the standpoint of the importance of grand fir's susceptibility to becoming hollow compared to other tree species but also from the standpoint that it would take a long time to develop the hollow tree characteristics required by fisher after treatment. While the conversion of grand fir stand types will not eliminate all trees with cavities, it might reduce the availability of fisher denning structures across broad areas as treatments convert grand fir dominance types to other dominance types.

Table 199. A comparison of natural range of variation (NRV) range, the desired conditions, and current conditions within dominance type where the desired conditions differ substantially from the NRV ranges

Broad Potential Vegetation Type	Dominance Type	Full NRV Range Percents	Dry NRV Range Percent	Desired Condition Range Management Area 3 Percent	Current Condition Percent
Warm Dry	Ponderosa pine mix	39–44	39–44	50–60	17
Warm Dry	Grand fir	19–28	19–27	2–10	33
Warm Dry	Western larch	0–0	0–0	1–2	2
Warm Moist	Ponderosa pine mix	0–1	0–1	10–20	2
Warm Moist	White pine	14–22	13–22	25–40	3
Warm Moist	Grand fir	29–38	27–36	5–15	46
Cool Moist	White pine	0–0	0–0	5–15	0
Cool Moist	Subalpine fir and spruce mix	39–63	32–56	25–35	60
Cool Moist	Douglas-fir and western larch	0–0	0–0	5–10	1

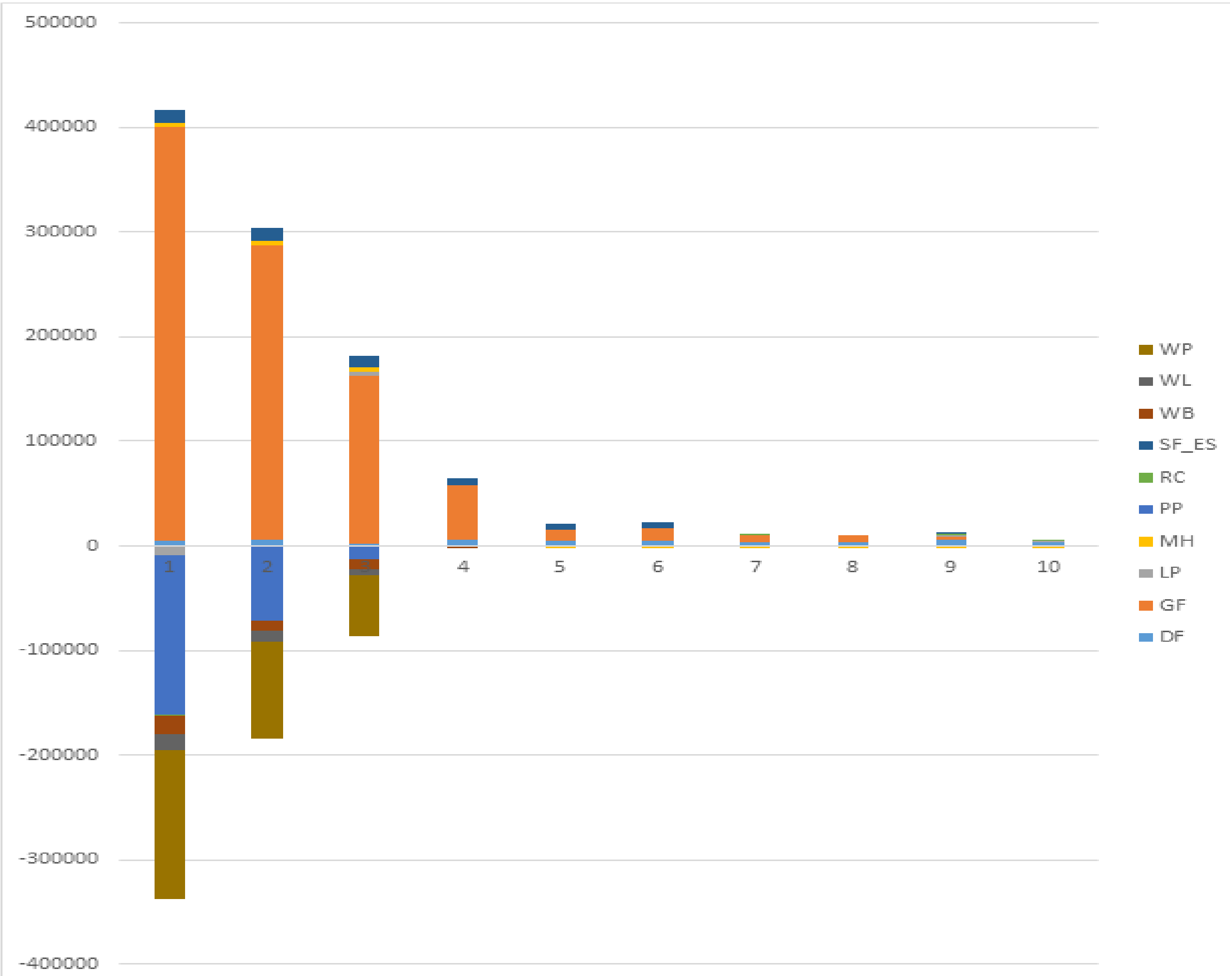

Figure 81. Trend toward desired condition by decade and dominance type

WP = Western White Pine. WL = Western Larch. WB = White Bark Pine. SF = Subalpine fir. ES = Engelmann Spruce. RC = Western Red Cedar. PP = Ponderosa pine. MH = Mountain Hemlock. LP = Lodgepole pine. GF = Grand fir. DF = Douglas-fir.

While the spatial model of fisher habitat is a useful tool for comparing alternatives, the pattern of fisher habitat at the landscape scale alone does not address the complexity of small-scale patterns discussed widely in fisher publications across their range. Fine scale habitat selection includes the presence of snags, coarse woody debris, and hollow trees. The Forest Inventory and Analysis data is a better tool to assess these habitat characteristics. Mature forest, snags, and downed wood were analyzed in the forested habitats section above. The modeling suggests that both snags and the large and very large size class increase under all the alternatives.

All alternatives in addition to the Preferred Alternative were designed from the beginning with workload, capacity, and budget constraints in mind. The analysis assumes that the objectives, timber outputs, natural disturbances, and desired conditions are achievable and will be the expected outcome of the plan. However, there is uncertainty in the amount of disturbance that will occur from year to year and from decade to decade. Furthermore, budget and capacity availability can change to either facilitate or constrain progress towards achievement. Other sources of uncertainty include wildfire occurrence can fluctuate at multiple scales and is stochastic in nature. While the model assumptions take into account suppression, actual patterns of firefighting efforts are made on a case-by-case basis, based on specific circumstances of each fire event. Litigation can delay or prevent implementation of projects and will likely be a source of variability in implementation rates. In conclusion, the treatment schedule modeled in SIMPPLLE is proposed and intended but actual implementation might differ substantially and should be esteemed as an estimate of the amount of disturbance, but the outcome might be different because of the uncertainties describe here.

Modeling Conclusions

The SIMPPLEE model found that all the alternatives will decrease the available total fisher habitat by roughly the same degree. This is not surprising because all the alternatives share a common set of desired conditions for future forest dominance types and plan direction (FW-STD-TBR-04) assures treatments are designed to achieve desired conditions. Grand fir, for example, is an important dominance type for fisher (Schwartz et al. 2013) that currently represents nearly half of the warm moist potential vegetation type (PVT). Current conditions for grand fir are outside of the natural range of variation (NRV), and well above the desired conditions represented by the alternatives. Much of the change in grand fir dominance is expected to occur within the warm dry PVT group but also within the warm moist, as grand fir is replaced by Ponderosa pine (see Forestlands section), a change that results in the loss of fisher habitat (Schwartz et al. 2013).

Although the loss of mature, mesic forest will affect fisher habitat availability, the SIMPPLEE model predicted that total fisher habitat in all the alternatives would fall within the NRV, including the Preferred Alternative. While the pace of restoration in the alternatives indicated an increasing gradient of impacts to fisher habitat, the pace under all alternatives is within the disturbance amounts similar to or less intensive than amounts of disturbance in Washington, Oregon, or California, that supports fishers on other lands managed for multiple uses or even industrial timber lands as noted above. The treatment schedule, as indicated by model testing, might represent a tradeoff of habitat alteration under the controlled conditions of forestry treatments rather than through large scale a loss by uncharacteristic wildfire resulting from the interaction of fuels build up and climate change, two of the key threats identified for fisher habitat by the threats assessment (See threats assessment in Appendix C).

In contrast, the outputs from the moving windows analysis found that the availability of suitable habitat to support a fisher home range would fall precipitously, and ultimately fall outside the NRV for all alternatives. The findings from the moving windows analysis highlight the importance of understanding how the spatial dynamics of the landscape, independent of habitat availability alone, affect fisher habitat suitability. The total acreage of open or sparse vegetation fell well within the NRV, but the patch size and distribution did not. Restricted by plan direction (for example, FW-STD-TBR-05), the restoration treatments common to all the alternatives generally created a greater number of small patches of open or sparse vegetation as compared to the large fires that represent the historic source of disturbance. Within the moving windows analysis the juxtaposition of an opening next to a stand of mature forest has a substantial effect on the suitability of the stand as fisher habitat. By creating more openings in the landscape relative to the NRV, the treatments in effect reduce the suitability of more acres of mature forest than would a large fire of equal acreage. Figure 82 and Figure 83 provide a visual representation of the importance to fisher of the spatial arrangement of disturbance. In both hypothetical examples, the same landscape is subjected to the same amount of disturbance, but different patterns in the distribution of disturbance regimes. In the first example (Figure 82), disturbance is concentrated in large blocks representative of the arrangement typical of historic fires. The disturbance regime results in a few large openings with total percent similar to desired condition ranges, but also leaving large stands of mature forest clustered together with few openings (Figure 82). In the second example (Figure 83), disturbance is dispersed into small blocks as is more typical of silvicultural practices. The disturbance regime results in stands of mature forest that are more fragmented with many small openings (Figure 83). Although each example is based on approximately the same acreage of available mature forest and the same acreage of open habitat, the change in the distribution of disturbance has substantial consequences for modeled fisher habitat suitability (Figure 82 and Figure 83). The findings from the moving windows analysis suggest that restoration efforts may have potential deleterious effects for fisher due to increased habitat fragmentation if not carefully considered within the context of the surrounding landscape. Landscape pattern treatments that allow for larger openings would allow treatments to replicate the larger size of disturbances that occurred under natural disturbance.

It should be noted that PRISM does not consider factors that influence the feasibility of timber harvest when choosing spatial locations for harvest. Because additional factors like the proximity to roads, slope, or other factors often influence the choice of harvest locations, it is likely that future timber harvests will be more clustered than the model predicts. As a result, the model may be overestimating the decline in spatially constrained habitat.

The overall theme of the plan components, including within Management Area 3, is to manage the landscape pattern in a way that reflects natural disturbance regimes, maintain live tree retention, and reduce the chances for high severity fire. Examples of plan components that suggest this management are found in all the vegetation broad potential vegetation types and in all management areas. Examples include MA3-DC-FOR-01, MA1 and MA2-DC-FOR-06, MA3-DC-FOR-02, FW-DC-FOR-07, MA1-DC-FOR-02, MA3-DC-FOR-03, FW-DC-FOR-08, MA1 and MA2-DC-FOR-07, MA3-DC-FOR-04, FW-DC-FOR-10, MA3-DC-FOR-05, FW-DC-FOR-11, MA1 and MA2-DC-FOR-08, MA3-DC-FOR-06. The model did not incorporate the direction in plan that speaks to the landscape pattern and distribution of disturbance. Instead, it prioritized treatments and disturbances to meet the plan's desired dominance types and size class distribution and only incorporated a 40-acre constraint on forestry treatments without adjacency constraints. The 40-acre constraint on timber treatments forced the model into a landscape pattern that differs substantially from the disturbance patterns under natural disturbance. The plan's 207-acre maximum regeneration treatment size (before regional forester's approval is required) would trend patch sizes and distributions towards a landscape pattern more like those developed under natural disturbance. While informative about how landscape scale disturbance patterns might affect the probability of fisher occupancy, the model outcomes should be interpreted with caution because they represent conditions that differ from real management in the future under the plan, which would follow the guidance in these plan components for landscape distribution.

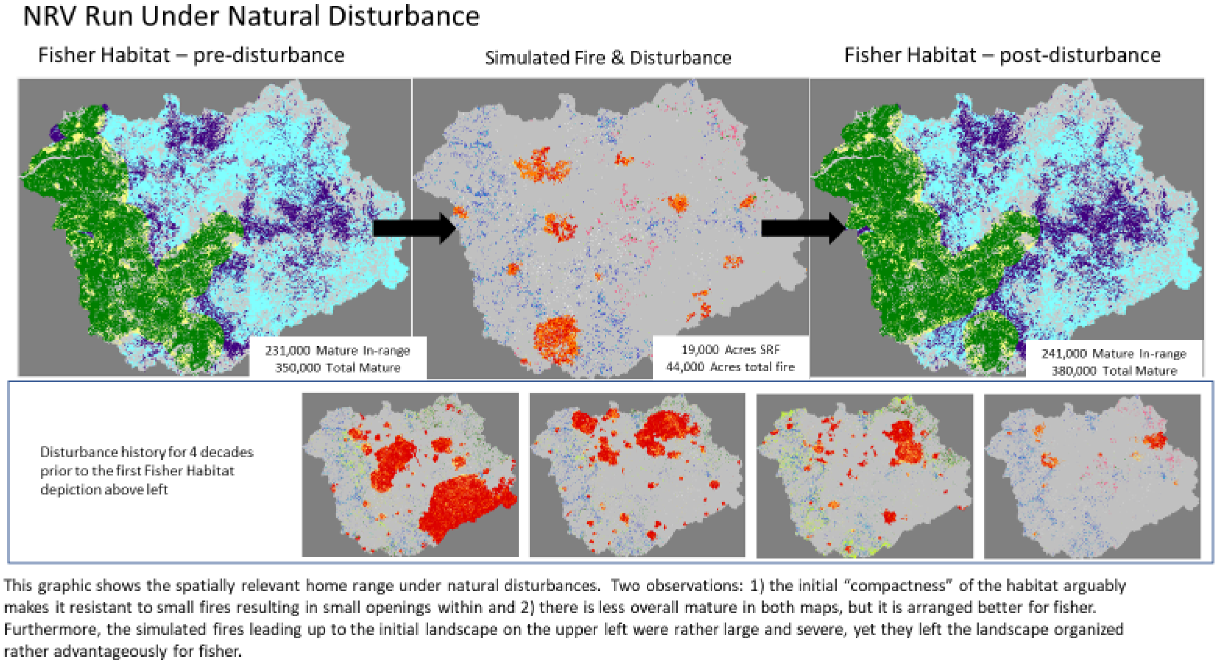

Figure 82. Model simulations in SIMPPLLE under natural disturbance parameters

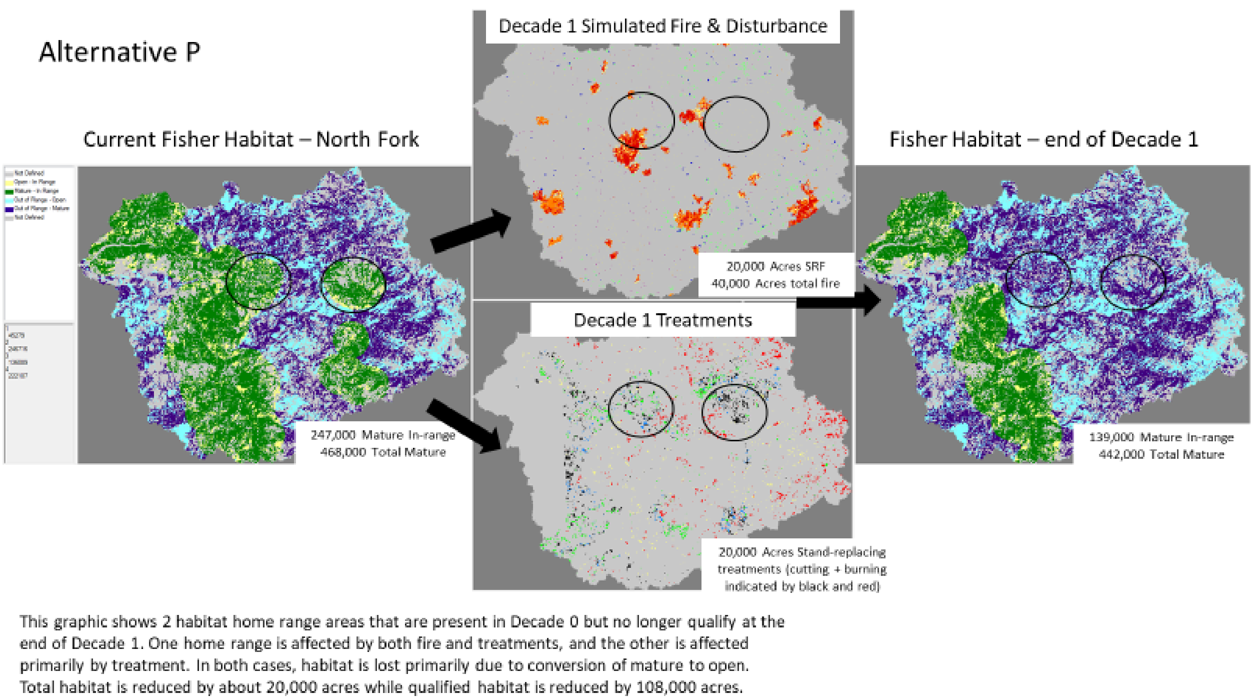

Figure 83. Example of one decadal time step simulating future conditions under the Preferred Alternative

Relatedly, while prescribed fire would more closely reflect natural disturbance, it is not possible to replicate the pattern of natural disturbance with forestry treatments because of operational, logistical, and social constraints. The limits of forestry equipment, like slope limitations, limit where forestry treatments are feasible. Forestry practices struggle to replicate the fine scale variability produced by fires, and regeneration harvests on the scale of tens to hundreds of thousands of acres would not be socially acceptable. Also, fires burn forests without regard for size distribution, whereas forestry treatments must typically be economically feasible and therefore disproportionately treat larger size classes for lumber value. Forestry treatments designed to produce timber leave less residual biological legacies compared to natural disturbance. Furthermore, constraints in the Land Management Plan impose restrictions on achieving a natural pattern of disturbance. For example, fires and tree diseases know no boundaries, but land allocations constrain the location, types, and purposes of forestry treatments. Similarly, fires often burn across riparian areas whereas plan components like FW-STD-RMZ-01 constrain mechanical treatments within riparian zones which will act as a natural constraint on the size of treatments. Additionally, the constraints in the alteration of lynx habitat imposed by the Northern Rockies Lynx Direction constrain treatments in lynx habitat. Finally, while the plan's constraint on patch size found in FW-STD-TBR-06 which imposes a 40-acre limit with exceptions that allow treatment up to 207 acres without regional forester approval, limit the capacity to treat landscapes consistent with the size and distributional pattern of natural disturbance. However, the larger patch size exception will allow a trend towards a distributional pattern more representative of natural disturbances. An alternate strategy that can still maintain fisher habitat is to ensure that forestry treatments are sized, shaped, and distributed such that they main connectivity and complexity of mature forest, while being mindful of the distribution of open habitats, and employing a firm commitment to leaving biological legacies especially live trees, so that as regenerating forests regrow, they contain features useful for fisher resting and denning. This would be a strategy consistent with the direction in the plan.

The estimates of current fisher habitat availability derived from the both the SIMPPLLE model query and the more nuanced moving windows analysis are similar to habitat-use and occupancy studies of fisher in the Northern Rockies (Krohner 2020, Sauder 2014, Sauder and Rachlow 2014, Olson et al. 2014). The moving windows analysis estimated that approximately 59 percent of the mature, mesic forest within the plan area is likely providing suitable habitat for fisher (that is, greater than 40 percent chance of occupancy). Congruence with the baseline conditions found in other studies not only further supports the importance of the plan area as one of two core fisher habitat areas in the Northern Rockies but gives credence to the other model outputs. Still, it is important to put the findings from the models in context. Out of necessity, the models simplify very complex and dynamic relationships. Though the best available scientific information was used to build the models, there remains a high degree of variability and an element of uncertainty.

The models also did not distinguish between sources of disturbance. Although fisher are generally sensitive to forest openings, the structure inherent to an opening ultimately determines whether fisher will use or avoid an opening. Silvicultural practices that reduce forest density and structural complexity can reduce habitat suitability (Powell and Zielinski 1994, Olson et al. 2014, Schwartz et al. 2013); however, in some cases the effects may be short-term and unlikely to lower occupancy or persistence (Sweitzer et al. 2016) if treatments maintain the large trees and local habitat features preferred by fisher (Zhao et al. 2012, Niblett et al. 2017, Jones and Garton 1994). Plan direction (for example, FW-DC-TBR-01) identifies timber harvest methods and how vegetation treatments are achieved, with some components (for example, MA3-GDL-FOR-06, MA2 and MA3-GDL-FOR-05, MA3-DC-FOR-04, MA2 and MA3-GDL-FOR-01, and FW-DC-TBR-03) ensuring that the microhabitat elements fisher rely upon remain available (see Forestlands section). Similarly, fisher will use areas affected by wildfires (Hanson 2015), but high-intensity fires are more likely to reduce the availability of local habitat features (for example, large down wood, large snags) preferred by fisher (Sweitzer et al. 2016, Blomdahl et al. 2019). Plan direction (for example, FW-DC-FIRE-01, FW-DC-FIRE-02, MA1 and MA2-DC-FOR-07, MA3-DC-FOR-04, FW-DC-WL-04 and FW-DC-TBR-06) creates a landscape that is more resilient to fire, and thus less likely to result in a large, high intensity fire that may lead to largescale losses of fisher habitat; however, the plan also directs post-fire treatment (for example, FW-STD-TBR-07) that may have negative effects on the availability and distribution of the local habitat features fisher prefer (see Fire Management and Timber sections). As the models did not encapsulate the variation inherent to various types of disturbance, there is additional uncertainty for how disturbance may ultimately shape fisher habitat suitability.

During timber harvest, Jones and Garton (1994) suggested that fisher habitat management may require a landscape-based approach to maintain the integrity of ecological systems. Applying such an approach would require land managers to adopt long-term, large-scale plans that would mimic natural landscape patterns and processes. Such an approach would keep a certain proportion of forests in various successional stages, together with a specific frequency distribution of various patch size and linkage areas across the landscape. Such an approach would help ensure the viability of fisher populations within a managed landscape (Jones and Garton 1994). This type of approach is what the Land Management Plan employs.

All alternatives were designed to provide ecosystem integrity by providing a common set of desired conditions that mostly represent the natural range of variability with some exceptions of some dominance types designed to increase resiliency under warmer-drier future climates and restore more prominent amounts of tree species more shade intolerant species that are resilient to fire. The decline is the natural consequence of managing towards desired vegetation conditions representative of warmer-drier periods of the natural range of variation (NRV), conditions under which fisher habitat was at its NRV low. Naturally, fisher habitat under that management regime would trend towards its NRV low. It is also the consequence of departing from the NRV in dominance types at least over intermediate time scales while the conversion takes place. As that is the common set of desired conditions, all alternatives trend towards the lower end of NRV and the outcomes are similar across all alternatives. The primary difference is the pace at which that change occurs, which varies by alternative. Alternatives with a higher pace present some risk to impacting fisher habitat abruptly enough that it can lower probabilities of occupancy which ultimately could force fishers to live in suboptimal habitat or result in actual population declines. The higher pace combined with the shift in dominance types prominent in fisher habitat, could interact to result in a landscape that is less ideal from a fisher's perspective. From a fisher conservation standpoint, alternatives with a slower pace towards desired conditions represent a more conservative approach to shifting tree dominance types within the appropriate timeframe to conserve fisher populations. However, such an approach might also leave fisher habitat more prone to losses from natural disturbances like uncharacteristic wildfire. Concern about the pace of the trends is moderated by the fact that the total disturbance amounts of 53,000 to 64,500 acres of desired total disturbance, which also encompasses timber disturbance, is within the estimated range of total disturbance under the NRV and is the same across all alternatives. These are amounts, from a disturbance per year standpoint, at which fisher populations habitats have been sustained in other parts of its range. Furthermore, the plan's guidance to retain legacy structures forestwide will help ameliorate the effects of regeneration harvest as has been demonstrated even on lands managed for timber production.

Although the exact magnitude of the effects associated with the reduction of mature, mesic forest and the increase in fragmentation may be uncertain, there is reasonable certainty that at the landscape scale, the overall suitability of fisher habitat within the plan area will be reduced. However, it is important to realize that the models suggest a decline in fisher habitat suitability, not extirpation. Even given the caveats of the moving windows analysis, the analysis supports the notion that the plan area will continue to provide suitable habitat for fisher to persist on the Nez Perce-Clearwater because the plan provides a framework for managing the landscape within the amounts of disturbance typical of the natural range of variation (NRV), includes direction to manage forestlands landscape patterns consistent with natural disturbance, within limits that have sustained fisher populations in other areas, and within amounts that the national forest has already sustained in past decades of extractive uses that created conditions today that support fisher populations. The plan's species-specific desired condition for fisher FW-DC-WL-04 will help manage towards conditions that will support fisher habitat. Management under the Revised Forest Plan will differ from the natural landscape pattern of disturbance, but plan direction supports a strategic approach to how disturbance is distributed on the landscape that can help to ameliorate such effects. The Revised Forest Plan contains plan direction in the Forestlands section to address the landscape distribution of disturbances. The desired conditions for fisher found in the Wildlife section of the Revised Forest Plan describe habitat use of fisher at various scales to inform habitat management.

The key points from the modeling exercise:

- The availability of the mature, mesic forest types that fisher prefer is expected to decline under all alternatives but remain within the natural range of variation.
- The availability of mature, mesic forest in the next 10 to 40 years is sensitive to the pace of restoration, showing a faster rate of decline under alternatives with faster rates of attainment, though the availability of mature, mesic forest is similar across all alternatives by the fifth decade.
- Restoration efforts that lead to disturbance patterns that depart from the natural range of variation in size and distribution may reduce the availability of habitat that is suitable to support a fisher home range.

The availability of habitat that is suitable to support a fisher home range in the next 10 to 20 years is sensitive to the pace of restoration, showing a faster rate of decline under alternatives with faster rates of attainment; however, the availability of habitat that is suitable to support a fisher home range is similar across all alternatives by the fifth decade, although the variation is greater than the variation in the availability of mature, mesic forest.

Plan Direction that Contributes to Fisher Habitat

Most of the plan direction that contributes to fisher habitat includes ecosystem plan components found in the Forestlands section of the Land Management Plan. Also contributing to fisher habitat are plan components within the Aquatic Ecosystems and Fisheries section, especially those that address riparian habitats. Desired conditions for size class distribution within the warm dry, warm moist, and cool moist broad potential vegetation types (PVTs), especially for those 10 inches diameter at breast height (DBH) or taller, would help provide a range of mature forested habitats similar in percent to those described by Sauder and Rachlow (2014) that provide for fisher habitat. For example, depending upon the management area, the amount of mature forest 10 inches and greater within the warm moist broad PVT ranges between about 40 percent on the low end to 83 percent on the high end. If the Nez Perce-Clearwater manages towards the middle of this range, then the amount of fisher habitat in the mature condition would support fisher with nearly 55 percent in a mature condition. Similarly, within the warm dry size class distribution, these size classes range from between 42 to 83 percent; management towards roughly the middle of this range would promote size classes the provide mature forest for fisher, and the same pattern holds within the cool moist, where adequate amounts of mature forest would be present under the desired conditions. It is also a broad PVT that does not provide much fisher habitat though it might become more used by fishers as climates warm.

Within the smaller size classes, the percent of habitat below the 4.9-inch size class were evaluated. These include the grass and forb and shrub stage and the 0- to 4.9-inch size class. The desired range for these size classes is between 6 and 30 percent combined within Management Area 3 in the warm moist broad PVT. The ranges within the Land Management Plan are consistent with the natural range of variation (NRV). However, the distribution of these open habitats matters for fisher. Under natural disturbances, there were broad areas burned in fires that had a much higher amount of this age class locally. At the landscape scale, they were clustered where fires burned. There were also areas locally that had less than 5 percent in these size classes that served as fisher habitat. The appropriate landscape pattern is critical to understanding and appropriately managing fisher habitat. If management within these ranges is applied across the landscape evenly, as they did in the model, then they would not replicate the pattern of disturbance that fisher evolved with. This type of management would render forested habitats less suitable to fisher because of fragmentation and would result in a lower probability of occupancy within fisher habitat.

The Land Management Plan does include desired conditions that address landscape pattern in each broad potential vegetation group section within the Forestlands section. Examples include plan components MA1 and MA2-DC-FOR-07 and MA3-DC-FOR-04. They provide direction for the landscape pattern to be arranged in vegetation patches consistent with typical fire histories. These desired conditions also contain language to retain live retention trees in early seral age classes. These measures would help provide for fisher, if followed.

Other plan direction that would help fisher includes the following:

- FW-DC-FOR-07 and 08, MA2 and MA3-GDL-FOR-01, MA2 and MA3-GDL-FOR-03-05, and FW-DC-WL-04 will retain snags and downed wood that are important to fisher.
- A trend towards historic conditions and the desired conditions for vegetation (FW-DC-FOR-01, FW-DC-FOR-03-09, FW-DC-FOR-11, and FW-DC-FIRE-03) will change the distribution and amount of fisher habitat nearer to what would have been present under natural disturbance processes.

Geographic area direction that improves or maintains connectivity includes GA-DC-GH-01 and GA-DC-SR-03. Additionally, FW-DC-WL-01-05 maintains connectivity.

Ecosystem Plan Components

Plan components which contribute to the ecological condition for fisher are summarized in Table 200. These plan components help provide the structure, function, composition, and connectivity to provide for fisher habitat.

Table 200. Summary of plan direction, components, and effects which contribute to the ecological condition for fisher

Plan Direction	Plan components	Effects
Desired conditions	FW-DC-TE-01 FW-DC-TE-05 FW-DC-TE-06 FW-DC-FOR-05 MA1 and MA2-DC-FOR-06 MA3-DC-FOR-02 FW-DC-FOR-06 FW-DC-FOR-07 FW-DC-FOR-08 MA1 and MA2-DC-FOR-07 FW-DC-FOR-09 FW-DC-FOR-10 FW-DC-FOR-11 MA1-DC-FOR-02 MA1-DC-FOR-03 MA1-DC-FOR-07 MA1-DC-FOR-08 MA2-DC-FOR-02 MA2-DC-FOR-03 MA2-DC-FOR-07	Plan components will contribute to mature, closed canopy habitat important to for fisher. Plan components call for retaining dead, dying, and live legacy trees, which are more likely to contain heart rot and provide appropriate denning sites. These components provide for size class distribution that matches the natural range of variability. Older age classes provide for the structure components needed by fisher. Plan direction in some components address landscape pattern of disturbances. Aquatic plan components provide for connectivity and habitat used by fisher. Specifically, riparian habitat desired conditions and guidelines will provide connectivity. The plan contains a species-specific desired condition for fisher which describes the ecological conditions that sustain fishers. Some plan direction for dominance types would cause a decrease in preferred fisher habitat. This includes FW-DC-FOR-03, FW-DC-FOR-06, and FW-DC-FOR-09 for dominance types in the warm dry, warm moist, and cool moist broad potential vegetation types. Specifically, the change from grand fir or spruce-subalpine

Plan Direction	Plan components	Effects
	MA2-DC-FOR-08 MA2-DC-FOR-10 MA3-DC-FOR-03 MA3-DC-FOR-04 MA3-DC-FOR-05 MA3-DC-FOR-06 MA3-DC-FOR-10 MA3-DC-FOR-11 FW-DC-RMZ-01 FW-DC-WL-02 FW-DC-WL-04MA1 and MA2-DC-FOR-08 MA3-DC-FOR-06 FW-DC-FIRE-01 FW-DC-FIRE-02 FW-GDL-FIRE-01 Plan components for riparian protection FW-DC-WTR-02	fir into other dominance types would alter preferred fisher habitat. The effect would be indirect via a decrease in habitat. Plan direction for the desired amounts of size classes, dominance types, within stand characteristics, and density will provide the ecological conditions to provide ecosystem integrity to contribute to the long-term persistence of fisher. These plan components do not include protections for grand fir, Douglas-fir, or Engelmann spruce–grand fir old growth, which are dominance types used by fishers. The Plan does include protections for redcedar old growth, which are important for fisher. However, grand fir old growth would contribute to fisher habitat. The lack of protection for some old growth types might result in the decline of these old growth types and potentially impact fisher denning habitat.
Guidelines	MA2-GDL-FOR-02 MA2-GDL-FOR-03 MA3-GDL-FOR-07 MA3-GDL-FOR-06—varies by alternative with Alternative Z providing better than Alternatives W, X, and Y MA2 and MA3-GDL-FOR-01 MA2 and MA3-GDL-FOR-02 MA2 and MA3-GDL-FOR-03 MA2 and MA3-GDL-FOR-04 MA2 and MA3-GDL-FOR-05—varies by alternative with Alternative Z providing better than the Preferred Alternative and Alternatives W, X, and Y	Guidelines restrict management to activities designed to increase resiliency of the stand, which may contribute to long-term fisher habitat stability. Plan components provide structural components important to fisher, such as snags, large live trees, and downed coarse woody debris, especially during management.
Standards	FW-STD-RMZ-01 FW-STD-RMZ-04 FW-STD-RMZ-05 FW-STD-RMZ-06 FW-GDL-WL-01	Standards reduce thinning in riparian management zones, which provide habitat and connectivity for fisher. These standards provide for downed wood and denning structures within these areas.

Effects to Fisher Habitat from Other Resources

The effects from other resources to fisher are summarized in Table 201. The table below identifies plan direction that would have consequences to fisher. In most cases, the effects are described briefly, but some effects required further explanation in the table below.

Table 201. Effects to fisher habitat from other resources

Resource Area	Environmental Consequences	Explanation
Terrestrial Ecosystems across the landscape	Yes	Desired conditions support diverse habitat conditions that may be beneficial to fisher. Specifically, FW-DC-TE-01, FW-DC-TE-05, and FW-DC-TE-06 would support fisher habitat.
Biophysical Features	No	No consequences
Forestlands	Yes	See the Effects from Forestlands section below for adverse effects. See the Ecosystem Plan Components table above for beneficial effects.

Resource Area	Environmental Consequences	Explanation
Carbon Storage and Sequestration	No	No consequences, may have beneficial consequences to fisher.
Meadow, Grassland, and Shrubland	No	No consequences, may have beneficial consequences to fisher because healthy meadows, grasslands, and shrublands could provide for fisher prey.
Fire Management	Yes	See the Fire Management section below for plan direction pertaining to fire.
Invasive Species	No	These plan components promote native vegetation that would contribute to fisher habitat.
Soil Resources	No	No consequences to fishers. Soil plan direction would guide management towards healthy soils, that provide the basis for healthy vegetation that supports many wildlife species including fishers.
Aquatic Ecosystems	Yes	Plan components contribute to habitat and connectivity for fisher.
Water and Aquatic Resources	No	No consequences, may have beneficial consequences to fisher because healthy aquatic resources could benefit fisher habitat and prey.
Conservation Watershed Network	No	No consequences, may have beneficial consequences to fisher. These plan components identify watersheds that are prioritized for restoration which over the long term, will improve fisher habitat.
Riparian Management Zones	Yes	Riparian habitats contribute to fisher habitat and connectivity. The plan components would contribute to fisher habitat by ensuring connectivity even when timber harvest occurs within fisher habitat.
Infrastructure (Aquatic and Riparian)	Yes	Plan components move or locate roads into upland habitats used by fisher. The consequences should be minor.
Energy and Minerals (Aquatics and Riparian)	No	No consequences, may be beneficial to fisher habitat.
Livestock Grazing (Aquatics and Riparian)	No	No consequences. Grazing does not generally occur within fisher habitat to a great extent because the types of habitats that fisher use are typically not grazed by livestock due to lack of forage.
Lands and Special Uses (Aquatics and Riparian)	No	No consequences, but may be beneficial to fisher habitat.
Recreation (Aquatics and Riparian)	No	No consequences, may have beneficial effects on fisher habitat.
Wildlife	Yes	Wildlife plan components should contribute to conserve fisher habitat. Specifically, FW-DC-WL-03, FW-DC-WL-04, and FW-GDL-WL-01 should contribute to fisher habitat conservation and connectivity.
Multiple Use Wildlife	Yes	Habitat for big game is often in early seral or non-forested conditions. Management to provide these features may require treatment of fisher habitat. Habitat for elk often includes early seral conditions to provide high quality nutrition. Some of the areas where elk would receive high quality nutrition would include habitat that fisher use, such as those in the warm moist and warm dry broad potential vegetation type. Providing high quality nutrition to elk would require treatment of the habitat areas that could impact or fragment fisher habitat.
Air Quality	No	No consequences, may have beneficial consequences.

Resource Area	Environmental Consequences	Explanation
Tribal Trust	Yes	FW-OBJ-TT-01 may alter some fisher habitat to produce huckleberry. Huckleberry plants prefer unshaded or partially shaded areas and grow within grand fir and spruce-fir habitat types. The pace of this treatment should be compatible with fisher habitat.
Cultural Resources Tribal Trust	No	No consequences
Municipal Watersheds	No	No consequences
Sustainable Recreation	Yes	Sustainable recreation plan components would influence development and human use of the Nez Perce-Clearwater. Suitability of uses identify where some activities could occur under the Land Management Plan. In some cases, fisher habitat may be impacted by recreation developments and human disturbance. Developments would represent permanent loss of fisher habitat, however, would be limited in scale and impact to fisher.
Scenery	No	No consequences. Some management of scenery may be beneficial to fisher.
Public Information, Interpretation, and Education	No	No or minimal consequences
Infrastructure	Yes	Maintenance and objectives for road rerouting in the Land Management Plan could impact fisher habitat in some cases. The footprint of these activities would reduce fisher habitat. The scale and intensity to habitat would only have minor consequences for fisher.
Land Ownership and Land Uses	Yes	Beneficial effects. FW-DC-LND-01 states that land ownership supports habitat for species of conservation concern, including fisher. FW-GDL-LND-02 is designed to conserve resources through land ownership.
Ecosystem Services	No	Generally compatible with fisher conservation but some activities identified in desired conditions could reduce or destroy fisher habitat. In most cases, these activities would occur over a scale and intensity that would essentially have only a minor impact on fisher habitat.
Suitability	yes	Nearly all suitable uses could impact fisher habitat. Suitability for timber harvest, timber production, road construction, temp roads, prescribed fire, and minerals could result in habitat impacts. Other suitable uses could result in disturbance but not likely changes to ecological conditions for fisher.
Timber	Yes	See the Timber section below.
Energy and Minerals	Yes	Plan direction makes forestlands available for these activities in the future. These activities could result in loss of fisher habitat. In most cases, these activities would occur over a scale and intensity that would essentially have only a minor impact on fisher habitat. However, some projects could be large and impactful. The effects of individual projects would
Livestock Grazing	Yes	Livestock grazing plan direction would serve to direct management of livestock grazing to conserve fisher habitat. FW-GDL-GRZ-03 limits grazing to 35 to 55 percent utilization, which is considered moderate grazing intensity and would serve to maintain healthy rangelands. These would help reduce the impact to fisher from livestock grazing.

Resource Area	Environmental Consequences	Explanation
Special Forest and Botanical Products	Yes	These plan components contain direction for providing firewood. Firewood harvest can reduce snags and downed logs. These features are important to fisher habitat. Firewood harvest is typically limited to areas near roadways. Areas away from roads would continue to have snags and downed wood to provide for fisher habitat. Firewood harvest should only have limited impact to fisher habitat.
Designated Wilderness	Yes	Natural processes contribute to the mosaic of forest conditions that are beneficial to fisher. They are managed with natural ecological processes, which are more random and variable. Designated wilderness areas prohibit many activities that reduce fisher habitat through suitability. Wildfire management in wilderness areas may reduce fisher habitat in some cases. Wilderness areas have limited amounts of fisher habitat.
Designated Wild and Scenic Rivers	Yes	Management direction in wild and scenic river corridors would benefit fisher habitat. While all designated rivers provide some benefit, wild rivers are more protective than recreational rivers. While timber harvest is suitable, timber production is limited. Any treatment in fisher habitat would need to comply with wild and scenic river plans and maintain the free-flowing qualities and outstandingly remarkable values.
Recommended Wilderness plan components and direction	Yes	Recommended wilderness management would have similar effects as designated wilderness, with some exceptions. They would be managed to preserve wilderness character. Natural processes would be the primary agents of ecological change. MA2-DC-RWILD-04 identifies these areas as connectivity areas for wildlife. While timber harvest is suitable in these areas, timber production is prohibited. Suitability varies by alternative for a variety of non-conforming uses. These alternatives are analyzed above. Recommended wilderness management would be protective of fisher habitat because many activities are unsuitable within recommended wilderness.
Eligible and Suitable Wild and Scenic Rivers	Yes	Management would be similar to designated wild and scenic rivers. Rivers and their corridors would be managed to protect their outstandingly remarkable values and free flowing conditions. Timber production would not be allowed, but timber harvest would be allowed. Management would generally be protective.
Lolo Trail National Historic Landmark	Yes	The Lolo Trail National Historic Landmark would be managed to maintain the integrity of the landmark. Natural processes are the primary agents of change, though prescribed fire is suitable. Some management seeks to maintain the viewshed of the landmark, which may impact some fisher habitat. Scenic integrity guidelines in the Land Management Plan would contribute to fisher habitat. The Landmark would not allow firewood cutting, which would provide for habitat features like snags and downed wood. Neither timber harvest nor production are suitable uses.

Resource Area	Environmental Consequences	Explanation
Idaho Roadless Rule Areas	Yes	Plan components contribute to the connectivity of fisher habitat. MA2-DC-IRA-02 directs that composition, structure, and pattern of vegetation reflect natural disturbances. This should help conserve fisher habitat in these areas. These areas provide for the connectivity of wildlife habitat. Some habitat may be impacted by new motorized trails. These would be minor impacts to fisher and limited to the footprint of the trails. The Idaho Roadless Rule governs many of the activities that would occur. These would contribute to conservation of fisher habitat. Timber harvest could affect some fisher habitat. Fisher habitat is projected to decline in Idaho Roadless Rule areas in the SIMPPLLE model under all alternatives as a result of timber harvest to meet desired vegetation conditions and climate change.
Research Natural Areas	Yes	Plan direction would contribute to the conservation of fisher habitat. These areas are managed to emphasize natural processes as a baseline for research. However, prescribed fire is a suitable use and may affect some fisher habitat. These areas are limited in scope.
Lower Salmon River Geographic Area	Yes	Plan direction in the Lower Salmon Geographic Area emphasizes Ponderosa pine restoration, including for species limited to this area of the Nez Perce-Clearwater. In some cases, management here would treat fisher habitat to restore or increase Ponderosa pine.
Gospel-Hump Geographic Area	Yes	The Gospel-Hump Geographic Area emphasizes management for multiple uses. There is a substantial amount of fisher habitat within this geographic area. It emphasizes wildlife habitat, fisheries, motorized and non-motorized recreation, timber, and research. Part of this area includes an emphasis on timber production and could result in effects to fisher habitat.
Pilot Knob Geographic Area	No	No consequences, may have beneficial consequences for fishers.
Special Areas	Yes	Some special areas are old growth cedar groves that provide denning habitat for fisher. The plan components seek to increase public awareness and visitation to these areas, which could increase disturbance for fisher. Fisher are not reported to be sensitive to human disturbances, but this may not have been studied. While use could change or increase in these areas, the disturbance likely would not be in wintertime when fisher are denning.

Fire Management

Fire management was designed to achieve desired vegetation conditions. While fire is a natural process, it interacts with vegetation treatments to impact fisher habitat. The effects of wildfires, prescribed fires, and vegetation treatments can result in reduction of fisher habitat. The changes in the amount of fisher habitat within Management Area 2 are mostly driven in the SIMPPLLE and PRISM models by wildfire and prescribed fires. These trends do not vary much by alternative in Management Area 2. Fuels management projects would contribute to the decline of fisher habitat within Management Area 3 and may be used in places that are not suitable for harvest or are too steep for harvest. Regeneration harvests followed by prescribed fire would kill live leave trees and potentially burn retained snags. Plan direction encourages the use of wildfire and prescribed fire to meet other resource objectives. This has potential to impact fisher habitat.

Timber

These plan components are designed to direct the manner in which timber production and harvest are conducted. Timber plan direction would directly impact fisher habitat and result in both short-term and long-term consequences for fisher. Timber production alters fisher habitat for long periods of time because it removes trees, changes seral stage, and alters density or composition of habitat. Different treatments have different effects. Even-aged harvest strategies remove most of the living trees, resulting in the loss of fisher habitat used for foraging by up to 40 years, and removes denning habitat structures much longer for time periods of time potentially for more than 100 years. Intermediate treatments or thinning reduces stand complexity, though these types of treatments can increase the rate at which trees obtain larger size classes. Roughly 40 percent of fisher habitat occurs in Management Area 3 and, according to the Sauder model, the majority of the high-quality habitat mostly resides in Management Area 3 where timber harvest would mostly occur. Salvage operations for snags can impact fisher habitat negatively by removing trees and snags that would provide for fisher habitat as forests regenerate.

Plan direction in the Timber section prescribes the situations in which different types of treatments are required as standards. FW-DC-TBR-01 is designed to contribute to a sustainable flow of saw timber and non-saw timber through vegetation treatments intended to restore resilient ecosystem structure and function. It encourages this use where identified as suitable. FW-DC-TBR-03 directs that dead and dying trees in excess of those required for minimum snag retention are available for harvest. This direction would allow removal of dead and dying trees important to fisher denning habitat but would also require retention of those needed to meet guidelines in the forestlands section of the plan. FW-DC-TBR-06 would decrease the loss of fisher habitat to wildfire and would be beneficial for fisher.

FW-STD-TBR-01 and FW-STD-TBR-02 would constrain timber activities only to lands suitable for timber harvest. FW-STD-TBR-04 would ensure restocking happens to speed the recovery of fisher habitat after harvest. FW-STD-TBR-05 assures treatments are designed to achieve desired vegetation conditions. As noted in many cases, it would require even aged management, such as replanting clear-cuts with desired tree species. It has exceptions for when treatments could differ. FW-STD-TBR-05 constrains treatments to ensure their ability to meet desired conditions and not based solely on economics or unit output of timber. FW-STD-TBR-06 restricts openings to 40 acres and does not require consideration of adjacent recent treatments when conducting timber production on Nez Perce-Clearwater lands nor those of other ownerships. This is the case when harvesting at only the 40-acre sized treatments. The standard allows larger openings up to 207 acres before regional forester approval is required and could be used when determined necessary to help achieve desired ecological conditions for the plan areas. The larger opening size would allow treatments to replicate the larger size of disturbances that occurred under natural disturbance and trend the Nez Perce-Clearwater towards a more natural distribution of patch sizes found under the natural range of variation.

FW-STD-TBR-08 specifies that the restrictions on sizes of treatments would not apply in response to a loss from stand replacing natural disturbances. This would allow practices like salvage logging to occur in fisher habitat impacted by these events. The removal of remnant trees and hollow snags would reduce the value of the habitat for fisher and slow the amount of time it would take for these habitats to recover. FW-STD-TBR-09 would ensure clearcutting would be required when dominance types exceed desired conditions and when managing in situations when working with an undesirable dominance type. This would require clearcutting in many situations when working in fisher habitat and would cause the loss of fisher habitat over long periods of time. It would ensure that cutting of diseased trees or trees with mistletoe would require clearcut harvesting. These are features important to fisher habitat and would be lost during treatments, potentially resulting in a century or more to become fisher habitat again.

Other standards and guidelines are similar in restricting treatments to certain types during some situations, such as seed tree harvest and shelterwood harvest. The circumstances where these types of harvests would be used would be restricted, facilitating other types of treatments that may be harmful to fisher habitat. FW-STD-TBR-12 would limit harvest to the sustained yield limit but provides broad exceptions that could facilitate additional impacts to fisher habitat. FW-GDL-TBR-02 would ensure that treatments within grand fir habitats would regenerate after treatment to the desired species. FW-GDL-TBR-04 requires regeneration treatments to have reached at least a certain age before treatment. These ages are generally less than that needed to provide hollow trees, though they would meet mature forest criteria. Timber management direction of the plan provides a basis for methods to manage forestlands to achieve desired conditions, which has the potential to reduce the amount of habitats suitable for home ranges while increasing resilience over longer time frames.

Climate Change

Climate change may alter the distribution of wildlife species directly through changes in suitable climatic conditions as well as indirectly through changes in vegetation. For example, reductions in snowfall accumulation associated with climate change (Klos et al. 2015) are likely to directly affect the distribution of fisher within the state and the plan area. The accumulation of snow is presumed to limit the distribution of fishers (Raine 1983, Krohn et al. 1995, Krohn et al. 1997), therefore as snowpack declines, fisher distribution is expected to increase as more suitable habitat is accessible (Suffice et al. 2017)(Zielinski et al. 2017).

Although the most apparent effect of climate change on fisher is likely changing snow conditions, the effect of climate change on fisher habitat are more nuanced. Climate change alters the availability and distribution of wildlife habitat directly, through altered vegetation growth, mortality, and regeneration, as well as indirectly through changes in disturbance regimes and other ecosystem processes (Keane et al. 2018).

Within the Northern Rockies the forest types that typify fisher habitat have generally lower vulnerability to climate change (Hansen and Phillips 2015) except, where due to fire suppression, they have expanded into drier sites (Keane et al. 2018). Indeed, climate change is generally expected to increase the availability of fisher habitat on the landscape (Olson et al. 2014) due to increased productivity in more mesic locations (Keane et al. 2018). Importantly, however, the distribution of suitable fisher habitat is expected to shift to higher elevations and further to the north and west, with consequences for the availability and connectivity of suitable habitat within the plan area (Olson et al. 2014). In general, fisher habitat within the plan area is expected to contract to higher elevation, leading to overall greater fragmentation (Olson et al. 2014). The findings from the literature are in congruence with the outputs from the SIMPPLLE model (see Timberland section), which suggests that conditions within the plan area will represent the dry and warm end of the natural range of variation, favoring forest communities tolerant of such dry conditions.

Although climate induced changes in the distribution of conditions capable of supporting the vegetation indicative of fisher habitat will ultimately affect the distribution of fisher, changes in disturbance regimes will likely have more profound and immediate effects (Keane et al. 2018). In the short term, fire frequency and the proportion of forest burned annually are likely to increase (Rocca et al. 2014, Westerling et al. 2011), increasing the risk to the mature, mesic forests (Lesmeister et al. 2019) that fisher prefer (Powell and Zielinski 1994, Olson et al. 2014, Schwartz et al. 2013). As outlined in the analysis of fisher habitat (see below), wildfire, particularly high-intensity fires (Sweitzer et al. 2016, Blomdahl et al. 2019), can reduce the value of forest as fisher habitat. Moreover, wildfire can fragment existing habitat, further exacerbating the direct effects of habitat loss (Sauder and Rachlow 2014). The findings from the literature concerning how climate change may affect fisher habitat (for example, Olson et al. 2014) are in congruence with the outputs of the moving window analysis (see below), which suggests that disturbance would result in a lower abundance of fisher habitat and increased fragmentation. In the moving windows analysis, warmer drier conditions allowed for greater probabilities of fire spread, as well as increased mortality due to insect and disease outbreaks (see Fire Management section). Preliminary runs that considered a higher proportion of stand replacing fires versus mixed severity fire resulted in even less fisher habitat, suggesting the model is sensitive to the rate and intensity of wildfire. If fire patterns under future climates increase or change, especially if they change from mixed severity fire to more stand replacing fire, then the decline in fisher habitat may be more precipitous, However, the total amount of fisher habitat remained within the natural range of variability predicted by the model.

The additive effects of an increasingly fragmented distribution of climatic conditions capable of supporting fisher habitat (Olson et al. 2014) along with increased rates of disturbance (Rocca et al. 2014, Westerling et al. 2011), will lead to fisher habitat that is more disjunct. Fishers are capable of dispersing over large distances (Schwartz et al. 2013), but in a highly fragmented landscape individuals must increasingly use non-habitat patches that often fail to provide suitable resources resulting in a decrease in effective dispersal distances (Gilbert-Norton et al. 2010). As a result of such barriers, individual fisher may be incapable of moving between disjunct pieces of mature, mesic forest even if it exists on the landscape (Olson et al. 2014)(Tucker et al. 2017). The implications from our modeling exercise suggests the primary effect of fragmentation could be that it would reduce the number of home ranges available with habitat characteristics fishers prefer and increases the number of potential home ranges that have characteristics that are less optimal or perhaps not suitable depending upon their tolerance of such conditions.

Climate change has the potential to effectively reduce habitat availability and accessibility (Olson et al. 2014); however, efforts to restore ecological processes and increase dominance types that are more resilient to future climatic conditions and the disturbance regimes they foster, may help ameliorate some of these effects. Moreover, although climate change may increase fragmentation of habitat within the plan area, plan components that provide for protection of riparian areas may also provide important corridors that may offset the consequences habitat fragmentation (Gilbert-Norton et al. 2010).

Cumulative Effects

The cumulative effects area for fisher encompasses the Northern Rocky Mountain population of fisher in Idaho and western Montana. There are two core areas of fisher habitat in the Northern Rockies, the larger predominantly occurring within the Nez Perce-Clearwater National Forest, while a smaller core area occurs primarily within the Idaho Panhandle National Forest (Sauder 2014, Olson et al. 2014, Krohner 2020). Although the fisher range within the Northern Rockies encompasses a variety of landownership, the majority of suitable habitat occurs on public lands, as habitat suitability tends to be lower on industrial timberlands (Sauder and Rachlow 2014) even within landscapes that otherwise support fisher (Olson et al. 2014, Sauder 2014, Krohner 2020). As such, the key stressors and threats affecting the Northern Rockies fisher population outside of the Plan Area are themselves managed by the Forest Service. The Idaho Panhandle Final Environmental Impact Statement (pg. 325) concluded that implementation of the Idaho Panhandle National Forest Plan is not likely to result in the loss of viability for fisher populations on the Idaho Panhandle National Forest, in large part due to plan components that help to retain the ecological conditions (for example, snags, downed wood, connectivity) necessary to support the species. However, SIMPPLLE modeling conducted during revision of the Panhandle plan also showed a steep drop in fisher habitat dropping to the low end of natural range of variation (NRV) as well. Recent studies in that area suggest that the population is very low on in the Cabinet Mountains in Montana (Inmann and Coltrane

2022) and higher in that range in Idaho, with evidence of local extinction in the Selkirk and Purcell mountains and is not well connected genetically (Lucid 2019).

In addition to Forest Service management, the Idaho Statewide Wildlife Action Plan (2015) identifies fisher as a species of greatest conservation need. The Idaho Statewide Wildlife Action Plan recommends conserving any remaining old white pine, restoring white pine with disease resistant strains, addressing insects and disease, increasing stand diversity to withstand insect and disease, promoting responsible firewood harvest, protecting legacy trees, restoring long lived early seral trees, restocking after fire with white pine and western larch, restoring the natural fire interval, leaving fire killed trees, designing silvicultural prescriptions that promote historical forest conditions, trending age class and patch size towards the NRV assessing connectivity and gene flow between mountain ranges, and monitoring fisher. For low density carnivores, including fisher, the Statewide Wildlife Action Plan includes recommendations to manage habitat for connectivity, assess gene flow, analyze declines in fisher numbers, monitor climate, increase mature forest, promote timber practices that create small patch cuts interspersed with large connected uncut areas, and monitor the population and distribution trends. This direction complements plan components included in all alternatives explored here, as well as plan component within the Idaho Panhandle National Forest Plan, all of which are designed to provide sufficient fisher habitat by promoting forest condition that are resilient to disturbance and maintaining key habitat elements such as large trees and snags. The State of Idaho wrote a letter in response to findings in the process to determine if fishers warranted federal listing under the Endangered Species Act. The letter pointed to evidence of fisher data collected over the last 50 years by Idaho Department of Fish and Game indicating an upward trend in the species abundance and a low rate of incidental trapping while targeting other species (Idaho Office of Species Conservation, 2010). Trapping of fishers in Idaho is not currently allowed by state regulations. The Idaho Department of Fish and Game is also in the process of finalizing their Fisher, Wolverine and Lynx management plan that is due out in 2023.

Occupancy studies suggest that populations in Montana exist at low occupancy rates (Krohner 2020) with the best occupancy rates near the Idaho-Montana border. National Forests in Montana manage fishers as either sensitive species or species of conservation concern which helps ensure their long-term persistence.

Fisher populations extend south from the plan area into other portions of Idaho including the Payette National Forest, the Boise National Forest, and the Salmon-Chalis National Forest that exist at lower occupancy levels than in the plan area. These forests reside within the Intermountain Region of the Forest Service, and the Intermountain Region identifies the fisher as a Sensitive Species that manages such that the species will not lose viability or will persist long term.

The U.S. Fish and Wildlife Service (2017) determined in their species status assessment that fishers habitat availability in the Northern Rockies was high enough and connected enough to provide resiliency, redundancy and representation to sustain populations in the future. Their analysis considered a number of threats including fire, forestry, climate change, and more. Based on this information, the U. S. Fish and Wildlife Service determined that fishers are not warranted for listing.

Conclusion

The 2012 Planning Rule requires the responsible official to determine whether plan components provide the ecological conditions necessary to maintain a viable population of each species of conservation concern within the plan area (36 CFR 219.9(b)(1)). Key ecological conditions necessary to support a viable fisher population within the planning area include: 1) the availability of mature, mesic forests that includes the local features (for example, larger trees and snags, down woody debris) that fisher prefer, 2) habitat patch dynamics that can support fisher home ranges, and 3) connectivity among habitat patches.

Determination: Plan components provide the ecological conditions necessary to maintain a viable population of fisher within the plan area.

Justification:

1. Plan components shaping the desired future conditions for the planning area ensure that fisher habitat remains available for all alternatives considered. In a 50-year time horizon, the projected availability of the mature, mesic forests that fisher prefer ranges from 1,235,586 to 1,336,605 acres depending on the alternative, with the Preferred Alternative projected to include 1,247,842 acres. The U. S. Fish and Wildlife Service estimated that the Minimum Critical Area needed to support a population of fishers was 2,500 square kilometers which equals 617,763 acres and which is the area needed to support 50 breeding individuals needed to avoid inbreeding effects. Under all alternatives, the projected availability of total fisher habitat within the plan area after 50 years will be more than twice as much as the critical habitat threshold thought necessary to ensure population viability (U.S. Fish and Wildlife Service 2017). Furthermore, the pace of restoration is consistent with or below levels that have sustained fisher habitat here in the past, and elsewhere within the fisher's range even on industrial timber ground.
2. Plan components shaping the desired future conditions for the planning area ensure that the availability of habitat that is suitable to support a fisher home range remains high for all alternatives considered. In a 50-year time horizon, the projected availability of habitat suitable to support preferred female fisher home ranges varies between 407,511 to 562,754 acres depending on the alternative, with the Preferred Alternative projected to include 410,126 acres. Assuming female fishers require 49.3 square kilometers or 12,182 acres each, this amount would support 34 female home ranges with the spatial characteristics of preferred or high-quality female home ranges. An additional 837,716 acres would support fisher home ranges but at potentially lower occupancy levels. This does not include male fishers who show tolerance for a higher percent of open habitats within their home range (Lewis 2012). Under all alternatives, the projected availability of habitat that has the spatial characteristics of preferred female home ranges within the plan area is close to the critical habitat threshold (617,763 acres) thought necessary to ensure population viability (USFWS 2017).
3. Close to half of all fisher habitat occurs in either designated wilderness, recommended wilderness or Idaho Roadless Rule Areas that impose constraints on timber harvest activities which should help them be secured from fragmentation effects of timber production.
4. Plan components that direct landscape pattern of disturbances and the conservation of riparian habitats support habitat connectivity and provide for movement within the plan area as well as immigration and emigration beyond the plan area. These plan components could help land managers design treatments in a landscape pattern more representative of natural disturbance patterns and help ensure fisher habitats to remain connected. This will help mediate the effects of fragmentation of home ranges to support use.
5. Plan components that provide biological legacies to include live tree retention of larger trees, large diameter snags, and down woody debris ensure habitat has the necessary structural features at the stand level to support resting or denning and ensure that even regenerating successional stages provide these structures.

Harlequin Duck

Harlequin ducks are sea ducks that spend most of the year in near-shore sea environments but move inland to fast-moving streams to breed. The breeding season range for the Pacific population of harlequin ducks occurs across most of Alaska and British Columbia, as well as portions of the Yukon, Washington, Oregon, Idaho, Colorado, and Montana. Aquatic ecosystems, including fast-moving streams, provide key breeding habitat for harlequin ducks in Montana (Marks et al. 2016). Montana is at the eastern edge of the range of the Pacific population, which extends south to northwest Wyoming. They form lifelong pair bonds on the coastal wintering grounds and the pairs migrate to the stream where the female was born (Hansen 2014). During the breeding season, harlequin ducks use clear, low-gradient, fast-moving mountain streams with abundant aquatic insects. Females are known to lay eggs in a wide variety of microsites, including cliffs, under downed logs in burned areas, on instream logjams, or on streambanks with thick shrub or tree cover (Cassirer and Groves 1994). Key habitat characteristics include high water quality; a complex stream structure; aquatic prey; deep pools for escape; and rocks or large downed logs for loafing, as well as dense vegetative or log cover on the shoreline to reduce disturbance and protect birds from avian predators during incubation (Wiggins 2005). There appears to be a correlation between harlequin duck presence and mature or old growth stands and stands with unlogged buffers along streams (Cassirer and Groves 1994). Cover also provides stream shading that promotes cool water temperatures and associated higher oxygen levels important to the aquatic invertebrates that harlequins feed upon. On the west side of the Continental Divide, calm backwaters along rivers or beaver ponds may be important for brood rearing (Wiggins 2005, Kuchel 1977). Harlequin broods may move downstream from the fast-moving streams where they are born to larger streams and rivers as the summer season progresses (Cassirer and Groves 1994, Kuchel 1977), and they are often easier to observe at this time.

Like many other sea ducks, male harlequins depart the breeding grounds immediately after females begin incubation, so females do not frequently re-nest in the event of a nest failure. Relative to many other species of ducks, harlequins occur at very low population densities on their breeding grounds and exhibit high breeding site fidelity, low reproductive rates, and delayed reproduction (Wiggins 2005). Thus, they may be susceptible to local extirpations. Bond et al. (2009) estimated survival probability for 144 adult female harlequin ducks at four breeding areas in western North America. They found that survival was lowest during incubation, with the highest number of mortalities attributed to predation. Adult survival likely drives population dynamics. If a nesting pair is lost, the habitat may not be occupied by another pair in that or subsequent seasons. Because harlequins are on their nesting streams early in the season, nesting success may be affected by changes in waterflow. In Glacier National Park, breeding pairs inhabit Upper McDonald Creek from late April through mid-June and females with broods are on the creek during July, August, and early September. Late spring high waterflows in 2014 may have caused reduced detectability or failed reproduction on some streams where breeding had been observed in the past (Wiggins 2005). In Montana, nesting has not been monitored long enough or consistently enough to know whether climatic variation causes harlequins to move or causes nest failure, and, if so, how many years of nest failure they may be able to tolerate before a female will no longer return to a stream reach (Hansen 2014).

There are somewhat conflicting scientific findings regarding the effects of instream recreation and road related disturbance on harlequin ducks. Although harlequins are generally tolerant of people, they may be sensitive to types of disturbance at certain times of year. Hansen's analysis (Hansen 2014) in Glacier National Park indicated that harlequin ducks did not avoid high-quality habitats adjacent to roads and other sites with high recreational use. However, harlequin ducks have been observed avoiding boats, rafts, pack rafts, and kayaks in breeding stream reaches during incubation and the first four weeks after hatching (Kuchel 1977)(Clarkson 1992, Reichel and Genter 1996).

In all monitored watershed subbasins on the Nez Perce-Clearwater that have known harlequin duck nesting, the overall watershed condition is high, indicating that habitat diversity and quality for harlequin ducks on the Nez Perce-Clearwater is high at the watershed scale. According to PACFISH and INFISH Biological Opinion (PIBO) data monitoring, there is an improved trend in aquatic habitat metrics in reference and managed watersheds (U.S. Department of Agriculture 2019d). Habitat conditions, such as large wood, pool fines, percent pools, and residual pool depth have trended upwards since sampling began in 2001. Some stream reaches that appear to provide suitable stream characteristics and water quality are not known to be used by harlequin ducks, but only two breeding streams have been consistently surveyed and harlequin ducks can be very difficult to detect while on the nest.

Important harlequin duck habitat features include clear water and rocky substrates that support the benthic macro-invertebrates upon which the ducks feed. Harlequin duck habitat is particularly susceptible to forest management activities, water development projects, and human recreational use. Other habitats that have been identified as important to harlequin ducks include wide riparian vegetation zones, braided or multichannel streams with islands for nesting, rocky substrate, streams 10 meters or wider, mature or old growth vegetation overhead, and high-water quality (Wiggins 2005). Harlequin ducks are vulnerable to changes in these attributes.

Wiggins (2005) identified strategies that would help conserve harlequin duck habitat. The following is a list of actions proposed by Wiggins (2005):

- Introduce buffer zones along montane riparian habitats
- Avoid activities, such as clear-cut logging, that may alter the natural water flow regimes of montane streams or rivers
- Avoid building new roads near riparian areas and eliminate or stabilize obsolete logging roads
- Prevent livestock grazing along stream and riverbanks
- Manage water development proposals along breeding streams
- Require approved minerals management plans in watersheds that support harlequin ducks
- Discourage or prohibit recreational boating, trail and campground construction, and fishing activities from May to June on harlequin duck breeding streams
- Develop education materials, such as brochures, for the public

The intent of these actions includes protecting water quality, preserving the flow regime, minimizing disturbance, decreasing sedimentation, maintaining riparian vegetation, and reducing disturbance.

Existing Condition

Several river systems in the plan area contain harlequin duck observations. The most prominent is the Lochsa River and its tributaries, which have had multiple observations of breeding pairs over several years. Fish Creek and Colt Killed Creek both have several observations near the Lochsa River. The North Fork Clearwater River and Kelly Creek have also had several observations. The Selway River in the Selway-Bitterroot Wilderness area near the eastern border of the Nez Perce-Clearwater has had several observations, as well. Other observations are more sporadic and include the South Fork of the Clearwater, the Salmon River, Bear Creek, the lower Selway River, Weitas Creek, Orogrande Creek, Crooked River, Red River, Bargamin Creek, Brushy Fork Creek, and Tamarack Creek. Many of these observations were incidental, and these rivers have not been consistently surveyed. There are potentially more rivers within the Idaho Roadless Rule and wilderness areas that might have harlequin duck use but have not been surveyed or visited enough to have incidental observations.

Harlequin ducks are known to breed on the Lochsa River, the Selway River, and the Northfork Clearwater River and its tributaries. The Nez Perce-Clearwater provides habitat for regionally important populations of this species in Idaho. For example, per the Idaho Species Diversity Database in 2019, 38 percent of all harlequin duck observations in Idaho were recorded on the Nez Perce-Clearwater. This is possibly due to the highly accessible Lochsa corridor that may allow increased observations. The Northfork of the Clearwater has not been surveyed as intensively as the Lochsa and is not traveled by as many people.

The population trend on the Nez Perce-Clearwater is thought to be moving downward. Idaho Department of Fish and Game surveys suggest the population on the Lochsa River dropped from about 18 breeding pairs down to two over the past decade. The causes of the decline are not known but are concerning. Other rivers in the plan area have not been surveyed as intensively to determine trends.

Key Threats and Stressors

Threats were identified by Wiggins (2005) and included logging, mining, changes to water quality, sedimentation, hunting, recreational disturbance, livestock grazing, and pollution. They may also be vulnerable to changes in their ocean habitats from events like oil spills. Threats were evaluated in the plan area as described below.

Harlequin ducks are affected by threats that primarily impact their habitat. Thus, aquatic environmental threats are the preponderance of factors that threaten harlequin ducks. Of the threats identified in the Appendix C Wildlife Species and Habitat Summary, none are categorized as higher than “medium.” The threats were assessed for each at-risk species with a rule-based system for recognizing the magnitude of threats on the Nez Perce-Clearwater. The NatureServe methodology was used to evaluate the threats (Master et al. 2012). The administrative boundary of the Nez Perce-Clearwater comprised the scale of the evaluation. The NatureServe method uses a combination of scope and severity to assign a relative magnitude of threats. The scope represents the spatial overlap of the threat with the distribution of the species or its habitat in the plan area. The severity of the threat was determined by expert opinion and was assessed as the degree to which a given threat would either reduce populations or reduce the distribution of the species. Threats identified included permanent roads found on the transportation network; motorized trails; past timber management (pre-1980); fishing and harvesting aquatic resources; river rafting; fire suppression, including historical changes due to long-term suppression; uncharacteristic wildfire; direct and intentional channelization and bank alteration; rip rap and other streambank alteration; non-native invasive animal species; natural rarity; soil movement and deposition; avalanches and landslides; habitat shifting and alteration due to climate change; drought; temperature extremes; and storms and flooding.

Some of these threats have permanently altered harlequin duck habitat. For example, roads along the major rivers used by harlequin ducks have affected and permanently altered riparian habitat next to these rivers. Also rip rap and stream alterations implemented to prevent erosion and damage to roadways represent permanent alterations. While these are permanent alterations, it is not well understood how much these factors affect harlequin ducks. It should be noted that the NatureServe method takes a precautionary approach to unknown information. When the severity of a threat is unknown, the method identifies it as a medium threat if the scope is either pervasive or large. Nearly all of the threats identified using this method were the result of a lack of knowledge about the severity of these threats. Few publications address these factors in the published literature. Table 3 in Appendix C shows the threat category, the scope of the threat in the plan area, and the severity of the threat. Other threats were thought less impactful due to them not having a widespread scope or they are not occurring with enough intensity to cause population effects.

Ecosystem Plan Components

Plan components within the Land Management Plan include measures to enhance or restore stream habitat complexity and water quality. Aquatic desired conditions emphasize sustainable and diverse invertebrate and vertebrate aquatic species that are essential nutrition for harlequin ducks. Recreation desired conditions allow for nesting sites to remain undisturbed. Riparian management zone desired conditions will allow for adequate cover along stream banks and will provide overhead cover and shade to maintain the water temperature needed for invertebrate species, as well as protection from aerial predation. Table 202 identifies the plan components that are designed to provide ecological integrity of the aquatic and riparian zones and maintain or restore the ecological conditions needed to provide for a viable population of harlequin ducks that will persist long-term in the plan area. These plan components will direct management to provide for the harlequin duck through coarse filter habitat requirements.

Plan direction for the harlequin duck includes mostly coarse filter components found within the Aquatic Ecosystem section of the Land Management Plan; these components are strongly protective of aquatic habitats for federally listed fish. These restrictions in the plan on activities within aquatic and riparian habitats would provide well for harlequin ducks because they protect water quality and riparian habitats.

Table 202 provides a summary of plan direction, plan components, and effects to harlequin ducks.

Table 202. Plan direction, plan components, and effects to harlequin ducks

Plan Direction	Plan components	Effects
Desired conditions	FW-DC-WTR-01 FW-DC-WTR-02 FW-DC-WTR-03 FW-DC-WTR-04 FW-DC-WTR-05 FW-DC-WTR-06 FW-DC-WTR-07 FW-DC-WTR-09 FW-DC-WTR-10 FW-DC-WTR-11 FW-DC-RMZ-01 FW-DC-RMZ-02 FW-DC-ARREC-01 FW-DC-RMZ-01 FW-DC-CWN-01 FW-DC-CWN-03 FW-DC-ARINF-01 FW-STD-ARINF-02 FW- STD-ARINF-03 FW-STD-ARINF-05 FW-STD-ARGRZ-01 FW-STD-ARGRZ-02 FW-DC-ARREC-01	These plan components direct management to maintain or restore the integrity of aquatic ecosystems, including the structure, function, composition, and connectivity of the habitats that harlequin ducks use. The desired conditions provide many of the features used by harlequin ducks. The presence of beavers would benefit groundwater and aquatic habitat complexity. The desired conditions would direct management of many activities to reduce the effects.
Guidelines	FW-GDL-WTR-02 FW-GDL-WTR-05 FW-GDL-WTR-06 FW-GDL-WTR-07 FW-GDL-RMZ-09 FW-GDL-RMZ-01 FW-GDL-RMZ-02 FW-GDL-RMZ-03 FW-GDL-RMZ-04 FW-GDL-RMZ-05 FW-GDL-RMZ-06 FW-GDL-RMZ-07 FW-GDL-RMZ-08 FW-GDL-RMZ-09 FW-GDL-ARINF-01 FW-GDL-ARINF-02 FW-GDL-ARINF-03	These plan components reduce sediment and contaminants in aquatic habitats, which would help provide for harlequin duck habitat. Minimizing ground and vegetation disturbance in riparian areas would help conserve these areas, retaining processes for stream and bank complexity. These plan components prevent impacts to water quality and riparian habitats.

Plan Direction	Plan components	Effects
	FW-GDL-ARINF-04 FW-GDL-ARINF-06 FW-GDL-ARINF-07 FW-GDL-ARINF-09 FW-GDL-ARINF-10 FW-GDL-AREM-01 FW-GDL-AREM-02 FW-GDL-AREM-03 FW-GDL-AREM-04 FW-GDL-ARGRZ-01 FW-GDL-ARGRZ-02 FW-GDL-ARREC-01 FW-GDL-ARREC-02 FW-GDL-ARREC-03 FW-GDL-ARREC-04 FW-GDL-ARREC-05 FW-GDL-ARREC-06	
Standards	FW-STD-WTR-02 FW-STD-WTR-03 FW-STD-RMZ-01 FW-STD-RMZ-02 FW-STD-RMZ-04 FW-STD-RMZ-05 FW-STD-RMZ-07 FW-STD-ARGR-01 FW-STD-ARGR-03 FW-STD-CWN-01 FW-STD-CWN-02 FW-STD-CWN-03 FW-STD-AREM-01 FW-STD-AREM-02	Timber harvest standards would increase bank and stream complexity and provide for desired habitat conditions. Aquatic standards would help conserve aquatic habitat and food resources for harlequin ducks. They would prevent sedimentation and pollution from entering waterways.

Effects to Harlequin Duck Habitat from Alternatives

Management Areas

Harlequin duck observations have been made in all management areas and tend to be associated with river characteristics rather than a clear association with land use. The most observations have been along the Lochsa River, probably a result of good habitat and high visibility along this river from the highway. Many of these observations were made within the designated wild and scenic river section but other observations occur upstream in what would be Management Area 3. The North Fork of the Clearwater has observations that fall both within and outside roadless rule areas and in portions of the river in Management Area 3. The Southfork of the Clearwater has fewer observations and most of those were within Management Area 3. A stretch along the Selway River in the Selway-Bitterroot Wilderness area shows several harlequin duck observations, which would be within Management Area 1. Several harlequin duck observations have been made on Crooked Fork, a tributary of the Lochsa River within Management Area 3. Several observations have been made along Kelly Creek that extends up into the Hoodoo Recommended Wilderness areas, which would be Management Area 2. Observations show no clear patterns in relation to management area or land use. Habitat within Management Area 1 is protected as outlined below in designated wild and scenic rivers. Management Area 2 would be relatively well protected. Activities within Management Area 3 may have greater impacts. Activities that cause sedimentation, water quality changes, pollution, alteration of river channels, and alteration of riparian habitats. These activities were identified above and assessed as threats. Essentially, these threats are addressed through plan component protections, but plan direction in these management areas can have a substantial influence on factors that affect aquatic and riparian habitats.

Designated Wilderness

Designated wilderness management would provide protection for harlequin ducks because management direction would prevent activities that alter harlequin duck habitat. The Plan's wilderness areas direction emphasizes natural processes, solitude, and the protection of wilderness character. Suitability within designated wilderness areas only allows grazing and prescribed fire. These activities would have only minor impacts on harlequin duck habitat, if any. Other uses are unsuitable in wilderness areas. Designated wilderness areas would protect rivers, such as the Selway River and Bear Creek that have known harlequin duck observations. There are perhaps other rivers that contribute to harlequin duck habitat within the designated wilderness areas that have not been surveyed. Rivers that might also have harlequin ducks include the Moose Creek and tributaries, Big Sand Creek, Colt Killed Creek, Storm Creek, and Big Flat Creek.

Recommended Wilderness

Recommended wilderness area direction is similar to direction for designated wilderness. Recommended wilderness direction would provide good water quality, clean water, natural flows, and proper functioning waterways because they would be protected from many forest activities that impact aquatic habitats. Recommended wilderness direction includes desired conditions, guidelines, standards, and suitability plan components to maintain wilderness character. Suitability plan components identify which activities are and are not suitable within recommended wilderness areas. Activities that have potential to impact harlequin duck habitat are unsuitable or are only conditionally suitable in recommended wilderness areas. Examples of activities constrained by suitability components include timber production, road construction, some mineral activities, construction of new buildings, and recreational motorized travel. Only a few harlequin duck observations were within recommended wilderness areas and occur in Kelly Creek. The alternatives within proposed areas that have observations of harlequin ducks include the Hoodoo and Meadow Creek-Upper North Fork areas. Other recommended wilderness areas border rivers that have observations of harlequin ducks. These include the North Lochsa slope, Moose Mountain, Bighorn Weitas, Northfork Spruce White Sand, Pot Mountain, and Mallard Larkin.

Management in recommended wilderness areas is similar in effect as in designated wilderness areas, with some exceptions. Timber harvest is permitted to the extent allowed under the Idaho Roadless Rule, and temporary and permanent road construction is suitable, as allowed by the Idaho Roadless Rule. Otherwise, these areas would provide relatively well for harlequin duck habitat. The extent of these activities in recommended wilderness would be relatively limited.

The Land Management Plan has alternatives for recommended wilderness areas that vary from none in Alternative X to many roadless rule areas considered in Alternative Z. Alternative W would add parts of Colt Killed Creek, all of Cayuse Creek, significant portions of the North Fork of the Clearwater including above the confluence with Kelly Creek, Kelly Creek, Bargamin Creek, and Weitas Creek. Of these, there have been observations on Colt Killed Creek, Kelly Creek, the North Fork of the Clearwater, and Weitas Creek. Upper Big Sand Creek and Bargamin Creek have potential habitat for harlequin ducks. Alternative Y would include Kelly Creek which has observations of harlequin duck but would include few other rivers with known harlequin duck observations. It would only include portions of Bargamin Creek as a river that may have potential to have harlequin ducks. In Alternative Z, rivers included in recommended wilderness with harlequin duck observations include the North Fork of the Clearwater above confluence of Kelly Creek, Kelly Creek, and parts of the North Fork Clearwater near Pot Mountain. This alternative also includes parts of Bargamin Creek and upper Meadow Creek which have potential harlequin duck habitat. Under the No Action Alternative, rivers with known observations of harlequin ducks include Kelly Creek and a small portion of Colt Killed Creek. Only Cayuse Creek has potential harlequin duck habitat, but this creek has not had survey efforts nor observations of harlequin ducks. The Preferred

Alternative includes Kelly Creek and portions of the North Fork Clearwater in the Mallard Larkins that have known harlequin duck observations. It also includes Cayuse Creek and parts of Meadow Creek that have potential habitat. The alternatives with more recommended wilderness areas would benefit harlequin duck habitat more than those with less. Still, management for recommended wilderness is only slightly more protective than Idaho Roadless Rule area management, and all alternatives would include some areas with harlequin duck habitat within recommended wilderness.

The plan varies activities allowed within recommended wilderness such as winter motorized, mechanized and motorized use for administrative purposes, aircraft landings, mechanized travel, or motorized tools. These activities would have no effect on harlequin duck habitat.

Designated Wild and Scenic Rivers

About 70 percent of the observations of harlequin ducks have been observed within designated wild and scenic rivers, most of which have been on the Lochsa River. As noted above, this is in part because of the accessibility of this river. The Selway River is likely under surveyed and would potentially have more observations if the river were more accessible. Currently, designated wild and scenic rivers capture a significant portion of habitat for harlequin ducks. Rivers that also have significant amounts of harlequin duck habitat outside of these designated areas include the upper Lochsa River, the North Fork Clearwater River, Kelly Creek, Crooked Fork, and Fish Creek. The primary management direction for designated wild and scenic rivers is to retain their free-flowing condition, water quality, and the outstandingly remarkable values for which the river was designated in compliance with the wild and suitable river plan as in desired condition FW-DC-DWSR-01.

Suitability of uses within designated wild and scenic rivers may influence the conditions for harlequin ducks. The activities for which suitability could influence harlequin duck habitat include timber harvest, permanent road construction within scenic rivers, livestock grazing, mineral activities, and mechanized use, such as mountain biking. Other suitability has little or no effect. Wild and Scenic Rivers are differentiated into classes of rivers which include wild, scenic, and recreational rivers. The plan differentiates suitability within the different classifications with management in the wild classification more restrictive than management in the scenic and recreational classifications. In the wild classification timber production, timber harvest, road construction, saleable, leasable, and locatable minerals, motorized travel, and mechanized travel are unsuitable activities. Construction of new buildings is conditionally suitable only if consistent with the river management plan or Forest Service Manual direction. Thus, harlequin duck habitat within wild rivers would be protected from these activities. Within scenic and recreational rivers, timber production is not suitable, but timber harvest, road construction, mineral activities, construction of new buildings, motorized travel and mechanized travel are conditionally suitable. The conditions under which these activities are suitable are subject to the river management plan, Forest Service Manual direction, enabling legislation, and the General Mining Act of 1872. Grazing and prescribed fire are suitable in all wild and scenic classifications. Suitability plan components only identify whether a use would be suitable within those lands or not but does not authorize such uses. Furthermore, if an activity is unsuitable within a land allocation, that use would not be allowed. Authorization of suitable activities would require a project level environmental analysis before authorization. Any activities authorized would be subject also to MA1-STD-DWSR-01 and MA1-STD-DWSR-02. These plan standards require any authorized activities within the river corridor to comply with their individual comprehensive river management plans and shall protect and enhance their free-flowing character, water quality, and outstandingly remarkable values for which the river was designated. The effect would be that any actions authorized would have to meet those standards which would ensure they are conducted in a manner consistent with the protection of the rivers and their corridors. While some of the suitable activities could influence habitat conditions and disturbance of harlequin ducks, plan components would also add protection to these areas and should support good habitat conditions. The majority of harlequin duck observations are within designated wild and scenic rivers, this type of management will serve to help reduce degradation of harlequin duck habitat. Plan direction within designated wild and scenic rivers would be in effect along the Lochsa River, Selway River, and Salmon River which would provide for harlequin duck habitat. The Selway and Salmon rivers have much of their length also managed as designated wilderness which would afford harlequin duck habitat additional protections.

Wild and scenic river management includes recreational opportunities. Recreation has been thought to be a disturbance factor for harlequin ducks that can affect space use through avoidance behavior and abandonment of nesting areas. Identifying a river as suitable for inclusion into the wild and scenic river system has the potential increase recreation activity to that river.

Eligible and Suitable Wild and Scenic Rivers

Harlequin duck populations were identified as outstandingly remarkable values for the alternatives for wild and scenic river eligibility. Harlequin ducks were identified because the rivers in the plan area contain regionally important populations of this species. Harlequin ducks are river dependent and have been identified as an at-risk species. Rivers that contained observations of harlequin ducks in the Idaho Species Diversity Database were identified as having outstandingly remarkable values because of the presence of this species. These rivers formed the eligible rivers to consider for suitability in the alternatives. The rivers that were identified because of harlequin duck observations, among other outstandingly remarkable values, include the following rivers: Fish Creek, Bear Creek, Crooked River, Weitas Creek, Crooked Fork, the South Fork of the Clearwater, the North Fork of the Clearwater River, Kelly Creek, Red River, Waw’aalamnime Creek, Imnamatnoon Creek, White Sand Creek (formerly Colt Killed Creek), Brushy Fork, segments of the upper Lochsa River, and Bargamin Creek. A variety or combination of different rivers were considered for wild and scenic suitability under the alternatives. The various alternatives are listed in Chapter 2. Table 203 shows the rivers identified as having harlequin ducks and which rivers were identified as suitable as wild and scenic rivers under the alternatives.

Table 203. Rivers with harlequin duck observations considered in the alternatives for wild and scenic river suitability

River Name	No Action-Eligible only	Alternative W	Alternative X	Alternative Y	Alternative Z	Preferred Alternative
Upper Lochsa River	No	No	No	No	Yes	No
Crooked Fork	No	No	No	No	Yes	No
Brushy Fork	Yes	No	No	No	Yes	No
Colt Killed Creek	Yes	No	No	No	Yes	Yes
Kelly Creek	Yes	Yes	Yes	Yes	Yes	Yes

Weitas Creek	No	Yes	Yes	Yes	Yes	Yes
Little North Fork Clearwater River	Yes	Yes	Yes	Yes	Yes	Yes
Fish Creek	No	Yes	No	Yes	Yes	Yes
Waw'aalamnine Creek	No	No	No	No	No	No
South Fork Clearwater River	Yes	No	Yes	Yes	Yes	No

River Name	No Action-Eligible only	Alternative W	Alternative X	Alternative Y	Alternative Z	Preferred Alternative
Salmon River	Yes	Yes	No	Yes	Yes	Yes
Bargamin Creek	Yes	No	No	No	Yes	No
Red River	No	No	Yes	No	No	No
Bear Creek	Yes	No	No	No	Yes	No
Crooked River	No	No	Yes	No	No	No

Not all rivers are equal in their importance to harlequin ducks. An examination of the number of observations can provide a hint as to the importance of each river to harlequin ducks. Recall that we identified rivers with observations of harlequin ducks as eligible for inclusion in the wild and scenic river system. Some rivers have more observations than others. Table 204 shows the number of harlequin duck observations along each river. A note of caution is in order for the interpretation of this data. First, survey efforts have not been equal among the rivers. Rivers with good access, good views of the river, and more people have more observations than those that do not. For example, the Lochsa River has had more survey efforts, and more exposure to people being along Highway 12, compared to other rivers like the sections of the Selway River in the Selway Bitterroot Wilderness or Kelly Creek. Given the previous considerations, the more important rivers to harlequin ducks appear to be the Lochsa River within the designated Wild and Scenic River area, the Lochsa River above the designated wild and scenic river area, the Selway, Crooked Fork, the North Fork Clearwater River especially above the confluence with Kelly Creek, Kelly Creek, the Little North Fork Clearwater, and Fish Creek. Rivers that might also be important but that have lower observability include Brushy Fork, Colt Killed Creek, and Bear Creek. Rivers that have good accessibility, but fewer observations include Weitas Creek, South Fork of the Clearwater, Red River, Salmon River, and Crooked River. The South Fork of the Clearwater has a lot of access, good views of the river, and a larger number of people but has comparatively fewer harlequin duck observations and may not be as important to harlequin ducks.

Table 204 The number of harlequin duck observations from the Idaho Species Diversity Database (accessed January 2023) on rivers identified as wild and scenic eligible because of harlequin duck populations

River Name	Number of Observations (Idaho Species Diversity Database)
Lochsa River Within WSR system	277
Upper Lochsa River Outside of designated Wild and Scenic River	23
Selway River Within Wild and Scenic River System	14
Crooked Fork	16
Brushy Fork	3
Colt Killed Creek	3
Kelly Creek	5
North Fork Clearwater Above Confluence with Kelly Creek	10
North Fork Clearwater Below Confluence with Kelly Creek	5
Weitas Creek	1
Little North Fork Clearwater River	9
Fish Creek	26

River Name	Number of Observations (Idaho Species Diversity Database)
Waw'aalamnine Creek	1
South Fork Clearwater River	8
Salmon River	2
Bargamin Creek	1
Red River	3
Bear Creek	2
Crooked River	2

The plan's alternatives considered a number of rivers with harlequin duck observations as suitable for inclusion into the wild and scenic river system. Of those, the best alternative for harlequin ducks is Alternative Z, which is the river systems approach, and it includes the most rivers with harlequin duck observations (see Table 203). The alternative with the least rivers included is Alternative W which includes five rivers with harlequin duck observations. Other alternatives are intermediate to these two and include seven rivers each in Alternative X and Y. Alternative X is slightly better than Alternative Y because it includes Fish Creek that has a higher number of observations. The Preferred Alternatives includes five rivers with harlequin duck observations as suitable for inclusion into the wild and scenic river system which would provide additional management considerations for these rivers. Of these rivers, the Preferred Alternative identified Fish Creek, Weitas Creek, Kelly Creek, and Colt Killed Creek as suitable for wild and scenic river consideration and known for populations of harlequin ducks. Fish Creek, Kelly Creek, and Colt Killed Creek have comparatively more harlequin duck observations. Management of these rivers under the Preferred Alternative would include maintaining their free-flowing characteristics, water quality, and outstandingly remarkable values. This management would serve to preserve and enhance these rivers, which would benefit harlequin ducks. This alternative would provide additional protection for harlequin duck habitat. Other harlequin duck habitats are protected by the designated wild and scenic rivers along the Lochsa River and Selway River and by the Selway-Bitterroot Wilderness. It should be noted that plan components in the Aquatics Ecosystems section of the plan would provide for harlequin duck habitat even if the rivers were not selected as suitable for inclusion in the Wild and Scenic River system.

Idaho Roadless Rule Areas

Idaho Roadless Rule areas provide management that would generally maintain harlequin duck habitat. Rivers that contain harlequin ducks often form, or are near, the boundary of roadless rule areas. Roadless rule areas that border rivers with known harlequin duck use include the Lochsa Face, North Lochsa Slope, Rackliff-Gedney, Bighorn-Weitas, North Fork Spruce-White Sands, Moose Mountain, Mallard Larkin, Hoodoo, and Pot Mountain. Management in these and other Idaho Roadless Rule areas influence conditions of tributaries that may support harlequin duck nesting and the water quality of the larger rivers where they brood their young. Overarching management would vary depending upon roadless rule themes, with wildland recreation and primitive being more protective than backcountry restoration. The primary agent of change would be wildland fire, though timber harvest is also suitable within these areas.

Management emphasizes maintaining roadless character and is primarily accomplished consistent with Idaho Roadless Rule themes. They also provide recreational opportunities, such as motorized and non-motorized recreation, and wildlife habitat. Plan suitability that could affect harlequin duck habitat includes timber harvest; road construction, as allowed by the Idaho Roadless Rule; livestock grazing; mineral activities; motorized travel; and mechanized travel. These activities could contribute to sedimentation and the alteration of harlequin duck habitat. However, the Land Management Plan has plan components that would help protect these activities from impacting river and riparian habitats. All alternatives would provide for harlequin ducks. While these activities are suitable, they are less likely to occur than in Management Area 3.

Recreation Opportunity Spectrum

Summer recreation alternatives vary the amount of area suitable for a variety of recreational uses. The recreation opportunity spectrum (ROS) is the mechanism identifying where motorized uses are suitable or not among the alternatives. While the plan identifies where motorized uses are suitable, it does not authorize motorized uses. Instead, the plan provides the guidance under which new motorized uses would be authorized, after a site-specific environmental analysis and decision authorizing motorized uses. Motorized settings identify where motorized uses could potentially occur, but it would require a site-specific environmental analysis and decision to authorize motorized uses. Motorized uses are authorized through a travel plan decision, timber project or individual project authorizing new motorized roads or trails. While it is reasonable to assume that areas identified as suitable for motorized uses could experience new motorized roads or trails, where, when or the amount of new motorized uses is unknown. Not all areas identified as suitable for motorized uses would experience new motorized roads and trails.

The potential effects of motorized uses on harlequin duck habitat include impacts to aquatic resources from motorized routes, but the effects depend on where routes are located, and how they are constructed. Effects include sedimentation, alteration of waterways, and disturbance. Plan direction in the Aquatic Ecosystem section of the plan includes measures to minimize sediment and alteration of waterways and riparian areas, such that impacts from motorized route development and use would be minimized. Therefore, the impact of motorized suitability is largely neutralized.

The ROS also determines the level of development and expected user experience of recreation areas. Increasing development could draw more people to harlequin duck habitat, which could increase disturbance. Changes in summer motorized travel could increase the probability of sedimentation into waterways. Plan direction in the Aquatic Ecosystems and Fisheries section of the Land Management Plan would help prevent sedimentation to help conserve water quality and clarity for harlequin ducks. The alternatives that have more areas as motorized and that have higher levels of development under the summer ROS settings would have a higher probability of effects to harlequin ducks and their habitat. The effects from the winter ROS were not analyzed because harlequin ducks migrate during the winter so there are no effects to the species from winter motorized suitability. The discussion below includes a description of the changes and the relative consequences from the summer ROS settings across the alternatives. The summer recreation alternatives are defined by percentages of availability.

- No Action Alternative: In the No Action Alternative, the existing Forest Plan would remain as the guiding direction for the Nez Perce-Clearwater. Recreation opportunity spectrum settings were not used to determine motorized suitability. Instead, the 1987 plans had multiple management areas each with specific objectives for maintaining objectives for elk habitat effectiveness, which is influenced by motorized route density. Objectives specified areas maintain a minimum of 25 percent, 50 percent, 75 percent, or 100 percent elk habitat effectiveness. Motorized uses were not allowed within wilderness areas, and road construction was limited within Idaho Roadless Rule Areas. The Clearwater Travel Plan identified the suite of system routes, identified where motorized uses were authorized and changed most areas of the national forest into a closed unless designated open system. Because the Nez Perce National Forest has not undergone travel planning, forest lands are open unless designated closed. There was no mechanism to identify where motorized uses are suitable or not. Motorized routes could be developed so long as the Forest Plan's elk habitat objectives were met.

- Alternative W: The primitive setting will increase by 9 percent, from 21 to 30 percent; semi-primitive non-motorized opportunities will decrease by 10 percent, from 34 to 24 percent; semi-primitive motorized opportunities will increase by 1 percent, from 22 to 23 percent; roaded natural opportunities will decrease 3 percent, from 23 to 20 percent; and rural opportunities will increase 4 percent, from 0 to 4 percent.
- Alternative X: The primitive opportunities will increase by 9 percent, from 21 to 30 percent; semi-primitive non-motorized opportunities will decrease by 21 percent, from 34 to 13 percent; semi-primitive motorized opportunities will increase by 10 percent, from 22 to 32 percent; roaded natural opportunities will decrease 1 percent, from 23 to 22 percent; and rural opportunities will increase 4 percent, from 0 to 4 percent.
- Alternative Y: The primitive opportunities will increase by 9 percent, from 21 to 30 percent; semi-primitive non-motorized opportunities will decrease by 8 percent, from 34 to 26 percent; semi-primitive motorized opportunities will decrease by 3 percent, from 22 to 19 percent; roaded natural opportunities will decrease 2 percent, from 23 to 21 percent; and rural opportunities will increase 4 percent, from 0 to 4 percent.
- Alternative Z: The primitive opportunities will increase by 9 percent, from 21 to 30; semi-primitive non-motorized opportunities will decrease by 7 percent, from 34 to 27; semi-primitive motorized opportunities will decrease by 4 percent, from 22 to 18 percent; roaded natural opportunities will decrease 2 percent, from 23 to 21 percent; and rural opportunities will increase 4 percent, from 0 to 4 percent.

Preferred Alternative: Opportunities for motorized access increase in the Preferred Alternative, particularly in the summer. Area suitable for summer and motorized uses include 55 percent suitable for summer and 60 percent suitable for winter motorized travel. About 45 percent of the national forest would be unsuitable in summer while 40 percent would be unsuitable in winter. The number of rivers with harlequin duck observations that falls within motorized ROS settings is similar among the alternatives, with most rivers falling within a motorized setting. Kelly Creek and the Selway River are the rivers that fall within non-motorized settings in all alternatives. In Alternative W, the North Fork of the Clearwater has some additional rivers with harlequin duck observations that fall within non-motorized settings. In all other alternatives, most rivers with observations are within motorized settings, so there is little difference among the alternatives for motorized suitability.

Alternatives harlequin ducks did not avoid high-quality habitats adjacent to roads and other sites with high recreational use in Glacier National Park (Hansen 2014). However, harlequin ducks have been observed avoiding boats, rafts, pack rafts, and kayaks in breeding stream reaches during incubation and the first four weeks after hatching (Hansen 2014). It is unknown whether these activities have population level effects or reduce distribution. The alternatives that have higher amounts of rural and roaded natural settings would have the potential to increase disturbance because these sites would be more attractive to forest visitors. Disturbance probably does not have population level consequences on harlequin ducks. However, there are standards and guidelines to maintain harlequin duck habitat within the Aquatic Ecosystems section of the Land Management Plan that would mitigate or prevent developments in riparian areas. There are also plan components that prevent the effects of sedimentation into river habitats. The overall consequences of these alternatives would still be relatively low.

Vegetation Restoration, Timber Suitability, and Timber Volume

Vegetation restoration is unlikely to influence riparian habitat directly. Plan direction in the Aquatic Ecosystems and Fisheries section of the Land Management Plan would limit the alteration of riparian areas. The larger effect is the effects of sediment into waterways following vegetation manipulation. Sediment could decrease harlequin duck foraging habitat if it occurs outside of natural levels and periodicity. The watershed condition classes suggest that the most degraded watersheds are within multiple use areas, such as Management Area 3. Watersheds in better condition are those within areas like roadless and wilderness areas. Still, the trend in aquatic conditions is generally upwards, even in multiple use areas, since PACFISH and INFISH protections were instituted. The Land Management Plan provides extensive measures to protect rivers from the effects of sedimentation in the Aquatic Ecosystems section of the plan. While these measures help, they would not prevent all effects, as some increase in sediment could occur from roads and timber production.

The treatment of vegetation includes acres of restoration and acres of timber harvest. Under the No Action Alternative, vegetation treatment includes 40,000 acres annually. All the other alternatives include between 53,000 and 64,500 acres annually. Essentially, these would be composed of a combination of treatment types, which include prescribed fire, mechanical treatments, timber harvest using a variety of methods, and timber production. The purpose of these treatments could be restoration of dominance types, changes to forest size classes, improved forest density, white pine restoration, wildlife habitat treatments, hazardous fuels reduction treatments, wildland fire to achieve land management plan objectives, or timber production.

The timber outputs are expected to be in part a product of these treatments. Under the No Action Alternative, timber production would occur on 4,300 acres annually. Alternative W would include timber production on 12,600 acres annually; Alternative X would include timber production on 14,000 acres; Alternative Y would include timber production on 7,500 acres annually; Alternative Z would include timber production on 3,700 acres; and the Preferred Alternative would include timber production on 8,825 to 10,000 acres.

Timber suitability varies by alternative but the difference between all alternatives is less than 1.5 percent of the Nez Perce-Clearwater. Timber suitability includes lands that are suitable for timber production, suitable for timber harvest to meet other resource objectives, and lands that are unsuitable for timber harvest. Treatments for timber production would occur in areas suitable for timber harvest, which includes most of Management Area 3. There are few rivers with harlequin duck observations in management areas suitable for timber production. Rivers with harlequins in areas suitable for timber production include Red River, Crooked River, South Fork Clearwater River, and North Fork Clearwater, mostly above the confluence with Kelly Creek. However, riparian areas themselves forestwide are not suitable for timber production and receive protection and guidance by plan components found within the riparian management zone (RMZ) section of the plan. They do so because they constrain a number of activities with the potential to impact aquatic and riparian habitats. For example, FW-STD-RMZ-01 limits vegetation management to a specific distance from the edges (either 100 or 150 ft depending on stream category) and only to restore or enhance aquatic and riparian-associated resources. Furthermore FW-STD-RMZ-01, specifies vegetation management may occur in the outer RMZs to meet desired conditions for fuel loading and silvicultural desired conditions, so long as project activities retain functions of the outer RMZ, including sediment filtering, large wood recruitment to streams, and protection of the inner RMZ from windthrow. Guidelines like FW-GDL-RMZ-01, FW-GDL-RMZ-02, FW-GDL-RMZ-03, FW-GDL-RMZ-05, FW-GDL-RMZ-06, FW-GDL-RMZ-09 constrain a number of activities within riparian areas. These plan components protect river habitat and the vegetation surrounding them.

Timber harvest for resource benefits is limited in distribution, mostly occurring within the one-quarter mile designated wild and scenic river corridors. These areas would experience timber harvest mostly from existing roads but would not be conducted for purposes of producing timber. However, the area could be harvested for timber if the project required for another purpose such as to meet vegetation desired conditions or restore or improve wildlife habitat. Many observations of harlequin ducks fall within areas that are suitable for timber harvest but not production. These include the Lochsa River corridor, most of the North Fork Clearwater below the confluence with Kelly Creek, Kelly Creek, and the Selway River outside of the wilderness boundaries. Timber harvest in these areas would require following plan desired conditions, standards, and guidelines found in the aquatic ecosystem section of the plan and would be conducted for purposes other than for timber production. In many cases, these areas would be treated with prescribed fire rather than harvest.

Wilderness areas are not suitable for harvest nor production, and many Idaho Roadless Rule Areas are also not suitable. The Selway River in the Selway Bitterroot Wilderness area and Bear Creek would not be suitable for timber harvest. There would be no effects to harlequin duck habitats from timber harvest in these areas. Instead, vegetation change would mostly occur through wildfire.

Wildfire is a less precise tool and may burn some riparian areas near or on harlequin duck habitat. Prescribed fire, in comparison, is a more controlled but still variable tool. Timber harvest has much more control of where treatments occur and the extent at which these are conducted. The primary factor of these effects is whether riparian areas are treated. The sediment conditions after treatments result in consequences for harlequin ducks. It is unlikely many mechanical vegetation treatments would occur within riparian areas, but fire has the potential to impact some riparian habitats. The results differ as well. Wildfire tends to produce an increased pulse of sediment that then declines as vegetation regrows, whereas sediment load from timber harvest can be a pulse but also a longer-term source of sediments due to associated roads. It is assumed that harlequin ducks and riparian habitats have evolved with fire in these systems. Vegetative restoration under all the alternatives will be unlikely to impact harlequin duck populations due to their dependence on riparian areas and the protections afforded through plan components. In some cases, sediment delivery from these activities may impact water quality for harlequin ducks.

Geographic Areas

Lower Salmon River Geographic Area has limited harlequin duck habitat. Observations have been made only on the Salmon River just outside of the Lower Salmon River Geographic Area. There are currently no documented sightings of harlequin ducks in this geographic area. Desired conditions within this geographic area are not specific to aquatic ecosystems. Instead, the focus of this geographic area is to manage warm dry potential vegetation types, especially Ponderosa pine habitats. Forestwide aquatic guidelines and standards should conserve harlequin duck habitat in this geographic area.

Gospel-Hump Geographic Area contains suitable habitat for harlequin duck, and there have been observations in the vicinity of the South Fork of the Clearwater River. Timber harvest is suitable in the Sourdough, Big Meadows, and Indian Creek areas. Harvest in the Sourdough and Big Meadows areas has guidelines to trend towards achievement of aquatic desired conditions at the HUC12 scale, which should be adequate for harlequin duck conservation. Roadside hazard tree mitigation in the Indian Creek area has the potential to impact harlequin duck habitat if it occurs on roadsides in direct vicinity of Indian Creek.

Pilot Knob Geographic Area is in the vicinity of Leggett Creek on the South Fork of the Clearwater River. There are no recorded sightings of harlequin ducks in the area. Plan components describe conditions that concern cultural resources. Forestwide aquatic guidelines and standards should conserve harlequin duck habitat in this geographic area.

The Lolo Trail National Historic Landmark Geographic Area does not contain observations of harlequin ducks and would have no effects on the species.

Effects of Plan Direction

A summary of environmental consequences to substrate habitats from other resources due to plan direction is included in Table 205.

Table 205. Environmental consequences to harlequin duck substrate habitats from other resources due to plan direction

Resource Area	Environmental Consequences	Explanation
Across the Landscape	Yes	This section also contains a desired condition for riparian vegetation to include native assemblages of hardwood trees, deciduous shrubs, conifers, and, where appropriate, unique coastal disjunct species. It includes an objective to restore riparian areas. These should be beneficial over the long-term for harlequin duck habitat because they reflect the natural range of variation for these habitats. Achievement of this desired condition might require short-term disturbance to some riparian areas to restore or maintain these conditions.
Cave and Karst Features	No	No consequences
Forestlands	Yes	Forestlands plan components were designed to restore the natural range of variation and provide ecosystem integrity for forests, which should provide for the diversity and abundance of wildlife. It sets desired conditions, goals, and objectives to establish size class, density, landscape pattern and composition informed by the natural range of variability. Achieving forestland desired condition would require a number of actions that result in disturbance and forest regeneration. Desired conditions are differentiated by management areas and the actions to achieve desired conditions would also differ. In Management Area 1, disturbance is via natural processes. In Management Area 2 disturbance would be through a combination of natural disturbance, prescribed burning, and limited timber harvest. While in Management Area 3, desired conditions would be accomplished largely through timber harvest. Meeting desired conditions would require increased vegetation manipulation via multiple methods including timber harvest, mechanical treatments, and wildland fire. These treatments would potentially increase sediment within harlequin duck habitat over the short-term. Timber production is often accompanied by road construction which could increase sediment input. However, the aquatic ecosystem plan components reduce, minimize or eliminate these consequences.
Carbon Storage and Sequestration	No	No consequences
Meadow, Grassland, and Shrubland	No	No consequences
Fire Management	Yes	Changes to fire management direction would be positive for harlequin ducks. Historic fire suppression was identified as a threat to this species, and plan direction seeks to allow more flexibility to restore ecosystems with wildland fire. Plan direction encourages more fire. While some harlequin duck habitat may be changed by fire, it is assumed that harlequin ducks evolved with fire as a disturbance.
Invasive Species	Yes	Aquatic and riparian invasive species can affect aquatic and riparian habitats. Plan direction should help address this threat.
Soil Resources	No	No consequences
Aquatic Ecosystems	Yes	Aquatics plan components should conserve harlequin duck habitat. This overarching section contains several subsections that pertain to the protection of aquatic resources.

Resource Area	Environmental Consequences	Explanation
Water and Aquatic Resources	Yes	Aquatics plan components should conserve harlequin duck habitat. Plan components in Water and Aquatic Resource section are designed to provide healthy watershed and aquatic resources, connectivity, and good instream conditions. These plan components should have beneficial consequences for harlequin ducks.
Riparian Management Zone	Yes	Aquatics plan components should conserve harlequin duck habitat. These plan components constrain a number of activities within riparian areas designed to protect riparian areas and aquatic habitats. These plan components prevent or minimize impacts to riparian habitats as well as protect aquatic habitats from sedimentation and contaminants.
Conservation Watershed Network	Yes	Aquatics plan components should conserve harlequin duck habitat.
Infrastructure (Aquatic and Riparian)	Yes	Aquatics plan components should conserve harlequin duck habitat.
Energy and Minerals (Aquatic and Riparian)	Yes	Aquatics plan components should conserve harlequin duck habitat.
Livestock Grazing (Aquatic and Riparian)	Yes	Aquatic plan components should conserve harlequin duck habitat.
Lands and Special Uses (Aquatic and Riparian)	Yes	Aquatics plan components should conserve harlequin duck habitat.
Recreation (Aquatic and Riparian)	Yes	Aquatics plan components should conserve harlequin duck habitat.
Wildlife	No	No consequences
Multiple Use Wildlife	yes	Would encourage management of uplands for big game, which could have downstream effects from sedimentation. These should be short-term. Aquatic ecosystem plan components would prevent or minimize consequences from these activities.
Air Quality	No	No consequences
Tribal Trust	No	No consequences
Cultural Resources	No	No consequences
Municipal Watersheds	No	No consequences
Sustainable Recreation	Yes	These plan components encourage recreational use and development of the Nez Perce-Clearwater. The recreation activities that could arise from these plan components could disturb harlequin ducks and their habitat. However, the combination of aquatic ecosystem plan components, and those from sustainable recreation, should help prevent recreation facilities from altering harlequin duck habitat.
Scenery	No	No consequences
Public Information, Interpretation, and Education	No	No consequences
Infrastructure	No	No consequences
Land Ownership and Land Uses	No	No consequences

Resource Area	Environmental Consequences	Explanation
Ecosystem Services	No	No consequences
Timber	Yes	Timber harvest in the uplands has the probability to contribute sediment in harlequin duck habitat. Riparian Management Zone plan components should help conserve or enhance harlequin duck habitat when these activities occur. The 207-acre maximum patch size limit would increase the size of some openings compared to the 40-acre limit. Larger opening sizes in most cases would generally require less roads for access for harvest. This would result in lower long term sediment contributions. In the short term there would be a temporary increase in water yield which should have negligible or beneficial effects. Openings temporarily increase sediments which could affect foraging habitats until vegetation recovers. With larger opening size the amount of sediment would naturally be larger as well. However, natural disturbances are often much larger than 207 acres and the increase is temporary. However, aquatic plan components were designed to reduce or prevent sediment.
Energy and Minerals	Yes	Mineral activities may impact harlequin duck habitat and disturb them. Mineral activities have the potential to pollute and alter harlequin duck habitat. Mining activities were cited as the cause of extirpation of harlequin ducks in Colorado. The plan's energy and mineral plan components basically follow mining and mineral laws.
Livestock Grazing	Yes	Livestock grazing could impact riparian habitats. However, plan components that direct the intensity or utilization of these habitats would mitigate or prevent consequences of this activity in harlequin duck habitat. Aquatics plan components should conserve harlequin habitat. Livestock grazing components specify that utilization rates are restricted to conserve rangelands, which would help prevent effects to harlequin ducks. Furthermore, aquatic ecosystem (livestock grazing) additionally address impacts from livestock grazing to riparian habitats. In general, livestock grazing is not thought to be a significant threat to harlequin ducks because other than nest sites, ducks are more dependent upon in stream conditions than they are to riparian habitats.
Special Forest and Botanical Products	No	No consequences
Designated Wilderness	Yes	Provides for protection of some harlequin duck habitat. Management emphasizes natural disturbances and preserves wilderness character. Suitability plan components find timber harvest, timber production, road construction, mineral activities (except those existing at the time of designation), construction of new buildings, motorized travel, and mechanized travel unsuitable and restricted in designated wilderness lands. Livestock grazing is suitable so long as it was ongoing when designation happened, which is limited. Prescribed fire is suitable as well. This management direction would prevent many activities that could affect harlequin ducks or their habitat. Therefore, the plan direction has beneficial consequences.
Designated Wild and Scenic Rivers	Yes	Harlequin duck habitat occurs within wild and scenic rivers. Designated Wild and Scenic lands emphasize retain their free-flowing condition, water quality, and the outstandingly remarkable values for which the river was designated, emphasize compliance with their comprehensive management plans, shall protect and enhance their free-flowing character, water quality and outstandingly remarkable values for which the river was designated. Suitability plan components identify timber production unsuitable. Timber harvest, mineral activities, motorized travel, road building, and mechanized travel are conditionally suitable. and would have beneficial effects on harlequin ducks and their habitat.

Resource Area	Environmental Consequences	Explanation
Recommended Wilderness	Yes	Beneficial consequences
Eligible and Suitable Wild and Scenic Rivers	Yes	Beneficial Consequences. Some rivers have harlequin ducks as an outstandingly remarkable value. Eligible and suitable wild and scenic river management would provide protection and management would be added onto protections already afforded through the aquatic ecosystem plan components.
Idaho Roadless Rule Areas	Yes	No consequences or beneficial consequences. Management in Idaho Roadless Rule is focused on maintaining roadless character, emphasizing vegetation conditions within the natural range of variation and promoting wildlife habitat. Suitability plan components address activities like road building, energy and minerals, timber harvest in a manner that would be beneficial or no consequence for harlequin duck habitat. Suitability plan components tier to what is allowed or disallowed in the Idaho Roadless Rule.
Research Natural Areas	No	No consequences
Special Areas	No	No consequences
Lower Salmon	No	No consequences
Gospel-Hump	No	No consequences
Pilot Knob	No	No consequences
Lolo Trail National Historic Landmark	No	No consequences

Cumulative Effects

Cumulative effects are impact on the environment resulting from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions. For programmatic actions like forest plans, cumulative effects consider the effects of the plan in context with the effects of other programs, plans, initiatives, and actions whose effects overlap in time and space with the proposal. The area for cumulative effects analysis is the Nez Perce-Clearwater's administrative boundary. Other plans that overlap the planning area in space and time include the various state plans, county plans, other federal plans, and other broad scale planning efforts. Plans that pertain to habitats used by the harlequin duck in include Idaho's Water Plan, Idaho's Statewide Wildlife Action Plan, Bull Trout Recovery Plan, and Endangered Species Act Recovery Plan for Snake River Idaho Spring/Summer Chinook and Steelhead Populations. Idaho's Water Plan addresses how the State's water is to be used. This plan is consistent with the Forest Plan for the management of the Nez Perce-Clearwater's water resources. Idaho's Statewide Wildlife Action plan identifies the harlequin duck as a species of greatest conservation need and includes goals and objectives to increase information about harlequin duck populations and seeks to address threats to harlequin duck habitat. The recovery plans for bull trout, steelhead, and Chinook seek to protect and conserve habitat for these species. These plans have beneficial consequences to harlequin ducks and their habitats. Therefore, there are beneficial cumulative effects from these plans and the Forest Plan should complement the goals and objectives of these plans.

Conclusion

The plan's aquatic ecosystem plan components provide a robust framework for protection of aquatic habitats that harlequin ducks use, which should ensure the ecological conditions to provide for harlequin ducks long-term. In addition, the plan's direction for designated wild and scenic rivers currently protects the Lochsa and Selway rivers which combine for the majority of known harlequin duck observations in the plan area (see Table 204). This management includes a combination of plan desired conditions, standards, and suitability of uses that restrict activities that would alter the river's free flowing characteristics, water quality, and protect outstandingly remarkable values. Similarly, plan direction for designated wilderness area provides additional protections for the Selway River. Not all rivers considered are equal in terms of their importance to harlequin ducks. The Preferred Alternative includes rivers like Kelly Creek, Colt Killed Creek, and Fish Creek as suitable for inclusion in the wild and scenic river system, which would provide additional protection for those rivers. Because harlequin ducks are identified as outstandingly remarkable values for these rivers, the plan direction would require projects to protect and enhance harlequin ducks as a standard. The plan's coarse filter plan components, especially for aquatic ecosystem plan components, provides ecological conditions to ensure the long-term persistence of harlequin ducks. For additional analysis related to harlequin duck habitat, see the analysis for Aquatic, Wetland, Water and Riparian habitats section of the Final Environmental Impact Statement above.

Mountain Quail

Mountain quail is a secretive species that lives in dense shrub and forest habitats. They are distributed along the mountains of the Pacific Coast and western Great Basin of North America, with Idaho populations representing the northern and eastern extremes of their range. While populations are secure across much of their range, major declines have occurred in populations in Idaho in the last several decades (U.S. Department of the Interior n.d.). Mountain quail occur in Idaho, centered in the lower Salmon River Canyon and Hells Canyon along the Snake River. Small, isolated populations likely occur in the Boise Mountains and Bennett Hills in southwest Idaho and near Dworshak Reservoir in northern Idaho (U.S. Department of the Interior n.d.). In the plan area, mountain quail observations have been recorded along the Salmon River, in the Lower Slate Creek drainage, in the Allison Creek drainage, near Rapid River, and northward in the area known as the island area of the Nez Perce-Clearwater, which is on the west side of the Salmon River Ranger District. The "island area" refers to Nez Perce-Clearwater lands between the west side of the Salmon River and Snake River that border the Wallowa Whitman National Forest. These areas make up the core of mountain quail habitat in the plan area. Sporadic and older observations have been recorded in the South Fork of the Clearwater drainage, near the Clearwater River on the west side of the plan area, and the lower North Fork Clearwater drainage.

The Idaho Statewide Wildlife Action Plan (Idaho Department of Fish and Game 2017b) estimates that the mountain quail population occupancy in Idaho has declined by 95 percent since 1938. Population declines are often attributed to deterioration and loss of habitat due to intensive agriculture, improper grazing, and fire suppression. However, there is no direct research or evidence linking declines to specific causes. It is also suspected but not confirmed that there may be competition for resources with other game birds introduced to Idaho, particularly California quail and chukar (*Alectoris chukar*). Small, isolated mountain quail populations are potentially at risk due to extreme environmental events, habitat changes, and genetic isolation. Mountain quail were petitioned for listing under the Endangered Species Act in 2000, but the U.S. Fish and Wildlife Service concluded listing was not warranted. Although still classified as a game bird, the hunting season for mountain quail was closed in Idaho in 1984 (Idaho Department of Fish and Game 2017b).

In 2016, the Intermountain Bird Observatory (Miller et al. 2016) conducted targeted surveys for mountain quail on the Nez Perce-Clearwater. Surveys for mountain quail were conducted across a wide stratum of presumed suitable habitat in hopes of discovering mountain quail in previously unknown areas; all habitat types where historical observations have occurred were quantified across the Nez Perce-Clearwater. Out of 54 survey grids, mountain quail were only detected on two survey routes located in the Rapid River area and one survey route in the Slate Creek area. The probability of detecting a mountain quail using call broadcast was calculated to be 0.54, given that one was present. Overall, transect scale occupancy was low at 0.07. The probability of encountering a mountain quail at any given point within the stratum was estimated to be 0.01 (Miller et al. 2016). While the probability of detection was relatively high, mountain quail detections and the probability of occupancy were low. The surveys failed to detect the species within areas where the species had previously been observed in the plan area. These survey results follow statewide trends in mountain quail declines. Given the limited distribution in the plan area and the steep decline in populations in both Idaho and the plan area, mountain quail were identified as a species of conservation concern for the Nez Perce-Clearwater. All the known populations and most observations of mountain quail fall within the Land Management Plan's proposed Salmon River Geographic Area.

The state of knowledge of mountain quail ecology is incomplete. The mountain quail is probably the least-studied upland game bird in the United States because of its secretive habits, low population levels, and use of dense vegetation and rugged terrain (Vogel and Reese 1995c, a, b) Rocklage and Edelmann 2003). Mountain quail inhabit brushy, early successional habitats, often within coniferous forests and on steep slopes. However, in Idaho, they typically occur in dense shrubs in steep riparian draws (Idaho Department of Fish and Game 2017b). In all habitats, mountain quail use areas of dense, tall shrubs within close proximity to water. Mountain quail breed and winter in shrub-dominated communities, often within coniferous forests and on steep slopes (Vogel and Reese 1995c, a, b) Rocklage and Edelmann 2003). The composition of these communities consists of hawthorn, willow, and chokecherry in riparian areas of the intermountain west (Vogel and Reese 1995c, a, b). The species is a year-round resident, but many mountain quail may migrate altitudinally, moving between lower wintering areas and higher forested habitats during the summer Wisdom et al. (2000c, a, 2000d). Diet is dominated by plant material, though invertebrates are very important in the diet of chicks early in life. Perennial forbs and mast-producing shrubs are important food sources (Vogel and Reese 1995c, a, b, Wisdom et al. 2000c, a, b, Rocklage and Edelmann 2003).

Based on these needs, the species requires suitable dense shrub habitats either in non-forested or forested areas as their primary key ecological requirement. In many parts of its range, mountain quail occur in uplands as well as within riparian areas but in Idaho, the shrub habitats the species prefers are often within riparian areas more than in other parts of its range. Therefore, the key common features are shrub habitats in forested, non-forested, and riparian vegetation. For coarse filter analysis, mountain quail were grouped into the non-forested vegetation habitat group and the shrublands subgrouping. The species may also have logically been assigned to the riparian habitat grouping but because of its close association with shrub habitats. The effects of the plan to these habitat groups were analyzed above in the Terrestrial Habitats section of the Final Environmental Impact Statement above.

An interagency team of wildlife biologists from the Idaho Department of Fish and Game, the Nez Perce Tribe, and the Forest Service used the NatureServe methodology to identify threats to mountain quail in the plan area. Threats identified included livestock grazing, fire suppression, invasive animals (potentially California quail or chukar), invasive plant species, natural rarity, climate change resulting in shifting habitats, and drought or temperature extremes. Threats outside the plan area could also impact mountain quail and impact the plan area's ability to support a population of mountain quail. For example, mountain quail often winter at lower elevations off National Forest System lands and impacts to winter habitat could affect the persistence of mountain quail that summer in the plan area. It should be noted that the NatureServe method takes a precautionary approach to unknown information, and several aspects of how mountain quail respond to these threats are unknown. When the severity of a threat is unknown, the method identifies it as a medium threat if the scope is either pervasive or large. Scientific literature suggests that declines in other areas have been associated with degradation of riparian and brush habitat due to livestock grazing, fire exclusion, and water development. The full threats' assessment for mountain quail can be viewed in Appendix C.

The species could be vulnerable to habitat loss and degradation from forest succession, fire exclusion, weed invasion, and natural rarity. The impact of livestock grazing, invasive animals, invasive plant species, introduced genetics, and climate change are unknown, but the scope of these impacts are pervasive, meaning they occur between 71 to 100 percent of the occupied habitat of mountain quail in the plan area. In most cases, the scope is 100 percent for these threats. Livestock grazing can degrade riparian and shrubland habitat depending upon the intensity. The degradation or loss of riparian and shrub habitats could be impactful to the species in the plan area because of the strong affiliation mountain quail have to these habitats. Long-term fire suppression can cause a loss of habitat through forest succession. Interspecific competition from California quail or chukar may also be a factor (Wisdom et al. 2000c, a, b). Of these two species, California quail are the most likely to overlap in habitat use and diet. However, mountain quail and California quail co-occur in other parts of the species' range. Invasive plant species are prevalent among the areas occupied by mountain quail in the plan area, but the effects are unknown. Invasive plant species can dominate areas to the exclusion of native plants and may reduce the plant species mountain quail depend for foraging, nesting, or hiding. Invasive plants like cheat grass can also change fire frequency. Perhaps the largest threat to their continued persistence in the plan area is their limited distribution and natural rarity. The impact of climate change is largely unknown and outside Forest Service control. Because of their migratory habit, factors that cause habitat loss of forestlands could affect the continued persistence of mountain quail in the plan area.

Course filter plan components for mountain quail habitats include those in the Aquatic Ecosystems section for riparian areas, warm dry broad potential vegetation type forests in the Forestlands section, and those in the Meadow, Shrubland, and Grassland section. The threats of invasive plant species are addressed in the Invasive Species section. The conclusions in the analysis of these habitats above in the Final Environmental Impact Statement were that the plan would provide for ecosystem integrity in these habitats. The Land Management Plan includes species-specific plan components for mountain quail in the Salmon River Geographic Area. GA-DC-SR-02 is a desired condition that seeks to specifically address mountain quail habitat. GA-DC-SR-03, as well as FW-DC-FOR-02, and all the plan components under the warm dry potential vegetation type sections specifically address restoration of Ponderosa pine habitats where mountain quail often summer. GA-OBJ-SR-01 is an objective designed to restore mountain quail habitat.

Evidence suggests that mountain quail respond positively to fires. Brunk et al. (2023) studied mountain quail response to fire in California and found that occupancy was positively correlated with high-severity as a function of shrub regeneration, while low-moderate-severity fire had a neutral correlation with occupancy presumably because these fires reduce the understory while retaining canopy.

Ecosystem Plan Components

Plan direction, components and effects to mountain quail are summarized in Table 206.

Table 206. Plan components that provide habitat conditions for mountain quail or address threats

Plan Direction	Plan components	Effects
Desired conditions	FW-DC-TE-01 FW-DC-TE-05 FW-DC-TE-06 FW-DC-FOR-03 MA1-DC-FOR-01 FW-DC-INV-01 Riparian Management Zones desired conditions GA-DC-SR-02 GA-DC-SR-03 FW-DC-FOR-02	Plan components address the warm dry potential vegetation type, which will generally benefit mountain quail, as well as plan components that specifically address mountain quail habitat. Desired conditions direct management to conserve riparian habitats important to mountain quail and address the spread and establishment of noxious plant species that may alter mountain quail habitats.

Plan Direction	Plan components	Effects
Objectives	FW-OBJ-INV-01 GA-OBJ-SR-01	Plan components are specifically designed to restore mountain quail habitat.
Guidelines	FW-GDL-INV-01 FW-GDL-INV-02 Riparian Management Zone guidelines	Protects riparian areas, including those important to mountain quail.
Standards	Riparian Management Zone standards	Protects riparian areas important to mountain quail.

Alternatives that could affect mountain quail habitats include recommended wilderness allocations, eligible and suitable wild and scenic rivers, objectives of acres of treatment or disturbance, timber harvest output, and timber suitability. Alternatives for activities allowed within recommended wilderness would have no effect on mountain quail habitat. The plan components that do not affect mountain quail habitats will not be analyzed in detail.

Modeling

Modeling in SIMPPLLE was improved between the Draft and Final Environmental Impact Statements. Several aspects of mountain quail habitat were modeled. Queries that inform mountain quail habitat include the dry forest-associated species query presented in the analysis for open mature forest above. Second a riparian query habitat query was conducted in SIMPPLLE. The query was revised between draft and final and included a more accurate delineation of riparian areas to better replicate riparian response to disturbance and management zone buffers. The model was calibrated to show the trend in riparian vegetation from natural and man-made disturbances. Disturbance patterns in riparian areas are like adjacent uplands, as found from on-the-ground data. The model was adjusted to reflect this pattern. While the riparian query includes more riparian areas than those occupied by mountain quail, that query also contributes to information related to mountain quail habitat and is analyzed above in the Riparian Habitats section above.

A mountain quail specific habitat query was also conducted in SIMPPLLE, and results are presented here. We assume that nesting habitat, defined as dry forest cover types, within 500 feet of water, in a shrub (that is, 0-4.9-inch DBH) successional stage, is most limiting.

- The query design for mountain quail includes the following layers:
- The spatial footprint from the riparian habitat conservation area (national wetlands inventory and national hydrography dataset) query above will be used for mountain quail, but further limited as follows:
- Habitat type group/cover type: Warm dry forest including the following habitat groups: Include vegetation stage along with habitat type group
    - ♦ NF1B, NF1C, NF2, NF2A, NF2B, NF2D
    - ♦ A2
    - ♦ B1
    - ♦ B2
    - ♦ C1A
    - ♦ C1B

- Tree size class: 0- to 4.9-inch DBH
- Canopy cover less than 40 percent
- Geographical feature: containing perennial water
- This query was limited to the South Fork landscape only

SIMPPLLE modeling conducted by the Ecosystem Research Group suggests that mountain quail habitat would remain static over the next 50 years under all alternatives with little difference between alternatives. The results are reflective of the limited distribution of mountain quail habitat and the narrow geographic distribution of the query which was limited to habitat within a short distance to water.

Recommended Wilderness Alternatives and Consequences

The only recommended wilderness section that contains mountain quail populations is the Rapid River recommended wilderness area. Alternatives W, Y, and Z includes the Rapid River area as recommended wilderness. This area contains populations of mountain quail. While Alternatives W, Y, and Z all contain populations of mountain quail, Alternative Y and W contain an additional area that has multiple observations of mountain quail. Alternative W excludes this portion. Mountain quail appear to respond positively to fire, and mountain quail habitat may need restoration or active management to maintain the populations. If the Rapid River area were selected as recommended wilderness, it would be managed so that natural disturbance would prevail over-active management. Generally speaking, this type of management increases the amount of area that is in an early seral condition because of an increase in fire because of a lack of suppression activities, which would be beneficial to mountain quail. However, management via natural disturbance would be challenging because of the nearby communities and residences in the Riggins Area. Natural disturbances like wildfire might require suppression to prevent threats to life and property in this area even if the Rapid River area were included in recommended wilderness. Additionally, recommended wilderness management might constrain treatment of invasive weeds, therefore, it is unclear if recommended wilderness would be better for mountain quail. The only threat to mountain quail addressed by recommended wilderness management is fire suppression. All other threats are not addressed by recommended wilderness management. However, many active management activities that could restore mountain quail habitat would not be allowed under recommended wilderness management.

Recommended wilderness management would be identified as recreation opportunity spectrum non-motorized setting and would be unsuitable for motorized uses except those explicitly allowed in the Idaho Roadless Rule. Roads have not been discussed in scientific literature as a threat to mountain quail. However, motorized uses may result in loss of habitat from the motorized route footprint, and some individuals might be struck by vehicles. Overall motorized uses are not identified as a threat to mountain quail within published literature, though this might require more study. Therefore, we assume motorized uses have negligible consequences for mountain quail.

Recommended wilderness management would limit timber production and timber harvest. These activities would be beneficial for mountain quail because they would increase the amount of early seral habitat producing the dense shrub conditions that mountain quail favor. Recommended wilderness management would not affect livestock management nor prescribed fire as those would both be suitable within recommended wilderness. Recommended wilderness management under the Preferred Alternative would constrain some mineral activities, construction of new buildings, road construction, recreational vehicle travel, mechanized travel, commercial use of structures, recreational aircraft landings, and over-snow vehicle use. If these activities were found unsuitable in the wreck Rapid River recommended wilderness area they would have slight positive beneficial consequences. However, since these are not considered threats to the mountain quail, these protections would be only slightly beneficial. While pesticide and bio control use would be suitable in recommended wilderness areas, the lack of access would complicate pesticide application to address the threats to mountain quail from invasive plant species.

Overall, if Rapid River were included in recommended wilderness, it would have some slight beneficial consequences but also complicate active management of vegetation through mechanical means and control of noxious weeds. Mountain quail conservation may require the full range of management activities that would be possible if the area were not identified as recommended wilderness. The Preferred Alternative would not include Rapid River as recommended wilderness. The consequences of this for mountain quail are that it would allow the full range of management options to improve and maintain mountain quail habitat.

Eligible and Suitable Wild and Scenic River Alternatives and Management

The plan contains alternatives for eligible and suitable wild and scenic rivers that includes mountain quail habitat. Rivers that are considered eligible or suitable wild and scenic river alternatives that also contain mountain quail habitat include the Salmon River, Slate Creek, and Whitebird Creek. All three of these rivers are eligible under the No Action Alternative. The Salmon River is a Wild and Scenic suitable river in Alternatives W, Y, Z, and the Preferred Alternative, but is not suitable in Alternative X. Neither Slate Creek nor White Bird Creek are identified as suitable in any alternative. No other rivers considered in the alternatives would have consequences for mountain quail because they do not contain mountain quail populations.

Suitable Wild and Scenic River management emphasizes managing for free-flowing characteristics and protecting or enhancing outstandingly remarkable values. This type of management prioritizes the protection and enhancement of these values and disincentivizes activities that do not. Mountain quail were not identified as outstandingly remarkable values because they were not river dependent. However, suitable wild and scenic river management would conserve riparian areas and the river itself as well as the river corridor which would also help conserve quail habitat. Projects to enhance mountain quail habitat would need to be consistent with the direction in the plan for suitable wild and scenic rivers and protect and enhance outstandingly remarkable values to proceed. While projects to improve mountain quail habitat would be possible, it would add additional considerations that might encumber such projects. This would apply to the Salmon River and the one-quarter mile around the river under the Preferred Alternative. Overall, the consequences are positive for mountain quail to include the lower Salmon River as suitable for wild and scenic inclusion.

Recreation Opportunity Spectrum and Motorized Access Alternatives

The recreation opportunity spectrum (ROS) determines the level of recreation one might expect and determines the suitability of motorized uses. Within mountain quail areas, there is little difference between the alternatives because most are currently within motorized ROS settings. Alternatives W, X, Y, and Z are similar to the No Action Alternative for mountain quail. However, in the Preferred Alternative, the settings change from one motorized setting to a different motorized setting with most mountain quail habitat going from either semi-primitive motorized or roaded natural to the rural setting. Areas with mountain quail are within areas where the travel system is already well established so new roads within mountain quail habitat would not be likely. The change would perhaps facilitate an improvement in the condition of existing motorized routes enabling more traffic or higher speeds. Roads and motorized uses have not been identified nor discussed as a threat to mountain quail in the scientific literature. The primary impacts of motorized uses to mountain quail are that individuals could be struck by vehicles, and new road development would reduce mountain quail habitat within the road footprint. The change in the Preferred Alternative might result in slightly increased possibility of road strikes if the road system is improved. However, it would not likely have population level impacts. There are slight consequences to mountain quail from the change in the Preferred Alternative.

Timber Suitability, Vegetative Disturbance, and Timber Volume

Timber suitability varies only slightly by alternative and there is little to no change in timber suitability for the Preferred Alternative. Most mountain quail observations occur within riparian areas which are not suitable for timber production, but some riparian areas are suitable for harvest to meet other resource objectives. Adjacent uplands in many cases are suitable for timber production except in the Rapid River Idaho Roadless Rule Area, which is not suitable for harvest nor production

Alternatives vary how much timber volume is produced and the acres harvested annually. Alternative X has the most while Alternative Z has the least. The Preferred Alternative is intermediate and proposes 8,825 to 10,000 acres compared to the No Action Alternative which is approximately 4,300 acres. In addition, the total amount of disturbance from timber harvest, prescribed fire, wildfire, fuels treatments and more is estimated at 40,000 acres in the No Action Alternative and 53,000 to 64,500 acres in all other alternatives.

Gutierrez (2020) suggested that timber harvest may be beneficial to mountain quail habitat because it would produce shrublands and logging in Pacific Coast region probably increased total amount and distribution of habitat. Most likely the increase in disturbance including timber production would likely be beneficial to mountain quail and increase mountain quail habitat overall.

Environmental Consequences

Environmental consequences of plan direction by other resources to mountain quail are summarized in Table 207.

Table 207. Environmental consequences of plan direction by other resources to mountain quail

Resource Area	Environmental Consequences	Explanation
Terrestrial Ecosystems	Yes	Plan direction that encourages more early seral or shrub habitats would benefit mountain quail. Plan direction under this broad heading that provides ecological conditions for mountain quail include those for Forested lands, Meadow, Grasslands, and Shrublands, fire management, invasive species contribute positively to mountain quail habitat enhancement. These are discussed more in below in their respective row.
Across the Landscape	Yes	FW-DC-TE-04 provides vegetation that reflects natural disturbance regimes, and composition, structure, function, and connectivity of native plant communities are appropriate for a given landscape and climatic setting. Also FW-DC-TE-05 provides native assemblages of hardwood trees, deciduous shrubs, conifers, and, where appropriate, unique coastal disjunct species within riparian habitats. These plan components have beneficial consequences because they were designed to provide good conditions for many species including mountain quail.
Cave and Karst Features	No	No consequences

Resource Area	Environmental Consequences	Explanation
Forested Lands	Yes	Plan direction in the Forested Lands section of the plan encourages providing a variety in vegetation successional stages, and variety in dominance types. Desired conditions for size classes are designed to encourage more vegetation in seral grass/shrub stages in a variety of broad potential vegetation types which would benefit mountain quail and increase habitat. Plan direction encourages appropriate patch size and distribution of habitats which should also benefit mountain quail. Plan direction for warm dry potential vegetation types contribute positively to mountain quail habitat enhancement.
Carbon Storage and Sequestration	No	No consequences
Meadow, Grassland, and Shrubland	Yes	Plan direction for Meadow, Grasslands, and Shrublands contribute positively to mountain quail habitat enhancement. These plan components provide direction to enhance and maintain natural meadows, grasslands, and shrublands including species composition and condition. These plan components are designed to encourage managing these habitats in good condition
Fire Management	Yes	Changes to fire management direction would be positive for mountain quail compared to the No Action Alternative. Fire suppression was identified as a primary threat to this species and plan direction seeks to allow more flexibility to restore ecosystems with wildland fire. Some actions that could occur as a result of the plan direction is that mountain quail habitat could be treated to reduce fuels or burned from prescribed fire in efforts to meet fuels and fire objectives. These actions could result in short term impacts to mountain quail habitat but have longer term benefits for the species.
Invasive Species	Yes	Invasive species can affect the vegetation characteristics for mountain quail. Plan direction should help address this threat because it provides direction designed to reduce weed infestations, and prevent new infestations
Soil Resources	No	No consequences
Aquatic Ecosystems	Yes	Aquatics plan components should conserve mountain quail habitats.
Water and Aquatic Resources	Yes	Aquatics plan components should conserve mountain quail habitats. Plan components are designed to provide healthy watershed and aquatic resources, connectivity, instream conditions. These plan components should have beneficial consequences for mountain quail habitats.
Conservation Watershed Network	Yes	Aquatics plan components should conserve mountain quail habitats. These plan components emphasize intact aquatic resources and restoration, and maintenance of roadways to minimize sediment deliver. Standard FW-STD-CWN-01 requires projects to be designed and implemented in a manner that supports and contributes towards the recovery of federally listed species and the achievement of these desired conditions for aquatic and riparian habitats. Several drainages that have mountain quail populations are identified as conservation watershed networks. These include Slate Creek, White Bird Creek, and Rapid River. These plan components should help provide habitat for mountain quail.

Resource Area	Environmental Consequences	Explanation
Riparian Management Zones	Yes	Aquatics plan components should conserve mountain quail habitats. Riparian plan components are designed to provide good quality riparian habitats. Riparian areas provide mountain quail with important habitat. The plan components emphasize protection, proper function, and restoration of riparian habitats. These plan components would have beneficial consequences to mountain quail.
Infrastructure (Aquatic and Riparian)	Yes	Aquatics plan components should conserve mountain quail habitats. These plan components are designed to ensure that transportation system has minimal impacts on aquatic and riparian conditions. Most plan components focus on maintaining connectivity and reducing sediment input into waterways from infrastructure.
Energy and Minerals (Aquatic and Riparian)	Yes	Aquatics plan components should conserve mountain quail habitats. Plan components are designed to ensure that energy and minerals activities have reduced impacts on aquatic and riparian habitats. They address the manner in which energy and mineral activities are conducted within riparian areas and near aquatic habitats.
Livestock Grazing (Aquatics and Riparian)	Yes	Plan direction provides direction to relocate trailing Constraints in plan components like FW-STD-ARGRZ-01 direct that livestock grazing shall be authorized or reauthorized only when measures are included in the authorization to avoid or mitigate adverse effects to fish and riparian habitat that may result from grazing practices. FW-STD-ARGRZ-02 requires moving livestock trailing, bedding, watering, salting, loading, off road vehicle use for managing or gathering livestock, when these activities impact riparian habitats. FW-GDL-ARGRZ-01 requires minimum stubble heights of a minimum of 4-6 inches for the conservation of riparian areas. While these measures will not prevent all effects from grazing, they should serve to reduce impacts to mountain quail habitat and balance sustainable livestock grazing with riparian vegetation health.
Lands and Special Uses (Aquatic and Riparian)	Yes	Aquatics plan components should conserve mountain quail habitats. These plan components were designed to address impacts from hydroelectric and water development activities.
Recreation (Aquatic and Riparian)	Yes	Aquatics plan components should conserve mountain quail habitats. These plan components were designed to address impacts of recreational facilities to riparian habitats. They address the location and impacts of campgrounds, facilities, and trails. These plan components should reduce impacts of exiting and new recreational features to aquatic and riparian habitats used by mountain quail.
Wildlife	Yes	Wildlife plan components emphasize recovery of federally listed species, sustainable and resilient habitat for of species conservation concern, and connectivity of habitats. These plan components are designed to provide for species of conservation concern including mountain quail.
Multiple Use Wildlife	Yes	Plan components in the multiple uses wildlife section emphasize early seral conditions to provide nutrition. This should result in more mountain quail habitat.
Air Quality	No	No consequences

Resource Area	Environmental Consequences	Explanation
Tribal Trust	Yes	Plan components emphasize providing ecological conditions to ensure the exercise of treaty reserved rights. FW-DC-TT-01 was designed to provide for sustainable diversity of habitats necessary to provide plant and animal species that are of tribal importance. FW-DC-TT-02 is designed to provide habitats that support huntable and harvestable wildlife and resources. These plan components would help ensure habitat conditions for mountain quail and would have beneficial consequences for this species.
Cultural Resources	No	No consequences
Municipal Watersheds	No	No consequences
Sustainable Recreation	No	Plan components in the Sustainable Recreation establish the recreation opportunity spectrum settings which indicate the expected recreational experience and establish motorized use suitability. Recreation opportunity spectrum alternatives were analyzed above. Other plan components address how recreation experiences, facilities, trails, and infrastructure are to be managed. Other than consequences for Recreation Opportunity Spectrum (see above), these plan components would have no consequences for mountain quail.
Scenery	No	No consequences
Public Information, Interpretation, and Education	No	These plan components direct how public information and education efforts and infrastructure are managed. These plan components have no consequences for mountain quail.
Infrastructure	No	These plan components direct how existing roads and infrastructure is to be maintained. These plan components have no consequences
Land Ownership and Land Uses	No	These plan components deal with maintaining and prioritizing ownership and access via right of ways, marking boundaries, and providing for energy and communication infrastructure. These plan components would have no consequences to mountain quail.
Ecosystem Services	No	Ecosystem service plan desired condition encourage clean water, clean air, wood products, forage, hunting, trapping, fishing, fish, cultural values, heritage values, subsistence food gathering, and spiritual values, scenery, recreation, flood control and soil stabilization. Plan guidelines emphasize maintaining motorized access. These plan components would have minimal effect on mountain quail habitat.
Timber	Yes	This activity could change some mountain quail summer habitats. Opening the canopy could improve mountain quail habitat by releasing the understory. Plan components for timber should have beneficial consequences for mountain quail.
Energy and Minerals	No	Plan direction emphasizes providing opportunities for mineral and energy activities and are designed to be consistent with laws pertaining to mineral and energy availability and accessibility. Some mineral activities could occur in mountain quail habitat which could impact mountain quail habitat but is not likely to occur at a scale and time frame to impact mountain quail habitat.

Resource Area	Environmental Consequences	Explanation
Livestock Grazing	Yes	Livestock grazing could impact shrublands or riparian habitats. Plan desired conditions emphasize domestic livestock grazing consistent with the capacity of the land to produce sustained forage for multiple uses. Objectives seek to provide approximately 29,800 to 34,400 animal unit months annually forestwide. The plan provides guidelines to ensure that grazing is conducted sustainably and reduces impacts to natural resources. Guideline FW-GDL-GRZ-01 restricts salting away from riparian habitats. FW-GDL-GRZ-03 constrains the intensity or utilization of rangeland vegetation down to between 35-55%, which would mitigate or reduce the chance that habitats are over used and degrade mountain quail habitat. In addition, livestock grazing would abide by plan components addressing grazing in the Aquatics ecosystem (grazing) components should conserve mountain quail habitats. These plan components would address this threat.
Special Forest and Botanical Products	No	No consequences
Designated Wilderness	No	No consequences
Designated Wild and Scenic Rivers	Yes	Rapid River contains habitat for mountain quail and management would benefit mountain quail.
Lolo Trail National Landmark	No	No consequences
Recommended Wilderness	Yes	Some mountain quail populations occur within some alternatives for recommended wilderness. The Preferred Alternative does not include any recommended wilderness areas with mountain quail populations. Recommended wilderness direction has no consequences for mountain quail.
Eligible and Suitable Wild and Scenic Rivers	Yes	The Salmon River would be suitable under the Preferred Alternative and would contribute to the conservation of some mountain quail habitat. However, habitat treatments to enhance mountain quail habitat would have to be consistent with suitable wild and scenic river direction, which in some cases could constrain these activities.
Idaho Roadless Rule Areas	Yes	Some mountain quail populations occur within some roadless areas. Regulations directing the management of some roadless themes may prevent active management to enhance or restore mountain quail habitat. On the other hand, Idaho Roadless Rule plan direction would also help prevent some activities that could impact mountain quail habitat.
Research Natural Areas	No	No consequences
Lower Salmon	Yes	The Lower Salmon River Geographic Area has specific direction to address mountain quail habitats. These plan components are designed to maintain or improve mountain quail habitat.
Gospel-Hump	No	No consequences
Pilot Knob	No	No consequences
Lolo Trail National Historic Landmark	No	No consequences
Lochsa	No	No consequences
Special Interest Areas	No	No consequences

Cumulative Effects

The area for cumulative effects for mountain quail is the area of the Idaho Department of Fish and Game's Clearwater Region. This area encapsulates much of Idaho's mountain quail populations. The plans that affect mountain quail habitat management include Idaho's Statewide Wildlife Action Plan, land management plans of the Bureau of Land Management (BLM), and management plans for Craig Mountain Wildlife Management Area. County natural resource plans may also apply. For programmatic actions like Forest Plans, cumulative effects are effects of other plans that overlap in space and time with the Forest Plan.

The Idaho Statewide Wildlife Action Plan identifies mountain quail habitat within riverine-riparian forest and shrubland, dry lower montane foothill forest, and lower montane foothill grassland and shrubland habitat types. The Idaho plan has objectives for control of noxious weeds, conducting mountain quail surveys, maintaining and protecting high quality riverine and aquatic riparian habitat, maintaining the conditions of springs and ground water, decreasing or eradicating noxious weeds, improving resilience to climate change, restoring historic fire intervals, maintaining resilient native plant communities, managing livestock to maintain rangeland health, and maintaining responsible rangeland uses. These plans and actions are consistent with the Forest Plan under the Preferred Alternative. Idaho also includes plans for mountain quail in their Idaho Upland Game Management Plan 2019 to 2025 (2019). This plan identifies mountain quail as a game species with a closed season. It identifies needs for surveys for mountain quail.

The BLM's Land Use Management Plan for the Cottonwood District, titled the Cottonwood Resource Management Plan, includes actions to monitor and survey for sensitive species, follow best management practices for sensitive species, and promote sensitive species conservation through land tenure adjustments, conservation easements, restoration projects, and cooperative planning. The plan appendices identify the mountain quail as a Type 3 sensitive species. This plan also emphasizes that the lower Salmon River be managed as a suitable wild and scenic river and emphasizes managing the Salmon River Scenic and Recreational areas to protect the river's outstandingly remarkable values. These plans are consistent with the Forest Plan under the Preferred Alternative and would have no consequences for mountain quail because it would provide management to help ensure long term persistence of mountain quail.

Idaho County's natural resource plan was released in 2016. The plan is comprehensive, addressing many aspects of natural resource management. It includes objectives, desired conditions, guidelines, and standards pertaining to natural resource management. The plan addresses coordination, economics, aquatic ecosystems, terrestrial ecosystems, energy and minerals, livestock grazing, agriculture and irrigation, water rights, recreation, access, communication sites, cultural, cultural geologic and paleontological resources, forest products, and land allocations and their management. The plan emphasizes natural resource management beneficial to the county and its residents. The wildlife portion of Idaho County's natural resource plan contains desires to have wildlife habitat exist in abundance to sustain viable and harvestable populations of big game, furbearers, waterfowl, and upland game species and a diversity of other game and non-game species. Desired conditions also encourage the full breadth of wildlife management tools to manage predators and address wildlife conflicts. It includes objectives to address impacts from federal Endangered Species Act listings. This plan is consistent with the Forest Plan and Preferred Alternative. The Idaho County Natural Resource Plan would have no consequences for mountain quail.

Mountain quail occur on lands administered by the Idaho Department of Lands (IDL). These lands are managed for the primary purpose of providing revenue to support public schools with other uses secondary. IDL lands with mountain quail are located along the Salmon River adjacent to or at lower elevations than Nez Perce-Clearwater lands and within the Craig Mountain Area. The 2020 Idaho Forest Action Plan directs the management of IDL lands and is a long-term, coordinated strategy for reducing threats to Idaho's forests while increasing the social, economic, and environmental benefits they provide. The overarching goals for the plan are to reduce threats and enhance the benefits of Idaho's forests. They include 1) Idaho's forests are diverse and resilient to climatic changes and other threats (fire, insects, disease, noxious weeds, etc.), 2) Forestlands that provide the highest ecosystem benefits are identified, maintained, and enhanced. 3) Forest ecosystems are more resilient to human activities (development, harvest operations, etc.), 4) Forest-based wood products markets are economically vibrant and sustainable, and 5) Idaho has a framework for implementing the Forest Action Plan, to guide project prioritization across boundaries. The plan identifies priority landscape areas and addresses threats to forest health and identifies benefits from forest management. The plan identified and considered areas with high wildlife diversity and species of concern. Goals included specifically for wildlife include a desire to protect and provide habitat for native fish, wildlife, and plants. It also includes goals to promote wildlife connectivity between undeveloped areas. Project ranking priorities include wildlife as a criterion for consideration. These measures would include consideration for mountain quail because mountain quail are identified as a species of greatest conservation need by Idaho's Statewide Wildlife Action Plan. Some actions conducted as a result of the 2020 Idaho Forest Action Plan could affect mountain quail habitat but measures in this plan should help provide and prioritize habitat for mountain quail. Some forestry actions might benefit mountain quail habitat by providing early seral shrub habitats used by mountain quail. Therefore, this plan would have no consequences for mountain quail habitat.

Private lands within the Salmon River area contain populations of mountain quail. These lands are managed in a variety of ways and include development, agricultural uses, forestry, and more. These land uses can impact mountain quail habitat and in particular winter habitats as most private lands occur at lower elevations where mountain quail winter. However, many private lands are managed in a way that sustains mountain quail habitat.

The plan alternatives including the Preferred Alternative would not result in cumulative environmental consequences because the plan contains direction to encourage increasing or maintaining mountain quail habitat that are common in all alternatives.

Conclusion

Mountain quail occur within a limited area of the Nez Perce-Clearwater, primarily along the lower Salmon River canyon. The Land Management Plan identified the Lower Salmon River Geographic Area specifically and contains plan components to help conserve some of the unique wildlife that occurs within this area of the Nez Perce-Clearwater. Included in this suite of species is the mountain quail that occupies riparian habitats within this geographic area. A number of coarse filter ecosystem plan components guide management to provide healthy mountain quail habitat and address threats. For example, plan direction in the Invasive Species section and the Riparian Management Zone section provide additional coarse filter plan direction that should help conserve the habitat for mountain quail. Fire management direction would help ensure that fire operates properly within these areas to the benefit of mountain quail. The Nez Perce-Clearwater can provide for some, but not all, of the habitat required by mountain quail. Mountain quail, in many cases, winter outside the plan area in low elevation riparian areas; mountain quail might not persist without this habitat. These areas are outside of Forest Service control. However, a number of plans from other agencies also provide measures that consider or manage for healthy mountain quail habitat. Thus, the Land Management Plan provides the ecological conditions to contribute to the long-term persistence of mountain quail.

White-headed Woodpecker

Existing Condition

Description and Distribution

The white-headed woodpecker is a conspicuous, small-to-medium-sized woodpecker, with a distribution in south central British Columbia, Washington, Oregon, California, and west central Idaho (Garrett et al. 1996). It has a mostly black body with a white head. Although it is conspicuous, the species is considered uncommon, even in appropriate habitat. In Idaho, they are highly limited by suitable habitat, nesting in forests with large diameter Ponderosa pine trees and snags indicative of old growth systems (Idaho Department of Fish and Game 2017b).

In the plan area, the species is distributed in Ponderosa pine dominated stands and mixed stands of Ponderosa pine and other conifer species. These stands occur in the warm dry potential vegetation type (PVT) and, to a lesser extent, in the warm moist PVT. Warm dry PVTs occur in the Salmon River canyon, the Island, the Middle Fork of the Clearwater River, portions of the Lochsa and Selway Rivers, and a few limited areas on the Palouse Ranger District. See Appendix A for a map of PVTs. Suitable habitat for the species is typically fragmented, making accurate estimation of their range difficult. However, most white-headed woodpecker observations have been located where larger amounts of forests are dominated by Ponderosa pine, such as those in the lower Salmon River corridor, the mouth of the Clearwater River, and the South Fork of the Clearwater River near the western Nez Perce-Clearwater boundary. See Appendix A for a map of the white-headed woodpecker habitat.

Status

The white-headed woodpecker has a NatureServe global rank of G4 and a S2 rank for Idaho. A G4 rank means the species is apparently secure with a fairly low risk of extinction or elimination due to an extensive range or many populations or occurrences, but the species has possible cause for some concern because of local recent declines, threats, or other factors. A S2 rank indicates the species is imperiled because of rarity or because other factors demonstrably making it very vulnerable to extinction or extirpation; species with a S2 ranking typically have only 6 to 20 recorded observations. White-headed woodpeckers are generally uncommon or rare in appropriate habitat in Washington and Idaho and quite rare in British Columbia (Garrett et al. 1996).

The Idaho Statewide Wildlife Action Plan estimated that there are approximately 320 white-headed woodpeckers statewide (Idaho Department of Fish and Game 2017b). Range-wide, the population trend appears to be stable to slightly increasing. The species is identified as a species of Greatest Conservation Need by the State of Idaho (Idaho Department of Fish and Game 2017b). The species has been identified as a Sensitive Species by the Northern Region (Region 1), Intermountain Region (Region 4), and Pacific Northwest Region (Region 6) of the Forest Service. The species is on the U.S. Department of Interior's Bureau of Land Management State Director's Special Status List for Oregon and Washington.

In southcentral Oregon, white-headed woodpeckers are most abundant in old-growth Ponderosa pine forest types and essentially absent from mixed-conifer sites and those that contained younger seral stages (Dixon 1995a). Dixon (1995) calculated population densities based on point-count data of 0.00 to 2.53 birds per 40 hectares (98.8 acres). Densities based on absolute counts of breeding pairs include 0.18 to 0.49 birds per 40 hectares (98.8 acres) in south central Oregon (sample size is 3 counts) and 0.52 to 1.06 birds per 40 hectares (98.8 acres) in central Oregon (sample size is 4 counts). Declines due to forest fragmentation and modification have been noted in Idaho (Blair and Servheen 1995).

Migration and Seasonal Habitats

The white-headed woodpecker is generally sedentary, usually occupies the same home range throughout the year, and returns to the same breeding site year after year; however, limited wandering may occur during the non-breeding season to exploit locally and temporarily available abundant food sources of pine seeds (Garrett et al. 1996).

Historical Habitat Conditions

Before European settlement, habitat conditions for the white-headed woodpecker consisted of Ponderosa pine dominated forests in the warm dry potential vegetation type that were the result of a frequent, low intensity wildfire disturbance regime. Under this disturbance regime, stands can develop into large patches of an open, grown, old forest structure intermixed with smaller openings. These conditions can persist for centuries, provided moisture and temperature regimes do not dramatically change (U.S. Department of Agriculture 2014m).

Trend in Habitat

Ponderosa pine habitats within the plan area have experienced significant departure from their historic range of variability in terms of dominance types, size class abundance and distribution, density, and patch size distribution (U.S. Department of Agriculture 2014m). These changes are consistent with findings of Ponderosa pine habitats from across the Columbia River basin. Wisdom et al. (2000c, a, 2000d) evaluated the change since European settlement in source habitats in the Interior Columbia basin for 91 species of terrestrial vertebrates for which there was ongoing concern about population or habitat status. Species were grouped according to the common habitats they used. Those habitats were evaluated for trends as part of the Interior Columbia Basin Ecosystem Management Project to develop an ecosystem-based strategy for managing Forest Service and Bureau of Land Management lands within the basin. Wisdom et al. (2000b, c, 2000d) found that source habitats for the white-headed woodpecker occupies the same extent as historically, but the old structural stage used by the white-headed woodpecker has become scarce in these habitats throughout much of the Columbia River basin and there has been a gradual shift in stand composition from shade-intolerant tree species, such as Ponderosa pine, to shade-tolerant species, such as Douglas-fir and grand fir.

Habitat Preferences

Throughout the white-headed woodpecker range, their habitat includes an abundance of mature pines with large cones and abundant seed production, a relatively open canopy at 50 to 70 percent, and the availability of snags and stumps for nest cavities. The white-headed woodpecker is most closely associated with mature and old Ponderosa pine forests or mixed forests dominated by Ponderosa pine with species such as Douglas-fir, lodgepole pine, and white pine also present. Although it is associated with Ponderosa pine, it is absent from many areas dominated by Ponderosa pine. In southcentral Oregon, this species selects multistoried old-growth Ponderosa pine forests with canopies greater than 51 percent, a basal area of live trees greater than 12 square meters per hectare, a maximum canopy height of greater than 32 meters, and shrub cover greater than 30 percent (Dixon 1995b). Old-growth Ponderosa pine was also a dominant feature of white-headed woodpecker home ranges in central Oregon, and woodpeckers there preferred larger diameter trees with an average diameter at breast height of greater than 24 inches and a preference for an increasing diameter (Dixon 1995b). Woodpeckers typically excavate nest cavities in large, moderately decayed, Ponderosa pine snags (Dixon 1995a) Buchanan et al. 2003, Mellen-McLean et al. 2013).

Habitat evaluations using multivariate statistics suggest that white-headed woodpecker habitat selection is also influenced by factors at larger scales. Latif et al. (2015) found that the Habitat Suitability Index Modeling suggested that the white-headed woodpecker related positively with the percent Ponderosa pine at the home range and at the landscape scale, moderate levels of canopy cover of approximately 40 percent, and moderate-to-high levels of heterogeneity in forest structure. Areas with a larger percent of the land in mature Ponderosa pine are selected by white-headed woodpeckers. Closed canopy forests with cone-producing pine trees and insects may be important for year-round foraging, particularly outside the breeding season (Garrett et al. 1996) Mellen-McLean et al. 2013).

These birds can thrive in recently burned or cut areas, provided that large standing trees are still present (Idaho Department of Fish and Game 2017b). White-headed woodpeckers have also been found to use recently burned forests of Ponderosa pine (Saab and Dudley 1998, Wightman et al. 2010, Kozma 2011, 2012, Kozma and Kroll 2013, Forristal et al. 2007a). In southcentral Oregon, nest success was higher in burned habitats than unburned habitats (Forristal et al. 2007b, Mellen-McLean et al. 2013).

Studies conducted within the plan area found that the probability of detecting white-headed woodpeckers during surveys was positively related to the amount of Ponderosa pine forest and the number of large snags present in the survey area (Miller and Carlisle 2018) and negatively related to increasing canopy cover in two of three years studied. These surveys were conducted on 404 survey points located within 56 survey grids, with white-headed woodpeckers detected at eight points within five of the 56 survey grids. The probability of encountering a white-headed woodpecker within Ponderosa pine in the plan area was low at 0.01 (Miller and Carlisle 2018).

Diet

The white-headed woodpecker consumes invertebrates and pine seeds. It takes invertebrates off of trunks, branches, and needle clusters of large diameter live trees (Ligon 1973, Raphael and White 1984, Raphael et al. 1987). Pine seeds are obtained from large pinecones, which the white-headed woodpecker takes from predominantly large-diameter live Ponderosa pine trees (Dixon 1995b).

Nesting

Nest placement frequently occurs in open canopy forest patches, often adjacent to relatively closed canopy forests thought to provide critical food resources (Wightman et al. 2010, Hollenbeck et al. 2011). Nests are excavated from moderately decayed dead conifer snags, logs, or prostrate trees. Species of trees reported have included Ponderosa pine, quaking aspen, white fir, Jeffery pine, and red fir. In south central Oregon, all 16 nests studied by Dixon (Dixon 1995a) were in completely dead substrates with 37 percent in snags, 56 percent in stumps, and 6 percent in leaning logs and a mean diameter at breast height that averaged 31 inches. Typically, new nest cavities are excavated each year.

Threats and Stressors

Table 208 includes a summary of threats to white-headed woodpecker identified using the NatureServe methodology threats calculator. Habitat degradation from fire suppression, past timber harvest practices, and changes in precipitation and broad-scale hydrologic regimes represent the primary threats and stressors to the habitats white-headed woodpecker occupy in Idaho (Idaho Department of Fish and Game 2017b). The Idaho Statewide Wildlife Action Plan identifies changes in precipitation and broad-scale hydrologic regimes and emphasizes historic and current fire suppression that cause changes in the fire scope and severity in Idaho (Idaho Department of Fish and Game 2017b). See Appendix C for the full threats evaluation.

Table 208. Threats to white-headed woodpecker identified using the NatureServe methodology threats calculator

Threat	Scope	Severity	Impact level	Reason
Past timber practices (pre-1980s)	Large	Extreme	High	Based on treatments recorded in the FACTS database, area of past timber harvest was estimated to have impacted between 31 to 70 percent of white-headed woodpecker habitat. Severity was identified to be extreme because regeneration harvest was usually without retention of leave trees and snags, effectively eliminating habitat where this activity occurred.
Regeneration harvest (current practices)	Restricted	Serious	Medium	Based on the FACTS database, the area of past timber harvest was estimated to have impacted between 10 and 30 percent of white-headed woodpecker habitat since 1980. Severity was identified to be serious because regeneration harvest usually did not involve retention of leave trees and snags, which left those areas unusable by white-headed woodpeckers.
Historic livestock grazing	Large	Moderate	Medium	Long-term grazing can reduce fuel loads that also can influence fire return intervals, which would influence forest physiognomy that could reduce distribution. Historic grazing was intense and may have reduced competition with grasses, leading to higher shrub abundance and latter fuels in the understory. This grazing was estimated to have occurred over 30 to 70 percent of white-headed woodpecker habitats in the plan area and has left much of the habitat susceptible to stand replacing wildfire.
Fire and fire suppression	Pervasive	Serious	High	This threat has been estimated to have occurred in over 71 percent of the white-headed woodpecker habitat, leaving it susceptible to loss through stand replacing wildfire. The current trend suggests that Ponderosa pine habitat has been lost through succession and subsequent fires burning uncharacteristically hot in areas once dominated by Ponderosa pine and maintained by periodic low intensity fire.
Climate change—habitat shifting and alteration, drought, temperature extremes, changes in precipitation and broad-scale hydrologic regimes	Pervasive	Unknown	Medium[1]	This threat has occurred across nearly all the white-headed woodpecker habitat in the plan area. The severity of which is unknown.

1 - Due to uncertainty, the NatureServe methodology that recommends a medium threat when the severity is uncertain

Fires have historically maintained habitats for white-headed woodpeckers, and fire suppression has resulted in considerable changes to these systems, leaving them susceptible to loss from uncharacteristic wildfire. Changes in fire size and severity pose a threat to the retention of mature trees and large diameter and high-cut stumps (Idaho Department of Fish and Game 2017b). Fire suppression over the past 50 years has altered fire regimes so that Ponderosa pine forests are no longer maintained by frequent natural low intensity fire and are being replaced by Douglas-fir and true fir, such as grand fir, developing in the understory, thus, making these areas susceptible to stand-replacing fires. The mature trees that the white-headed woodpecker depends upon for seed mast and snags for nesting can be lost if fires burn uncharacteristically hot. Fire suppression has affected much of the white-headed woodpecker's habitat in the plan area, and the scope of this threat was estimated to have affected more than 71 percent of the habitat in the plan area; thus, it was identified as pervasive in the threat evaluations for this species.

Local population declines have occurred following the loss of large, open Ponderosa pine forests from timber harvest (Garrett et al. 1996). Logging practices, such as clear-cuts, even-aged stand management, snag removal, salvage logging, and forest fragmentation, have contributed to local declines, especially in the northern half of the species range (Garrett et al. 1996). More specifically, timber harvest practices, such as shorter timber rotations, larger cut units, and reseeding with different species, have reduced the abundance of late-seral Ponderosa pine forests, snags, and coarse woody debris; in addition, these practices have fragmented the landscape and altered forest species composition (Idaho Department of Fish and Game 2017b). The preferred large-diameter trees are prized for their commercial value, and the loss of large-diameter Ponderosa pine poses the greatest threat to this species in Oregon (Garrett et al. 1996). When these practices affect these forests at the landscape scale, they can represent significant threats to the species. For example, old-growth Ponderosa pine has declined 92 to 98 percent in the Deschutes and Fremont-Winema National Forests (Garrett et al. 1996, Dixon 1995b).

Forestry practices like clearcutting, even-age stand management, snag removal, and fire suppression are thought to have contributed to declines California (Kozma et al. 2020). White-headed woodpeckers appear to tolerate some harvest practices as long as it includes retention of large diameter trees, and snags (Kozma et al. 2020). The presence of large and very large trees greater than 21 inches at relatively low levels (between 8.5 and 9.8 trees per acre) intermixed with younger Ponderosa pine or mixed Ponderosa conifer stands may provide suitable habitat for the white-headed woodpecker (Linstrand and Humes 2009, Kozma 2011). Forestry practices designed to restore the historical conditions of Ponderosa pine forest structure and composition increased white-headed woodpecker abundance in Washington under a frequent low intensity fire regime (Gaines et al. 2007, Gaines et al. 2010). These treatments included thinning, understory burning, and retention of large live and dead Ponderosa pine trees.

Changes in precipitation and broad-scale hydrologic regimes, coupled with the effects of fire suppression, have created hazardous fuels conditions throughout the west, and fires are now more severe than they were historically. In dry mixed-conifer forests, decades of fire suppression have resulted in an increase in fuel loading, shifts in species composition toward shade tolerant species less resistant to fire and increases in fire severity. Many legacy stands of Ponderosa pine are at risk of being lost to fire. Because of fire suppression, these stands often have an understory of Douglas-fir, grand fir, or lodgepole pine, which serve as ladder fuels when fire does occur and causes the fires to crown into the mature Ponderosa pine trees.

In the plan area, the NatureServe methodology for analyzing the magnitude of threats (Salafsky et al. 2003) was used to identify the threats for the white-headed woodpecker. The findings are like those identified in the published literature listed above. The NatureServe methodology identified past timber management practices (pre-1980s) as a high threat, regeneration timber harvest practices as a medium threat, historic livestock grazing practices as a medium threat, fire suppression as a high threat, and habitat shift and alteration from climate change as a medium threat. These primary threats affect this species in the plan area. See Appendix C for the white-headed woodpecker threat calculator results.

It should be noted that other forestry practices, such as intermediate treatments, sanitation, salvage logging, or other practices that restore these forests to their historic structural conditions or that retain large live trees and snags, are not considered significant threats because these practices are beneficial. This species persists in burned or cutover forests with residual snags and stumps; thus, populations are more tolerant of disturbance than those species associated with closed-canopy forests (Garrett et al. 1996, Raphael and Morrison 1987).

Measures Proposed and Taken to Prevent Effects and Restore Habitats

The proposed conservation strategy for Idaho (Blair and Servheen 1995) involves management of white-headed woodpecker habitat, primarily Ponderosa pine forest, through modifications in existing timber harvest and fire suppression, along with programs of snag retention and monitoring of woodpecker abundance and habitat response. Specific snag retention recommendations include 45 suitable large snags to maintain a target population of five pairs of white-headed woodpeckers per 40 hectares. These numbers equate to about 0.46 snags per acre and are like those reported by (Bollenbacher et al. 2009a) as the average number of snags larger than 20 inches diameter at breast height (DBH) in the Ponderosa pine forest types.

Casey et al. (Casey et al. 2012, 2011, Casey and Altman 2007) identified the following attributes to describe optimal Ponderosa pine breeding habitat for white-headed woodpeckers:

- late-successional forests in patches greater than 250 acres with moderately open canopy cover of 20 to 60 percent
- greater than 40 percent shrub cover
- greater than 1.6 snags per acre with a greater than 18 inches DBH
- greater than 1 snag per acre with a greater than 28 inches DBH

Restoration Needs in the Plan Area

The extent of Ponderosa pine dominated forests within the warm dry potential vegetation type and other potential vegetation types has been reduced from its natural range of variability because of encroachment from Douglas-fir and grand fir. Thus, restoration across the plan area landscape should restore the amount of this forest type in the warm dry potential vegetation type. Increasing dominance of Ponderosa pine, especially those with larger trees, should increase the distribution of white-headed woodpeckers in the plan area long-term. Additionally, existing Ponderosa dominated stands should be restored to their natural range of structure, including lower density and larger size class, through practices that replicate a low intensity, high frequency disturbance regime. The pace of restoration would need to be urgent enough to prevent loss by uncharacteristic wildfire in encroached stands that have existing large and old Ponderosa pine trees. These treatments would need to retain large and very large live and dead trees to provide for the key ecological requirements for the white-headed woodpecker. This restoration would need to be conducted largely through timber harvest in Management Area 3, prescribed fire in Management Area 2, and wildfire in Management Area 1. For example, restoration treatments in Ponderosa pine forests that included thinning, understory burning, and retention of snags in the eastern Washington Cascades had a positive effect on white-headed woodpecker presence and abundance (Gaines et al. 2007, Gaines et al. 2010). Restoration of Ponderosa pine habitats includes understory thinning to reduce ladder fuels and restoring density to historic conditions through prescribed fire to reinstate the natural disturbance regime.

Effects of the Plan Components and Alternatives

Management Areas

Management areas strongly influence the effects to the white-headed woodpecker in the plan area because they direct or influence actions or prohibit activities over broad areas of the Nez Perce-Clearwater. Thus, they influence the scope of impacts in the plan area. Chapter 1 of this document describes the management areas and how they are managed. This direction is summarized here for evaluation of effects. White-headed woodpecker observations have mostly occurred in Management Area 3, though warm dry habitats that could contain white-headed woodpeckers also occur within Management Areas 2 and 1. Broad direction within these areas influences the types of management these habitats could undergo. Management Area 3 has the most potential for restoration, while Management Area 2 and 1 have fewer options. Active restoration is likely needed, in many cases, for restoration of the open Ponderosa pine dominated forests preferred by white-headed woodpeckers.

Coarse Filter Plan Components

The coarse filter plan components emphasize restoration of the conditions needed to restore Ponderosa pine forest structure, dominance types, and densities. This restoration includes objectives, goals, desired conditions, standards, and guidelines that will restore potential vegetation types that contain Ponderosa pine dominated habitats, such as warm dry and warm moist potential vegetation types (PVTs); thus, restoring habitat for the white-headed woodpecker. Specifically, plan components include measures to restore structure, function, composition, and connectivity of warm dry PVTs and will restore habitat for white-headed woodpeckers. Forestlands desired conditions for warm dry PVTs emphasize restoring the structure of Ponderosa pine by reducing density and increasing the extent of Ponderosa pine dominance types. The following table identifies the plan components that were designed to provide ecological integrity of the warm dry PVT and maintain or restore the ecological conditions needed to provide for a viable population of white-headed woodpeckers that will persist long-term in the plan area. These plan components will direct management to provide for the white-headed woodpecker through coarse filter habitat requirements. Table 209 identifies specific plan components that apply forestwide that would contribute to white-headed woodpecker habitat. Some plan objectives that contribute to white-headed woodpecker habitat restoration vary by management area and alternative (see Table 210). The objectives vary by alternative because the alternatives vary the pace at which vegetation desired conditions are achieved. Alternatives with a faster pace towards the desired conditions would be better for white-headed woodpecker because of the emphasis in the plan on restoring Ponderosa pine dominance and structure, and because the risk of losing mature and old Ponderosa pine to wildfire due to fuel build up and encroachment by other tree species.

Table 209. Plan condition, components, and effects that pertain to white-headed woodpecker habitat management

Plan Component	Plan components	Effects
Desired Conditions	FW-DC-TE-01 FW-DC-TE-05 FW-DC-FOR-02 FW-DC-FOR-03 FW-DC-FOR-04 MA1-DC-FOR-01 MA2-DC-FOR-01 MA3-DC-FOR-01 FW-DC-FOR-05 MA1 and MA2-DC-FOR-06 MA3-DC-FOR-02 FW-DC-FOR-06 FW-DC-FOR-07	These plan components direct management to maintain or restore the integrity of ecosystems, including the structure, function, composition, and connectivity of habitats that the white-headed woodpecker uses. They specifically address potential and existing Ponderosa pine dominated forest structure, function, composition, and connectivity. For example, FW-DC-FOR-03 specifies a desired condition to increase Ponderosa pine dominance in each of the three broad management areas. FW-DC-FOR-04 specifies a desired structure within stands including live legacy trees and snags from past disturbance persisting well into the next generation including primarily the largest Ponderosa pine, and they are present and distributed across the habitat type

Plan Component	Plan components	Effects
	MA1-DC-FOR-02 MA2-DC-FOR-02 MA3-DC-FOR-03 FW-DC-FOR-08 MA1 and MA2-DC-FOR-07 MA3-DC-FOR-04 MA1 and MA2-DC-FOR-08 MA3-DC-FOR-06 MA3-DC-FOR-10 MA3-DC-FOR-11 GA-DC-SR-02	groups. MA1-DC-FOR-01, MA2-DC-FOR-01, and MA3-DC-FOR-01 describe the desired stand density which would be consistent with white-headed woodpecker habitat preferences. FW-DC-FOR-05 describes the dominance types within the warm dry broad potential vegetation type, which suggests a desire to increase the amount of Ponderosa pine dominated stands which will also increase white-headed woodpecker habitat. Other plan components similarly direct the Nez Perce-Clearwater to maintain or restore white-headed woodpecker habitat. Plan components in the Lower Salmon Geographic Area emphasize managing for Ponderosa pine ecosystems that support species like white-headed woodpecker.
Guidelines	MA3-GDL-FOR-02 MA3-GDL-FOR-03 MA3-GDL-FOR-04 MA3-GDL-FOR-05	Some old growth types were historically Ponderosa pine forests but have become encroached by grand fir or Douglas-fir. Treatments that remove these species can be used to restore old growth dominated by Ponderosa pine. Without these treatments, old growth Ponderosa pine is susceptible to loss from wildfire. These plan components guide treatment in old growth forest types, including old growth Ponderosa. These guidelines allow active management, with limitations, in old growth Ponderosa pine to restore white-headed woodpecker habitat. They also require retention of snags that would provide habitat for white-headed woodpeckers.
Standards	MA3-STD-FOR-01	Would prevent old growth Ponderosa pine and other types from meeting the definition of old growth when managed. This standard would help conserve habitats for white-headed woodpeckers when these stands are managed.

Table 210. Objectives that support white-headed woodpecker habitat restoration objectives, by broad potential vegetation group and alternative

Effects of Alternatives

From the forestwide perspective, the amount of white-headed woodpecker habitat in the plan area includes about 49,690 acres. About 52 percent is in Management Area 3 and subject to timber production. Eighteen percent is in Management Area 2, which may be managed with treatments designed to restore the natural range of variation, often through prescribed fire or harvest for other resource objectives. About 30 percent of the white-headed woodpecker habitat is in wilderness, which is not actively managed. Thus, about 82 percent of the white-headed woodpecker habitat in the plan area could be impacted with some form of treatment. The most potential for intense management would be within the 52 percent of habitat in Management Area 3. Effects of actions in white-headed woodpecker habitat would be analyzed separately in project level analysis, and it is assumed that the plan direction noted above would apply to these treatments; thus, conserving, and in many cases restoring, white-headed woodpecker habitat in the plan area.

Adjustments to the SIMPPLLE model were made to address fire assumptions. The adjustments in the model changed the outcome of model results. The SIMPPLLE model suggests that the habitat for the white-headed woodpecker in closed dry forest increases under the No Action Alternative, Alternative X, and Alternative Z, and a decrease in this forest type under Alternatives P, W, and Y. The modest shift from closed to open forest under Alternatives P, W, and Y suggests that vegetation management activities are contributing positively to this shift in stand structures and suggests that long-term habitat sustainability is improving. These modeled outcomes suggest that habitat for dry forest-associated species such as the flammulated owl, white-headed woodpecker, and pygmy nuthatch is not being placed at risk by these management alternatives. There is a decrease in open dry forest habitat under all alternatives over the five decades. These results seem counterintuitive since all alternatives emphasize restoring large, open stands of Ponderosa pine. Declines in habitat are likely due to much higher anticipated levels of high severity wildfire, attributable to 70 years of accumulating fuels from successful past wildfire suppression. While the modeled decline of this habitat is alarming, the fact that the decline within wilderness and Idaho Roadless Rule Areas is no less than that within the lands managed for multiple uses. Other Management Areas suggests that the decline is both inevitable and unavoidable due to long-term fuel accumulations resulting from fire suppression. The amount of Ponderosa pine dominated forest increased in all alternatives over time, and since white-headed woodpeckers can use both closed and open forest structure, these trends in stand conditions would still sustain white-headed woodpecker habitat long term. Modeling also suggests that large and very large trees would also increase on a forestwide level and within all potential vegetation types. Overall, these trends would be positive for white-headed woodpecker

The alternatives that most affect the white-headed woodpecker are those that alter or manage forested habitats, particularly Ponderosa pine habitats. These would include management for vegetation and fire treatments to achieve vegetation desired conditions. The alternatives suggest achieving vegetation conditions at different rates. Those with faster rates of attainment would increase Ponderosa pine dominance types faster than those with slower rates of attainment. The faster rate would help to slow the loss of these stands to stand replacing wildfire. Since all the alternatives attempt to achieve the same desired vegetation conditions, all the alternatives are designed to eventually achieve higher amounts of Ponderosa pine habitat with an increased resilience to wildfire loss.

The alternatives for recommended wilderness, wild and scenic river suitability, and the recreation opportunity spectrum would have little impact on white-headed woodpeckers. Naturally, areas with more white-headed woodpecker habitat included in recommended wilderness would be slightly more beneficial for this species long term because fires from natural starts are allowed to burn restoring the natural disturbance patters of that these systems. However, it would also preclude active restoration needed to prevent potential loss from fuel build up resulting in uncharacteristic fire that could result in loss of mature Ponderosa pine trees. Most of the areas considered as recommended wilderness do not have white-headed woodpecker habitat, however. The exception is the Rapid River area, which could benefit white-headed woodpecker habitat by reducing the impacts of timber harvest in that area; it would also preclude restoration actions that may benefit white-headed woodpeckers.

The white-headed woodpecker is not a river dependent species and therefore, wild and scenic river suitability would have little effect on white-headed woodpeckers. Similarly, the alternatives that include the recreation opportunity spectrum classifications would have little effect on white-headed woodpeckers, with the exception that motorized access would allow firewood collection of Ponderosa snags. These activities would occur from existing roads and trails but are limited to the areas along roadsides. These activities may remove snags for white-headed woodpeckers. However, Ponderosa pine is not the most preferred tree species for firewood, though some people would collect some Ponderosa pine for firewood. Tree species more preferred for firewood include western larch, Douglas-fir, and lodgepole pine.

No Action Alternative

Under the No Action Alternative, vegetation conditions will continue to be departed from their historic natural range of variability. This is because the No Action Alternative directs management to manage the Nez Perce-Clearwater in the way that causes the departure in the first place. Restoration activities would continue at a lower rate, shade tolerant species would continue to be favored, and landscape pattern and patch size would continue to be departed. Similarly, fires would continue to be suppressed in much of the Nez Perce-Clearwater and would not move towards the natural range of variability. This direction would not restore Ponderosa pine habitats at a rate needed to restore the historical dominance of Ponderosa pine, nor maintain the open structure of past Ponderosa pine habitat. While these trends would continue, natural fire is projected to trend the Nez Perce-Clearwater back towards desired conditions regardless of restoration efforts. The land allocations would remain as currently composed.

Alternative W

Alternative W proposes an aggressive schedule to restore the natural range of variability. The aggressive schedule for restoration would best restore Ponderosa pine habitat to prevent loss from fuel build up and subsequent uncharacteristically hot fire. It also proposes the most recommended wilderness, which would only be slightly more protective than other alternatives because there is no white-headed woodpecker habitat in recommended wilderness areas. Alternative W recommends the Rapid River area as recommended wilderness which contains the most white-headed woodpecker habitat of the potential recommended wilderness areas considered in the alternatives. The Meadow Creek recommended wilderness area also contains limited amounts of white-headed woodpecker habitat. This alternative would include both of these areas as recommended wilderness. However, there is not much difference between management of Idaho Roadless Rule areas and recommended wilderness. The primary difference is whether timber harvest is suitable to meet other resource objectives. Timber harvest to meet other resource objectives is not suitable in recommended wilderness areas, therefore, restoration would need to occur via prescribed fire or more likely via wildfire. However, in much of the Nez Perce-Clearwater areas, fire would be the main operative disturbance, which would better restore size class, patch distribution, and forested habitats in most dominance types. Since Ponderosa pine forests have fuel build up as a result of fire exclusion, they would potentially burn hotter resulting in crowning and loss of mature trees. However, the modeling predicts that the trend towards these conditions will happen regardless of the alternatives. Alternatives of activities allowed within recommended wilderness would have little to no effect on white-headed woodpeckers. This alternative prohibits most activities in recommended wilderness except the use of motorized tools for the public and administrative uses. These would have no effect on white-headed woodpeckers.

Alternative X

Alternative X proposes the most aggressive schedule of disturbance to restore the natural range of variability. The aggressive schedule for restoration would best restore Ponderosa pine habitat to prevent loss from fuel build up and subsequent uncharacteristically hot fire, therefore, this would be the best alternative for restoring the structure and dominance types of white-headed woodpecker. Regardless of the alternative selected, the trend in the Nez Perce-Clearwater predicted by the SIMPPLLE model is that forest conditions will continue to trend towards similar conditions across all alternatives by Decade 5. Therefore, the effects to most of these habitats are similar in all alternatives because the desired conditions for forestlands do not vary. This alternative would be only slightly less protective than the other alternatives for wildlife habitats because Idaho Roadless Rule areas are fairly restrictive and would protect many of these habitats whether they are wilderness or not. All activities suitable within roadless rule areas would also be suitable within the various areas considered as recommended wilderness under this alternative. However, none of these activities would have much effect on white-headed woodpecker habitat, except that perhaps motorized suitability could allow some limited firewood gathering that might reduce some snags along existing roads or motorized trails.

Alternative Y

Alternative Y recommends lower amounts of recommended wilderness and is intermediate in the amount of vegetation management proposed. This alternative has a considerably slower rate of treatment to achieve desired vegetation conditions. This alternative achieves fewer acres of open forest structure in the dry broad potential vegetation type by the end of the 5-decade period in the SIMPPLLE model. This alternative would be only slightly less protective than the other alternatives for wildlife habitats because Idaho Roadless Rule areas are fairly restrictive and would protect many of these habitats. Regardless of the alternative selected, the trend in the Nez Perce-Clearwater predicted by the SIMPPLLE model is that forest conditions will continue to trend towards similar conditions across all alternatives by Decade 5. The effects to most of these habitats are similar in all alternatives.

Alternative Z

Alternative Z is intermediate in the amount of recommended wilderness it provides. The amount of recommended wilderness has little effect on the habitat for wildlife species over Idaho Roadless Rule areas. In some cases, recommended wilderness areas replicate natural disturbance patterns better than Idaho Roadless Rule areas. Alternative Z would best provide for species that use snags and dead trees as habitat because it would require the retention of 10-inch snags and larger. These measures would increase the number of snags retained by about a hundred snags in each potential vegetation type or dominance type within each 100 acres treated. Additionally, it would provide for those species that select smaller snags as preferred habitats. Regardless of the alternative selected, the trend in the Nez Perce-Clearwater predicted by the SIMPPLLE model is that forest conditions will continue to trend towards similar conditions across all alternatives by Decade 5. Therefore, the effects to most of these habitats are similar in all alternatives.

Preferred Alternative

The Preferred Alternative selects a pace to achieving desired vegetation conditions within 40 years. The desired vegetation conditions include an increase in Ponderosa pine dominance types both through the removal of encroaching vegetation and through harvest and planting of Ponderosa pine. The Land Management Plan also provides a timber harvest amount that may also remove some mature Ponderosa pine. Overall, Ponderosa pine increases as the total amount of large and very large Ponderosa pine increases. This should be beneficial to white-headed woodpeckers. A faster pace towards desired vegetation conditions is more beneficial to white-headed woodpeckers than a slower pace. The Preferred Alternative takes a more intensive approach that would restore these habitats more quickly. Under this alternative, white-headed woodpecker habitat increases because of forest management.

Effects to White-headed Woodpecker from Other Resources

Effects to white-headed woodpeckers from other resources resulting from plan direction are included in Table 211.

Table 211. Effects to white-headed woodpeckers from other resources resulting from plan direction

Resource Area	Environmental Consequences	Explanation
Terrestrial Ecosystems	Yes	Plan direction for warm dry potential vegetation types contributes positively to white-headed woodpecker habitat enhancement.
Biophysical Features	No	No consequences

Resource Area	Environmental Consequences	Explanation
Forestlands	Yes	Plan direction for warm dry potential vegetation types contributes positively to white-headed woodpecker habitat enhancement. Plan direction to conserve old growth Ponderosa pine habitats, along with the ability to alter them to change dominance to Ponderosa pine, would help to conserve white-headed woodpeckers.
Carbon Storage and Sequestration	No	No consequences
Meadow, Grassland, and Shrubland	No	No consequences
Fire Management	Yes	Changes to fire management direction would be positive for white-headed woodpecker compared to the No Action Alternative. Fire suppression was identified as a primary threat to this species and plan direction seeks to allow more flexibility to restore ecosystems with wildland fire.
Invasive Species	No	No consequences
Soil Resources	No	No consequences
Aquatic Ecosystems	No	No consequences
Water and Aquatic Resources	No	No consequences
Conservation Watershed Network	No	No consequences
Riparian Management Zones	No	No consequences
Infrastructure (Aquatic and Riparian)	No	No consequences
Energy and Minerals (Aquatic and Riparian)	No	No consequences
Lands and Special Uses (Aquatics and Riparian)	No	No consequences
Livestock Grazing (Aquatic and Riparian)	No	No consequences
Recreation (Aquatics and Riparian)	No	No consequences
Wildlife	Yes	Plan direction would provide for white-headed woodpeckers.
Multiple Use Wildlife	No	No consequences
Multiple Uses Elk	No	No consequences
Air Quality	No	No consequences
Tribal Trust	No	No consequences
Cultural Resources	No	No consequences
Municipal Watersheds	No	No consequences
Sustainable Recreation	No	No consequences
Scenery	No	No consequences
Public Information, Interpretation, and Education	No	No consequences
Land Ownership and Land Uses	No	No consequences

Resource Area	Environmental Consequences	Explanation
Infrastructure	No	No consequences
Suitability	No	No consequences
Ecosystem Services	Yes	Providing the opportunity to collect firewood could affect some white-headed woodpecker habitat features along roadways.
Timber	Yes	This activity could change some white-headed woodpecker habitats. Some timber production practices, especially those that regenerate mature Ponderosa pine, would be detrimental to white-headed woodpecker habitat and would take a long time to recover.
Livestock Grazing	Yes	Livestock grazing could impact shrublands or riparian habitats. However, plan components that direct the intensity or utilization of these habitats would mitigate or prevent consequences of this activity in white-headed woodpecker habitat. Aquatics plan components should conserve White-headed woodpecker habitats. These plan components would address this threat.
Energy and Minerals	No	No consequences
Special Forest and Botanical Products	No	No consequences
Designated Wilderness	Yes	Beneficial effects on white-headed woodpecker habitats.
Wild and Scenic Rivers	No	No consequences
Lolo Trail National Landmark	No	No consequences
Recommended Wilderness	Yes	Some white-headed woodpecker populations occur within some alternatives for recommended wilderness. Plan components directing management of recommended wilderness may prevent active management to enhance or restore white-headed woodpecker habitat.
Idaho Roadless Rule Areas	Yes	Some white-headed woodpecker populations occur within some roadless areas. Regulations directing management of some roadless themes may prevent active management to enhance or restore white-headed woodpecker habitat.
Research Natural Areas	No	No consequences
Lower Salmon	Yes	The Lower Salmon River Geographic Area has specific direction to address white-headed woodpecker habitats.
Gospel-Hump	No	No consequences
Pilot Knob	No	No consequences
Lolo Trail National Historic Landmark	No	No consequences
Special Interest Areas	No	No consequences

Conclusion

The effects to white-headed woodpeckers and their habitat from the suite of plan components vary across the range of alternatives within the Land Management Plan, mostly in the pace to achieving desired vegetation conditions. Prescribed fire, fuels treatments, and harvest will become an increasingly important tool for managing the Nez Perce-Clearwater and achieving desired ecosystem conditions. The action alternatives vary the intensity and acres of treatment used for fuels treatments, prescribed burning, vegetation restoration, and harvest but do reflect an increase in these activities from the current pace of treatments. The amount of recommended wilderness area and wild and scenic river suitability matter little to white-headed woodpeckers. Plan direction would move away from historical approaches of managing towards fire suppression to an approach that trends towards conditions that would benefit white-headed woodpeckers. Coarse filter plan components are the primary means to conserve white-headed woodpeckers, and the modeling supports the conclusion that the species would benefit from the proposed management and alternative selected.

Threatened, Endangered, Candidate, and Proposed Wildlife Species

The following analysis addresses the effects to federally listed threatened, endangered, candidate, and proposed (TECP) species and their habitat from the suite of plan components and range of alternatives considered in the Land Management Plan. This analysis will evaluate how the suite of plan components and alternatives provide for ecosystem integrity as it relates to federally listed wildlife and how the plan components and alternatives contribute to the recovery of federally listed threatened and endangered species and conserve proposed and candidate species.

Data was obtained from the most recent list of threatened, endangered, and candidate species via the U.S Fish and Wildlife Service's Information for Planning and Consultation (IPaC) database, accessed multiple times throughout the planning process. The most recent list updated list was obtained prior to closure on the biological assessment from the U.S. Fish and Wildlife Service's Idaho Department of Fish and Wildlife Office via the IPaC obtained on June 2, 2023, Project Code: 2023-0088941 (USFWS 2023). Information to develop plan components and complete the analysis was derived from various sources, including recovery plans, petitions for listing, 12-month findings, and other documents produced by the U.S. Fish and Wildlife Service. Plan components for lynx are identical to those in the Northern Rocky Mountains Lynx Direction (U.S. Department of Agriculture 2007d).

The Land Management Plan establishes direction for various wildlife habitats in relation to structure, function, composition, and connectivity. The plan also includes direction for the protection, enhancement, and restoration of threatened and endangered species and their habitats. The Land Management Plan interdisciplinary team worked closely to integrate plan direction during the development of the plan components, especially wildlife, vegetation, fire, and access or recreation.

Providing for ecological integrity is an outcome of the Land Management Plan. It starts with a comparison of the current abundance and condition of various habitats with ecological reference conditions (historic range of variability) based on knowledge of the past and an understanding of ecological processes, such as fire, flooding, insects, and disease. This coarse filter approach delivers ecological conditions that provide for the diversity and abundance of wildlife. The coarse filter approach is reflected in the Forestlands' desired conditions in the Land Management Plan. The coarse filter approach forms the foundation of the analysis for each species.

The best available scientific information about federally listed threatened, endangered, proposed, and candidate species was reviewed to understand how the required ecological conditions and ecological integrity contribute to the recovery or conservation of these species. In doing so, key ecosystem characteristics required by each species and key threats and stressors were identified and evaluated to determine whether they were in effect on the Nez Perce-Clearwater under the 1987 Plans and, if so, to what extent.

Generally, plan components were first developed to offer coarse filter ecosystem characteristics to deliver ecological conditions that would provide for ecological integrity and contribute to the recovery of threatened or endangered species and conserve candidate species. When ecological conditions were insufficient to contribute to the recovery of federally listed threatened or endangered species or conserve candidate species, species-specific plan components were developed where appropriate. The species-specific plan components include desired conditions, goals, objectives, suitability, standards, and guidelines.

A spatial and temporal analysis provided the basis for conclusions about the effects of plan direction and plan components on threatened, endangered, candidate and proposed (TECP) species. In general, the analysis area for environmental consequences for these species includes the National Forest System lands within the Nez Perce-Clearwater. Areas selected for analysis of cumulative effects were large enough to include the consequences of activities on all lands but not large enough to obscure effects. The cumulative effects for each species are identified in their respective sections.

A thorough review of scientific information was completed, and the best available scientific information was used to inform the planning process and develop plan components. Key information on the population, life history, and status of TECP animal species on the Nez Perce-Clearwater was obtained from a variety of sources. Part 219.3 of the 2012 Planning Rule requires the responsible official to use the best available science to determine what is most accurate, reliable, and relevant. For the best available scientific information, the Nez Perce-Clearwater used available peer-reviewed articles and data in which reliable statistical or other scientific methods were used to establish the accuracy or uncertainty of any findings (Forest Service Handbook 1909.12 Zero Code 07.12). For best relevance, the Nez Perce-Clearwater used studies conducted in proximity to the plan area in north central Idaho, eastern Washington, eastern Oregon, western Montana, or western North America in habitat conditions like those that occur in the plan area. If these were not available, articles were selected that considered ecological processes or conditions relevant to the analysis area. The Nez Perce-Clearwater attempted to avoid professional opinion or publications that have not been peer-reviewed when peer-reviewed information was available. However, in accordance with 2012 Planning Rule directives on sources of scientific information, scientific information that may be considered the best available scientific information may include expert opinions, panel consensuses, inventories, or observational data prepared and managed by the Forest Service, other federal agencies, universities, national research networks, other reputable scientific organizations and data from public and governmental participation. In some cases, there is opposing, incomplete, or unavailable scientific information about a species or its habitat. This was also considered in accordance with requirements of the National Environmental Policy Act. Data and information gaps exist, but the breadth and depth of the available scientific information is sufficient to determine the key stressors and plan components to address those key stressors.

Existing Condition

The Nez Perce-Clearwater queried the U.S. Fish and Wildlife Service's Information for Planning and Consultation (IPaC) database for a list of federally listed species and is included below (Table 212). Because of the size of the spatial data used in the request, queries were requested separately for the Nez Perce and Clearwater National Forests, but the species lists for the two forests were the same.

Table 212. List of wildlife species in the plan area identified as federally listed by the U.S. Fish and Wildlife Service

Common name	Latin name	Federal listing	Comments
Grizzly Bear	*Ursus arctos horribilis*	Threatened; No Critical Habitat Designated; Plan Area Contains Part of the Bitterroot Recovery Zone	Transitory grizzly bears may be present in portions of the Plan Area. The Plan Area does not have a population of grizzly bears
Canada Lynx	*Lynx canadensis*	Threatened; No Critical Habitat Designated	Clearwater National Forest is occupied, Nez Perce National Forest is unoccupied. Transitory

Common name	Latin name	Federal listing	Comments
			lynx may be present within any portion of the Plan Area
North American Wolverine	*Gulo gulo*	Proposed Threatened; No critical habitat has been designated for this species.	Occupies the Nez Perce-Clearwater National Forest
Northern Idaho Ground Squirrel	*Urocitellus brunneus*	Threatened; No critical habitat has been designated for this species.	Does not occur on the Nez Perce-Clearwater National Forest (but does occur in Idaho County).

Bull trout, whitebark pine, and Spalding's catchfly were also identified as occurring within the plan area but are addressed in other sections. The Northern Idaho Ground squirrel (*Urocitellus brunneus*) is included in the list of threatened and endangered species received from U.S. Fish and Wildlife Service, but this species is not known to occur within the plan area. While there is no established population of grizzly bears, they may be present in the Nez Perce-Clearwater. Furthermore, the plan area contains portions of the Bitterroot Recovery Zone, and the grizzly bear has been a subject of interest from the public in comments and will be addressed below.

Past resource use and the exclusion of fire for almost 100 years has caused changes in some wildlife habitats. As documented in the Land Management Plan analysis, defining and measuring the status of ecosystems now and comparing them to desired future conditions is the foundation for sustainability of ecosystems on the Nez Perce-Clearwater. The vegetation features assessed as “key indicators” for wildlife considered include changes in forest composition, structure, and pattern. These features are very much related to the quality and quantity of wildlife habitats.

The allocation of lands on the Nez Perce-Clearwater has been divided in the past by congressional or agency designations, such as designated wild and scenic rivers, designated wilderness, and Idaho Roadless Rule areas. Thus, the bulk of the land area consists of these designated areas. While many people are interested in what happens in the managed front, about two-thirds of the Nez Perce-Clearwater is influenced by these designations. It made sense during the development of the plan to identify these different areas as management areas. The distribution of the various management areas has greater influence on the overall impact of the management of the Nez Perce-Clearwater on wildlife. See the Land Management Plan for the management area descriptions.

Lynx

On March 24, 2000, the U.S. Fish and Wildlife Service published the final rule listing the contiguous United States distinct population segment of Canada lynx as a threatened species (65 FR 16052). In its analysis of threats to the species, the U.S. Fish and Wildlife Service concluded that the single factor threatening the distinct population segment was the inadequacy of existing regulatory mechanisms, specifically the lack of guidance for conservation of lynx in National Forest System land, resource management plans, and Bureau of Land Management land use plans. The U.S. Fish and Wildlife Service prepared a recovery outline for the Canada lynx (U.S. Department of the Interior 2005a). A recovery outline is intended to provide interim guidance for consultation and recovery efforts until a formal recovery plan has been approved. No recovery plan has been developed for lynx. The recovery outline did not establish recovery goals but did identify a preliminary set of objectives and potential recovery actions for each area. Under the recovery outline, lynx habitat was stratified into core, secondary, and peripheral areas based on lynx occupancy, reproduction, and use, as documented by historical and current records. The U.S. Fish and Wildlife identified core areas where there was strong evidence of long-term persistence of lynx populations, including both historical records of lynx occurrence over time and recent evidence of presence and reproduction within the past 20 years. Both the Nez Perce and Clearwater National Forests are secondary areas for Canada lynx, as identified by the U.S. Fish and Wildlife Service (U.S. Department of the Interior 2005a).

The Northern Rockies Lynx Management Direction (NRLMD) amended 18 forest plans for the national forests in Idaho, Montana, Utah, and Wyoming, including the Nez Perce-Clearwater (U.S. Department of Agriculture 2007c). The amendment adopted forest plan components applicable to vegetation management, livestock grazing, human uses, and linkage areas to conserve and promote the recovery of the lynx by reducing or eliminating adverse effects from land management activities on National Forest System lands while preserving the overall multiple-use direction in existing plans. In March of 2007, the U.S. Fish and Wildlife Service issued a biological opinion on the effects of the Northern Rocky Mountains Lynx Amendment on the distinct population segment of Canada lynx in the contiguous United States. In its 2007 biological opinion, the U.S. Fish and Wildlife Service concluded that the level of adverse effects to lynx that may result from implementation of the NRLMD are not reasonably expected to either directly or indirectly appreciably reduce the likelihood of survival and recovery of the lynx distinct population segment in the wild by reducing the reproduction, numbers, or distribution of lynx (Interagency Lynx Biology Team 2013). The Clearwater National Forest was considered occupied while the Nez Perce National Forest was considered unoccupied. Both national forests are considered secondary habitat for Canada lynx. The effects were considered differently between the national forests—the effects on the Clearwater National Forest were evaluated for resident lynx while the effects on the Nez Perce National Forest were considered for transient lynx.

Methodology and Analysis Process

Canada lynx use of habitat within their home range is dependent upon vegetation condition. Lynx analysis units are landscape units that approximate the size of a female lynx's annual home range and encompass all seasonal habitats. These may also contain areas of non-lynx habitat, such as open meadows, especially in mountainous regions (Interagency Lynx Biology Team 2013). The existing vegetation condition of Canada lynx habitat is estimated for each lynx analysis unit on the Nez Perce-Clearwater based upon past vegetation treatments and historic fire occurrence data.

For the Land Management Plan, habitats across the Nez Perce-Clearwater have been grouped into broad potential vegetation types (PVTs). These are groupings based upon habitat types. PVTs serve as a basis for describing certain ecological conditions across the Nez Perce-Clearwater and are useful in understanding the various ecosystems and their potential productivity, natural biodiversity, and the kinds of processes that sustain these conditions. PVTs are based upon vegetation potential, whereas dominance types describe existing vegetation.

In 2014, as part of the Land Management Plan process, the mapped lynx habitat was revised to develop consistent mapping criteria across both the Nez Perce and Clearwater National Forests and to include the best available scientific information concerning lynx population dynamics, distribution, habitat use, competitor interactions, prey species, and human interactions that have become available since 2007. This mapping was also completed in coordination with the U.S. Fish and Wildlife Service and was based upon broad PVTs. This process resulted in the revised mapping of 78 lynx analysis units across the Nez Perce-Clearwater (U.S. Department of Agriculture 2014d). The revised lynx analysis units will be used to display the amount, relative quality, and distribution of lynx habitat across the Nez Perce-Clearwater. See the 2014 Nez Perce-Clearwater Forest Plan Assessment (U.S. Department of Agriculture 2014d) for more details on this and other aspects of the methodology and analysis process. This analysis and change in lynx analysis units is in line with guidance within the Northern Rockies Lynx Management Direction (NRLMD) with review and approval by regional staff.

After this mapping effort, the Nez Perce-Clearwater experienced large wildfires between 2015 and 2018. The amount of habitat currently unsuitable for lynx required updating to have an accurate accounting of effects and modeling with PRISM and SIMPPLLE. Therefore in 2018, the Nez Perce-Clearwater updated the habitat spatial data to update the amount of habitat currently unsuitable within lynx analysis units (Lutes 2019). The update consisted of using the Forest Service Activity Tracking System (FACTS) database to update areas currently unsuitable due harvest activities and updating the amount of habitat that changed from unsuitable to suitable as a result of forest aging and used burn severity data from sources, such as Rapid Assessment of Vegetative Condition after Wildfire (RAVG), Burned Acres Reflectance Classification (BARC), or Monitoring Trends in Burn Severity (MTBS), to identify areas of potential lynx habitat which burned at moderate to severe levels which were considered currently unsuitable for lynx. For more detailed information about the lynx habitat mapping process see the Nez Perce-Clearwater National Forest' Forest Plan Assessment (U.S. Department of Agriculture 2014d) and the U.S. Department of Agriculture's 2019 Lynx Habitat Mapping Update 2018 Process Steps (Lutes 2019).

In Olson (2021) and others developed a refined model of lynx habitat across the northwestern United States using environmental predictors and GPS data from lynx populations in Washington, Montana, and Wyoming. This model indicates high relative probability of lynx habitat on the Idaho and Montana sides of the Lolo Pass area, south of Powell in the Wind Lakes, Kooskookia Meadows, and Elk Summit Area. This habitat model is currently under review for use as a habitat analysis and management tool within the Northern Region. If adopted, lynx analysis unit boundaries may be re-delineated to better line up with the new model.

PRISM modeling was used to estimate forest growth, trends, and yield. The PRISM results were then run through SIMPPLLE to project out 50 years on how the Nez Perce-Clearwater will interact with wildfire, insects and disease, and vegetation management under the alternatives. The SIMPPLLE model is a spatially explicit model that uses logic pathways to predict how forests respond over time to succession, wildfires, and insect and disease risks based on cover types, size classes, crown closure, aspect, and slope (Chew, Moeller, and Stalling 2012). This model was used for assessments of the natural range of variation and the potential future consequences of alternatives. For the Final Environmental Impact Statement, SIMPPLLE model pathways and assumptions were updated to better reflect the northern Idaho climate, tree growth, dominance type behavior, and fire behavior. The updated models and assumptions provided improved estimates of the natural range of variability and vegetation and responses to management. The changes are described in the Forestlands section and appendices.

Information Sources and Incomplete or Unavailable Information

A synthesis of information on lynx biology and ecology that is relevant to lynx at the national scale can be found in *Ecology and Conservation of Lynx in the United States* (Ruggiero and McKelvey 1999) and in the Canada Lynx Conservation Assessment and Strategy (Interagency Lynx Biology Team 2013). The final rule listing lynx (65 FR 16052) and the notice of remanded determination (68 FR 40076) evaluated population status and threats for the contiguous United States distinct population segment. The recovery outline (U.S. Department of the Interior 2005a) provided preliminary recovery objectives and actions based on an understanding of current and historical lynx occurrence and lynx population dynamics in the contiguous United States.

At the forest scale, some information used to assess lynx habitat is incomplete or unavailable. At any given point in time in a forest stand's development, it may provide habitat in a suitable condition, or it may provide lynx habitat in a temporarily unsuitable condition, depending upon the existing vegetation condition. Vegetation condition is dependent upon time due to disturbances, such as fire and timber harvest, and the rate of forest succession. Satellite imagery and forest databases can be used to accurately classify recently harvested and burned areas, which helps to identify areas that provide lynx habitat in an unsuitable condition on a temporary basis. However, satellite imagery is poor at detecting the dense horizontal cover that provides snowshoe hare habitat in a multistory forest structure, which is an important feature of lynx foraging habitat, and downed woody material for denning habitat. Therefore, no forestwide estimates were made for these components of lynx habitat. During site-specific planning, habitat types used for the modeling and mapping of lynx habitat are verified and refined and lynx habitat is further characterized to estimate the amount and distribution of foraging and denning habitat components.

In February 2009, the U.S. Fish and Wildlife Service designated revised critical habitat in Montana, Wyoming, Idaho, Washington, and other states. Critical habitat was not designated on the Nez Perce or Clearwater National Forests. On September 26, 2013, the U.S. Fish and Wildlife Service published a proposed rule for revised critical habitat in the Federal Register (50 CFR Part 17—Canada Lynx). No critical habitat was proposed for the Nez Perce-Clearwater in the proposed rule.

Analysis Area and Temporal Scale of Analysis

The period considered for the analysis of indirect effects of the alternatives is the anticipated life of the Land Management Plan, which is about 15 years. However, because lynx habitat is dynamic, the anticipated vegetation and changing climate conditions were evaluated over longer time periods. The SIMPPLLE model was used to estimate the natural range of variation as it would have influenced forest ecosystems on the Nez Perce-Clearwater going back about 1,000 years (See Appendix B). The effects of the alternatives on lynx habitat were modeled over the next 50 years by the Ecosystem Research Group in 2019. The Ecosystem Research Group modeled several scenarios for comparison purposes, including a warmer, drier climate over the next five decades and acres burned. Lynx habitat on the Nez Perce-Clearwater is subdivided into lynx analysis units for the analysis of effects on Canada lynx. Lynx habitat within the U.S. Fish and Wildlife Service Northern Rockies Geographic Area has been divided into lynx analysis units to facilitate analysis, management, and monitoring. A detailed description of how lynx habitat and lynx analysis units were mapped can be found in the 2014 Assessment (U.S. Department of Agriculture 2014d) and a summary of those efforts are presented below. A map of the lynx analysis units and lynx habitat are found within the Final Environmental Impact Statement Appendix A.

The area used for the analysis of indirect effects on Canada lynx is the Nez Perce-Clearwater's modeled lynx habitat (U.S. Department of Agriculture 2014d). Habitat mapping criteria were developed to represent important life history characteristics, including foraging and denning. Lynx analysis unit delineations and habitat mapping actions directed by the Canada Lynx Conservation Assessment and Strategy (Ruediger et al. 2000a) were completed for both the Nez Perce and Clearwater National Forests. Mapping of primary habitat was based on forest types necessary to support lynx survival and reproduction specific to each geographic area (Ruediger et al. 2000b, Sandberg et al. 2002). The Nez Perce National Forest initially mapped lynx habitat between 2000 and 2002 and then revised the mapped habitat in 2004. The Clearwater National Forest revised its mapped lynx habitat in 2007. This mapping was completed in coordination with the U.S. Fish and Wildlife Service. The area of lynx habitat modeled and mapped by the Nez Perce-Clearwater in 2014 was 1,457,768 acres.

The size of the lynx analysis unit reflects female home range size in the geographic unit. Enough habitat must be present within the lynx analysis unit to support a female lynx. For example, in the western United States, it appears that at least 10 square miles of primary vegetation must be present. The arrangement of habitat within the lynx analysis unit should take into consideration the daily movement distances of resident females. Since the lynx analysis unit represents a hypothetical female home range and is the basis for analysis, it can be larger and contain more lynx habitat than an actual home range.

Lynx analysis units on the Nez Perce-Clearwater are in accordance with guidance provided in the Canada Lynx Conservation Assessment and Strategy (Interagency Lynx Biology Team 2013) and the Northern Rockies Lynx Management Direction. There are 79 lynx analysis units that are wholly or partially within the Nez Perce-Clearwater. These lynx analysis units encompass a total of about 2,505,072 million acres on the Nez Perce-Clearwater. Changes to lynx analysis units may only be made if site-specific habitat information demonstrates it is needed and after review by the Forest Service Northern Region Regional Office. As there is no critical habitat for lynx in the plan area, there are no effects to critical lynx habitat.

The Northern Rockies Geographic Area encompasses 18 national forests and an estimated 18.5 million acres of lynx habitat in Montana, Idaho, Wyoming, and Utah. The Northern Rockies Geographic Area provides context for the analysis of cumulative effects. Adjoining areas in Canada were also considered with respect to connectivity. See Appendix A for a map of the lynx habitat and linkages.

Forest and Lynx Ecology

Across their range, lynx typically occur in boreal and subalpine coniferous forests dominated by subalpine fir and spruce in landscapes with gentle topography (Squires et al. 2013). On the Nez Perce-Clearwater, the cool moist and cold potential vegetation types (PVTs) are capable of growing subalpine fir, Engelmann spruce, and lodgepole pine, but the dominance type and structural stage can change over time due to factors, such as fire, insects and disease, vegetation management, and forest succession (U.S. Department of Agriculture 2014l). Engelmann spruce and subalpine fir tree species may also be found in other forest dominance types because they are very shade tolerant and commonly occur in mid-story and understory tree canopy layers with western larch, lodgepole pine, and Douglas-fir in the overstory. Lodgepole pine has been found to be an important component of mixed conifer stands in lynx habitat (Holbrook, Squires, Olson, DeCesare, and Lawrence 2017). Lodgepole pine is a fire adapted species that can dominate after wildfire. It can also be a component in mixed conifer stands. Lynx modeling incorporated these broad PVTs within the cold and cool moist broad PVTs as modeled lynx habitat.

During the winter and early spring, availability of den sites is important to lynx. Boutros et al. (2007) and Moen et al. (2008) found that coarse downed woody material provides kittens with protection from extreme temperatures, precipitation, and predators (Interagency Lynx Biology Team 2013). Lynx dens are typically found in multistory stands of spruce-fir forests with dense horizontal cover and abundant coarse downed woody material. Squires et al. (2008) found that 80 percent of dens were in mature forest stands and 13 percent in mid-seral regenerating stands. Young stands that were either naturally sparse or mechanically thinned were seldom used for denning. Denning habitat is generally abundant across the coniferous forest landscape of north central Idaho and is not likely to be limiting for lynx (Squires et al. 2008, 2010, Squires et al. 2006).

In Montana, Squires et al. (2010) reported that horizontal cover was denser at lynx kill sites than along travel paths. They further reported that lynx kill sites were associated with a higher proportion of spruce-fir overstory than lodgepole pine overstory and that neither snow depth nor snow penetrability influenced lynx kill sites. In Ruggiero et al. (2007), Hodges reported that snowshoe hare abundance is also positively associated with dense horizontal cover. In western Montana, Griffin and Mills (2007) found the highest snowshoe hare densities in regenerating conifer stands that had a high density of saplings, defined as more than 2,267 stems per acre, in mature multistory conifer stands that had abundant saplings. Hare abundance was negatively affected in stands treated with traditional pre-commercial thinning prescriptions that reduced stem densities to about 263 to 526 stems per acre (Griffin and Mills 2007).

Squires et al. (2010) compared lynx resource selection in summer versus winter, including lynx success in capturing snowshoe hares, their primary prey. During winter, lynx foraged primarily in mid- to high-elevation forests at 4,134 to 7,726 feet composed of mature large-diameter trees with a diameter at breast height greater than 11 inches. In a comparison of use versus availability within a lynx home range, Squires et al. (2010) found that lynx selected forests with relatively denser horizontal cover, more abundant hares, and deeper snow. They preferred forests that had a multistory structure with dense horizontal cover provided by the young trees in the understory and conifer boughs touching the snow surface, which could support snowshoe hare populations at varying snow depths throughout the winter. Engelmann spruce and subalpine fir were the dominant tree species in forests used by lynx, but these forests contained a mix of other conifer species, including lodgepole pine, western larch, and Douglas-fir. Squires et al. (2010) stated that the primary limiting factor for Canada lynx in northwest Montana appears to be suitable winter foraging habitat.

During the summer months, lynx in Montana broaden their preferred habitat use to include more of the early-successional forest stand initiation structural stage with dense horizontal cover provided by abundant shrubs, spruce and fir saplings, and small-diameter trees (Squires et al. 2010). These conditions can occur in forests burned by wildfire, regenerated by insects or disease, or regenerated by timber harvest. Squires et al. (2010) found that lynx used slightly higher elevations during the summer but, as in winter, were located below the alpine zone and above the low-elevation dry forests dominated by Ponderosa pine. The low-elevation Ponderosa pine forests were not modeled as potential lynx habitat on the Nez Perce-Clearwater.

Young regenerating stands of 20 to 40 years can support high densities of snowshoe hares before growing into a structure that no longer provides the needed dense horizontal cover. A regular influx of this “early stand initiation stage” of forest succession created by processes such as fire or vegetation management can help to enhance snowshoe hare production. Cheng et al. (2015) studied snowshoe hare densities in areas of Glacier National Park that were burned by wildfire in 1988 and 1994. Hare pellet densities in lodgepole pine stands were 10 times higher 17 years post-fire at the time of their study than in the 11-year post-fire forests or other mature forests. Their “best” model for habitat predicted that the mean pellet density for 17-year-old lodgepole forests equates to hare densities nearly three times the threshold believed necessary to support lynx populations. Among the continuous habitat parameters measured in the Cheng et al. (2015) study, only understory cover at a height of 0 to 20 inches above the ground surface and percent canopy cover were identified as predictors of hare density. Mean pellet density increased slowly with understory cover up to 80 percent, above which pellet densities declined (Cheng et al. 2015). Mean pellet densities increased from 10 percent canopy closure to 70 percent canopy closure when other variables were held at typical values. Cheng et al. (2015) stated that snowshoe hares’ association with diregenerating lodgepole pine forests is transient because these forests will eventually grow tall enough and dense enough to no longer provide the habitat conditions selected by snowshoe hares.

At the landscape scale, a mosaic of forest structure, from young regenerating to mature multistory stands, is recommended to provide for the habitat needs of lynx (U.S. Department of Agriculture 2020a). Kosterman et al. (2018) collected field data on denning and offspring survival in northwest Montana from 1998 to 2012, studying the relationship between female lynx reproductive success and habitat composition and arrangement at the scale of a lynx home range on the Kootenai and Lolo National Forests. Kosterman et al. (2018) found that abundant and connected mature forests and intermediate amounts of small-diameter regenerating forests defined whether the female produced kittens or not. Small-diameter regenerating forests were described as “smaller sized” trees with an approximate diameter at breast height of 3.93 to 5.9 inches, intermediate canopy cover, and high horizontal cover. Reproductive success was highest for females with small-diameter regenerating forests between 12 to 20 percent and higher connectivity of mature forest. Reproductive success remained high when forests had small-diameter sized trees up to 20 percent and then declined slightly beyond 20 percent. Kosterman et al. (2018) suggested that in addition to the connectivity of mature forest, the amount of small-diameter regenerating forests aids the reproductive success of female lynx.

The Canada lynx range extends from Alaska, across much of Canada, except for the coastal forests, with southern extensions into parts of the western United States, the Great Lakes region, and the northeast. Lynx distribution is closely tied to the distribution of snowshoe hares and boreal forests (McKelvey, Aubry, and K. 1999). The Nez Perce-Clearwater is in the U.S. Fish and Wildlife Service's Northern Rocky Mountain Region of the contiguous distinct population segment of Canada lynx.

Snowshoe hares are the primary winter prey of lynx (Squires and Ruggiero 2007), as they are throughout the range of lynx (Ruggiero et al. 1999). Lynx are highly specialized predators of snowshoe hares with unique adaptations that include a lightweight body frame and large paws that enable them to travel on top of deep snow. In their study of lynx winter diets in northwest Montana, Squires et al. (2013) described 86 lynx kills that included 7 prey species. Snowshoe hares contributed about 96 percent of prey biomass, whereas red squirrels, the second most common prey, provided only about 2 percent of prey biomass (Squires et al. 2006).

Lynx do not occur everywhere within the range of snowshoe hares in the contiguous United States, as discussed in both Bittner and Rongstad (1982) and McCord and Cardoza (1982). This may be due to inadequate abundance, density, the spatial distribution of hares in some places, the absence of snow conditions that would allow lynx to express a competitive advantage over other hare predators, or a combination of these factors (U.S. Department of the Interior 2014c). In the southern part of its range, the low densities of lynx populations are likely a result of naturally patchy habitat and lower densities of their snowshoe hare prey (Adams 1959, Griffin and Mills 2004, Koehler et al. 1979, Mills et al. 2005).

The most commonly reported causes of Canada lynx mortality include (1) starvation, especially of kittens, and (2) human-caused mortality, including trapping and shooting (Interagency Lynx Biology Team 2013). Predation of lynx by mountain lion, coyote, wolverine, gray wolf, fisher, and other lynx has been confirmed (Interagency Lynx Biology Team 2013). Squires and Laurion (1999) reported that two out of six mortalities of radio-collared lynx in Montana were due to mountain lion predation.

About 0.23 percent, or about 3,352.8 acres, of lynx habitat in lynx analysis units was treated by regeneration harvest on the Nez Perce-Clearwater since 2000 (FACTS data, accessed August 2019). Holbrook et al. (2018) evaluated lynx resource use of silviculture treatments over a temporal gradient of 1 to 67 years after treatment. They found that, while lynx used treatments, lynx use was low until approximately 10 years of age for all forest treatment types, including thinning, selection cuts, and regeneration cuts. Furthermore, cumulative use in both winter and summer by lynx reached 50 percent at approximately 20 years after a thinning treatment.

While it took about 20 years for lynx to begin using regeneration and selection cuts (Holbrook et al. 2018), it took approximately 34 to 40 years after a selection or regeneration cut for cumulative lynx use to reach 50 percent. Lynx use of regeneration cuts in the winter was best explained by time since treatment. In summer, the composition and abundance of forest structural stages surrounding a particular treatment also influenced lynx use (Holbrook et al. 2018). Lynx appeared to use regeneration and selection cuts similarly over time, suggesting that the difference in vegetation impact between these treatment methods makes little difference relative to potential impacts to lynx.

Holbrook et al. (2017) found that snowshoe hares were associated with horizontal cover and that hare use increased with increasing amounts of horizontal cover. Horizontal cover increased with the abundance of subalpine fir and Engelmann spruce forests. Holbrook et al. (2017) also demonstrated a relationship between the abundance of lodgepole pine and snowshoe hare abundance in addition to horizontal cover. Snow depth was an important covariate to predict snowshoe hare occupancy, and snow depth is predicted to decrease under future climates. Their data indicated that dense horizontal cover within multistoried forests with a substantial component of medium-sized trees of 5 to 10 inches produced the highest use by snowshoe hares (Holbrook, Squires, Olson, Lawrence, and Savage 2017). Results from their data support conclusions like previous studies in that disturbing multistoried forests with high stem densities, particularly in the understory, by cutting or burning would likely have a negative effect on snowshoe hares in the short-term but may benefit them in the future (Holbrook, Squires, Olson, Lawrence, and Savage 2017).

Under some conditions, motorized over-snow vehicle use may have detrimental effects on lynx. In the past, some researchers have speculated that compacted trails could indirectly affect Canada lynx by serving as travel routes that might enable competing predators, such as coyotes, to access snowshoe hare prey in lynx habitat (Murray and Boutin 1991, Murray et al. 1994, Ruggiero et al. 1999). However, in its remanded determination (68 FR 40076), the U.S. Fish and Wildlife Service (2003) found no evidence of competition between lynx and other predators or no evidence that it exerts a population-level impact on lynx if competition exists. Therefore, the U.S. Fish and Wildlife Service did not consider compacted trails to be a threat to lynx. Additionally, Kolbe et al. (2007) completed a study of the effect of snowmobile trails on coyote movements in lynx habitat in northwest Montana. They reported that coyotes in their study area were primarily scavengers in winter since snowshoe hare kills composed only three percent of coyote feed sites. Furthermore, coyotes did not forage closer to compacted snowmobile trails than random expectation and the overall influence of snowmobile trails on coyote movements and foraging success appeared to be minimal (Kolbe et al. 2007). However, because snow compaction results varied across the 18 national forests encompassed by the Northern Rockies Lynx Management Direction, guideline HU G11 specified that designated over-the-snow routes or designated play areas should not be expanded outside baseline areas of consistent snow compaction unless designation serves to consolidate use and improve lynx habitat. Squires et al. (2010) reported on the effects of snowmobiling on Canada lynx in their Seeley Lake, Montana study area. They were unable to quantify the number of snowmobiles using National Forest System roads in lynx home ranges, but one primary groomed trail was used by approximately 130 snowmobiles per day. They reported that they found no evidence that lynx selected areas away from National Forest System roads or groomed snowmobile trails during winter.

Effects of winter recreation on lynx were studied in Colorado. Olson et al. (2018) tracked 18 lynx and concurrently tracked snowmobilers and backcountry skiers. They found that lynx decreased their movement rate in areas with high-intensity back-country skiing and snowmobiling and adjusted their temporal patterns so that they were more active at night in areas with high-intensity recreation but did not find consistent evidence of spatial avoidance of recreation. Lynx exhibited some avoidance of areas with motorized recreation but selected areas near non-motorized recreation trails. Lynx did avoid high intensity use ski resorts, especially when use was intense. Olson et al. (2018) concluded that lynx did not exhibit strong negative responses to dispersed recreation but instead altered their behavior and temporal patterns in a nuanced response to recreation, perhaps to decrease direct interactions with recreationists. Based on observed avoidance of developed recreation, Olson et al. (2018) concluded that there may be a threshold of human disturbance above which lynx cannot coexist with winter recreation.

Affected Environment—Canada Lynx Habitat

The lynx recovery outline (U.S. Department of the Interior 2005a) stratified lynx habitat into three categories: core, secondary, and peripheral. Core areas are places where long-term persistence of lynx and recent evidence of reproduction have been documented and where the quality and quantity of habitat provides for both lynx and snowshoe hare. The lynx recovery outline emphasized focusing conservation efforts on core areas to ensure the continued persistence of lynx in the contiguous United States. Six core areas were identified in the recovery outline while other areas were identified as secondary habitats for lynx. The Nez Perce-Clearwater is located entirely within secondary areas.

Specimen records of lynx in Idaho during the early 1900s are relatively common (McKelvey, Aubry, and K. 1999). McKelvey et al. (1999) reported 22 museum specimens of lynx from 1874 to 1917, all of which were collected north of the Snake River plain in Idaho. Thirteen other verified records prior to 1960 were also from the north central and northern regions of the state (McKelvey, Aubry, and K. 1999). There are 35 verified records from 1960 to 1991 with most coinciding with lynx eruptions in the 1970s.

Idaho Department of Fish and Game personnel surveyed 20 routes that had adequate snow conditions from 2004 to 2006 and detected no lynx (Interagency Lynx Biology Team 2013). From 2010 to 2013, the Idaho Department of Fish and Game conducted forest carnivore surveys in the Selkirk, Purcell, and West Cabinet Mountains, finding one male lynx in the Selkirk's in 2010 and one male lynx in the Idaho Purcell Mountains in 2011. In 2012, a lynx was found on the Salmon-Challis National Forest. One lynx was also found in northern Idaho in 2013. In February of 2014, a lynx was captured and collared in the West Cabinet Mountains. Lucid et al. (2016) surveyed for multiple species between 2010 and 2014 in a multi-basin initiative in the Panhandle region of Idaho. During these surveys, Lucid et al. (2016) detected two male and three female Canada lynxes within the Purcell, Cabinet, and Selkirk Mountains. Lynx were not detected in the Coeur d'Alene or Saint Joe National Forests (Lucid et al. 2016).

Using protocol developed by Squires et al. (Squires et al. 2004, Squires et al. 2012), snow track surveys in 2007 (Ulizio et al. 2007) and again in 2013 (Stone et al. 2013) on the Nez Perce National Forest did not detect lynx. In 2013, an experienced lynx tracking crew covered all routes twice, which strengthens the detection probability that can suggest absence with 95 percent certainty if present, or conversely (Squires et al. 2012). Much of the surveyed area appears to be suitable habitat that supports snowshoe hare and the lack of detection suggests that lynx are rare or infrequent to the Nez Perce National Forest. Following the protocol established by McKelvey et al. (1999), five transects hair snare surveys during the summer and fall of 2008 on the Nez Perce National Forest also did not detect lynx (Bonn 2008).

Lynx are wide-ranging animals. The presence of a population would be detected given the vast network of roads and trails given the lynx-specific survey work conducted on the Nez Perce National Forest and extensive surveys for other species using hair snares, snow track surveys, and camera stations conducted on the Clearwater National Forest, such as the U.S. Fish and Wildlife Service grizzly bear survey between 2008 to 2009, the Forest Service fisher survey between 2002 to 2014, and the Idaho Department of Fish and Game yearly aerial surveys for many species. Historical sightings that have been confirmed may be the result of transient lynx moving through the Nez Perce-Clearwater, but the infrequency of such reports suggests that lynx are incidental to the area (Ulizio et al. 2007).

In the Northern Rockies Lynx Management Direction (NRLMD), the Nez Perce National Forest was reportedly unoccupied while the Clearwater National Forest was considered to be occupied based on the best scientific information available at the time of the NRLMD Forest Plan Amendment. However, due to inconsistencies on the status of lynx presence or occupancy on the Nez Perce National Forest, the U.S. Fish and Wildlife Service sent a letter addressed to Forest Supervisor Rick Brazell on December 10, 2012, stating that "there is consensus that transient lynx may be present on the Nez Perce National Forest, at least occasionally" (U.S. Fish and Wildlife Service, 2012).

The U.S. Fish and Wildlife Service referenced two pieces of information to come to this conclusion:

- Ulizio et al. (2007) noted "historical sightings that may have been confirmed may be the result of transient lynx moving through the forest, but the infrequency of such reports suggests lynx are incidental to the area."
- McKelvey et al. (1999) reported numerous verified historical records from Idaho County.

The letter also stated that the issue of lynx occupancy on the Nez Perce National Forest is a separate but related matter that is not the focus of this letter and did not change the Nez Perce National Forest status as "unoccupied" (U.S. Fish and Wildlife Service, 2012). Therefore, under the NRLMD, the Nez Perce National Forest is considered unoccupied, and the Clearwater National Forest is considered occupied. The U.S. Fish and Wildlife Service has determined that lynx "may be present" on both national forests, and both are secondary areas. While lynx have occasionally been sighted on the national forests, currently, little evidence exists of a resident lynx population or reproduction on the Nez Perce-Clearwater due to the infrequent nature of lynx observations. The 2005 Canada Lynx Recovery Area map identified the Nez Perce-Clearwater as a "secondary" Canada lynx area (U.S. Department of the Interior 2005b). The U.S. Fish and Wildlife Service's 2014 reexamination of critical habitat for lynx concluded that the lands in the Nez Perce and Clearwater National Forests "were likely not occupied by lynx at the time of listing and are not currently occupied by lynx populations" (79 FR 54818 2014).

Nevertheless, since there were two observations since 1999, the Clearwater National Forest met the criteria for identification by the U.S. Fish and Wildlife Service to be considered occupied. Still, lynx occurrences on the Nez Perce-Clearwater are, at best, limited and, even in the occupied portion of the national forest, lynx observations are sporadic, uncommon, or rare. However, there is no evidence that lynx cannot migrate into the Nez Perce-Clearwater from other areas, as most observations have been thought to be transient individuals. More research is needed to understand why lynx have not re-established populations across the plan area in seemingly suitable wilderness and roadless habitats. This is especially puzzling considering that SIMPPLLE modeling suggests that subalpine fir and Engelmann spruce dominance types, known to be preferred by lynx, are currently thought to be above the high end of the natural range of variation.

The NRLMD applies to forests occupied by lynx, as stated in the NRLMD Record of Decision (U.S. Department of Agriculture 2007f). This included the Clearwater National Forest. The Record of Decision also suggested that "…the direction should be 'considered' for unoccupied units but would not have to be followed until such time as lynx occupy the unit. The Nez Perce, Salmon Challis, Beaverhead-Deerlodge, Bitterroot, Ashley, and Bighorn National Forests and the disjunct mountain ranges on the Custer, Gallatin, Helena, and Lewis and Clark National Forests are unoccupied based on the best scientific information available at this time." At this time, the Nez Perce National Forest is considered unoccupied, and the Northern Rockies Lynx Management Direction will be considered when managing lynx habitat, recognizing that lynx may be present.

Compared to cores areas, secondary areas are defined as having fewer and more sporadic records of lynx occurrence, and the quality and quantity of habitat to support populations of snowshoe hares and lynx in secondary areas is questionable (U.S. Department of the Interior 2005b). The snow in lynx habitats on the Nez Perce-Clearwater may be subjected to more freezing and thawing than in the northern portion of lynx range. Crusting or compaction of snow may reduce the competitive advantage that lynx have in soft snow with their long legs and low-foot loadings (Ruggiero et al. 1999). At lower snow depths, an increase in competition for prey occurs and there is an increase in potential predation on lynx.

In the southern part of the range of Canada lynx, which includes parts of Idaho, lynx population density and productivity are lower than in the northern part of its range; harvest may be an additive source of mortality, and lynx may be highly vulnerable to overexploitation (Koehler 1990). State wildlife management agencies regulate the trapping of furbearers. Trapping and snaring of lynx is currently prohibited across the contiguous United States. Incidental trapping or snaring of lynx is possible in areas where regulated trapping for other species, such as wolverine, coyote, fox, fisher, marten, bobcat, and wolf, overlaps with lynx habitats (Squires and Laurion 1999). A trapped lynx can be released but there is potential for accidental injury or mortality (Kolbe et al. 2003). The magnitude of illegal shooting of lynx is unknown. Incidents have been reported throughout the range of the species. Devineau et al. (2010) reported a substantial number of shootings of lynx during the first 10 years after their reintroduction into Colorado, with 14 known shootings and 5 probable shootings out of 102 known mortalities. Aubry et al. (1999) hypothesized that human-caused mortality, such as illegal or incidental harvest, could significantly reduce lynx population numbers in southern regions. The state wildlife agencies have taken actions to reduce incidental or illegal trapping and shooting. State wildlife agencies work to reduce lynx mortality by disseminating information to the public and providing hunters with guides to the identifying characteristics of lynx.

An important consideration for the long-term persistence of lynx in the Northern Rockies is maintaining connectivity with lynx populations in Canada (Interagency Lynx Biology Team 2013). Squires et al. (2013) combined resource selection, step selection, and least-cost path models predict movement corridors for lynx in the Northern Rockies. The models identified a few corridors that extend south from the international border with Canada but those fall outside of the plan area. Lynx are managed provincially in Canada, with each province responsible for its own management program, harvest (trapping) policies, and conservation strategies. Lynx are considered secure in all provinces except New Brunswick and Nova Scotia (Bell et al. 2016).

Lynx Habitat Distribution and Management Area Direction

Modeled lynx habitat occurs on an estimated 1,457,768 acres of Nez Perce-Clearwater lands (Table 213). Within the Nez Perce-Clearwater, approximately 40 percent of modeled lynx habitat falls within designated wilderness, 43 percent falls within Idaho Roadless Rule areas, and about 17 percent falls within the areas managed for multiple uses. Under the alternatives, the amount of designated wilderness and Idaho Roadless Rule areas will not change. Nor will the Idaho Roadless Rule themes and associated direction change. The Idaho Roadless Rule includes several themes, which varies the management activities allowed and the purpose for which those activities may be conducted. See the Designated Areas section for a description of the Idaho Roadless Rule themes and associated direction. All recommended wilderness areas under the alternatives fall within Idaho Roadless Rule areas. After the alternatives are selected, the Nez Perce-Clearwater will make a recommendation to the Chief of the Forest Service recommending a change in the Idaho Roadless Rule theme to the wildland recreation theme for any areas identified as recommended wilderness, if needed. The Idaho Roadless Rule theme of wildland recreation is the most restrictive theme. As Idaho Roadless Rule area direction already restricts many activities in all themes, a change to recommended wilderness would result in only slightly more restrictive management and slightly more protections for lynx. Management Area 2 would be composed of Idaho Roadless Rule areas, recommended wilderness, suitable wild and scenic rivers, and proposed research natural areas. Management Area 3 includes general forest managed for multiple uses.

Table 213. Amount and percentage of lynx habitat by management area under the No Action Alternative

Management Areas	Acres of Lynx Habitat	Percent of Lynx Habitat
Designated Wilderness	615,893	40
Idaho Roadless Rule Area	607,309	43
General Forest	234,567	17
Grand Total	**1,457,768**	**100**

The acres of lynx habitat and percent of lynx habitat within different management direction areas are shown in Table 213. Designated wilderness, Idaho Roadless Rule, and recommended wilderness areas are managed more restrictively than general forest areas. Prohibited, restricted, or reduced activities in designated wilderness areas include timber production, timber harvest, road building, developments, motorized recreation or access, and other developments. Note that livestock grazing does occur within designated wilderness areas as guided by the wilderness plans and enabling legislation. Similarly, Idaho Roadless Rule areas restrict roads and vegetation management. Thus, about 83 percent of lynx habitat is protected from many human-caused threats. Limited access lowers the influence of factors like incidental trapping. The distribution of lynx habitat within the different land allocation areas sets the scope of impacts. That leaves only about 17 percent of lynx habitat acres subject to general forest management, which emphasizes multiple uses. Examples of activities allowed in general forest areas include timber production, fuels treatments, wildlife habitat management, range improvements, motorized recreation, special uses, and developed campgrounds.

Dynamics of Habitat for Snowshoe Hare and Lynx on the Nez Perce-Clearwater

Historically, fire, insects, and disease have been the primary processes that have affected forest vegetation in lynx habitat, reverting the vegetation to an early stage of succession or creating openings within the forest canopy. Immediately after a disturbance, forest areas are not yet able to support snowshoe hares and lynx because of the lack of live trees and shrubs so these areas are in a temporarily unsuitable condition. The Northern Rockies Lynx Management Direction (U.S. Department of Agriculture 2007f) defines lynx habitat in an unsuitable condition as being in the stand initiation structural stage where trees have not grown tall enough to protrude above the snow in winter, which the typical average time on the Nez Perce-Clearwater is estimated to be less than approximately 25 years. As a result, trees in this structural stage are too short or too open to provide dense seedling-sapling forage for snowshoe hares during winter but the trees will become taller and denser as the forests go through vegetative succession.

As vegetation regrows after a disturbance, the burned or harvested areas first develop into summer hare habitat. Then, after between 20 to 30 years, trees and some shrubs will have grown tall enough to have branches at the snow surface and be dense enough to provide winter food and cover for hares, depending upon site condition. During the next couple of decades, this stage of forest succession will likely continue to provide winter snowshoe hare habitat, but this depends upon the species composition and density of regenerating trees. As trees continue to grow, forests may move into the “stem exclusion” structural stage where food for hares is lacking. In this stage, tree branches grow out of reach of the hares, tree crowns close, and understory trees and shrubs decline due to too much shade. The denser the regenerating forest stand, the faster trees, such as lodgepole pine, lose their lower live branches and grow out of reach of hares.

Subalpine fir is the indicated climax species across most of the Nez Perce-Clearwater cold and cool moist potential vegetation types. Given enough time, these shade-tolerant species will eventually dominate. However, both subalpine fir and Engelmann spruce are intolerant of drought and fire due to their shallow roots, thin bark, and tree crowns that extend to the ground, making them susceptible to being killed by even low-severity fires. Though they may regenerate into the opening created by a fire, they have comparably slow growth rates and are soon overtopped by other early-successional species, such as lodgepole pine or western larch. However, their shade tolerance allows them to persist indefinitely and, eventually, they will dominate the site over many decades to centuries unless there is a fire event or other stand-replacing disturbance that re-initiates succession with early-successional species.

On the Nez Perce-Clearwater, the prevalence of subalpine fir and spruce-dominated forests is closely tied to the frequency of fire. More frequent fires will reduce the presence and dominance of these species and long fire-free intervals and the lack of a seed source of other species will favor their dominance. Forests dominated by subalpine fir and Engelmann spruce tend to support higher-severity fires due to the lower fire frequency, higher tree densities, multiple canopy layers, and greater litter depths and fuel loads typical in these stands. These stand-replacing fires make lynx habitat temporarily unsuitable. The multistory forest conditions that typically develop in subalpine fir and Engelmann spruce-dominated forests are also highly susceptible to damage from western spruce budworm. In contrast to stand-replacing wildfires, beetles may only kill some of the overstory trees, allowing the understory to respond.

Past Disturbances and Natural Range of Variation

The U.S. Forest Service's SIMPPLLE model (SIMulating Patterns and Processes at Landscape scaLEs) was used to model the natural range of variation for lynx habitat. The Ecosystem Research Group provided the Nez Perce-Clearwater with an assessment of SIMPPLLE model outputs (See Appendix B).

Preliminary modeling results suggest the acreage of lynx habitat in a temporarily unsuitable condition across the Nez Perce-Clearwater fluctuated a great deal from decade to decade. Preliminary modeling results of the natural range of variability for lynx habitat suggests that lynx habitat is currently near the high end of its natural range of variation. It is out of balance with dominance types and size classes and has shifted from what they were prior to European settlement. For example, modeling results suggest that subalpine fir and Engelmann spruce dominate a slightly higher proportion of the modeled lynx habitat today than it did pre-settlement. Similarly, modeling results suggest that slightly less of the forest in lynx habitat is in a younger size class than it was before widespread fire suppression. There are currently more stands of the 5- to 14.9-inch size class than historically. Likewise, there are fewer stands within the 0- to 4.9-inch, 15- to 19.9-inch, and 20 plus inch size classes than there were under natural disturbance.

Fires are a natural driver of forests in the Nez Perce-Clearwater. The Nez Perce-Clearwater has experienced many large fires since record keeping began. Most of the currently unsuitable habitat within the plan area is the result of wildfire with very few acres created by vegetation management. This is because most of the lynx habitat falls within designated wilderness and Idaho Roadless Rule areas.

The 2014 Assessment (U.S. Department of Agriculture 2014l) provides the number and acres of currently unsuitable habitat by lynx analysis unit; the amount of lynx habitat within Idaho Roadless Rule areas, designated wilderness areas, and general management areas; and the lynx habitat subject to timber management, including the amount of lynx habitat by timber suitability.

The SIMPPLLE model was also used to estimate the maximum and minimum amounts of the stand initiation structural stage, which may have provided hare habitat, occurring historically due to naturally occurring fires. Modeling indicates that the stand initiation phase and stand initiation hare habitat are well below historic levels. This is because the stand initiation phase occurs for a relatively short period of time following major disturbances, such as stand-replacing fire; it typically begins once small trees and shrubs have regenerated but may only last another decade or two until the stand moves into stem exclusion condition, depending upon factors such as elevation and stem density.

Like effects from wildfire, regeneration harvest units do not develop into stand initiation snowshoe hare habitat until 20 years post-harvest on average. The stand initiation structural stage has also been created in lynx habitat by vegetation management activities, including timber harvest.

Existing Vegetation Conditions

To provide context, the following text discusses existing vegetation conditions relative to the Northern Rockies Lynx Management Direction (NRLMD) vegetation standards. Within the lynx analysis units on the Nez Perce-Clearwater, an estimated 1,457,479 acres provide potential lynx habitat where NRLMD management direction applies. The remainder of Nez Perce-Clearwater lands occur at low elevations lacking deep, fluffy snow or are inclusions that are not capable of producing boreal forest habitat, such as dry forest types and non-forested lands. See Appendix A for a map of the distribution of lynx habitat within the three management areas.

Under the NRLMD standard VEG S1, if more than 30 percent of the lynx habitat in a lynx analysis unit is currently in a stand initiation structural stage that does not yet provide winter snowshoe hare habitat, no additional habitat may be regenerated by vegetation management projects unless a broad scale assessment has been completed that substantiates different historic levels of stand initiation structural stages.

As of 2019, only one out of 106 lynx analysis units on the Nez Perce-Clearwater were modeled as having more than 30 percent of lynx habitat being in an early stand initiation condition as a result of stand-replacing wildfires and vegetation management (Table 214). These areas are estimated to be in early stand initiation, which does not yet provide winter snowshoe hare habitat. The only lynx analysis unit with more than 30 percent identified as currently unsuitable occurs entirely within designated wilderness. Only nine lynx analysis units are over 20 percent in early stand initiation and all of them are located in-part or wholly within designated wilderness. Of these nine, all the early stand initiation is the result of wildfire.

Overall, wildfire has clearly been the driver in creating substantial acreages on the Nez Perce-Clearwater in a condition where they do not yet provide winter snowshoe hare and lynx habitat. The total amount of habitat in an unsuitable condition forestwide is about 110,431 acres, or about 7.5 percent, of all the lynx habitat in the plan area. None of the lynx analysis units are estimated to exceed VEG S1 due to regeneration harvest on National Forest System lands. The percentage of lynx habitat affected by regeneration harvest has generally been minor in comparison to wildfire.

4 - N/A = not applicable

Under the Northern Rockies Lynx Management Direction (NRLMD) standard VEG S2, no more than 15 percent of lynx habitat on National Forest System lands can be regenerated by timber management projects within a lynx analysis unit in a 10-year period unless it meets criteria applicable to the wildland urban interface. Since 2000, only 0.23 percent of all lynx habitat in the plan area has been treated by timber activities (FACTS database, accessed August 2019).

Table 214 displays the condition of lynx analysis units based on the forestwide lynx model. All of the lynx analysis units over 15 percent fall entirely or partially within either designated wilderness or Idaho Roadless Rule areas where timber management is not allowed or is restricted. Thus, none of lynx analysis units over 15 percent were the result of timber management. Since the Forest Plan was amended to include the NRLMD in 2007, none of the lynx analysis units have had more than 15 percent of lynx habitat acres regenerated by timber management projects in the last decade. At a forestwide scale, the numbers presented above suggest a lack of sufficient disturbance in lynx habitat for lynx kitten production in the future because a stand must go through early stand initiation before it can become small-diameter forest as described in Kosterman (2018).

Table 214 also shows the amount of lynx habitat within each lynx analysis unit, the size of each lynx analysis unit and the amount of habitat estimated as currently unsuitable on the Nez Perce-Clearwater. In addition, the table shows whether the lynx analysis unit is in designated wilderness or Idaho Roadless Rule areas.

It is assumed that forests burned by stand-replacing wildfire from 1993 to 2018 are not yet winter snowshoe hare habitat. Acres burned by wildfire are estimates for comparison with standard VEG S1. These percentages are estimates based upon forest-scale data and need to be verified at the project level.

Acres are based on the Forest Service Activity Tracking System (FACTS) database, which does not include decisions not yet implemented. This percentage is shown for comparison to standard VEG S2, which requires 15 percent or less in a 10-year period unless exempted for fuels reduction projects in the wildland urban interface.

In its biological opinion on the Northern Rockies Lynx Management Direction (NRLMD)(U.S. Department of the Interior 2017c), the U.S. Fish and Wildlife Service concluded that there was a potential for incidental take to occur in lynx habitat, mostly due to the exemptions and exceptions to the vegetation standards which could diminish the value of lynx habitat and impair feeding and reproduction by adult female lynx and the survival of kittens. Because of the difficulty of determining the incidental take of lynx, the U.S. Fish and Wildlife Service used the total estimated acreage of the exemptions and exceptions as a surrogate measure.

As defined under the Endangered Species Act, take means "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct." Incidental take is an unintentional but not unexpected taking. Take and incidental take are common terms used when discussing federally listed species.

The amount of incidental take was anticipated to be represented by fuels treatments on up to 6 percent, or 729,000 acres, of lynx habitat across the entire Northern Rockies analysis area over 10 years and by precommercial thinning for other resource benefits on up to 64,320 acres, less than 0.5 percent, of snowshoe hare habitat (lynx foraging habitat) over a 10-year period. The U.S. Fish and Wildlife Service provided reasonable and prudent measures and terms and conditions to minimize incidental take. Standards VEG S1, VEG S2, VEG S5, and VEG S6 include an exemption for fuels treatments to protect communities at risk in lynx habitat within the wildland urban interface. Such fuels treatments may not occur on more than 6 percent of lynx habitat on each National Forest considered “occupied,” as defined in the NRLMD, which limits fuels treatments to about 44,607 acres on the Clearwater National Forest (U.S. Department of the Interior 2017c). Since 2007, the Nez Perce-Clearwater has used none of the exempted acres allowed under that take statement. Instead, all fire and fuels projects have abided by the NRLMD standards and guidelines and consulted on individual projects. The incidental take statement was amended by the U.S. Fish and Wildlife Service to extend exempted acres for an additional five years in the Forest Service’s Northern Region (U.S. Department of the Interior 2012).

Annual monitoring and reporting are a requirement of the NRLMD biological opinion (U.S. Department of the Interior 2017c) to ensure that the level of incidental take is not exceeded. None of the lynx analysis units exceeded the VEG S2 standard of 15 percent in the last 10 years because the Nez Perce-Clearwater did not use the exemptions.

Standard VEG S5 also contains six listed exceptions that allow for precommercial thinning in lynx habitat to meet other specific resource objectives. VEG S6 contains several listed exceptions for vegetation management projects that reduce snowshoe hare habitat in multistory mature or late-successional forests.

The estimated acres that would possibly be treated through precommercial thinning exceptions are shown in Appendix K of the Final Environmental Impact Statement for the Northern Rockies Lynx Management Direction. For the Clearwater National Forest, the estimated number of acres to be thinned under the exceptions to the vegetation standards was 5,510 acres over a 10-year period in the Clearwater National Forest and 12,370 acres in the Nez Perce National Forest, totaling approximately 0.4 percent of the lynx habitat on the Nez Perce-Clearwater. Combined these total 17,880 acres. The acres treated by thinning in lynx habitat on the Nez Perce-Clearwater from 2007 to 2019 was 17,257 acres, which is about 1.1 percent of the lynx habitat in the Nez Perce-Clearwater. According to the updated lynx habitat model, only 1380 acres of these treatments were considered as causing unsuitable lynx habitat (FACTS database, accessed August 2019). The allowable level of incidental take has not been exceeded for the northern Rockies analysis area (U.S. Department of Agriculture 2017d) nor for the Nez Perce-Clearwater.

Winter Recreation

In 2017, the Clearwater National Forest issued the decision for its motorized winter recreation plan, as part of the Clearwater Travel Plan (USDA, 2017). The decision clarified where, when, and under what conditions motorized over-snow vehicles are allowed on the Clearwater National Forest. The decision abided by Northern Rockies Lynx Management Direction (NRLMD) guideline HU G11:

> Designated over-the-snow routes or designated play areas should not expand outside baseline areas of consistent snow compaction, unless designation serves to consolidate use and improve lynx habitat. This may be calculated on a lynx analysis unit basis, or on a combination of immediately adjacent lynx analysis units.

The motorized winter use on the Clearwater National Forest is thus consistent with the NRLMD guidelines. At the time, there were 115 miles of groomed over-snow vehicle baseline routes in lynx habitat within the Clearwater side of the national forest and no additional groomed routes were proposed in lynx habitat. The Nez Perce National Forest has not yet undergone travel planning for motorize winter recreation. Currently, all areas that are not designated wilderness are open to motorized over-snow travel. Therefore, there are no designated play areas nor designated over-the-snow routes within the Nez Perce portion of the national forest. Furthermore, the Nez Perce National Forest is considered open to motorized winter travel unless designated closed. The 1987 Forest Plans did not use the winter recreation opportunity spectrum (ROS) to identify areas suitable for motorized uses, and therefore the winter r ROS settings proposed in the alternatives are a new concept in the Land Management Plan. Instead under the No Action Alternative the ROS was a guide towards which to manage but was not a constraint on activities.

Table 215 provides a summary of acres and percent lynx habitat by winter ROS for the No Action Alternative, while Table 216 summarizes the percent of current lynx habitat within motorized and non-motorized winter ROS settings. No additional groomed routes in lynx habitat are proposed in any action alternative. Instead, the alternatives and plan will identify where motorized uses could be suitable, but the authorization of those uses would require a subsequent site-specific analysis and consultation before it could be authorized.

Table 215. Acres of lynx habitat and percent of total lynx habit by winter recreation opportunity spectrum (ROS) setting under the No Action Alternative. Note that the winter recreation opportunity spectrum did not identify uses as not suitable for motorized uses.

Winter ROS Setting	No Action Alternative	Percent habitat
Primitive	581,905	40
Roaded Natural	28,892	2
SPM	736,803	51
SPNM	110,168	8

Table 216. Amount of lynx habitat within motorized and non-motorized winter recreation opportunity spectrum (ROS) settings

Winter ROS Setting	Percent Current Condition
Non-motorized	48
Motorized	52

Habitat Connectivity

The Northern Rockies Lynx Management Direction (NRLMD) identified lynx linkage areas, which are intended to maintain connectivity and allow for the movement of lynx between blocks of habitat that are otherwise separated by intervening non-habitat areas, such as basins, valleys, and agricultural lands or places where habitat naturally narrows due to topographic features. The NRLMD contains plan components requiring conservation measures in lynx linkage areas, including objectives, standards, and guidelines. These linkage areas were initially identified on the basis of expert opinion and were coarsely mapped at a broad scale. Linkage areas on the Nez Perce-Clearwater are shown in Appendix A. Subsequently, Squires et al. (Squires et al. 2013) used telemetry data for 64 lynx monitored from 1998 to 2007 to create a broad-scale resource selection model that predicted probable lynx habitat and "putative movement corridors" across the species' distribution in the northern Rocky Mountains. This analysis included quantification of the relative likelihood of lynx crossing major highways—one of the major hypothesized anthropogenic threats to lynx connectivity. The areas where Squires et al. (2013) mapped lynx connectivity did not include the Nez Perce-Clearwater. Most of the lynx sightings on the Nez Perce-Clearwater appear to be observations of transient individuals, suggesting that lynx move through the plan area.

Squires et al. (2013) stated "given that increased traffic and urbanization are projected for the northern Rockies, mitigation such as land purchases and conservation easements may be necessary to preserve connectivity among lynx populations." Private land development, especially along highway corridors in mountain valleys, may also fragment habitat and impede the movement of lynx. The Nez Perce-Clearwater does not have jurisdiction over state or federal highways or lands under other ownerships, such as private, state, and tribal. The Forest Service can support habitat connectivity through its management of National Forest System lands by encouraging or acquiring conservation easements along highways or cooperating in identifying appropriate locations for installation of highway crossing structures. The Forest Service can also seek to acquire parcels that could aid in connectivity for wildlife. Activities of other ownerships are discussed in the analysis of cumulative effects.

Key Indicators for Analysis

Resource elements discussed in the analysis are based upon anthropogenic influences identified in the 2013 Lynx Conservation Assessment and Strategy, which relates to risk factors and habitat effectiveness. The analysis determines effects from the alternatives based on how plan components change the scope, severity, or both for these threats as described above. Table 217 provides a summary of key indicators for assessing effects to lynx.

Table 217. Key indicators for assessing effects to Canada lynx

Resource element	Indicator
Amount and proportion of lynx habitat within different management areas by alternative	The amount of lynx habitat by alternative that falls within Management Area 1, Management Area 2, and Management Area 3. Management areas set broad direction for large portions of the Nez Perce-Clearwater and largely control potential effects.
Vegetation management	Terrestrial ecosystems and Canada lynx habitat diversity. Amount of lynx habitat suitable for timber production. Changes in vegetation conditions modeled in SIMPPLLE.
Fire management	The amount of lynx habitat through time susceptible to uncharacteristic wildfire under future climates. Changes in vegetation conditions modeled in SIMPPLLE.
Habitat fragmentation	Anticipated changes to Canada lynx habitat connectivity linkage areas.
Recreation	Suitability for motorized over-snow vehicle use and Canada lynx habitat from winter recreation opportunity spectrum.
Minerals	Distribution or suitability of minerals operations in Canada lynx habitat.
Forest/backcountry roads	Forest/backcountry roads and indirect effects of motorized access on the risk of trapping and shooting.
Livestock grazing	Livestock grazing and vegetation change in Canada lynx habitat.
Driver/Stressor	Anticipated changes in climate and effects on Canada lynx habitat.

Consequences Common to All Alternatives

All alternatives would retain the management direction in the Northern Rockies Lynx Management Direction (NRLMD) for the conservation of lynx, as implemented in FW-STD-WL-01 in the Land Management Plan and Appendix 8. FW-STD-WL-01 states that “Canada lynx habitat shall be managed in accordance with Northern Rockies Lynx Management Direction (U.S. Department of Agriculture 2007f) and Record of Decision.” This language means that the plan will direct management to be consistent with the NRLMD, until such time as it is amended or changed in the future through National Environmental Policy Act and U.S. Fish and Wildlife Service consultation and will remain in place until that happens. However, Land Management Plans that are revised under the 2012 Planning Rule apply a different definition of the plan components and how they are applied compared to those under the 1982 Planning Rule, which was the rule under which the NRLMD was originally developed. The consultation with the U.S. Fish and Wildlife Service on this Land Management Plan and future implementation of NRLMD under the revised plan assumes that the new definitions for plan components and how they are to be applied will be consistent with the 2012 Planning Rule.

The habitat direction from the NRLMD is retained in the Land Management Plan through standard FW-STD-WL-01. The plan will carry forward the objectives, standards, and guidelines that were developed to conserve lynx; however, the use of the terms “standards” and “guidelines” in the NRLMD is consistent with the definitions of these terms as used in the Land Management Plan. The definition of “objectives” as used in the NRLMD is consistent with the definition of “desired conditions” found in the Land Management Plan. The NRLMD plan components in this appendix are incorporated throughout the Land

Management Plan (for example, in the terrestrial ecosystems and vegetation, wildlife species, recreation, and infrastructure sections).

The effects of the Northern Rockies Lynx Management Direction (NRLMD) are discussed as consequences common to all alternatives. The NRLMD can be found in Appendix 8 of the Land Management Plan. Plan components in the Land Management Plan are common to all alternatives, except for those related to nonconforming uses allowed in recommended wilderness, those for retention of snags during vegetation management, and objectives for the achievement of the rate of attainment of desired vegetation conditions.

The Lynx Conservation Assessment and Strategy (Interagency Lynx Biology Team 2013) identified anthropogenic influences that may affect lynx and lynx habitat, sorted into either the "upper tier" or the "lower tier." The upper tier includes the anthropogenic influences that are of greatest concern to the conservation of the lynx: vegetation management, prescribed fire, fragmentation of habitat, and climate change. The lower tier of anthropogenic influences includes recreation, primarily snowmobiling; minerals and energy management; forest and backcountry roads and trails; grazing by domestic livestock; and mortality due to incidental trapping or illegal shooting. It is thought that the lower tier activities could affect individual lynx but are not likely to have a substantial effect on lynx populations; these are of less concern for conservation of the species.

Key Stressors

Key stressors are discussed in the "Affected Environment" section and are summarized below.

Vegetation and Timber Management

Vegetation management activities, such as timber harvest, planting, and thinning, can affect lynx habitat conditions, such as forest composition, structure, dominance type, size class, and distribution. Specifically, timber management can affect the amount and distribution of dense horizontal cover providing snowshoe hare habitat, the amount and availability of large downed wood providing denning habitat, and the development of multistory hare habitat used by lynx for winter foraging (Interagency Lynx Biology Team 2013). The allocation of management areas can affect where timber management occurs. Only about 17 percent of the lynx habitat on the Nez Perce-Clearwater is outside of Idaho Roadless Rule areas and wilderness areas, meaning only about 17 percent is in a management area that allows timber production.

The Land Management Plan was developed to be consistent with the direction within the Idaho Roadless Rule for all alternatives, so each alternative applies constraints of the Idaho Roadless Rule. While timber harvest is allowed in Idaho Roadless Rule areas, timber production is not. Roadless Rule areas are considered suitable for timber harvest for specific purposes but do not allow timber production. Timber harvest is only allowed in some Idaho Roadless Rule themes. The most permissive theme is the backcountry restoration theme. Timber harvest can be conducted in the backcountry restoration theme, but it is only allowed in specific situations and for specific purposes. Timber cutting, sale, or removal is prohibited in Idaho Roadless Rule backcountry restoration except:

- To reduce hazardous fuels conditions outside a community protection zone if the project generally retains large trees as appropriate for the forest type and consistent with land management plan.
- To reduce hazardous fuel conditions outside a community protection zone where there is a significant risk that a wildland disturbance event could adversely affect an at-risk community or municipal water supply.

- In a portion of a backcountry/roadless area that has been substantially altered by construction of a forest road and timber cutting, prior to October 16, 2008.
- To improve threatened, endangered, proposed, or sensitive species habitat.
- To maintain or restore the characteristics of ecosystem composition, structure, or processes.
- To reduce the risk of uncharacteristic wildland fire effects to an at-risk community or municipal water supply.
- For personal or administrative use or where incidental to the implementation of an activity not prohibited.
- Where cutting, sale, or removal is incidental to the implementation of a management activity not otherwise prohibited by this subpart.

These actions must be approved by the regional forester and:

- Maintain or improve one or more of the roadless characteristics.
- Maximize the retention of large trees as appropriate for the forest type to the extent these trees promote fire-resilient stands.
- Are consistent with land management plan components.

Wildland recreation is the most restrictive and timber harvest is allowed only as follows:

Timber cutting, sale, or removal is prohibited except for personal or administrative use or where incidental to the implementation of an activity not prohibited.
Other Idaho Roadless Rule area themes fall between the backcountry restoration and wildland recreation themes for timber harvest in terms of what is allowed and why it is allowed. The Final Environmental Impact Statement for the Idaho Roadless Rule projected that 0.01 percent of the lands managed under Idaho Roadless Rule would be affected by timber removal or road construction in the first 15 years. For the nearly 1,500,000 acres of roadless areas on the Nez Perce-Clearwater, this would total 1,500 acres over the 15-year period, or approximately 100 acres per year (U.S. Department of Agriculture 2008b). In the 10-year period from October 2008 to September 2018, approximately 1,800 acres have been affected through community protection zone fuels reduction, fuel breaks constructed during wildfires, and removal of post-fire roadside hazard trees. This estimate of 1,800 acres in the first 10 years is greater than the Idaho Roadless Rule projection. However, several extreme fire seasons have occurred during that time, and much of the tree removal has been tied to fire and post-fire hazard activities. If there is conflicting direction, the Idaho Roadless Rule will take precedent. While these numbers account for timber harvest, treatments to restore forest composition, structure, function, and connectivity are expected, as outlined in the objectives in the Forestlands section of the plan.

The amount of lynx habitat by Idaho Roadless Rule theme is shown in Table 218. Idaho Roadless Rule areas prevent the development of new roads, which makes much of the timber inaccessible or largely economically infeasible. Thus, vast areas of the Nez Perce-Clearwater have significant mechanisms to prevent impacts to lynx habitat from timber management. Neither timber harvest nor timber production are allowed in wilderness areas nor in recommended wilderness. Approximately 43 percent of lynx habitat forestwide is protected from timber harvest in Idaho Roadless Rule areas and approximately an additional 40 percent is located in designated wilderness. Timber production is not allowed in about 56 percent of lynx habitats and timber harvest is restricted, reduced, or limited in an additional approximate 30 percent.

Table 218. Acres of lynx habitat in each roadless rule theme and percent of lynx habitat forestwide that falls into each theme

Idaho Roadless Rule Area Theme	Acres of Lynx Habitat in Each Roadless Rule Theme	Percent Lynx Habitat[1]
Backcountry Restoration	327,452	22.46
Land Management Plan Special Area	2,680	0.18
Primitive	154,873	10.62
Special Area of Historic or Tribal Significance	20,506	1.41
Wildland Recreation	119,642	8.21
Total	**625,153**	**42.88**

1 - Lynx habitat in each theme divided by total amount of lynx habitat in the plan area

About 17 percent of lynx habitat occurs within the general forest Management Area 3. Not all of the 17 percent of lynx habitat in Management Area 3 is suitable for timber production because areas, such as riparian zones or steep slopes, are not suitable. Table 219 shows the amount of lynx habitat on the Nez Perce-Clearwater proposed in the different timber suitability categories, and Table 220 shows the percent of lynx habitat by timber suitability category. The alternatives only vary slightly for timber suitability. Under the Preferred Alternative, approximately 14 percent is suitable for production, 12 percent is suitable for harvest to meet other resource objectives while approximately 73 percent is unsuitable. Even when suitable, plan components in the Northern Rockies Lynx Management Direction constrains timber activities in lynx habitat.

Table 219. Acres of lynx habitat by timber suitability category

Timber Suitability within Lynx Habitat	No Action Alternative Acres Lynx Habitat	Alternative P Acres Lynx Habitat	Alternative W Acres Lynx Habitat	Alternative X Acres Lynx Habitat	Alternative Y Acres of Lynx Habitat	Alternative Z Acres Lynx Habitat
Not Suitable for Timber Production or Harvest	1,084,339	1,091,437	1,183,858	1,081,950	1,101,785	1,133,915
Suitable for Timber Harvest for Other Resource Objectives	191,772	184,225	91,795	193,151	174,191	144,702
Suitable for Timber Production	211,759	212,209	212,217	212,769	211,894	209,253

Table 220. The percent of lynx habitat by timber suitability category

Suitable for Timber Production	14%	14%	14%	14%	14%	14%

Plan direction for timber management is associated with plan direction for achieving the desired vegetation conditions outlined in the Forestlands section; however, there are also plan components specific to timber production. The primary driver of timber harvest under the plan is to achieve desired conditions in Forestlands section 2.1.3. However, timber harvest is only a subset of the methods that will be used to achieve desired vegetation conditions. Other methods include prescribed fire, wildfire managed to achieve land management plan objectives, fuels treatments, and wildlife habitat restoration.

Currently, plan direction under the Northern Rockies Lynx Management Direction (NRLMD) governs many vegetation and timber management activities forestwide. Standards and guidelines in the NRLMD provide protection or reduces the impact to lynx from timber harvest. Direction from the NRLMD vegetation standard Veg S2 currently limit the scope of timber management to no more than 15 percent of lynx habitat within a lynx analysis unit within a 10-year period and standard Veg S1 limits vegetation management projects to no more than 30 percent total of a lynx analysis unit may be in a in a stand initiation structural stage that does not yet provide winter snowshoe hare habitat. Standard Veg S5 prevents precommercial thinning projects and Veg S6 prevents impacts to multi-story habitat. Thus, the scope of this threat in the plan area is constrained by 1) wilderness and roadless direction and 2) the NRLMD. Combined, using the nature serve method, the scope of timber management is probably slight (less than 10 percent of lynx habitat) and at most is restricted (between 11 and 30 percent) NRLMD would apply regardless of which alternative is selected.

Timber management within lynx habitat has been avoided since the Canada lynx was listed. A query of the Forest Service's Facts Activities database (accessed August 2019) shows that, since 2000, only 3,295 acres of total lynx habitat have been impacted by timber harvest, which is less than one percent of the lynx habitat in the plan area.

Timber harvest can have temporal and physical effects on lynx habitat. Squires et al. (2010) suggests seasonal patterns in resource selection of Canada lynx in the Northern Rockies. During winter, lynx preferentially foraged in mature, multilayer forests with Engelmann spruce and subalpine fir in the overstory and mid-story. Forests used during winter were composed of larger diameter trees with higher horizontal cover, more abundant snowshoe hares, and deeper snow compared to random availability. Multilayer, spruce-fir forests provided high horizontal cover with tree branching that touched the snow surface. Lynx were insensitive to snow depth or penetrability in determining where they killed prey. During summer, lynx broadened their resource use to select younger forests with high horizontal cover, abundant total shrubs, abundant small-diameter trees, and dense saplings, especially spruce-fir saplings. Lynx avoided recent clear-cuts or other open patches.

Squires et al. (2010) recommended that management maintain habitat mosaics, which should include abundant multistory mature spruce-fir forests with high horizontal cover that are spatially well-distributed. Potential treatments for timber production and other vegetation treatments, if conducted in lynx habitat, would reduce winter foraging habitat for lynx for about 40 years. Depending upon the shape and size of these treatments, lynx might be reluctant to cross these openings but could go around them. Any opening would have to be required to have regional forester approval if larger than 375 acres.

Potential treatments would also increase summer habitats and provide diversity in stand structure. Such treatments would need to be conducted consistent with Northern Rockies Lynx Management Direction (NRLMD) plan components. The impacts of timber management on lynx habitat depends upon the type of treatments conducted, the time frames considered, and the forest type it is conducted in. Holbrook et al. (2017) found that lynx used timber treatments but took longer to achieve 50 percent use of regeneration and selection cuts between 34 and 40 years than thinning in about 20 years. Thus, full use of timber treatments by lynx can take as long as 40 years and varies by treatment type. These results show that, when timber management happens, it can result in loss of habitat in the short-term, depending on treatment. Within the scope, the severity of this threat when it happens, given a 15-year timeframe assumption for assessment, is classed as a serious threat within its scope using the nature serve method of assessing threats. The combined scope and severity assessment of threat impacts using the NatureServe methodology for identifying the magnitude of threats is estimated to be a medium threat with a scope of restricted and severity of serious when it happens.

Although standards and guidelines carried forward from the 2007 NRLMD provide direction for many aspects of land management, the action alternatives have additional plan components that integrate Canada lynx habitat with desired conditions for vegetation that are tied to potential vegetation types (PVTs) within the context of the natural range of variation (NRV). The following paragraph discusses the effects of these plan components on Canada lynx.

Desired conditions in all the alternatives are aligned with conservation measures for vegetation management in the core habitat listed in the 2013 Lynx Conservation and Assessment Strategy (Interagency Lynx Biology Team 2013). Desired conditions for vegetation patterns are tied to fit the NRV within PVTs. The majority of modeled Canada lynx habitat is in the cool moist and cold broad PVT groups, which correspond to boreal forest habitat types capable of growing spruce fir and lodgepole pine types.

A desired condition is a description of specific social, economic, or ecological characteristics of the plan area, or a portion of the plan area, toward which management of the land and resources should be directed. Desired conditions are not commitments or final decisions approving projects and activities. The desired condition for some resources may currently exist but for other resources they may only be achievable over a long time. Forestwide desired condition FW-DC-WL-03 promotes providing the structure and pattern of forest vegetation across the landscape to contribute to structure and connectivity by PVT. Implementation of desired conditions should direct management actions in a way that would promote proper structure and distribution to promote connectivity for lynx habitats.

Lynx habitat primarily occurs within the cool moist and cold broad PVTs. Desired conditions in Sections 2.1.3.3 and 2.1.3.4 would direct management of cold and cool moist PVT groups. They outline the desired composition of dominance types in the cool moist broad PVTs. The desired conditions are lower than the NRV. For example, according to SIMPPLLE modeling, the NRV for subalpine fir and Engelmann dominance types in the cool moist broad PVT is 39 to 63 percent, with an average of 52 percent. Under warmer, drier conditions the NRV modeling suggested the range for the cool moist broad PVT was between 32 to 56 percent as could potentially be expected in future climates. The current conditions for the dominance of subalpine fir and Engelmann spruce dominance types are approximately 71 percent and 50 percent in the cool moist broad and cold broad potential vegetation types, respectively. Comparatively, the desired condition range is 25 to 35 percent. Management towards these desired conditions would reduce the amount of subalpine fir and Engelmann spruce dominance types, which would potentially impact lynx habitat use because lynx preferentially use Engelmann spruce and subalpine fir dominated forests (Holbrook, Squires, Olson, DeCesare, and Lawrence 2017). The degree of impact would depend on the impact these changes have on snowshoe hares, their primary prey.

The habitats in which hares occur in northern and southern forests vary in terms of species composition, stand structure, and the amount of disturbance from fire or harvest, leading to speculation that hare dynamics are related to habitat structure and the degree of interspersion of different habitat types rather than tree species (Hodges 1999). It is now well established that snowshoe hare abundance is associated with horizontal cover.

Agee (1999) evaluated the disturbance ecology of North American Boreal Forests for lynx. Across much of the range of lynx in North America, a high severity fire regime occurs, and succession follows a series of paths from early to late successional communities. Within a given forest type, many potential sequences may be possible: a function of fire duration and soil heating, species composition at the time of the fire, post-fire climate, biotic interactions, and other factors. The rate of succession will also vary depending on site conditions. After a stand replacement event, the post-fire sere will include an herbaceous stage; a shrub and sapling stage; a dense, small tree stage; a transition stage, often a hardwood to conifer transition but in others just a shift in conifer species; and a mature or old growth stage.

Agee (1999) went on to suggest the nature of disturbance also can influence the outcome of species compositions. If the overstory is removed through blow down or insect outbreaks, the remaining understory of shade tolerant species would dominate; whereas, if the understory is disturbed as occurs during fires, then overstory species (typically shade intolerant species) will come to dominate. Across the range of western boreal forests, many fire return intervals are long enough that relatively short-lived lodgepole pine may be removed from the stands by mountain pine beetles before another fire event occurs. In such cases, the old growth dominant Engelmann spruce and subalpine fir may compose the dominant tree component but, when burned, the spruce and fir are killed, and the species do not quickly re-establish. The seeds of both species are large, so they are not easily dispersed by wind, and they do not easily establish on freshly burned sites. Tree colonization may take decades to centuries, although spruce or fir will immediately regenerate occasionally.

The natural landscapes of the boreal forest within which lynx have successfully existed have been profoundly affected by disturbance, primarily by fire. Although most of the lynx range is included in the high-severity fire regime, there is considerable range in the frequency with which fire occurred on these landscapes and, because of that, a wide variation in successional stages present. Further variation has occurred due to local site conditions, intensity and duration of the fire, forest age at the time of fire, and post-fire climate. Mimicking this pattern of natural disturbance has been suggested as a way to maintain biodiversity in managed forests.

For the boreal forest, there are several general principles that must be addressed in landscape management plans when incorporating harvest or fire disturbance (Agee 1999):

- The habitat will be a product of the cumulative effect of all disturbances. The substitution of logging for fire, for example, is only meaningful if fire can be successfully removed from the environment and, even then, logging will not totally mimic fire as a disturbance process because of roading and coarse woody debris differences.
- Typical models used for fire history studies suggest that fire selected a range of stand ages to burn. Harvesting only the oldest ages will decrease the average stand age of the landscape and will remove the complex boreal stand structure that may be critical for lynx denning. Young and old stands need to be part of any landscape disturbance plan.

- Size and juxtaposition of stands is critical. Most fires are small. Most of the landscape, however, is affected by larger fire patches, with unburned areas inside the fire perimeter (stringers, islands, fire skips).

Desired conditions in the cold and cool moist potential vegetation types would, over time, direct management to reduce dominance types from Engelmann spruce and subalpine fir to other types. As subalpine fir and Engelmann spruce dominance types decrease, lodgepole, western larch, whitebark pine, and white pine dominance types would increase over the long term. Nevertheless, all of the cool moist and cold potential vegetation types are considered lynx habitat and would still be lynx habitat even if the dominance type changes. Based upon SIMPPLLE modeling, the plan components and alternatives would change only a low percent of the spruce-fir habitats into other types mostly because of constraints of treatments in areas not suitable for timber harvest. A small percent change is expected in these types. While the dominance type may change, Engelmann spruce and subalpine fir will still be components of these stands and will move through succession through time to provide for lynx and snowshoe hares.

In designated wilderness, the desired conditions would be achieved through natural processes, which would be in about 43 percent of lynx habitat. Similarly, in Idaho Roadless Rule areas, the desired condition would be largely achieved through a combination of planned and unplanned wildland fire. Planting in these areas would be minimal. Most likely, fire would reset succession and may shift dominance types. For example, dominance may shift from spruce-fir to lodgepole as a result from burning a spruce-fir stand that has a lodgepole pine component. Through time, spruce and fir would proceed through succession back into a spruce-fir dominated stand. Species without a seed bank, such as western larch, western white pine, and whitebark pine, would have to be replanted to change the dominance type. Desired conditions for dominance type may be challenging in Idaho Roadless Rule and wilderness areas because of the restrictions on timber management and planting.

If the natural range of variation modeling is a good representation of the true range, then current conditions for subalpine fir and Engelmann spruce dominance types are well above the natural range of variability. For example, current dominance in the cool moist broad potential vegetation type is currently at 71 percent, while spruce fir dominance in the cold potential vegetation type is at approximately 50 percent forestwide. Thus, a natural decline is expected because of wildfire and vegetation treatments.

The Northern Region Existing Vegetation Classification System (Barber et al. 2011) explains how dominance types are classified. According to that document, dominance is the extent to which a given species has an influence in a setting or map feature because of its size, abundance, or coverage. In the Northern Region, canopy cover, basal area, or trees per acre are used to determine dominance. A dominance type is determined by the species with the greatest abundance of canopy cover, basal area, or trees per acre within a setting or map feature. The species that determine the dominance type are always of the same lifeform. Therefore, it is first necessary to identify the dominant lifeform and tree lifeform subclass before determining dominance type. Dominance, in this context, is determined by 60 percent plurality. Plurality refers to the plant species that has the most canopy cover, basal area, or trees per acre in a setting. Tree dominance group 60/40 is based on two thresholds of tree abundance: 60 percent and 40 percent. If the single most abundant tree species comprises at least 60 percent of the total abundance of the classification attribute, the class assigned is the species code. While a species may dominate 60 percent of the stand, an additional 40 percent of the stand would contain other species. Thus, even though dominance type may change, species like Engelmann spruce and subalpine fir will still be components of stands in cool moist and cold potential vegetation types and should provide the horizontal cover needed for snowshoe hares. Desired conditions in the cool moist and cold potential vegetation types suggest a range of size classes. Lynx research suggests that a mix of connected mature and advanced regeneration forest provide conditions for female reproduction (Kosterman and Holbrook 2019). These size classes were based on the range of conditions modeled as the natural range of variation in SIMPPLLE. Modeling suggests that grass-forb-shrub conditions ranged from between 2 to 25 percent, and size classes in the 0- to 4.9-inch ranged from 7 to 28 percent. Holbrook et al. (2019) suggested that stands must go through these stages to become advanced regeneration conditions. Combined, these size classes suggest that more early seral conditions were present than allowed under the Northern Rockies Lynx Management Direction (NRLMD).

The rate at which restoration occurs varies within the alternatives. Alternative W seeks to achieve desired conditions in 30 years, Alternative X in 20 years, Alternative Y in 50 years, and Alternative Z in 100 years. The No Action Alternative would continue at the same pace of the forest over the past three years. At this rate, it is like Alternative Z in its timeframe to achieve desired conditions. PRISM modeling was used to estimate the acres of treatment required by alternative to achieve these desired conditions. See the Forestlands section for additional details. In roadless and wilderness areas, which combined make up more than 80 percent of the lynx habitat in the plan area, wildland fire is the primary disturbance projected to be needed to meet vegetation desired conditions for dominance types. Long-term management towards these desired conditions may decrease dominance types preferred by lynx in multistoried spruce fir dominated forests but would be within the natural range of variability.

The Preferred Alternative selected a range of vegetation treatment amounts to reflect the realities of the internal capabilities of the Forest Service to achieve restoration. The Preferred Alternative would provide a potential timber sale quantity of between 190 to 210 million board feet annually, which would represent approximately 8,825 to 10,000 acres of treatment each year. Most of that production would come from Management Area 3 but only a portion of it would come from lynx habitat. The acres of disturbance or restoration required to achieve desired conditions within the Preferred Alterative timeframe would be between 54,000 and 64,500 acres annually.

The NRLMD standards and guidelines would be followed in conducting these treatments. Thus, only 30 percent of a lynx analysis unit could be unsuitable and only 15 percent could be in an unsuitable condition within a 10-year period for lynx. These constraints were programed into PRISM for all alternatives; thus, the amounts of treatments under all alternatives meet the NRLMD guidelines. The NRLMD does not have any constraints on changing dominance types within lynx habitat. During modeling, the NRLMD constraints maintained subalpine fir and Engelmann spruce dominance types despite the desired condition ranges.

Desired conditions FW-DC-FOR-10 and MA1 and MA2-DC-FOR-04 address within-stand conditions in the cool moist broad potential vegetation type and contain specific language to promote spruce and fir dominated stands to achieve a multistoried condition, which was written specifically to address lynx habitat needs. These desired conditions would allow maintenance of multistoried stand conditions within spruce and fir dominated stands in the cool moist group.

Preliminary modeling for most of the action alternatives project forest conditions in the future and will trend slightly towards less dominance of subalpine fir and Engelmann spruce dominance types, with a slight increase in both the 0- to 4.9-inch and greater than 15-inch size classes over the next 50 years. Kosterman (2018) found that the number of small diameter trees at the landscape scale, defined as 3.93- to 5.9-inch diameter at breast height, influence whether lynx produce kittens and the probability a female having kittens increased until there was about 20 percent of the landscape in this size class, beyond which probability of a litter decreased but only slightly. The Land Management Plan size class breaks do not match up with those in Kosterman (2018) but size classes from 0- to 4.9-inch would contain trees that size, as would the 5-to-14.9-inch size classes. Most of this change is projected to occur following wildland fire, as well as through forest succession because of the distribution among land designation types, such as Idaho Roadless Rule and designated wilderness. The shift in dominance types would most likely slightly trend from spruce-fir dominated stands towards an increase in lodgepole pine, whitebark pine, and some larch. However, Engelmann spruce and subalpine fir will remain as a component of these stands and still contribute to lynx and hare habitat. All of these changes are trending towards or within the natural range of variability for lynx habitat. These changes occur under all action alternatives but at different rates. These conclusions are based upon preliminary modeling results from SIMPPLLE, and the model is currently being refined.

Holbrook (2017) showed that female lynx exhibited decreasing use of stand initiation structures by up to a maximum availability of 25 percent. Stand initiation structures, as defined in their paper, include very young stands, generally five years old and younger, with very few trees and open canopies resulting from recent disturbances, such as timber harvest or severe fire. The Northern Rockies Lynx Management Direction (NRLMD) Standard VEG S1 limits disturbances from timber harvest or prescribed fire that result in the stand initiation (SI) structural stage not yet providing snowshoe hare habitat during winter to no more than 30 percent of mapped lynx habitat within a lynx analysis unit. However, stand initiation structures, as defined in this paper, and the stand initiation structural stage defined in the NRLMD are not the same; stands in the stand initiation structural stage as defined in the NRLMD, and that apply to Standard VEG S1, approach 20 to 25 plus years of age before moving to young regenerating stands that provide snowshoe hare habitat during winter. Thus, the stand initiation structure class defined in this paper is a subset of the stand initiation structural conditions used in NRLMD Standard VEG S1 to establish the 30 percent stand initiation condition threshold.

The terms Kosterman et al. (2018) used to describe habitat use by lynx are very similar to those used in Holbrook et al. (2017). However, forest structural classes described in both papers and the classes described in Kosterman (2018) are not the same as those structural classes used to define and develop objectives, standards, and guidelines in the Northern Rockies Lynx Amendment. The forest structural classes described include sparse, stand initiation, advanced regeneration, and mature. Forest structural classes used in the NRLMD are based on structural stages defined by Oliver and Larson (1996) and do not “crosswalk” well with the structural classes used in Holbrook (2017a) or those in the Kosterman thesis (2014) or Kosterman et al. (2018). Staff in the Forest Service Northern Region Regional Office are working with research scientists at the Rocky Mountain Research Station to better interpret the structure classes used in these studies with how they compare with those used in the NRLMD.

Of the five structure classes used to define habitat conditions in Kosterman et al. (2018), the open, sparse, and small-diameter regeneration forest classes are most likely to meet the unsuitable habitat conditions that define the 30 percent threshold in standard VEG S1. Mean values within female lynx core use areas determined by Kosterman et al. (2018) for the open, sparse, and small-diameter classes where 4 percent, 10 percent, and 13 percent, respectively, and, collectively, would equal approximately 27 percent. Per structural class definitions in Table 1 of Kosterman et al. (2018), the open and sparse structural classes lack horizontal cover and do not provide habitat for snowshoe hare; thus, both classes meet the unsuitable definition described in standard VEG S1. However, it is unclear if the same is true for the small-diameter class defined by Kosterman et al. (2018); this class provides dense horizontal cover for snowshoe hare, but it is not known if this class includes young trees tall and dense enough to provide habitat during winter. In addition, structural habitat conditions described in Kosterman et al. (2018) occurred within known female lynx core use areas; such conditions may not be the same within the larger home range or lynx analysis units used in the Northern Rockies Lynx Management Direction (NRLMD) to approximate home ranges. Thus, because of the habitat differences and uncertainties described, it is unclear how, or if, the conclusions in Kosterman et al. (2018) stating the probability of producing a litter was highest for females that had core-use areas with approximately 12 to 20 percent of small-diameter regenerating forest relates to the 30 percent stand initiation structural stage threshold described in the NRLMD standard VEG S1. As stated previously, staff in the Forest Service Northern Region Regional Office are working closely with research scientists at the Rocky Mountain Research Station to better interpret, understand, and crosswalk structural conditions described in research papers with those used to define management direction provided in the NRLMD.

FW-DC-TBR-03 is a desired condition that states “Dead or dying trees in excess of those needed for snags, snag recruitment, and course wood material are salvaged, where practicable, in areas suitable for timber production (see MA3-GDL-FOR-05 for requirements).” While the amount of salvage harvest is not predictable, new research suggests that beetle killed trees provide conditions selected by lynx.

Squires (2020) provides the first assessment of how Canada lynx, a specialized forest carnivore, navigated a disturbed landscape created by an extensive bark-beetle outbreak. The field study was conducted in the San Juan mountains of southern Colorado on public lands administered as the Rio Grande National Forest and investigated the influence of large-scale disturbance on movements, habitat use, and the complexities of resource selection by Canada lynx in spruce-fir forests affected by spruce beetles (*Dendroctonus rufipennis*), a species of bark beetle. While the Canada lynx has occupied boreal and subalpine montane forests structured by natural disturbance processes for millennia, lynx at the southern range periphery might be particularly sensitive to large-scale fire and insect disturbances that alter forest structure and composition for potentially many decades. These large-scale disturbances also pose contemporary challenges for forest managers administering this disturbed landscape and balancing resource needs of Canada lynx with forest management activities like timber salvage.

The investigators predicted that Canada lynx would:

- Select for patches of live canopy cover with dense sub-canopies of Engelmann spruce and subalpine fir and mature green forests, to the extent possible, when confronted with a highly altered landscape from spruce beetle impacts.
- Select forest stands with higher understory (high horizontal cover) compared to random locations within home ranges and along movement paths.
- Exhibit a functional response and become increasingly selective for forest structures associated with horizontal cover (that is, high subcanopy cover) in areas where horizontal cover was sparsely distributed.

Contrary to the initial prediction in this study and previous research in the northern Rocky Mountains demonstrating the importance to Canada lynx of mature live-forest structures, lynx in beetle-impacted forests in the study area selected home ranges, use-areas within home ranges, and movement paths in forests with higher tree mortality and generally larger diameter trees than expected under random conditions. Overall, Canada lynx preferentially selected forest stands composed of large-diameter and abundant beetle-killed trees with developed live Engelmann spruce and subalpine fir understories.

Field data collected at lynx locations in home ranges indicated they generally selected stands with greater live components of subalpine fir and live canopy of Engelmann spruce at a finer resolution within the disturbed landscape. Areas selected by lynx within home ranges supported approximately 2.5 times the number of live subalpine fir trees from 3–8.9 feet diameter at breast height compared to areas randomly available. Canada lynx were found to select areas with higher Engelmann spruce and subalpine fir subcanopy at a landscape extent, while selecting for areas within home ranges with higher horizontal cover. Lynx in winter exhibited particularly strong positive functional responses for horizontal cover, canopy cover of live Engelmann spruce, and for larger beetle-killed trees of approximately 20 centimeters in diameter. Similarly, lynx selected forest patches of large-diameter beetle-killed trees when they were rare in home ranges and used them in proportion to their availability when they were abundant. Study results and mapping products demonstrated that forests with extensive overstory mortality are heterogenous in the subcanopy and not "dead" to Canada lynx. Within the landscape of high beetle mortality, lynx at a finer scale selected stands with subcanopies dominated by Engelmann spruce and subalpine fir beneath the changed overstory. Collectively, the authors conclude that (1) Canada lynx actively use and select forests impacted by spruce bark beetles, (2) the live trees remaining are important to maintain lynx habitat, and (3) horizontal cover from Engelmann spruce-subalpine fir subcanopy are strongly selected by Canada lynx within the context of spruce-beetle impacted forests.

It is not possible to predict the amount of salvage that would occur in lynx habitat under the plan. If this activity occurred, it could reduce habitat selected by lynx. Complex socioeconomic interactions between natural disturbance processes and the desire to promote timber salvage can result in a cascade of ecological and environmental consequences in actively managed landscapes post-disturbance.

Consequences of Other Vegetation Management Treatments

The U.S. Fish and Wildlife Service's biological opinion on the Northern Rockies Lynx Management Direction (NRLMD) (U.S. Department of the Interior 2017c) stated that limited exceptions to vegetation standards VEG S5 and VEG S6 could occur for other resource benefits, such as to restore western white pine and whitebark pine, which is a threatened species under the Endangered Species Act. Under all of the alternatives, the estimated acres that could have vegetation management treatments under the numbered exceptions to standards VEG S5 and VEG S6 was estimated to be 1,930 acres for white pine under Appendix K of the NRLMD. It was estimated to be 1,650 acres for restoration of western larch on the Clearwater National Forest and 120 acres on the Nez Perce National Forest.

Plan components in the NRLMD provide for the conservation of Canada lynx and their habitat. They are aligned with the conservation measures for vegetation management in core habitat listed in the 2013 Lynx Conservation and Assessment Strategy (Interagency Lynx Biology Team 2013) at the forestwide scale, considering exceptions allowed by the incidental take statement.

In summary, standard VEG S1 limits regeneration by vegetation management projects if more than 30 percent of the lynx habitat in a lynx analysis unit is currently in a stand initiation structural stage that does not yet provide winter snowshoe hare habitat with certain exceptions or exemptions allowed under the incidental take statement. Only 1 out of 106 lynx analysis units on the Nez Perce-Clearwater were modeled as having more than 30 percent of lynx habitat being in an early stand initiation condition as a result of stand-replacing wildfires. VEG S1 limits adverse effects to lynx because regeneration by vegetation management projects cannot occur until vegetation regrows into snowshoe hare habitat. As a result of recent large wildfires, an additional nine lynx analysis units are over 20 percent in early stand initiation and all of them are located in-part or wholly within designated wilderness or roadless areas.

Standard Veg S1 suggests that a departure from the 30 percent limit in the standard is possible. The following is the standard Veg S1: "Unless a broad scale assessment has been completed that substantiates different historic levels of stand initiation structural stages, limit disturbance in each lynx analysis unit as follows: If more than 30 percent of the lynx habitat in an lynx analysis unit is currently in a stand initiation structural stage that does not yet provide winter snowshoe hare habitat, no additional habitat may be regenerated by vegetation management projects." SIMPPLLE modeling of the Nez Perce-Clearwater would qualify as a broad scale assessment that substantiates different historic levels of stand initiation structural stages. For example, SIMPPLLE model results suggest that the amount of stand initiation structural stages grass-forb-shrub and 0- to 4.9-inch diameter at breast height size classes ranged from between 2 and 38 percent across the planning area.

Standard VEG S2 limits regeneration by vegetation management projects to no more than 15 percent of lynx habitat on National Forest System lands within a lynx analysis unit in a 10-year period with certain exceptions or exemptions allowed under the incidental take statement. By limiting the rate of regeneration harvest in each lynx analysis unit, these standards would contribute to a mosaic of habitat over time, which would benefit lynx by supporting the distribution of prey resources within a lynx analysis unit and across the landscape. Projections for acres harvested by PRISM modeling considered the limits imposed by VEG S1 and S2 of a maximum of 30 percent unsuitable in a lynx analysis unit and no more than 15 percent unsuitable in a 10-year period. These were imposed upon the amount of vegetation management and prescribed burning within analysis units by incorporating those as constraints in the model. The number of acres treated in the PRISM outputs projected under each alternative include those constraints and abide by VEG S1 and VEG S2. Therefore, each alternative provides ecological conditions for lynx through time. While PRISM can project growth, forestry outputs and general trends in vegetation, it does not project these spatially nor consider the stochastic nature of fires given the assumptions in the model and plan objectives. SIMPPLLE modeling projects these spatially and simulates fires stochastically through multiple runs. Potential multi-storied lynx habitat is abundant, although projected to decline. Modeled multi-storied hare habitat declines slightly in all alternatives by time step 5 with minimal differences between alternatives. There is very little difference in how the alternatives affect multi-storied habitat, with only 24,268 acres difference between Alternative Z (the most disturbance) and X (the least disturbance). The lack of differences between alternatives suggests that the decline is inevitable and unavoidable due to increasing wildfires. The level of habitat at decade 5 is still relatively abundant compared to the natural range of variation, suggesting that the availability of multi-storied habitat is not a limiting factor to lynx recovery on the Nez Perce-Clearwater.

Standard VEG S5 limits precommercial thinning projects during the stand initiation structural stage until the stand no longer provides winter snowshoe hare habitat with certain exceptions or exemptions allowed under the incidental take statement. The intent is to maintain the habitat conditions that are expected to produce high densities of snowshoe hares, which would benefit lynx by supporting high-quality habitat. There are six exceptions to standard VEG S5 that could be used to meet other resource objectives. The exceptions to VEG S5 for precommercial thinning are anticipated to result in the short-term loss of lynx foraging habitat in some treated stands, which could have an adverse effect on lynx survival and reproduction by reducing prey resources, but this effect is limited in intensity and extent. Precommercial thinning at administrative sites and for research or genetic tests would generally have little or no adverse effect on lynx because few acres are involved, and the acres impacted are widely distributed. Thinning to enhance whitebark pine and aspen would benefit other wildlife species and would occur on a limited number of acres of lynx habitat, resulting in a minor adverse effect on lynx. Daylight thinning would be allowed around individual western white pine in a manner that retains most winter snowshoe hare habitat. Daylight thinning might reduce lynx habitat quality in the short-term but might allow the development of multiple dense canopy layers in the long-term. Standard VEG S6 limits vegetation management projects that would reduce winter snowshoe hare habitat in multistory mature or late-successional forests with certain exceptions or exemptions allowed by the standard. Timber harvest would be allowed in areas that have the potential to improve winter snowshoe hare habitat that presently have poorly developed understories and do not provide winter snowshoe hare habitat, benefiting lynx by developing forests with a dense understory to support their snowshoe hare prey. The effects of the numbered exceptions to VEG S6 would create short-term loss of hare habitat quality or quantity but these are anticipated to be minor because they are limited in intensity and extent. Implementation of standard VEG S6 would benefit lynx by retaining and developing important winter habitat over much of the Nez Perce-Clearwater.

As stated in the Land Management Plan Appendix 8, VEG O1, VEG O2, and VEG O4 encourage management of vegetation to mimic or approximate natural succession and disturbance processes while maintaining lynx habitat components. Guideline VEG G1 encourages the development of projects that are designed to recruit a high density of conifers, hardwoods, and shrubs where such habitat is scarce or not available. Guideline VEG G5 is to provide habitat for alternative prey species, particularly red squirrel, in each lynx analysis unit. Guideline VEG G10 states that all the vegetation standards should be considered when designing fuel treatment projects within the wildland urban interface to promote lynx conservation and that this consideration should be explained in the project National Environmental Policy Act documentation. Guideline VEG G11 describes how denning habitat should be retained and distributed in each lynx analysis unit. These guidelines benefit lynx by encouraging practices that create or maintain lynx habitat components and would continue to be considered as site-specific projects are developed under all the alternatives. Plan components provide for a mosaic of habitat conditions over time that support dense horizontal cover and high densities of snowshoe hare with winter snowshoe hare habitat provided by the stand initiation stage and by mature multistory conifer vegetation in support of lynx conservation. Analysis of Forest Inventory and Analysis data on snags and large downed woody material for the Nez Perce-Clearwater Land Management Plan shows that the availability of snags and large downed woody material was similar in wilderness and non-wilderness (Bollenbacher et al. 2009a), suggesting that snags for denning habitat will be present in both wilderness and non-wilderness. Snag retention guidelines in the Forestlands section will help ensure that there are snags for lynx denning.

Guideline VEG G11 of the Northern Rockies Lynx Management Direction requires considerations for denning habitats when working in lynx habitat. Plan guidelines require minimum snag densities under all alternatives but differ at the scale they apply, and the size of snags required to be retained. Alternatives W, X, and Y would require snags be retained from 15 inches with some proportion of those snags being greater than 20-inch diameter at breast height (DBH) and larger. Alternative Z requires retention of snags 10-inch DBH and larger with some proportion of those snags required to be 15-inch and larger and some 20-inch and larger. Under Alternative Z, the number of snags would be from between 600 and 700 snags per 100 acres 10-inch DBH and larger depending upon potential vegetation type.

The numbers for snags in the guideline are based upon the average number of snags reported by broad potential vegetation type in northern Idaho, as stated in Bollenbacher et al. (2009). For north Idaho forests, this represents between 600 and 700 snags per 100 acres of 10-inch diameter at breast and larger in the subalpine habitat type group, as in Alternative Z, versus between 0 and 400 snags per 100 acres 15-inch DBH and larger, as under Alternatives W, X, and Y. Under all alternatives, these are required to be retained at the project area scale. These plan components would ensure that snags retained would be sufficient to ensure that denning habitat would be available after vegetation projects in areas of lynx habitat where these activities occur. Snag guidelines under all alternatives would provide potential denning habitat.

This effect to lynx would only happen in about 17 percent of the lynx habitat within Management Area 3. While plan components for snags in Management Area 2 do not vary by alternative, emphasis for vegetation management in Management Area 2 stresses restoration of forest structure, composition, function, and connectivity and snags would probably be retained during restoration treatments but not required. Furthermore, treatments in Management Area 2 are expected to be conducted through wildland fire to restore habitats, which will naturally leave more snags.

Summary of Modeled Alternative Consequences

In the Canada Lynx Conservation and Assessment Strategy (Interagency Lynx Biology Team 2013), no conservation measures are identified for climate change due to the limited ability of federal land management agencies to alter the current trajectory. The conservation measures for vegetation include the following:

Conduct a landscape evaluation to identify needs or opportunities for adaptation to climate change. Consider potential changes in forest vegetation that could occur as a result of climate change e.g.,(Gärtner et al. 2008). Identify reference conditions relative to the landscape's ecological setting and the range of future climate scenarios. For example, the historical range of variability could be derived from landscape reconstructions e.g., (Hessburg and Smith 1999, Blackwell and Gray 2003, Gray and Daniels 2006).

Plan alternatives were analyzed using a landscape evaluation that considered reference conditions relative to the landscape's ecological settings and the range of future climate scenarios, considering the interaction of vegetation management, wildland fire, and possible effects on fragmentation of habitat.

The Ecosystem Research Group modeled the effects of the alternatives. The natural range of variation was modeled going back about 1,000 years and the effects of the alternatives were projected for the next 50 years, including anticipated changes in climate and the fire suppression logic of the model. Effects of vegetation management associated with each management area, combined with modeling of natural processes such as wildfires, insects and disease, and forest succession, were modeled in 2019. The Ecosystem Research Group modeled the effects of several future scenarios for comparison purposes, including a warmer and drier climate over the next five decades that would result in more acres burned due to expected climate change and continuing the current level of fire suppression into the future. Effects were modeled using SIMPPLLE and PRISM models. The SIMPPLLE and PRISM models provide a probabilistic assessment of the subset of federal actions that provide a programmatic framework for vegetation management activities across the Nez Perce-Clearwater over a 50-year future time period. However, since the exact location, extent, and timing of future fires, timber harvest, thinning, and planting are unknown, future site-specific actions would be subject to the requirements of Section 7 of the Endangered Species Act at a future time.

Ecosystem Research Group's modeling used the GIS layer of modeled and mapped lynx habitat for the Nez Perce-Clearwater. Two analyses for lynx were done to assess their habitat requirements: (1) a stand initiation habitat analysis and (2) a potential multistoried habitat analysis. Stand initiation hare habitat was modeled as any cover types within the footprint of lynx habitat updated in 2018. Stand initiation hare habitat was modeled as the 0- to 5-inch size class as seedling and sapling with a canopy cover class of 40 to 100 percent and 20 or more years since the previous stand-replacing disturbance, such as high-severity fire or regeneration harvest. Modeled multistoried habitat is limited to cover types that contain subalpine fir or Engelmann spruce, which may be mixed with other species, within subalpine fir-spruce habitat groups. Multistoried lynx habitat is provided by forests with a high proportion of trees in the diameter classes of 7 to 11 inches and 11 plus inches (Squires 2010, Squires et al. 2006) and a dense understory providing snowshoe hare habitat. Although snowshoe hare require a dense understory, the SIMPPLLE model is dependent on the Northern Region VMap classes and did not allow the incorporation of understory density. Updating of lynx habitat was conducted according to the Lynx Conservation Assessment and Strategy (2013) and is described in Lutes (2019).

The most important lynx habitats include Engelmann spruce, subalpine fir, spruce-fir, and lodgepole pine. Modeling results estimating the natural range of variability for lynx habitats suggests that they are departed from their natural range of variability. The departure is represented by an increase in Engelmann spruce and subalpine fir with a concurrent decrease in lodgepole pine and white bark pine. In other words, spruce-fir stands dominate more than they did under natural fire regimes while lodgepole and whitebark pine dominate less than they did in the past. Modeling results from PRISM suggest that, under all alternatives, the departure from the natural range of variability declines but the rate of that decline varies by alternative. That is because the alternatives vary the rate at which restoration of the natural range of variability is achieved, primarily by varying objectives for restoration. Objectives that restore or treat lynx habitat are mostly those that treat the cold and cool, moist potential vegetation types.

Given these objectives and various assumptions and constraints in the models, the modeling results suggest that, in all alternatives, subalpine fir, Engelmann spruce, and spruce-fir dominance types increases but the rate of that decline is faster in some alternatives than others. As these types increase, lodgepole pine and white bark pine dominance also increase. In Alternatives Z and the No Action Alternative, spruce-fir dominance types remain more constant and increase at a similar rate. Restoration back to the natural range of variation in these types take up to and beyond 70 years. In the Preferred Alternative, the amount of spruce-fir dominance change is from 592,330 acres to 796,493 by the end of the 5-decade time frame.

The amount of harvest or wildland fire required to achieve these results fluctuates between about 20,000 acres to a high of about 40,000 acres per decade time step, depending upon the timestep. This amount of treatment per decade was constrained by the PRISM model and is consistent with VEG S1 and S2 of the Northern Rockies Lynx Management Direction. Treatments projected to achieve this include both vegetation management and wildland fire.

Through time, under all alternatives, the proportion of large diameter size class would progress to the very large class while other size classes would remain relatively similar in abundance through time. The heterogeneity in size classes within a stand would increase because desired conditions will direct management to retain live trees within stands, which will grow into the very large size classes. Thus, even regenerating stands will still contain large and very large trees.

Under the 2012 Planning Rule, the assumption for wildlife is that species are well adapted to the dynamic nature of their forested habitats and may even require forests to function within the natural range of variation to persist and obtain optimal population performance. For most species, these assumptions are not explored rigorously in the scientific literature. Lynx habitat use has not been studied in relation to how forests function within their natural range of variation so effects to lynx from direction to restore the natural range of variation is not completely understood. However, a few clues from the published lynx and snowshoe hare literature can help make inferences about the effects.

Holbrook (2017) suggested that lynx used what they termed advanced regeneration increasingly as it increased on the landscape. Advanced regeneration generally holds the most snowshoe hares while lynx hunt more efficiently in mature forest. In this study, Canada lynx demonstrated use of mixed conifer forests and a mosaic of structural stages with canopies composed of spruce-fir and lodgepole. These findings underscore the importance of both types of stand conditions. Holbrook (2017) defined advanced regeneration as follows:

> Early–mid-seral stands of age ~25–40 yr with a mixed species composition, but spruce-fir tends to occur the most frequently (Appendix S1). Advanced regeneration exhibited a median basal area-weighted DBH of 8 inches or 20 cm (IQR = 5–10 inches or 14–27 cm); however, of the 51 plots examined 70% of them were classified at size classes between 5 and 15 inches (12.7–38 cm). Advanced regeneration exhibited median canopy cover of 45% (IQR = 30–70%), median tree height of 51 ft or 16 m (IQR = 34–64 ft or 10–20 m), and median basal area of 89 ft2/acre or 20 m2/ha (IQR = 39–124 ft2/acre or 9–28 m2/ha). Tree density for trees larger than 5 inches (12.7 cm) was 167 trees/acre or 416 trees/ha (IQR = 72–289 trees/acre or 178–714 trees/ha). Tree density for trees <5 inches (12.7 cm) was 900 trees/acre or 2223 trees/ha (IQR = 150–2549 trees/acre or 370–6298 trees/ha).

Holbrook (2017) defined mature forest as:

> Mid-seral stands of age ≥40 yr arranged in a multi-storied structure with a mixed species composition, but spruce-fir tends to occur twice as much as any other species (Appendix S1). Mature exhibited a median basal area-weighted DBH of 10 inches or 25 cm (IQR = 7–14 inches or 18–35 cm). However, of the 194 plots examined 45% were classified at size classes between 5 and 10 inches (12.7–25.4 cm), 25% at size classes between 10 and 15 inches (25.4–38 cm), and 21% of them were classified at size classes between 15 and 25 inches (38–64 cm). Mature exhibited median canopy cover of 56% (IQR = 40–70%), median tree height of 65 ft or 20 m (IQR = 53–88 ft or 16–27 m), and median basal area of 140 ft2/acre or 32 m2/ha (IQR = 91–209 ft2/acre or 21–48 m2/ha). Tree density for trees larger than 5 inches (12.7 cm) was 217 trees/acre or 535 trees/ha (IQR = 144–331 trees/acre or 357–818 trees/ha). Tree density for trees <5 inches (12.7 cm) was 1500 trees/acre or 3705 trees/ha (IQR = 300–4200 trees/acre or 741–10,374 trees/ha).

Kosterman et al. (2018) showed abundant mature forest and its connectivity contributed to lynx reproduction. They also showed that the amount of small diameter regenerating forest conditions improves lynx reproduction until it reaches about 20 percent at a landscape scale and declines slightly after that amount (Kosterman et al. 2018). The graph in the publication shows the probability of producing a litter approaches 1.0 at approximately 15 percent of the area being in small diameter forest and stays at close to 1.0 until approximately 20 percent then falls to between 0.75 and just under 1.0 as small diameter approaches 25 percent open. Kosterman et al. (2018) did not have data to show the relationship of probability of reproduction beyond 25 percent. However, the probability of reproduction does not fall as much at 25 percent small diameter as when the amount of small diameter forest makes up 10 percent or less. Thus, Kosterman et al. (2018) showed that the Northern Rockies Lynx Management Direction standard Veg S1's threshold of 30 percent within a lynx analysis unit is appropriate even though it is slightly higher than ideal and suggests that more lynx analysis units ought to be managed closer to between 15 to 25 percent small diameter than at lower levels. Thus, both mature connected forests and intermediate amounts of small diameter regenerating forests are likely important for lynx.

Kosterman et al. (2018) defined mature forest conditions as:

> A multistoried or uneven-aged stand with a median DBH of 26 cm (10 inches). This DBH is reflective of the multistoried nature of the structure class, but despite this DBH, there was a comparatively high proportion (i.e., 22%) of large trees (≥38 cm in DBH or 15 inches). Common attributes in this class were substantial understory (e.g., seedlings and saplings) and horizontal cover, continuous canopy, and no evidence of recent disturbance.

Kosterman et al. (2018) defined small diameter regenerating forest as:

> Regenerating forests generally due to forest management with smaller sized (~10–15 cm DBH or 4-6 inches) trees, intermediate canopy cover, and high horizontal cover.

SIMPPLLE modeling results for the revised natural range of variation runs suggest that, on average, the cool moist potential vegetation type averages between 17 and 22 percent in the 0- to 4.9-inch size class and between 19 to 21 percent in the 5- to 9.9-inch size class, suggesting the natural distribution of these size classes contribute to lynx habitat. Naturally, stands must go through the 0- to 4.9-inch size class in appropriate amounts to become stand initiation structure known to host the highest snowshoe hare counts.

In another publication, Holbrook et al. (2017) studied multi-scale relationships of forest metrics and snowshoe hare use. They found that snowshoe hares require horizontal cover, and that horizontal cover was associated with medium sized trees of 5 to 9 inches. While they found that spruce and fir forests produced high horizontal cover used by hares, they found a positive relationship with the amount of canopy cover of lodgepole pine within mixed conifer settings, both at the landscape scale and the plot scale. Work by Ellsworth et al. (2013) suggested that lodgepole pine was more nutritious to snowshoe hares than other conifer species.

Berg et al. (2012) found the lowest densities of snowshoe hares in young lodgepole at low density and late seral stands of mixed whitebark and spruce-fir stands and the highest densities of snowshoe hares were found in young lodgepole at high density and late seral multi-storied stands of mixed spruce-fir, mixed aspen spruce-fir, and mixed lodgepole spruce-fir.

Together, these studies suggest that landscapes with a variety of size classes, structural stages, and proportions of forest structures can affect lynx selection and reproduction and snowshoe hare abundance. Management proposed at landscape scales under the Land Management Plan would create conditions like those described above in some stands that would contribute to lynx selection and snowshoe hare abundance (Berg et al. 2012, Holbrook, Squires, Olson, Lawrence, and Savage 2017, Kosterman et al. 2018, Holbrook, Squires, Olson, DeCesare, and Lawrence 2017).

Under all alternatives, dominance would shift from more spruce-fir to more lodgepole. Lodgepole pine can contribute positively to snowshoe hares as a component of a mixed conifer stand and a 30 to 70-year-old stand of lodgepole. While treatments could make some stands unsuitable for lynx short-term, those stands would grow into conditions preferred by lynx through time. As time went on, a greater proportion of the lynx habitat would be in a size class, such as advanced regeneration, which promotes lynx use or reproduction. As long as these treatments follow plan guidance within the Northern Rockies Lynx Management Direction, they should contribute to lynx recovery.

To estimate the current condition, available data sets are not able to estimate horizontal cover associated with snowshoe hare and lynx habitat, but overall density can be estimated based upon Forest Inventory and Analysis field measurements of canopy cover. A large portion of the Nez Perce-Clearwater—about 65 percent of the area in the cool moist potential vegetation type—is currently in a moderate- to high-density class. Over the first three decades, modeling estimates that this proportion remains steady but then declines while the proportion of low-density forest increases. In the model, lower forest densities are largely driven by natural disturbances, such as fire, insects, and disease, which convert large areas to early successional forest in the latter modeled decades with temporarily less canopy cover. The increasing proportion of forest with low canopy cover may temporarily reduce the quality and connectivity of lynx habitat; however, this would improve over time with development of vegetation in the understory and mid-story. According to the modeling of the natural range of variation, fire cycles affecting the amount of multistoried and stand initiation habitat have occurred in the past and are likely to occur in the future in the mid- to high-elevation subalpine fir and spruce forests of the Nez Perce-Clearwater. This is a natural fluctuation over time associated with the characteristic fire regimes and disturbance processes.

The Ecosystem Research Group modeled a multistory forest that provides snowshoe hare and lynx habitat over the next five decades. Since the model is not able to discern whether a dense understory is present or not, this should be interpreted as areas with a potential to provide winter snowshoe hare and lynx habitat. The model depicted a trend in forest stands that are most likely to have a multistoried structure, high canopy closure, and presence of subalpine fir and spruce. For potential multistory habitat, the range between maximum and minimum natural range of variation is very large at a little more than 350,000 acres between natural range of variation high and low. Since the model reduces harvest based upon lynx standard VEG S6 and applies fire suppression logic as well as forest succession for all alternatives, levels of modeled multistoried lynx habitat remain within the natural range of variation in all decades. The change is primarily driven by modeled levels of fire or insects and disease allowing succession to increase modeled multistoried habitat. If insects and disease kill scattered patches of trees in the overstory of multistoried forests, that could increase the density of the understory, creating multistoried stands after a lag time of a few decades, provided the loss of canopy cover is not too great. In contrast, stand-replacing wildfires would create more stand initiation habitat which also increases in all alternatives at about the same pace because the trends are driven mostly by natural disturbances. Over the next five decades, the acres of modeled stand initiation habitat increase as well but remain within the natural range of variation. The Preferred Alternative, in combination with natural processes, shows that potential multistory hare and lynx habitat is expected to stay within the natural range of variation. The modeling results discussed above are believed to be a worst-case scenario with respect to changing climate, stand-replacing wildfire, and insects and disease.

In the updated modeling, the Nez Perce-Clearwater also tested the effects of an earlier increase in stand-replacing wildfire. This resulted in stand-replacing wildfire occurring on about 80,000 more acres. This would initially create more temporarily unsuitable habitat for Canada lynx for about the first two decades, followed by an increase in stand initiation hare habitat for subsequent decades.

Under all the alternatives, there would be no change to the plan components for lynx. The effects to lynx that were described in the Northern Rockies Lynx Management Direction 2007 Final Environmental Impact Statement (Volumes 1 and 2), biological assessment, biological opinion, and record of decision are incorporated by reference. Continued implementation of the Land Management Plan is anticipated to maintain or improve lynx habitat in the long-term, although some short-term adverse effects may occur, primarily due to the reduction of snowshoe hare habitat allowed under the exemptions to the vegetation standards. These actions would provide diversity and resiliency to lynx habitat. The Land Management Plan direction will promote conservation of the lynx population.

Threat: Wildfire, Fire Suppression, Fire Management, and Fuels

Stand-replacing wildfires are the most common type within lynx habitat on the Nez Perce-Clearwater. They remove understory vegetation and tree canopy cover in the short-term but can promote development of dense horizontal cover and recruitment of downed wood in the longer term. During the early post-fire period, a large stand-replacing fire may negatively affect the ability of a lynx to secure food resources within its home range. Lynx are known to use unburned patches in large, newly burned fire areas.

Fuels projects aim to reduce hazardous fuels through vegetation management, depending on the treatments. These changes can affect lynx habitat by reducing downed wood, simplifying forest structure, decreasing horizontal cover, removing understory vegetation, and reducing overstory and understory. These effects can vary depending upon the treatments used. The fuels treatments are usually localized around communities and infrastructure and evaluated on a site-specific basis but can be widespread in some cases. The Incidental Take Statement for the Northern Rockies Lynx Management Direction (NRLMD) recognized impacts from fuels treatments and granted limited exceptions from Land Management Plan standards for these activities within the Wildfire Community Protection Zones, which were discussed as the wildland urban interface in the NRLMD and Incidental Take Statement. The Clearwater National Forest was identified as occupied and consulted with the U.S. Fish and Wildlife Service on the amount of lynx habitat exempted from the NRLMD standards for fuels treatments. The amount of lynx habitat anticipated to be exempt from Land Management Plan standards within the NRLMD is about 44,607 acres on the Clearwater National Forest. The Nez Perce National Forest was considered unoccupied and was not required to consult on acres exempted from standards in the NRLMD for fuels treatments. This analysis assumes that the NRLMD will be implemented on the Nez Perce National Forest and will consult with the U.S. Fish and Wildlife Service on fuels exemptions for that Forest for fuels treatments within Community Protection Zones.

The revised Forest Plan is also proposing to adopt Community Wildfire Protect Plan (CWPP) wildland urban interface (WUI) boundaries, this changes where exemptions to VEG S1, VEG S2, VEG S5, and VEG S6 may be applied. The change to the CWPP WUI boundaries would provide flexibility when planning fuels reduction projects and align them with county designations. It would not increase the total exemptions acres above the six percent analyzed under the U.S. Fish and Wildlife Service Incidental Take Statement.

Since the development of the NRLMD Idaho, Clearwater and Latah counties have developed CWPPs to define WUI areas. Approximately 276,046 acres of lynx habitat on the national forest overlaps with portions of the CWPP WUI areas, this represents about 19 percent of the lynx habitat across the national forest, exceeding the 6 percent limit set forth in the NRLMD. Adoption of CWPP WUI boundaries would allow the national forest greater flexibility when locating and implementing hazardous fuels projects across the national forest. However, the cumulative total of acres of exempted fuels treatments within the wildland urban interface that do not meet the vegetation standards would remain capped at 89,272 acres or 6 percent of the lynx habitat across the national forest (Table 221). Given that the national forest has used none of the wildland urban interface exemption acres allotted to the national forest since 2007, instead developing and implementing projects so that they meet NRLMD, it is expected that this number will not be exceeded throughout the life of the revised Forest Plan.

Table 221. Total acres and proportions of exception and exemption acres proposed

Acre Category	Occupied Lynx Habitat	Unoccupied Lynx Habitat	Total
Total Acres of lynx Habitat	743,275	744,596	1,487,871
Acres of Lynx Habitat in CWPP WUI	78,112	197,934	276,046
Maximum acres of snowshoe hare habitat Treated Using Exemptions for Fuels Treatment Projects in CWPP WUI	44,596 (6%)	44,676 (6%)	89,272 (6%)
Maximum acres of snowshoe hare habitat Treated Using Exceptions for Activities for Other Resource Benefits	2,410 (0.3%)	2,530 (0.3%)	4,940 (0.3%)
Total Acres of Snowshoe Hare Habitat Treated Using Exemptions or Exceptions	47,006 (6.3%)	47,206 (6.3%)	94,212 (6.3%)

In its previous biological opinion on the Northern Rockies Lynx Management Direction (U.S. Department of the Interior 2007b), the U.S. Fish and Wildlife Service assumed that fuel treatments within the wildland urban interface would not be excessively concentrated in adjacent lynx analysis units because fuel treatment projects may not result in more than three adjacent lynx analysis units exceeding standard VEG S1 (that is, 30 percent or greater currently unsuitable). These limitations would continue to limit the concentration of impacts to Canada lynx in the future.

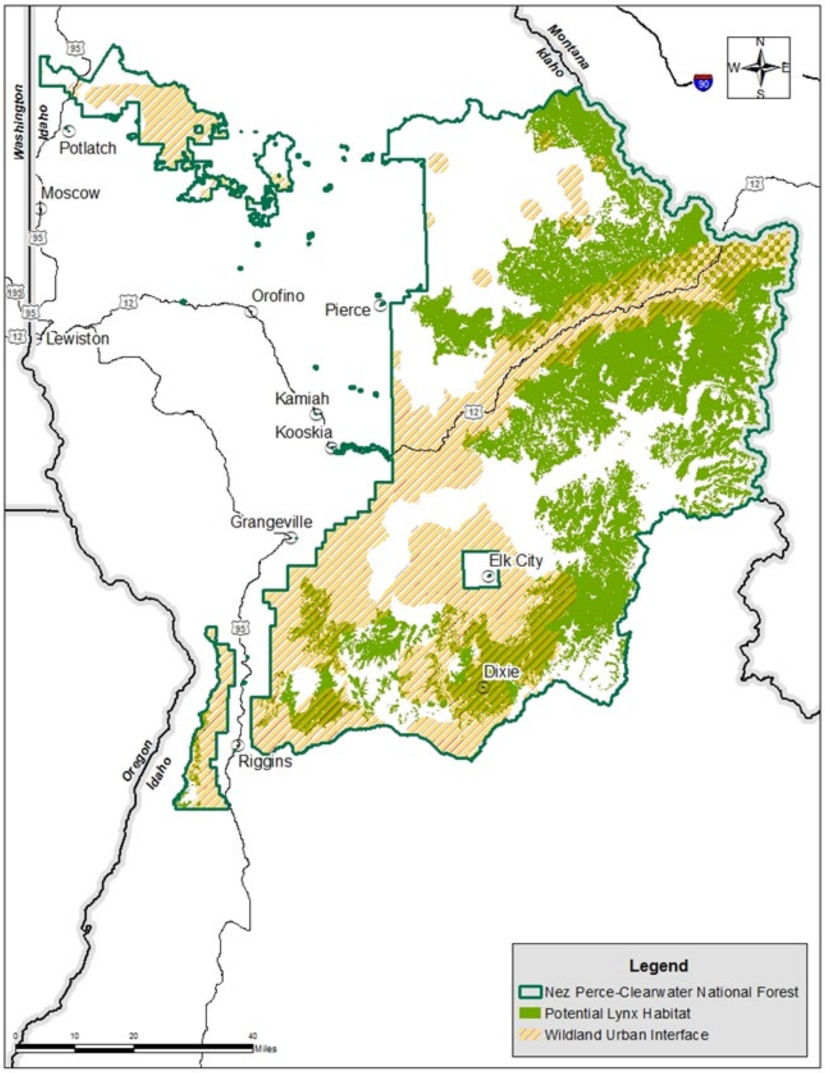

Figure 84. Wildland urban interface areas proposed for fuels exemptions

To date the total amount of fuels treatments occurring in lynx habitat on the Nez Perce-Clearwater amounts to 17,257 acres, which is about 1.2 percent of the lynx habitat in the plan area. However, since 2007, the Nez Perce-Clearwater has used none of the exempted acres analyzed in the Incidental Take Statement. Instead, all fire and fuels projects have abided the Northern Rockies Lynx Management Direction (NRLMD) standards and guidelines (that is, no thinning or reduction of the understory in multi-story habitat was conducted in lynx habitat) and individual projects went through consultation. Fuels treatments in the wildland urban interface are anticipated to have adverse effects on lynx and their snowshoe hare prey because the intent would be to maintain lower tree density in these areas, resulting in less area of dense horizontal cover.

Reductions in snowshoe hare habitat due to fuels treatments, including commercial harvest and precommercial thinning, could lead to lowered reproduction and survival of lynx. However, adverse effects are limited in their extent and distribution. In its previous biological opinion on the NRLMD (U.S. Department of the Interior 2017e), the U.S. Fish and Wildlife Service assumed that fuel treatments within the wildland urban interface would not be excessively concentrated in adjacent lynx analysis units because fuel treatment projects may not result in more than three adjacent lynx analysis units exceeding

Standard VEG S1. Except to create defensible space, the exceptions may not be used in lynx analysis units that have more than 30 percent in stand initiation structural stage that does not yet provide winter snowshoe hare habitat. These limitations would continue to limit the concentration of impacts to Canada lynx in the future. As previously stated, a sound rationale for the need and efficacy of fuels treatments is needed when claiming the exemptions to the Northern Rockies Lynx Management Direction (NRLMD) Vegetation Standards for fuels reduction projects implemented in the wildland urban interface.

The Standards, Objectives, and Guidelines laid out in the NRLMD only apply to occupied lynx habitat. Since the Nez Perce portion of the national forest is currently considered unoccupied NRLMD directs that projects need only consider applicable Standards, Objectives, and Guidelines. As with the Incidental Take Statement (ITS) for the NRLMD, the ITS for the Forest Plan Revision Lynx Biological Assessment will not include exemption or exception acres assigned to the unoccupied portion of the Nez Perce-Clearwater. Despite this the intent is to develop projects and analyze the effects of individual projects on this portion of the national forest as if it were occupied which is in line with regional forester direction. As a result, exemption acres will be applied to projects and tracked for reporting at such a time as the national forest is considered occupied.

Past fire regimes are described in the Assessment (U.S. Department of Agriculture 2014l, k), the Forestlands section, and Fire Management section. Fire regime differs by broad potential vegetation type, which for lynx is the cool, moist, and cold potential vegetation types. Fire regimes in these potential vegetation types are characterized by many frequent small fires and periodic large stand replacing fires. Within stand replacing fires, burn severity can vary because of temperature, humidity, time of day or night, and wind, leaving the habitat within a burned landscape variable. The majority of fire starts result in small acreages burned, adding heterogeneity to size classes, patch size, and forest structure. However, the greatest change agent in lynx habitat is stand replacing fire. The assumption is that most wildlife species are adapted to take advantage of the characteristics of this fire adapted ecosystem through time. Lynx use wide landscapes and some evidence suggests they reproduce better in those that have some mix of early seral and mature multistory (Kosterman et al. 2018).

Fire suppression over long periods of time can affect forest composition, dominance types, size class distribution, forest density, forest structure in single multi-story versus single story, habitat heterogeneity in distribution and size of habitat patches, and change in fire return intervals. Over shorter timeframes, fire suppression increases the amount of older age classes, decreases younger age classes, favors shade tolerant tree species over shade intolerant species, increases patch size resulting in less heterogeneity, increases forest density, and increases woody debris. Over longer time frames, fuel conditions build up and increase the chance of stand replacing wildfires. They are also more susceptible to insect outbreaks. Recovery from uncharacteristic fires takes longer and may not provide lynx habitat because of their size. The effects of changes in lynx habitat because of fire suppression is not well studied but some effects could be inferred from what is known about lynx and their prey.

Characterizing the impact of fire suppression as a threat to lynx is complex. Before European settlement, Native Americans were allowing wildfire to burn the landscape and managing the forest by active ignition in some cases, possibly since the Pleistocene. Shortly after European settlement, fires were suppressed across the Nez Perce-Clearwater, resulting in stand conditions today.

More recently, much of the plan area has been designated as wilderness where natural processes such as wildfires have been encouraged to take place. These areas are moving towards their natural range of variation through time. Yet, effects from suppression prior to wilderness designation still have some residual effects where some areas continue to be departed.

Given that about 43 percent of lynx habitat is in wilderness, which is trending towards its historic range of variability, and assuming that the rest of the lynx habitat on the Nez Perce-Clearwater has been under suppression for more than 100 years, the scope of effects of fire suppression is estimated to be somewhere between 30 to 70 percent. This puts the estimated scope in the large category using the NatureServe's rule-based methodology for determining threat magnitude. See Appendix C for additional details.

Severity of impacts from fire exclusion is difficult to assess using NatureServe methodology. Fire suppression probably enhanced lynx habitat over the intermediate term because Engelmann spruce and subalpine fir dominance types are estimated to have increased (U.S. Department of Agriculture 2014l). Similarly, fire suppression has probably increased the amount of multi-storied mature forests, which are known to be selected by lynx.

Long-term, fire suppression leaves many multi-storied stands susceptible to uncharacteristic wildfire. Fires have increasingly burned larger, longer, and hotter than they have both historically and prehistorically across the western United States (Dennison et al. 2014). Large wildfires burning uncharacteristically have the potential long-term to reduce much of the multi-storied forest stands to a stage that is unsuitable for lynx use. For more information about fire within the Nez Perce-Clearwater see the Fire Management section.

Evidence from the Nez Perce-Clearwater suggests that the most significant factor changing lynx habitat into a currently unsuitable condition over the last decade or longer has been wildfire. This is evident when considering that the predominant cause of lynx analysis unit's trending towards more than 30 percent in an unsuitable condition was caused by wildfire. Table 222 shows the total amount of habitat that falls within a fire perimeter that has burned since about 2000 when the Canada lynx was listed. Not all the habitat within these perimeters have burned nor have they burned at high severity.

Table 222. Acres of lynx habitat that fall within the perimeter of fires since lynx were listed

Fire Perimeters	Acres Lynx Habitat	Percent of Habitat
Unburned	1,050,035	72
Burned	407,444	28
Total	1,457,479	100

This analysis uses Burned Area Reflectance Classification (BARC) data to evaluate how fires have burned in lynx habitat. BARC data uses a satellite-derived data layer of post-fire vegetation condition. The BARC has four classes: high, moderate, low, and unburned. Burn severity data is only recorded on fires larger than 1,000 acres and has only been available since about 2000. Table 223 shows the burn severity of all fires in the plan area that had burn severity data collected and shows the acres and percent of burn severity by broad potential vegetation type. Thus, not all burned acres should be considered unsuitable for lynx, only those that burned at high or moderate burn severity. An estimated 28.97 and 26.03 percent of acres of lynx habitat in the cold and cool moist potential vegetation type groups burned at high severity within these burn perimeters. So, while 28 percent of lynx habitat fell within a fire polygon, only about 27.2 percent burned at high severity. High severity burns include acres of cool moist potential vegetation type plus acres of cold potential vegetation type combined divided by total acres of these potential vegetation types burned. Fires have been, by far, the largest agent of disturbance in lynx habitat in the plan area, followed by insects and disease.

Table 223. Percentage and acres of burn severity by broad potential vegetation types

Broad Potential Vegetation Type	Acres Cold	Acres Cool Moist	Acres Warm Dry	Acres Warm Moist	Percent Cold	Percent Cool Moist	Percent Warm Dry	Percent Warm Moist
High Severity	52,632	65,778	32,795	18,246	29%	26%	10%	10%
Low Severity	39,720	59,265	130,827	72,718	22%	23%	40%	39%
Moderate Severity	48,997	67,474	62,487	40,772	27%	27%	19%	22%
Unburned to Low Severity	40,337	60,151	97,128	53,149	22%	24%	30%	29%
Total	**181,686**	**252,669**	**323,237**	**184,885**	**100%**	**100%**	**100%**	**100%**

Data Source: BARC data within fire perimeters since burn severity was recorded in BARC

Under the assessment, modeling results from SIMPPLLE estimate that the amount of forest in early seral age classes has declined (U.S. Department of Agriculture 2014m). Early seral habitats and mature multi-story habitats are both known to support higher snowshoe hare numbers (Berg et al. 2012, Ruggiero et al. 1999). The amount of fire before fire suppression was much higher previously than today.

Holbrook et al. (2017) studied lynx selection in Montana. They found that lynx increasingly used advanced regeneration forest structures as they became more available at up to a maximum availability of 40 percent. Holbrook et al. (2017) suggested that land managers have an opportunity to promote lynx habitat in the form of advanced regeneration but are required to go through the stand initiation phase. Fire suppression reduces the amount of advanced regeneration because there is less in early stand initiation stage. Under all alternatives, the plan direction is to increase the amount of early seral conditions in the plan area, though the rate at which it is accomplished varies by alternative. These activities should reduce the size and extent of wildfires that could contribute to abundance of early seral forest in lynx habitat.

Fuels may interact with warmer or drier conditions. Large wildfires in lynx habitat are also believed to be strongly associated with changing climate factors. Westerling et al. (2006) compiled information on large wildfires in the western United States from 1970 to 2004 and found that large wildfire activity increased suddenly and markedly in the mid-1980s with a higher frequency of large wildfires, longer wildfire durations, and longer wildfire seasons. The greatest increases occurred in mesic, mid-, and high-elevation forest types in the northern Rocky Mountains. Westerling et al. (2006) stated that fire exclusion (suppression) has had little impact on the natural fire regimes of these higher-elevation forest types in this area; instead, climate appears to be the primary driver of forest wildfire in these stand replacing fire regimes. Alternatives in the plan that expedite returning the forest to natural range of variation conditions more quickly would reduce the risk of uncharacteristic wildfires. Alternative X achieves the return towards desired conditions more quickly than the others, followed by Alternative W then Alternative Y. Alternative Z is continuing at similar levels to current activity over the last few years under the No Action Alternative. The Preferred Alternative is like Alternative W.

On all lands, large wildfires in lynx habitat are believed to be strongly associated with changing climate factors. Wildland fires are likely to be actively suppressed to prevent loss of infrastructure and investments on all lands. Wildfires are likely to play a natural role in cumulative effects.

Fuels Reduction Treatments in the Wildland Urban Interface

As stated in the Northern Rockies Lynx Management Direction (NRLMD) (U.S. Department of Agriculture 2007f) and associated Incidental Take Statement (U.S. Department of the Interior 2012), the wildland urban interface is defined by the Healthy Forests Restoration Act. The U.S. Fish and Wildlife Service's biological opinion on the NRLMD (U.S. Department of the Interior 2017c) stated that fuels treatment projects in the wildland urban interface would be exempted from compliance with VEG S1, VEG S2, VEG S5, and VEG S6 under certain conditions designed to protect communities at risk in recognition of the escalating monetary and societal costs associated with fires in the wildland urban interface. For NRLMD analysis purposes, the wildland urban interface was modeled in 2007 as a 1-mile buffer surrounding communities with more than 28 people per square mile. Over the entire northern Rocky Mountains' geographic area analyzed by the U.S. Fish and Wildlife Service, about 6 percent of lynx habitat was found to be within one mile of communities. The 2007 Incidental Take Statement, updated in 2017, constrains wildland urban interface exemption treatments to no more than 6 percent cumulatively of lynx habitat on an individual national forest.

All action alternatives would carry forward the 6 percent exemption for vegetation treatments within the wildland urban interface, which is 44,607 acres for the Clearwater National Forest, for the life of the Land Management Plan. The Nez Perce National Forest was not required to consult on acres of fuels treatment exempt from the vegetation standards found in the NRLMD because it was found unoccupied by lynx.

Fuels treatments in the wildland urban interface are anticipated to have adverse effects on lynx and their snowshoe hare prey because the intent would be to maintain lower tree density in these areas, resulting in less area of dense horizontal cover. Reductions in snowshoe hare habitat due to fuels treatments and precommercial thinning could lead to lowered reproduction and survival of lynx. However, adverse effects are limited in their extent and distribution. In its previous biological opinion on the NRLMD (U.S. Department of the Interior 2017c), the U.S. Fish and Wildlife Service assumed that fuel treatments within the wildland urban interface would not be excessively concentrated in adjacent lynx analysis units because fuel treatment projects may not result in more than three adjacent lynx analysis units exceeding Standard VEG S1. Except to create defensible space, the exceptions may not be used in lynx analysis units that have more than 30 percent in stand initiation structural stage that does not yet provide winter snowshoe hare habitat. These limitations would continue to limit the concentration of impacts to Canada lynx in the future.

Wildland Fire Management

As stated in the NRLMD, VEG O3 encourages fire use activities that restore ecological processes and maintain or improve lynx habitat. Under guideline VEG G4, prescribed fire activities should not create permanent travel routes that facilitate snow compaction and permanent firebreaks should not be constructed on ridges or saddles. As displayed in the "Affected Environment" section, fire has historically played a substantial role in creating forested landscape patterns on the Nez Perce-Clearwater and fire continues to do so. The Nez Perce-Clearwater has experienced several large stand-replacing wildfires since 2000. In the next 15 to 25 years, a substantial portion of burned forest is expected to develop sufficient height and density to provide dense horizontal cover of branches at the snow surface to provide snowshoe hare habitat under all alternatives. The plan promotes greater use of wildfire within Management Areas 1 and 2, while wildfire in Management Area 3 would likely be suppressed due to proximity to values such as private property, infrastructure, and natural resources. See Section 2.1.6 of the Land Management Plan for fire management plan components. Natural ecosystem processes, such as wildfire, would contribute to denning habitat for Canada lynx, as would forestwide plan components for old growth, snags, and downed wood.

Fragmentation of Habitat

Human-caused alterations of natural landscape patterns can reduce the total area of habitat, increase the isolation of habitat patches, and affect movement between those patches of habitat (Interagency Lynx

Biology Team 2013). Habitat fragmentation may be permanent, such as when converting forest habitat for residential developments or agricultural use, or temporary, such as when creating a forest opening through timber harvest until trees and shrubs regrow. Fragmentation of lynx habitat in the plan area due to anthropogenic developments is very low because the Nez Perce-Clearwater is a large contiguous block of area with much of it managed as wilderness or Idaho Roadless Rule areas. The scope of permanent fragmentation is small, and the severity is slight.

Temporary fragmentation occurs because of departure of historic patterns of vegetation pattern. The amount of departure at a landscape scale is large, but the effect of this departure on fragmentation is probably slight. This could change if fires burn uncharacteristically in relation to their historic fire regime. Plan components in the Forestlands section of the Final Environmental Impact Statement address the distribution of disturbance suggestive of the natural range of variation.

Changing Climate

The Lynx Conservation Assessment and Strategy did not provide management recommendations specific to changing climate, although it did identify several information needs. Possible effects on lynx because of future changes in climate are:

- Potential upward shifts in elevation or latitudinal distribution of lynx and their prey.
- Changes in the periodicity of when snowshoe hares change color or loss of snowshoe hare cycles in the north.
- Reductions in the amount of lynx habitat and associated lynx population size due to changes in precipitation, particularly snow suitability and persistence, and changes in the frequency and pattern of disturbance events, such as fire and insect outbreaks.
- Changes in the demography of lynx, such as survival and reproduction rates.
- Changes in predator-prey relationships.

There is a high level of uncertainty about some of these hypothesized effects. These effects are not expected to be realized fully within the next 15 years. At most, within the 15-year timeframe of the plan, the severity would probably fall between slight with affects between 0 and 10 percent and moderate with affects between 11 and 30 percent for this threat under the NatureServe methodology for evaluating threats. Climate change is pervasive in extent in the plan area and may interact with wildfire and wildfire suppression to shift the distribution and amount of lynx habitat over time. Climate change is influencing 100 percent of all lynx habitat in the plan area; thus, the scope is pervasive. Using the moderate severity category estimates, the overall impact from climate change is estimated to be a medium threat by the combination of pervasive scope and moderate severity. Over longer timeframes, the effects could be much more severe.

Winter and Summer Recreation

Some kinds of recreational activities cause loss of habitat, behavioral responses to human disturbance, or snow compaction. Permanent habitat loss can occur within ski resorts from the clearing of trees for permanent infrastructure. Changes in winter habitat can result from vegetation removal and grooming of ski runs. The plan area does not contain ski resorts. Studies in Colorado of lynx and winter recreators showed that lynx do not avoid winter recreation until it gets more intensive (Olson et al. 2018) and suggests lynx are tolerant of human activities. A variety of behavioral responses may be expected from individual lynx and in different contexts (Interagency Lynx Biology Team 2013). Recreation can occur across all lynx habitat but accessibility limits both the distribution and intensity of recreation and may vary seasonally. Mechanized recreation is disallowed in designated wilderness so recreation must be accessed on foot or horseback. This leaves the scope of this threat overall as large but the severity slight for an overall threat impact of low using the NatureServe methodology for assessing threats. The alternatives vary in the amount of habitat that is open to motorized recreation(Table 224 and Table 225). Alternative W has the least amount of lynx habitat in a summer motorized recreation opportunity spectrum setting at 30 percent. All other alternatives have between 50 and 59 percent open within motorized settings. These amounts are driven primarily by the allocation of recommended wilderness. The Preferred Alternative has 743,105 acres of lynx habitat within a motorized winter recreation opportunity spectrum setting while 744,995 acres are non-motorized.

Squires et al. (2019) studied lynx habitat use concurrently with snowmobile recreation. They distributed GPS units to winter recreationists and documented 2,143 spatial movement tracks of recreationists engaged in motorized and nonmotorized winter sports for a total cumulative distance of 56,000 km from 2010 to 2013. They also deployed GPS radio collars on adult Canada lynx that were resident in the mountainous topography that attracted high levels of dispersed winter recreation. Squires et al. (2019) found that resource-selection models for Canada lynx were significantly improved when selection patterns of winter recreationists were included in best-performing models. Canada lynx and winter recreationists partitioned environmental gradients in ways that reduced the potential for recreation-related disturbance. Although the inclusion of recreation improved the resource-selection models model for Canada lynx, environmental covariates explained most variation in resource use. The environmental gradients that most separated areas selected by Canada lynx from those used by recreationists were forest canopy closure, road density, and slope. Canada lynx also exhibited a functional response of increased avoidance of areas selected by motorized winter recreationists for snowmobiling off-trail and hybrid snowmobiling compared with either no functional response with hybrid skiing or selection for backcountry skiing areas suitable for nonmotorized winter recreation. Under the No Action Alternative, about 47 percent of the lynx habitat on the Nez Perce-Clearwater is closed to over-snow motorized vehicle use, leaving 53 percent open to winter motorized recreation. Primitive and semi primitive non-motorized are the two categories of the recreation opportunity spectrum that do not allow motorized over-snow travel. Other recreation opportunity spectrum settings are open to motorized over-snow travel. The amount of lynx habitat in winter recreation opportunity spectrum settings changes under the alternatives because the alternatives motorize settings are adjusted to account for the change in the amount of recommended wilderness. The alternatives also vary by the amount of non-conforming uses that are allowed in the recommended wilderness areas. The semi-primitive motorized and non-motorized settings change the most by alternative. Alternative W allows the least over-snow motorized use and Alternatives X and Z have the highest percent of lynx habitat in a motorized setting (Table 225).

Table 224. Acres of lynx habitat within each summer recreation opportunity spectrum (ROS) setting by alternative

Acres	Alternative W	Alternative X	Alternative Y	Alternative Z	Preferred Alternative
Primitive	597,361	597,361	603,547	603,547	582,396
Rural	533	533	533	533	2,579
Roaded Natural	182,981	210,473	194,495	189,357	223,600
Semi-Primitive Motorized	247,500	427,696	214,004	192,648	365,334
Semi-Primitive Non-motorized	429,394	221,706	445,189	471,683	314,192

Table 225. Percent lynx habitat in motorized or non-motorized winter recreation opportunity spectrum

Percent lynx habitat	Alternative W	Alternative X	Alternative Y	Alternative Z	Preferred Alternative
Non-motorized winter setting (semi-primitive non-motorize and primitive)	70%	41%	50%	41%	50%
Winter motorized setting (roaded natural and semi primitive motorized)	30%	59%	50%	59%	50%

As discussed previously, Kolbe et al. (2007) found that compacted trails from over-snow motorized vehicles in their study area in western Montana did not promote a competitive interaction between coyotes and lynx. Squires et al. (2010) found no evidence that lynx selected areas away from National Forest System roads or groomed snowmobile trails during winter.

Although the Nez Perce-Clearwater is closed to lynx trapping, a potential indirect effect of motorized over-snow vehicle use is that it could facilitate access to lynx habitat and increase the vulnerability of lynx to incidental or accidental trapping or illegal shooting. Motorized over-snow vehicles provide access for trapping of other furbearers, which has the potential to increase the risk of incidental trapping of lynx; however, actual occurrences of incidental trapping of a lynx in Idaho is a rare event and usually results in live release. Wilderness areas and recommended wilderness on the Nez Perce-Clearwater are closed to motorized use and the majority of the lynx habitat is within either wilderness or recommended wilderness and is largely inaccessible during trapping seasons. Shifting areas suitable for motorized over-snow vehicle use within the Nez Perce-Clearwater would slightly increase the risk of accidental or incidental trapping in some alternatives.

In our plan area, snowmobiling recreation is not intense in most areas because the forested vegetation inhibits this activity in many locations. Thus, over-snow travel is often limited to designated routes and known areas of use.

To estimate where over-snow motorized uses are preferred, a combination of known use areas, as identified by user groups, and known groomed routes were used, combined with modeling of landscape factors that promote snowmobile use like methods published in Olson et al. (2018). Olson et al. (2018) used snowmobile use data collected from GPS units carried by winter recreation users. Those criteria were applied to the landscape to model the probability of snowmobile use based on topography, vegetation, climate, and access to predict where snowmobiling has a higher probability of occurrence. Many areas that do have a high probability of use correspond well to where recreation is known to occur. The primary exception is in areas where groomed trails have been established and use is primarily on those routes based upon modeling results. The model outcomes of the snowmobile model are shown in Figure 89 in the wolverine section, which also shows the areas that are non-motorized under the Preferred Alternative. While snowmobiling is possible in any portion of the Nez Perce-Clearwater, the terrain and vegetation render many areas as not preferred for winter motorized snowmobile recreation.

The Land Management Plan does not make site-specific determinations on snowmobile route grooming or snowmobile recreation areas. Rather, it controls where the activity would be suitable and the settings under which those activities may be conducted after a site-specific analysis. Alternatives X and Z would have higher amounts of area suitable for over-snow travel. The Preferred Alternative allows approximately 50 percent of lynx habitat to be suitable for motorized uses while approximately 50 percent would not be suitable. The No Action Alternative did not have winter recreation opportunity spectrum settings as suitability plan components, and so these are new constraints imposed by the plan. Instead, winter motorized recreation was open everywhere unless closed by travel decisions like the clearwater travel plan or site-specific closures. Additional snow compaction would occur on some but not all this acreage because there are portions where tree cover is too dense for snowmobiles to navigate.

Guideline HU G11 of the Northern Rockies Lynx Management Direction states that designated motorized over-snow vehicle routes or designated play areas should not expand outside baseline areas of consistent snow compaction unless designation serves to consolidate use and improve lynx habitat within a lynx analysis unit or a combination of immediately adjacent lynx analysis units. Based on scientific findings on snow compaction, competing predators, and risk of accidental trapping mortality relevant to the Northern Rockies, there would be minimal risk to lynx from over-snow vehicle use.

Increased competition from other predators due to snow compaction is a minor concern. As discussed previously, Kolbe et al. (2007) found that compacted trails from motorized over-snow vehicles in their study area of western Montana had only minimal impacts on coyote movements and foraging success and that snowshoe hares were an insignificant portion of the winter diet of coyotes, indicating that snow compaction did not promote a competitive interaction between coyotes and lynx. Furthermore, evidence from Colorado suggests lynx naturally choose to use areas not typically used by winter motorized recreational users because lynx tend to use forested habitats where winter recreational users often prefer non-forested areas (Squires et al. 2019). In summary, the level and distribution of winter recreation is not likely to negatively impact the overall lynx population, although there is some risk of injury or mortality to individual lynx.

In vicinities that are already heavily used by motorized over-snow vehicles, there is a potential for the additional suitable areas to result in an increase in consistent snow compaction, as defined by the Northern Rockies Lynx Management Direction. The effects of this increase on Canada lynx are anticipated to be minor based upon scientific findings (Kolbe et al. 2007, Squires et al. 2013, Squires 2010). In addition, not all the acreage in the added suitable areas would be expected to have an increase in consistent snow compaction because terrain and vegetation influence where motorized over-snow vehicles can physically go. Vegetation conditions are dynamic over time and change in response to disturbance and succession. Wildfire may initially open up dense forests for motorized over-snow vehicle use but areas previously open to motorized over-snow vehicle use become unavailable because the machines cannot physically maneuver between or over the trees as high densities of dead trees fall or as succession occurs.

Winter Recreation—Developed Ski Areas

Downhill ski resorts typically are located at high elevations in areas with coniferous forests and deep snow, which coincides with lynx habitat. There are no ski resorts on Nez Perce-Clearwater lands, and none are proposed.

Mining and Energy Development

The Nez Perce-Clearwater has a long history of mineral exploration and development activity. Most of the mining has been oriented around rivers or in hard rock but a few of them are open pit mines. Most mine activities on the Clearwater National Forest have been outside of lynx habitat. Mines on the Nez Perce National Forest do extend up into lynx habitat around Elk City and southward along Crooked River. They likely have little effect on lynx habitat and would not affect a transient lynx.

No oil and gas sites have been developed and no foreseeable oil and gas exploration is expected. The geology under the Nez Perce-Clearwater has low potential for oil and gas production. As stated in Land Management Plan Appendix 8, HU O5 says to manage human activities, including minerals and oil and gas exploration and development, to reduce impacts to lynx and lynx habitat. Guideline HU G4 encourages remote monitoring of mineral and energy development sites and facilities to reduce snow compaction. Guideline HU G5 addresses development of a reclamation plan to restore lynx habitat when mineral and energy development sites and facilities are closed. HU G12 limits winter access for non-recreation special uses and mineral and energy exploration and development to designated routes or designated over-the-snow routes. The application of these measures is expected to minimize adverse effects on lynx.

Many acres of National Forest System lands on the Nez Perce-Clearwater are withdrawn from mineral entry. Designated wilderness, Idaho Roadless Rule areas, wild and scenic rivers, and research natural areas have withdrawn or restricted mineral exploration.

Withdrawal of large areas of the Nez Perce-Clearwater from mineral development reduces the risk of Canada lynx habitat loss, disturbance, displacement, and mortality. All withdrawals are subject to valid existing rights. The Forest Service does not have the discretion to deny the right to exercise an outstanding mineral right. However, the developer does not have unrestricted rights because the developer's rights are limited to using only as much of the surface as is reasonably necessary to explore, develop, and transport materials. The developer must provide an operating plan to the Nez Perce-Clearwater. The Nez Perce-Clearwater has some ability to manage surface resources. Forest Service Manual 2832 provides direction for administration of outstanding mineral rights.

National Forest System and Backcountry Roads

On the Nez Perce-Clearwater, the majority of roads occur within the lands managed as general management in Management Area 3 and outside of lynx habitat, as most of the lynx habitat is within Idaho Roadless Rule areas and wilderness where new road construction is prohibited. About 17 percent of lynx habitat occurs within Management Area 3 so most of the effects of backcountry roads are limited to this area, though some existing roads do separate or are cherry stemmed into Management Areas 1 and 2. Within Roadless Rule areas, roads travel between roadless areas but are already established. The Land Management Plan will not make any specific decisions on roads but establishes the setting governing future proposed roads.

As stated in the Northern Rockies Lynx Management Direction, four plan guidelines concern National Forest System roads:

- HU G6 says to use methods that avoid or reduce effects on lynx when upgrading unpaved roads to Maintenance Levels 4 or 5.
- HU G7 discourages building new permanent roads on ridgetops, saddles, or forested stringers or in areas identified as important for lynx habitat connectivity.

- HU G8 says that brush cutting along low-speed, low-traffic-volume roads should be done to the minimum level necessary to provide for public safety.
- HU G9 says that public motorized use should be restricted on new roads built for projects.

These plan components would continue to limit the potential local impacts of roads on lynx and lynx habitat.

Road construction results in a small reduction of lynx habitat by removing forest cover. On the other hand, if a road is closed, regrowth of dense vegetation may provide good snowshoe hare habitat, and lynx may use the roadbed for travel and foraging (Koehler and Brittell 1990). Extensive backtracking studies in Montana found that lynx did not avoid gravel forest roads (Squires 2010). Trails are typically narrow routes with a native surface; there is no information to suggest that trails have negative impacts on lynx (Interagency Lynx Biology Team 2013). Road densities within lynx habitat on the Nez Perce-Clearwater are low because most lynx habitat occurs within roadless and wilderness. Thus, the overall impact is low because of its small scope in lynx habitat and low severity in effects.

Livestock Grazing

Livestock grazing occurs on less than 15 percent of the Nez Perce-Clearwater. Twelve livestock grazing allotments, all located on the Nez Perce half of the plan area, include lynx habitat. No lynx habitat is located within livestock grazing allotments on the Clearwater. The Northern Rockies Lynx Management Direction (Land Management Plan Appendix 5) contains one objective and four guidelines pertaining to livestock grazing management in lynx habitat in occupied habitat. Objective GRAZ O1 provides direction to manage livestock grazing to be compatible with improving or maintaining lynx habitat. Guideline GRAZ G1 states livestock grazing should be managed in fire- and harvest-created openings so impacts do not prevent shrubs and trees from regenerating. Under guideline GRAZ G2, livestock grazing in aspen stands should be managed to contribute to the long-term health and sustainability of aspen. Under guideline GRAZ G3, livestock grazing in riparian areas and willow carrs should be managed to contribute to maintaining or achieving a preponderance of mid- or late-seral stages, similar to conditions that would have occurred under historic disturbance regimes. Under guideline GRAZ G4, livestock grazing in shrub-steppe habitats that are in the elevation ranges of forested lynx habitat in lynx analysis units should be managed to contribute to maintaining or achieving a preponderance of mid- or late-seral stages, similar to conditions that would have occurred under historic disturbance regimes. With these components in place, the effects of livestock grazing on lynx and lynx habitat were judged to be minimal across the analysis area in the northern Rockies

The management direction only applies to occupied lynx habitat. Since the Nez Perce currently has unoccupied lynx habitat, the direction should be “considered” but would not have to be followed until such time as lynx occupy the unit. Any authorization or re-authorization of grazing allotments should consider the management direction.

The livestock grazing allotments are the same under all alternatives. Table 226 shows the amount of lynx habitat located within allotments. Two allotments that include 60,668 acres of lynx habitat are vacant and not currently grazed. Approximately 72,627 acres are located in active allotments.

No existing research indicates that grazing or browsing by domestic livestock on federal lands would reduce the snowshoe hare prey base or have a substantial effect on lynx (Interagency Lynx Biology Team 2013). However, it is possible that livestock browsing or grazing could reduce the forage and dense horizontal cover needed by snowshoe hares in some environments.

About five percent of the total lynx habitat overlaps with active livestock allotments. Not all areas of allotments are grazed, and most multistory forest is not grazed because it does not produce enough forage for livestock. Proposed desired conditions under the action alternatives promote a diverse mix of native plant communities and guidelines limit upland forage utilization (FW-GDL-GRZ-03) and maintenance of stubble heights of at least 10 to 15 centimeters along the greenline (FW-GDL-ARGRZ-01). The overall impact from this threat is assessed as low with a small scope and slight severity. Effects to lynx habitat would be negligible in the plan area.

Table 226. Acres lynx habitat by allotment

Allotment Name	Status	Acres of Lynx Habitat	Percent of Allotment
Allison-Berg	Active	6,308	17%
Butte Gospel	Active	22,261	57%
Cannon Ball	Active	4,983	19%
Cow Creek	Active	2,589	9%
Fiddle Creek	Active	1,253	15%
Florence	Vacant	27,681	52%
Hanover Mountain	Active	6,387	41%
Hungry Ridge	Active	6,218	20%
Mallard Creek	Vacant	32,987	89%
Papoose	Active	2,416	18%
Peter Ready	Active	13,246	28%
White Bird Creek	Active	6,967	21%
Total	Vacant	60,668	n/a%
Total	Active	72,627	n/a%

Mortality Due to Highways and High-Speed Forest Roads

Mortalities of lynx due to vehicle collisions have been documented in Colorado (reintroduced animals on paved highways), in Minnesota (on paved highways), in Maine (on high-speed gravel roads), and in Montana (on highways). Collisions are unlikely to occur on National Forest System roads, which are traveled at slower speeds and have lighter traffic volumes than highways. Comparatively, few paved roadways traverse through the Nez Perce-Clearwater. The longest paved roadways include U.S. Highway 12 along the Lochsa River, the Salmon River Road, portions of the Selway River Road, and Highway 14 along the Southfork Clearwater River. Other paved roadways include Highway 8 and Highway 3 through limited portions of the Palouse district and a few other portions of paved roads that end shortly after entering National Forest System lands. Highway 12 and Highway 14 allow traffic speeds between 45 to 50 miles per hour so it may be possible on rare occasions for a lynx to be struck by a moving vehicle on these roads. However, these roads have comparatively low traffic volumes and most of these road miles do not travel through lynx habitat because of their lower elevation. There are no major roadways that travel north to south in the plan area. Few, if any, lynx have been reported as killed on the paved roads in the plan area. The overall impact from these roads is low because roads on the Nez Perce-Clearwater only travel through a limited portion of the plan area (small scope) and the severity is slight (not expected to impact more than 10 percent of the lynx population) because most paved roads do not travel through lynx habitat and few lynx are expected to be struck on these roads. Perhaps the most significant impact is to lynx habitat connectivity. These roads currently represent only very minor impacts to connectivity.

Mortality Due to Incidental Trapping or Illegal Shooting of Canada Lynx

The Forest Service usually does not regulate trapping activities on National Forest lands and defers to the state on regulations regarding hunting, fishing, and trapping activities by the public. Trapping, snaring, and shooting of lynx is currently prohibited in the contiguous United States. In Idaho, there is no open season for trapping lynx, and it has been prohibited since 1996 though the Center for Biological Diversity versus Otter (No. 1: 14-CV-258-BLW) case expressed concerns about incidental trapping of lynx when targeting other fur bearers. If a trapper traps a “non-target” animal such as a lynx, it must be “released immediately” if alive and taken “into possession” if dead (Title 36 Fish and Game, Chapter 11 Protection of Animals and Birds). Idaho has not adopted any laws that limit the types of traps that may be used in lynx habitat. However, incidents of inadvertent trapping of lynx in Idaho have been low. As an example, between January 2012 and February 2014, there were four reported incidental trappings of lynx in Idaho. The Center for Biological Diversity versus Otter (No. 1: 14-CV-258-BLW) case reviewed data stating three of these lynx were released alive while only one was mistaken for another species and killed by a hunter rather than the trap itself. None of the four incidents where lynx were incidentally trapped occurred in the Clearwater Region. Similarly, in Montana, a total of three lynx were captured during the eight license years between 2008 to 2015 and all were released uninjured; overall, lynx “take” during 2000 to 2007 averaged 1.6 per year (U.S. Department of the Interior et al. 2016). Most trapping of other furbearer species occurs in winter.

The distribution of legal trapping is influenced by the distribution of roads. Save for a few areas, the distribution of roads influences winter travel because forested vegetation makes over-snow travel difficult. About 51 percent of lynx habitat is in either recommended wilderness or designated wilderness under the Preferred Alternative, which makes accessibility to trappers more difficult. Wilderness and recommended wilderness are unsuitable for motorized or mechanized travel, including over-snow vehicles under the preferred alternative. Similarly, Idaho Roadless Rule areas also make accessibility more challenging to trappers because of a lack of roads. So, while the scope of trapping is technically available in all lynx habitats, in reality, because of accessibility, the scope is probably largely limited to less than an estimated 50 percent of lynx habitat, leaving the scope using the NatureServe methodology as large. Because lynx trappings are exceedingly rare in Idaho, let alone in the plan area, and lynx mortalities from trapping are also uncommon when lynx are trapped, the severity, or the extent to which lynx populations would be reduced, is estimated as slight. The overall magnitude of this threat is low with a large scope and slight severity. Regulation of trapping is under the authority of the State of Idaho, and the Forest Service only regulates this activity under specific circumstances. The alternatives vary in the amount of recommended wilderness and in whether over-snow travel would be suitable in recommended wilderness. The amount of recommended wilderness and whether over-snow travel is suitable could affect incidental trapping and access during winter. See the discussion below on recommended wilderness. In the Preferred Alternative, no motorized over the snow travel would be allowed in recommended wilderness.

Consequences from Changes in Management Area Direction

Consequences of plan components, other forestwide plan components, and management area direction are the same for all action alternatives, save for variations on snag retention, rate of attainment of desired vegetation conditions, the amount of over-snow motorized travel, differences in the types of non-conforming uses allowed within recommended wilderness areas, summer motorized recreation opportunity spectrum settings, restocking rates, live trees retained per acre, amount of timber production, and whether communication sites are allowed on Pilot Knob. The primary difference in alternatives from a management area perspective is in the mix of recommended wilderness and the amount of land identified as suitable wild and scenic rivers. Thus, the effects were analyzed separately for each alternative and each variation in plan component because any piece of the alternatives that varies could have been selected to make a unique combination. These alternatives were considered individually and make a unique combination in the Preferred Alternative.

Management area allocations provide the on-the-ground framework that guides which allowable uses may occur in areas of the Nez Perce-Clearwater. This section characterizes the management areas in Canada lynx habitat and discusses the effects of the resulting management direction on the species.

Under the alternatives, the amount of designated wilderness and Idaho Roadless Rule areas will not change. The Idaho Roadless Rule themes could change if selected as recommended wilderness; otherwise, Roadless Rule themes do not vary by alternative. The Idaho Roadless Rule includes several themes which vary the management activities allowed and the purpose for which those activities may be conducted. All areas under consideration for recommended wilderness under the alternatives fall within Idaho Roadless Rule areas. After the alternatives are selected, and if needed, the Nez Perce-Clearwater will make a recommendation to the Chief of the Forest Service recommending a change in Roadless Rule theme to the wildland recreation theme for any areas identified as recommended wilderness. An Idaho Roadless Rule area theme of wildland recreation is the most restrictive Roadless Rule theme. As Roadless Rule area direction already restricts many activities in all themes, a change to recommended wilderness would result in only slightly more restrictive management and slightly more protections for lynx.

Recommended Wilderness and Nonconforming Uses

The recommended wilderness plan components in alternatives varied individually to make a unique combination of the amount of recommended wilderness and uses allowed in each alternative. Thus, for each alternative and for each variation in plan component, the effects are analyzed separately.

The amount of recommended wilderness varies by alternative. Recommended wilderness under Alternative W contains the most lynx habitat with up to 29 percent of all lynx habitat in the plan area while recommended wilderness under Alternative Z contains no lynx habitat. The Preferred Alternative includes a total of 258, 210 acres of lynx habitat in recommended wilderness which is approximately 12 percent of lynx habitat.

Table 227 shows the amount of lynx habitat that falls within each alternative. The No Action Alternative currently has 9 percent of the total lynx habitat within recommended wilderness. Alternative X would not recommend any wilderness, including areas currently recommended. The Preferred Alternative is most like Alternative Y, except that there were boundary adjustments for each of the recommended wilderness areas. The boundary changes occurred in the Hoodoo and Mallard-Larkin recommended wilderness and in the Preferred Alternative, the boundary was adjusted to accommodate recreation while protecting resources like mountain goats. The differences in boundary changes between alternatives are of little consequence because the suite of lands considered for recommended wilderness were all Idaho Roadless Rule areas managed for roadless character which helps protect lynx habitat. The one area where it matters is for winter motorized recreation where motorized recreation would be unsuitable in recommended wilderness but would be suitable in Idaho Roadless Rule Areas as evaluated above.

Table 227. Amount of lynx habitat occurring within the proposed recommended wilderness areas by alternative (Alt)

Recommended Wilderness Name	No Action Alternative Acres	NA %	Alt W Acres	W %	Alt Y Acres	Y %	Alt Z Acres	Z %	Alt X Acres	X %	Preferred Alternative Acres	P%
Bighorn - Weitas	0	0	131,312	9	0	0	0	0	0	0	0	0

Rawhide	0	0	0	0	0	0	5,548	0	0	0	0	0
Sneakfoot Meadows	8,042	1	21,774	1	0	0	18,301	1	0	0	0	0
Total Lynx Habitat and percent	**98,478**	**7**	**425,749**	**29**	**136,238**	**9**	**243,882**	**17**	**0**	**0**	**258,210**	**12**

Alternatives in recommended wilderness could influence lynx habitat connectivity. Several recommended wilderness areas are identified as linkage areas for lynx (U.S. Department of Agriculture 2007f). In particular, the Hoodoo area, East Meadow Creek, and Sneakfoot areas are identified as linkage areas for lynx. Changes to the Hoodoo recommended wilderness areas in Alternative Y would reduce the amount of linkage area compared to the No Action Alternative. This change would allow snowmobile use in these linkage areas while currently it is not allowed. The effects to transient lynx from intensive over-snow travel is unclear. The types of nonconforming uses allowed in recommended wilderness varies by alternative. The Preferred Alternative does not allow most nonconforming uses within recommended wilderness, except for aircraft landings and mechanized or motorized tools being allowed for administrative use.

MA2-STD-RWILD-02 varies by alternative. Under the No Action Alternative and Alternatives W, X, and Y, winter motorized recreation would be unsuitable in recommended wilderness while winter motorized recreation would be suitable as a non-conforming use under Alternative Z. Therefore, Alternative Z would allow over-snow travel and its effects within recommended wilderness. Winter motorized recreation would not be suitable in recommended wilderness under the Preferred Alternative. The analysis of the effects of over-snow motorized use identified habitat loss from disturbance and increased competition from other carnivores through snow compaction. The conclusions are that winter recreation would have minor impacts to lynx overall because of their tolerance of the winter recreation and evidence suggesting that other predators do not generally make enough use of compacted trails to greatly affect lynx.

The Lynx Conservation and Assessment Strategy (2013) concluded that:

Most backcountry ski hut sites are primitive in nature. Some facilities may have utilities, summer road access, and on-site storage for grooming equipment and fuel. Use by snowmobile clubs and the general public is often focused or concentrated around these sites. Many have developed trail systems that loop around the site or provide access to other remote areas. These facilities are generally located along designated cross-country ski and snowmobile routes. Users compact the snow along the route to and from the huts and in the immediate vicinity. Off-trail travel has the potential to create larger areas of compacted snow. However, as indicated above, this local snow compaction is short-term and not likely to change the competitive interactions between lynx and coyotes.

These buildings are currently existing and would not represent new developments. Their use would have minor impacts on lynx distribution and disturbance. The allowance of this activity would have only minor differences in impacts to lynx.

Designated and Eligible Wild and Scenic Rivers (Management Area 1)

The amount of suitable wild and scenic rivers varies by alternative. Under the alternatives, most of the wild and scenic rivers either fall outside of lynx habitat because they are lower in elevation, or they fall within Idaho Roadless Rule areas, recommended wilderness, or designated wilderness. The Nez Perce-Clearwater has four designated rivers—the Selway, the Lochsa, the Middle Fork Clearwater, and the Salmon River. During Land Management Plan, rivers eligible for wild and scenic designation were identified base upon their outstandingly remarkable values. Wild and scenic river segments are classified as wild, scenic, or recreational segments. Timber harvest is not allowable in river segments classified as wild. River segments classified as scenic or recreational are not suitable for timber production, but timber harvest may be allowed to meet desired social, economic, or ecological conditions. Wild and scenic river direction for designated rivers is managed as Management Area 1 while those found suitable are managed under Management Area 2 direction. Management direction for both designated and suitable wild and scenic rivers help to maintain wide forested corridors along major waterways that may facilitate lynx movement through the landscape, providing connectivity. Most rivers being considered suitable as wild and scenic rivers under the alternatives, and which also occur within lynx habitat, are located within Idaho Roadless Rule areas or designated wilderness areas. Thus, most of them have substantial restrictions already. Suitable wild and scenic river direction would apply to these areas in addition to guidance for Idaho Roadless Rule areas and designated wilderness area direction. Lynx are not river dependent, so they were not considered a criterion for determining wild and scenic river eligibility. One of the few rivers not within wilderness or roadless areas but within lynx habitat considered under the alternatives is Crooked Fork Creek. It flows through the checkerboard area of the Nez Perce-Clearwater and that area is identified as a linkage area. If this river were identified as suitable, it would enhance connectivity for lynx through this area, at least on National Forest System lands. The Preferred Alternative identified the second lowest acreage for wild and scenic rivers of the alternatives, save for Alternative X which had none. The Preferred Alternative identified Cayuse Creek, Fish Creek, Hungery Creek, Kelly Creek, North Fork Kelly Creek, South Fork Kelly Creek, Middle Fork Kelly Creek, Colt Killed Creek, and Meadow Creek. It also identified two eligible rivers, the Little North Fork and Salmon River. These rivers, and the quarter mile area surrounding them, would contribute to the conservation of lynx habitat.

National Historic Landmark

Most of the Lolo Trail National Historic Landmark lies within lynx habitat. This management area is to be managed consistent with the guidance for which it was designated. This management area is not suitable for timber production, nor is it suitable for commercial use of non-timber forest products. Vegetation management may be allowed to maintain desired ecological conditions and values. Effects to lynx are largely beneficial.

Research Natural Areas

Less than one percent of potential lynx habitat is located within research natural areas under all the alternatives. Research natural areas are generally natural appearing, and human influence on their ecological processes is limited and is guided by the Rocky Mountain Research Station. This management area is not suitable for timber production. Vegetation management may be allowed for study and research purposes or to protect the values for which the research natural area was designated, if needed. Although very limited in number and size, research natural areas help provide a continuum of security habitat and connectivity for lynx.

Management Area 3

Approximately 17 percent of lynx habitat is located within Management Area 3. The amount of area in Management Area 3 varies slightly by alternative. These alternatives are mostly driven by rivers found suitable for wild and scenic river designation under the alternatives. Otherwise, Management Area 3 does not vary by alternative. Management Area 3 is anticipated to have the highest intensity of timber harvest because it is suitable for timber production. Thirteen percent of the lynx habitat forestwide is suitable for timber production while four percent of the lynx habitat forestwide falls within Management Area 3 but is not suitable. Management Area 3 is managed for multiple uses. Road building, recreational development, and both winter and summer motorized travel are generally allowed. The primary disturbance to vegetation is through timber management and fuels reductions. Fires have been suppressed to protect the timber resource and this would continue in this management area under the revised plan. In this management area, active management activities, including prescribed fire, timber harvest, fuels reduction, precommercial thinning, commercial thinning, and planting are most likely to continue to create a mosaic of forest conditions. Much of Management Area 3 is in the wildland urban interface where fuels management is anticipated to be higher. Management Area 3 is where exemptions to the vegetation standards for lynx are most likely to result in short-term adverse effects but long-term benefits to hare habitat by creating a mosaic of successional stages. Recreation is managed to provide a variety of settings, most of which emphasize developed and motorized settings. Recreation is also most intense in this management area. However, plan components in the Northern Rockies Lynx Management Direction would reduce the effects of these activities in Management Area 3. All of these factors could impact lynx to some extent.

Fragmentation of Habitat

Many actions that fragment habitat, such as highway expansions and residential developments, are not under the authority of the Forest Service. However, Land Management Plan components under all alternatives are beneficial to Canada lynx by maintaining or improving habitat connectivity on National Forest System lands and would help to reduce or minimize adverse effects. Standard ALL S1 specifies that are new or expanded permanent developments and vegetation management projects must maintain habitat connectivity in a lynx analysis unit or linkage area. In linkage areas, potential highway crossings will be identified (LINK S1) and National Forest System lands should be retained in public ownership (LINK G1). Guideline ALL G1 says that methods that avoid or reduce effects on lynx should be used when constructing or reconstructing highways or highways across federal land. Guideline HU G6 says that methods to avoid or reduce the effects on lynx in lynx habitat should be used when upgrading unpaved roads to Maintenance Levels 4 or 5 if the result would be increased traffic speeds and volumes or a foreseeable contribution to increases in human activity or development in lynx habitat. Guideline HU G7 states that new permanent roads should not be built on ridgetops or saddles or in areas identified as important for lynx habitat connectivity. New permanent roads and trails should be situated away from forested stringers. LINK O1 encourages working with landowners to pursue conservation easements, habitat conservation plans, land exchanges, or other solutions in mixed ownership areas to reduce the potential of adverse impacts on lynx and lynx habitat. These plan components help to reduce fragmentation of lynx habitat and provide for habitat connectivity. Most lynx linkage areas are composed of at least some designated wilderness or Idaho Roadless Rule areas, and these contribute to connectivity for lynx. The primary exception is one linkage area around Lolo Pass that travels through checkerboard ownership. Forest lands within this checkerboard area are composed of lands managed for multiple uses. Forest lands to the northwest of the checkerboard areas are currently recommended wilderness.

Designated wilderness, recommended wilderness, and Idaho Roadless Rules areas prevent or inhibit most of the threats that disrupt connectivity for lynx.

Alternatives W, Y, and Z identify the East Meadow Creek area as recommended wilderness. Were this area to become recommended wilderness, it would slightly increase protections for lynx connectivity over its current status under the Idaho Roadless Rule wildland recreation theme, as recommended wilderness is slightly more restrictive than wildland recreation direction. The East Meadow Creek area would connect the Frank-Church Wilderness with the Selway-Bitterroot designated wilderness areas which would slightly benefit lynx connectivity. The Preferred Alternative identifies the East Meadow Creek area as recommended wilderness with boundary adjustments.

The amount of recommended wilderness varies by alternative and may affect linkage areas for lynx. Lynx linkage areas would be enhanced by all alternatives except Alternative X. Alternative Y would reduce protections slightly by shrinking some existing recommended wilderness areas. However, the change would be minor, and perhaps even negligible, because these lands would continue to be Idaho Roadless Rule areas, which have substantial protections from anthropogenic influences that could affect connectivity.

Plan components vary by alternative in what is allowed in recommended wilderness areas. Alternative Z allows over-snow travel. While allowed, over the snow travel is constrained by the Northern Rockies Lynx Management Direction guidelines to disallow new snow compaction areas from baseline amounts. These variations would have limited effects on lynx connectivity because they would not prohibit or disrupt traveling lynx.

In addition to plan components that are common to all alternatives, additional plan components address habitat connectivity and travel corridors. Forestwide plan components for riparian management zones and wildlife support connectivity of lynx habitat by providing for cover conditions that support lynx travel and access to foraging habitats and provide for distribution of cover across the Nez Perce-Clearwater. Plan components that would apply to summer corridors identified by Squires et al. (2013) would also facilitate long-distance movements and potential range shifts.

FW-DC-WL-03 would guide management towards a pattern that would facilitate connectivity for wildlife, such as lynx, and replicate the natural range of variation.

Connectivity of mature forest, percent composition of young regenerating forest, low perimeter-area ratio of young regenerating forest patches, and adjacency of mature to young regenerating forest types are important for lynx reproduction and survival at the scale of a lynx home range (Kosterman 2014). The perimeter-area ratio of young regenerating forest patches is anticipated to be highly variable across the Nez Perce-Clearwater, depending upon whether patches are created by wildland fire or by vegetation management activities, such as timber harvest. Plan components for old growth and riparian management zones, integrated with plan components for vegetation management, help to provide for adjacent mature and regenerating forests at the scale of a lynx home range; lynx are likely to travel through such habitat while accessing patches of boreal forest within their home range.

While many actions that fragment habitat, such as highway expansions and residential developments, are not under the authority of the Forest Service, these features are limited in the plan area and no new developments are anticipated within the life of the plan. Plan components in the Land Management Plan are beneficial in maintaining or improving habitat connectivity on National Forest System lands and would help to reduce or minimize adverse effects. Management direction allows for activities to occur to meet social, economic, and multiple-use objectives of the Nez Perce-Clearwater while promoting the recovery of the Canada lynx population.

Future Changes in Climate

The preliminary Northern Region Adaptation Partnership risk assessment for the Canada lynx (McKelvey and Buotte 2018) states that lynx have little or no adaptive capacity to live in areas lacking snow and limited ability to shift their diet away from snowshoe hares. There is a potential that climate change will reduce the extent of deep snow habitats preferred by lynx. McKelvey et al. (2018) estimated that contiguous areas of spring snow cover would become smaller and more isolated throughout the Columbia River Basin with greatest losses at the southern periphery but possible increases in snow at higher elevations in the lynx core, including the Nez Perce-Clearwater. Regardless of snow depth, the timing of snowmelt has been occurring about two weeks earlier in recent decades. Mills and Johnson (Mills and Johnson 2013) used an ensemble of locally downscaled climate projections and forecasted that the annual average duration of snowpack will decrease by 29 to 35 days by midcentury. Unless snowshoe hares show enough plasticity to adapt to earlier snowmelt, the reduced snow duration will increase the number of days that white snowshoe hares will be mismatched on a snowless background. This lack of camouflage coloration may make lynx more successful in detecting their primary prey, but in the long-term, it may also reduce snowshoe hare numbers, especially at relatively lower elevations where snow reductions in the Northern Rockies are anticipated to be greatest. McKelvey and Buotte (2018) estimate that the likelihood of future climate change effects is high, with a moderate magnitude of effects by 2030 and a high magnitude of effects by 2050.

As discussed above, stand-replacing wildfires within fire regimes IV on the Nez Perce-Clearwater have been the dominant force for creating early stand initiation habitat since lynx were listed. Increases in wildfire may initially create more habitat that is temporarily unsuitable for snowshoe hares and lynx foraging but may greatly increase suitable habitat within a few decades (Vanbianchi et al. 2017). Plan components for fire would allow the Nez Perce-Clearwater to adapt its future management to changing conditions.

Effects of Plan Direction

Terrestrial Ecosystems Across the Landscape

Plan direction within the terrestrial ecosystems section of the Land Management Plan would have no effect or beneficial effects on Canada lynx. Desired conditions FW-DC-TE-01, FW-DC-TE-05, and FW-DC-TE-06 would contribute to ecosystem integrity and provide a diversity of habitat conditions for Canada lynx.

Biophysical Features

Plan direction within the biophysical features section of the Land Management Plan would have no effect on Canada lynx.

Forestlands

Plan direction for the forestlands section proposes changes to dominance types, size classes, and forest density; addresses landscape pattern; and alters some habitats used by Canada lynx. Plan components in this section are informed by modeling the natural range of variation and should contribute to ecosystem integrity. The effects would provide for the diversity and abundance of wildlife that could contribute to Canada lynx prey. However, these plan components would direct management to alter some habitats that would be used by Canada lynx and their prey. Alteration of these habitats would be through timber harvest, wildland fire, planting, mechanical vegetation management, and other forestry or restoration methods after site specific analysis. Since Canada lynx tend to use high elevation forested habitats, habitats used most by Canada lynx would be within the cold and cool moist broad potential vegetation types. Specifically, plan components in this section would direct management of cool moist broad potential vegetation types. The desired dominance types identified in this section identify less Engelmann spruce and subalpine fir dominance types than currently occurs and less than was identified though modeling of the natural range of variation, though there is some overlap in the ranges. The natural result of these desired conditions would be to direct management to reduce Engelmann spruce and subalpine fir dominated forests into other desired dominance types identified in that section. Because Engelmann spruce and subalpine fir forests are preferred by Canada lynx, these desired conditions could have adverse consequences for Canada lynx. This section also has desired conditions for size classes. These desired size class distributions would direct management to shift size classes in the cool moist broad potential vegetation type. Currently, the Nez Perce-Clearwater is over the desired range in the 0-to-4.9-inch class and the 5-to-9.9-inch size class so management would seek to shift other size classes into these size classes. This may affect the amount of mature multistory habitat in this broad potential vegetation type.

A similar desired condition range is seen in the cold potential vegetation type with desired conditions that would direct management to reduce Engelmann spruce and subalpine fir dominance types, while expanding whitebark pine dominance types. This would have consequences to lynx habitats, from changes in dominance types and changes in size classes. However, the plan must follow the Northern Rockies Lynx Management Direction when implementing these activities. The Northern Rockies Lynx Management Direction would constrain many of these activities to maintain lynx habitats.

Meadow, Grassland, and Shrubland

Plan direction within the meadows, grasslands, and shrublands section of the Land Management Plan would have no effect or beneficial effects on Canada lynx. Desired conditions within this section would contribute to ecosystem integrity and provide a diversity of habitat conditions.

Carbon Storage and Sequestration

Plan direction within the carbon storage and sequestration section of the Land Management Plan would have no or beneficial consequences on Canada lynx.

Fire Management

Fire management plan components would allow and encourage fire to play its natural role, across the planning area. Fire is likely to play a dominant role in shaping Canada lynx habitat over the life of the plan. FW-OBJ-FIRE-01 in the fire management section would seek to treat by vegetation treatments, managed wildfire, or actively burning between 530,000 and 645,000 acres, some of which would be Canada lynx habitat. FW-OBJ-FIRE-02 sets the objectives for fuels treatments at 227,242 acres per decade under the Preferred Alternative. Some of these acres could occur in lynx habitat but would be conducted within the wildland urban interface and would be constrained by the Northern Rockies Lynx Management Direction. FW-OBJ-FIRE-03 would encourage fire to play a natural role to reduce uncharacteristic and undesirable wildfire through management of natural unplanned ignitions on 360,258 acres per decade under the Preferred Alternative. These would also occur within some lynx habitats, particularly in the Idaho Roadless Rule areas, recommended wilderness, and designated wilderness. Fire has been the dominant agent of change in lynx habitat since lynx were federally listed and will continue to be under the Land Management Plan.

Invasive Species

Plan direction for the invasive species section would have negligible effects on Canada lynx. Canada lynx habitats do not currently have many invasive species, and treatments within Canada lynx habitat would not likely have any direct consequences on Canada lynx.

Soil Resources

Plan direction in the soil resources section of the plan would have negligible effects or beneficial effects on Canada lynx habitats. They would serve to protect and restore soil resources from management activities. Soil objectives propose restoration activities, but those would have lower probabilities occurring within Canada lynx habitat and would have short-term impacts locally on Canada lynx prey. They would not occur at an extent that would have negative consequences on lynx.

Water and Aquatic Ecosystems

Plan direction in the water and aquatic ecosystems section would have negligible effects or beneficial effects on Canada lynx because they would restore, enhance, and protect aquatic ecosystems.

Riparian Management Zones

Plan direction in the riparian management zones section would have negligible effects or beneficial effects on Canada lynx because they would restore, enhance, and protect riparian areas.

Conservation Watershed Network

Plan direction in the conservation watershed networks section would have negligible effects or beneficial effects on Canada lynx because they would restore, enhance, and protect aquatic habitats. Some of these treatments would occur within lynx habitats after a site-specific analysis. Due to their limited scope and the limited amount of lynx habitat they would affect, Canada lynx would not likely be sensitive to these restoration activities. Lynx would benefit from proper functioning aquatic habitats.

Infrastructure (Aquatic and Riparian)

Plan direction in the aquatic and riparian infrastructure section would have negligible effects or beneficial effects on Canada lynx because they would restore, enhance, and protect aquatic habitats. Canada lynx would not be sensitive to restoration activities and would benefit from proper functioning aquatic habitats.

Energy and Minerals (Aquatic and Riparian)

Plan direction in the aquatic and riparian energy and minerals section would have negligible effects or beneficial effects on Canada lynx because they would protect aquatic habitats.

Livestock Grazing (Aquatic and Riparian)

Plan direction in the aquatic and riparian livestock grazing section would have negligible effects or beneficial effects on Canada lynx because they would protect aquatic habitats.

Wildlife

Plan direction in the wildlife section would have negligible effects or beneficial effects on Canada lynx. FW-DC-WL-01 would provide conditions for federally listed species. FW-DC-WL-03, FW-DC-WL-06, and FW-GDL-WL-01 would promote connectivity for Canada lynx. FW-STD-WL-01 requires that the Nez Perce-Clearwater follow the Northern Rockies Lynx Management Direction (NRLMD). Guidance in the NRLMD would contribute beneficial consequences to Canada lynx habitats. However, some direction within the NRLMD would also have a chilling effect on needed treatments within Canada lynx habitat.

Multiple Uses Wildlife

Plan direction in the Multiple Uses Wildlife section directs the Nez Perce-Clearwater to provide ecological conditions for species commonly used by the public for hunting, trapping, fishing, gathering, or watching. This type of management could potentially occur within Canada Lynx habitat. Many wildlife species have needs that differ from those of Canada lynx and such management may impact lynx habitats.

Multiple Uses Elk

Plan direction in the Multiple Uses Wildlife section would direct the Nez Perce-Clearwater to restore or enhance habitat for elk through active management. They seek to increase or enhance elk nutrition, which would mean increasing early seral conditions. The objectives for elk nutrition are nested within the vegetation plan components, except that they direct a proportion of treatments to areas that would produce higher nutritional responses. Sites with higher nutrition potential are those that are more mesic and have better quality soils. Some of these treatments could occur within lynx habitats and would reduce lynx use for approximately 30 to 40 years. These treatments would be required to abide by the Northern Rockies Lynx Management Direction, which restricts the amount of lynx habitat that could be treated within a lynx analysis unit to ensure they protect lynx habitat.

Air Quality

Plan direction in the air quality section would have no effect on Canada lynx.

Tribal Trust

Plan direction in the tribal trust responsibilities section would have negligible or beneficial effects on Canada lynx.

Cultural Resources

Plan direction for the cultural resources section would have few environmental consequences for Canada lynx. Objectives for cultural resources would seek to improve huckleberry stands. Some of these stands might occur within lynx habitats and would represent short-term impacts in localized areas.

Municipal Watersheds

Plan direction for the municipal watersheds section would have no environmental consequences for Canada lynx.

Sustainable Recreation

Lynx are generally tolerant of human recreational activities. However, some recreation plan direction could have some consequences for lynx. Plan direction in the sustainable recreation section may lead to management that would increase disturbance to Canada lynx. Specifically, FW-DC-REC-11 could facilitate additional future winter recreation into Canada lynx habitat. FW-DC-REC-10 would potentially facilitate additional motorized, mechanized, and pedestrian trails in lynx habitat. Recreational facilities result in the loss of lynx habitat from their footprint. These impacts would be minor.

Many activities are either suitable or unsuitable in different recreation opportunities spectrum classes. If lynx habitat occurs within the various recreation opportunity spectrum classes, future actions found suitable through recreation opportunity spectrum classes could occur after a site-specific analysis. Similarly, activities found not suitable would be prohibited and serve to protect lynx habitat. Timber production, permanent road construction, temporary road construction, building permanent structures, over-snow vehicle use, and motorized travel are prohibited within primitive and semi-primitive non-motorized recreation opportunity spectrum classes, all of which would help protect lynx habitat. Timber production, timber harvest, permanent road construction, temporary road construction, construction of new buildings or structures, over-snow vehicle use, and mechanized and motorized travel would be suitable in semi-primitive motorized, roaded natural, and rural recreation opportunity spectrum classes. Prescribed fire, livestock grazing, locatable minerals, and leasable minerals would be suitable in all recreation opportunity spectrum classes. Recreation infrastructure, such as motorized trails or hiking trails, may increase access for trapping, which could result in limited incidental take; however, incidental take of Canada lynx in Idaho is rare. Trapping is allowed on National Forest System lands but is regulated by the Idaho Department of Fish and Game. However, trapping of lynx is prohibited under Idaho law.

Scenery
Plan direction in the scenery section would have negligible or no effect on Canada lynx.

Public Information, Interpretation, and Education
Plan direction in the public information, interpretation, and education section would have negligible or no effect on Canada lynx.

Infrastructure
Plan direction in the infrastructure section may lead to management that would increase disturbance to Canada lynx. Specifically, this direction could encourage increased road access into Canada lynx habitat, which could alter Canada lynx habitat. There is no direction in the plan that constrains road building or motorized trails, other than within some recreation opportunity spectrum settings designated wilderness, or recommended wilderness. Recreation infrastructure, such as roads, may increase access for trapping activities, which could result in limited incidental take; however, incidental take of Canada lynx is rare. Trapping is allowed on National Forest System lands but is regulated by the Idaho Department of Fish and Game. However, trapping of lynx is prohibited under Idaho law.

Land Ownership and Land Uses
Plan direction in the land ownership and land uses section would have both negative and beneficial consequences on Canada lynx. FW-DC-LND-01 specifically would direct land acquisitions to prioritize habitat for at-risk species, which would have beneficial consequences for Canada lynx connectivity and habitat conservation. On the other hand, FS-DC-LND-06 could facilitate some impacts to Canada lynx habitat from energy developments. However, a large portion of the Canada lynx habitat is in designated wilderness where these facilities would not be allowed. Potential for oil or gas extraction is low to very low on the Nez Perce-Clearwater, so there would be little chance to have oil and gas extraction projects. Wind energy potential is also low, so there is less likely to be wind energy developments. More likely would be rights-of-way for electrical grid, or oil and pipelines could occur. These types of infrastructure usually have temporary impacts during construction but then would have low impacts after completion. The footprint would be limited to only a very small percent of Canada lynx habitat in the plan area.

Ecosystem Services
Plan direction in the ecosystem services section would have consequences to Canada lynx. Specifically, FW-GDL-ES-01 would constrain the closing of existing routes. In the event a route was closed, it would direct the Nez Perce-Clearwater to consider opening a new road when closing other roads, essentially redistributing the road system. In many areas of the Nez Perce-Clearwater, road densities are high or very high and may need to be reduced due to resource concerns. If this happens, new roads or motorized trails could potentially need to be created to maintain access. This guideline would create a situation where watersheds or areas with low road densities in Canada lynx habitat would possibly see an increase in access because of road closures in high road density areas for resource benefits. This would not happen in lynx habitat within recommended or designated wilderness but could happen with roads in Management Area 3 or with motorized trails in areas suitable for summer motorized uses in Management Area 2 that are suitable for motorized uses under the preferred alternative. Roads in Idaho Roadless Rule Areas are not allowed, unless granted an exception from the Idaho Roadless Rule. So new roads in Idaho Roadless Rule Areas are unlikely. The plan component requires decision makers to consider opening new motorized routes but doesn't require new motorized routes to be opened. A potential outcome is that efforts to reduce motorized uses for resource reasons would be more challenging. It might not result in additional motorized routes because in each case, a route would also be closed. This plan component would also require that any closure of over-snow areas would require other areas to be opened to maintain the net amount.

Timber

Plan direction in the timber section would direct the manner in which timber production and harvest are conducted. These plan components establish direction that would achieve desired conditions for vegetation found in the Forestlands section of the plan. Timber production could potentially alter some Canada lynx habitats, mostly in Management Area 3. However, all timber harvest would need to follow the Northern Rockies Lynx Management Direction per standard FW-STD-WL-01 which imposes constraints in lynx habitat on vegetation treatments. Most lynx habitat is unsuitable for timber harvest and timber production, and therefore this direction has limited capability to alter lynx habitat. The direction in the timber harvest section specifies the size of openings allowed, which would typically be 40 acres but is allowed up to 207 acres under specific conditions. The larger patch size would be more consistent with the patch size of lynx habitat under natural disturbances wherein these habitats burn with stand replacing fires. Timber production has the potential to reduce lynx habitat use for up to 30 to 40 years.

Energy and Minerals

Plan components in the energy and minerals section may have some environmental consequences to Canada lynx habitats if mining or energy extraction activities take place in Canada lynx habitat under the plan. In the event they do, it would result in temporary or permanent loss of Canada lynx habitat. However, the extent of mining or mineral activities would likely be over only a small proportion of Canada lynx habitat so the effects would be minor.

Livestock Grazing

Plan direction in the livestock grazing section would potentially have minor environmental consequences for Canada lynx because it could alter vegetation that provides habitat for snowshoe hares. However, livestock grazing only overlaps with a portion of lynx habitat and would have only indirect consequences to lynx prey.

Special Forest and Botanical Products

Plan direction in the special forest and botanical products section would have negligible environmental consequences for Canada lynx.

Designated Wilderness

Plan direction in the designated wilderness section would have beneficial consequences for Canada lynx.

Wild and Scenic Rivers

Plan direction in the wild and scenic rivers section would have negligible or beneficial consequences for Canada lynx.

Recommended Wilderness

Plan direction in the recommended wilderness section would have negligible or beneficial consequences for Canada lynx.

Idaho Roadless Rule Areas

Plan direction in the Idaho Roadless Rule areas section would have negligible effects or beneficial effects on Canada lynx.

Research Natural Areas

Plan direction in the research natural areas section would have negligible effects or beneficial effects on Canada lynx.

Gospel-Hump

Plan direction in the Gospel-Hump geographic area section would have negligible consequences or beneficial effects on Canada lynx.

Lower Salmon

Plan direction in the Lower Salmon geographic area section would have negligible consequences on Canada lynx.

Pilot Knob

Plan direction in the Pilot Knob geographic area section would have negligible or no consequences for Canada lynx.

Lolo Trail National Landmark

Plan direction in the Lolo Trail National Landmark geographic area section would have negligible or no consequences for Canada lynx.

Cumulative Effects on Canada Lynx

As described previously, the Lynx Conservation Assessment and Strategy (Interagency Lynx Biology Team 2013) identified four anthropogenic influences as being of greatest concern to the conservation of lynx: climate change, vegetation management, wildland fire management, and fragmentation of habitat. The lower tier of anthropogenic influences includes recreation, minerals and energy management, forest and backcountry roads and trails, grazing by domestic livestock, and mortality due to incidental trapping or illegal shooting. Although these lower-tier activities could affect individual lynx, they are not expected to have a substantial effect on the overall lynx population and are unlikely to cause cumulative adverse effects. Therefore, they are not discussed in detail. The analysis of cumulative effects considers the previous analysis and decision under the Northern Rockies Lynx Management Direction Final Environmental Impact Statement (U.S. Department of Agriculture 2007f).

The cumulative effects analysis area is predominantly National Forest System lands, state managed lands, tribal lands, and private lands. The cumulative effects area for lynx is managed through implementation of a consistent set of Land Management Plan objectives, standards, and guidelines (U.S. Department of Agriculture 2007f). Habitat management on these units, in concert with the Nez Perce-Clearwater, promotes the conservation of lynx.

In response to reducing uncharacteristic wildfire, fuels reduction programs have increased in recent decades and are expected to continue on managed portions of Forest Service, state, tribal, and private lands within the boundaries of the Nez Perce-Clearwater geographic areas, particularly in the wildland urban interface. Only about 1.18 percent of the lynx habitat in the plan area has been treated with fuels treatments since lynx were listed.

On national forests in the cumulative effects' analysis area, the wildland urban interface has vegetation treatments using the exceptions or exemptions to the Northern Rockies Lynx Management Direction (NRLMD) vegetation standards, which may adversely affect stand initiation or multi-story hare and lynx habitat. However, the amount of these areas represents 6 percent of lynx habitat on forest lands and the amount is consulted on with the U. S. Fish and Wildlife Service. They determined that this was not enough impact to jeopardize lynx. On the Clearwater National Forest, the maximum acres of lynx habitat that could be affected by the wildland urban interface exemption is 55,800 acres. Exceptions for precommercial thinning projects for resource benefits are limited to 1,930 acres. Combined, the exemptions and exceptions could affect about 3.9 percent of the lynx habitat on the Nez Perce-Clearwater. However, the Nez Perce National Forest did not consult on incidental take because they were considered unoccupied. The wildland-urban interface boundary where exemptions apply is determined by community wildfire protection plans and so could change slightly over time, but these changes would not cause an appreciable difference in the percent of lynx habitat where exemptions could occur. Thus, the Nez Perce National Forest was not issued exemptions or exceptions for these activities. To date, the level of effects to lynx is substantially lower than that anticipated in the record of decision for the NRLMD because the actual amount of treatments on the Clearwater National Forest total only about 15,399 acres under the wildland urban interface exemption (Hanvey 2017).

National forests in the cumulative effects analysis area manage lynx habitat to provide forest landscapes supporting a mosaic of differing successional forest stages and containing the presence of snowshoe hares and their preferred habitat conditions. These national forests follow management direction in the NRLMD. During the last decade, timber harvest practices have been more favorable for lynx as a result of forest plan amendments, with fewer acres impacted by temporary loss of multistory stands that provide snowshoe hare and lynx habitat. In fact, less than one percent of the lynx habitat has been manipulated by timber management in the plan area. The U.S. Fish and Wildlife Service determined that the NRLMD would not jeopardize the Canada lynx.

The Idaho Department of Lands manages thousands of acres of forested habitats to the west of the Nez Perce-Clearwater, most of which is not lynx habitat because it is too low in elevation. The Idaho Department of Lands does not generally adjust their management for lynx. The Idaho Department of Lands manages their lands for sustainable timber production and in accordance with state law.

Most private lands within the cumulative effects area are at elevations too low to be lynx habitat, but lynx do travel through some of these areas. Large portions of forested lands in Idaho, west and north of the plan area, are managed by Potlatch Deltic Corporation for timber production. Their management may affect lynx habitat and could be characterized as prioritizing timber production. Similar to Idaho Department of Lands, most of the forested areas they manage are too low in elevation to be lynx habitat. Their primary management efforts are to maximize profits from private forestry.

A much smaller amount of the cumulative effects area is managed by individuals who own forested lands. Many of these habitats are also lower in elevation and mostly are not lynx habitat. However, private lands in the checkerboard ownership near Lolo Pass occur in lynx habitat. Some of these landowners are clearing vegetation to reduce the risk of wildfire, which may reduce the potential for lynx foraging, although whether lynx would forage in close proximity to human dwellings and dogs is unknown. Fuels treatments in lower montane forests that burned naturally with mixed severity may help to prevent uncharacteristically severe fires from occurring or spreading to lynx habitat at higher elevations.

Although lynx are known to cross openings, Squires et al. (2013) found that lynx generally use habitat within about 300 feet of cover. Because cover is altered by wildfire, insects, disease, and actions on other land ownerships, it is difficult to predict when or where these effects to cover would occur.

A number of highways occur in lynx habitat in the cumulative effects areas. Various studies have documented lynx crossings of highways. Highways pose a risk of direct mortality to lynx. Two-lane or four-lane highways with high traffic volumes or impediments, such as fences on both sides of a highway, may impede lynx movement. According to Alexander et al. (Interagency Lynx Biology Team 2013), traffic volumes between 3,000 and 5,000 vehicles per day may be the threshold above which successful crossings by carnivores are impeded. None of the roads in the plan area have this much traffic. U.S. Highway 12 west of the Nez Perce-Clearwater is a two-lane highway and has much higher traffic volumes than those on the Nez Perce-Clearwater and may impede lynx crossings between Kooskia and Lewiston. There are no four-lane highways in the cumulative effects analysis area and few roads have enough traffic to affect lynx travel. It is not anticipated that traffic volumes are expected to increase dramatically within the life of the plan. The plan does not make travel management decisions, it only identifies where such uses are suitable.

Connectivity to source populations of lynx in Canada is considered critical to the persistence of populations in most parts of the range in the United States (Squires et al. 2013) (68 FR 40076). While connectivity from Canada has not been evaluated for lynx, other studies have evaluated connectivity hypothetically for 105 species using resistance kernel modeling (Cushman et al. 2012). Cushman et al. (2012) showed that the Nez Perce-Clearwater is well connected to Canada. While connectivity was high, they found species associated with high elevations and species associated with lower elevations were predicted to have limited extent of connected habitat. Species associated with high elevations were predicted to have the vast majority of their connected habitat protected by federal Forest Service and National Park Service lands. Connectivity from the Nez Perce-Clearwater to Canada is relatively well connected through forested habitats that would facilitate lynx travel.

Lynx are known to be strong dispersers. Populations in Canada reduce population density through dispersal, in addition to mortality and low recruitment, during snowshoe hare population lows (Mowat et al. 1999). Mowat et al. (1999) documented 15 straight-line dispersal distances of 310 to 683 miles. The straight-line distance from the United States-Canadian border to the northern boundary of the Nez Perce-Clearwater, as measured using GIS mapping, was between approximately 130 and 150 miles which is well within the dispersal capabilities of lynx. Most of the land from the Nez Perce-Clearwater boundary to the Canadian border through northern Idaho or western Montana includes National Forest administered lands that make up the Idaho Panhandle, Kootenai, and Lolo National Forests.

These lands would present little resistance to a strong disperser like Canada lynx. As an example, lynx introduced into southern Colorado were fitted with satellite telemetry collars and dispersed far from Colorado after release. Some individuals moved from southern Colorado northward through Colorado, Wyoming, and Montana and as far away as North Idaho, with observations on the Nez Perce-Clearwater and north of the plan area. Other individuals made it to Iowa, southern Utah, Kansas, Nebraska, northern Arizona, and southern New Mexico (Devineau et al. 2010). The places where lynx moved from that study would be far more inhospitable to lynx dispersal than the lands between Canada and the Nez Perce-Clearwater. Lynx dispersing from Canada moving south would most likely arrive somewhere along the northern boundary of the Nez Perce-Clearwater. The northern boundary of the Nez Perce-Clearwater is made up of recommended wilderness areas or Idaho Roadless Rule areas that would provide for good conditions for lynx arrival.

The distance to known and well-studied lynx breeding populations near Seeley Lake, Montana was measured at about 60 miles from the nearest Nez Perce-Clearwater boundary near Lolo Pass. Though the track around Missoula and the surrounding communities would be more difficult for lynx than from Canada, these distances are well within the dispersal capability of lynx. Potentially, the best path would include lynx travelling north of Missoula, Montana, into the Lolo National Forest and continue on the Nez Perce-Clearwater near the Hoodoo recommended wilderness area or near Lolo Pass. The Hoodoo area is included in most alternatives as recommended wilderness, including the Preferred Alternative. Other areas where lynx could potentially arrive from the Seeley Lake, Montana, population area along the eastern boundary of the Nez Perce-Clearwater, which is mostly composed of roadless rule areas or designated wilderness, save for the checkerboard ownership near Lolo Pass. Most areas along the eastern Nez Perce-Clearwater boundary would provide for lynx arriving from the east. Once here, the Nez Perce-Clearwater is a large block of contiguous public land composed of mostly wilderness and roadless areas surrounded on the north, east, and south by other Forest Service administered lands. Save for a couple of relatively low traffic roads, it is very well connected and represents very low barriers to connectivity for lynx.

Recreational Activities

Scientific evidence to date indicates that most recreational activities pose a low risk of having negative effects on lynx (Interagency Lynx Biology Team 2013). Within the cumulative effects analysis area outside the Nez Perce-Clearwater, there are two ski areas on private lands near the national forest. These ski resorts are Snow Haven, south of Grangeville, Idaho, and Bald Mountain, northwest of Orofino, Idaho. Both are small ski areas with very little development at the base. These ski areas are not within lynx habitat so any effects to lynx are minor. There is one ski area on the Kootenai National Forest called Turner Mountain. This is a very small ski area with only one lift and very little development at the base. The ski area affects about 263 acres of lynx habitat, with 164 acres of cleared ski runs and 98 acres of gladed skiing, so any effects to lynx are minor. Additionally, there are approximately five miles of groomed cross-country ski trails in lynx habitat within lynx analysis units and another five miles that are designated for cross-country ski use on the Kootenai National Forest.

Trapping and snaring of lynx is currently prohibited across the contiguous United States. Incidental trapping or snaring of lynx is possible in areas where regulated trapping for other species overlaps with lynx habitat (Squires and Laurion 1999). State wildlife management agencies regulate the trapping of furbearers. On all lands, areas open to motorized over-snow vehicle use occur in lynx habitat, and these areas may have increased risk of incidental trapping of lynx because trapping seasons for other species occur in the winter. However, many areas of lynx habitat have limited accessibility for off-route motorized over-snow vehicle use due to high tree densities and rugged topography. On the Kootenai National Forest, there are approximately 120 miles of groomed motorized over-snow vehicle routes and approximately another 46 miles of designated motorized over-snow vehicle routes in lynx habitat within lynx analysis units. One lynx was reported trapped on the Kootenai National Forest in December 2012 and was released unharmed. Incidental trapping of lynx is a rare event in Idaho and lynx have usually been released alive when it occurs.

On the Kootenai National Forest, no leasable minerals, such as oil, gas, coal, and geothermal resources, are being produced. All leases are currently suspended in accordance with the 1985 court decision of Conner v. Burford (848 F. 2d 1441 (9th Cir. 1988)). The Troy copper and silver mine was in operation for over 20 years on the Kootenai National Forest and affects approximately 50 acres on National Forest System lands and an additional 400 acres of private lands. There are no plans of operation or notices of intent to explore or operate any commercial mines in lynx habitat on the Lolo National Forest. The Cotter Basin Mine on the Helena National Forest produced copper and silver in the past. In its biological opinion on the Northern Rockies Lynx Management Direction, the U.S. Fish and Wildlife Service (U.S. Department of the Interior 2017c) concluded that the application of the amendment guidelines would result in no or only minor adverse effects to lynx due to minerals and energy development. No adverse cumulative effects are anticipated.

Much of the lynx habitat on the Kootenai, Lolo, and Helena-Lewis and Clark National Forests overlaps with grizzly bear habitat, where road construction and motorized use is constrained. Additionally, the objectives and guidelines related to lynx in the amended forest plans reduce or minimize any potential adverse effects (U.S. Department of the Interior 2017c), and no adverse cumulative effects are anticipated. Roads can facilitate access for trappers and trapping that may incidentally catch some lynx, but inadvertent trapping of lynx is rare in Idaho and usually results in live release as evaluated above.

The effects of livestock grazing were anticipated to be minimal under the Northern Rockies Lynx Management Direction (U.S. Department of the Interior 2017c) and there is no new information to suggest that this has changed. No adverse cumulative effects are anticipated.

Wolverine

When the Nez Perce-Clearwater's Assessment was published (U.S. Department of Agriculture 2014d), the U.S. Fish and Wildlife Service had recently published a proposed rule to list the North American wolverine as a threatened distinct population segment in the contiguous United States (U.S. Department of the Interior 2013a). However, on August 13, 2014, the U.S. Fish and Wildlife Service withdrew its previous proposal. On April 14, 2016, the U.S. District Court for the District of Montana Missoula Division remanded the matter to the U.S. Fish and Wildlife Service for further consideration consistent with order CV 14-246-M-DLC (consolidated with case nos.14-247-M-DLC and 14-250-M-DLC) (U.S. Department of the Interior 2014c). The U.S. Fish and Wildlife Service withdrew the proposed rule to list the North American wolverine in the contiguous United States as a threatened species under Endangered Species Act in October 2020 (U.S. Department of the Interior 2014c). This was based on their conclusion that the loss of habitat due to climate change is not as significant as believed at the time of the proposed rule. They also found that wolverines in the contiguous United States do not qualify as a distinct population segment. Additional litigation followed, and the U.S. Fish and Wildlife Service requested a voluntary remand of their decision in the spring of 2022. On May 26, 2020, the District Court for the District of Montana vacated the 2020 withdrawal of the proposed rule and wolverine was once more considered "proposed" under the Endangered Species Act which is its current status.

The Nez Perce-Clearwater completed a thorough review of scientific information to inform the planning process, develop plan components, and assess consequences of alternatives. Recent studies included the evaluation of the effects of winter recreation on wolverines and the results of multi-state efforts to survey for wolverines with camera traps. Data and information gaps exist, but the breadth and depth of the available scientific information are sufficient to assess potential effects of alternatives.

Wolverines live at low densities and occupy remote areas with persistent snowpack, which they use for denning. Their global distribution is circumpolar, as they occupy the boreal regions on several continents. They rely on small mammals and ungulates as food sources, both scavenging and hunting their prey. Winter food resources influence habitat selection (Krebs et al. 2007) and survival (Krebs et al. 2004).

The U. S. Fish and Wildlife Service (2018b) Species Status Assessment for the North American wolverine concluded that the wolverine's physical and ecological needs include:

- large territories in relatively inaccessible landscapes; at high elevation (1,800 to 3,500 meters (5,906 to 11,483 feet))
- access to a variety of food resources, that varies with seasons; and
- physical/structural features (for example, talus slopes, rugged terrain) linked to reproductive behavioral patterns.

The analysis will consider these ecological needs in the context of how land allocations and plan components would affect the North American wolverine and address threats and stressors (U.S. Department of the Interior 2017b).

The U. S. Fish and Wildlife Service issued an addendum to their 2018 Status Assessment with new information on the population trend, distribution, and habitat factors (U.S. Fish and Wildlife Service 2023). The core conclusion was that:

- wolverine populations in the contiguous United States are small, fragmented, and relatively isolated from larger populations in Canada and are at risk from genetic factors because female wolverines appear to have virtually no recent population connectivity based on genetic analyses.
- Core wolverine habitats are projected to become smaller and more fragmented in the future as the result of climate change and human disturbance because climate change is projected to shrink wolverine habitat, increased backcountry winter recreation is likely in shrinking core habitats and human developments could reduce connectivity.

Analysis of the effects of the alternatives on wolverines and their habitat is based upon wolverine habitat models that are designed and updated by researchers. Current wolverine models include persistent spring snow as a factor in modeling habitat suitability, but different models assess and use this factor in different ways. The U.S. Fish and Wildlife Service initially modeled wolverine habitat across the United States in 2013 (U.S. Department of the Interior 2013a), incorporating the work of two groups of scientists (Copeland et al. 2010, Inman et al. 2011). Since that time, Inman (2011) produced a more refined model that delineated areas of the western United States predicted to be maternal wolverine habitat suitable for use by reproductive females, primary wolverine habitat suitable for survival and use by resident adults, female dispersal habitat suitable for relatively brief female dispersal movements, and male dispersal habitat suitable for relatively brief male dispersal movements. This model is based on a resource selection function developed with wolverine telemetry locations from 2001 to 2010 in the Greater Yellowstone Ecosystem of Montana, Idaho, and Wyoming (Inman et al. 2012). The model by Copeland et al. (2010) used satellite data to classify areas of persistent spring snow based upon coarse-scale satellite data collected over a seven-year time period from 2000 to 2006 in which snow cover varied from year to year. This model displayed the number of years out of seven that a GIS pixel was classified as snow. Copeland et al. (2010) studied all known wolverine dens in Norway and Sweden, finding that areas with persistent spring snow at least five years out of seven were preferred. Since that time, Inman (2013) produced a more refined model that delineated areas of the western United States predicted to be maternal wolverine habitat suitable for use by reproductive females, primary wolverine habitat suitable for survival and use by resident adults, female dispersal habitat suitable for relatively brief female dispersal movements, and male dispersal habitat suitable for relatively brief male dispersal movements. The models are based on a resource selection function developed with wolverine telemetry locations from 2001 to 2010 in the Greater Yellowstone Ecosystem of Montana, Idaho, and Wyoming (Inman et al. 2012b). Inman (2013) models are used in this analysis.

The area modeled by Inman et al., (2013) as providing primary habitat encompasses much of the higher elevation areas of the Nez Perce-Clearwater, whereas the area modeled as providing for maternal habitat is more limited and restricted to only the highest elevations. An estimated 144,371 km^2 (49,258 mi^2) of wolverine habitat occurs in the occupied area in Montana, Idaho, Oregon (Wallowa Range), and Wyoming (U.S. Department of the Interior 2013a). Modeled wolverine habitat from Inman (2013) for the Northern Region of the Forest Service is shown in Figure 85. While modeled primary wolverine habitat from the model predicts wolverine habitat across the landscape, wolverine maternal habitat is thought to be more limited. Protecting maternal habitat may be important to the conservation of the wolverine. Wolverine habitat models may be refined in the future as more scientific information becomes available.

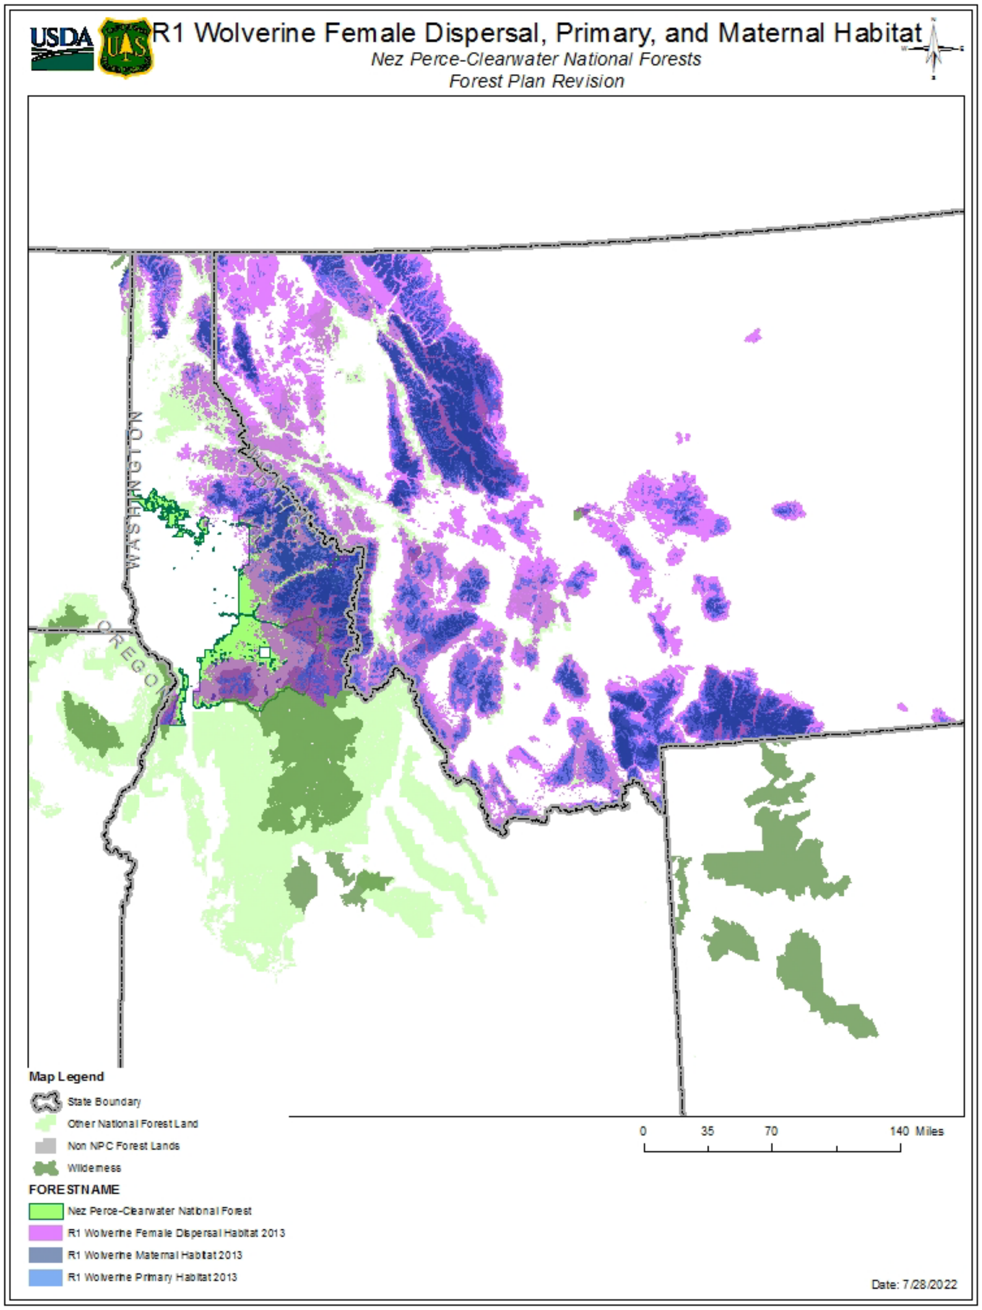

Figure 85. Modeled maternal, primary, and female dispersal primarily Northern Region of the Forest Service

Wolverine habitat is distributed at higher elevations across the Nez Perce-Clearwater National Forest, with substantial amounts of habitat concentrated eastward towards the Idaho-Montana border. Wolverine habitat as modeled by Inman (2013) includes primary habitat, maternal habitat, and female dispersal habitat. The Nez Perce-Clearwater has approximately 753,576 acres of maternal habitat, 1,334,238 acres of primary habitat, and 3,024,135 acres of female dispersal habitat (GIS layer of modeled habitat based on Inman (2013)). The Nez Perce-Clearwater has a total of 1,334,238 acres of primary wolverine habitat which makes up about 12.6 percent of the 10,554,788 acres of wolverine primary habitat within the

Northern Region of the Forest Service. The majority of wolverine habitat in the planning area occurs within designated wilderness, recommended wilderness, or Idaho Roadless Rule Areas. For example, only 93,487 acres of modeled primary wolverine habitat or about seven percent of the Nez Perce-Clearwater National Forest total is within general forest areas (managed to emphasize multiple uses). Similarly, only 35,024 acres or about 4.6 percent of modeled maternal wolverine habitat is within general forest areas. The total amount of modeled wolverine habitat is shown in Table 228.

Table 228. The acres of modeled wolverine habitat found within the Nez Perce-Clearwater National Forest, the total within the Northern Region, and the percent of the Northern Region total represented by the wolverine habitat within the Nez Perce-Clearwater National Forest

Type of Wolverine Habitat (based on Inman et al. 2013)[1]	Total Acres within the Nez Perce-Clearwater	Total Acres within the U.S. Forest Service Northern Region	Percent of Northern Region Wolverine Habitat Within the Nez Perce-Clearwater
Maternal	753,576	4,822,636	15.3
Primary	1,334,238	10,554,788	12.6
Female Dispersal	3,024,135	24,884,989	12.2

(Inman 2013)

Maternal and primary habitat is primarily situated at higher elevations and has relatively low road densities when compared to dispersal habitat, which occupies lower elevation areas with higher levels of human access. Primary and maternal habitats support a wide range of potential wolverine prey, including small and medium-sized mammals particularly marmots, deer, elk, moose, bighorn sheep, and mountain goat. Modeled maternal wolverine habitat is the most limited compared to primary and female dispersal habitat. Modeled maternal wolverine habitat is also the most important regarding the effects analysis because it indicates the effects to wolverine reproduction. Figure 86 below shows female dispersal habitat, Figure 87 shows modeled primary wolverine habitat, and Figure 88 shows modeled maternal wolverine habitat.

As Magoun et al. (2017) pointed out, "to manage wolverines and their habitat and incorporate persistent spring snow in models of future wolverine habitat, we must understand the relationship of wolverines to snow and measure persistent spring snow at an appropriate resolution and scale that is biologically meaningful for the species." As summarized by Magoun et al. (2017), the spatial and temporal coarseness of the model and analysis by Copeland et al. (Copeland et al. 2010) introduced uncertainty regarding the obligatory nature of the relationship between persistent spring snow through May 15 and wolverine habitat. Magoun et al. (2017) stated the "use of snow-covered den sites may not be obligatory through 15 May, or may not be obligatory at the scale in Copeland et al. (2010); nevertheless, wolverines may continue to use snow-covered sites as long as they are available." Magoun et al. (2017) discuss that scattered patches of snow that are not detectable by remote sensing techniques at the den-site scale may persist long enough in spring to provide cover for wolverines, even when considering future climates. These authors encouraged more research on the relationship of wolverines to smaller patches of spring snow at the den-site scale to determine if snow is necessary for successful reproduction; if it must be present for the entire denning season; if other structures, such as boulders or down trees, afford protection for wolverine kits near the end of the denning season; if wolverine distribution is tied to factors that have not yet been measured and defined; or if other possible uses of snow are an important component of wolverine habitat.

Snow in wolverine habitat may be affected by changes in climate. For this Final Environmental Impact Statement, the Nez Perce-Clearwater used a compilation of climate change effects published for the Northern Region Adaptation Partnership (Halofsky, Peterson, et al. 2018a, b) that summarizes climate change projections by subregions. Downscaled climate models were used to predict the effects of a changing climate. Future climate uncertainty and anticipated variability is associated with scale. Potential effects of future changes in snow cover and persistence are uncertain or variable due to geographic location, atmospheric circulation patterns, such as the Pacific Decadal Oscillation, and elevation. A study by Webb et al. (Webb et al. 2016) found that wolverines in the boreal forest region of northern Alberta were not as closely associated with persistent spring snow as wolverines in the Rocky Mountains and suggested that these two very different habitats should be separated for analysis purposes and for the study of climate change effects.

Aronsson and Persson (2017) and Jokinen et al (2019) demonstrated wolverine denning in areas without persistent snow, questioning the absolute necessity of persistent springtime snow for wolverine denning success. Aronsson and Persson (2016) showed that the wolverine population in Sweden has expanded considerably into the boreal forest landscape, and colonized areas without persistent spring snow cover. Similarly, Jokinen et al (2019) documented female wolverines appear to be using locally-available denning structures in the lowland boreal forest, despite a lack of deep snow, persistent spring snow cover, or large boulders documented in other studies. A study by Webb et al. (2016) found that wolverines in the boreal forest region of northern Alberta were not as closely associated with persistent spring snow as wolverines in the Rocky Mountains and suggested that these two very different habitats should be separated for analysis purposes and for the study of climate change effects.

Kortello (2019) tested hypotheses that explored a number of factors that explain the distribution of wolverines at different scales in Southern British Columbia just north of the Idaho-Canadian border. They tested four factors: climate, food, human disturbance, and trapping harvest. Top models included food and human disturbance. Of the four food items examined (caribou, mountain goat, moose, and hoary marmot) wolverine occurrence was most closely related to hoary marmot habitat. With regards to human disturbance, they documented a negative association with forestry road density and a positive association with protected areas. Their research suggested that that marmot habitat is important to wolverine in winter and suggest that management actions for conservation prioritize factors related to female occurrence, as these were more clearly defined than male habitat and that human disturbance is a major driver of wolverine distribution (Kortello et al. 2019). The importance of climate was low compared to the food and disturbance hypotheses. However, Kortello (2019) noted that if the forest road density variable is removed from the analysis, persistent spring appears in both the female top models. Hence, they state that their results do not reject the hypothesis that wolverine occurrence is constrained by an obligate association with persistent spring snow but do suggest the alternative explanation that the relationship between spring snow and wolverine distribution could be functionally related to the distribution of food, disturbance, or mortality risk. Kortello (2019) suggested that the negative relationship with forest road density is indicative of anthropogenic disturbance because of the high level of snow machine operation in their study area. They also suggested that avoidance of forestry road density was due to disturbance rather than trapping because trapping kills were not negatively related to distribution. Protected areas were strongly and positively related to wolverine presence in the top-ranked models and the primary difference between protected areas and the surrounding landscapes in winter is lower human use (Kortello et al. 2019).

Predicting the future of mountain snowpack is complex with multiple drivers and with a strong elevation dependence, however topographical aspect can be an important factor for predicting mountain snowpack (Barsugli et al. 2020). Barsugli (2020) modeled snowpack in two areas: one in Northwestern Montana and another in Colorado. Their results suggest that springtime snowpack is projected to persist in the upper half of the current denning zone for many future scenarios to the mid-21st century and find a strong dependence of snow loss on topographical aspect such that northerly slopes could provide refugia for snow adapted species.

Methodology and Analysis Process

The analysis area for indirect effects of the Land Management Plan is the areas of modeled habitat encompassed by the administrative boundary of the Nez Perce-Clearwater. Because wolverines are wide-ranging, the analysis of cumulative effects is discussed in the context of the northern Rocky Mountains area.

Affected Environment

Population, Life History, and Distribution

In North America, wolverines are year-round residents across Alaska and Canada. The southern portion of the species' range extends into high-elevation alpine portions of Washington, Idaho, Montana, Wyoming, California, and Colorado. Wolverines occur at low densities, range widely, inhabit remote and rugged landscapes away from human populations, and are difficult to detect, so conducting research on wolverines is challenging (Idaho Department of Fish and Game 2014b). Wolverine populations in Idaho were heavily trapped in the early 1900s and were near extinction. Wolverine population growth and expansion has been documented in the North Cascades and northern Rocky Mountains (U.S. Department of the Interior 2014b). In Idaho, wolverines have been reported in 34 of 44 counties (77 percent) and presently occur in most, if not all, historically occupied habitat in Idaho (Idaho Department of Fish and Game 2014b).

Lukacs et al. (2020) conducted a multi-state occupancy study that sought to define the limits to the current distribution, identify potential gaps in distribution, and provide a baseline dataset for future monitoring and analysis of factors contributing to changes in the distribution of wolverines. They used remotely triggered cameras and hair snare DNA samples to develop spatial occupancy models within 183 of 633 potential wolverine sites that comprised suspected wolverine ranges in these four states. Wolverines were detected in 59 of 183 cells (32.2 percent). Based on occupancy calculations, it was estimated that 268 of the 633 cells (42 percent) were used by wolverines. Wolverines were detected via camera or DNA at another 31 supplemental stations for 93 cells with positive detections. Several cells were sampled within or near the Nez Perce-Clearwater, where both males and females were detected. Their results suggest wolverine habitat is weakly correlated with modeled wolverine habitat but that no other covariates examined were correlated with wolverine occupancy. Occupancy rates were highest in the Northern Continental Divide Ecosystem, intermediate in the Cascades and central mountains of Idaho, and lower in the Greater Yellowstone Ecosystem. However, reasons for the different occupancy rates are unknown. Wolverine was detected from 240 DNA samples obtained during the survey period, which included 202 samples from 51 official survey stations and 38 samples from 18 supplemental stations. Of these wolverine-positive samples, 145 (60 percent) were of sufficient quality to determine sex and to identify the individual. Both males and females were broadly distributed, and samples identified 26 unique females and 24 unique males. Results demonstrated that all of the large areas of predicted wolverine habitat within the four states contained wolverines.

A few other studies have been conducted on the Nez Perce-Clearwater that indicate wolverine use. In January through March 2018, a multi-species mesocarnivore survey was conducted throughout the Nez Perce-Clearwater, excluding wilderness and roadless areas. During this survey time, one wolverine was detected at one out of four camera stations located in modeled wolverine habitat near Lolo Pass. Two other samples of wolverine DNA were collected in 2015 from hair snare samples near the Adam Ranger Station. These samples were not high enough quality to determine sex or individual identities.

The Idaho Species Diversity Database records (accessed January 2019) show observations of wolverines and other wildlife in Idaho. In that database, a total of 66 observations of wolverines have been documented throughout the plan area from 1962 to 2015. From 1962 to 2015, observation frequency was relatively steady with an average of 1.2 observations per year with 0 to 11 observations recorded annually. Observations were the result of both incidental observations and targeted surveys and were composed of visual observations, tracks identified as wolverine, individuals in hand, and photographs.

According to the U.S. Fish and Wildlife Service (U.S. Department of the Interior 2014a), "within the area known to currently have wolverine populations, relatively few wolverines can coexist due to their naturally low population densities, even if all areas were occupied at or near carrying capacity. Given the natural limitations on wolverine population density, it is likely that historic wolverine population numbers were also low."

Wolverine populations fluctuate in response to prey availability, juvenile dispersal, and mortality of adult females. The U.S. Fish and Wildlife Service stated that the northern Rocky Mountains portion of the North American wolverine is thought to be the largest subpopulation and the most genetically resilient of the current subpopulations within the United States (U.S. Department of the Interior 2014b). Inman et al. (2013) estimated the current population, as well as the population capacity for regions of the western United States. The Nez Perce-Clearwater is in the Salmon-Selway region. They estimated that the current population in the Salmon-Selway region is near its capacity and estimated to be about 101 individuals out of a capacity of about 105 individuals. However, no recent research that would estimate population levels has been conducted for wolverine on the Nez Perce-Clearwater.

The Idaho Department of Fish and Game established wolverine priority conservation areas as a framework for managing wolverines in the state of Idaho. The areas across the state with wolverine habitat were categorized as Tier I, Tier II, or Tier III as a means to prioritize conservation work for wolverines. Nearly all the lands of the Nez Perce-Clearwater were identified as either Tier II moderate or Tier III low.

Wolverines are constantly on the move and are known to make long-distance movements that are not impeded by topography or deep snow (Copeland and Yates 2006, Squires et al. 2007) nor large rivers like the Salmon River (Idaho Department of Fish and Game 2019a). Copeland and Yates (2006) estimated that adult female wolverines have home ranges averaging 55 square miles. Adult males ranged over an even larger area, with home ranges that averaged 193 square miles (Copeland and Yates 2006). Home range boundaries are dynamic, as are population demographics.

Habitat

For wolverine habitat across the western United States, Inman et al. (2013) reported that, in general, wolverines are distributed in areas of higher elevation where there is steeper terrain, more snow, fewer roads, and less human activity and in areas closer to high-elevation talus, tree cover, and snow cover persisting to April 1. Year-round habitat includes rocky alpine habitats, glacial cirque basins, and avalanche chutes that provide food sources, such as marmots, voles, and carrion (Hornocker and Hash 1981, Magoun and Copeland 1998, Inman et al. 2007, Copeland et al. 2007). Wolverines appear to rely on the cold and snow to cache carrion (Inman et al. 2012). Wolverines also travel through the area where snow persists, and they minimize travel through low-elevation habitat (McKelvey et al. 2011). Persistent spring snow cover is also correlated with gene flow because this is where the wolverine's within-home-range movements and dispersal occur year-round (Schwartz et al. 2009).

Magoun and Copeland (Magoun and Copeland 1998) described two types of reproductive dens: natal dens where young are born and maternal dens where the mother may move the kits if conditions are no longer suitable at the natal den. Sites used for maternal dens are often close to the natal den and have a similar structure. Prior to the Glacier National Park study, not much was known about the den sites of reproductive female wolverines in Montana because den sites are often in remote terrain that is very difficult to study. During the first three years of the study, data was collected for 19 wolverines and information about reproductive dens was obtained for two adult females that raised four offspring (kits). Copeland et al. (2010) found that dens were excavated in the snow and were on upper slopes in sparse timber beneath downed woody debris or rocks. Dens are typically used through late April or early May. Females used two to three different dens prior to the weaning of kits at six to seven months of age. Kits gather at rendezvous sites that are primarily in boulder, talus, and cliff areas (Copeland et al. 2010). Survival of young was low, even in the National Park Service setting where trapping was not allowed and motorized disturbance did not occur in winter or spring. Wolverine den sites may not occur in the same exact spot year after year, and specific maternal or natal den sites on the Nez Perce-Clearwater are unknown.

Primary wolverine habitat is also characterized by low levels of human development (Hornocker and Hash 1981, Copeland 1996, Krebs et al. 2007). This negative association with frequent human presence is sometimes interpreted as active avoidance of human disturbance but it may reflect the wolverine's preference for cold, snowy, and high-elevation habitat that humans do not often develop. The U.S. Fish and Wildlife Service assessed the effects of a variety of human activities that can affect wolverines and their use of habitat.

The U.S. Fish and Wildlife Service (2013d) stated that it is unlikely that wolverines avoid the type of low-use forest roads that generally are found in wolverine habitat. Based on the best available science, the U.S. Fish and Wildlife Service concluded that wolverines do not avoid human development of the types that occur within suitable wolverine habitat and that there is no evidence that wolverine dispersal is affected by infrastructure development.

Krebs et al. (2007) modeled male versus female wolverine habitat selection in British Columbia, hypothesizing that food, predation risk, and human disturbance affected habitat selection. Krebs et al.

(2007) based their model on 39 adult wolverines—23 females and 16 males—that were located a total of 2,125 times within two study areas. These authors modeled selection in two time periods: winter and non-winter. The winter season was defined as the period when there was persistent snow cover at the treeline. Human use variables incorporated into the models included those associated with winter recreation activity, roads, and timber harvesting. Winter recreation data included estimates of snowmobile primary use sites, locations of runs for two helicopter skiing companies in the Columbia Mountains study area, and backcountry ski use centered on the Trans-Canada Highway corridor within and adjacent to Mount Revelstoke and Glacier National Park. These authors stated that extensive timber harvesting had occurred within a large portion of the study area. Krebs et al. (2007) concluded that male wolverines were most closely associated with food availability in both summer and winter. Moose winter ranges, valley bottom forests, and avalanche terrain were positively associated with winter male wolverine use.

Krebs et al. (2007) stated:

"Habitat associations of females were more complex; combinations of variables supporting food, predation risk, or human disturbance hypotheses were included in most supported models from both summer and winter in both study areas. Females were associated with alpine and avalanche environments where hoary marmot and Columbia ground squirrel prey are found in summer. Roaded and recently logged areas were negatively associated with female wolverines in summer. In the Columbia Mountains, where winter recreation was widespread, females were negatively associated with helicopter and backcountry skiing. Moose winter ranges within rugged landscapes were positively associated with females during winter. Our analysis suggests wolverines were negatively responding to human disturbance within occupied habitat. The population consequences of these functional habitat relationships will require additional focused research. Our spatially explicit models can be used to support conservation planning for resource extraction and tourism industries operating in landscapes occupied by wolverines."

Recreational Use in Wolverine Habitat

The threshold for the amount of human activity that can occur before it affects male and female wolverine habitat selection is unknown. Some scientists have expressed concern about the effects of human activities on female wolverines with young kits during the mid-February to mid-May time period because food resources are scarce for foraging females. As the kits mature, the mother will leave them for longer periods of time to find food, but the kits cannot travel with their mother until they are at least 10 weeks old. If a female wants to move kits to a new location or to another den, she must carry them in her mouth. If the female needs to move the kits very far, the probability of kits dying increases. Reproductive females and kits are at risk of predation (Magoun and Copeland 1998) and females are most vulnerable to energetic pressures due to the high cost of lactation during this period (Krebs et al. 2007). The predominant activity in some portions of wolverine habitat during this time period is backcountry recreation.

Winter backcountry recreation opportunities in the northern Rocky Mountains include snowshoeing, snowboarding, skiing, heli-skiing, snowcat- or trackster-assisted skiing and snowboarding, snow bikes, and snowmobiling. Studies of winter recreation have produced mixed conclusions. Wolverines have been documented to persist and reproduce in habitats with high levels of human use and disturbance, including developed alpine ski areas and areas with motorized snowmobile use (Heinemeyer 2012, Heinemeyer and Squires 2013). Heinemeyer and Squires (2014) stated "wolverines appear to tolerate winter recreation in their home ranges, including denning females. Based on our preliminary findings, potential wolverine habitats that have even high levels of winter recreation may support resident wolverines despite the potential human disturbance." This suggests that wolverines can survive and reproduce in areas that experience human use and disturbance; however, there is uncertainty with respect to the amount, type, and timing of human recreational use and its effects on female wolverines. Additional, more recent publications from this study are discussed below.

Heinemeyer et al. (2017) studied effects of winter recreation on wolverines in the Greater Yellowstone Area. They found that wolverines responded to backcountry winter use in different ways but, given the extent of overlap between winter recreation and wolverine distribution, suggested that wolverines tolerate winter recreation to some degree. In this study, wolverines reacted negatively to higher levels of recreation use in winter, with stronger responses to dispersed use than to use on designated routes, indicating that wolverines may have a higher tolerance for more predictable patterns of winter recreation use. Wolverines reacted to both motorized and nonmotorized winter recreation. However, since motorized equipment allows humans to travel further and faster than nonmotorized means of transport, motorized winter recreation could affect larger proportions of wolverine habitat.

Heinemeyer et al. (2019) suggested stronger negative responses to winter recreation than previous publications suggested. They fit GPS collars on wolverines to monitor responses to winter recreation and other resources in mid- and late-winter (January–March) and concurrently sampled the spatial patterns of winter recreationists with three methods: GPS tracking of volunteer recreationists, infra-red trail use counters, and aerial surveys. Datasets were obtained from Idaho, Wyoming, and Montana, spanning more than 1.1 million acres; however, the Nez Perce-Clearwater Land Management Plan area was not included. From the data, they developed resource selection functions for wolverines with a use: availability design to estimate the relative probability of selection, assess the effect of winter recreation on wolverine habitat selection, and evaluate indirect habitat loss from winter recreation. They also tested whether wolverines showed functional responses to winter recreation based on the relative intensity of winter recreation to which they were exposed. Winter recreation activities varied in the number of recreationists and types of recreation, and each study area had a unique combination of backcountry recreation, including snowmobiling; skiing, including snowboards; snowmobile-accessed skiing and boarding (hybrid); cat-skiing; heli-skiing; and yurt-supported skiing. They obtained collar data from 24 wolverines that were tracked between one and four years and obtained 53,301 locations used in the spatial modeling and 6,603 locations for model validation. They concurrently obtained 5,899 GPS tracks from a variety of winter recreation uses and obtained trail use estimates from 25 trail use counters to obtain recreation intensity.

Motorized recreation occurred at higher intensity across a larger footprint than non-motorized recreation in most wolverine home ranges. Wolverines avoided areas of both motorized and non-motorized winter recreation with off-road recreation, eliciting a stronger response than road-based recreation. Female wolverines exhibited a stronger avoidance of off-road motorized recreation and experienced higher indirect habitat loss than male wolverines. Wolverines showed negative functional responses to the level of recreation exposure within the home range, with female wolverines showing the strongest functional response to motorized winter recreation. Wolverines maintained multi-year home ranges within landscapes that support winter recreation and some resident animals had greater than 40 percent of their home range within the footprint of winter recreation. This suggests that wolverines tolerate winter recreation at some scale. However, within home ranges, wolverines avoided all forms of winter recreation and showed increasing avoidance of areas as the amount of off-road winter recreation increased, resulting in indirect habitat loss or degradation of moderate- or high-quality habitats. This study suggests indirect habitat loss, particularly to females, could be of concern in areas with higher recreation levels. Potential for backcountry winter recreation to affect wolverines may increase under climate change if the reduced snowpack concentrates winter recreationists and wolverines in the remaining areas of persistent snow cover.

Actual use by winter recreation or winter motorized users is likely less than where it is allowed because of vegetation characteristics, slope, terrain, and access from passable roads in the winter. The analysis and plan draw from several sources of information to evaluate the effects of winter recreation on wolverines. Actual winter use was estimated by a combination of information provided by winter motorized user groups, the distribution of groomed routes, and geospatial modeling that estimated the probability of winter recreation use based upon the preferences of winter recreators studied in Colorado (Olson et al. 2017). In Olson's study, the variables that predicted snowmobile use included topography, access, vegetation, and climate.

In order to better understand the probability of winter recreation use, the Rocky Mountain Research Station modeled the probability of use on the Nez Perce-Clearwater, using similar methods used by Olson et al. (2017). The values of the environmental covariates on the Nez Perce-Clearwater were sometimes far outside of the mean and range of the values that went into the Colorado model. That means that applying the model here was beyond the range of what it was trained on, and this can create unreliable predictions. In order to account for this, several models were produced and then validated. Two versions of the snowmobile models were created and two were created for backcountry skiing, one in which the covariates were standardized similar to Colorado and one in which they were standardized relative to the range of conditions on the Nez Perce-Clearwater. Standardizing is basically just a common modeling step which includes subtracting the mean and dividing by the standard deviation so that all the covariates are put into a similar scale.

Olson et al. (2017) created the following models for the plan area: a backcountry skiing model standardized to Colorado conditions, a backcountry skiing model standardized to Idaho conditions, an on-roads snowmobile model standardized to Colorado conditions, an on-roads snowmobile model standardized to Idaho conditions, an off-road snowmobile model standardized to Colorado conditions, and an off-road model standardized to Idaho conditions. All covariates were standardized by subtracting the mean and dividing by the standard deviation. In order to determine which model was the best fit for recreation on the Nez Perce-Clearwater, a team of Forest Service recreation specialists from each zone with on-the-ground knowledge of snowmobile and back country skiing use was assembled to evaluate the models. As part of that exercise, spatial data was used to further evaluate the models. The data used included groomed routes, maps of the plan area, and data provided by recreation groups on where they go. The model identified as the best fit in the North and Central Zones was the Idaho Standard off-road model. This model was also the best fit to the user data provided by snowmobile user groups. However, specialists felt the model over projected snowmobile areas in the South Zone. The specialists felt the Idaho Standard backcountry skiing model was the best fit for backcountry skiing in the plan area but that some known groomed routes were not showing in the model.

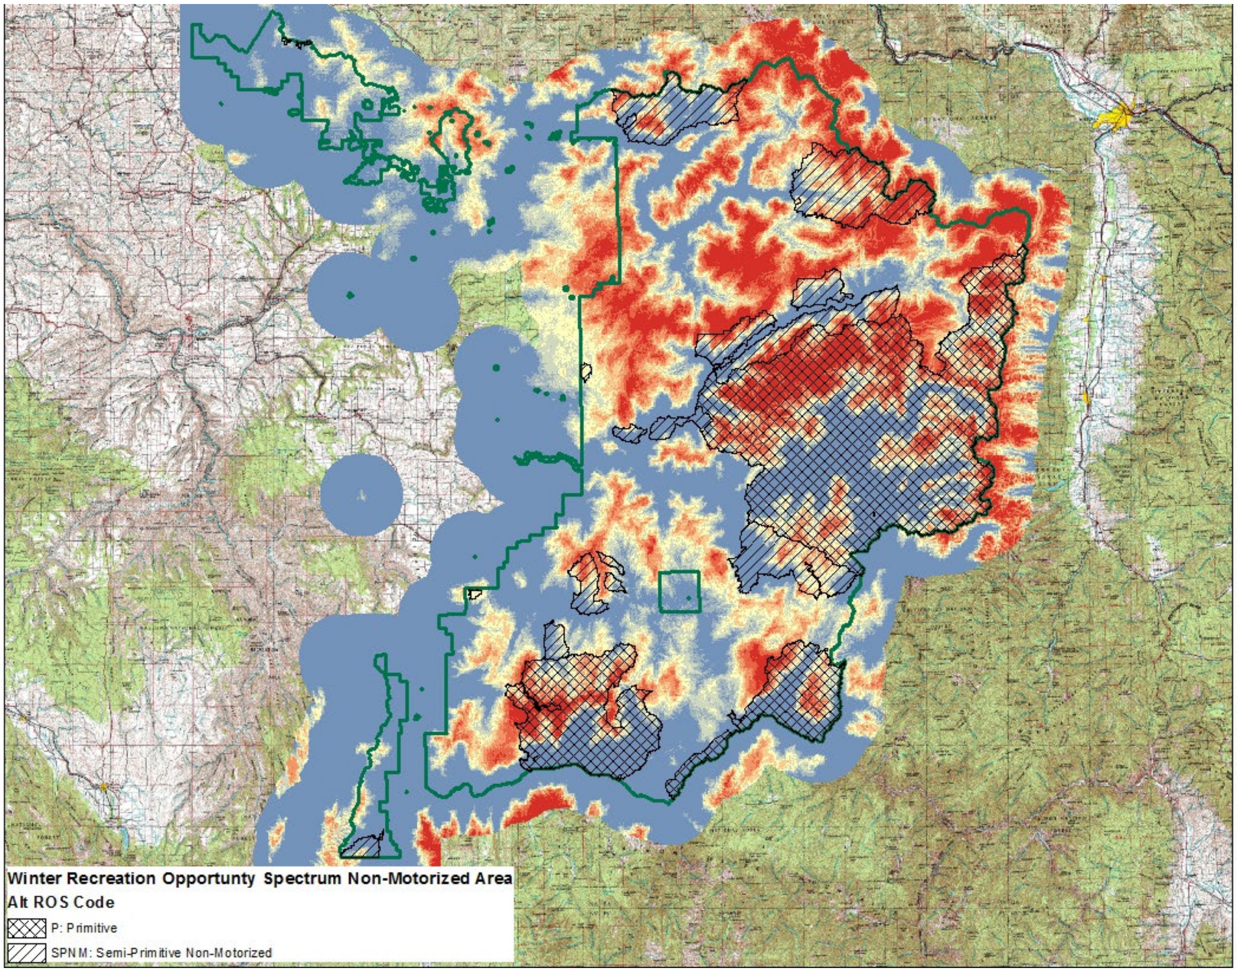

Figure 89. The Idaho Standard off road Snowmobile model developed by Lucretia Olson to estimate snowmobile user selection on the Nez Perce-Clearwater National Forest. Warmer colors represent areas where snowmobilers are predicted to select to use, where cooler colors represent areas snowmobilers might not select based on user preferences from Colorado. Crosshatched and line shaded areas would be non-motorized for winter recreation under the Preferred Alternative.

These models suggest variability in the probability of snowmobile and backcountry skiing use at any given location. These are probabilistic models that represent only the relative probability of use. The models only account for the area that has the terrain and access features that would promote use and does not represent administrative decisions about where that use is allowed. For example, some areas in the Selway-Bitterroot Wilderness were identified, but motorized over-snow use is not allowed. The models represent a smaller footprint of where snowmobile use has a high probability of occurrence than where snowmobile use is allowed under the No Action Alternative. Under the No Action Alternative, most roadless rule and general forest areas are open to winter recreation. In reality, lower elevation areas and steep slopes are shown in the model as having a low probability of use even though they are technically open to that use. Similarly, areas with heavy tree cover show a low probability of use. There could be some variability in the model predictions for various users. Highly skilled users might be able to use areas of lower model values, whereas average users might be more constrained.

Some precautions are in order about the application and interpretation of these models to the Nez Perce-Clearwater. First, Olson et al. (2017) developed these winter recreation models in Colorado where conditions and use patterns may differ from those in on the Nez Perce-Clearwater. In developing the models, Olson et al. (2017) used the mean and standard deviation from Colorado to make the conditions similar to what the model expected or the mean and standard deviation from Idaho to allow for the differences in environmental conditions there. These models were developed for snowmobiles and backcountry skiing but do not predict winter motorized use on machines like snow bikes. It should be noted that, in Colorado, the model was validated statistically with GPS snow tracks of actual use. The validation of Nez Perce-Clearwater models used expert opinion and polygons provided by the user groups that were delineated onto maps and then transferred to an electronic format. These validation methods are not likely as robust as those generated from statistical methods. Since this is a “relative” probability that means that inference cannot be applied from the actual predicted number, meaning a value of 0.5 does NOT mean a 50 percent probability. Because of this, the predictions were binned into 10 equal area intervals, which means that 10 percent of the area is in each bin. That way, a location in bin 1 is known to be in the lowest 10th percentile of probabilities (“bad” rec habitat), while a location in bin 10 is in the highest 10th percentile of probabilities (“good” rec habitat). Depending on where the breakpoints are, the model can over project or under project actual use. Models would have to be created and evaluated with actual use data to identify a threshold probability at which use is not preferred. The best way to interpret the model is that the areas with the highest percentiles likely are the easiest or most enjoyable to use, or the most accessible, while those in lower bins might be interpreted as more difficult or unpleasant to use, or where there is little access. The model does not predict use intensity or actual use in the plan area. It only predicts where people might want to go based on the model parameters. The model could be useful for a variety of purposes, including understanding the effects on users when areas are found unsuitable for winter recreational uses, understanding areas where there might be user conflicts, identifying new areas that could provide winter recreation, identifying areas that could be improved by management for winter recreation, or, as in this case, understanding the potential effects of recreation on resources, such as wildlife habitat.

The models were used as a guide or a piece of information to consider, but they were not used alone in evaluating the potential effects of the plan and alternatives. Other sources of information included snowmobile user data; wildlife habitat models; administrative boundaries, such as those from recommended wilderness; the presence of known groomed routes or use areas; the presence of roads and trails; and other information. It is likely that areas predicted to be higher probability winter recreation use areas could be constrained by topographic barriers that preclude use, even when predicted to have high relative probabilities by the model.

Interestingly, the areas modeled as wolverine habitat visually coincide with areas the model predicts as having a higher winter recreation relative probability, though this was not quantified. This is likely because the model identifies higher probabilities, in part by snow depth and elevation, where wolverines are known to prefer to reside. A map of the winter habitat models is shown in the figures below.

In areas open to motorized over-snow vehicle use, the amount of use has likely increased over the last few decades due to technical advances in motorized over-snow vehicles and human population growth though this has not been quantified nor have the effects to wolverine. Backcountry skiing has also increased in popularity.

Connectivity and Wolverine Habitat

Cegelski et al. (2006) found wolverines in Idaho to have the lowest genetic diversity levels among eight populations evaluated across the Rocky Mountains and high levels of genetic structure. They concluded, despite some evidence of immigration of wolverines from Canada to the United States, Idaho populations were genetically isolated, even from populations in Montana. However, the sample size used for evaluating the Idaho population was small (sample size is 15) and limited to central Idaho (USFWS

2018). Overall, wolverines in the Northern Rockies exist as small and semi-isolated subpopulations within a larger metapopulation that requires regular dispersal of individuals between habitat patches for maintenance (Aubry et al. 2007, Inman et al. 2013). Mitochondrial analysis provides support that all contiguous United States historical and contemporary wolverine populations are likely descendants of immigrants from Canada (U.S. Department of the Interior 2018b). The U.S. Fish and Wildlife Service considers wolverines that occupy the contiguous United States to be genetically continuous with wolverines in adjacent Canadian provinces and that wolverines are not genetically isolated from wolverines in Canada (U.S. Department of the Interior 2020c).

Inman et al. (2013) reported that the United States' Northern Rockies include most of the major core areas, the majority of the current population, and connections to larger populations in Canada. They identified six regions that can likely function as major population cores where primary habitats exist as large blocks of relatively contiguous, publicly owned lands that include significant portions of designated wilderness or National Parks, and are capable of supporting 50 or more wolverines. These are the Northern Cascade, Northern Continental Divide, Salmon-Selway, Greater Yellowstone, Southern Rockies, and Sierra-Nevada regions. Maps in Inman et al. (2013) suggest the plan area retains high levels of connectivity both within the plan area and to other wolverine regions.

Inman et al. (2013) stated "the greatest potential for wolverine dispersal was concentrated in western Montana and along Montana's borders with Idaho and Wyoming proximate to this area." This modeling suggests the Nez Perce-Clearwater provides, and will continue to provide, for connectivity because it is a large contiguous block of publicly owned land that contains high amounts of wilderness and roadless areas. Schwartz et al. (2009) mapped wolverine connectivity with least cost path methods. Predicted connectivity was highest in the plan area along the Idaho-Montana border. Schwartz et al. (2009) identified the Bitterroot Mountains between Montana and Idaho as a critical artery of gene flow. This area genetically links wolverines of central Idaho to those in the Bob Marshall Wilderness and Glacier National Park in Montana and through them on to Canada.

Key Stressors

Land Management

Few land management activities are thought to affect wolverines. Those thought to have some effects include recreation activities, in particular winter recreation. Wolverines are adaptable and generally tolerant of human recreation activities but there is scientific uncertainty about the types of winter recreation activities and the amount of disturbance that may affect female wolverines with kits.

Trapping

Trapping wolverines has been prohibited in Idaho since about 1965. Fourteen incidentally trapped wolverines have been reported during Idaho furbearer seasons since 1965. Eight of the incidental catches were released alive and six resulted in mortality. From 1965 to 2014, non-target catches accounted for an average of 0.29 wolverines annually with 0.12 wolverine catches resulting in mortality (McKelvey et al. 2014). This count included four wolverines incidentally trapped during the 2013 to 2014 furbearer season. These statewide numbers suggest that incidental trapping of wolverine is rare in Idaho. The effects from incidental trapping are largely outside of Forest Service control, except in regard to how access decisions inadvertently facilitate or impede trapping activities.

Highways

The Idaho Transportation Department has authority to manage highways on the Nez Perce-Clearwater. Wolverine mortality from collisions with vehicles has occurred in the state but at low levels. Wolverines do not usually come into contact with high-traffic-volume roads, except in those areas where highways cross over mountain ranges, such as major passes. Wolverines killed on roads in valleys between mountain ranges are likely the result of dispersal attempts by wolverines, but these appear to be rare occurrences (U.S. Department of the Interior 2013c). The Nez Perce-Clearwater contains Lolo Pass and Hoodoo Pass, which may have a higher chance of a wolverine strike. Most of Highway 12 and Highway 14 occur at lower elevation not considered primary habitat, but a wolverine crossing through the plan area might have to cross these highways. The U.S. Fish and Wildlife Service (2018b) evaluated roadkill and concluded "Roads present a low stressor to wolverines at the individual and population level in most of its current contiguous United States range." Their basis for that conclusion was that there was a low proportion of major highways in both modeled primary habitat and a low mean density of roads at high elevations where wolverines have been observed. They suggest that the effects of roads continue to be at low levels in the future and that there is no information that indicates that mortality from roads or disease would increase within the range of wolverine in the contiguous United States in the future.

Changing Climate

Climate change and inadequate regulatory mechanisms related to climate change is the only primary threat to the wolverine distinct population segment (DPS) identified by the U.S. Fish and Wildlife Service. Other threats were classified as secondary as they may work in concert with climate change to affect the conservation status of the species (U.S. Department of the Interior et al. 2013).

The Species Status Assessment identifies abiotic and biotic factors when assessing the impact of climate change on wolverines. On abiotic factors it concludes:

> Observed trends and future climate model projections indicate warming temperatures for much of the western United States, including areas within the Current Potential Extent of the wolverine. The degree of future warming varies by region and is dependent upon the future emission scenario used during the modeling process. Future precipitation trends are less certain for many regions, in part, due to naturally high inter-annual variability; some regions are projected to experience greater winter precipitation. Wolverines have been found to have a wide range in critical temperature depending on season and undergo seasonal changes in fur insulation to adapt to warmer temperatures in summer. Wolverines also exhibit changes in behavior, such as moving to higher elevations in summer months. Wolverines continue to occupy areas that have exhibited increases in temperature (e.g., California, parts of Montana and Washington); however, no empirical studies have evaluated these physiological and behavioral adaptations, including sub-lethal effects, relative to warming temperatures.

The 2013 proposed rule for the North American wolverine identified threats to the long-term persistence of the species. The primary threat, at that time, was determined to be potential changes in climate (U.S. Department of the Interior 2016), including effects on connectivity of meta-populations. The U.S. Fish and Wildlife Service is currently evaluating potential changes in climate within wolverine habitat based upon more refined models. The effects of climate change are outside Forest Service control, though the Forest Service has the authority to manage other activities that could affect changing wolverine habitats through time.

Although the goods and services provided by National Forest System programs and activities have been and will undoubtedly continue to be affected by climate change, the activities described in the Preferred Alternative and action alternatives are not the cause of climate change. Some activities and direction in the plan can mitigate the effects of climate change or act as a sink for greenhouse gases that contribute to climate change. While the agency has no authority over climate change, climate change can interact with Forest Service activities to exasperate effects of climate change on wolverines. For example, climate change could interact with winter recreation potentially concentrating winter recreation activities into a smaller intensified areas that would be increasingly important to wolverines in the future. Similarly, climate change can interact with wildfire behavior and conditions that result in higher severity acres burned. The desired vegetation conditions can drive management to increase vegetation resiliency to the effects of climate change.

Activities in the plan that could interact with the effects of climate change are the suitability of winter motorized uses within wolverine habitat, plan components for recreation, the coarse filter ecosystem plan components for terrestrial ecosystem, and plan components related to fire management.

Key Indicators

Coarse filter plan components provide for habitat diversity that benefits wolverines. Key stressors on all lands are discussed in the section on cumulative effects to the wolverine. There are no species-specific plan components proposed in the plan for wolverine. Most of the wolverine habitat already falls within either designated wilderness or Idaho Roadless Rule areas. Alternatives affect the amount of recommended wilderness and the uses allowed within recommended wilderness, which can affect the amount of wolverine habitat that would be affected by a number of activities common on Forest Service lands. The alternatives affect the amount of areas identified as motorized or non-motorized under the recreation opportunity spectrum. Thus, a key indicator is the amount of wolverine habitat contained within the various management areas, recommended wilderness areas, roadless rule areas, and areas within the various recreation opportunity spectrum settings that govern the scope of potential disturbance. The scope is determined by the extent to which the amount of wolverine habitat falls within the management areas, recreation opportunity spectrum settings, recommended wilderness proposed by alternative, and the risk of human disturbance to wolverines from suitability of uses allowed under the alternatives in recommended wilderness, Idaho Roadless Rule areas, and general forest. The severity of the effects is influenced by the extent to which these disturbances reduce the population or the extent to which it would reduce wolverine habitat.

Environmental Consequences

Effects Common to All Alternatives

All alternatives include plan components designed to maintain or restore diverse, resilient vegetation conditions that would provide for wolverine prey species. As described in the “Affected Environment” section above, research results suggest that wolverines are generally tolerant of human disturbance associated with recreation developments and activities (Heinemeyer and Squires 2014). The thresholds for the amount of development or human recreational use that individual wolverines will tolerate in their home ranges is unknown. With all alternatives, plan components would support key ecosystem characteristics for wolverines because a substantial amount of modeled wolverine habitat is in designated wilderness (Table 229). In wilderness, the risk of human disturbance is low because motorized uses and mechanized transport, such as snowmobiling, helicopter-assisted skiing or snowboarding, and snow bikes, are not allowed.

Table 229. The acres of modeled primary and maternal wolverine habitat within designated wilderness within the Nez Perce-Clearwater National Forest

Wilderness Name	Primary Wolverine Habitat Acres	Maternal Wolverine Habitat Acres
Frank Church-River of No Return Wilderness	23,894	8
Gospel-Hump Wilderness	48,539	358
Selway-Bitterroot Wilderness	524,630	303,616

Wilderness Name	Primary Wolverine Habitat Acres	Maternal Wolverine Habitat Acres
Total	597,063	303,982

The forest planning area under the action alternatives is broadly divided into three management areas with similar management. Management Area 1 is composed of lands designated by congress with high levels of protection. Land under this broader management area includes designated wilderness direction, designated wild and scenic river direction, and direction for the National Historic Landmark. Management Area 2 includes management of Idaho Roadless Rule and areas that are proposed for designation such as Recommended Wilderness, Research Natural Areas, and eligible and suitable wild and scenic rivers. Management Area 2 has a range of protective measures but can generally be characterized as moderate amounts of protections. Management Areas 1 and 2 are discussed in more detail below. Table 230 shows the amount of modeled wolverine habitat within the three management areas.

Perhaps, of the most relative importance, in terms of potential impacts, is the distribution of wolverine habitat within Management Area 3. Management Area 3 are lands managed for multiple uses and thus is the management area most likely to experience a wide array of human activities and uses. A wide variety of activities like timber production, motorized uses, snowmobile use, recreation, and more will occur within Management Area 3. These will affect relatively little of the wolverine habitat within the plan area. The table below shows the amounts and percentage of primary wolverine habitat that is distributed within the three broad management areas. Since only approximately 7 percent of wolverine habitat is within Management Area 3, only that amount will experience the most intense effects of human disturbance, dispersed recreational activities, infrastructure development, road development, and has the most access related to trapping. The other land allocations are protected to various degrees and are not expected to experience as many or as much of these types of activities as explained further below. Of more importance, most maternal habitat also is contained within protective land allocations and management which is also shown in Table 230.

Table 230. The distribution of modeled wolverine primary habitat under the compared to the existing condition

Management Area (MA)	Acres of Modeled Primary wolverine habitat within management areas	Percent of Modeled Primary wolverine habitat within management areas
MA1	623,830	46.76%
MA2	616,921	46.24%
MA3	93,487	7.01%

Land allocations would support key ecosystem characteristics for wolverines because about 44.7 percent of modeled primary wolverine habitat, along with 40.3 percent of modeled maternal wolverine habitat, is in designated wilderness. Plan direction for wilderness management emphasizes managing for wilderness character. In wilderness, the risk of human disturbance is low because motorized uses and mechanized transport, such as snowmobiling, helicopter-assisted skiing or snowboarding, and snow bikes, are not allowed. Plan direction for the recommended wilderness would have beneficial effects for wolverine.

The majority of the modeled wolverine habitat occurs in designated wilderness areas or in Idaho Roadless Rule areas (Table 231). On the Nez Perce-Clearwater, about 597,017 acres of modeled primary wolverine habitat and 303,982 acres of maternal habitat is in designated wilderness where motorized uses, including snowmobiling, helicopter-assisted skiing or snowboarding, and track steer-assisted skiing or snowboarding, are not suitable uses and thus would not be allowed. Nonmotorized uses, such as backcountry skiing, are not restricted in wilderness or recommended wilderness. However, it is also difficult to access for non-motorized winter recreation because much of the wilderness area on the Nez Perce-Clearwater is large and remote and access points are limited. Wilderness areas provide habitat where the risk of human disturbance to wolverines is very low during the time period when females have dependent young. The management direction within wilderness prevents or reduces threats from human disturbance, dispersed recreational activities, infrastructure, transportation corridors, land management (except prescribed burning), and reduces access to trapping. They also provide connectivity to conserve effects of small populations and genetic diversity.

Table 231. The acres of modeled maternal wolverine habitat within various land allocations

Land Allocation Type	Acres of Modeled Maternal Wolverine Habitat	Percentage of the Total amount of Maternal Habitat
Management Area 2- Idaho Roadless Rule	409,205	54.3
Management Area 2- Research Natural Area	3,202	Less than 1%
Management Area 1-Designated Wild and Scenic Rivers	2	Less than 1%
Management Area 2- Suitable Wild and Scenic Rivers	7,538	1
Management Area 1- Designated Wilderness	303,982	40.3
Management Area 2- Recommended Wilderness	83401	11
Management Area 3-General Forest Managed for Multiple Uses	35,036	4.6

Note: Total wolverine maternal habitat equals 753,576 acres. The amounts add up to more than the total because several land management allocations overlap. For example, Recommended wilderness overlaps with Idaho Roadless Rule Area. Also, Research Natural Areas, and some Suitable Wild and Scenic Rivers overlap wilderness areas, recommended wilderness or Idaho Roadless Rule Areas.

The amount of modeled wolverine habitat by Idaho Roadless Rule area theme is displayed in Table 232. Idaho Roadless Rule areas restrict some management activities, such as road building, vegetation management, and some mineral activities. These land allocations would protect wolverine habitat from experiencing these types of activities. The different Idaho Roadless Rule themes vary in the activities they constrain. The plan will not change Idaho Roadless Rule distribution, and all action alternatives implement the Idaho Roadless Rule as core direction. As a result, management activities disallowed under the Idaho Roadless Rule will continue to be prohibited. The Idaho Roadless Rule area themes are not going to change under the Preferred Alternative either. Idaho Roadless Rule areas direction reduces or prevents infrastructure as it addresses some type of mining, transportation corridors (prohibits road building), and land management (constrains timber harvest). Because road construction is constrained, access is constrained which reduces some human disturbances, and access to trapping. Thus, a little more than half of the wolverine habitat has some protections against some of these activities. These restrictions are enforced by suitability plan components (see forest plan suitability tables in Land Management Plan for the specific restrictions and allowances for Idaho Roadless Rule Areas). Approximately 47.5 percent (634,380 acres) of modeled primary wolverine habitat falls within Idaho Roadless Rule areas. Approximately 54.3 percent of modeled maternal habitat is within Idaho Roadless Rule areas. The alternatives vary how much of the Idaho Roadless Rule lands would also be within recommended wilderness, which would add extra protections. The recommended wilderness areas discussed below are also Idaho Roadless Rule areas as they overlap. Thus, in some Idaho Roadless Rule areas are additionally protected by the constraints present in recommended wilderness as discussed below. Under the Preferred Alternative, 20.3 percent (or 83,401 acres) would also be recommended wilderness.

Winter motorized recreation would be a suitable use within Idaho Roadless Rule Areas unless they are also within recommended wilderness or are identified as non-motorized in the winter Recreation Opportunity Spectrum settings. Non-motorized winter recreation is also suitable within Idaho Roadless Rule Areas. The effects of winter recreation include displacement, avoidance behavior and disturbance effects, but does not typically result in direct mortality. Thus, about half of the wolverine habitat within the plan area would be subject to the effects of winter recreation. However, many areas where wolverine habitat is suitable for motorized winter recreation are steep or has forested vegetation which reduces or eliminates the probability of motorized recreation, which provides refuge areas from this activity. Plan direction for Idaho Roadless Rule Areas would contribute to the conservation of wolverine and their habitats and provide the ecological conditions for wolverines.

Table 232. Acres of modeled primary and maternal wolverine habitat within Idaho Roadless Rule areas by roadless rule area theme

Idaho Roadless Rule Area Theme	Acres of Modeled Primary Wolverine Habitat	Acres of Modeled Maternal Wolverine Habitat
Backcountry Restoration	299,809	205,795
Land Management Plan Special Area	2,347	1,648
Primitive	130,711	77,097
Special Area of Historic or Tribal Significance	18,006	10,090
Wild Land Recreation	183,507	114,535
Grand Total	**634,380**	**409,205**

Summary Alternative Consequences

The amount of modeled maternal wolverine habitat within recommended wilderness is shown in Table 233 while the amount of primary wolverine habitat is shown in Table 234. Under the No Action Alternative, approximately 162,310 acres of wolverine habitat occur within recommended wilderness, which are all currently also wildland recreation theme Idaho Roadless Rule areas and represent about 12.2 percent of wolverine habitat in the plan area. Over-snow motorized vehicles are currently not allowed within recommended wilderness. Alternative W would have the most modeled primary and maternal wolverine habitat included as recommended wilderness and would be the best for wolverines. The lowest alternative is Alternative X which has no recommended wilderness and so has no modeled wolverine habitat. The Preferred Alternative has the second least amount of modeled maternal wolverine habitat in recommended wilderness. Alternative Y would have 148,861 acres of wolverine habitat, which is 11.2 percent forestwide, and Alternative Z would have 297,293 acres, or about 22.3 percent, of wolverine habitat. The Preferred Alternative is similar to Alternative Y, except the boundaries of the Hoodoo are slightly different compared to Alternative Y. The boundaries of the Preferred Alternative are also slightly different than those in the No Action Alternative. The Preferred Alternative would have 140,761 acres of modeled primary wolverine habitat, which would make up 10.5 percent of the total primary wolverine habitat forestwide. There is little difference in management for recommended wilderness and management under the Idaho Roadless Rule backcountry recreation theme, other than whether over-snow motorized recreation and mechanized travel is allowed. These numbers would be additional to the 39.6 percent of wolverine habitat in designated wilderness. Thus, between 39.6 and 68 percent of the wolverine habitat in the plan area would have a low risk of human disturbance in areas of modeled wolverine habitat, depending upon which alternatives are selected.

The Preferred Alternative's boundary change in included some additions and some subtractions in the Hoodoo. The change resulted in approximately 13,747 acres less primary wolverine habitat and 12,131 fewer acres of maternal habitat within the Hoodoo recommended wilderness area compared to the No Action Alternative. The reduction amounts to about 1 percent of the total primary wolverine habitat and about 1.6 percent of the total maternal wolverine habitat within the plan area. While they will no longer be recommended wilderness, they will be managed as Idaho Roadless Rule Wildland Recreation theme, the most restrictive theme of the Idaho Roadless Rule.

Table 233 and Table 234 show the acres of primary and maternal wolverine habitat in recommended wilderness under the 1987 plans compared to the action alternatives. The action alternatives differ from one another in how much habitat is within recommended wilderness. The Preferred Alternative includes about 10.5 percent of primary habitat and about 11.1 percent of maternal wolverine habitat as recommended wilderness. Even though the amount of recommended wilderness increases under the Preferred Alternative, the amount of wolverine habitat within recommended wilderness decreases on account of a boundary change in the Hoodoo and Mallard Larkin recommended wilderness areas and because North Fork Spruces-White Sand and Sneakfoot Meadows would no longer be considered recommended wilderness. The addition of the Meadow Creek recommended wilderness does not add much modeled primary and maternal wolverine habitat because of its lower elevations. The Hoodoo recommended wilderness area contributes the most acres of maternal wolverine habitat of the recommended wilderness areas. The overall change represents about 21,549 acres less of primary habitat and 24,842 acres of maternal habitat that will not be recommended wilderness compared to the No Action Alternative. However, modeled wolverine dispersal habitat within recommended wilderness will increase because most of the Meadow Creek Recommended Wilderness Area is female wolverine dispersal habitat. More modeled female maternal habitat in recommended wilderness would better conserve the wolverine because these areas would receive greater protection against development and human disturbances, such as winter recreation.

Table 233. The acres of modeled maternal wolverine habitat within recommended wilderness under the 1987 Forest Plans and the alternatives

Recommended Wilderness	No Action Alternative	Alternative P	Alternative W	Alternative Y	Alternative Z	Alternative X
Bighorn - Weitas	0	0	115,249	0	0	0
East Meadow Creek	0	0	1,286	1,286	1,242	0

West Meadow Creek	0	0	0	0	2,724	0
Total	**162,310**	**140,761**	**491,013**	**148,861**	**297,293**	**0**

Allocations of recommended wilderness in the Preferred Alternative were in part informed and influenced by the distribution of wolverine habitat. For the Preferred Alternative, of the 47.5 percent (634,380 acres) of modeled primary wolverine habitat in Idaho Roadless Rule Areas, there are about 140,761 acres (22.1 percent of acres in roadless rule) that are recommended wilderness. A total of 83,401 acres of modeled maternal wolverine habitat occurs within recommended wilderness under the Preferred Alternative. Winter motorized recreation is not allowed in recommended wilderness or designated wilderness under the Preferred Alternative. Recommended Wilderness areas are nearly as protective as wilderness areas. They constrain most of the same types of activities that wilderness areas constrain. Within recommended wilderness, wolverine habitats would be protected from motorized winter recreation. Recommended wilderness would provide good protection against disturbance. About 51.3 percent of maternal habitat would be within either designated wilderness or recommended wilderness combined. In addition, about 634,451 acres of modeled primary wolverine habitat and 409,205 acres of modeled maternal wolverine habitat is in Idaho Roadless Rule areas where suitability plan components constrain road building and timber harvest.

Former Hoodoo Recommended wilderness areas would be within Semi-Primitive Motorized settings and would be suitable for winter motorized uses. Summer motorized uses would be constrained by MA2-SUIT-IRA-03 which specifies that roads are suitable in these areas only under strict conditions specified in the Idaho Roadless Rule where they areas are mapped as Semi-Primitive Non-motorized in the summer recreation opportunity spectrum settings. Therefore, summer motorized uses would not be suitability in these formerly recommended wilderness areas. Specific effects from this change are that future travel planning projects might open these areas to winter motorized uses, and if so, wolverines could experience disturbance and displacement because of winter motorized uses. Furthermore, if winter motorized uses are authorized there in the future, allowing winter motorized access in these areas potentially increases the chance of illegal winter motorized uses by the public in adjacent recommended wilderness. However, the public use of adjacent recommended wilderness areas for winter motorized uses is not authorized, and restrictions on this illegal use will be reduced through law enforcement. More details on the effects of winter motorized uses are included in the section on the summer and winter recreation opportunity spectrum of the wolverine analysis below.

Connectivity has been identified as an important facet to wolverine conservation (Schwartz et al. 2009, Idaho Department of Fish and Game 2014b) and recommended wilderness alternatives could contribute to connectivity. The different proposed recommended wilderness areas differ in the extent to which they provide connectivity. The areas that provide the best connectivity for wolverine are:

- Hoodoo
- Meadow Creek - Upper North Fork
- Rawhide
- North Fork Spruce - White Sand
- Sneakfoot Meadows

As noted above, the most important areas for connectivity on the Nez Perce-Clearwater are along the Idaho-Montana border. Other areas that are important for connectivity are along the ridges above the Salmon River between Sabe Creek and MacKay Bar. The area above the Salmon River is already designated wilderness. Those alternatives that propose recommended wilderness lands in these areas would provide more connectivity than those that do not. Recommended wilderness areas that occur along the Idaho-Montana Border include Hoodoo, Meadow Creek Upper North Fork, and Rawhide. The No

Action Alternative, Alternative W, Alternative Y, Alternative Z, and the Preferred Alternative all include all, or a portion, of Hoodoo as recommended wilderness; only Alternative X does not. However, the alternatives vary by how much of the Hoodoo area is included as recommended wilderness.

Collectively, Alternative W provides the greatest area important to wolverine connectivity (Schwartz et al. 2009, U.S. Department of the Interior 2014b) while Alternative X provides the least amount with zero. Alternative Z provides just slightly less acres than Alternative W followed by the No Action Alternative. Alternative Y is second to last. The Preferred Alternative is intermediate in providing connectivity but includes the Hoodoo and adds connection between the Selway-Bitterroot, the Gospel-Hump, and the Frank Church by adding the Meadow Creek recommended wilderness area. These recommended wilderness areas, combined with designated wilderness areas, include most of the areas in the Nez Perce-Clearwater identified by Schwartz et al. (2009) as important to wolverine connectivity, save for the checkerboard area near Lolo Pass. These areas also contain some of the areas in the national forest that may provide denning habitat for female wolverines.

While recommended wilderness provides the greatest amount of protection of connectivity areas, the management under the Idaho Roadless Rule would keep these lands relatively free from human development, which is the primary cause of loss of connectivity.

The checkerboard area appears to be an important connectivity area for lynx, fisher, and wolverine. Desired conditions FW-DC-LND-01 would apply to decisions about this area. Land ownership, rights-of-way, and conservation easements allow the Nez Perce-Clearwater to meet Land Management Plan desired conditions, provide access for recreation, and facilitate restoration or conservation of high value resources, including habitat for Species of Conservation Concern and listed fish and wildlife species and significant cultural sites.

While modeled primary wolverine habitat predicts wolverine habitat across the landscape, female maternal habitat is more important and thought to be more limited. Protecting maternal habitat may be important to the conservation of the wolverine. Copeland et al. (2010) modeled female denning habitat based upon female den locations across the global range of the wolverine (Copeland et al. 2010). The modeled female denning habitat was based upon the amount of persistent spring snow. Copeland et al. (2010) produced a model that delineated areas of the western United States predicted to be maternal wolverine habitat, which are areas predicted to be suitable for use by reproductive females. Areas that have persistent spring snow are much more limited and could be important for wolverine denning.

The alternatives differ in how much maternal habitat is included in recommended wilderness. Table 233 shows the amount of maternal habitat found within the different areas considered for recommended wilderness and by alternative. The best alternative for maternal habitat is Alternative W, followed by Alternative Z, then the No Action Alternative, then the Preferred Alternative and last is Alternative Y.

Suitability plan components identify a number of activities that are or are not suitable (and thus not allowed) within different land allocations including recommended wilderness (see suitability table in the Recommended Wilderness Section of the Revised Forest Plan) and these varied by alternative. Recommended wilderness management is only slightly less restrictive than designated wilderness management. This type of management would protect wolverines from disturbance and habitat impacts within recommended wilderness. Recommended wilderness management protects wolverine habitat from many human disturbances, dispersed recreation activities (except those accessed by foot or stock), transportation corridors, and land management activities (except prescribed fire). They also reduce the access to trapping and conserves connectivity to assist with effects of small populations. Whether over-snow vehicle use is allowed within recommended wilderness varies by alternative as shown in Table 235.

Under the No Action Alternative, Alternative W, and Alternative Y, over-snow motorized travel would not be allowed in recommended wilderness. Within Alternative X, it is not applicable because there would be no recommended wilderness. While under Alternative Z, over-snow travel would be allowed in recommended wilderness. If allowed, it would have disturbance and displacement effects on female wolverines. The Preferred Alternative would not allow motorized over-snow travel to be suitable within recommended wilderness. A few other uses vary as to their suitability in recommended wilderness such as mechanized tool use for administrative purposes, mechanized tools for public use, mechanized travel, aircraft landing for administrative uses, and aircraft landing for recreational uses. Most of these have no or minor impacts to wolverines. Allowing mechanized travel would allow mountain bikes which could have some disturbance or displacement effects. Alternative Z would allow mechanized travel whereas the other alternatives do not. Recreational landing of aircraft could facilitate disturbance and perhaps leave the door open for heliskiing which would disturb wolverines during denning seasons. Again, Alternative Z would allow recreational aircraft landing. The Preferred Alternative allows motorized and mechanized tools for administrative uses, and aircraft landings for administrative uses. Neither of these would have impacts to wolverines. All other uses that varied by alternative are not suitable within recommended wilderness in the Preferred Alternative.

Table 235. Motorized over-snow travel suitability within recommended wilderness, by alternative

Alternative	Motorized Over-snow Travel Suitable in Recommended Wilderness
No Action	No
W	No
X	Yes, all wolverine habitats outside designated wilderness would be suitable for motorized over-snow because there would not be any recommended wilderness.
Y	No
Z	Yes
Preferred	No

Summer and Winter Recreation Opportunity Spectrum

In addition to whether motorized over-snow travel is suitable within recommended wilderness, the alternatives also determine whether areas across the national forest are suitable for both summer and winter motorized uses. The mechanism to determine motorized suitability is the summer recreation opportunity spectrum settings for summer travel and the winter recreation opportunity spectrum for winter travel. The amounts of wolverine primary and maternal habitat within summer recreation opportunity spectrum settings are shown in Table 236 and Table 237. The total amount of wolverine maternal and primary habitat suitable or unsuitable for motorized uses in summer by alternative is shown in tables Table 238 and Table 239. Summer motorized travel can impact habitat within the footprint of the road, can cause mortality via vehicle strikes, and can be a disturbance or displacement factor. Major highways can act as a barrier to dispersal. However, the U. S. Fish and Wildlife Service (2018) determined that roads present a low stressor to wolverines at the individual and population level in most of its current contiguous United States range. This is true for the plan area given that the majority of wolverine habitat (70 percent) is in a non-motorized summer recreation opportunity spectrum setting.

The alternatives with the most wolverine habitat as suitable for summer motorized travel are Alternative X, followed by the Preferred Alternative, followed by Alternative Y then W and last Z. Alternatives with less area suitable for wolverines is better for wolverines. The 1987 plans (No Action Alternative) did not use the recreation opportunity spectrum to identify suitability for motorized uses. Instead, all areas were open until closed by a travel management decision. Other factors like elk habitat effectiveness measures, PACFISH and INFISH, and other resource considerations were factored into decisions on the travel system. Thus, the action alternatives represent a new mechanism in the revised plan to identify where motorized uses could be suitable.

The winter recreation opportunity spectrum settings have the potential to have more influence on wolverine conservation than summer recreation opportunity spectrum. Heinemeyer et al. (2017) studied the response of wolverines to winter recreation in in Idaho, Wyoming, and Montana. In that study, wolverines avoided areas of both motorized and non-motorized winter recreation with off-road recreation, eliciting a stronger response than road-based recreation. Female wolverines exhibited stronger avoidance of off-road motorized winter recreation and experienced higher indirect habitat loss than male wolverines. Wolverines showed negative functional responses to the level of recreation exposure within the home range, with female wolverines showing the strongest functional response to motorized winter recreation. Hienemeyer et al. (2017) suggested indirect habitat loss, particularly to females, could be of concern in areas with higher recreation levels. They speculated that the potential for backcountry winter recreation to affect wolverines may increase under climate change if reduced snow pack concentrates winter recreationists and wolverines in the remaining areas of persistent snow cover (Heinemeyer et al. 2017). These findings suggest that the amount of female wolverine denning habitat affected by the alternatives could have meaningful consequences to the conservation of the wolverine on the Nez Perce-Clearwater.

The amount of modeled female wolverine maternal habitat and modeled primary wolverine habitat that falls within winter recreation opportunity spectrum settings is varies by alternative and is displayed in Table 240 and Table 241. Table 242 and Table 243 show the amount of modeled primary and maternal habitat within motorized and non-motorized settings. The alternatives range from between 83 and 46 percent of primary wolverine habitat and between 84 and 42 percent of modeled habitat in non-motorized winter recreation opportunity spectrum settings. Alternative W has the most acres of modeled maternal and primary wolverine habitat in non-motorized settings, followed by the Preferred Alternative, then Alternative Y, and Alternatives Z and X have the same percentages of wolverine habitats in non-motorized settings. The Preferred Alternative has the second most of the alternatives and would have 61 percent of primary and 58 percent of maternal habitat within non-motorized winter recreation opportunity spectrum settings. More modeled wolverine maternal habitat in non-motorized settings would better conserve the wolverine because these areas would receive greater protection against motorized winter recreation.

Winter recreation opportunity spectrum alternatives would determine where winter over-snow travel would be suitable and potentially authorized in future decisions. While suitable, some areas of the Nez Perce-Clearwater have characteristics that naturally limit motorized over-snow travel or make it more difficult (see Figure 89 above). Therefore, many areas have a lower probability of snowmobile use while technically suitable. Even if identified as suitable, a site-specific travel management decision would need to be made to allow these uses. The snowmobile model estimates where over-snow motorized travel has a higher probability to occur, and where it is less likely to occur. The modeling was based upon findings from Olson et al. (2017). In their study, winter recreationalists volunteered to carry GPS while snowmobiling or participating in winter non-motorized recreation. Statistics were used to identify selection of remotely sensed environmental characteristics, including topography, vegetation, climate, and road access, that were selected by winter recreationalists, such as snowmobilers and backcountry skiers.

Olson et al. (2017) found that snowmobilers selected areas with greater forest road densities, lower canopy cover, and smoother, less steep terrain. Olson et al. (2017) modeled these areas on the Nez Perce-Clearwater using parameters from their study in Colorado. To validate the models, the Land Management Plan team met with Forest Service staff who had on-the-ground expertise of where snowmobile use occurs on the Nez Perce-Clearwater and used data such as spatial data for groomed routes and roads layers. The Land Management Plan team was also provided with information from winter motorized user groups about where their members recreate. This information was used to verify whether the models reasonably predict snowmobile recreation in the plan area. The team found that the Idaho Standard off road snowmobile model performed well at predicting known use.

Many areas of the Nez Perce-Clearwater had low predicted probability of use because of the higher amounts of canopy cover, lower snow depths, steep or broken terrain, or lack of roads. These are landscape features that make it difficult to use snowmobiles but could provide refuges that could contribute to wolverine habitat.

In contrast, areas with low canopy, flatter and less complex terrain, and with access from roads or groomed trails were preferred by snowmobilers. The percent or amount of area with these characteristics represent a subset of the areas where motorized uses would be suitable. Therefore, even in areas suitable for motorized uses, there is a portion of area not capable of providing winter motorized uses. Areas that had a higher probability of use in modeled wolverine habitat include the area near Lolo Pass and some portions of areas near the Gospel-Hump. Most other areas had a low probability of use by snowmobilers. These models do not apply to snow bikes that have an easier time navigating through trees.

Suitable and Eligible Wild and Scenic River Suitability

Alternatives for suitable wild and scenic rivers would establish river corridors that would be managed in a way that that could potentially benefit wolverines. While management in suitable wild and scenic rivers would not be directed towards wolverines, management of suitable rivers could have some indirect beneficial consequences to wolverines as several rivers considered for suitability have wolverine habitat within the river corridor, which is a quarter mile. If found suitable, river corridors would have protections that would be present even when the suitable river is within designated wilderness.

Table 244 shows the amount of modeled wolverine habitat within suitable wild and scenic river corridors by alternative. Suitability plan components found in the Land Management Plan would apply to river corridors to constrain some activities to the benefit of wolverines. The benefits would be modest though. River corridors would constrain activities to different levels depending upon whether they are classified as wild, recreational, or scenic. Table 244 and Table 245 show the amount of modeled primary and maternal wolverine habitat within river corridors considered for eligibility or suitability to be included in the wild and scenic river system by alternative. The Preferred Alternative would include 15,904 acres of primary habitat and 7,538 acres of maternal habitat in suitable river corridors.

Alternative X does not propose any suitable wild and scenic rivers. In and of themselves, the area of the river corridors for suitable wild and scenic rivers under the alternatives represent only a very small difference overall. Rivers found suitable for wild and scenic river designation would be less likely to have dams constructed on them.

Most of the rivers considered for suitability lay within Idaho Roadless Rule areas or designated wilderness areas so the protections are only slightly better than the surrounding landscape for wolverine habitat. However, two alternatives have the potential to influence land management in the roaded front. A small portion of Meadow Creek, the upper sections of the North Fork Clearwater River, small sections of Cayuse Creek, and portions of Crooked Fork each have small portions where the potential suitable wild and scenic rivers have wolverine habitat and occur within the managed front. Alternatives that include these rivers or portions of these rivers could provide small acres with increased protection outside of Roadless Rule areas or wilderness areas.

No Action Alternative

Under the No Action Alternative, the extent to which wolverines are conserved is intermediate to the best alternative for wolverines (Alternative W) and those that provide the least protections (Alternatives X and Z). The No Action Alternative provides intermediate amounts of recommended wilderness in areas important to wolverine connectivity, more than Alternatives X and Y but less than Alternatives W and Z. The No Action Alternative contributes at an intermediate level towards modeled wolverine habitat acres. Forestwide objectives for restoration and vegetation treatments vary by alternative. The No Action Alternative would provide among the lowest acres of vegetation management. However, while the amount differs, the effects of vegetation treatments have little consequences for wolverines, except to their prey. Wolverines eat a wide variety of prey, including large ungulates like moose, caribou, and mountain goats, and a variety of small and medium sized mammals. Ungulates benefit from more early seral vegetation so alternatives with more aggressive vegetation management would benefit wolverine prey. They are less likely to be affected by vegetation treatments because they live in rocky, cold, high elevation habitats. For the most important factor that varies, which is winter motorized suitability, this alternative would allow the current amount of winter motorized use. Currently winter motorized uses are allowed nearly forestwide except for in designated wilderness, nor in the current amount of recommended wilderness areas. In contrast, the Preferred Alternative identifies more areas as recommended wilderness, and less suitable for motorized over-snow travel.

Alternative W

In terms of the ability to conserve wolverine habitat, Alternative W would be the best for wolverines because it would provide the most wolverine habitat in recommended wilderness and the most area unsuitable for winter motorized uses. Modeled wolverine habitat would be unsuitable to over-snow motorized travel on over 80 percent of modeled wolverine habitat in the plan area. This alternative would be the best to reduce potential probability of adverse consequences to wolverine habitat use from winter motorized uses. The amount of recommended wilderness under Alternative W provides the most areas for wolverine connectivity. This alternative also provides the largest acreage that contains modeled maternal wolverine habitat, which is a substantial increase over the No Action Alternative. Objectives for vegetation treatments in this alternative have a quicker pace to achieving desired vegetation conditions compared to the other alternatives, but vegetation treatments are not expected to have any effects on wolverine habitat. The higher amounts of vegetation treatments would be better for wolverine prey compared to the No Action Alternative, which could lead to beneficial consequences to wolverine forage.

Alternative X

In comparison with Alternative W, Alternative X would not identify any recommended wilderness. This alternative would protect the least amount of wolverine habitat. Thus, all roadless rule areas, including those that are currently recommended wilderness under the 1987 plans, would be suitable for winter motorized travel, resulting in about 58 percent of the modeled wolverine habitat on the Nez Perce-Clearwater as suitable for winter motorized recreation while leaving 42 percent unsuitable. This alternative, along with Alternative Z, conserves wolverines the least, at least in terms of recommended wilderness and suitable over-snow motorized travel. Alternative X does not have any connectivity areas in recommended wilderness areas. Objectives for vegetation treatments in this alternative lean towards the highest amounts of vegetation management. The higher amounts would be better for wolverine prey compared to the No Action Alternative, which could lead to beneficial consequences to wolverine forage.

Alternative Y

Alternative Y is intermediate for wolverine conservation and intermediate to Alternative X and Alternative W with moderate amounts of recommended wilderness and has high amounts of motorized suitability. Under this alternative, approximately 58 percent of modeled wolverine habitat is suitable for over-snow motorized travel and 42 percent unsuitable. Alternative Y is modest in the amount of primary and maternal wolverine habitat within recommended wilderness compared to other alternatives. Objectives for vegetation treatments in this alternative favor an intermediate pace towards achieving desired conditions vegetation conditions compared to the other alternatives. They are less than

Alternatives W, X, and the Preferred Alternative but more than the No Action Alternative. The lower amounts would have less benefits for wolverine prey compared to the other alternatives.

Alternative Z

While the amount of recommended wilderness under Alternative Z is intermediate to Alternative W and X, the effects on wolverine conservation are more similar to Alternative X because any recommended wilderness would be suitable for over-snow travel under this alternative. Effectively, this would leave around 54 percent of modeled wolverine habitat as suitable and 46 percent as unsuitable for winter motorized uses and roughly equivalent to Alternative X. Alternative Z provides the second most amount of wolverine connectivity in recommended wilderness with only slightly less than Alternative W. This is because it includes Hoodoo, Meadow Creek-Upper North Fork, Rawhide, North Fork Spruces White Sand, and Sneakfoot Meadows as recommended wilderness. These areas are all occur in important connectivity areas along the Idaho-Montana border. Alternative Z is similar but slightly more than the No Action Alternative in the amount of modeled maternal wolverine habitat in recommended wilderness with about 80,732 acres. While it contains similar acres, the amount of protection this affords female denning habitat is negated by the allowance of winter motorized recreation as a suitable use. Objectives for vegetation treatments in this alternative strike a balance towards less vegetation management and fall at the second lowest pace compared to the other alternatives. The lower amounts would not be as beneficial for wolverine prey.

Preferred Alternative

The Preferred Alternative identified the Mallard Larkin, Hoodoo, and Meadow Creek Idaho Roadless Rule areas as recommended wilderness. This alternative is most similar to Alternative Y for recommended wilderness, except that there were some boundary adjustments to the recommended wilderness areas compared to the other alternatives. The Preferred Alternative would include 140,761 acres of the total wolverine habitat and 83,401 acres of wolverine maternal habitat in recommended wilderness. Again, the change from Idaho Roadless Rule management into recommended wilderness represents only slight changes in on-the-ground management. Under the Preferred Alternative, most of the nonconforming uses would not be allowed in recommended wilderness, including motorized over-snow travel. The exception is that nonconforming uses, such as administrative chainsaw operation and administrative aircraft landing would be allowed. These would have minimal effect on wolverines. Winter motorized travel would be suitable in 32 percent, and not suitable in 68 percent of primary wolverine habitat. It would allow 39 percent of maternal wolverine habitat to be suitable for motorized uses whereas 61 percent would be unsuitable. This combination is an improvement over all but Alternative W. The amount of timber harvest is more aggressive in this alternative; however, this may have beneficial impacts to wolverines because it would provide better conditions for their large ungulate prey that depend on disturbance for high quality nutrition. Alternatives for wild and scenic rivers would have little effect on wolverine habitat but might help conserve small percentages of habitat. The Preferred Alternative found Cayuse Creek, Fish Creek, Hungery Creek, Weitas Creek, Kelly Creek, North Fork Kelly Creek, Middle Fork Kelly Creek, South Fork Kelly Creek, Colt Killed Creek, the Salmon River, and Meadow Creek suitable as wild and scenic rivers and portions of these areas fall within modeled wolverine habitat.

Effects of Plan Direction

Terrestrial Ecosystems

Plan direction within the terrestrial ecosystems section of the Land Management Plan would have no effect or beneficial effects on wolverines. Desired conditions FW-DC-TE-01, FW-DC-TE-05, and FW-DC-TE-06 would contribute to ecosystem integrity and provide a diversity of habitat conditions for wolverine prey.

Biophysical Features

Plan direction within the biophysical features section of the Land Management Plan would have no effect on wolverines.

Forestlands

Plan direction for the forestlands section proposes changes to dominance types, size classes, and forest density and addresses landscape pattern, which would alter some habitats used by wolverines. Plan components in this section are informed by modeling of the natural range of variation so should contribute to ecosystem integrity. The effects would be to provide for the diversity and abundance of wildlife that could contribute to wolverine prey. However, these plan components would direct management to alter some habitats that would be used by wolverines and wolverine prey. Alteration of these habitats would be through timber harvest, wildland fire, planting, mechanical vegetation management, and other forestry or restoration methods after site-specific analysis. Since wolverines tend to use high elevation habitats, forested habitats used most by wolverines would be within the cold and cool moist broad potential vegetation types. Wolverines also cross through lower elevation habitats so plan direction for all broad potential vegetation types might be affected. However, as analyzed above, wolverines do not appear to be adversely affected by timber activities, prescribed fire, and other methods of vegetation manipulation. The U.S. Fish and Wildlife Service (2013b) stated:

> Few effects to wolverines from land management actions such as grazing, timber harvest, and prescribed fire have been documented. Wolverines in British Columbia used recently logged areas in the summer and moose winter ranges for foraging (Krebs et al. 2007). Males did not appear to be influenced strongly by the presence of roadless areas (Krebs et al. 2007). In Idaho, wolverines used recently burned areas despite the loss of canopy cover (Copeland 1996)...
>
> Intensive management activities such as timber harvest and prescribed fire do occur in wolverine habitat; however, for the most part, wolverine habitat tends to be located at high elevations and in rugged topography that is unsuitable for intensive timber management...Wolverines are not thought to be dependent on specific vegetation or habitat features that might be manipulated by land management activities, nor is there evidence to suggest that land management activities are a threat to the conservation of the species.

Therefore, while plan components for forested lands would direct management to alter forest vegetation near and within wolverine habitat, they would not likely have negative environmental consequences to wolverines.

Meadow, Grassland, and Shrubland

Plan direction for the meadows, grasslands, and shrublands section of the Land Management Plan would have no effect or beneficial effects on wolverines. Desired conditions within this section would contribute to ecosystem integrity and provide a diversity of habitat conditions for wolverine prey.

Carbon Storage and Sequestration

Plan direction within the carbon storage and sequestration section of the Land Management Plan would have no effect or beneficial effects on wolverines.

Fire Management

Fire management plan components would allow and encourage fire to play its natural role across the planning area. Fire is likely to play a dominant role in shaping wolverine habitat over the life of the plan.

Wolverines appear tolerant of changes due to fire. For example, wolverines use recently burned areas despite the loss of canopy cover (U.S. Department of the Interior 2013b). Increased early seral conditions across wolverine habitat should provide improved nutritional conditions for wildlife, such as ungulates. Plan direction for fire management would have beneficial consequences for wolverines.

Invasive Species

Plan direction for the invasive species section would have negligible effects on wolverines. Wolverine habitats do not currently have many invasive species, and treatments within wolverine habitat would not likely have direct effects on wolverines.

Soil Resources

Plan direction in the soil resources section of the plan would have negligible effects or beneficial effects on wolverine habitats. They would serve to protect and restore soil resources from management activities. Soil objectives propose restoration activities but those would have lower probabilities of occurring within wolverine habitat and would have, at most, short-term impacts locally on wolverine prey. They would not occur at an extent in wolverine habitat that would be measurable.

Water and Aquatic Ecosystems

Plan direction in the water and aquatic ecosystems section would have negligible effects or beneficial effects on wolverines because they would restore, enhance, and protect aquatic ecosystems. Wolverines are known to eat beavers occasionally and these habitats would provide for them.

Riparian Management Zones

Plan direction in the riparian management zones section would have negligible effects or beneficial effects on wolverines because they would restore, enhance, and protect riparian areas.

Conservation Watershed Network

Plan direction in the conservation watershed networks section would have negligible effects or beneficial effects on wolverines because they would restore, enhance, and protect aquatic habitats. Wolverines would not be sensitive to restoration activities and would benefit from proper functioning aquatic habitats.

Infrastructure (Aquatic and Riparian)

Plan direction for the aquatic and riparian infrastructure section would have negligible effects or beneficial effects on wolverines because they would restore, enhance, and protect aquatic habitats. Wolverines would not be sensitive to restoration activities and would benefit from proper functioning aquatic habitats.

Energy and Minerals (Aquatic and Riparian)

Plan direction in the aquatic and riparian energy and minerals section would have negligible effects or beneficial effects on wolverines because they would protect aquatic habitats.

Livestock grazing (Aquatic and Riparian)

Plan direction in the aquatic and riparian livestock grazing section would have negligible effects or beneficial effects on wolverines because they would protect aquatic habitats.

Wildlife

Plan direction for the wildlife section would have negligible effects or beneficial effects on wolverines. FW-DC-WL-01 would provide conditions for federally listed species including the proposed wolverine. FW-DC-WL-03 and FW-DC-WL-06 would promote connectivity for wolverines. FW-STD-WL-01 requires that the Nez Perce-Clearwater follow the Northern Rockies Lynx Management Direction. Lynx habitat overlaps with wolverine habitat and would contribute beneficial consequences to wolverine habitats.

Multiple Uses Wildlife

Plan direction in the multiple uses' wildlife section would have negligible effects on wolverines and would benefit wolverine prey.

Multiple Uses Elk

Plan direction for the multiple uses' elk section would have negligible effects on wolverines and would benefit wolverine prey. These plan components encourage addressing roads and would increase nutrition for ungulates.

Air Quality

Plan direction for the air quality section would have no effect on wolverines.

Tribal Trust

Plan direction for the tribal trust responsibilities section would have negligible or beneficial effects on wolverines.

Cultural Resources

Plan direction for the cultural resources section would have no environmental consequences for wolverines.

Municipal Watersheds

Plan direction for the municipal watersheds section would have no environmental consequences for wolverines.

Sustainable Recreation

Plan direction for the sustainable recreation section may lead to management that would increase disturbance to wolverines. Specifically, wolverines have been shown to avoid both motorized and non-motorized winter recreation, and plan direction for recreation may affect the amount and distribution of recreational activities. FW-DC-REC-11 could facilitate additional future winter recreation into wolverine habitat. Some activities suitable in various alternatives under the recreation opportunities spectrum may allow disturbance in wolverine habitat and could displace wolverines because of avoidance behavior. It is unknown whether displacement would have population level effects on wolverines. Recreation infrastructure, such as trails, may promote disturbance or increase access for trapping activities which could result in limited incidental take; however, incidental take during of wolverine while legal tapping for other species is rare.

Scenery

Plan direction for the scenery section would have negligible or no effect on wolverines.

Public Information, Interpretation, and Education

Plan direction for the public information, interpretation, and education section would have negligible or no effect on wolverines.

Infrastructure

Plan direction for the infrastructure section may lead to management that would increase disturbance to wolverines. Specifically, this direction could encourage increased road access into wolverine habitat, which could alter wolverine habitat. It is unknown whether access would have population level effects on wolverines. Recreation infrastructure, such as roads, may increase access for trapping activities, which could result in limited incidental take; however, incidental take of wolverines is rare.

Land Ownership and Land Uses

Plan direction for the land ownership and land uses section would have both negative and beneficial consequences on wolverines. FW-DC-LND-01, specifically, would direct land acquisitions to prioritize habitat for at-risk species, which would have beneficial consequences for wolverine connectivity and habitat conservation. On the other hand, FS-DC-LND-06 could facilitate some impacts to wolverine habitat from energy developments. However, a large portion of the wolverine habitat is in designated wilderness where these facilities would not be allowed. Potential for oil or gas extraction is low to very low on the Nez Perce-Clearwater so there would be little chance to have oil and gas extraction projects. Wind energy potential is also low so there is less likely to be wind energy development. More likely would be rights-of-way for electrical grid or oil and pipelines could occur. These types of infrastructure usually have temporary impacts during construction but then would have low impacts after completion. The footprint would be limited to only very a small percent of wolverine habitat in the plan area. Therefore, the impacts would be negligible.

Ecosystem Services

Plan direction for the ecosystem services section would have adverse consequences to wolverines. Specifically, FW-GDL-ES-01 would direct the Nez Perce-Clearwater to consider opening a new road when closing other roads. In many areas of the Nez Perce-Clearwater, road densities are high or very high and may need to be reduced due to resource concerns. In the event that happens, new roads or motorized trails would need be created to keep a net access amount. This guideline would create a situation where watersheds or areas with low road densities in wolverine habitat could see an increase in access because of road closures in other areas for resource benefits. However, because wolverine habitat occurs mostly on lands that do not allow motorized uses this is less likely.

Scrafford et al. (2018) showed that top winter and summer models indicated that wolverines avoided and increased speed near roads. Wolverine movement, but not avoidance, increased with traffic volume. Roads, regardless of traffic volume, reduce the quality of wolverine habitats, and higher-traffic roads might be most deleterious. Krebs et al. (2010) also showed a response to roads. Roaded and recently logged areas were negatively associated with female wolverines in summer. Roads are also well known to affect wolverine prey, such as elk. This plan component might also redistribute winter motorized uses into new areas in the event of closures elsewhere.

Timber

Plan direction for the timber section would alter some wolverine habitats mostly in Management Area 3. However, wolverines are not sensitive to vegetation management and will continue to use those areas. Therefore, there would be negligible consequences for wolverines from timber plan direction.

Energy and Minerals

Plan components for the energy and minerals section may have some environmental consequences to wolverine habitats if mining or energy extraction activities take place in wolverine habitat under the plan. In the event they do, it would result in temporary or permanent loss of wolverine habitat. However, the extent of mining or mineral activities would likely be over only a small proportion of wolverine habitat.

Livestock Grazing

Plan direction for the livestock grazing section would potentially have negligible environmental consequences for wolverine.

Special Forest and Botanical Products

Plan direction in the special forest and botanical products section would have negligible environmental consequences for wolverine.

Designated Wilderness
Plan direction for the designated wilderness section would have beneficial consequences for wolverine.

Wild and Scenic Rivers
Plan direction for the wild and scenic rivers section would have negligible or beneficial consequences for wolverines.

Recommended Wilderness
Plan direction for the recommended wilderness section would have negligible or beneficial consequences for wolverine.

Idaho Roadless Rule Areas
Plan direction for the Idaho Roadless Rule areas section would have negligible effects or beneficial effects on wolverine.

Research Natural Areas
Plan direction in the research natural areas section would have negligible effects or beneficial effects on wolverine.

Gospel-Hump
Plan direction in the Gospel-Hump geographic area section would have negligible consequences or beneficial effects on wolverine.

Lower Salmon
Plan direction in the Lower Salmon geographic area in section would have negligible consequences on wolverine.

Pilot Knob
Plan direction in the Pilot Knob geographic area section would have negligible or no consequences for wolverines.

Lolo Trail National Landmark
Plan direction in the Lolo Trail National Landmark section would have negligible or no consequences for wolverines.

Cumulative Effects

Land Management
The cumulative effects area for wolverines is the Selway-Salmon management regions as delineated by Inman (2013). The majority of wolverine habitat is located in higher-elevation areas that are largely administered by the Forest Service. This area includes National Forest System lands in Idaho that include the Payette, Boise, and some areas on the Wallowa Whitman National Forest in Oregon. Additionally, they occur where many areas are designated wilderness, recommended wilderness, and Idaho Roadless Rule areas, or lands that are relatively unavailable for development. Designated wilderness areas that contribute to wolverine habitat includes the Frank Church-River of No Return, the Gospel-Hump, The Selway-Bitterroot, and the Hells Canyon Wilderness. Forest Plans for other national forests in the northern Rocky Mountains provide direction for activities, such as timber harvest, livestock grazing, and motorized use of forest roads and trails, such that these activities are not expected to negatively affect wolverines or their habitat. Diverse prey items are available for wolverines throughout the cumulative effects analysis area so prey should continue to be available. The U.S. Fish and Wildlife Service determined that Forest Service Land management Plans alleviate several stressors identified in the 2018 Wolverine Species Status Assessment (USFWS 2018).

These plans allow winter motorized uses consistent with their plans and manage decisions on the travel system through site specific decisions that establish the travel system including for winter motorized travel. Some winter motorized recreation occurs in wolverine habitat on national forest lands in this area, but like on the Nez Perce-Clearwater, they include areas that are inventoried roadless, and they do not allow motorized winter recreation in designated wilderness. The identification of winter motorized suitability would continue this use in much of the Nez Perce-Clearwater but would reduce it in other areas of the national forest that would be newly unsuitable for this use.

Lands managed by the State of Idaho and private lands include areas surrounding the Nez Perce-Clearwater on the west. Cumulative adverse effects to the wolverine are not expected as a result of management actions on state lands. Both state and private lands are not generally located in modeled wolverine habitat, though some modeled wolverine habitat exists on these lands.

The Idaho Department of Fish and Game prioritized wolverine conservation in their wolverine conservation plan (U.S. Department of the Interior 2014b). They identified areas with wolverine habitat as Tier I, Tier 2, and Tier3, where Tier I receives the highest priority. Most areas on the Nez Perce-Clearwater were identified as Tier II or Tier III areas. They stated that many areas in the state were not ranked as Tier I due to permanent protections provided by wilderness and roadless designations, which limit potential threats. The Idaho management plan for the Conservation of Wolverines in Idaho identifies seven objectives for actions that would help conserve wolverines. These objectives address concerns about threats to wolverines and would not be inconsistent with this plan. The Nez Perce-Clearwater Land Management Plan would be consistent with these plans and would not lead to cumulative effects.

This area has existing highway systems that are managed by the state or as freeways. Some examples include Highway 95. Most roads on National Forest System lands are unpaved, are traveled at slower speeds, and have lighter traffic volumes than highways. These roads are less likely to result in vehicle strikes. Comparatively few paved roadways traverse through the Nez Perce-Clearwater. The longest paved roadways include Highway 12 along the Lochsa River, the Salmon River Road, portions of the Selway River Road, and Highway 14 along the Southfork Clearwater River. Other paved roadways include Highway 8 and Highway 3 through limited portions of the Palouse District and a few other portions of paved roads that end shortly after entering National Forest System lands. Highway 12 and Highway 14 allow traffic speeds between 45 and 50 miles per hour, so it may be possible on rare occasions for a wolverine to be struck by a moving vehicle on these roads. Highway 12 crosses through areas of wolverine habitat near Lolo Pass. Other paved roads on the Nez Perce-Clearwater cross through modeled wolverine habitat for minor stretches, if any. However, these roads have comparatively low traffic volumes and the majority of these road miles do not travel through wolverine habitat because of their lower elevation. There are no major roadways that travel north to south in the plan area. Few, if any, wolverine are known to have been killed on the paved roads in the plan area. The overall impact from these roads is low because roads in on the Nez Perce-Clearwater only travel through a limited portion of the plan area (small scope) and the severity is slight and not expected to impact more than 10 percent of the wolverine population during the life of the plan because most paved roads do not travel through wolverine habitat and few wolverine are expected to be struck on these roads. Perhaps the most significant impact is to wolverine habitat connectivity where Highway 12 crosses Lolo Pass. These roads currently represent only minor impacts to connectivity because of their limited distribution in wolverine habitat. The Nez Perce-Clearwater is a largely intact block of land with few higher speed roads and provides connectivity and remote locations for wolverines. Squires et al. (2007) concluded that wolverine movements are unpredictable and are not easy to incorporate in the planning of structural highway mitigation projects. The Nez Perce-Clearwater Land Management Plan is unlikely to result in new highways.

Major highways are not abundant in north central Idaho and most of them do not cross through modeled wolverine habitat. In Montana, Highway 93 and I-90 may affect wolverine dispersal and gene flow, as well as developments in western Montana. I-90 may also represent a barrier to connectivity from wolverines in Canada. Highway 95 mostly travels through lower elevation areas, or developed areas where vehicle strikes on wolverines are less likely.

Access during the winter season may indirectly affect the area accessible for trapping. Any cumulative effects to the wolverine resulting from trapping in relation to winter recreation access on the Nez Perce-Clearwater and surrounding lands would be uncommon. Incidental trapping of wolverines is a rare event in Idaho as evident from data (U.S. Department of the Interior 2014b) and, in many cases, the wolverine can be released alive. Some wolverines may cross from the Nez Perce-Clearwater into Montana where wolverine trapping is allowed. Trapping is not regulated by the Forest Service and decisions in the plan are not likely to increase exposure to trapping, as motorized access is widespread in the plan area and trapping is an ongoing activity.

Changing Climate

According to the models used in an assessment by McKelvey et al. (2011), the Nez Perce-Clearwater, northern Montana, the southern Bitterroot Mountains, and the Greater Yellowstone Ecosystem will retain significant spring snow in the next 50 years, whereas, central Idaho south of the Nez Perce-Clearwater is projected to lose significant spring snow. There are variations in climate models, but models generally indicate earlier snowmelt in the northern Rockies in the future, a pattern that has been ongoing since at least the 1950s. Although wolverines are known to spend the majority of their time at high elevations, the degree to which earlier snowmelt may affect wolverines and the connectivity of metapopulations is uncertain. McKelvey et al. (2011) predicted that the geographic extent and connectivity of suitable wolverine habitat in western North America will decline with continued global warming.

At a regionwide scale, the preliminary Northern Rockies Adaptation Partnership risk assessment for the wolverine (Northern Rockies Adaptation Partnership 2015) states that there is no evidence that wolverines in the northern Rocky Mountains can persist in areas distant from extensive areas of spring snow, and their adaptive capacity appears to be low. The authors estimated that the magnitude of effects would be low in 2030 and moderate in 2050, with a high likelihood of effects across all time periods. Across the Northern Rockies as a whole, losses of current levels of persistent spring snowpack are estimated to be around 30 percent by mid-century (Northern Rockies Adaptation Partnership 2015). However, it is likely that snow will persist on some slopes and aspects at higher elevations. Due to the low density of wolverine populations, there may continue to be sufficient snow to meet the needs of the population as a whole. There may be microsites important to wolverines, such as mountain cornices, shaded cirque basins, or talus areas that retain snow during most years or retain snow longer into the spring than surrounding areas. McKelvey et al. (2011) stated “although wolverine distribution is closely tied to persistent spring snow cover, we do not know how fine-scale changes in snow patterns within wolverine home range may affect population persistence.” The U.S. Fish and Wildlife Service concurred with this finding, stating that “an improved understanding of how microclimatic variation alters the habitat associations of wolverines at fine spatial scales is needed” (U.S. Department of the Interior 2014b).

Wolverines are a highly wide-ranging species. Recent research in Glacier National Park has demonstrated that habitat connectivity from Glacier National Park to Canada currently provides for wolverine movement (Copeland and Yates 2006).

Plan components provide for connectivity of wolverine habitat. The natural range of variation for persistent spring snowpack on the Nez Perce-Clearwater is unknown, but variation from year to year is common. High-elevation areas with persistent spring snow at least five years out of seven are more likely to retain snow as the climate changes, whereas lower-elevation areas that retain persistent spring snow only one year out of seven are more likely to lose snow in the future as the climate changes. The Nez Perce-Clearwater provides over 727,320 acres of habitat available to wolverines that is remote and difficult to access by any means during the time periods when wolverines may be sensitive to disturbance.

The 2012 Planning Rule requires the Nez Perce-Clearwater to determine whether the plan components provide the ecological conditions necessary to conserve proposed and candidate species. Key ecosystem characteristics for the wolverine, a proposed species, include high elevations with persistent spring snow, habitat for dispersal, and features, such as rocky alpine areas, glacial cirque basins, and avalanche chutes, that provide food sources, such as marmots, voles, and ungulate carrion. Maternal and natal denning habitat with relatively low levels of human development are important, although the thresholds are unknown. The plan provides for wolverine pray through coarse filter ecosystem plan components that provide for most species. The Land Management Plan is unlikely to reduce population levels of prey species substantially.

The Nez Perce-Clearwater does not anticipate substantial changes to wolverine maternal or natal denning habitat over the anticipated life of the plan but, if conditions change in the future, or if research or monitoring indicates there is a need to address specific threats that are within Forest Service authority or capability to manage, the Land Management Plan may be amended or revised in the future if necessary.

Grizzly Bear Recovery

Changes Between the Draft and Final Environmental Impact Statements

Just before the release of the Draft Environmental Impact Statement, grizzly bear 927 entered the plan area. Prior to that time grizzly bears were not considered "may be present," and so the focus of the analysis in the Draft Environmental Impact Statement was limited to whether the plan provides the ecological conditions within the Bitterroot Recovery Zone to sustain a future population of grizzly bears. In addition, the tight timelines for release of the Draft Environmental Impact Statement did not allow a more developed analysis of ecological conditions for grizzly bears. In response to comments and the arrival of Bear 927, the analysis was adjusted to address whether conditions outside the recovery zone would provide the ecological conditions for connectivity.

Since that time, the analysis has become fully developed, and additional species-specific plan components were added to the plan for grizzly bears. The analysis still primarily rests on whether the plan will provide the ecological conditions to contribute to recovery of grizzly bears within the recovery zone, but also evaluates how the Nez Perce-Clearwater provides the ecological conditions to support connectivity to the recovery zone including the potential for the establishment of resident grizzly bears outside the recovery zone. The grizzly bear analysis now includes several spatial overlays of the various land allocations with secure habitat as an indicator, and includes an in-depth evaluation of how plan components would affect conditions for grizzly bears.

Grizzly Bear Analysis

This section of the analysis focuses on the effects of the plan on maintaining the ecological conditions within the Bitterroot Recovery Zone to contribute to recovery, as well as the effects of the plan on the ecological conditions to provide for connectivity and even support grizzly bears that may live outside the recovery zone in the future. Because there are no current grizzly bear populations in this area, there is little scientific information from this area from which to draw inferences. Therefore, the analysis draws from scientific information produced from the other grizzly bear ecosystems in the lower 48 states with the recognition that many aspects of grizzly bear ecology in this area are currently unknown. To compensate, the analysis assumes that grizzly bear behavior, demographics, ecology, and the effects to grizzly bears and their habitat would be similar here as they are in other grizzly bear ecosystems. The analysis is primarily focused on how the plan would affect the ecological conditions or habitat to support future grizzly bear populations both inside and outside of the Bitterroot Recovery Zone, and how the plan supports ecological conditions to allow connectivity of grizzly bears to become established through migration, dispersal, or gradual expansion. With this emphasis, this analysis also evaluates effects to transient individuals that may be present.

The historical range of the grizzly bear in the continental United States extended from the central Great Plains, west to California, and south to Texas and Mexico. Between 1800 and 1975, grizzly bear populations in the lower 48 states declined from over 50,000 to less than 1,000. As European settlement expanded westward, the grizzly bear was extirpated from most of its historical range (U.S. Department of the Interior 1993).

Four areas in Montana, Wyoming, and Idaho currently support grizzly bear populations. These areas are the Greater Yellowstone Ecosystem (GYE), Northern Continental Divide Ecosystem (NCDE), Cabinet-Yaak Ecosystem (CYE), and Selkirk Ecosystem (SE). According to the 2020 Grizzly Bear Recovery Program Annual Report, it is highly unlikely that the Northern Cascade Ecosystem (NCE) contains a grizzly bear population and there has been no confirmed evidence of grizzly bears within the United States portion of the NCE since 1996 (U.S. Department of the Interior 2022c). The sixth area, the Bitterroot Ecosystem was identified as having potential for providing for another population of grizzly bears. When the revised Grizzly Bear Recovery Plan was finalized, the Bitterroot Ecosystem had been loosely defined and there were questions as to whether it had a population of grizzly bears.

The grizzly bear recovery plan (U.S. Department of the Interior 1993) identified recovery zones that encompass the above five areas as well as the Bitterroot Ecosystem and the San Juan Ecosystem. The Bitterroot Ecosystem Recovery Plan Chapter was not published until 1996. Within the ecosystems, the U.S. Fish and Wildlife Service establishes recovery zones in cooperation with land management areas that are composed of a large proportion of federal lands, including wilderness and national park lands that are protected from the influence of many types of human uses and activities occurring on lands elsewhere. Recovery zones are defined as areas that are necessary for the recovery of the species and are to be managed with an emphasis on conserving grizzly bear habitat. The Bitterroot Ecosystem was never delineated explicitly, though the Bitterroot Chapter of Recovery Plan contains a map of the Bitterroot Ecosystem which included most of the Nez Perce-Clearwater National Forest (See Figure 90 and Figure 91).

The Recovery Zones represent a small fraction (less than 2 percent) of the grizzly bear's historical range (U.S. Department of the Interior 1993). While the range of bears in some ecosystems has significantly expanded since 1975, the overall range and distribution of bears in the lower 48 states remain below historical levels at approximately 6 percent of historical range (U.S. Department of the Interior 2022c).

The U.S. Fish and Wildlife Service suggested in the Grizzly Bear Recovery Plan Bitterroot Chapter that recovery would require reintroduction of bears from other areas and offered alternatives to consider for recovery. In response, the U.S. Fish and Wildlife Service completed the required analysis under the National Environmental Policy Act and decision to establish a final rule to reintroduce grizzly bears in 2000 (50 C.F.R 17.84 (I)), Final Rule 65 Federal Register 69,624 Nov. 17, 2000). In 2000, the U.S. Fish and Wildlife Service issued a 10(j) rule establishing the Bitterroot Grizzly Bear Experimental Population Area, an area in which the U.S. Fish and Wildlife Service considered the population of grizzly bears would be a non-essential experimental population after reintroduction (50 CFR 17.84 (I) 10-1-01 edition, Final Rule 65 Federal Register 69,624 Nov. 17, 2000). It also established that grizzly bears would be reintroduced under Section 4 and 10(j) of the Endangered Species Act (50 C.F.R 17, 65 Federal Register

69,623 Nov. 17, 2000). The decision and associated final rule established the Bitterroot Grizzly Bear Experimental Population Area and delineated the "Bitterroot Grizzly Bear Recovery Area," an area of recovery emphasis within the Experimental Population Area (50 CFR 17.84 (I) 10-1-01 edition, Final Rule 65 Federal Register 69,624 Nov. 17, 2000). The Bitterroot Recovery Area consists of the entirety of the Selway-Bitterroot and Frank Church-River of No Return Wilderness Areas plus limited areas outside of wilderness like the Magruder Road (See Figure 90 of the wilderness areas, and Figure 91 of the Bitterroot Recovery Area and wilderness within the plan area below) (50 CFR 17.84 (I) Final Rule 65 Federal Register 69,624 Nov. 17, 2000, Codified at 50 C.F.R § 17.84(l)). Areas of the Nez Perce-Clearwater National Forest outside these Designated Wilderness Areas are not included in the Bitterroot Recovery Area as delineated except for some very limited areas near the Magruder Road and near Burnt Knob, which were not included as wilderness within the Central Idaho Wilderness Act.

Of importance to note is that the U.S. Fish and Wildlife Service refers to the Bitterroot Recovery Area as the "Bitterroot Recovery Zone" in many of their publications such as the Species Status Assessment for the Grizzly Bear (U.S. Department of the Interior 2021c). Therefore, this document refers to the Bitterroot Recovery Area delineated in 50 C.F.R 17.84 (I) as the Bitterroot Recovery Zone which is shown in Figure 91. The greater area identified in the recovery plan will be referred to in this document as the Bitterroot Ecosystem. In 2001, citing opposition from the States involved and considering other recovery needs, the U.S. Fish and Wildlife Service issued a proposed rule to remove the 10(j) rule from the Code of Federal Regulations. In that notice, the U.S. Fish and Wildlife Service proposed to select the No Action Alternative, although this rule was never finalized. Therefore, the direction currently found in 50 C.F.R. § 17.84(l) for the Selway-Bitterroot ecosystem is still technically in effect. The federal register stated that if grizzly bears naturally dispersed to the Bitterroot Ecosystem, they would be protected as a threatened species under the Endangered Species Act. The U. S. Fish and Wildlife Service has not designated critical habitat within the Nez Perce-Clearwater National Forest.

The U.S. Fish and Wildlife Service reaffirmed in a letter dated January 21, 2020, that:

> …the current Endangered Species Act (ESA) section 10(j) rule for grizzly bears in the Bitterroot Grizzly Bear Experimental Population Area (BGBEPA), 50 CFR § 17.84(1), does not apply to grizzly bears that have dispersed into the BGBEPA on their own…[and]…grizzly bears that are present in the BGBEPA are not covered by the 10(j) rule and are considered threatened under the ESA. This means that ESA section 7 consultation obligations apply to proposed federal agency actions that may affect grizzly bear in the BGBEPA (U.S. Department of the Interior 2020d).

The Alliance for the Wild Rockies challenged the U.S. Fish and Wildlife Service in District Court for failing to finalize the 2001 Proposed Rule, failing to comply with the 2000 Record of Decision and Final rule, and violating National Environmental Policy Act (NEPA) and the Administrative Procedures Act by failing to prepare a supplemental environmental impact statement (EIS). The matter was remanded back to the U. S. Fish and Wildlife Service with direction to prepare a supplemental EIS and if warranted, a new Record of Decision and final rule. The U. S. Fish and Wildlife Service proposed and was granted permission by the court to initiate a new NEPA process, including a draft and final EIS and a new Record of Decision rather than supplementing the 2000 EIS. A key requirement for 10(j) non-essential experimental status is that no members of the species exist in the area where the experimental population is to be established. The U.S. Fish and Wildlife Service cited changes in circumstances arising from individual bears dispersing within the Bitterroot Ecosystem with greater regularity as rational for a new EIS.

The 2000 Final Environmental Impact Statement (U.S. Department of the Interior 2000a, b) explored a variety of alternatives to meet recovery objectives. The alternatives included whether grizzly bears would be translocated either as 10(j) or as threatened species, or established through natural dispersal, with the full protection of the Endangered Species Act. Alternatives also varied about who would have management responsibility, with either a citizen committee or the U.S. Fish and Wildlife Service as alternatives. Also, the alternatives varied where the boundaries of the Bitterroot Recovery Zone depending on whether grizzly bears were translocated or were established through natural dispersal. The different alternative boundaries included different amounts of lands administered by the Nez Perce-Clearwater National Forest. With the preparation of a new Environmental Impact Statement, the U.S. Fish and Wildlife Service anticipates considering a range of alternatives, including options to facilitate natural recolonization through affirmative actions, such as identifying connectivity areas, addressing sanitation issues, future augmentation, and revising the recovery plan chapter for the Bitterroot Ecosystem.

The presence of grizzly bears in the Bitterroot Ecosystem is currently through natural dispersal because no grizzly bears have been translocated to date. The plan area is outside other grizzly bear recovery zones and encompasses areas where grizzly bears could come from mainly the North and East into the Bitterroot Recovery Zone, though less likely, they could also come from the Yellowstone Ecosystem. The Bitterroot Recovery Zone has been identified as one possible path for genetic interchange from the Selkirk, Cabinet Yaak, and Northern Continental Divide Ecosystem (NCDE) into the Greater Yellowstone Ecosystem. Therefore, the Nez Perce-Clearwater has the distinctive role and contribution of providing ecological conditions for grizzly bears to recolonize the Bitterroot Recovery Zone and maintain the ecological conditions to allow for migration, dispersal, and genetic interchange between grizzly bear recovery zones (Figure 90). Figure 92 shows the spatial relationship between the Bitterroot Recovery Zone, the Nez Perce-Clearwater National Forest, and the other grizzly bear Recovery Zones.

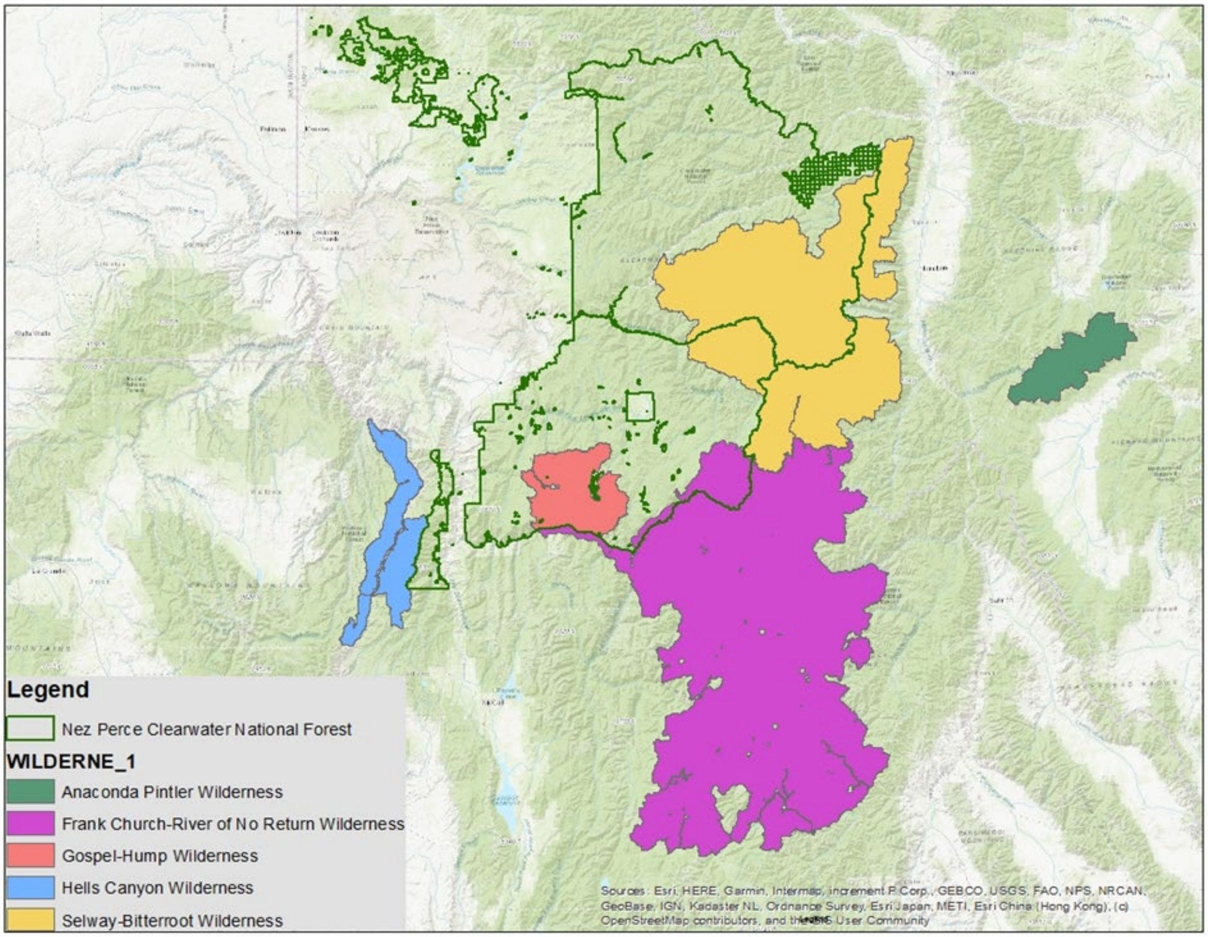

Figure 92. Nez Perce-Clearwater lands in relation to the Selway-Bitterroot, Frank Church-River of No Return, Gospel-Hump, and other nearby designated wilderness areas. The Selway-Bitterroot and the Frank Church-River of No Return Wilderness areas make up the majority of the Bitterroot Recovery Zone.

Regulatory Framework

Aside from the requirements of the 2012 Planning Rule, there is species specific direction for grizzly bears in the Forest Service Manual that apply. Forest Service policy states that forest plan management direction will contribute to the recovery of federally listed species (Forest Service Manual 2622). The responsible official may consult on the plan as a “conservation program” for listed species to comply with Endangered Species Act Section 7(a)(1). If a plan, plan revision, or amendment may affect federally listed species or critical habitat, the responsible official will consult on the forest plan (Forest Service Manual 1920.3) in accordance with the provisions of Endangered Species Act Section 7(a)(2) and accompanying regulations that guide interagency cooperation (50 CFR § 402). If the action may result in the incidental take of a listed species, the consultation may include issuance of a permit for incidental take in accordance with Endangered Species Act Section 10.

The regulations guiding interagency cooperation under the Endangered Species Act (50 CFR § 402.02) define a *framework programmatic action* as a broad-scale plan that provides the framework for development of future action(s) that are authorized, funded, or carried out at a later time. An incidental take statement may be provided, recognizing that actual take of a listed species would not occur unless and until those future action(s) are authorized, funded, or carried out and subject to their own future

Section 7 consultation. This consultation on the forest plan fits the definition of a framework programmatic action.

Forest Service policy found within Forest Service Manual 2676 provides species specific direction for grizzly bears, as listed below.

1. Cooperate with state agencies, the U.S. Fish and Wildlife Service, National Park Service, Bureau of Land Management, and other agencies and groups to carry out active programs to conserve the grizzly bear over the long term.
2. Implement Forest Service commitments for the conservation of grizzly bears and their habitat through coordinated planning and management.
3. Provide appropriate protection for individual grizzly bears that roam outside of delineated recovery zones and primary conservation areas. Work with the states to identify the areas where management for grizzly bears is biologically suitable and socially acceptable and coordinate management of nuisance bears.
4. Establish and implement uniform planning and management procedures concerning grizzly bears and their habitat. These should include cumulative effects analysis processes, public information and education, sanitation, and management of unnatural foods, and coordinated management of motorized access.
5. Establish and implement communication, education, assistance, and land management programs to eliminate preventable mortality of grizzly bears and minimize grizzly-human conflicts.
6. Conduct multiple-use management of grizzly bear habitat in a manner that is compatible with the goal of grizzly bear conservation.
7. Periodically monitor and report on habitat and population conditions and trends at appropriate spatial and temporal scales.

Distinctive Roles and Contribution

The plan area contains a large proportion of the Bitterroot Recovery Zone. The Selway-Bitterroot Wilderness and the Frank Church-River of No Return Wilderness make up the core of the Bitterroot Ecosystem for the federally listed threatened grizzly bear. These two wildernesses make up the largest contiguous block of federal land remaining in the United States and the largest block of wilderness in the Rocky Mountains. Re-establishment of the grizzly bear in this recovery zone is currently through natural dispersal. This zone is in relatively close proximity to other grizzly bear recovery zones and encompasses areas where grizzly bears could come from the north and east into the Bitterroot Recovery Zone. The Bitterroot Recovery Zone has been identified as one possible path for genetic interchange from the Selkirk, Cabinet-Yaak, and Northern Continental Divide ecosystems into the Greater Yellowstone Ecosystem. Therefore, the Nez Perce-Clearwater has the distinctive role and contribution of providing ecological conditions for grizzly bears to recolonize the Bitterroot Recovery Zone and maintain the ecological conditions to allow for migration, dispersal, and genetic interchange between grizzly bear recovery zones.

Current Status of Grizzly Bears in the Bitterroot Ecosystem

The grizzly bear is native to and was once common in the Bitterroot Ecosystem of Montana and Idaho (Servheen et al. 1995). Members of the Lewis and Clark expedition killed at least seven grizzly bears, including one female and two cubs, while camped near present-day Kamiah, Idaho. Hunters, trappers, and settlers around the turn of the century killed a substantial number of grizzly bears. Conservative estimates indicate trappers and hunters killed 25 to 40 grizzly bears annually in the Bitterroot Mountains until the early 1900s. Sheepherders killed many more in subsequent decades. Ultimately, the grizzly bear population in this area was lost due to high human-caused bear mortality. Prior to recent observations since before 2007, the last verified death of a grizzly bear in the Bitterroot Ecosystem was in 1932 and the last verified tracks were documented in the 1940s (Servheen et al. 1995). In the past half century, several studies, including annual aircraft wildlife surveys by state wildlife personnel, black bear studies, DNA hair snares, and remote camera surveys, have been conducted that were designed to or were likely to have incidentally identified grizzly bear presence in the Bitterroot Ecosystem. However, no grizzly bears were detected by those studies.

Melquist (1985), conducted a survey on the Clearwater National Forest using ground and aerial surveys and grizzly bear observations and compiled 88 reports of grizzly bears between 1900 and 1984. No signs of bears were found during aerial or ground surveys. No verifiable observations were reported. Of the 88 reports, there were 2 confirmed—one from around Grangemont in 1909 and one along Colt Killed Creek near Powell in 1956. However, the 1956 observation was subsequently found to NOT be a grizzly bear. Groves (1987) compiled and reviewed 175 historical grizzly bear reports from central and northern Idaho, including 77 reports on all national forests except the Sawtooth and Bitterroot from within the Bitterroot Grizzly Bear Recovery Zone. Most of the reports (62) came from the Clearwater National Forest. Groves did not document any additional evidence that confirmed any of the reports. Servheen et al. (1990) and Kunkel et al. (1991) surveyed for grizzly bears during two summers in the Upper North Fork using remote cameras. No photos of grizzly bears were recorded; however, the small area and low camera densities were cited as a reason to caution against confirming the absence of bears. More recently, from 2008 to 2009, Servheen and Shoemaker (2010) conducted a camera and DNA survey of the Bitterroot Mountains. No grizzlies were detected during either the 2008 or 2009 surveys.

The U.S. Fish and Wildlife Service systematically surveyed for grizzly bears throughout the northern Bitterroot Mountains between U.S. Highway 12 in Idaho and Montana Highway 200 and between Missoula, Montana and Avery, Idaho during 2008 and 2009. Barbed wire DNA hair corrals and remote cameras were deployed. No grizzly bears were detected, but their methods did not allow them to conclude that they were absent from the area. Their failure to document grizzly bears in this survey indicates that if they were regularly occupying the Bitterroot Ecosystem, there were very few individuals and they existed at very low densities (U.S. Department of the Interior 2011c). The U.S. Fish and Wildlife Service considers the Bitterroot Ecosystem to be unoccupied (U.S. Department of the Interior 2021c).

In 2007, a male grizzly bear was accidentally shot and killed on the North Fork Ranger District near Kelly Creek by a hunter who mistook the bear for a black bear. This bear was genetically tested and found to be most closely related to bears in the Selkirk Ecosystem. The distance from the nearest boundary of the Selkirk Ecosystem to the spot where this bear was killed is approximately 141 air miles. The Northern Continental Divide Ecosystem population has been expanding its distribution and a few grizzly bears have been documented to move southward recently. There have been a handful of verified grizzly bear observations in the northwest portion of the Bitterroot Valley and in the Sapphire Mountains. In 2002, a grizzly bear was verified on private property on Sunset Bench southeast of Stevensville, Montana. That bear is thought to have crossed the Sapphire Range from the Rock Creek drainage. In October of 2018, a young male grizzly bear was trapped at the Whitetail Golf Course east of Stevensville and relocated to the southern end of the Northern Continental Divide Ecosystem. This bear was trapped about 11 miles from the eastern boundary of the Bitterroot Recovery Zone.

Bear 927, a radio-collared male augmentation bear was released in the West Cabinet Mountains near Spar Lake on July 21, 2018. An augmentation bear is a bear transplanted into the Cabinet Yaak Ecosystem to increase genetic diversity. This bear crossed I-90 on June 4, 2019 and headed south into the Nez Perce-

Clearwater. Nearly as soon as he entered the Nez Perce-Clearwater, he was photographed by game cameras near a bear bait operated by an outfitter and guide who has a permit to guide on the Nez Perce-Clearwater. The outfitter reported the observation to the Idaho Department of Fish and Game and the Forest Service shortly after detecting the bear. This bear continued to move southeast through the plan area and crossed into the Bitterroot Recovery Zone near Lolo Pass. Bear 927 spent two months moving around the Bitterroot Ecosystem, including time within the Bitterroot Recovery Zone before heading back north into the Cabinet Mountains to den in October (Costello and Roberts 2021). In 2020, he went northwest upon den emergence and lost his collar. One other observation confirmed as a grizzly bear was made near Lolo Pass in 2019 and is suspected to have been Bear 927.

A few anecdotes can be inferred from this event. First, the bear was detected quickly after it entered the Nez Perce-Clearwater, suggesting that, if there were other grizzly bears present, they might also be quickly detected by bear hunter’s cameras at bear bait sites. Second, the ability of this bear to cross through the northern half of the Nez Perce-Clearwater and into the Bitterroot Ecosystem suggests that the Nez Perce-Clearwater is relatively permeable at least for male grizzly bears.

There were two verified sightings in 2019 south of Grangeville, Idaho of the same individual male bear that was not Bear 927. There was another sighting east of Whitebird, Idaho that was photographed by a game camera over bear bait. It is unknown if the Whitebird sighting was the same bear as near Grangeville (approximately 14 air miles apart). Verified observations of grizzly bears are shown in Figure 93 below, which was provided by the U. S. Fish and Wildlife Service’s Grizzly Bear Recovery Office on September 6, 2022.

The criteria for a population of grizzly bears were defined in 50 C.F.R. § 17.84(l) after consulting with 37 scientists familiar with bear populations as:

> A grizzly bear population is defined by verified evidence within the previous six years, consisting of photos within the area, verified tracks and/or sightings by reputable scientists or agency personnel, of at least two different female grizzly bears with young or one female seen with different litters in two different years in an area geographically distinct (separate) from other grizzly bear populations...

Despite the observations, the criteria for a population of grizzly bears have not been met in either the Bitterroot Ecosystem or in the Recovery Zone as defined above, and so it is considered unoccupied. However, grizzly bears may be present as evident from the observations mentioned above (Figure 94 below) and was established by the observations shown in Figure 93. This figure represents the current distribution of where grizzly bears “may be present,” but we acknowledge that where grizzly bears may be present may change over the course of the plan. Grizzly bears are a wide-ranging species and much of the plan area is within the dispersal capabilities of as many as three grizzly bear ecosystems. Based on recent observations of dispersing grizzly bears, additional grizzly bears may enter the Nez Perce-Clearwater, and new areas have a high likelihood of becoming areas where grizzly bears “may be present” over the course of the plan.

Based on this information, the U.S. Fish and Wildlife Service recently expanded their determination of where they consider grizzly bears to be present as part of a new consistency modeling approach (U.S. Department of the Interior 2019). This document identifies the criteria by which the U.S. Fish and Wildlife Service identifies area where bears may be present. There is no way to know how many bears will enter the planning area, where they will enter, and whether they will stay; however, based on current trends, numbers are likely to remain low. It is likely there will be more male grizzly bears moving into the area before females arrive. The Northern Continental Divide, Selkirk, and Cabinet-Yaak ecosystems are within the maximum grizzly bear dispersal range. It is assumed that grizzly bears will continue to recolonize the Bitterroot Ecosystem, albeit slowly (U.S. Department of the Interior 2019). There will not be reproduction until females enter the planning area. The analysis in many ways is based on conditions to support a future bear population but is based on factors known to affect grizzly bear survival in other areas.

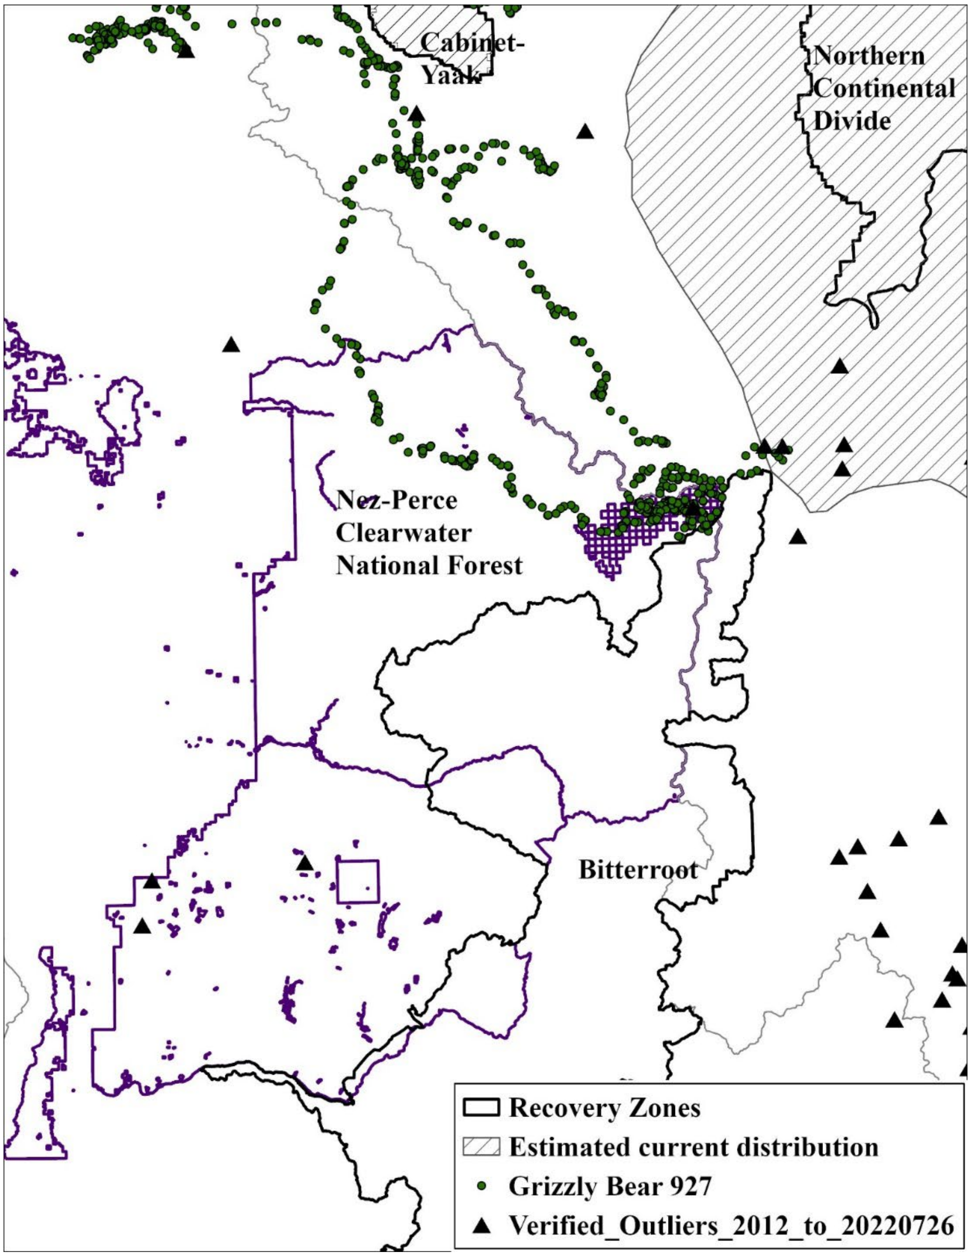

Figure 93. The observations of grizzly bears within the Nez Perce-Clearwater National Forest and the surrounding lands. Verified outliers are grizzly bears who made atypical movements outside of the known estimated current distribution. Note that the bear killed in 2007 is not shown on the map because the observation is more than 10 years old. Map provided by the U.S. Fish and Wildlife Service 9/06/2022.

Criteria for Recovery

The Grizzly Bear Recovery Plan (1993), including the Bitterroot Ecosystem Recovery Plan Chapter (Servheen 1996), lays out the criteria needed for recovery. The criteria for when the populations will be viable are when they meet the demographic recovery targets and it can be demonstrated that adequate regulatory mechanisms exist to ensure continued population and habitat management after delisting (U.S. Department of the Interior 1993). The overall goal of the recovery plan is to remove the grizzly bear from threatened status in each of the ecosystems in the 48 conterminous states.

For the Bitterroot Ecosystem, the criterion includes 14 females with cubs over a running six-year average. The method by which this would happen would be through natural dispersal (Federal Register: June 22, 2001, Volume 66, Number 121), however because the final rule was never finalized, 50 CFR § 17.84(l) for the Selway-Bitterroot ecosystem is still technically in effect. The goal for human caused mortality is 0 until at least 90 grizzly bears are established, after which a goal of human cause mortality is not to exceed 4 percent and no more than 30 percent of which would be limited to females. A total of approximately 280 grizzly bears is the tentative long-term recovery objective for the Bitterroot Ecosystem (Supplement: Bitterroot Ecosystem Recovery Plan Chapter (1996)). The recovery plan suggested that management should strive to prevent all human-caused mortality within and surrounding the Bitterroot Ecosystem. Naturally to achieve recovery, female grizzly bears must disperse into the Bitterroot Recovery Zone through connectivity from the other grizzly bear ecosystems and then must reproduce, once established, to grow the population.

The grizzly bear recovery plan anticipated that grizzly bears can and will exist outside the boundaries of the recovery zones. The Recovery Plan (1993) recognizes that grizzly bears occasionally will move and even reside permanently in areas outside of recovery zones. It states that:

> Bears can and are expected to exist outside recovery zones lines in many areas. However, only the area within the recovery zone will be managed primarily for grizzly bear habitat.

However, the recovery plan also acknowledged that linkage would be necessary for isolated populations to increase and sustain themselves at recovery levels. The recovery plan (U.S. Department of the Interior 1993) stated that one factor that may affect the sustainability of grizzly bear populations in the future is the ability of individual animals to move between ecosystems. Accurate information is necessary to assess the potential for this type of movement in linkage zones between existing adjacent grizzly bear recovery zones (U.S. Department of the Interior 1993). Future land management activities within these areas may be critical to maintaining their utility as linkage zones (U.S. Department of the Interior 1993). Thus, outside the recovery zones, the emphasis is on linkage zones. Linkage zones are areas between currently separated populations that provide adequate habitat for low densities of individuals to exist and move between two or more larger areas of suitable habitat (U.S. Department of the Interior 2021c).

According to the recovery plan, mortality from direct and indirect sources within and surrounding the Recovery Zone must be addressed if grizzly bears are to recover (Servheen 1996). Sources of direct mortality include illegal killing, accidental deaths, and management associated removals. Accidental deaths include mistaken identities by black bear hunters and other big game hunters, road kills, or handling errors when bears are captured for management or research. Mortality can also result from control actions by private citizens, such as livestock operators, apiarists, outfitters, resort operators, landowners protecting their property, and by hunters defending their kills. Direct mortality may also occur during agency control of nuisance bears for livestock conflicts, property damage, or situations threatening to human life or self-defense (Servheen 1996). Indirect mortality includes deaths that occur with those actions that bring bears and people into conflict, such as road use, land development, and recreation (Servheen 1996). The grizzly bear recovery plan recommends that every effort should be made to limit mortality to zero in the initial phases of recovery when the number of bears will be low.

Habitat Requirements and Life History

The 2021 grizzly bear species status assessment (U.S. Department of the Interior 2021c) identified large intact bocks of land, cover, high-caloric foods, and dens as habitat needs for the grizzly bear in the lower 48 states. For demographic needs, it identified connectivity, adequate fecundity and survival, genetic diversity, population trend, and abundance as ecosystem-level needs for resiliency. For analysis of current and future condition, the status assessment selected a subset of these needs, two habitat factors and six demographic factors that are most influential to ecosystem resiliency and that could be measured relatively consistently across all six ecosystems. The two habitat factors and six demographic factors used to evaluate condition were: natural, high-caloric foods, large intact blocks of land, adult female survival, abundance, population trend, fecundity, inter-ecosystem connectivity, and genetic diversity (U.S. Department of the Interior 2021c).

Habitat Use

Grizzly bears are large animals that have high metabolic demands during the non-denning season. Adequate nutritional quality and quantity are important factors for successful reproduction. Grizzly bears are omnivorous and use a wide variety of habitats, including meadows, shrublands, and forests from valley bottoms through alpine habitats, to locate food sources. Available food sources vary annually, seasonally, and even day-to-day (Mietz 1994). Grizzly bears are dependent upon learned food locations within their home ranges and can switch food habits according to which foods are available (Aune and Kasworm 1989b, Kendall 1986, Mace and Jonkel 1986, Servheen 1983).

Grizzly bears use a wide variety of habitats. Since grizzly bears are generalists with a high variability in diet among individuals, seasons, and years (Schwartz et al. 2003, Servheen 1981, Mattson, Blanchard, and Knight 1991, Mattson, Gillin, et al. 1991, Interagency Grizzly Bear Committee 1987b, Felicetti et al. 2004, Northern Continental Divide Ecosystem Subcommittee 2013, Aune and Kasworm 1989b), they generally have an omnivorous diet (Jacoby et al. 1999, Schwartz et al. 2003). The historical distribution of grizzly bears is evidence of their habitat plasticity, as they inhabited diverse ecosystems throughout their historic range from Northern Alaska and Canada south to Central Mexico.

Home Range

Adult grizzly bears are normally solitary, except females with cubs or during short breeding relationships. They will tolerate other grizzly bears at closer distances when food sources are concentrated, and siblings may associate for several years following weaning from their mother (Egbert and Stokes 1976). Home ranges of subadult females generally overlap with the maternal home range (Blanchard and Knight 1991). Males consistently exhibit greater indices of movement and less fidelity to home ranges than females (Blanchard and Knight 1991).

Home range size varies with the availability of food resources, sex, age, reproductive status, and other factors (Blanchard and Knight 1991, Interagency Grizzly Bear Committee 1987a). Across their range, home range sizes for female grizzly bears are approximately 150 square miles (96,000 acres) (Interagency Grizzly Bear Committee 1987a) though habitat quality can affect the size. Females with cubs-of-the-year have the smallest home range sizes (Blanchard and Knight 1991, Mace and Roberts 2011). The annual home range of adult male grizzly bears in the lower 48 states is typically 2 to 3 times the size of an adult female's annual home range (Interagency Grizzly Bear Committee 1987a).

No estimates exist for home range size for the Bitterroot Ecosystem so the assumptions are that they would be similar to those in other grizzly bear ecosystems. Home range sizes are smaller in the Northern Continental Divide Ecosystem (NCDE) than in the Greater Yellowstone Ecosystem (GYE). For example, in the NCDE, female annual home range size (95 percent isopleth using the fixed kernel method) ranged from an average of about 50 square miles for females with cubs-of-the-year to an average of about 93 square miles for subadult females (Mace and Roberts 2011). In the GYE, average home range size (using the minimum convex polygon method) was 108 square miles for all adult females and 141 square miles for subadult females (Blanchard and Knight 1991). Annual home range size for adult males in the GYE study area averaged 337 square miles. Home ranges in the NCDE have been reported for female grizzly bears by Mace and Waller (1997) at 48 square miles, and by Aune and Kasworm (1989b) at 159 square miles. In the greater Yellowstone, female home ranges have been reported to average 341 square miles (Blanchard and Knight 1991). Lifetime female home ranges in the Cabinet-Yakk Ecosystem (CYE) averaged 216 square miles (U.S. Department of Agriculture 2020d), while those in the Selkirk Ecosystem (SE) averaged 161.7 square miles (U.S. Department of Agriculture 2020d). Young, female grizzly bears usually establish home ranges within or overlapping their mother's and this pattern of home range establishment can make dispersal of females across landscapes a slow process (U.S. Department of the Interior 2021c). According to the Grizzly Bear Species Status Assessment (U.S. Department of the Interior 2021c), grizzly bear females average 138 mi^2 in the NCDE, 50mi^2 in the GYE, 127 mi^2 in the CYE, and 115 mi^2 in the SE. Male grizzly bear's home ranges average 527 mi^2 in the NCDE, 183 mi^2 in the Greater Yellowstone Ecosystem, 835 mi^2 in the CYE, and 241 mi^2 in the SE. Home range size is affected by resource availability, sex, age, and reproductive status (U.S. Department of the Interior 2021c). Estimates of home range size can also be influenced by the timeframe through which data were collected, and the method used to delineate them from telemetry data. Examples of home range methods include minimum convex polygon method, kernel density estimators, and so forth. This analysis assumes that grizzly bear home ranges would range in size somewhere between the estimates above. Home ranges sizes are useful consideration for evaluating effects of future projects against baseline conditions, and each new project conducted under the direction of the Revised Forest Plan will undergo site specific analysis and consultation for effects to grizzly bears.

The sizes of female home ranges have informed the size of management units within recovery zones such as Bear Management Units (BMUs) and subunits. BMUs and subunits are analysis areas delineated by the Interagency Grizzly Bear Committee and were established to meet recovery criteria outlined in the recovery plan (U.S. Department of the Interior 1993). BMUs have been delineated typically only within recovery zones and have not been delineated in areas outside of recovery zones. BMUs in other recovery zones vary in size from approximately 250 km^2 (96 mi^2) to 1,380 km^2 (532 mi^2) and were usually delineated using topographic and hydrologic features. BMUs are established by the Interagency Grizzly Bear Committee when appropriate. Thereafter, BMUs were adopted as the boundaries to establish conservation measures in land management plans such as forest plans. Neither BMUs nor subunits have been established within the Bitterroot Recovery Zone.

The plan does not include direction for BMUs nor subunits; however, these are typically established by the Interagency Grizzly Bear Committee and can be implemented outside of the Forest Plan. Also given the limited use by grizzly bears no estimate exists for home range size in the Bitterroot Ecosystem, as such this analysis assumes that grizzly bear home ranges would be like those in other ecosystems. Each new project conducted under the direction of the Revised Forest Plan will undergo site specific analysis and consultation and at that time best available science will guide the analysis for grizzly bear both within and outside the Bitterroot Recovery Zone. There is no available data to inform the size of grizzly bear home ranges within the Bitterroot Ecosystem.

Denning

Grizzly bears are quite variable in their selection of denning habitat and structures (Schwartz et al. 2003). Grizzly bears usually dig dens on steep slopes where wind and topography cause an accumulation of deep snow and where the snow is unlikely to melt during warm periods. In addition, grizzly bears are more likely to den in areas with greater canopy cover (Pigeon et al. 2016) and at elevations above 6,371 feet (greater than 1,942 meters) (Mace and Waller 1997). Grizzly bears usually excavate their dens for hibernation in areas that will be covered with a blanket of snow (Craighead and Craighead 1972). Grizzly bears generally enter their dens from September to November and remain until mid-March or late April (Dood et al. 2006). Males typically enter dens later in the fall and emerge earlier in the spring than do females. Both males and females have a tendency to use the same general area for hibernation year after year, but the same den is rarely reused by an individual (Linnell et al. 2000). In the Northern Continental Divide Ecosystem, most grizzly bear dens were documented at elevations above 6,400 feet in northwestern Montana (Mace and Waller 1997) with the average elevation somewhat higher on the Rocky Mountain front (Aune 1994). Upon emergence from the den, grizzlies move to lower elevations, drainage bottoms, avalanche chutes, and big game winter ranges to exploit spring food resources.

Diet

Grizzly bears have a high degree of dietary plasticity and are capable of shifting to alternate food sources when key food items are scarce or unavailable. Gunther et al. (2014) documented 266 species of plant, animal, fungi, algae, and soil consumed by grizzly bears in the Greater Yellowstone Ecosystem. Important food items include berries, ungulate biomass, mast (for example, whitebark pine seeds), ants, clover, dandelion, vegetation, and fish. Grizzly bears use numerous different habitats for foraging. Use tends to be more frequent in areas that offer some type of hiding cover nearby, particularly during daylight hours (Aune and Kasworm 1989b, Mace and Waller 1997). Waller (1992) reported that grizzly bears avoided lower-elevation, more accessible harvested stands, as well as stands less than 30–40 years old where the vegetation had not recovered enough to provide cover. Vegetation management may alter the amount and arrangement of cover and forage available to bears. Timber harvest and fire can locally increase bear foods by stimulating the growth of grasses, forbs, and berry-producing shrubs. Associated roads and human activity can negatively affect grizzly bears by disturbing or displacing bears during logging activities and by increasing mortality risk (Zager et al. 1983).

Grizzly bears have a strong sense of smell which they use to find food sources. They are known to travel far distances following their sense of smell to find forage. They also tend to return to high quality nutritional resources repeatedly and habitually as a strategy to gain weight to meet the demands of hibernation. Their keen sense of smell sometimes leads them to human foods and attractants that lead to conflicts and affects their survival. Human-grizzly bear conflicts can be caused by unsecured attractants, habituation to human presence, and food conditioning of bears. These conflicts lead to grizzly bear mortality or removal (Knight et al. 1988). Developed recreation sites that support overnight public use are thought to have a higher potential to increase both the levels of bear attractants and grizzly bear mortality risk (Northern Continental Divide Ecosystem Subcommittee 2018).

Secure Habitat and Motorized Access

Historically, grizzly bear populations persisted in landscapes without permanent human presence where the frequency of contact with humans was low (Mattson and Merrill 2002). Maintaining large blocks of secure habitat is important to the survival and reproductive success of grizzly bears, especially females (Mace et al. 1999, Schwartz, Haroldson, and White 2010). The most important predictors of survival in the Greater Yellowstone Ecosystem were the amount of secure habitat within a bear's home range and road densities outside of secure habitat (Schwartz, Haroldson, and White 2010). In the Northern Continental Divide Ecosystem, human-caused mortality was the most important factor driving grizzly bear survival rates (Mace et al. 2012). The majority of management removals of grizzly bears resulted from human-bear conflicts at sites with frequent or permanent human presence and unsecured attractants, such as garbage, human foods, pet and livestock foods, and orchard fruit.

Numerous studies using various methods have documented that roads in grizzly bear habitat affect behavior and habitat use and can lower a bear survival rate during the non-denning season (Mattson et al. 1987, Mattson et al. 1996, Boulanger and Stenhouse 2014, Waller and Mace 1997, McLellan and Shackelford 1988). Research demonstrates that roads and associated human activities impact grizzly bears during the non-denning season by displacing them from important habitats and lowering their survival and reproduction rates (Boulanger and Stenhouse 2014, Mace and Waller 1996, Mattson et al. 1987, McLellan and Shackelford 1988). Displacement may be responding with a relatively short term, short distance response or may be displaced with a longer-term avoidance response and movement to another area. Motorized access can affect bears by increasing human interaction and the potential for conflict, increasing the chance of habituation to humans, and increasing energetic requirements related to disturbance by humans (U.S. Department of the Interior 2011c). Displacement from habitat or increased stress levels may be especially problematic for female grizzly bears attempting to reproduce by causing decreased nutritional status (Mattson et al. 1987). The amount and pattern of motorized access in grizzly bear habitat is a stressor that can be influenced by Forest Service management of National Forest System lands.

Although road density provides a tool to describe human-caused effects to grizzly bears based on existing literature, it fails to consider traffic volume, proximity to forage resources and how road placement affects habitat patch size (Proctor et al. 2019). Secure areas are a major component of grizzly bear habitat because they provide opportunities for bears to meet energetic needs with low potential for disturbance from human intrusions.

Studies have shown that female grizzly bears selected for, or survived better in, areas with greater secure habitat (Mace et al. 1996, Wakkinen and Kasworm 1997). Mace et al. (1996) showed females selected for home ranges with 56 percent secure habitat compared to 30 percent secure habitat outside the composite female home ranges. Across the border in Canada, researchers found that female grizzly bears selected for, and survived better in, areas with 56 percent secure habitat as compared with available areas with 46 percent secure habitat (Proctor et al. 2019). While these values are useful for comparative purposes, this information does not justify a specific threshold towards which to manage because the amount of secure habitat is a continuous variable that occurs on a spectrum of ranges across a variety of landscape conditions. Thus, a specific, justifiable threshold is unlikely to exist, and instead would more likely represent a decreasing probability of survival as the amount of secure habitat decreases. Determining the relationship would necessarily require evaluating many more than the 13-bear sample size used by Mace (1996) and would require evaluating vital rates in many landscapes across the range of grizzly bears rather than from one area. Also, interpretation of these values requires understanding the context under which the studies were conducted and the questions the research was attempting to answer. The purpose of Mace's (1996) study was not to identify what the minimum threshold for secure habitat required for female reproduction and survival as a minimum absolute value but to answer what were the conditions in a landscape managed for multiple uses (timber harvest, roads and recreation) under which female grizzly bears were successful at produce surviving cubs into sub-adulthood. Furthermore, it would be inappropriate to apply such a metrics from Mace's (1996) limited study from a different area as a constraint or management objective in the plan to an unoccupied landscape like the Bitterroot Recovery Zone which has no site-specific information on grizzly bear use in this area. Any comparisons in this analysis to these secure habitat ranges are limited to evaluating whether (and where in) the Planning Area has 1) the current existing conditions similar to those that have supported grizzly bear female survival or reproduction in other areas, and 2) whether the plan would maintain those conditions for future potential occupancy.

The Grizzly Bear Recovery Plan (U.S. Department of the Interior 1993) noted that the most crucial element in grizzly recovery is securing adequate effective habitat for bear populations, which include food, cover, denning habitat, solitude, and space (Craighead and Mitchell 1982). With respect to grizzly bears, habitat is "secure" generally when recurring human use is low. For the purposes of conservation and recovery of grizzly bear populations, secure habitat has commonly been defined as areas of a specified minimum size that are beyond a specified distance from motorized routes (Mace et al. 1996, Boulanger and Stenhouse 2014). Grizzly bear secure habitat is defined slightly differently in grizzly bear literature and in different conservation strategies.

Female home-range selection and survival also has related to the proportion of habitat greater than 500 meters from an open or gated road, often termed "secure habitat" (Proctor et al. 2019). Wakkinen and Kasworm (1997) demonstrated that smaller-sized core blocks tended to be underutilized by their study animals, particularly those of less than two square miles (1,280 acres). However, while more than 97 percent of the use by successfully reproducing females occurred in blocks greater than two square miles, actual use occurred in blocks as small as 0.22 square miles (141 acres). However, there have not been any studies that identify the minimum size of secure habitat that grizzly bears will use.

Human use of public lands is highly correlated to the availability and distribution of motorized access. The intersection between secure habitat and motorized use occurs due to associated mortality factors such as bear-vehicle collisions, potential lawful or illegal hunter harvest, and interaction with humans. Jaeger (Jaeger 2000, Jaeger et al. 2005) found the distribution and configuration of roads can influence secure habitat patch sizes significantly. For instance, even in areas with overall low road density, there may be patches of high road density interspersed with patches of low road density or unroaded areas, influencing how grizzly bears use the landscape. Identifying secure habitat incorporates the effects of motorized use while better addressing spatial issues associated with variable road density within an area.

Schwartz et al. (2010) determined that secure habitat within female home ranges had a larger influence on their survival than road densities. Schwartz (2010) suggested that secure habitat is correlated with road densities but provided distinct and important contribution to grizzly bear survival modeling and showed that increased road density had a greater effect on predicted survival as secure habitat decreased. The most important predictors of survival in the best survival models were the amount of secure habitat within a bear's home range and road densities outside of secure habitat (Schwartz, Cain, et al. 2010). They concluded that managing the landscape to reduce hazards to grizzly bears requires balancing road density standards with the amount of secure habitat available (Schwartz, Cain, et al. 2010). Multiple studies concluded general that areas with a higher percentage of secure habitat showed greater selection for and survival of female grizzly bears (Mace et al. 1996, Wakkinen and Kasworm 1997, Gibeau et al. 2001). The amount of secure habitat metric more adequately represents the potential effects related to motorized access as it provides a more accurate indication of the spatial mix of motorized routes and secure habitat (Proctor et al. 2019).

Winter Recreation

The impacts of winter recreation activities on denning bears are not well studied. The Grizzly Bear Species Status Assessment (U.S. Department of the Interior 2021c) suggested it is important to consider the potential impact from winter recreation because grizzly bears are easily awakened in their dens. It also suggested that disturbance of grizzly bears in the den can result in cub abandonment or early den exit, which could kill a grizzly. The Species Status Assessment (U.S. Department of the Interior 2021c) found no studies in the peer-reviewed literature documenting the effects of snowmobile use on any denning bear species and no records of litter abandonment by grizzly bears in the lower 48 states due to snowmobiling; the information that is available is based on opportunistic sightings and small sample sizes, for example Hegg et al. (2010). The Species Status Assessment cited evidence from studies from Scandinavia (Swenson et al. 1997) suggesting that abandonment is possible as a result of den disturbance.

Reproduction and Dispersal

Grizzly bears live at relatively low population densities, disperse slowly, and are vulnerable to human-caused mortality. Female grizzly bear dispersal occurs gradually over several years and over short distances (McLellan and Hovey 2001b, Proctor et al. 2004, Proctor et al. 2015). A genetic analysis to estimate dispersal distances in Canada estimated the average dispersal for female grizzly bears was about 8.9 miles and about 26 miles for males away from their natal home ranges (Proctor et al. 2004). Another study used radio collared and marked bears to estimate dispersal after family break up (McLellan and Hovey 2001b). McLellan and Hovey (2001a) measured the distances between the home range center of a mother and her dispersed offspring over 20 years. Their study looked at 30 offspring, 12 females, and 18 males. This study suggested that female bears dispersed about on average 6 miles from their natal home range between one to four years after the family break up. Males in this study dispersed on average 18.5 miles from their natal home range. The farthest distances dispersed were 41.6 miles for males and 12.42 miles by females in this study.

On average, females reach sexual maturity sometime between four and seven years of age and give birth to one to three cubs about every three years (Schwartz et al. 2003). Depending upon where female grizzly bears eventually enter the forest, and if they follow their typical pattern of dispersal, it could take generations of females living in portions of the Nez Perce-Clearwater before they reach the Bitterroot Recovery Zone. However, the distances are all within the dispersal capabilities of female grizzly bears. There are no known recent observations of female grizzly bears within the plan area since they were extirpated. According to the U.S. Fish and Wildlife Service, a female known as Ethyl passed within approximately 6.2 miles (10 km) from the Nez Perce-Clearwater's northern boundary. Ethyl was a management bear that was relocated several times and exhibited unusual, very long-range movements in response to relocation, that are not typical of most female grizzly bears. This female traveled on both sides of I-90. She returned to the Northern Continental Divide Ecosystem (NCDE) and dropped her radio collar which at the time was very far from the plan area boundaries.

Most females demonstrate smaller dispersal ranges, long-distance dispersal does occur occasionally. The next closest female locations are approximately 25 miles away and north of I-90. The closest verified sighting of a known female was approximately 37 miles to the east, south of I-90. Females typically establish home ranges 6 to 8.8 miles away from the center of their mother's home range. However, long-distance dispersal by females has been documented up to 49.7 to 55.9 miles, typically on the edge of expanding populations. While it is unknown how long it will take females to enter the plan area, given the normal dispersal tendencies of female grizzly bears, it could be a long time until female grizzly bears disperse onto the national forest, but we cannot discount that females could arrive earlier. Thus, female dispersal into the Nez Perce-Clearwater during the life of the Forest Plan has a low probability but cannot be discounted.

Proctor et al. (2012) used genetic data from 3,134 grizzly bears along with radio telemetry location data from 792 grizzly bears across the distribution in western Canada and northern United States to assess large-scale movement patterns and genetic connectivity among bear populations. In the northern more remote portion of their distribution, grizzly bear populations were found to be well connected with movement, dispersal, and gene flow influenced by distance and natural topographic features such as icefields, as would be expected. In contrast, in the southeastern part of their distribution, rates of movement and genetic interchange were impaired. Population fragmentation in these areas was associated with human settlements, highways, and human-caused mortality. Maintaining or improving connectivity is critical for isolated populations, such as the Greater Yellowstone Ecosystem; small populations, such as in the Cabinet-Yaak Ecosystem; and unoccupied areas, such as the Bitterroot Ecosystem. Proctor et al. (2012) found that male grizzly bears generally move more frequently and over longer distances than females. The maximum dispersal distances estimated by Proctor et al. (2012) were about 47 miles for a female and 104 miles for a male. The distance between the currently occupied areas around the Northern Continental Divide Ecosystem to the Bitterroot Ecosystem are approaching or within the dispersal range of female bears.

It is to be expected that any grizzly bears outside the recovery zones are likely to experience a higher level of adverse impacts and will occur at lower densities than within the recovery zones. Nevertheless, Section 9 of the Endangered Species Act prohibition against "taking" applies irrespective of where the animal occurs, and the areas outside recovery zones can play a significant role in supporting movement of bears between recovery zones. Successful dispersal of bears is important to enable recolonization of vacant habitat (that is, improving redundancy and security against stochastic events across the range); bolster small populations, such as in the Cabinet-Yaak Ecosystem; and provide genetic connectivity between the other ecosystems and the isolated population in the Greater Yellowstone Ecosystem.

Threats and Stressors to Grizzly Bears

Interactions with people are by far the leading factors affecting grizzly bear populations. Motorized access routes (roads and trails) detract from secure habitat and has been shown in several studies to displace bears and adversely affect grizzly bear survival because it brings people in proximity to bears. The Interagency Grizzly Bear Committee (1998, 1994) recognized the impacts of human access on grizzly bear habitat. Specifically, motorized vehicle access has been shown to increase human interactions with bears and potentially increase associated grizzly bear mortality risk, increase grizzly bear displacement from important habitats, increase bear habituation to human presence, reduce reproduction, and reduce habitat security. Motorized access routes (roads and trails) and areas of concentrated human use (developed site footprints) detract from secure habitat.

The same likely holds true for grizzly bears that inhabit or pass through the Nez Perce-Clearwater National Forest. Permitted livestock grazing allotments contain live animals, livestock feed and supplements, and occasionally livestock carcasses that may attract grizzly bears into potential conflict situations with people. Developed sites provide places for people to concentrate use, which can contribute disturbance factors that may displace wary bears, while at the same time storing, preparing and eating food, or disposing of garbage, which may act as attractants for less wary bears. Availability of secure habitat, key natural food sources, and human-related attractants, can influence grizzly bear survival, reproductive success, and distribution.

According to the recovery plan, mortality from direct and indirect sources within and surrounding the recovery zone must be addressed if grizzly bears are to recover (Servheen 1996). Sources of direct mortality include illegal killing, accidental deaths, and management associated removals. Accidental deaths include mistaken identities by black bear hunters and other big game hunters, road kills, or handling errors when bears are captured for management or research. Mortality can also result from control actions by private citizens, such as livestock operators, apiarists, outfitters, resort operators, landowners protecting their property, and by hunters defending their kills. Direct mortality may also occur during agency control of nuisance bears for livestock conflicts, property damage, or situations threatening to human life or self-defense (Servheen 1996). Indirect mortality includes deaths that occur with actions that bring bears and people into conflict, such as road use, land development, and recreation (Servheen 1996). The grizzly bear recovery plan recommends that every effort should be made to limit mortality to zero in the initial phases of recovery when the number of bears will be low.

The recent five-year review of grizzly bear recovery (U.S. Department of the Interior 2021c) evaluated stressors and other actions that can positively or negatively affect grizzly bears. Stressors were fit into three broad categories including those with habitat-related effects, sources of human-caused mortality, and other stressors. Stressors with potential habitat-related effects include motorized access and its management, developed recreation sites, livestock allotments, mineral and energy development, recreation, vegetation management, habitat fragmentation, development on private lands, and activities that may disturb dens. Sources of human-caused mortality included management removals, accidental killings (for example, train and vehicular strikes), mistaken identity kills, illegal killings, and defense of life kills. Other stressors included natural mortality; connectivity and genetic health; changes in food resources; effects of climate change; and catastrophic events, earthquakes, and volcanic eruptions. The stressors above will be evaluated below as to how the plan addresses or ameliorates these factors.

Some research has been conducted on potential winter recreation effects on grizzly bears by identifying the characteristics of grizzly bear denning habitats from telemetry data, then use GIS to project or model areas of the landscape that have these characteristics and then evaluate the spatial overlap of modeled denning habitat with winter recreation use areas. For example, Podrunzny (2002) used modeling to evaluate the potential effects of winter recreation on grizzly bear denning in the Greater Yellowstone Ecosystem. These studies suggest potential for disturbance to denning bears (Podruzny et al. 2002). These types of studies are not available for the Bitterroot Recovery Zone.

In order to be considered the best available scientific information, the science should be accurate, reliable, and relevant as described above and in the directives for the 2012 Planning Rule (U.S. Department of Agriculture 2015b). There are three documents that are not considered to be the best available scientific information for grizzly bears for reasons related to their accuracy, reliability, and relevance (U.S. Department of Agriculture 2015b). The specific documents are titled “The Grizzly bear Promised Land, Past, Present and Future of Grizzly Bears in The Bitterroot, Clearwater, Salmon and Selway Country” authored by David Mattson (2021), “Grizzly Bear Denning Habitat and Demographic Connectivity in Northern Idaho and Western Montana” authored by Mike Bader and Paul Sieracki in (2021) and “Grizzly bear denning habitat and demographic connectivity in northern Idaho and western Montana” by Mike Bader and Paul Sieracki which was published in Northwestern Naturalist (Bader and Sieracki 2022). Mattson (2021) and Bader and Sieracki (2021) have not undergone peer review and are considered gray literature produced by non-governmental organizations. Bader and Sieracki (2022), while peer reviewed, is based on the same data and very similar analysis and contains some of the same challenges with assumptions and methodology that Bader and Sieracki (2021) have.

Mattson (2021) was recently reviewed by the Bitterroot Science Team of the Interagency Grizzly Bear Bitterroot Subcommittee (U.S. Department of Agriculture 2023a). The Science Team review summarized this document as follows:

> “The Mattson monograph is not peer-reviewed and was self-published by the non-profit advocacy group Grizzly Bear Recovery Project. It draws upon a broad range of literature across numerous topics to explore “the past history, present conditions, and future prospects of grizzly bears and... habitat (p. 4) in central and north-central Idaho.” Importantly, Mattson’s monograph presents little new information, infers certainty from historic information that is impossible to verify, relies on gray literature that has not been peer-reviewed, and extrapolates from peer-reviewed literature beyond their scope. The author presents analysis specific to projected population viability, delineation of Bear Management Units, and existing habitat security. However, these analyses have not undergone peer-review, nor can such a review be conducted based upon the information provided; the document does not describe the methods and assumptions used in a clearly articulated fashion that is typical of peer-reviewed publications. Without such detail it is impossible to replicate the study or further test the assumptions made in the document, which makes it likewise impossible to weigh the value and validity of the modeled findings. In many cases, the author also does not clearly identify the data sources used. Mattson’s conclusions are over-confident at times and strained by data limitations and layered assumptions, particularly with respect to historic and existing conditions on the Nez Perce-Clearwater National Forest. The author acknowledges some of the constraints and limitations of his review, as well as the need for additional research in multiple areas.”

The accuracy is questionable because of the layered assumptions, reliance on gray literature, extrapolation of peer reviewed literature beyond their scope, and lack of peer review. In short, the reliability of Mattson’s monograph is questionable because of the lack of supportable evidence of current and historic conditions, and its results and conclusions cannot be regarded as the best available scientific information because it is not accurate, nor reliable (U.S. Department of Agriculture 2015b).

Bader and Sieracki (2021) and (2022) used grizzly bear den locations to model grizzly bear denning habitat. They obtained data for a number of bear den sites to derive characteristics of den sites and then modeled denning habitat across a wider area. The 2021 study was not peer reviewed and was funded by advocacy groups. A subsequent study based on the same data and similar analysis was published in the Northwestern Naturalist in 2022 (Bader and Sieracki 2022).

These two documents (Bader and Sieracki 2022) and (Bader and Sieracki 2021) were reviewed by a team of wildlife biologists made up of representatives from the U. S. Forest Service and U. S. Fish and Wildlife Service. The team produced a written document to evaluate the merits of these studies. The review concluded that there are substantial concerns regarding their methodology and conclusions, as well as statements about research and current management direction. They state that the non-peer-reviewed version (Bader and Sieracki 2021) was widely distributed in 2021 and should not be cited or used. For the review of the 2022 publication (Bader and Sieracki 2022), the team cited concerns about assumptions, data analysis, statistical irregularities, geographic information systems irregularities, a temporal mismatch of denning locations and motorized data, inadequate evaluation of results compared to other studies, biased interpretations of results and unrelated management recommendations in conclusions as problematic. The Review Team does not regard (Bader and Sieracki 2022) as best available science due to its numerous issues with accuracy and reliability. These two publications are not considered best available science in this analysis for the same reasons.

Evidence from published literature on dens suggests that mortality, or poor outcomes during denning season, are rare or uncommon. There is not much evidence in peer reviewed literature, even after observing hundreds of denning bears, that den site quality matters in terms of survival or reproductive success. Aune and Kasworm (1989a), observed 68 dens, but did not mention any failed dens; Craighead and Craighead documented 11 dens from 22 bears, but did not mention failed dens; (Kasworm et al. 2021) evaluated 129 dens from 1983 to 2020 and noted no grizzly bear mortality was observed during the denning season. Servheen and Klaver (1983) studied ten dens used by radio equipped bears but did not report mortality from failed or abandoned dens. Linnell (2000) evaluated dozens of studies on dens of black bear, polar bear, and brown bears and reported den abandonment, mostly in relation to human disturbance within the immediate area early in the denning season. While Linnell (2000) did identify some dens being abandoned because of flooding, the study did not otherwise identify any differences in survival or outcome related to den site quality. Linnell (2000) noted that when dens were abandoned, bears often reinitiated new dens soon after. While grizzly bears prefer denning areas with some characteristics, there appears to be limited consequences to dens located in less preferred areas.

Existing Direction in the 1987 Plans

The grizzly bear was listed as a threatened species in the lower 48 states on July 28, 1975. No critical habitat has been designated. The U.S. Fish and Wildlife Service proposed critical habitat for the grizzly bear in 1976 (41 FR 48757, November 5, 1976); however, the designation was never finalized. Until recently, the grizzly bear was considered extirpated from the plan area.

Management Direction Under the 1987 plans for the Nez Perce and Clearwater Forest contain elements that contributed to grizzly bear recovery. The Nez Perce Forest Plan (1987b) has forestwide direction as amended states:

- “The Forest will cooperate in the recovery of species listed in accordance with the Endangered Species Act.”
- “In compliance with assigned objectives in the Grizzly Bear Recovery Plan, the present status of the grizzly bear will continue to be monitored and updated. Habitat within the Selway Bitterroot Grizzly Bear Recovery Zone will be inventoried and evaluated to determine its capability to support viable grizzly bear populations. Established proactive actions will be exercised in accordance with current federal and state regulations.”
- “In compliance with sub-section 7(a)(2) of the Endangered Species Act a biological evaluation will be prepared (as described in FSM 2672.42) for all proposed management activities.”

The grizzly bear was a Management Indicator Species on the Nez Perce National Forest as well.

The Clearwater National Forest Plan (1987a) also contains elements or direction for grizzly bears as follows:

- "Manage habitat to contribute to recovery of each threatened and endangered species occurring on the Forest, including the grizzly bear, gray wolf, and bald eagle."
- "Cooperate with future recovery efforts on behalf of the gray wolf, bald eagle, and grizzly bear."

The 1987 plans have elk plan components that contribute to conserving habitat for future grizzly bear occupation via management of elk habitat effectiveness and elk vulnerability. These plans manage elk habitat effectiveness and elk vulnerability through roads management and use, and other factors (Leege 1984, Servheen et al. 1995). The elk vulnerability model estimates the effects of access and hunter effort activities during fall hunting seasons on elk at the game management unit scale. It considers both open and closed roads in the calculation of elk habitat effectiveness.

Direction in the 1987 Forest Plans required lands to provide for elk by maintaining areas with specified amounts of elk habitat potential. The 1987 plans imposed standards that required different areas to maintain certain levels of elk habitat potential. The elk habitat potential standards were associated with land allocations in the 1987 plans and elk habitat effectiveness (EHE) was the metric used to calculate elk habitat potential. The 1987 plans standards required projects to analyze factors, such as road density, livestock grazing, in relation to elk habitat preferences including quality, quantity, and distribution of cover, forage, and security areas. The Clearwater Plan was later amended and emphasized elk habitat effectiveness and reducing elk vulnerability. The 1987 Plans from both forests used elk analysis units as the scale for which effects were analyzed. The plan standards required that each elk analysis unit was identified to maintain a minimum amount of elk habitat effectiveness of either 25 percent, 50 percent, 75 percent, or 100 percent. Elk analysis units are not delineated within wilderness.

The U.S. Fish and Wildlife Service issued the Nez Perce-Clearwater's interim direction for Section 7 consultation for considering grizzly bear habitat management in or adjacent to the Bitterroot Ecosystem (1995a) as a result of efforts to reintroduce grizzly bears into the Bitterroot Recovery Zone (Letter from Fish and Wildlife Service dated November 13th, 1995). Direction from the U.S. Fish and Wildlife Service in that letter was that the Forest Service should:

> consider the effects to grizzly bear habitat as being incorporated into the analysis for big game habitat. As long as the Forest Plan Standards for big game are being met, and/or big game issues are sufficiently covered within NEPA documents, projects would be considered to be in compliance with section 7(a)(1) of the Endangered Species Act. In addition, grizzly bear habitat will be incorporated into effects analysis and management direction for big game habitat. If big game issues are properly dealt with in the NEPA process then it will be assumed that grizzly bear habitat issues are also adequately addressed.

This was given as interim guidance (USFWS Letter to the U.S. Forest Service, November 13th, 1995). In response, the Forest Supervisor wrote a letter directing the District Rangers (Letter written by James Caswell, Forest Supervisor to District Rangers, December 4, 1995) that "If big game issues are properly dealt with in the NEPA process then it will be assumed that grizzly bear habitat issues are also adequately addressed."

In 2008 when the Idaho Roadless Rule was established, many areas that had objectives for elk analysis units to maintain 75 percent and 100 percent habitat effectiveness, were identified as having roadless character and thus were designated as Idaho Roadless Rule Areas, though the process for identification of areas with roadless character were not directly related to elk measures. Elk and grizzly bears both prefer to use and survive better in habitats without motorized access. The restrictions on activities in the Idaho Roadless Rule Areas established a new mechanism to provide ecological conditions to contribute to grizzly bear recovery because the roadless rule restricts road construction or reconstruction, timber and vegetation management, and some mineral uses as outlined below in the Idaho Roadless Rule direction. These new mechanisms imposed by the Idaho Roadless Rule, in part, replaced the need for elk habitat effectiveness measures in the proposed plan within Idaho Roadless Rule Areas.

The existing road and motorized trail, along with newly proposed routes, are one the main factors calculated that determines elk habitat effectiveness outcomes within each elk analysis unit. The mathematics involved in calculating elk habitat effectiveness included consideration of open routes, closed routes, and the types of closures they were (for example, gates or barriers), and whether they were open or closed during hunting season. These standards imposed significant restrictions on motorized routes forestwide based on different levels of required elk habitat effectiveness objectives (Figure 95). The 100 percent and 75 percent elk habitat effectiveness objectives imposed limits of either no or very low amounts of motorized uses, whereas even in areas allocated for multiple uses for example, the elk habitat objective of 25 percent allowed more roads, but imposed a more permissive limit.

Many of the areas with objectives for high amounts of elk habitat effectiveness later became Idaho Roadless Rule areas when the Idaho Roadless Rule was established in 2008 as these areas were maintained without roads by the elk habitat effectiveness direction in the 1987 plans. Thus, the need for elk security measures in the Forest Plan has been reduced or eliminated because most of the areas protected by elk habitat effectiveness measures in the 1987 plans were subsequently designated as Idaho Roadless Rule Areas. Therefore, Idaho Roadless Rule area now protects many areas that were managed for elk security which replaced the need to management for elk habitat effectiveness in the Revised Forest Plan in those areas. For example, the acres and percentage of elk habitat effectiveness areas from the 1987 plans now designated as Idaho Roadless Rule areas are shown in the table below. Approximately 99.8 percent of areas that had a 1987 plan objective of 100 percent elk habitat effectiveness was either already in wilderness (32.3 percent) or became Idaho Roadless Rule areas (67.5 percent) for a total of about 1,562,770 acres (see Table 246 and Table 247). Similarly, approximately 84.36 percent of areas with a 1987 Forest Plan elk habitat effectiveness objective of 75 percent became Idaho Roadless Rule Area. Approximately 18.29 percent and 22.1 percent of areas with 1987 plan elk habitat effectiveness objectives of 25 percent and 50 percent respectively was later designated as Idaho Roadless Rule. Figure 95 shows the elk analysis units and their elk habitat effectiveness objectives. Note that the different objectives correspond to the different amounts of secure habitat presently existing. Therefore, the majority of areas that had objectives for elk habitat effectiveness in the 1987 plans were designated Idaho Roadless Rule areas or wilderness areas and are now protected against roads. Thus, because Idaho Roadless Rule areas restrict roads with only limited exceptions depending upon Roadless Rule Theme, and Wilderness Areas outright prohibit roads and motorized trails, there is no longer a need to manage for elk habitat effectiveness objectives in the Revised Forest Plan.

Table 246. The acres of area in the 1987 Forest Plans with 25%, 50%, 75% and 100% elk habitat effectiveness objectives. Note the acres within the Idaho Roadless Rule Areas.

Elk Habitat Effectiveness Objective	Acres within Non-Roadless	Acres with Wilderness	Acres within Idaho Roadless Rule
Acres of area with 25% EHE	570,819	46	127,800
Acres of area with 50% EHE	379,521	241	107,125
Acres of Area with 75% EHE	95,699	223	516,362
Acres of Area with 100% EHE	1,686	262,457	548,516
Sum of Acres	**1,047,725**	**262,967**	**1,299,803**

Table 247. The percent of area with elk habitat objectives of 25%, 50%, 75%, and 100% within non-roadless, Designated Wilderness, and Idaho Roadless Rule areas. Note that high percentages of elk habitat objectives became Idaho Roadless Rule Areas.

Elk Habitat Effectiveness Objective	Percent within Non-Roadless	Percent within Wilderness	Percent Within Idaho Roadless Rule
Percent of areas with a 25% Elk Habitat Effectiveness Objective	82.00%	0.01%	18.29%
Percent of Areas with a 50% Elk Habitat Effectiveness Objective	77.99%	0%	22.01%
Percent of areas with a 75% Elk Habitat Effectiveness Objective	15.64%	0%	84.36%
Percent of Areas with a 100% Elk Habitat Effectiveness Objective	0.21%	32.30%	67.50%

Note that minor spatial errors resulted from misalignment of elk habitat effectiveness layer boundaries with wilderness, non-roadless rule and Idaho Roadless Rule boundaries. This is why some percentages add up to slightly over 100%.

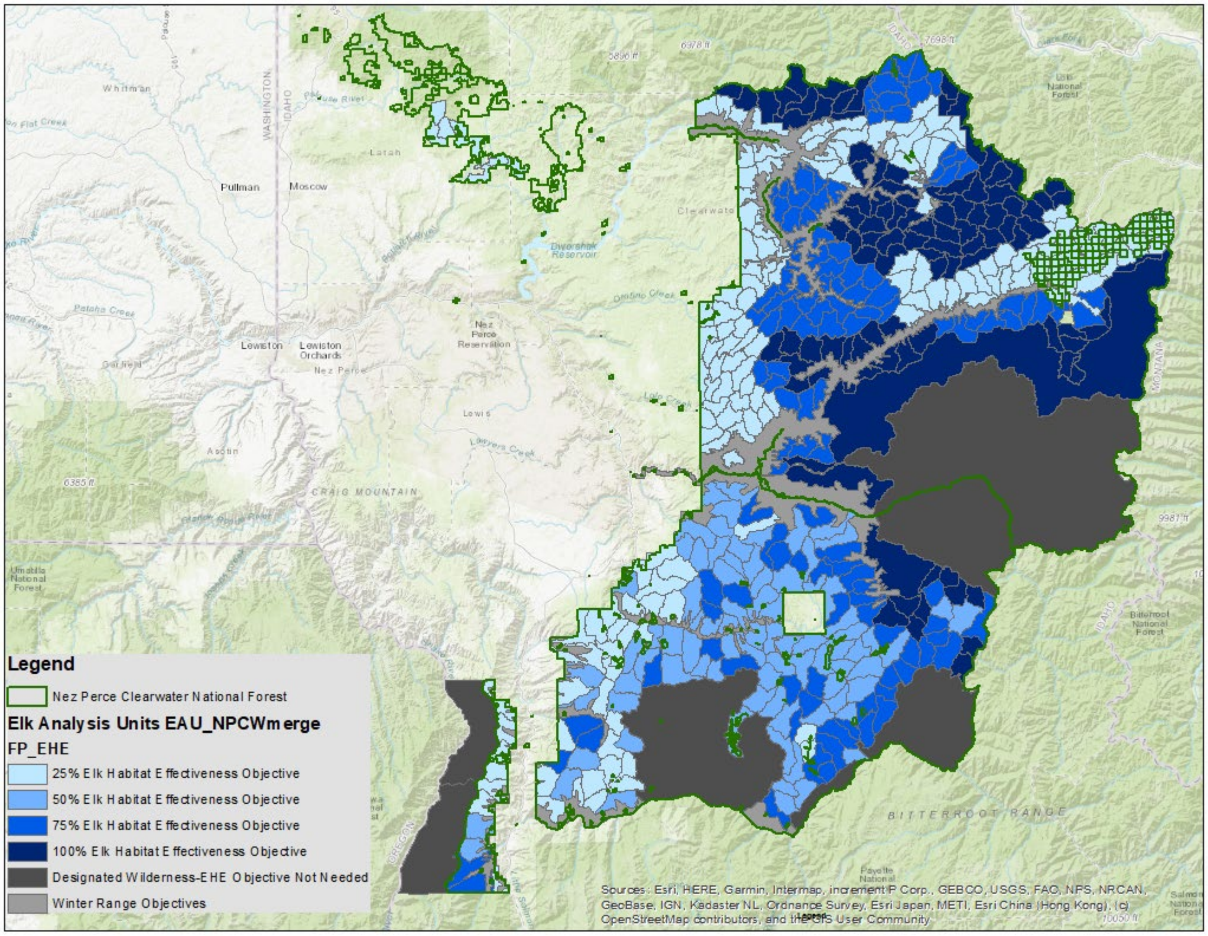

Figure 95. The elk habitat effectiveness objectives within elk analysis units from the 1987 Forest Plans

Instead, the Revised Forest Plan would shift to plan components that emphasize integrating nutrition and evaluates the useability of that nutrition in relation to the displacement effects of roads. The Idaho Roadless Rule will also help provide secure areas for grizzly bears.

The revised Forest Plan will change the allocation of management areas and management area emphasis. The revised Forest Plan will simplify management into three management areas, each with unique management emphasis and they are further subdivided into sub-management areas.

Designated Wilderness

Of the 3,939,056 acres administered by the Nez Perce-Clearwater National Forest, there are approximately 1,139,059 acres of designated wilderness. These consist of three designated wilderness areas, two of which extend South across forest boundaries on to other national forests. Congress has designated approximately 1,139,059 acres of wilderness within the plan area. These include the Gospel-Hump, the Selway-Bitterroot, and Frank Church-River of No Return Wilderness areas. The Selway-Bitterroot and Frank Church-River of No Return Wilderness Area makes up the entirety of the Bitterroot Recovery Zone.

The Selway-Bitterroot Wilderness and the Frank Church-River of No Return Wilderness make up the core of the Recovery Zone for the federally listed threatened grizzly bear. These two wildernesses make up the largest contiguous blocks of federal land remaining in the United States and the largest block of wilderness in the Rocky Mountains. Reestablishment of grizzly bear in this recovery zone is currently through natural dispersal.

The Bitterroot Recovery Zone lies almost entirely within the Selway-Bitterroot Wilderness and the Frank Church-River of No Return Wilderness. The area known as the Bitterroot Ecosystem is centered around the federally designated Wilderness Areas of central Idaho, while a small portion extends eastward over the crest of the Bitterroot Mountains into Montana. It includes about 26,072 square miles of contiguous national forest lands in central Idaho and western Montana (50 C.F.R. § 17.84(l). These include portions of the Bitterroot, Boise, Salmon-Challis, Clearwater, Nez Perce, Payette, Sawtooth, and Panhandle National Forests in Idaho, and the Bitterroot and Lolo National Forests in western Montana. By contrast, the Bitterroot Recovery Zone (Servheen 1996) is approximately 3,731,733 acres (5,831 mi^2) in size and lies almost entirely within the Selway-Bitterroot Wilderness Area and the Frank Church-River of No Return Wilderness Area. The Bitterroot Ecosystem encompasses most of the Nez Perce-Clearwater National Forest (Servheen 1996). The Bitterroot Recovery Zone overlaps with the southeast side of the Nez Perce-Clearwater. On the Nez Perce-Clearwater, the Bitterroot Recovery Zone lies almost entirely within the Selway-Bitterroot Designated Wilderness and the Frank Church-River of No Return Wilderness, the only exception being the Magruder road. About 23.6 percent of the Nez Perce-Clearwater is included within the Bitterroot Ecosystem's grizzly bear Recovery Zone, also known as the Bitterroot Recovery Zone. The acres of Designated Wilderness Areas are shown in Table 248.

Approximately 1,139,059 acres, just under 30 percent, of the Nez Perce-Clearwater is within three designated wildernesses. Portions of the Frank Church-River of No Return, portions of the Selway-Bitterroot, and the Gospel-Hump wilderness areas lie within the Nez Perce-Clearwater.

Table 248. Wilderness acres on the Nez Perce-Clearwater

Wilderness	Jurisdiction (National Forest)	Nez Perce-Clearwater (size in acres)	Total (size in acres)
Selway-Bitterroot	Bitterroot, Lolo[3] and Nez Perce-Clearwater[4]	823,151	1,348,663
Frank Church-River of No Return	Boise[1], Bitterroot, Nez Perce-Clearwater, Payette and Salmon-Challis[2] and BLM lands	110,236	2,359,948
Gospel-Hump	Nez Perce-Clearwater	205,672	205,672

1 Management of acres located on the Boise National Forest have been assigned to the Challis National Forest (now combined with the Salmon to form the Salmon-Challis National Forest)

2 The Salmon-Challis National Forest is the lead agency for management of the Frank Church-River of No Return, pursuant to plan direction for the appropriate Forest.

3 Management of acres located on the Lolo National Forest have been assigned to the Bitterroot National Forest

4 The Bitterroot National Forest is the lead agency for management of the Selway-Bitterroot Wilderness, pursuant to plan direction for the appropriate Forest.

Table 249. Acres of the Nez Perce-Clearwater inside and outside of the Bitterroot Recovery Zone

Nez Perce-Clearwater National Forest	Acres	Percent
Acres within the Bitterroot Recovery Zone	935,715*	23.7%
Acres outside the Bitterroot Recovery Zone	3,003,341	76.2%
Total acres	**3,939,056**	**100%**

*The Bitterroot Recovery Zone contains the Magruder corridor, which is not wilderness. Therefore, the Bitterroot Recovery Zone is slightly bigger than the wilderness areas.

Wilderness management is governed not only by the Revised Forest Plan but by law, and policy. Wilderness management restricts many activities that can affect federally listed species. The Wilderness Act states that a wilderness area is to be managed so that it is “untrammeled by man” and “generally appears to have been affected primarily by the forces of nature, with the imprint of man’s work substantially unnoticeable.” It also directs agencies to manage wilderness to preserve natural ecological conditions. The act directs the management of wilderness “for the use and enjoyment of the American people in such a manner as will leave them unimpaired for future use and enjoyment as wilderness, and so as to provide for the protection of these areas, the preservation of their wilderness character.”
Section 4(c) of the Wilderness Act states the following regarding roads:

“Except as specifically provided for in this Act, and subject to existing private rights, there shall be no commercial enterprise and no permanent road within any wilderness area designated by this Act and, except as necessary to meet minimum requirements for the administration of the area for the purpose of this Act (including measures required in emergencies involving the health and safety of persons within the area), there shall be no temporary road, no use of motor vehicles, motorized equipment or motorboats, no landing of aircraft, no other form of mechanical transport, and no structure or installation within any such area.”

The Wilderness Act also prohibits motorized or mechanical entry, via cars, trucks, off-road or all-terrain vehicles, bicycles, aircraft, or motorboats, except in emergencies and in specified circumstances. The exceptions to motorized prohibitions are very narrow and rarely used.

Forest Service Policy also governs management of wilderness areas. Forest Service Manual 2320 includes the following direction:

- Where there are alternatives among management decisions, wilderness values shall dominate over all other considerations except where limited by the Wilderness Act, subsequent legislation, or regulations.
- Manage the use of other resources in wilderness in a manner compatible with wilderness resource management objectives.
- In wildernesses where the establishing legislation permits resource uses and activities that are nonconforming exceptions to the definition of wilderness as described in the Wilderness Act, manage these nonconforming uses and activities in such a manner as to minimize their effect on the wilderness resource.
- Cease uses and activities and remove existing structures not essential to the administration, protection, or management of wilderness for wilderness purposes or not provided for in the establishing legislation.
- Because wilderness does not exist in a vacuum, consider activities on both sides of wilderness boundaries during planning and articulate management goals and the blending of diverse resources in forest plans. Do not maintain buffer strips of undeveloped wildland to provide an informal extension of wilderness. Do not maintain internal buffer zones that degrade wilderness values. Use the Recreation Opportunity Spectrum (FSM 2310) as a tool to plan adjacent land management.
- Manage each wilderness as a total unit and coordinate management direction when they cross other administrative boundaries.
- Use interdisciplinary skills in planning for wilderness use and administration.

- Gather necessary information and carry out research programs in a manner that is compatible with the preservation of the wilderness environment.
- Whenever and wherever possible, acquire non-Federal lands located within wildernesses, as well as non-Federal lands within those areas recommended for inclusion in the system.
- Inform wilderness visitors that they face inherent risks of adverse weather conditions, isolation, physical hazards, and lack of rapid communications, and that search and rescue may not be as rapid as expected in an urban setting in all publications and personal contacts.
- Manage primitive areas as wilderness areas consistent with 36 CFR 293.17 until their designation as wilderness or to other use is determined by Congress.

It is the five qualities of wilderness character that the agency leans on as a way to monitor to meet the intent of the Wilderness Act. So, as a matter of policy, managing an area to be untrammeled, natural, and undeveloped is managing for grizzly bear and other wildlife special features such as lynx or wolverine for example. The existing wilderness areas are managed to preserve wilderness character. Five qualities help describe wilderness character (Landres et al. 2015).

- Untrammeled—Wilderness is essentially unhindered and free from modern human control or manipulation.
- Naturalness—Wilderness ecological systems are substantially free from the effects of modern civilization.
- Undeveloped—Wilderness is essentially without permanent improvements or modern human occupation.
- Outstanding opportunities for solitude or a primitive and unconfined type of recreation—Wilderness provides outstanding opportunities for people to experience solitude or primitive and unconfined recreation, including the values of inspiration and physical and mental challenge.
- Other features of value—Wilderness may contain ecological, geological, or other features of scientific, educational, scenic, or historical value.

With certain very limited exceptions, the Wilderness Act prohibits motorized equipment, structures, installations, roads, commercial enterprises, aircraft landings, and mechanical transport. The Act permits mining access to private lands, fire control, insect and disease control, grazing, water resource structures (upon the approval of the President), and visitor use. Restricted or prohibited activities include road building, motorized and mechanized uses, construction of structures or recreation sites, timber harvest, and in the case of the Selway Bitterroot and Frank Church-River of No Return, mineral rights were withdrawn. So, no new mineral or mining activities are allowed. Fire suppression activities are only allowed under certain conditions but are otherwise allowed to burn naturally. These measures would ensure that wilderness areas provide wild landscapes with little human alteration, little access, and fewer visitors. Thus, designated wilderness areas provide ecological conditions to contribute to recovery of federally listed species because this management framework restricts many activities that could affect listed species.

Wilderness management does not restrict grazing, recreational uses, nor does it address management of food or attractants. The Nez Perce-Clearwater National Forest does not have restrictions on management of food or attractants in place currently.

While grazing is allowed in wilderness, there are only 380 acres of one vacant allotment in the Selway-Bitterroot wilderness area. So, this activity is not currently occurring within the Selway-Bitterroot and

Frank Church Wilderness Areas nor within the Bitterroot Recovery Zone within the boundaries of the plan area. However, the vacant allotment at some point may again become active. The Central Wilderness Act (1980), which was the enabling legislation for the Selway-Bitterroot and Frank Church-River of No Return Wilderness areas, provided some allowance of grazing. It states:

> Within the River of No Return Wilderness and the Selway-Bitterroot Wilderness additions designated by this Act…the grazing of livestock were established prior to the date of enactment of this Act, shall be permitted to continue subject to such reasonable regulations as the Secretary deems necessary, as provided in paragraph 4(d)(4) of the Wilderness Act.

This language suggests that new grazing allotments not established prior to 1980 would be restricted within the Selway-Bitterroot and Frank Church-River of No Return Wilderness Areas.

Idaho Roadless Rule

Currently, the Idaho Roadless Rule contributes to the ecological conditions to provide for grizzly bear connectivity and contribute to recovery. As described above, the Idaho Roadless Rule contributes to the existing condition and ongoing actions that assist with protections for grizzly bears because the rule provides prohibitions with exceptions or conditioned permissions governing road construction, timber cutting, and discretionary mineral development (36 CFR Part 294 Federal Register/Vol. 73, No. 201). These activities have been known to affect grizzly bear habitat and the prohibitions contribute to grizzly bear conservation. The Nez Perce-Clearwater National Forest contains approximately 1,481,565 acres of Idaho Roadless Rule area within the five roadless rule area themes. The acres of each theme are shown in Table 250, a map showing the distribution of these themes are shown in Figure 96, and a summary of these prohibitions is included below. The current management of the Idaho Roadless Rule areas helps maintain grizzly bear habitats from the effects of the prohibited activities.

Factors that may affect grizzly bears not addressed by the Idaho Roadless Rule includes the construction and use of motorized trails, livestock grazing, some fuels treatments, some vegetation treatments, road construction within community protection zones, extraction of saleable minerals, leasable minerals, geothermal development, energy corridors, or wind or biomass energy. Idaho Roadless Rule areas also do not restrict primitive and semi-primitive recreation, address attractants, hunting or fishing activities, special use permits for outfitting and guiding, and there are some allowances for municipal water management. The plan will not change Idaho Roadless Rule Areas, Idaho Roadless Rule Themes, nor associated prohibitions and allowances established by the rule. All recommended wilderness areas, as well as some Research Natural Areas, the Lolo Trail National Historic Landmark, and some Suitable Wild and Scenic Rivers in the Preferred Alternative are also Idaho Roadless Rule areas.

Idaho's roadless areas make up the core of the last intact forest ecosystem in the lower 48 states. The U.S. Forest Service adopted a state-specific, final rule establishing management direction for designated roadless areas in the State of Idaho. The final rule designated 250 Idaho Roadless Areas (IRAs) and establishes five management themes that provide prohibitions with exceptions or conditioned permissions governing road construction, timber cutting, and discretionary mineral development (36 CFR Part 294 Federal Register/Vol. 73, No. 201). The Nez Perce-Clearwater National Forest contains approximately 1,481,565 acres of Idaho Roadless Rule area. Areas were divided into themes by the Idaho Roadless Rule and are managed differently within each theme. The acres of the different themes are shown in Table 250.

Table 250. The Idaho Roadless Rule themes and approximate acres of each of them within the plan area

Idaho Roadless Rule Theme	Approximate Acres within the Nez Perce-Clearwater
Backcountry Restoration	835,649
Forest Plan Special Areas	38,278
Primitive	311,154
Special Area of Historic or Tribal Significance	49,341
Wildland Recreation	247,133
Total	1,481,565

Acres differ from those reported in Chapter 2 of the EIS which is reported at 1,481,636 due to slight changes in calculated acres due to overlay errors in GIS that occurred when calculating secure habitat

Idaho Roadless Rule Areas make up approximately 37.6 percent of the plan area. The majority of Idaho Roadless Rule areas are distributed on the Clearwater National Forest, though significant Roadless Rule areas occur adjacent to the Selway Bitterroot Wilderness area and Frank Church Wilderness Area on the Nez Perce National Forest. The Idaho Roadless Rule restrictions and exceptions for each theme are summarized below and are shown in Figure 96 below.

The following sections summarize and contrast the different management restrictions on activities within each Idaho Roadless Rule Theme. For a complete description of the prohibitions with exceptions or conditioned permissions within each theme see the Idaho Roadless Rule (36 CFR Part 294 Federal Register/Vol. 73, No. 201).

Wildland Recreation Theme

Road Construction or Reconstruction

Prohibited except regional forester may authorize to meet statute, treaty, reserved or outstanding rights or other legal duty of the United States.

Timber and Vegetation Management

Timber cutting, sale, or removal is prohibited except for personal or administrative use or where incidental to the implementation of an activity not prohibited.

Minerals

Existing mineral leases can continue under leases, contracts, permits authorized before October 16, 2008. No change to minerals activities under General Mining Law of 1872. Roads will not be authorized for mineral leasing after October 16, 2008. Common variety mineral materials will not be sold after October 16, 2008.

Special Area of Historic and Tribal Significance Theme

Road Construction or Reconstruction

Prohibited except the regional forester may authorize to meet statute, treaty, reserved or outstanding rights or other legal duty of the United States.

Timber and Vegetation Management

Timber cutting, sale, or removal is prohibited except to improve threatened, endangered, proposed, or sensitive species habitat; to maintain or restore the characteristics of ecosystem composition, structure or processes; to reduce the risk of uncharacteristic wildland fire effects to an at-risk community or municipal water supply; for personal or administrative use or where incidental to the implementation of an activity not prohibited; or where cutting, sale or removal is incidental to the implementation of a management activity not otherwise prohibited by this subpart. These actions must maintain or improve one or more of the roadless characteristics; use existing roads or aerial harvest systems; maximize the retention of large trees as appropriate for the forest type to the extent these trees promote fire-resilient stands; be consistent with land management plan components; and be approved by regional forester.

Minerals
Existing mineral leases can continue under leases, contracts, permits authorized before October 16, 2008. No change to minerals activities under General Mining Law of 1872. Roads will not be authorized for mineral leasing after October 16, 2008. Common variety mineral materials will not be sold after October 16, 2008.

Primitive Theme

Road Construction or Reconstruction
Prohibited except regional forester may authorize to meet statute, treaty, reserved or outstanding rights or other legal duty of the United States.

Timber and Vegetation Management
Timber cutting, sale, or removal is prohibited except to improve threatened, endangered, proposed, or sensitive species habitat; to maintain or restore the characteristics of ecosystem composition, structure or processes; to reduce the risk of uncharacteristic wildland fire effects to an at-risk community or municipal water supply; for personal or administrative use or where incidental to the implementation of an activity not prohibited; or where cutting, sale or removal is incidental to the implementation of a management activity not otherwise prohibited by this subpart. These actions must maintain or improve one or more of the roadless characteristics; use existing roads or aerial harvest systems; maximize the retention of large trees as appropriate for the forest type to the extent these trees promote fire-resilient stands; be consistent with land management plan components; and be approved by regional forester.

Minerals
Existing mineral leases can continue under leases, contracts, permits authorized before 10/16/2008. No change to minerals activities under General Mining Law of 1872. Roads will not be authorized for mineral leasing after 10/16/2008. Common variety mineral materials will not be sold after 10/16/2008.

Backcountry Restoration Theme

Road Construction or Reconstruction
Prohibited unless regional forester determines that road is needed for public health and safety for imminent threat of loss of life or property; or in response to Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), Clean Water Act or Oil Pollution, or Statute, treaty, reserved or outstanding rights or other legal duty of the United States; or Road realignment to prevent irreparable resource damage that cannot be mitigate by normal road maintenance for roads essential for public or private access, natural resource management, or public health or safety; or road reconstruction for road safety on a road determined to be hazardous; or Secretary of Agriculture determines a Federal Aid Highway (Title 23 of the U.S. Code) is warranted.

Timber and Vegetation Management
Timber cutting, sale or removal is prohibited except to improve threatened, endangered, proposed, or sensitive species habitat; to maintain or restore the characteristics of ecosystem composition, structure or

processes; to reduce the risk of uncharacteristic wildland fire effects to an at-risk community or municipal water supply; for personal or administrative use or where incidental to the implementation of an activity not prohibited; where cutting, sale or removal is incidental to the implementation of a management activity not otherwise prohibited by this subpart. These actions must maintain or improve one or more of the roadless characteristics; use existing roads or aerial harvest systems; maximize the retention of large trees as appropriate for the forest type to the extent these trees promote fire-resilient stands; be consistent with land management plan components; and be approved by the regional forester.

Minerals
Existing mineral leases can continue under leases, contracts, permits authorized before October 16, 2008. No change to minerals activities under General Mining Law of 1872. Roads will not be authorized for mineral leasing after October 16, 2008 but surface use or mineral leasing without road construction or reconstruction may occur if consistent with Forest Plan. The use or sale of common variety mineral materials and associated road construction to access them may be authorized only if the use of these materials is incidental to an activity otherwise permissible in the backcountry.

Backcountry Restoration Theme—Community Protection Zones

Road Construction or Reconstruction
Responsible official may authorize temporary road construction or reconstruction for community protection zone activities if these cannot be reasonably accomplished without a road.

Timber and Vegetation Management
Same as backcountry restoration theme plus: To reduce hazardous fuels conditions within the community protection zone if it generally retains large trees and is consistent with land management plan.

Minerals
Existing mineral leases can continue under leases, contracts, permits authorized before October 16, 2008. No change to minerals activities under General Mining Law of 1872. Roads will not be authorized for mineral leasing after October 16, 2008, but surface use or mineral leasing without road construction or reconstruction may occur if consistent with Forest Plan. The use or sale of common variety mineral materials and associated road construction to access them may be authorized only if the use of these materials is incidental to an activity otherwise permissible in the backcountry.

Forest Plan Special Areas Theme

Road Construction or Reconstruction
Management under current Forest Plan not changed by Idaho Roadless Rule.

Timber and Vegetation Management
Management under current Forest Plan not changed by Idaho Roadless Rule.

Minerals
Management under current Forest Plan not changed by Idaho Roadless Rule.

The roadless rule allows motorized travel on existing roads and trails to continue. Decisions concerning future management of roads and trails are made in applicable travel management process. Grazing under existing grazing permits is not affected by the Idaho Roadless Rule. Motorized equipment and mechanical transport do not change under the Idaho Roadless Rule.

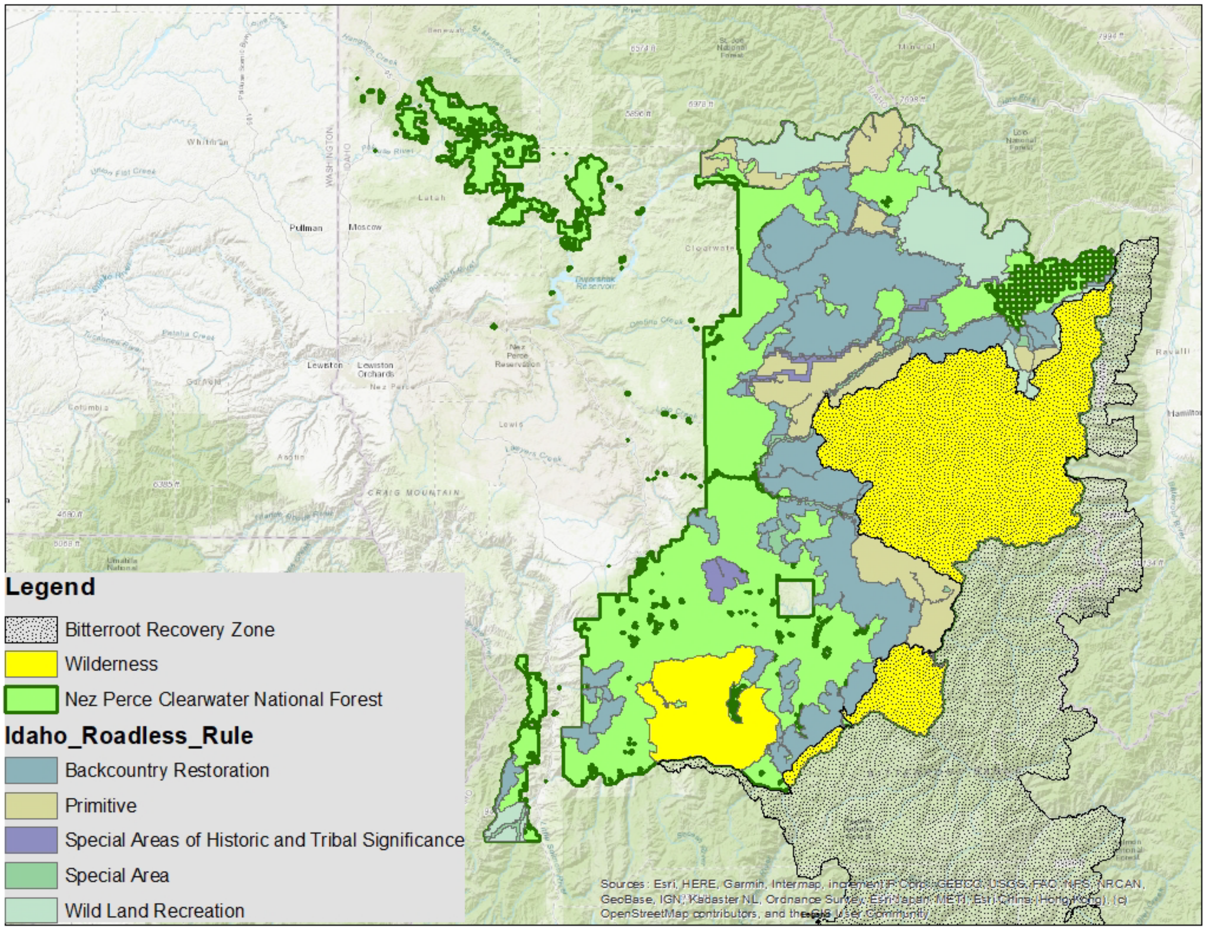

Figure 96. The distribution of Idaho Roadless Rule areas in relation to designated wilderness and the Bitterroot Recovery Zone

Recommended Wilderness

The 1987 Forest Plans recommended about 198,200 acres for wilderness, all within the boundaries of the Clearwater National Forest. More recent updated GIS data shows the area as about 197,695 acres (Table 251). These areas are Hoodoo, Mallard Larkin, North Fork Spruce-White Sands, and Sneakfoot Meadows. There were no wilderness recommendations in the Nez Perce National Forest Plan. The 1987 Clearwater National Forest plan standards for recommended wilderness state that the management standards for these areas will meet a visual quality objective of preservation and will manage all uses to maintain wilderness qualities and retain semi-primitive settings. Travel management in existing recommended wilderness areas was addressed in the Clearwater Travel Planning Record of Decision dated October 31, 2017. Under this direction, areas that are currently managed as recommended wilderness prohibit mechanized transport, including mountain bicycles or game carts, and motorized use, including wheeled and motorized over-snow vehicles. Road construction, timber harvest, and mineral activities may only be allowed to the extent permitted in the Idaho Roadless Rule.

Table 251. The existing condition for the acres of recommended wilderness areas

Recommended Wilderness Area	1987 Forest Plan Acres	Updated GIS Acres
Hoodoo	113,000	111,988

Recommended Wilderness Area	1987 Forest Plan Acres	Updated GIS Acres
Mallard-Larkins	66,700	66,377
North Fork Spruce-White Sand	9,800	9,865
Sneakfoot Meadows	8,700	9,465
Totals	**198,200**	**197,695**

Data Source: 1987 Forest Plans and updated Nez Perce-Clearwater GIS data. Note that in the 1987 Forest Plan Sneakfoot meadow, and Northfork Spruce-White sand were referred to as Storm Creek, Elk Summit, and Lakes.

These areas are also Idaho Roadless Rule Areas either under the Wildland Recreation theme or the Primitive theme and are currently managed to maintain their wilderness character. Management of recommended wilderness is similar to management for designated wilderness and Idaho Roadless Rule areas in the Wildland Recreation theme. These areas provide ecological conditions to contribute to recovery. Activities that are not prohibited in wilderness or roadless rule areas are also not prohibited in recommended wilderness.

Lolo Trail National Historic Landmark

The Lolo Trail, a National Historic Landmark administered in cooperation with the National Park Service, is part of the Nez Perce National Historical Park. It is managed with special direction that contributes to grizzly bear conservation. For example, it is designated and managed as Idaho Roadless Rule areas and in addition to maintaining the integrity of the monument which includes some restrictions on new road construction and vegetation treatments. The trail extends through the Nez Perce-Clearwater from Lolo, Montana to Weippe, Idaho. The Lolo Trail National Historic Landmark designated in 1963 is composed of 55,760 acres and is located through the heart of the Clearwater National Forest. Its significance lies in its roots as an ancient American Indian trail and comprises the route Lewis and Clark traveled from 1805 to 1806, as well as the path of flight taken by the Nez Perce Indians during the Nez Perce Indian War of 1877. The landmark stretches about 62 miles from the Nez Perce-Clearwater boundary near Musselshell Meadows to the Nez Perce-Clearwater boundary near Lolo Pass. It is an area designated by Congress thus, the plan will not change the landmark boundaries, but it will provide special direction for its management and is analyzed below. Management emphasis of this area is to maintain the National Register integrity of the landmark as high and convey its exceptional value and qualities in illustrating the heritage of the United States.

Travel Management

The Clearwater Travel Plan decided the travel system for the Clearwater National Forest. The Clearwater Travel Plan designated a site-specific transportation system and prohibited indiscriminate cross-country traffic. The Nez Perce National Forest has not completed travel planning, so the Nez Perce National Forest is open to motorized travel unless closed by a site-specific decision. Travel planning on the Nez Perce portion of the national forest will be completed in the future following the Land Management Plan. Travel planning on the Clearwater National Forest would continue to be revised under the Land Management Plan on a site-specific basis, as needed.

The Nez Perce-Clearwater overall has 7,680 miles of forest roads, accessing approximately 1,331,040 acres, or 34 percent, of the Nez Perce-Clearwater. A map of Management Area 3 can be found in Appendix A.

On November 9, 2005, the Forest Service published the final rule "Travel Management: Designated Routes and Areas for Motor Vehicle Use" in the Federal Register. The 2005 Travel Management Rule requires national forests to develop a minimum road system to accommodate resource needs. In 2015, a forest-level roads analysis was completed for the Nez Perce-Clearwater. This analysis established a minimum road system for arterial, collector, and important local class national forest roads on the Nez Perce-Clearwater. This broad-scale analysis encompassed all existing National Forest System roads on the Nez Perce-Clearwater. The report provided an assessment of the road infrastructure and a set of findings and recommendations for revisions to the Nez Perce-Clearwater transportation system. The report provided information to Nez Perce-Clearwater managers regarding the minimum road system needed for safe and efficient travel and for administration, utilization, and protection of the land.

As shown in Table 252 and Table 253, the total number of roads on the Nez Perce-Clearwater has been steadily decreasing since 1999. A total of about 1,625 miles of National Forest System roads and non-National Forest System roads have been decommissioned during this time. Most of this decommissioning took place on the non-system roads that were legacy roads from former timber harvest practices, which are no longer needed for new harvest techniques and roads in unstable terrain or with failing drainage structures. However, there have been additions to National Forest System roads during this time as well. These additions include the construction of approximately 46 miles of new roads for vegetation, special uses, recreation management, and watershed improvements by moving roads away from sensitive stream habitats. The majority of the increases are due to the need for better located roads that provide for a more stable, less impacting road system.

Table 252. Miles of roads decommissioned from 1999 to 2018 on the Clearwater National Forest

Year	Miles	Year	Miles
1999	127.8	2009	127.0
2000	67.3	2010	138.3
2001	92.0	2011	90.1
2002	42.7	2012	154.9
2003	41.9	2013	194.4
2004	156.9	2014	97.4
2005	29.6	2015	60.5
2006	55.0	2016	65
2007	52.1	2017	30
2008	114.4	2018	46

Table 253. Miles of roads constructed from 1999 to 2018 on the Nez Perce National Forest

Year	Miles	Year	Miles
1999	13.62	2009	1.58
2000	2.33	2010	1.13
2001	0.65	2011	0
2002	0.5	2012	4
2003	0.45	2013	6.6
2004	0.38	2014	9.88
2005	0	2015	0.13
2006	2.08	2016	2.4
2007	0	2017	0.1
2008	0	2018	0

Grizzly bears might encounter increased human presence and conflicts in areas with more roads. These conflicts often lead to bear deaths and so are detrimental to individual grizzly bears. There are far fewer acres of secure habitat within Management Area 3, with most of them smaller than 1,000 acres. These areas would not be biologically suitable nor socially acceptable for grizzly bear occupancy. A visual representation or map of the current travel situation is shown in Figure 98 and Figure 99 below.

The national forest often uses temporary roads to implement projects such as timber or fuels treatments. These features temporarily impact localized areas during project implementation but are subsequently removed shortly after projects are completed. Thus, their effects are temporary and localized. It is possible that temporary routes used for vegetation management could affect polygons of secure habitat in the future temporarily. Most temporary roads tend to occur in proximity to existing motorized routes. Temporary roads are prohibited within designated wilderness areas and so are not allowed in the Bitterroot Recovery Zone. The Idaho Roadless Rule included a provision to allow roads existing before the establishment of the rule to remain and be maintained, but new roads are only allowed with limited exceptions as outlined in above under the Idaho Roadless Rule direction. For example, they are allowed within the Backcountry/Restoration areas only within Community Protection Zone areas to treat hazardous fuels. These are limited areas even within the backcountry restoration theme. Thus, temporary roads are mostly used within the managed front where multiple uses are emphasized, which are areas that present risk to grizzly bear survival.

A private entity's non-compliance with the Nez Perce-Clearwater's access management is an illegal activity. While illegal use of the national forest via motorized access in areas unauthorized for such use may occur within the planning area, such illegal use is not considered a forest action and therefore not analyzed under effects of the Plan; however, their influence is considered for describing the existing condition.

While illegal motorized access has the potential to affect individual grizzly bears, the amount, location, duration, and timing of effects resulting from such illegal use is typically not known. Illegal motorized access is expected to be spatially disparate, temporary, and is not likely to collectively cause an adverse effect because most forest users follow travel regulations. When illegal use is observed or when user-created roads become apparent, the national forest corrects the situation as soon as they are able. Illegal use is, in part, facilitated by the presence of authorized forest routes because they allow access from which illegal uses can start. Thus, the effects are considered here as part of the existing condition but are not quantified because of uncertainty in predicting where, when, or how much it would occur. Most closed routes brush in quickly and are unusable because of the high productivity of vegetation growth on the national forests.

Airplane and Helicopter Use

Grizzly bears have been reported to be displaced by fixed wing aircraft and helicopter use (McLellan and Shackleton 1989b, McLellan and Shackleton 1989a). These studies used radio telemetry to evaluate response of grizzly bears to various human related disturbance activities and describe displacement of bears in response to recurrent helicopter and fixed wing aircraft uses. McLellan and Shackleton (1989b) describe displacement of grizzly bears from recuring flights in support of seismic activities. McLellan and Shackleton (1989a) showed displacement by grizzly bears in response to aircraft flights was farther when bears were in open habitat and the flight was less than 150 m (164 yards) away. Thus, helicopter and fixed wing flights can displace grizzly bears, especially when the flights are recurring or within close proximity.

The Forest Service does not have authority over whether aircraft can fly over National Forest System lands. Instead, the Forest Service has discretion and authority over whether aircraft interact with the ground such as when they land or take off from National Forest System lands, or when they drop or retrieve passengers or objects on National Forest System lands. Helicopters are used by the Forest Service and other agencies for emergency or administrative uses in some situations as explained below. The Nez

Perce-Clearwater National Forest has some ongoing aircraft and helicopter use currently for administrative purposes and this activity will continue under the Preferred Alternative.

The Nez Perce-Clearwater National Forest has seven designated airstrips. Public airstrips on the Nez Perce-Clearwater are considered infrastructure and are a segment of the transportation system. The seven airstrips on the Nez Perce-Clearwater are available for public use and are located in the following locations: Cayuse at Cayuse Creek in the North Fork Clearwater drainage, Dixie at Dixie Guard Station, Fish Lake in the Lake Creek drainage of the Lochsa River, Moose Creek along the Selway River at Moose Creek Guard Station, Orogrande along Crooked River, Shear Airstrip along the Selway River at Shear Guard Station, and Wilson Bar along the Salmon River. The Fish Lake, Moose Creek, and Shear airstrips are located within the Selway-Bitterroot Wilderness and are managed as wilderness airstrips. Wilson Bar is managed as a Wild and Scenic River airstrip. Landing airplanes by the public can only happen at the designated airstrips and is not allowed otherwise. Helicopters used by the public may also land at the seven designated airstrips.

The backcountry airstrips are valuable recreational infrastructure, and the 2012 Planning Rule requires consideration of air and recreational aviation uses. Members of the public may use the public backcountry airstrips without restrictions and this ongoing use will continue after the revised Forest Plan is finalized. Thus, they can be used by anyone including Forest Service administrative use, state agencies like Idaho Department of Fish and Game, private planes, or air transport shuttle companies. Under the existing condition, the airstrip at Moose Creek in the Selway Bitterroot Wilderness is limited to 800 visitors annually, which was established by the Selway Bitterroot Wilderness Plan, though the limit has not been reached in any year. The Nez Perce-Clearwater National Forest has not tracked airstrip use beyond monitoring the number landings at the Moose Creek airstrip. While use has been considered low, the use is growing with private plane landings. Airstrips encompass a relatively small footprint compared to roads and trails, usually around 2,500 feet by 75 feet. They are usually located in a relatively flat natural meadow. Backcountry airstrips are often maintained by pilot communities through the Forest Services' Volunteer program.

The Central Idaho Wilderness Act allowed continued use of backcountry airstrips and landing of aircraft within the Selway-Bitterroot and Frank Church-River of No Return Wilderness as follows:

“the landing of aircraft, where this use has become established prior to the date of enactment of this Act shall be permitted to continue subject to such restrictions as the Secretary deems desirable: Provided, That the Secretary shall not permanently close or render unserviceable any aircraft landing strip in regular use on national forest lands on the date of enactment of this Act for reasons other than extreme danger to aircraft, and in any case not without the express written concurrence of the agency of the State of Idaho charged with evaluating the safety of backcountry airstrips landing of aircraft within a designated unit.”

With the exception of backcountry airstrips, landing aircraft in designated wilderness areas is prohibited by the Wilderness Act. Use of these backcountry airstrips is retained in the revised Forest Plan consistent with the Central Idaho Wilderness Act.

Helicopters and fixed wing aircraft are commonly used in firefighting activities and prescribed burning. Aircraft and helicopter use associated with firefighting include surveillance, reconnaissance of new fires, to moving people to or away from fires, and to drop fire suppressing agents such as water or fire retardant. Helicopter and aircraft use during suppression activities do not require prior authorization.

During prescribed burning activities, helicopter and aircraft are used to ignite, monitor, and to maintain control of prescribed fire. These types of projects are authorized after a site-specific environmental analysis including Endangered Species Act consultation.

There have been some cases where requests have been made to allow landings in wilderness for scientific and research purposes. A minimum requirements analysis is required by law whenever land managers are considering a use prohibited by Section 4(c) of the Wilderness Act of 1964. These have been evaluated and authorized on a case-by-case basis after site specific analysis.

The Idaho Department of Fish and Game uses helicopters and fixed wing aircraft in their wildlife management and research activities. Wildlife management activities include areal wildlife surveys and sometimes use helicopters in the capture, radio collaring, relocation, or reduction of animals. Future activities related to aircraft use could also include research or monitoring of grizzly bears. These activities sometimes require landing helicopters or aircraft on national forest lands. They generally require coordination with the Forest Service in these activities outside of wilderness and require authorization within wilderness.

Some vegetation management is conducted through aerial harvest systems, utilizing helicopters. Aerial harvest is often desirable to avoid unacceptable resource damage such as the creation of new roads or to access timber not otherwise accessible. However, aerial methods of harvest are more expensive than other harvest types. Harvest using aerial methods are a relatively common practice on the Nez Perce-Clearwater National Forest. Like other actions, projects proposing aerial harvest systems for vegetation management are evaluated and authorized on a case-by-case basis as part of a project National Environmental Policy Act analysis and also undergo Endangered Species Act consultation.

Forests in other areas have had helicopters used in seismic exploration for oil and gas minerals. This type of exploration is not likely to occur on this forest because the area is considered to have low potential for oil and gas. These types of projects are required to undergo site specific environmental analysis and Endangered Species Act consultation as well prior to authorization.

The Revised Forest Plan will not make any decisions to authorize, nor close, aircraft use and does not make decisions to authorize nor close backcountry airstrips. Instead, the Preferred Alternative will provide plan components to guide future authorization of aircraft and helicopter use. Decisions on the establishment, maintenance, reauthorization or closing of backcountry airstrips, would require site specific environmental analysis and consultation and must comply with the Forest Plan. Plan direction governing aircraft use and the effects of that plan direction are described below in the effects to the Effects of Airplane and Helicopter Use section.

Winter Motorized Use

For winter motorized travel, the entire forest was open to winter motorized uses unless closed by a travel management decision. The Clearwater Travel Plan, and closures in designated wilderness, are examples of travel management decisions the established closures. While the national forest used the recreation opportunity spectrum settings to guide the recreation opportunities users could expect to experience, it was not used to identify areas where motorized uses were suitable.

Currently, motorized over-snow recreation is allowed nearly forestwide except in recommended wilderness areas and designated wilderness areas. Prior to the Clearwater Travel Plan Decision, recommended wilderness areas were open to over-snow motorized travel. The Clearwater Travel Plan closed recommended wilderness areas to over-snow motorized recreation.

Recreation Sites

There are several developed and dispersed recreation sites on the Nez Perce-Clearwater National Forest, some of which grizzly bears may travel through the national forest in route to the Bitterroot Recovery Zone. Of particular note are the campgrounds along the North Fork of the Clearwater and the Lochsa corridor. The plan area hosts 55 developed campgrounds, 53 dispersed camping facilities, 12 picnic sites, 16 lookouts or cabins, and 40 trailhead facilities. There are 121 miles of motorcycle trails, 1,018 miles of trails for vehicles less than 50-feet, and 63 miles of trails for vehicles larger than 50-feet. There are a total of 15 miles of bike trails, 3,211 miles of pack trails, and 15 miles of hiking only trails. There are 1,241 non-developed dispersed overnight sites and 109 dispersed trailheads. The majority of recreation use on the Nez Perce-Clearwater occurs in primitive dispersed sites rather than developed facilities. These recreation sites might attract grizzly bears and are potential sites for conflict. The national forest does not yet have a food storage order in place and lacks facilities to provide the public with bear safe storage. Many campgrounds need upgrades to refuse storage or new bear resistant dumpsters. Most developed sites are located within Management Area 3. To this point, there has not been an incident at a recreation site of a grizzly bear-human conflict. The Forest Service often posts signs to educate the public at recreation facilities recommending bear safety measures.

In the event that grizzly bears become established, a number of actions would be conducted by the Forest Service in partnership with the Interagency Grizzly Bear Subcommittee for the Bitterroot Ecosystem along with the Idaho Department of Fish and Game, the Nez Perce Tribe, and the U.S. Fish and Wildlife Service among others to take an adaptive approach to respond to the presence of grizzly bears. Among possible actions include a special forest order implementing a food storage order, installation of infrastructure for bear safety, a public outreach and education program, and coordination on bear-human conflict interventions as appropriate.

Northern Rockies Lynx Direction

The Northern Rockies Lynx Management Direction (NRLMD) is a Forest Plan amendment that amended 18 Forest Plans across the western United States for the conservation of the federally threatened Canada lynx. On March 23, 2007, the U.S. Fish and Wildlife Service issued a biological opinion and incidental take statement on the effects of the NRLMD on the Distinct Population Segment of Canada lynx (lynx) in the contiguous United States (U.S. Department of Agriculture 2007f), in accordance with Section 7 of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 et seq.). The NRLMD provides direction primarily for lynx habitat management to avoid or reduce the potential for projects proposed under Forest Plans to adversely affect lynx. The NRLMD indirectly conserves habitat for grizzly bear by promoting and conserving the habitat conditions needed to produce snowshoe hare (lynx primary prey) densities that are adequate to sustain lynx within their home ranges, and thus sustain lynx populations and promote recovery of lynx. Snowshoe hare habitat includes forested areas with multi-story characteristics which may provide cover for grizzly bears and restrictions on alteration of multi-story snowshoe hare habitat within the NRLMD constrains management of forests with these features. Implementation of the NRLMD will continue as planned under the revised Forest Plan via a plan standard which incorporates the NRLMD into the plan in its entirety.

Secure Habitat

Secure habitat is a key indicator for this analysis. As discussed above, this analysis adopted the definition of secure habitat from the Greater Yellowstone Ecosystem. We combined the road and motorized trails datasets into one dataset of motorized route, meaning both road and motorized trails. From that dataset, we then identified any motorized routes as “open motorized routes” that were either open, open seasonally, or open to administrative uses but closed to the public. Any roads or motorized trails that were closed permanently to all users were not included. We used ArcGIS to buffer any open motorized routes by a distance of 0.31 miles, then included areas outside of that buffer as secure habitat. In other words, we identified secure habitat as any lands outside of the 0.31-mile buffer distance from an open motorized route. While every attempt was made to include all road and trail features and accurately represent them, some inaccuracies or accidental omissions are possible in the data. This analysis did not include calculations or buffers of roads outside of National Forest System lands nor did we buffer the Forest Service Boundary in the calculation of secure habitats. Thus, some areas of secure habitat may be impacted by roads and trails outside National Forest System lands. However, Figure 108 in the cumulative effects section below shows that the Nez Perce-Clearwater National Forest is surrounded on three sides by other Forest Service lands. Lands along the western boundary are composed of a mix of private, state, tribal and industrial forest lands. However, there is little secure habitat on the national forest's western boundary because of existing forest roads. Thus, only limited amounts of secure habitat are impacted by roads outside of National Forest System lands.

For the Greater Yellowstone Ecosystem, secure habitat has been defined as any contiguous area greater than 10 acres that is greater than 0.31 miles from an open or gated motorized access route (road or trail) or recurring low level helicopter line during the non-denning period of March 1 through November 30 (Interagency Grizzly Bear Committee 1998 (Interagency Grizzly Bear Committee (IGBC) 1998, Interagency Conservation Strategy Team 2007). CFR 50 part 17 indicates that this size was selected for the Greater Yellowstone Ecosystem because the Interagency Grizzly Bear Study Team and Yellowstone Ecosystem Subcommittee concluded that all secure habitats are important for grizzly bears, regardless of size, particularly in peripheral areas. There is no scientifically based minimum secure habitat size based on statistically repeatable use-availability analysis for reproductive females for any of the currently occupied recovery zones. No current research on grizzly bear habitat use exists for the Bitterroot Ecosystem to inform a minimum size patch of secure habitat. While larger, less fragmented patches of secure habitat are likely better for a grizzly bear, even a small patch of secure habitat may afford a grizzly bear a valuable space to avoid the effects of motorized routes and to move through or find valuable habitat in the area, and thus may be important for connectivity. This is the definition that was adopted for use in this analysis, though unlike in the Greater Yellowstone Ecosystem, there are no associated requirements in the plan associated with this definition because there are no resident bears in the Bitterroot Recovery Zone. Its use is only for analysis purposes and was selected because secure habitats of any size probably contribute to grizzly bear ecology. However, recognizing that larger secure areas probably have more value to grizzly bears, we report the amount of secure habitat larger than 1,280 acres consistent with findings of Wakkinen and Kasworm (1997) that suggested that areas this size and larger were used more by grizzly bears than smaller blocks.

Secure habitat was evaluated spatially by identifying how much secure habitat would overlap with the land allocations and the suitability of various uses. Land allocations and their associated suitability of uses dictate where future activities have the potential to impact ecological conditions for grizzly bears. Where impactful activities are suitable, there is a higher potential for impacts. However, where activities are not suitable, there is low or no potential for impacts from those activities. Therefore, the land allocations explicitly control future potential impacts. For example, the amount of secure habitat that could potentially be affected by motorized uses are dictated by the distribution of lands where that activity is suitable. The potential future impact of timber activities, and associated roads, are dictated by the lands where that activity is suitability. There is virtually no potential for impact from timber or motorized uses within lands where that activity is not suitable. Even if an activity is suitable, it only means that this activity has potential to occur but does not mean that it will occur, even where it is suitable. Land allocations and their associated suitability affect potential future impacts to secure habitat include Management Area allocation, Designated wilderness, recommended wilderness, Idaho Roadless Rule areas, Recreation Opportunity Spectrum (ROS) settings, timber suitability, designated wild and scenic rivers, eligible and suitable wild and scenic rivers, the National Historic Landmark, and research natural areas. Each of these land allocations find various uses either suitable or not suitable to various extents, and thus dictate whether there is potential or no potential for effects from each activity. The suitability for each land allocation and the suitability of different activities are discussed in various sections below. While these delineations do not affect grizzly bears directly, they would dictate the broad direction in the plan that would apply to these areas and the types of activities allowed or disallowed. Land allocations and suitabilities could lead to either potential for future impacts in some cases or protections for grizzly bears in other cases. While activities that could affect grizzly bear habitat could occur in suitable areas, where, when, or how much of these activities is not yet known. In the event future activities are proposed under the plan, there would be a site-specific analysis, decision, and consultation with the U.S. Fish and Wildlife Service before implementation. The effects of these suitability plan components are analyzed below by evaluating the total area where these activities are suitable and describing the amounts of secure habitat that overlaps lands where various activities are either suitable or not in the plan based on land allocations.

Secure habitats were calculated by buffering all roads and motorized trails by 0.31 miles open to the public or closed to the public but open to administrative uses, and then included any areas that were within the Forest Service control, but outside of the road and motorize trail buffer as secure habitat. The secure habitat forestwide is shown in Figure 97. Secure habitats were then analyzed as to how they overlap spatially with the Preferred Alternative in the revised Forest Plan. The amount of secure habitat within various decisions in the plan were calculated using ArcGIS. Examples included the amounts and percentages of secure habitat within recommended wilderness, recreation opportunity spectrum, timber suitability, and the management areas. ArcGIS was used to calculate these amounts by using the identity tool in that software, repairing geometry, and then calculating acres.

We used the best available data when calculating secure habitat including the road data and the motorized trail data. To calculate secure habitat, we updated our spatial road and motorized trails data with all the known closures and added any routes that were known. Updating the motorized route data was a process that took approximately six months of full time GIS work to complete. This included updating any closures, road status, alignment, or other known discrepancies in the data. However, despite this extensive effort, it is still probable that there are cases where the road or motorized trail alignment is different on the ground than in the data. In some cases, some segments of road or motorized trail may extend farther on the ground than is represented in the data. There may be some user created features that are used by the public that are not reflected in the data. In some cases, these are unauthorized or illegal uses of motorized vehicles. Illegal uses are corrected on the ground as soon as they are known via signs or physical barriers. It should be noted that we believe that, despite the discrepancies, the methods used here in this analysis underestimates the amount of secure habitat on the ground because many of the administrative roads are in storage to be used at a future date but are not actually drivable currently. Maintenance of motorized road and trail data is an ongoing activity of the Forest Service and is continually updated to be as accurate as possible. Correcting the data to fix all errors would take a lot of time ground truthing and editing the data. It should be expected that the data will continue to be updated in the future to address any discrepancies and accurately reflect the amount of secure habitat. Additionally, the second tier of this programmatic consultation framework would provide us an opportunity to continue to update in the future via site specific consultations where appropriate.

In total there are about 2,463,079 acres of secure habitat larger than 10 acres, with the majority of it within the Idaho Roadless Rule areas, wilderness areas, and recommended wilderness areas. The forestwide total acres of secure habitat make up about 63 percent of the Nez Perce-Clearwater land base with about 37 percent not secure. Areas of secure habitat range in size from contiguous blocks of approximately 10 acres up to 1,103,922 acres, with the largest block centered in the Selway Bitterroot Wilderness area. There are 12 blocks of secure habitat that are larger than 5,000 acres but smaller than 10,000 acres and 26 that have greater than 10,000 acres each. The largest blocks of secure habitat are within designated wilderness and recommended wilderness. Most of the larger sized blocks outside of Designated wilderness are within Idaho Roadless Rule Areas within the Clearwater National Forest. The plan area contains 84 blocks and a total of 2,380,232 acres of secure habitat larger than 1,280 acres reported to compare to findings from Wakkinen and Kasworm (1997) that suggested grizzly bears preferred secure habitats this size and larger. Thus, 96.6 percent of secure habitat in the plan area are in blocks larger than 1,280 acres.

It should be noted that in our calculation of secure habitat, we excluded areas as secure habitat where we have roads closed to the public but open to administrative uses. Administrative roads were included in the secure habitat buffer analysis and therefore excluded from the calculation of secure habitat. On the ground they could be secure habitats for grizzly bears. We excluded these features from secure habitat to account for any potential effects from these features but in reality, the on-the-ground situation is that these roads are probably not usable in many cases. Roads closed to the public but open to administrative uses are in what are termed basic custodial care and are not typically drivable because vegetation grows on them, the culverts are pulled, and they often have barriers that prevent use. They are retained as roads in the databases so that future timber management could be performed without having to reconstruct road prisms in the event they are needed for future uses. The spatial data the Nez Perce-Clearwater has for these features does not have information about their usability, nor whether they are being used by the public, so they were buffered and excluded as secure habitat as a precaution. Calculations without administrative roads counting against secure habitat results in an estimate of secure habitat of 2,721,604 or about an additional 258,525 acres more of secure habitat compared to estimates where administrative roads are accounted. In all analysis below, areas with administrative roads were excluded as secure habitat.

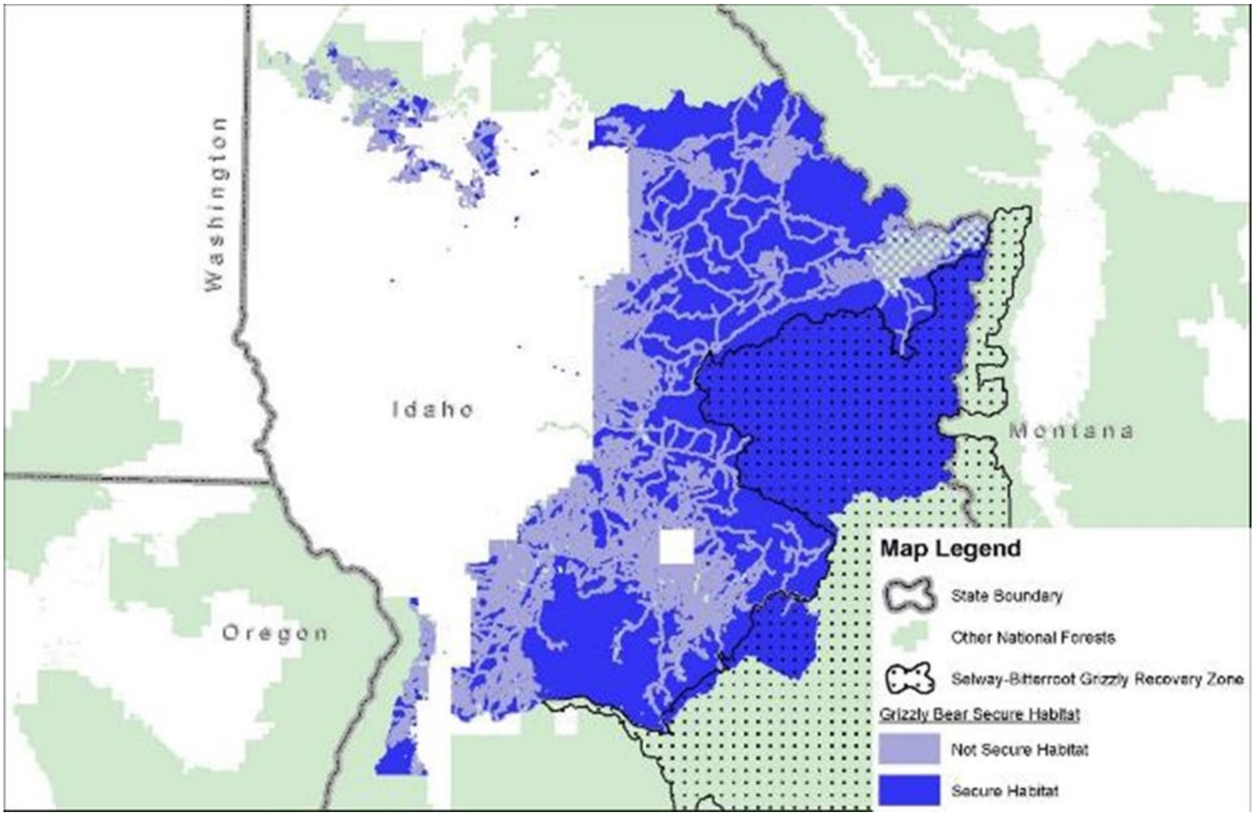

Figure 97. Secure habitat on the Nez Perce-Clearwater National Forest shown in dark blue, while areas in light blue are not secure due to roads or motorized trails open to the public and roads closed to the public but open for administrative use

It should be noted that many roads on the Nez Perce-Clearwater National Forest are open only part of the year and closed seasonally to reduce elk vulnerability during fall hunting season. Many roads are closed to motorized travel at the start of hunting seasons or at various times in the fall and remain closed until spring. They are typically gated, and the gates are closed and locked in the fall or late summer on specified dates. When calculating secure habitat, we considered roads as not secure if they were open to motorized uses at any time of the year and did not account for roads that are closed seasonally. In reality, seasonal closures potentially increase the amount of secure habitat at least temporarily.

The scale and units at which to evaluate secure habitat was carefully considered. Watersheds were used as the unit because these provide a consistent unit delineated by landscape features and are used broadly in natural resource management by many natural resource disciplines. They form discrete units that must fall within a range of sizes. The plan used HUC 10 or 5th code watersheds as the scale at which to evaluate secure habitat because this is the size of watershed most consistent with the size of female home ranges. HUC 12 or 6th level HUCs range in size from 10,000 acres to 40,000 acres and are too small generally to replicate female home range sizes. HUC 10 watersheds range in size between 40,000 and 250,000 acres (62 to 390 square miles). In comparison, as described above average female home ranges range from 30,720 to 101,760 acres (48 to 159 square miles) (Mace and Waller 1997, Aune and Kasworm 1989b, Blanchard and Knight 1991, Mace and Roberts 2011, Kasworm et al. 2022, Kasworm et al. 2021).

The amount and percent of secure habitat within HUC 10 (5th level) watersheds is shown in Table 254. HUC 10s range from 40,000 to 250,000 acres so they overlap the range of female home range in size. However, the calculations in Table 258 only included portions of the watersheds within the Nez Perce-

Clearwater boundaries, therefore some watersheds are only partially in the plan area, so some of them may be smaller than a female home range (Table 258). The data in Table 254 below only reflects the area and percent of secure habitat within watersheds and within the Forest Planning Area. Six watersheds that extend outside of the plan area boundaries fall within adjacent National Forest System lands. Assuming that a minimum female home range is 32,000 acres, 47 out of 63 or 74.6 percent of HUC 10 watersheds have enough secure habitat inside the planning area to provide for at least one female home range.

Table 254. The amount and percent of secure habitat within HUC 10 (5th level) watersheds. The calculation only includes lands administered by the Nez Perce-Clearwater National Forest. The asterisks indicate watersheds that extend outside of Nez Perce-Clearwater lands.

Figure 98 shows a visual representation of the percent of secure habitat within each watershed. The watersheds are colored to show secure habitat amount of between 0 and 25 percent secure habitat, 25 to 50 percent secure habitat, 50 to 75 percent secure habitat, and 75 to 100 percent secure habitat. It is assumed that higher percentages of secure habitat would provide for better connectivity for dispersing bears.

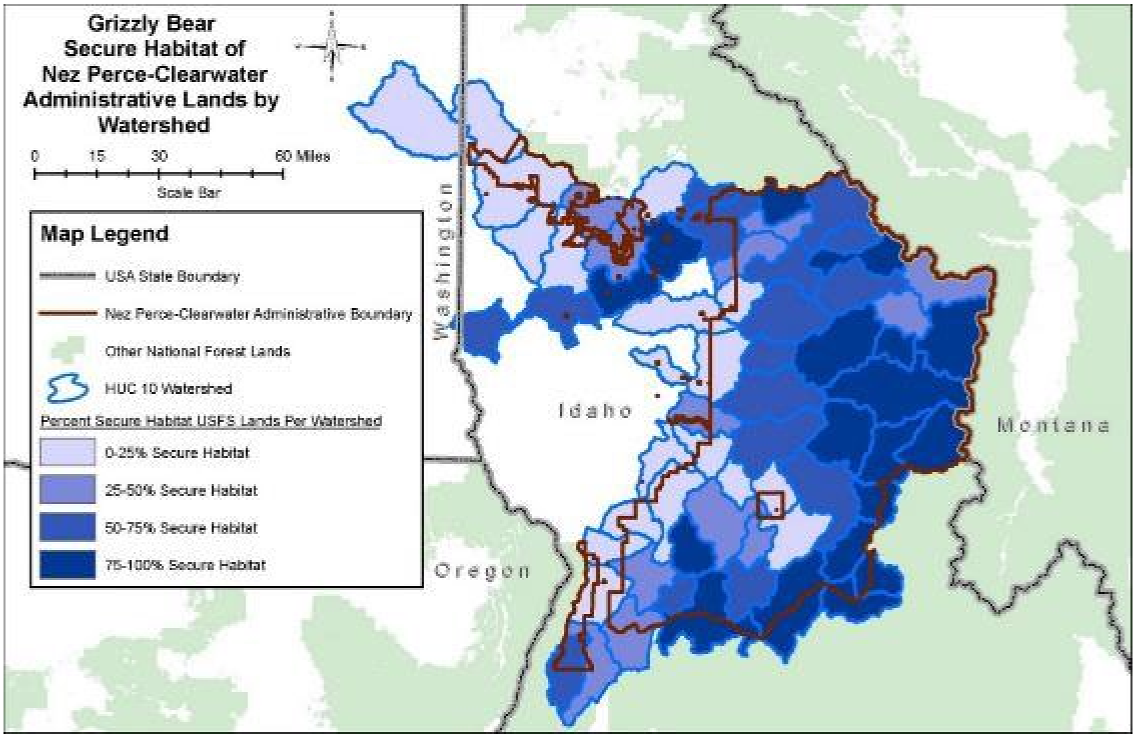

Figure 98.The amount of secure habitat by HUC 10 watershed broken out into four categories by percentage of secure habitat within the watershed. Categories include watersheds with between 0-25 percent secure habitat, 25-50 percent secure habitat, 50-75 percent secure habitat, and 75-100 percent secure habitat

Connectivity

Habitat connectivity is widely recognized as a crucial component for maintaining plant and animal diversity and managing for sustainable populations of native species (Western Governor's Association 2008, Hansen 2009, McIntyre and Ellis 2011, Cushman and Landguth 2012, Parks et al. 2012, Haber and Nelson 2015, Wade et al. 2015, McClure et al. 2016). There are two primary requirements for habitat connectivity. The first is that suitable habitats are present for species of interest, and the second is that landscapes are permeable to wildlife movement. Long-range dispersal movements may contribute to gene flow between populations, genetic rescue of small or isolated populations, and colonization of new areas (Parks et al. 2012). Habitat connectivity is crucial to the establishment of grizzly bears in the Bitterroot Recovery Zone and could contribute to genetic interchange and demographic support between occupied grizzly bear recovery zones.

The Species Status Assessment (U.S. Department of the Interior 2021c) states that connectivity is important to grizzly bear recovery and identified connectivity as an important demographic need and one of the six demographic factors important to resiliency. It identifies two types of connectivity important grizzly bear populations in the recovery zones, demographic, and genetic connectivity. For genetic connectivity, long distance dispersal by males enables immigrants to act as a counter to genetic fragmentation and loss of nuclear genetic diversity for example within the Greater Yellowstone Ecosystem. Male and female movements within and between ecosystems can enhance genetic diversity and reduce genetic fragmentation. Females tend to be the focus of demographic connectivity because they are necessary for reproduction. Female dispersal is gradual (McLellan and Hovey 2001b), usually significantly shorter than males (McLellan and Hovey 2001b, Proctor et al. 2004), and holds the potential for small population augmentation or demographic rescue through their ability to bear offspring post-immigration into small isolated populations. Female grizzly bear dispersal patterns suggest that to enhance or re-establish female connectivity, female occupancy of linkage areas is necessary to facilitate inter-generational connectivity (U.S. Department of the Interior 2021a).

Efforts have been made to evaluate and model grizzly bear connectivity across the different ecosystems in the lower 48 states and Canada(Craighead and Olenicki 2005), (Walker and Craighead 1997, Servheen, Shoemaker, and Lawrence 2003, Proctor et al. 2012, Proctor et al. 2015, Peck et al. 2017). While their methods to model habitat connectivity differed, these studies all identified roads or human developments as factors that affect connectivity. Highways in particular have been identified as restraints to grizzly bear dispersal (Peck et al. 2017, Proctor et al. 2005, Proctor et al. 2015, Kasworm et al. 2021, Servheen, Waller, and Sandstrom 2003). Features related to connectivity appear to be related to highways and developments outside of the Nez Perce-Clearwater National Forest. The best study to date was published by Sells (2023), which used grizzly bear movements from radio collared grizzly bears to identify preferred features used for travel, then extrapolated the results to a wide area that encompassed the Greater Yellowstone Ecosystem (GYE), the Cabinet-Yaak Ecosystem (CYE), and the Northern Continental Divide Ecosystem (NCDE), and the Bitterroot Ecosystem. Not surprisingly, the model shows that the plan area appeared to provide good connectivity within the North Fork Clearwater area and the Selway-Bitterroot Wilderness Area. Areas appearing important to grizzly bear connectivity include a route south of Hamilton through the Bitterroot National Forest, the Lolo Pass Area, the Hoodoo recommended wilderness, and the Mallard Larkin recommended wilderness area.

The most significant barriers to connectivity are outside the planning area and include the I-90 corridor, Montana Highway 200, and Montana Highway 93 and associated human development. I-90 appears to be a barrier between the Bitterroot Ecosystem and the NCDE, the CYE, and Selkirk Ecosystems. Servheen (2003) predicted several linkage areas through these developed areas into the Bitterroot Ecosystem. Passage of bears through these linkage areas may dictate where bears enter the Nez Perce-Clearwater and the Bitterroot Ecosystem to some extent.

Most fragmentation between the NCDE and Bitterroot Ecosystems occurs along the I-90 corridor between Missoula, Montana and Superior, Montana and along U.S. Highway 93 north of Missoula from Evaro Hill to Ravalli Hill. Missoula is a rapidly growing city and suburban development has been rapidly spreading west and north along these major highway corridors. Some connectivity areas were available between Alberton, Montana and Superior, Montana; between Superior, Montana and St. Regis, Montana; and northwest of St. Regis (Servheen, Waller, and Sandstrom 2003). Bears traveling through these linkage areas would most likely enter the Nez Perce-Clearwater through the Hoodoo or Mallard Larkin areas. The area between Lolo, Montana and Lolo Hot Springs along U.S. Highway 12 is well connected. Bears traveling through this area would have little trouble passing into the plan area and would do so near Lolo Pass.

Servheen (2003) did not evaluate connectivity south of Lolo, Montana. The spread of the NCDE population southward may enable this area to serve as a path through which bears may disperse. Bears dispersing through this area would also face significant barriers through Highway 93 and associated development into the Bitterroot Ecosystem area. However, if they made it through these areas, bears would have would enter into the Bitterroot National Forest and have passage into and through the Nez Perce-Clearwater National Forest to the Bitterroot Recovery Zone.

Large portions of the plan area appear to be well connected currently (Figure 99). For example, if it is assumed that large areas with high amounts of secure habitat in proximity to each other are used more by grizzly bears and would facilitate grizzly bear dispersal, then areas with these characteristics would facilitate connectivity. Based on these assumptions, Figure 99 visually displays secure habitats greater than 1,280 acres as the basis for potential pathways of secure habitat through the Nez Perce-Clearwater, wherein a grizzly bear could disperse through to the Bitterroot Recovery Zone under existing conditions. This is of course assuming that lands without roads (secure habitat) would provide more permeable habitat to provide potential passage of grizzly bears. Grizzly bears can pass through non-secure habitat as has been documented here with Bear 927 passing through the area with checkerboard ownership near Lolo pass, which has higher road densities.

Some of these areas were identified in the Preferred Alternative as non-motorized, in part to provide connectivity for grizzly bears. Areas identified as non-motorized for grizzly bear connectivity are displayed in Figure 99 below in the Recreation Opportunity Spectrum Setting section.

All federally managed lands generally provide protection from permanent residential and urban development. Grizzly bears may be able to pass through Forest Service lands in areas with higher road densities as well because roads are typically backcountry roads with lower traffic volumes and lower travel speeds. While backcountry roads perhaps are not as good for bears as un-roaded areas, they are likely more permeable than highways. Bear 927 for example, crossed through and spent time within the Lolo pass checkerboard area on his way to the Bitterroot Recovery Zone. The Grizzly Bear Recovery Program 2020 Annual Report showed a map of Bear 927's path and areas of use, which showed use of the Lolo Pass and nearby checkerboard ownership area. Grizzly bear 927 also passed between these areas, which have higher road densities and less secure habitat but perhaps is still relatively permeable.

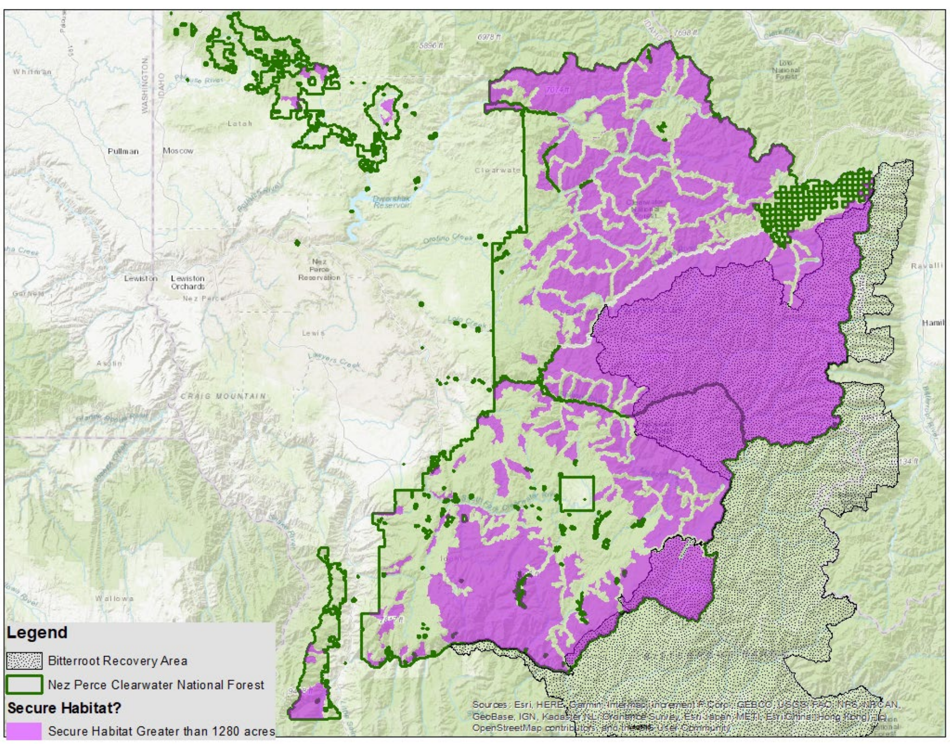

Figure 99. Secure habitat greater than 1,280 acres in size shown in purple that hypothetically provide permeable habitat that could provide for potential connectivity for grizzly bears. This graphic provides a rough visual representation of relative connectivity into the Bitterroot Recovery Zone based on the assumption that secure habitats larger than 1,280 acres in proximity would facilitate grizzly bear use and dispersal.

Some areas of multiple use management may be important for connectivity because of their location. Some are located where grizzly bears have a higher likelihood of encountering on their way into the

Bitterroot Recovery Zone. Specific examples include the checkerboard ownership areas near Lolo Pass, and two areas of Management Area 3 in the Kelly Creek Area in the North Fork Clearwater Area (Figure 99). Dispersing bears entering the Nez Perce-Clearwater from the north or east could encounter these areas. These areas have existing conditions that could potentially lead to human-bear conflicts because of higher road density and more human uses. Bear 927 used the checkerboard area near Lolo Pass (that is, mixed private and Forest Service landownership in a checkerboard pattern) and passed through the secure habitat between the multiple use areas near Kelly Creek. The grizzly in 2007 was accidentally killed near the Kelly Creek area. It is possible that grizzly bears could navigate around or through these areas when establishing new home ranges or passing through as Bear 927 did.

Rangeland Management and Grazing

Livestock grazing occurs through a permit system on Nez Perce-Clearwater lands. Table 377, Table 378, Table 379, and Table 380 in the Range Section below describe current grazing allotments, acres and types animals grazed on the Nez Perce Clearwater National Forest. (). Grazing allotments generally occur in areas of low amounts of secure habitat. They are arranged away from areas where grizzly bears might be expected to cross the Nez Perce-Clearwater and away from the Bitterroot Recovery Zone. Only one vacant cattle allotment overlaps with approximately 380 acres of the Frank Church-River of No Return Wilderness area. No new grazing allotments would occur within the Selway Bitterroot and Frank Church-River of No Return Wilderness because language in the Central Idaho Wilderness specifies that only allotments in place before 1980 would be allowed to continue (Central Idaho Wilderness Act 1980). While livestock grazing on the national forest is distributed mostly outside of the recovery zone, there are livestock allotments currently operating on the national forest where grizzly bears may possibly find them simply because grizzly bears are such wide-ranging animals that it is not discountable that they would probably encounter livestock at some point. If a grizzly bear were to encounter livestock, there could be livestock loss which might lead to human-bear conflict. Such conflicts between grizzly bears and domestic livestock can result in the capture, relocation, injury, or removal of grizzly bears. The revised Forest Plan will not authorize nor close grazing allotments. The plan only identifies where grazing is suitable or not. Instead, it would guide where, and how grazing would be managed. New authorizations or re-authorizations would occur after site-specific analysis and undergo Endangered Species Act consultation.

Grizzly bears are more prone to come into conflict with sheep grazing. In the Preferred Alternative, the only sheep allotment currently in the plan area would be found unsuitable under the Preferred Alternative. There are currently no active sheep allotments in the plan area. It is assumed that additional sheep grazing is unlikely under the revised Forest Plan in the future. Existing allotments are cattle allotments which have a lower probability of grizzly bear conflicts, but conflicts are still possible. There have been no documented grizzly bear mortalities associated with livestock that have occurred in the action area since their extirpation circa the 1930s.

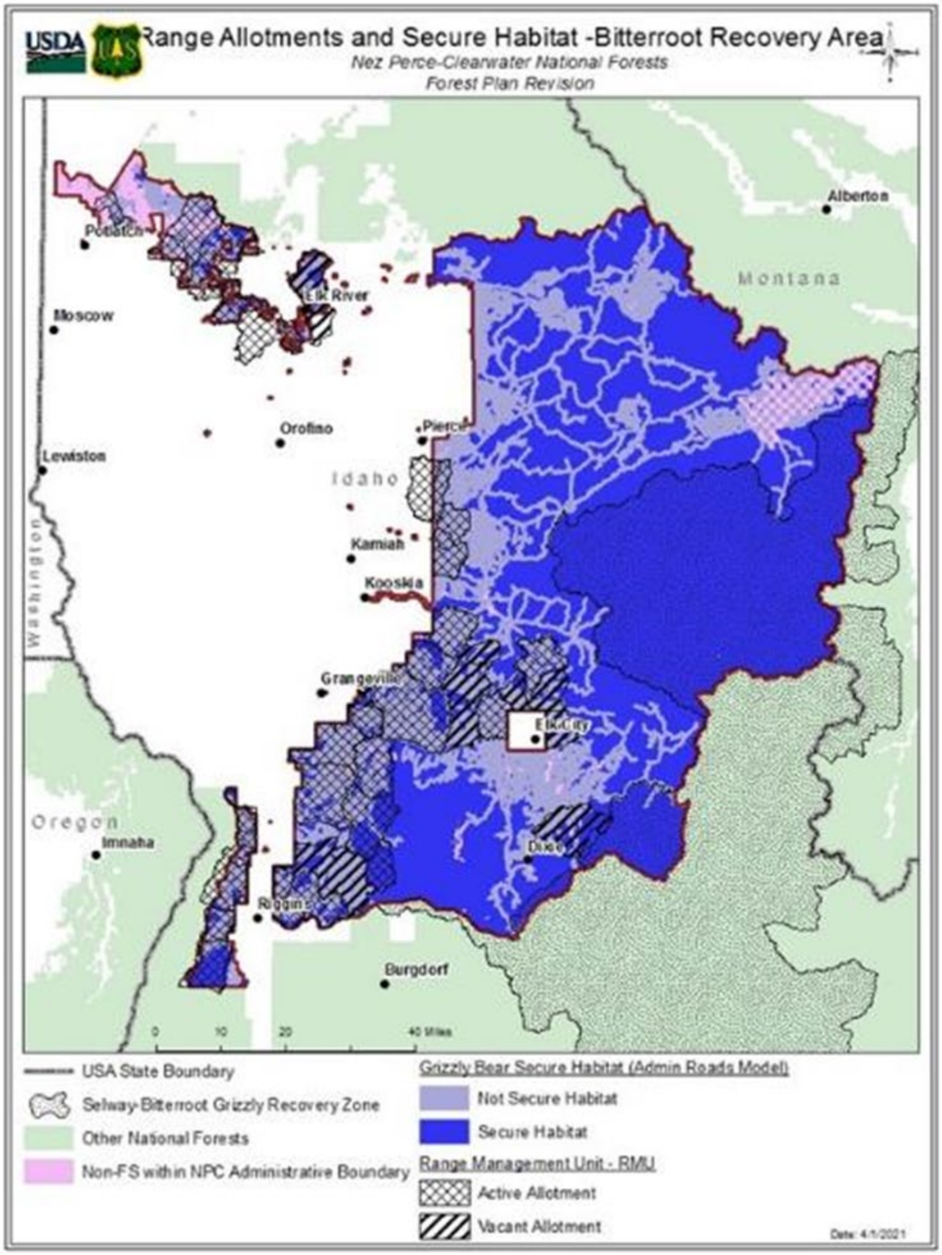

Figure 100. Range allotments in relation to the Bitterroot Recovery Zone and secure habitats

Vegetation Management

Vegetation management is an ongoing activity within the Nez Perce-Clearwater currently and will continue after the revised Forest Plan is revised. Vegetation management as considered here includes timber harvest, timber production, prescribed fire and fuels reduction, habitat restoration, forest restoration, and planting. The trend in vegetation management has changed through the decades in response to demand, capacity, and regulatory constraints. Table 255 shows the acres of harvest, prescribed fire, and fuels reductions since 1987.

Table 255. Vegetation management activities by type and decade from 1987 to 2018

Decade	Harvest[1] Acres	Prescribed Fire[2] Acres	Fuel Reduction[3] Acres
1987-1996	25,827	24,706	20,443
1997-2006	10,299	39,154	15,667
2007-2016	4,999	5,810	7,905
2017-2018	6,200	971	655

1 Harvest activities include even-aged, uneven-aged, and intermediate harvest treatments.

2 Includes overlap of burning in harvested stands. Prescribed fire activities include broadcast burning, jackpot burning, site preparation burning, and under burning. Wildfire acres are not included; see the Fire Management section for information on past wildfires, including those used for resource benefit.

3 Fuel reduction treatments include burning of piled material, chipping of fuels, compacting/crushing of fuels, fuel break, miscellaneous treatment of natural fuels, piling of fuels, rearrangement of fuels, and thinning for hazardous fuels reduction.

Data Source: FACTS database, acres completed by fiscal year up to September of 2018

Vegetation conditions within the Nez Perce-Clearwater National Forest are departed from historic conditions in some important ways. First, white pine was more prevalent than it is today, dominating many areas within the Clearwater National Forest. White pine has decreased through a combination of mostly mortality from blister rust but also some from historic harvest practices. White pine has been replaced by growth of Douglas-fir, grand fir, or western hemlock in its stead and now exists at a fraction of its former dominance. It is unknown how the change in dominance types has altered the ecological conditions to serve as grizzly bear habitat.

Decades of fire exclusion has also changed the composition and condition of vegetation. Fire exclusion has increased forest density, favored fire intolerant tree species, and decreased forest resilience. With fire exclusion, dense understories and thickets of conifers have produced stands that are highly susceptible to a variety of insect and disease epidemics and severe wildfires. Many stands have missed a complete fire return interval and are now considered departed from the historical or reference conditions. It is unknown what effect, if any, this would have on grizzly bears, once they re-establish in the plan area.

Whitebark pine is another species affected by blister rust and has declined in abundance. Whitebark pine is known to have provided mast thought important for grizzly bear nutrition. The loss of whitebark pine has potentially reduced a food source for grizzly bears. Ongoing restoration efforts have been made to restore whitebark and white pine. See the Whitebark Pine section of this document for more information.

The 1987 Forest Plans projected high timber outputs. For example, the Nez Perce Plan identified an allowable sale quantity of 108 million board feet in the first decade and which increased to 210 million board feet between 2018 and 2027. The Clearwater Plan identified a yearly timber volume of 173 million board feet per year. Despite these projections, the existing amount of timber production is the acreage conducted annually under the 1987 plans which has typically been 4,300 acres or 50 to 60 million board feet per year on both forests combined.

Most of this timber production occurs within the roaded front, while roadless rule areas receive limited timber harvest, and designated wilderness does not allow timber harvest. Even when allowed, timber harvest is limited within Idaho Roadless Rule areas. For example, the Final Environmental Impact Statement for the Idaho Roadless rule projected that less than 0.01 percent of roadless area per year of the lands managed under the Idaho Roadless Rule would be affected by timber removal or road construction in the first 15-years. For the nearly 1,500,000 acres of roadless areas on the Nez Perce-Clearwater, this would total 1,500 acres over the 15-year period, or approximately 100 acres per year (U.S. Department of Agriculture 2008e). Per the Idaho Roadless Rule, timber harvest activities must be conducted from existing roads or aerial harvest systems. In the 10-year period from October 2008 to September 2018, approximately 1,800 acres statewide have been affected through community protection zone fuels reduction, constructed fuel breaks during wildfires, and removal of post-fire roadside hazard trees. Timber harvest in the Idaho Roadless Rule areas usually must occur from existing roads. This trend and rate of timber harvest in Idaho Roadless Rule areas is expected to continue.

The acres of total vegetation treatments under the Preferred Alternative ranges between 53,000 and 64,500 acres. These acres include prescribed fire, wildland fire use, timber production, fuels treatments, wildlife habitat enhancement, and vegetation treatments designed to restore vegetation characteristics found in the Forest Plan desired conditions. These acres include treatments that would occur forestwide.

Forests are naturally dynamic and experience periodic disturbances like wildfire, insects and disease, and regrowth. Grizzly bears evolved within these dynamic landscapes and use different successional stages to meet their nutritional needs. They use mature forest for hiding, resting, and use early seral stages to forage. Diversity in successional stages provides diverse foods, cover, denning habitat, and space for this wide-ranging species. Vegetation conditions provide a variety of coniferous forests, deciduous forests, wetland and riparian areas, and grass/forb/shrub patches found in areas such as meadows, avalanche chutes, burned areas, and logged areas. Timber harvest, wildfire, prescribed fire, and other vegetation management activities also alter the seral stage, the amount and arrangement of cover, and forage. Vegetation management can increase the quantity and quality of grizzly bear foods through increased growth of grasses, forbs, and berry-producing shrubs (Kerns et al. 2004, Zager et al. 1983).

Fifty-eight studies, published from 1983 to 2020 evaluated the effects of timber harvest on grizzly bear habitat use (Colton et al. 2021). They found that all studies reported grizzly bear use of forest cut blocks, with several reporting grizzly bear selection of cut blocks, although with substantial variation in selection across seasons and ecoregions. (Colton et al. 2021) identified seven underlying factors that influence grizzly bear responses to forest harvest including natural forest openings, cut block design, silvicultural techniques, age since harvest, grizzly bear food availability, human activity, and grizzly bear sex and age. Furthermore, they suggested that grizzly bears may frequently use forestry cut blocks when forage is present, especially if human activity is minimal and natural forest openings are limited.

Forage Resources

The plan area likely has sufficient food resources to provide for a future population of grizzly bears. The plan area contains food sources such as ungulate populations, berries, insects, mast from trees such as whitebark pine seeds, vegetation, and fish including cutthroat trout, steelhead, and salmon. Food sources have changed over the last century due to a variety of factors and will continue to change. For example, whitebark pine has experienced a decline due to blister rust. Similarly, elk populations have fluctuated over time. Elk numbers are currently lower than they were in the past two decades but are much higher than they were in the early 1900s when elk were scarce (Space 1981, Cochrell 1970). Elk were also uncommon when Lewis and Clark came over the Lolo Trail in 1805. They never killed an elk in the entire Clearwater Valley, nor do they mention having seen one (Space 1981). Fruit resources such as berries fluctuate from season to season due to weather and precipitation, but also over longer periods with forest disturbance and succession.

Big Game Hunting

The Idaho Department of Fish and Game regulates hunting and hunting practices. Big game hunting is allowed on National Forest System lands and has in other areas led to grizzly bear-human conflicts when grizzly bears are attracted to big game carcass or encountered while hunting. Schwartz et al. (2010) found that bears that spent more time in areas open to hunting had lower survival than those that spent time in areas closed to hunting. Fifty-three outfitter and guides are permitted on the Nez Perce-Clearwater. Hunting occurs on the national forest by both guided and unguided hunters for big game. The use of bait for the purpose of taking resident game on National Forest System lands is a hunting practice. Where states permit the use of bait for attracting resident game, this activity is allowed on National Forest System lands, subject to state hunting laws and regulation, unless the authorized officer determines on a site-specific basis that there is a need to prohibit or restrict the practice (FSM 2640). Bear baiting for the purpose of hunting black bears is allowed by the State of Idaho. The state also allows black bear hunting with hounds, and hunters hunt black bears during the black bear season without the use of bait or hounds. Baiting can unintentionally draw in grizzly bears as happened in 2007 where a male grizzly bear was accidentally killed by a hunter near Kelly Creek within the Nez Perce-Clearwater National Forest.

Climate Change

The Climate Change Vulnerability and Adaptation in the Northern Rocky Mountains (Halofsky, Peterson, et al. 2018a, b) is the best available science on climate change and its effects on forested ecosystems in the Northern Rockies. Halofsky et al. (2018) asserts that global climate models project that the Earth's current warming trend will continue throughout the 21st century in the Northern Rockies. The Northern Rockies Adaptation Partnership region covers 183 million acres, spanning northern Idaho, Montana, northwestern Wyoming, North Dakota, and northern South Dakota, and includes 15 national forests and 3 national parks across the U.S. Forest Service Northern Region and adjacent Greater Yellowstone Area. Compared to observed historical temperature, average warming across the five Northern Rockies Adaptation Partnership subregions is projected to be about 4 to 5 degrees Fahrenheit by 2050, depending on greenhouse gas emissions. Precipitation may increase slightly in the winter, and slightly lower in summer than during the historical period of record, although the magnitude is uncertain. This document predicts that droughts of increasing frequency and magnitude are expected in the future, promoting an increase in wildfires, insect outbreaks, and nonnative species. These periodic disturbances will rapidly alter productivity and structure of vegetation, potentially altering the distribution and abundance of dominant plant species and animal habitat (Halofsky, Andrews-Key, et al. 2018). Some of these changes could already be occurring on the Nez Perce-Clearwater National Forest.

The most likely ways in which climate change may potentially affect grizzly bears are a reduction in snowpack levels, shifts in the denning season, shifts in the abundance and distribution of some natural food sources, and changes in fire regimes due to summer drought. The potential effects would likely be variable and are difficult to predict. Grizzly bears are habitat generalists and opportunistic omnivores, which may make them less susceptible to changes in plant communities than some other wildlife species.

Pigeon et al. (2016) studied the influence of ambient temperature on habitat selection patterns of grizzly bears in the managed landscape of Alberta, Canada. Grizzly bear habitat selection followed a daily and seasonal pattern that was influenced by ambient temperature, with adult males showing stronger responses than females to warm temperatures. The study demonstrated that ambient temperatures, and therefore thermal requirements, play a significant role in habitat selection patterns and behavior of grizzly bears.

Roberts et al. (2014) estimated the impact of warmer future climate on grizzly bears in the southern Canadian Rocky Mountains. They used presence-absence information to estimate ecological niches of food plants and projected changes in future distributions of each species. Many food items persisted or even increased, although several species were found to be vulnerable based on declines or geographic shifts in suitable habitat. Roberts et al. (2014) concluded that, a wide diet breadth of grizzly bears, as well as wide environmental niches of most food items, make climate change a much lower threat to grizzly bears than other bear species.

Analysis of Effects

Methods for Analysis of Effects

It is important to note that the Land Management Plan does not authorize, fund, or carry out site-specific allowances, prohibitions, or activities, rather it establishes overarching direction for future land management actions. Management direction in the Land Management Plan will go into effect once the final record of decision is signed by the forest supervisor and is expected to guide management and decision-making processes for approximately 15 years. Therefore, the effects of the plan components and land allocations on grizzly bears are indirect effects which could occur from activities conducted under the direction of the Land Management Plan in the future.

The primary focus of this analysis is the effects on connectivity and future potential occupancy of the Bitterroot Recovery Zone by grizzly bears. The key indicator is the spatial overlap and consequences of plan direction on secure habitat as a surrogate for effects to grizzly bears. The spatial overlap of land allocations and associated plan direction in many ways determines the effects. Loss of secure habitat could affect grizzly bear presence, survival, dispersal, and connectivity. The effects are comparative in that the analysis is evaluating the change in existing plan direction and conditions compared with direction in the alternatives. The analysis evaluates allocations of recommended wilderness, suitable wild and scenic rivers, timber suitability, suitability of lands for summer and winter motorized uses, suitability for various levels of recreation, allocation of management area, and associated direction. The analysis also evaluates plan direction for domestic livestock grazing, recreation, vegetation management, minerals and energy, and grizzly bear-human interactions. It also evaluates the effects of plan components and objectives identified in the plan. The analysis focuses on the effects of existing conditions and potential implementation of the Forest Plan on any grizzly bears that may be present, as well as considering the ability of the area to contribute to connectivity between grizzly bear recovery zones. The analysis assumes that grizzly bears would eventually establish a population within the plan area through natural dispersal. Grizzly bear presence within the plan area currently is sporadic and is composed of dispersing males. Therefore, the key indicators are how the Preferred Alternative would affect secure habitat that would be required in the event female grizzly bears migrate into the plan area. Lastly, the analysis indicates plan direction that might increase or decrease the probability of bear mortality of bears that may be present or grizzly bears that might move into the national forest in the future.

The analysis first evaluates how the alternatives, including the Preferred Alternative, would affect the potential for the Bitterroot Recovery Zone to host a future population of grizzly bears. The alternatives identify recommended wilderness, the amount of various classes of summer and winter recreation opportunity settings, the suitability of wild and scenic rivers and the associated one-quarter mile river corridor, the area suitable for timber production, and the acres of disturbance or restoration of forest vegetation per year. Thus, timber production amounts will not be analyzed spatially except where timber harvest is suitable. There is a high degree of uncertainty with the effects analysis because it is unknown where grizzly bears will come into the national forest, where they will reside once they arrive, and whether they will stay within the Bitterroot Recovery Zone.

Secure habitat was delineated spatially for use in analysis by excluding areas within 0.31 miles from a motorized route and those blocks larger than 10 acres as outlined in Schwartz et al. (2010). As explained above, this metric was chosen because it was selected in other grizzly bear ecosystems with the rational that secure habitats smaller than 10 acres could contribute to grizzly bear habitat. However, recognizing that larger secure areas probably have more value to grizzly bears, we report the amount of secure habitat larger than 1,280 acres consistent with findings of Wakkinen and Kasworm (1997) that suggested that areas this size and larger were used more by grizzly bears than smaller blocks. The analysis presents a range of sizes of secure habitats for analysis purposes that range from 10 acres to more than a million acres. Routes were included if they were closed to the public but would still allow administrative uses. Routes used for administrative uses could be roads or motorized trails that are gated but still in a useable state, or those in storage, without culverts, brushed in, and not usable without substantial improvements. It is also unknown whether the routes are passable by the public during illegal use. While illegal, use of closed routes does sometimes occur; however, the extent and frequency of use is unknown. Nez Perce-Clearwater spatial data for the travel system is currently unable to distinguish between these on the ground conditions, thereby excluding all of them from secure habitat. The amount of secure habitat used in analysis overestimates the actual usability of these features and, thus, a conservative estimate of secure habitat.

The 2012 Planning Rule adopted a coarse filter-fine filter approach to contribute to recovery of federally listed species. This analysis evaluates whether the plan and plan components provide the ecological conditions to contribute to the recovery of grizzly bears. It does so by first evaluating whether coarse filter ecosystem plan components provide for grizzly bear needs. Coarse filter ecological conditions provide for ecosystem integrity. This includes structure, function, composition, and connectivity. Structure is defined as the organization and physical arrangement of biological elements, such as snags, down woody debris, vertical and horizontal distribution of vegetation, stream habitat complexity, landscape pattern, and connectivity. Function is defined as ecological processes that sustain composition and structure, such as energy flow, nutrient cycling and retention, soil development and retention, predation and herbivory, and natural disturbances like wind, fire, and floods. Connectivity is defined as ecological conditions that exist at several spatial and temporal scales that provide landscape linkages that permit the exchange of flow, sediments, and nutrients; the daily and seasonal movements of animals within home ranges; the dispersal and genetic interchange between populations; and the long-distance range shifts of species, such as in response to climate change. These definitions originate from the 2012 Planning Rule. The analysis in the Diversity and Abundance of Wildlife Section 3.2.3.2 evaluates whether the plan components provide ecosystem integrity.

The analysis evaluates grizzly bear ecology and the spatial overlap of factors or conditions known to affect habitat quality and survival. In particular, this analysis analyzes the spatial overlap of existing "secure" habitat or areas that free from the impact of motorized vehicles (for example, cars, trucks, ATVs, motorcycles, electric bicycles) with the various land allocations in the plan, alternatives, and plan direction within the plan area. This analysis addresses known threats and stressors and whether the allocation of management areas and suitability of uses would address the threats to contribute to grizzly bear recovery.

This analysis evaluates the effects of alternatives and plan components on grizzly bear that may be present and the effects on connectivity and future potential occupancy of the Bitterroot Recovery Zone. For this analysis, the Nez Perce-Clearwater analyzed plan direction for areas suitable for motorized uses, secure habitat, domestic livestock grazing, management of food and attractants, developed recreation sites, vegetation management, minerals and energy, cover and grizzly bear habitat, denning-specific habitat, grizzly bear food availability, and interactions between grizzly bears and humans. The analysis focuses on the effects of existing conditions and potential implementation of the Forest Plan on any grizzly bears that may be present, as well as considering the ability of the area to contribute to connectivity between grizzly bear recovery zones.

The key indicators are how the spatial overlaps of forest plan alternatives would affect grizzly bear dispersal or connectivity and how the alternatives would affect the potential for the Bitterroot Recovery Zone to host a future population of grizzly bears. The analysis relies on the spatial overlap of various alternatives as a surrogate for the effects to grizzly bears. The plan alternatives vary in the amount of recommended wilderness, the number of various classes of summer and winter recreation opportunity settings, the area of wild and scenic river suitability, and the acres of disturbance or restoration of forest vegetation per year. Timber suitability is a decision in the Forest Plan but does not vary by alternative and, while timber production does vary, there is not a spatial layer for overlays. Timber suitability is analyzed spatially by overlaying lands suitable for timber production, timber harvest, and lands not suitable. After the spatial overlays are analyzed, the document then analyzes the effects of plan direction for various resources areas and their consequences to grizzly bears and how they would affect the potential for future occupancy. Lastly, the analysis indicates plan direction or alternatives that might increase the probability of mortality of bears that may be present or grizzly bears that might move into the national forest in the future. There is a high degree of uncertainty with the effects analysis because it is unknown where grizzly bears will come into the Nez Perce-Clearwater, where they will reside once they arrive, and whether they will actually stay within the Bitterroot Recovery Zone.

The period considered for the analysis of indirect effects of the alternatives is the anticipated life of the Forest Plan, which is about 15 to 20 years. However, the decisions made under the Forest Plan can have effects for much longer. For example, old growth may take centuries to reach the same age or size once lost. Travel planning decisions to authorize or construct roads or motorized trails can become permanent. The analysis area for indirect effects of the Forest Plan is the areas encompassed by the administrative boundary of the Nez Perce-Clearwater. Because grizzly bears are wide-ranging, the analysis of cumulative effects is discussed in the context of the Bitterroot Ecosystem.

Effects of the Plan on the Ecological Conditions Within the Bitterroot Recovery Zone

The Land Management Plan under all alternatives will not change the boundaries or characteristics of the Bitterroot Recovery Zone in how it contributes to the recovery of the grizzly bear because it is composed of congressionally designated wilderness, which will not be changing in the revised plan. Suitability plan components in the Recommended Wilderness Section of the Plan find the following activities unsuitable in wilderness: timber production, timber harvest, permanent road construction, temporary road construction, locatable minerals, leasable minerals, new facilities, motorize recreation, over-snow motorized recreation, and mechanical transport. Grazing may be suitable in allotments established before the wilderness was designated, depending upon the enabling legislation. Direction in designated wilderness does not vary by alternative.

The Designated Wilderness Section of the Plan includes direction for the management of designated wilderness areas that make up the Bitterroot Recovery Zone. MA1-DC-WILD-01 is a desired condition that states that management shall preserve and protect wilderness character as required by the Wilderness Act and enabling legislation. MA1-DC-WILD-02 is a desired condition for natural ecological processes and disturbance to be the primary forces affecting vegetation. Standards MA1-STD-WILD-01 and MA1-GDL-WILD-01 require management activities to be in accordance with Wilderness Management Plans and preserve wilderness character. Plan directions for suitability restrict several activities mentioned above. These plan components would maintain the ecological conditions to contribute to recovery. Plan direction does allow prescribed fire and some livestock grazing within the wilderness areas. Of course, as with all projects carried forth under the guidance of the Land Management Plan, these actions would still undergo National Environmental Policy Act analysis and Endangered Species Act consultation prior to authorization. Grazing is an ongoing activity that would undergo analysis and consultation before a reauthorization. These activities would also be required to be consistent with enabling legislation which allowed existing grazing to continue but constrained new authorizations.

Even though wilderness management keeps habitats intact, it does not protect bears from human-bear conflicts. There is no plan direction that requires storage of food or attractants. Such an order can be instituted outside the forest plan though a special order. Efforts to institute a special order are currently being considered. The lack of an order may place any bears that may be present at risk until a food storage order is implemented. However, FW-DC-WL-07, FW-DC-WL-08 seek to educate the public about bear safety measures and direction to provide infrastructure at developed recreation sites. Additionally, there are management approaches as other plan content to adapt to conditions as grizzly bears become established that suggest implementing measures like food storage orders as appropriate.

The Bitterroot Recovery Zone on the Nez Perce-Clearwater is largely ungrazed by domestic livestock, save for about 380 acres of one allotment that overlaps the recovery zone near the Big Mallard Creek trailhead within the Frank Church-River of No Return Wilderness. The allotment is currently vacant and not currently grazed. There is some risk to grizzly bears associated with livestock grazing within the Bitterroot Recovery Zone. Conflicts with livestock could lead to some bear removals or deaths. Because the livestock grazing allotment in the Recovery Zone permits cattle (not domestic sheep) and is currently vacant, the risk of adverse impacts on grizzly bears due to forage competition, displacement, or livestock-related mortality is lower than for other livestock types. The overlap and proximity to the Bitterroot Recovery Zone could lead to livestock depredation in the event the allotment resumes grazing and, in the event grizzly bears become present.

The Bitterroot Recovery Zone is mostly coincident with the Selway-Bitterroot and Frank Church-River of No Return Wilderness areas but does include some portions of the Magruder Corridor, which was excluded from wilderness in the Central Idaho Wilderness Act (1980). There are also some small areas that are not wilderness that were included in the Bitterroot Recovery Zone. The largest block of secure habitat in the plan area is a contiguous block of secure habitat of approximately 1,103,922 acres without any roads nor motorized trails and is centered over and around lands surrounding the Bitterroot Recovery Zone. The Nez Perce-Clearwater has 935,715 acres of the Bitterroot Recovery Zone, of which 926,732 acres are secure habitat by our definition. That is, the Bitterroot Recovery Zone is 99 percent secure habitat. The Bitterroot Recovery Zone within the Nez Perce-Clearwater only has one road, the Magruder Road or Forest Service 468, which passes through about six miles of the recovery zone before it passes into the Bitterroot National Forest. Some other roads along the border of the Recovery Zone affect secure habitat, but the roads do not cross into it. Resulting road density is 0.004 miles per square mile within the Recovery Zone. There is little to no possibility of new roads nor motorized trails being constructed in the future in the wilderness because these are prohibited by the wilderness act. These areas alone provide the ecological conditions to contribute to grizzly bear recovery so long as bears can disperse there. Only 9,002 acres (less than 1 percent) within the Bitterroot Recovery Zone is not secure habitat. The loss of some secure habitat is mostly due to the Magruder Road but also because of some other roads provide access points up to the wilderness boundary. Thus, the number of roads within the Recovery Zone is very low and are expected to remain low.

Timber harvest, silviculture treatments, fuels projects, and other vegetation management projects are generally not allowed within designated wilderness areas. Neither timber harvest nor timber production are suitable within wilderness areas and thus are prohibited under the Preferred Alternative. The plan components contain some direction to encourage treatment of noxious weeds in wilderness areas. The plan also allows prescribed fire as a suitable use in wilderness. These components and activities would have negligible effects or beneficial effects on grizzly bears. Prescribed fire treatments may create early seral conditions that can improve forage opportunities for grizzly bears. They may also form thick stands of shrub that could contribute to hiding cover. The Forest Plan does not authorize any of these activities, it only identifies these as suitable uses. In all cases, federal actions conducted under the guidance of the Forest Plan would be required to be consistent with the plan and undergo additional site-specific analysis and Endangered Species Act consultation prior to authorization.

New developed recreation sites are not allowed within designated wilderness. There are a few campgrounds near the boundary of the Bitterroot Recovery Zone. There are two developed recreation camp sites along the Magruder Road, which are on the boundary of the recovery zone near the Frank Church-River of No Return Wilderness. There are two other developed campgrounds near the Selway Bitterroot Wilderness, one near Elk Summit and another near Big Fog Saddle. These developed sites are outside of the recovery zone but near the boundary. Farther away are nine developed campgrounds along the Lochsa River that could potentially attract grizzlies outside of the Recovery Zone. When bears become established, these sites may attract bears from within the Recovery Zone and lead to human conflict and bear death. Measures to educate the public and provide food storage infrastructure, as in FW-DC-WL-07 and FW-DC-WL-08, would direct management to address these concerns if, and when necessary. The Nez Perce-Clearwater is currently engaging in efforts to educate the public about bear safety. There are several outfitter and guide operations that operate camp locations within designated wilderness areas, and most are issued special use permits to authorize their uses. The permits often contain information addressing resource concerns and provide direction for their operation. These permits often include information about bear safety to help prevent bear-human conflicts and encourage safe storage practices for attractants.

New minerals and energy developments are not allowed in designated wilderness, and most mineral rights were withdrawn with exceptions in enabling legislation. These would continue to be prohibited under the revised plan in the Bitterroot Recovery Zone in the future.

Essentially the Bitterroot Ecosystem Recovery Zone will continue to provide the ecological conditions to contribute to the recovery of the grizzly bear under all alternatives. However, because grizzly bears must disperse naturally into the Recovery Zone to become established, the way the plan provides for connectivity for grizzly bears is a key consideration for how the revised plan will contribute to the recovery of the grizzly bear and is evaluated below. Bears traveling into the Recovery Zone from other ecosystems face more threats and stressors.

Effects of Land Management Plan Direction and Alternatives on Grizzly Bear Connectivity

The analysis throughout the rest of the grizzly bear section is evaluating whether the plan provides for the ecological conditions for grizzly bear dispersal through the Nez Perce-Clearwater into the Bitterroot Recovery Zone and whether the areas outside the recovery zone are capable to support grizzly bears. The Revised Forest Plan establishes a framework with three overarching management areas referred to as Management Area 1, Management Area 2, and Management Area 3. The distribution of the three management areas varies only by an almost insignificant amount, which varies only because of additions to eligible or suitable wild and scenic rivers, which would change some Management Area 3 lands to Management Area 2 lands.

A description of these areas is included in Chapter 1 of the revised Forest Plan. To summarize, Management Area 1 includes designated areas such as designated wilderness and designated wild and scenic rivers. Management Area 2 includes areas recommended under the plan and the Idaho Roadless Rule Areas. Management Area 2 would include research natural areas, recommended wilderness areas, and suitable Wild and Scenic Rivers for example. Management Area 3 are lands for multiple uses. Management Area 3 occur within approximately 1,217,683 acres of the Nez Perce-Clearwater under the existing condition but is 1,240,340 acres under the Preferred Alternative. Management Area 3 would include areas that currently have more roads, most campgrounds and infrastructure, more human use, and are managed for timber production. While the plan does not authorize any of these uses, these types of activities would continue under the broad direction of the plan. Management Area 3 is identified in the plan to emphasize these uses. As such, most of these activities generally would be suitable within

Management Area 3 save for restrictions specified within plan components. For example, several activities are unsuitable or restricted within Riparian Management Zones.

In general, Management Area 3 has few restrictions on management activities. Objectives for a variety of activities are identified in the plan. Examples include timber production, fire or fuels objectives, vegetation restoration, restoration of hardwood species, aspen restoration, soil restoration, aquatic or riparian restoration, invasive species treatments, recreation maintenance, and road maintenance. It should be anticipated that projects and management would be moving towards or achieving desired conditions and that management would fulfill objectives.

This analysis evaluates how ecological conditions for grizzly bears provide for dispersal through these areas into the Bitterroot Recovery Zones. In many ways, these management areas and land allocations provide the ecological conditions to provide for dispersal and habitation outside of the Recovery Zone because they provide broad areas where many activities that could affect grizzly bears are prohibited or restricted through suitability plan components tied to the distribution of these land allocations.

Dispersal between disjunct populations can play an important role in the persistence of a species by increasing genetic diversity in the receiving population, facilitating colonization and recolonization of unoccupied habitats, and augmenting the numbers of small populations (Hanski and Gilpin 1997, Mattson and Merrill 2002). In the rest of the analysis below, the effect of the Nez Perce-Clearwater Revised Forest Plan is evaluated in this larger context for connectivity.

The Bitterroot Recovery Zone lies between populations of grizzly bears in other ecosystems. Thus, dispersing bears from one or more of the ecosystems is important to the establishment of bears into the Bitterroot Ecosystem. The plan area contributes to this dispersal from grizzly bear ecosystems north or east of the Nez Perce-Clearwater, namely the North Continental Divide, Cabinet-Yaak, and Selkirk Ecosystems. The Nez Perce-Clearwater could contribute to connectivity for grizzly bears between the Greater Yellowstone Ecosystem and the other Ecosystems, however connectivity is more likely through other routes than the Nez Perce-Clearwater. For the Bitterroot Ecosystem to have a population of grizzly bears, female grizzly bears would need to become established. Thus, the ability of the Nez Perce-Clearwater to provide connectivity both into and between the ecosystems for female grizzly bears is a key indicator for this analysis.

Table 256 shows the location of the Bitterroot Recovery Zone in relation to areas occupied by grizzly bears and the other recovery zones. The nearest areas occupied by grizzly bears are from the Northern Continental Divide Ecosystem where grizzly bears have become established outside the boundaries of the Northern Continental Divide Ecosystem. The edge of this occupied polygon is about 15 miles from the nearest Bitterroot Ecosystem boundary and about 13.5 miles from the boundary of the Nez Perce-Clearwater at the nearest locations, as measured in ArcGIS. This distance is near the maximum dispersal distance recorded by McLellan and others for female grizzly bears (McLellan and Hovey 2001b). Based upon these distances, the most likely source of female bears to show up in the Bitterroot Ecosystem by natural dispersal may be those from the Northern Continental Divide, the Cabinet-Yaak, or Selkirk Ecosystems. Despite the proximity, bears face significant barriers coming from Northern Continental Divide Ecosystem into the Nez Perce-Clearwater because of human development along the I-90 corridor (Servheen, Waller, and Sandstrom 2003).

The boundary of the Cabinet-Yaak Recovery Zone is about 35.8 miles from the northern boundary of the Nez Perce-Clearwater and about 69 miles from the nearest boundary from the Bitterroot Recovery Zone. The Selkirk Recovery Zone is about 86.9 miles from the nearest Nez Perce-Clearwater boundary and 172 miles from the nearest Bitterroot Recovery Zone boundary, as measured in ArcGIS. However, the incidences noted above from male bears that were observed in or near the Nez Perce-Clearwater have come from the Cabinet-Yaak (2019), Selkirk (2007), and Northern Continental Divide ecosystem (2018) populations and entered the northern or northeastern area of the Nez Perce-Clearwater. The arrival pattern is expected to continue, though some bears may make it into the Bitterroot Recovery Zone south of Stevensville, Montana.

While perhaps less likely, grizzly bears could also come from the Greater Yellowstone Ecosystem (GYE). The closest straight-line distance from the GYE recovery zone and the Bitterroot Recovery Zone is approximately 132 miles as measured in ArcGIS, though the arrangement of terrain and anthropogenic factors might require a grizzly bear to travel a farther distance between the two ecosystems. If we assume that grizzly bears would be more likely to travel along a mountainous path, then a potential travel corridor could exist from the GYE near the Eastern Centennial mountains through the mountainous area along the Idaho-Montana border through the Beaverhead range and into the Bitterroot Recovery Zone on the Bitterroot National Forest. A bear traveling this path would potentially cross the Caribou-Targhee, Salmon-Challis, Beaverhead Deer Lodge, and Bitterroot National Forest, passing North of Salmon Idaho and south of Hamilton Montana. Such a path would require a grizzly bear to cross I-15 and Highway 93 and travel approximately 200 miles. A second, more direct but more fragmented path might include a path from the Madison Range in the GYE north to the Tobacco Root Range, to the highland range, passing south of Butte Montana into the Sapphire Range and then crossing through the mountainous areas between Hamilton Montana and Salmon Idaho into the Bitterroot Ecosystem on the Bitterroot National Forest. This course would require a bear to travel about 150 miles and cross both I-15 and Highway 93.

Table 256. Distance between Nez Perce-Clearwater and Bitterroot Ecosystem Recovery Zone from areas occupied by grizzly bears

Grizzly Bear Recovery Zone or Ecosystem	Distance in miles from the Nez Perce-Clearwater boundary to nearest area occupied by grizzly bears	Approximate Distance in miles from the Bitterroot Ecosystem Boundary from nearest area occupied by grizzly bears
North Continental Divide Ecosystem	13.5	15
Selkirk Ecosystem	86.9	172
Cabinet-Yaak Ecosystem	35.8	69

Most of the area of the Nez Perce-Clearwater north of the Bitterroot Recovery Zone boundaries are composed of either recommended wilderness or Idaho Roadless Rule areas. Provided grizzly bears advance into the Nez Perce-Clearwater, Idaho Roadless Rule Areas, recommended wilderness areas and designated wilderness areas provide high levels of secure habitat and allow for connectivity to the Bitterroot Ecosystem. These areas are composed of HUC 10 watersheds that have more than 55 percent secure habitat, which should allow for survival and passage.

Areas in Management Area 3 have low amounts of secure habitat and reduce connectivity through some areas. The area near Lolo Pass that has checkerboard ownership has substantial acreage of private land and many miles of private roads. Private lands within the checkerboard area are outside of Forest Service control. Similarly, the general forest management areas of Deception Point and south of the Mallard Larkin area around Indian Henry Ridge has lower amounts of secure habitat. However, grizzly bears may be able to navigate around or even pass through these areas as Bear 927 did. Grizzly bears that enter the Nez Perce-Clearwater from the north or east would most likely enter recommended wilderness or Idaho

Roadless Rule areas. Figure 104 below shows the Bitterroot Ecosystem in relation to the Nez Perce-Clearwater recommended wilderness, Idaho Roadless Rule areas, and designated wilderness.

The Nez Perce-Clearwater is bordered on the north, east, and south by other National Forest System lands. Few Forest Service activities disrupt animal movements across the landscape. The landscape feature most important to the disruption of connectivity for grizzly bears is the road system, motorized trail system, and some recreation facilities.

Note that the use of motorized vehicles off existing designated roads and trails is not permitted on the Clearwater portion of the national forest, except for travel to dispersed campsites within 300 feet of an open route (U.S. Department of Agriculture 2017f). Roads and trails closed to public motorized use sometimes remain available to Forest Service personnel for administrative purposes, including wildfire suppression, search and rescue, medical emergencies, permit administration, data collection, noxious weed treatments, general management, and other activities (U.S. Department of Agriculture 2017f). However, they are not used often.

Grizzly bears may modify their behavior temporally in response to road use intensity. Northrup et al. (2012) found that grizzly bears in southwestern Alberta increased their use of areas near roads and moved across roads during the nighttime hours when traffic use was low. During the day, bears crossed and used the areas near roads that had low use (less than 20 vehicles per day) but avoided roads with moderate (20 to 100 vehicles per day) and high (greater than 100 vehicles per day) traffic volumes. Mace et al. (1996) evaluated seasonal use by grizzly bears of areas within a 0.3-mile buffer of surrounding roads in the Swan Mountains, Montana. Most grizzly bears exhibited either neutral or positive selection for buffers surrounding closed roads and roads receiving less than 10 vehicles per day but avoided buffers surrounding roads having greater than 10 vehicles per day. Ruby (2014) found that grizzly bear activity near open motorized routes and human developments in Swan Valley, Montana peaked during time periods when humans were likely to be less active. Because motorized trails are unlikely to be used at nighttime, there might be less impact on bears from the network of motorized trails than would be suggested by the Boulanger and Stenhouse (Boulanger and Stenhouse 2014) thresholds. The amount of use on most of the roads bordering the Nez Perce-Clearwater National Forest's Idaho Roadless Rule areas are assumed to be low but exact numbers are not available.

The forest plan does not make travel management decisions at a site-specific level. Instead, it sets the broad direction under which travel management decisions would occur in future projects under the plan. Plan direction that can influence travel management decisions include management area direction, Idaho Roadless Rule direction, wilderness designations, recreation opportunity spectrum settings, individual plan components, and suitability determinations.

The Idaho Roadless Rule area boundaries will not change during forest plan decisions. Idaho Roadless Rule area themes generally will not change in the plan unless the Idaho Roadless Rule area is selected as recommended wilderness. In that case, the Idaho Roadless Rule area theme would be managed as a Wildland Recreation Area. Idaho Roadless Rule areas do not allow new permanent road construction but do allow motorized trails to be constructed.

Secondly, the recreation opportunity spectrum classifications dictate the types of access allowed. The summer recreation opportunity spectrum is most relevant to grizzly bears while the winter recreation opportunity spectrum would not likely have effects on dispersing bears because they would be hibernating during winter travel. However, there are some possibilities that winter recreation may disturb hibernating grizzly bears. The effects of winter recreation on denning grizzly bears are evaluated below. However, wilderness areas and recommended wilderness areas are not suitable for winter motorized recreation and thus would not be allowed under the plan. The summer recreation opportunity spectrum varies by alternative, primarily because selection of recommended wilderness areas would change the recreation opportunity spectrum setting. These factors are analyzed in more detail below.

Demographic connectivity areas were considered during the development of the Final Environmental Impact Statement. Demographic connectivity areas are not needed at this time because of the existing regulations that occur as a natural result of roadless rule regulations and wilderness laws, which already provide this connectivity. Some non-motorized summer recreation opportunity spectrum settings in the Preferred Alternative were identified to help provide for grizzly bear connectivity (Figure 106). These are non-motorized settings near the Hoodoo recommended wilderness area.

Effects That Do Not Vary by Alternative

Effects of Suitability Plan Components

Suitability plan components are new type of plan components introduced in the 2012 Planning Rule. They identify the appropriateness of various uses or activities within a plan area. Identifying the suitability of lands for a use in the Forest Plan indicates that the use may be appropriate but does not make a specific commitment to authorize that use. Where uses are identified as not suitable, the specified activity would not be allowed in those areas. Therefore, the effects of suitability plan components are programmatic in nature and provide sweeping direction for broad areas within land allocations. Some land allocations do not vary by alternative (for example like designated wilderness, designated wild and scenic river corridors, Idaho Roadless Rule Areas, established research natural areas, and the National Historic Landmark) and the suitability plan components apply to these lands and also do not vary by alternative. Other land allocations vary in extent by alternative (for example, recommended wilderness, eligible and suitable wild and scenic rivers, proposed Research Natural Areas, Summer Recreation Opportunity Spectrum, Winter Recreation Opportunity Spectrum settings, or Timber Suitability), but the suitability plan components that apply to these do not vary by alternative. There is one exception; the suitability of some activities within recommended wilderness vary by alternative and are evaluated in the Recommended Wilderness analysis below. The alternatives that vary the extent of suitability are evaluated below and include the suitability of motorized uses which varies by alternative with the Summer and Winter Recreation Opportunity Spectrum settings, and timber suitability varies by alternative. This section discusses the suitability plan components that do not vary by alternative.

Suitability plan components are often associated with land allocations such as uses suitable within wilderness, Idaho Roadless Rule Areas, Wild and Scenic Rivers, Research Natural Areas, or areas set aside for general forest management that emphasizes multiple uses. However, they can also apply to areas such as Riparian Management Zones that are not a management area. Categories of activities addressed by suitability plan components include timber production, timber harvest, permanent road construction, temporary road construction, prescribed fire, livestock grazing, locatable minerals, saleable minerals, leasable minerals, new facilities, motorized uses, over-snow motorized recreation, and mechanical transport recreation travel, such as bicycling. Suitability plan components provide broad direction across the landscape for these activities. Each of these activities has the potential to affect grizzly bears.

Timber production is suitable in portions of Management Area 3. It is excluded everywhere else. Lands suitable for timber productions are areas where timber production is the primary mechanism to treat vegetation and can be conducted for the purpose of producing lumber for market. Timber production is associated with increased roads, which detract from secure habitat. Timber production is not suitable outside of Management Area 3. Timber harvest is tree cutting for purposes other than producing lumber. This may include activities to achieve vegetation desired conditions, fuels reduction, wildlife habitat improvement, or other similar activities. It can be less impactful than production because the purpose for the treatments can differ from production which can alter the methods used. It would usually be conducted from existing roads but can also be associated with temporary or permanent road construction. This is less common and may only occur where temporary or permanent roads are also suitable. Roads can alter habitat and detract from secure habitat. While all lands suitable for timber production is also suitable for timber harvest, lands suitable only for timber harvest are much more widely distributed compared to timber production. It is suitable everywhere except wilderness, the National Historic Landmark, and Idaho Roadless Rule wildland recreation theme areas, however, other roadless rule themes place very strict rules on when timber harvest could be done and generally require regional forester approval.

Temporary roads are not suitable within designated wilderness, the National Historic Landmark, suitable wild and scenic rivers wild classification areas, Idaho Roadless Rule themes of wildland recreation primitive, special areas of historic or tribal significance, backcountry recreation themes, primitive recreation opportunity spectrum settings, semi-primitive non-motorized settings, riparian management zones, and mass movement areas. They are suitable everywhere else. Temporary roads are used for timber harvest, production, vegetation management, or other activities but are closed after operations and have short-term effects. They are generally closed to the public when in use. They are decommissioned using a variety of techniques, once operations are finished. They can increase foot travel into forested areas until they are brushed in. While the plan has no time limit identified for when temporary roads should be closed, this generally occurs immediately after operations are finished, but at most within 5 years.

Prescribed fire is suitable across the whole forest. It can change seral conditions for vegetation, but bears use a variety of forested and non-forested conditions that provide different life requirements. While prescribed fire can reduce forest cover used by bears, it can also generate nutrition as well. Effects can occur during implementation by displacing bears. Fire also increases diversity in forest structure, function, composition, and density which provides for a broad variety of other wildlife and plants that provide for bear nutrition.

Livestock grazing is suitable within allotments everywhere except developed recreation sites and administrative sites. Grizzly bears may depredate livestock, which can lead to human bear conflicts, bear removal, or death. While livestock grazing is suitable across broad areas, it is managed within allotments that are generally located where there is sufficient forage. Livestock grazing under the plan may be available on a temporary basis on transitory forage made available following the reduction in conifer overstory from fire and timber harvest. Again, only allotments existing prior to wilderness designation are allowed within designated wilderness areas such as the Selway Bitterroot, Gospel-Hump, and Frank Church-River of No Return wilderness areas. No new allotments would be allowed within these wilderness areas.

The three types of mineral extraction are suitable across most of the planning area unless withdrawn. Withdrawal has occurred in designated wilderness and the National Historic Landmark and is not suitable in administrative or developed recreation sites. Some Idaho Roadless Rule themes, riparian management zones, and mass movement areas are not suitable for leasable or saleable mineral activities. The Forest Service must allow exploration and reasonable access to mining activities but may regulate surface occupancy to some extent and require plans of operation. The Forest Service has more regulatory discretion over saleable minerals. Mining can destroy habitat when surface is occupied and can produce contaminants. Mining activities may increase the probability of human-bear conflicts during operations. While suitable across wide areas, mining activities are often localized, and no large-scale commercial mining operations are present or proposed on the Nez Perce-Clearwater.

Motorized recreation is well documented in scientific literature to have effects on grizzly bears. Effects include displacement and decreased survival. Motorized suitability is determined by the Winter and Summer Recreation Opportunity Spectrum Settings and is also consistent with land management allocations such as Wilderness, Idaho Roadless Rule, and recommended wilderness. The revised Forest Plan does not make travel management decisions, instead it identifies where motorized travel is suitable. Motorized travel is not suitable in primitive and semi-primitive non-motorized settings and within recommended and designated wilderness areas under the Preferred Alternative. It is suitable in rural, roaded natural, and semi-primitive motorized settings. There are few other plan components that restrict new motorized travel. These are analyzed in detail below.

Motorized recreation usually occurs on open roads and motorized trails, though users sometimes create illegal trails by driving cross country or drive around gates and barriers on closed roads. On the Clearwater National Forest, the travel plan designated open roads and trails and changed management from an open until closed to a closed unless designated open system. On the Nez Perce National Forest, there is no travel plan that is finalized under the travel management act. Therefore, travel is open across the Nez Perce National Forest unless closed by a site-specific decision. Travel planning on the Nez Perce National Forest would occur under the direction of the Revised Forest Plan.

Over-snow winter motorized travel is not suitable within primitive and semi-primitive nonmotorized winter recreation opportunity spectrum settings and within recommended and designated wilderness. It is suitable in other settings. Because of hibernation, winter travel generally does not affect grizzly bears except for potential disturbance or when they emerge from their hibernacula. Winter recreation is analyzed in detail below.

Mechanical transport or recreation includes bicycling and the use of game carts. Mountain biking has led to bear-human conflicts and human deaths in some cases in areas occupied by grizzly bears. Mountain biking could also displace bears. Mechanized transportation of game carcasses has virtually no direct effect on grizzly bears other than it may allow hunters to transport their game from longer distances into backcountry areas. Hunting has been known to increase human-bear conflicts when hunting results in surprise encounters or while defending carcasses. Mechanized travel is not suitable in designated nor within recommended wilderness areas but is suitable everywhere else.

Permanent road construction is suitable in Management Area 3 without many constraints. Within Idaho Roadless Rule Areas, permanent roads under the plan are suitable only to the extent they are allowed within the roadless rule (see summary in above describing the Idaho Roadless Rule Direction above). Permanent roads are not suitable or allowed within Recommended Wilderness only to the extent allowed under the roadless rule. These areas would be managed like Wildland Recreation and Primitive theme areas. Roads are prohibited by law in Designated wilderness areas. Within designated wild and scenic rivers roads are allowed to the extent allowed by law and enabling legislation. Permanent roads are typically disallowed within Wild River corridors but allowed within Scenic and Recreation classes of wild and scenic rivers. To summarize, roads are generally unrestricted within Management Area 3, mostly restricted within Management Area 2, and even more restricted within Management Area 1 with the exception of some classifications of wild and scenic river areas. The suitability plan components were designed to be consistent with existing laws and regulations (for example, Idaho Roadless Rule, Wilderness Act), which supersede the plan, and is why many suitability plan components have exceptions that tier to the allowed exceptions in those laws. The plan cannot be inconsistent with those laws and regulations. The primary mechanism to establish motorized suitability is the summer and winter recreation opportunity spectrum settings that are analyzed in more detail below.

Suitability plan components are the primary mechanisms that will provide the ecological conditions for grizzly bear connectivity and recovery because they will maintain secure habitats, prevent actions identified above across broad areas that could affect dispersing bears, and maintain conditions within the Bitterroot Recovery Zone. Several sections of the grizzly bear analysis below detail effects from suitability associated with management area allocation including the Effects of Recommended Wilderness section, the Effects of Designated and Suitable Wild and Scenic Rivers section, the Timber Suitability, Production, Harvest, and Vegetation Restoration section, the Effects of Motorized Suitability and Summer Recreation Opportunity Spectrum section, the Effects of Winter Recreation Opportunity Spectrum section and more. Suitability plan components are found in several tables within the Revised Forest Plan.

Effects of Designated Wilderness Management

The plan will not change the distribution or amount of Designated Wilderness as these areas are designated by Congress and cannot be changed by the plan. However, the plan will establish how Designated wilderness areas are managed. The prevailing management direction within Designated wilderness areas are to manage these lands to maintain wilderness character, consistent with the Wilderness Act, as well as each wilderness area's enabling legislation and its specific management plan. Natural ecological processes and disturbances (for example, succession, wildfire, avalanches, insects, and disease) are the primary forces affecting the composition, structure, and pattern of vegetation.

Several activities are not suitable within wilderness areas (see suitability Table 26 of the Forest Plan). The plan finds wilderness areas unsuitable for timber production, timber harvest, permanent road construction, temporary road construction, mineral extraction, construction of new buildings or facilities, over-snow vehicle travel, motorized travel, mechanized travel and more. Because these uses are unsuitable in wilderness, these activities would not be allowed. Livestock grazing is limited to allotments existing only before designation, and allotments are mostly absent from wilderness areas (see Figure 100Figure 100 for the distribution of Range allotments in relation to grizzly bear secure habitat, wilderness and the recovery zone). See suitability plan components within the Designated Wilderness Section of the plan.

The three designated wilderness areas are a total of 1,139,059 acres in size combined. The fact that the majority of the Bitterroot Recovery Zone is within designated wilderness protects these habitats from most actions that could impact grizzly bears or their habitat. Human presence is generally by foot or horse packing and human presence is generally lower than in the other management areas.

Under the plan, the amount of secure habitat would be expected to remain the same or change only slightly in Management Area 1. Schwartz et al. (2010) studied grizzly bear survival in the Greater Yellowstone Ecosystem and found predicted survival was highest in wilderness, followed by national parks, multiple-use land, and nonfederal land when comparing whether there were differences in survival within different jurisdictions in univariate comparisons, suggesting that these lands are capable of providing conditions for recovery.

Designated Wild and Scenic River Management

Congress passed the National Wild and Scenic Rivers System Act in 1968 (Pub. L. 90-542; 16 U.S.C. 1271 et seq.) for the purpose of preserving rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The act promotes river management across political boundaries and public participation in developing goals for river protection. Management of the existing Wild and Scenic Rivers enhances and protects habitats for future grizzly bear occupancy within wild and scenic river corridors. Designated wild and scenic river distribution will not change in the revised Forest Plan. Instead, the plan will set management direction for these rivers and their corridors.

The Nez Perce-Clearwater has three designated Wild and Scenic Rivers: Middle Fork Clearwater River, Salmon River, and Rapid River. The Middle Fork Clearwater includes portions of the Lochsa and Selway Rivers. On the Nez Perce-Clearwater, designated rivers include 64 miles of the Lochsa River from the Powell Ranger Station to Lowell, Idaho; 58 miles of the Selway River from the Nez Perce National Forest boundary with the Bitterroot National Forest near Goat Creek to Lowell, Idaho; and 23 miles of the Middle Fork Clearwater River from Lowell, Idaho to the Upper Kooskia Bridge in Kooskia, Idaho. Portions of the Selway and Salmon rivers flow through the Bitterroot Recovery Zone.

The lands surrounding the designated Wild and Scenic Rivers were included as Wild and Scenic River corridors and are managed consistent with the Wild and Scenic Rivers Act . The Nez Perce-Clearwater National Forest contains approximately 57,891 acres of Designated Wild and Scenic River corridors within the administrative boundary.

Management of wild and scenic rivers is governed by the Wild and Scenic Rivers Act of October 2, 1968 (Pub. L. 90-542, 82 Stat. 906, as amended). This act established the National Wild and Scenic Rivers System with three classes of river systems: wild, scenic, and recreational. The purpose of the act is to protect the river "for the benefit and enjoyment of present and future generations."

For management purposes, river segments are classified as wild, scenic, or recreational.

- Wild River: Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.
- Scenic River: Those rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped but accessible in places by roads.
- Recreational River: Those rivers or sections of rivers that are readily accessible by road or railroad that may have some development along their shorelines and that may have undergone some impoundment or diversion in the past.

When designated, the five river segments were defined and classified as either wild or recreational segments. No segments were classified as scenic. Those river segments with adjacent roads were designated recreational and the others wild. The different classifications are associated with a variety of restrictions on activities such as timber harvest, the development of facilities and motorized routes. The acres of designated wild and scenic river corridors are shown in Table 257. Of the total five segments, four lie within the Nez Perce-Clearwater. Those segments are described in Table 258.

Table 257. Classification of Middle Fork Clearwater Wild and Scenic River within Nez Perce-Clearwater

River	Segment	Miles	Classification	Designating Legislation
Lochs	Powell Ranger Station to Lowell	64	Recreational	Wild and Scenic Rivers Act, 1968
Middle Fork Clearwater	Lowell to Kooskia	23	Recreational	Wild and Scenic Rivers Act
Selway	Lowell to Selway-Bitterroot Wilderness boundary	22	Recreational	Wild and Scenic Rivers Act
Selway[1]	Selway-Bitterroot Wilderness boundary to the Bitterroot National Forest boundary	36	Wild	Wild and Scenic Rivers Act
Rapid River	Segment located on the Nez Perce-Clearwater	13	Wild	Hells Canyon National Recreation Area Act, 1975

River	Segment	Miles	Classification	Designating Legislation
Salmon	Salmon Falls to Long Tom Bar	56	Wild	Central Idaho Wilderness Act, 1980

1 - This river system contains additional miles within the administrative boundaries of the Bitterroot National Forest.

Table 258. The acres within designated Wild and Scenic River corridors by classification within the Nez Perce-Clearwater National Forest

River Name	Acres Recreational	Acres Scenic	Acres Wild	Total
Middle Fork Clearwater (includes the Lochsa, Selway, and Middle Fork Clearwater Rivers)	32,751	0	11,631	44,382
Middle Fork Clearwater (includes the Lochsa, Selway, and Middle Fork Clearwater Rivers)	32,751	0	11,631	44,382
Rapid River	4,341	0	0	4,341
Salmon	0	0	9,164	9,164

Note, additional acres of designated wild and scenic river corridors extent outside the plan area.

Section (section 3(d)(1)) of the Wild and Scenic Rivers Act requires federal agency charged with the administration of each component of the national wild and scenic rivers system (designated wild and scenic rivers) to prepare a comprehensive management plan to provide for the protection of the river's outstandingly remarkable values. Thus, designated wild and scenic rivers have a comprehensive management plan that provides direction for its management. These plans provide guidance similar to plan components that guide management of the Wild and Scenic Rivers to protect outstandingly remarkable values.

Under the Wild and Scenic River Act, outstandingly remarkable values were assigned to all segments of the Middle Fork Clearwater River. In 2002, as part of the Snake River Basin water rights adjudication, the outstanding remarkable values were validated for all segments of the river. During the validation process in 2002, the determination was made that all the original outstandingly remarkable values should still be defined for the Middle Fork Clearwater, with one exception. Geology was not defined as an outstandingly remarkable value in 2002 but was in 1968. The other outstandingly remarkable values were defined in both 1968 and 2002. These values include scenery; recreation; fish; wildlife; prehistory, history, and, potentially, traditional, and cultural use; water quality; and vegetation and botany.

The Middle Fork Clearwater River and its tributaries play a vital role in the Nez Perce-Clearwater management of sensitive, threatened, and endangered fish species. The Middle Fork Clearwater subbasin is considered a core area for recovery of at-risk salmonids in the upper Columbia River basin. The river and its tributaries provide crucial habitat for threatened and endangered species listed on the Endangered Species Act, including steelhead trout and bull trout, which have also been identified as having outstanding remarkable value in this drainage. Additionally, hatchery spring Chinook salmon have been reintroduced to the river system and are currently listed as a U.S. Forest Service Northern Region Species of Conservation Concern, as is pacific lamprey. The Middle Fork Clearwater River functions as a critical migration corridor, connecting the Lochsa and Selway populations of listed fish within the South Fork Clearwater and Lower Clearwater River and tributaries. It affords relatively contiguous distribution of populations and suitable habitat so that the biological needs of these species can be met (U.S. Department of Agriculture 2002c). Designated Wild and Scenic River management benefit federally listed species either indirectly or directly.

The river corridor provides a diversity of high-quality habitat for wildlife of national and regional significance, and these were identified as outstandingly remarkable values. The 2002 assessment of Endangered Species Act listed species included the bald eagle, gray wolf, lynx, and grizzly bears (U.S. Department of Agriculture 2002c). The river corridor and adjacent areas continue to provide habitat for these species. Designated Wild and Scenic rivers will not change in the revised Forest Plan. Instead, the plan will set management direction for these rivers and their corridors.

The acres of designated wild and scenic river corridors and the acres of secure habitat contained within those corridors are shown in Table 259. These areas will not change under the plan and are already established by congress, but their management would be determined in the plan and would be consistent with applicable regulations.

Additional management direction is also provided in Wild and Scenic River Plans. Wild and Scenic River management plans are documents established either after designation that provide additional guidance to manage the river and its corridor. Wild and Scenic River plans typically consist of direction to protect outstandingly remarkable values of the river. The Wild and Scenic River plans will still be in effect when the revised Forest Plan is completed but could be revised under the guidance of the Revised Forest Plan in the future. Wild and Scenic Rivers are managed to maintain their free-flowing character, water quality and outstandingly remarkable values for which the river was designated. This management is generally beneficial to grizzly bears and would serve to maintain grizzly bear habitat because of the restrictive nature of wild and scenic river management. Also see analysis of suitability for restrictions and allowances in the plan in wild and scenic rivers. The plan includes components specific to designated Wild and Scenic Rivers under direction for Management Area 1 and through suitability of uses included in Table 28 of the revised Forest Plan. Allowed activities vary whether a river is identified as wild, scenic, or recreational, with wild rivers restricting more activities than scenic and recreational rivers. Wild and scenic river management contributes to populations of anadromous fish which could serve as a food source for grizzly bears.

Table 259. Acres of secure habitat within existing designated wild and scenic rivers

Designated Wild and Scenic River	Total Acres	Acres of Secure Habitat
Middle Fork Clearwater, Idaho	44,383	14,685
Rapid, Idaho	4,341	4,227
Saint Joe, Idaho	2	2
Salmon, Idaho	9164	8,313
Totals	**57,890**	**27,227**

Forest Service Handbook 1909.12 outlines the activities allowed within the different wild and scenic river classifications. Wild rivers restrict timber cutting, new mineral leases, roads, motorized travel, and allows only minimal recreation developments. The plan under all alternatives included direction consistent with these restrictions into the plan components for designated wild and scenic rivers, including appropriate suitability plan components (see the Designated Wild and Scenic River section of the plan). Management of Designated wild and scenic rivers would generally have beneficial effects on grizzly bears. However, some activities that could affect grizzly bears could occur in some classes of wild and scenic rivers. For example, the plan would find the following use suitable: permanent road construction, construction of new buildings, minerals, motorized travel, or other uses (see suitability table within the Designated Wild and Scenic River Section of the Plan). These activities would require site specific project analysis before being undertaken. Management of designated wild and scenic rivers protects the outstandingly remarkable values for which they were designated and maintains their free flow characteristics which are protective of riparian habitat for grizzly bears. Some designated Wild and Scenic River corridors overlap other land allocations such as designated wilderness, and the National Historic Landmark, research natural areas and Idaho Roadless Rule Areas. In these cases, all direction for the different land management allocations would apply. Overlap occurs on 46,544 acres of which 24,969 acres are secure habitat. About 11,336 acres are only designated wild and scenic river without any other overlapping land allocation and has 2,257 acres secure habitat. Designated Wild and Scenic Rivers contribute to protections of secure habitat and connectivity. Management of designated wild and scenic rivers protects the outstandingly remarkable values for which they were designated and maintains their free-flowing characteristics, which are protective of riparian habitat for grizzly bears.

Effects of Direction within the Lolo Trail National Historic Landmark

The Lolo Trail, a National Historic Landmark, administered in cooperation with the National Park Service, is part of the Nez Perce National Historical Park. It includes the trail and lands surrounding the trail. The trail consists of the remnants of the original trails used by indigenous peoples and Lewis and Clark, but also the Lolo Motorway which is a road that follows parts of the original trail. The plan will not change the national historic landmark because it was designated by congress, but it will set direction for the management of the landmark. The National Historic Landmark was set aside in the plan as Management Area 1 lands and have protective land management plan components associated with it. It is also designated as Idaho Roadless Rule Areas and is managed under the Special Areas of Historic and Tribal Significance theme. Therefore, all restrictions under that theme in the Idaho Roadless Rule would apply as well as any plan components. While it is limited in size and is a long narrow feature on the landscape, it will contribute to the conservation of ecological conditions for grizzly bears.

The prevailing management direction in the plan is that the landmark is managed so that the National Register integrity of the Lolo Trail National Historic Landmark is considered *high.* Natural processes are the primary drivers of change to, and composition of, vegetative communities. The plan contains a desired condition that roads and trails persist in a manner that do not detract from the National Register integrity of the landmark while providing for reasonably safe passage by the public consistent with designated uses. Another desired condition for these lands is that non-system roads are not present. Standard GA-STD-NHL-01 establishes that trees shall only be felled within the landmark corridor if they pose a hazard or safety threat. All other tree felling is prohibited. Guideline GA-GDL-NHL-05 establishes that new temporary or permanent road and trail construction should not be permitted within the Landmark unless the integrity of the National Historic Landmark is maintained, and the purpose of the action is to benefit the National Register integrity of the Landmark. This guideline only allows new motorized roads and trails when these conditions are met, which would be infrequent if at all.

The plan is explicit about actions that are and are not suitable within the Landmark. The suitability of management actions within the National Historic Landmark are found in the Lolo trail National Historic Landmark section of the plan. The National Historic Landmark is relatively small, consisting of 55,760, but the plan's direction would help these lands contribute to grizzly bear habitat. See the Suitability table in the National Historic Landmark section of the plan.

Effects of Plan Direction for Idaho Roadless Rule Areas

The Idaho Roadless Rule areas are primarily managed under Management Area 2 and have area specific plan components that apply to these lands. There are 34 separate mapped Idaho Roadless Rule areas that vary greatly in size, elevation, and habitat. In total, the Idaho Roadless Areas comprise approximately 1,481,565 acres across the Nez Perce-Clearwater. Note that some Idaho Roadless Rule Areas are in

Management Area 1 because they overlap with the National Historic Landmark, and some designated wild and scenic river corridors, and so the total amount of Idaho Roadless Rule Area is larger than Management Area 2.

Each Idaho Roadless Rule area is assigned one or more management themes as outlined in the Idaho Roadless Rule. The Idaho Roadless Rule themes assign various permissions and prohibitions regarding road building, timber cutting, and discretionary mineral activities.

The Revised Forest Plan specifies that Idaho Roadless Rule areas in the plan are managed in a manner that is consistent with the appropriate theme, as defined by the final rule outlined in 36 CFR Part 294 (Special Areas; Roadless Area Conservation; Applicability to the National Forests in Idaho; Final Rule). Each theme specifies permitted and prohibited actions for timber cutting, roads, and minerals. A summary of permitted and prohibited actions in Idaho Roadless Rule Areas are summarized above. Idaho Roadless Rule areas contribute greatly to the conservation of habitats that can contribute to grizzly bear recovery and connectivity. The plan will not change the boundaries nor the themes of the Idaho Roadless Rule areas as these were established and codified in the Idaho Roadless rule. The revised Forest Plan will however, set direction for the management of these areas and this direction was explicitly designed to be consistent with the prohibition and permitted activities specified by the Idaho Roadless Rule within their respective themes. The acres of area and secure habitats of the different Idaho Roadless Rule themes are shown in Table 260.

Desired conditions for Idaho Roadless Rule Areas emphasis maintaining the roadless characteristics and themes assigned to them in the Idaho Roadless Rule. The desired conditions specify that the composition, structure, and pattern of vegetation reflect natural disturbances and follow Idaho Roadless Rule themes, as assigned. The plan has specific desired conditions for Roadless areas to contribute to habitats for wide ranging species and connectivity for movement of wildlife and that these areas provide foraging, security, denning, and nesting habitat for wildlife. The plan's desired conditions also state that Roadless areas provide recreational opportunities for both motorized and non-motorized users all year long and is reflected in the appropriate recreation opportunity spectrum classes of primitive, semi-primitive non-motorized, and semi-primitive motorized opportunities. These desired conditions provide the prevailing direction towards which management of Idaho Roadless Rule lands are directed. The Idaho Roadless Rule defines Roadless characteristics as:

- High-quality or undisturbed soil, water, or air
- Sources of public drinking water
- Diversity of plant and animal communities
- Habitat for threatened, endangered, proposed, candidate, and sensitive species and for species dependent on large, undisturbed areas of land
- Primitive, semi-primitive nonmotorized, and semi-primitive motorized classes of dispersed recreation
- Reference landscapes
- Natural appearing landscapes with high scenic quality
- Traditional cultural properties and sacred sites
- Other locally identified unique characteristics

One standard and a set of suitability plan components provide the restrictions within Idaho Roadless Rule lands. Standard MA2-STD-IRA-01 states "The provisions in the Idaho Roadless Rule (36 CFR 294

Subpart C) shall take precedence over any inconsistent land management plan component unless and until the rule is amended. Land management plan components that are not inconsistent with the Idaho Roadless Rule will continue to provide guidance for projects and activities within Idaho Roadless Areas and those related to protection of threatened and endangered species (36 CFR 294.28(d)).” This direction enforces the prohibitions and allowances of the Idaho Roadless Rule as codified and will maintain ecological conditions for grizzly bear dispersal and occupancy because they will constrain a variety of activities within these areas that could affect grizzly bear habitat or increase the probability of human-bear conflicts.

Suitability plan components that determine which actions are and are not suitable in Idaho Roadless Rule areas are outlined in the description of the existing condition for Idaho Roadless Rule above. A broad range of actions are prohibited or allowed by suitability plan components and are consistent with Idaho Roadless Rule prohibitions and permissions within the themes. They primarily constrain road building, vegetation management, and mineral activities to various extents depending on roadless rule theme. The prohibitions or allowances are tiered to the Idaho Roadless Rule themes. A map of the Idaho Roadless Rule themes is provided in Figure 96 and a summary of restrictions and allowances in the Idaho Roadless Rule by theme are provided above in (see Other Management Direction—Idaho Roadless Rule). These suitability plan components will protect these lands from actions that could impact secure habitat or create conditions that have the potential to increase the probability of human bear conflicts. Actions constrained by suitability plan components and the Idaho Roadless Rule include timber production, timber harvest, permanent road construction, temporary road construction, mineral materials, construction of new buildings, and motorized travel, though exceptions are allowed in some areas depending upon theme. Note that community protection zones within Idaho Roadless Rule areas allow temporary roads which includes about 36,200 acres (2.4 percent of land within an Idaho Roadless Area on the Nez Perce-Clearwater).

The different themes provide different sets of restrictions which result in some variation in the level of protection the Idaho Roadless Rule and associated plan direction offers. The different themes offer different levels of restrictions and allowances that provide variation in the degree of protections that they offer. The “Other Management Direction” above provides a summary of the different protections and allowances found in the Idaho Roadless Rule; however, the full suite of activities can be found in the Roadless Rule itself (36 CFR 294.28(d)).

The U.S Forest Service consulted on the effects of the Idaho Roadless Rule on federally listed species, including on grizzly bears. In 2008, the U.S. Fish and Wildlife Service issued a biological opinion on the effects of the Idaho Roadless Rule on federally listed species including grizzly bears (U.S. Department of the Interior 2008). The biological opinion evaluated the effects of activities that could be allowed as a result of the Rule and evaluated the effects on grizzly bears from the suite of permissible and prohibited actions including timber harvest, sale, or removal; road construction and reconstruction; and mineral activities. It also evaluated helicopter logging, fire, fire suppression and prescribed fire. It concluded that as the Bitterroot Recovery Zone was currently unoccupied, the Idaho Roadless Rule will have no effect on the status of the Bitterroot Recovery Zone.

As mentioned above, the Idaho Roadless Rule contributes to secure habitats for grizzly bears. The amount of area and the amount of secure habitat by theme is shown in Table 260 below. Many of these areas were maintained without roads by elk habitat effectiveness objectives direction in the 1987 Forest Plans, they were maintained thereafter by the 2001 National Roadless Area Conservation Rule (36 CFR Part 294 Special Areas; Roadless Area Conservation; Final Rule) and since 2008 by the Idaho Roadless Rule. This management history has served to conserve these lands and the Idaho Roadless Rule and Revised Forest Plan Direction will continue that trend into the future.

Table 260. The total acres, acres of secure habitat, and percent secure habitat within Idaho Roadless Rule Themes

Idaho Roadless Rule Area Theme	Acres with the Plan Area	Acres of Secure Habitat Within Each Theme	Percent Secure Habitat
Backcountry Restoration	835,649	588,705	70.4
Primitive	311,154	254,227	81.7
Forest Plan Special Areas	38,287	16,025	41.9
Special Areas of Historic or Tribal Significance	49,341	24,432	49.5
Wildland Recreation	247,133	228,251	92.4
Totals	**1,481,565**	**1,111,642**	**75**

A number of other land allocations overlap Idaho Roadless Rule Areas, providing additional guidance and restrictions above those required by the Idaho Roadless Rule. They include the National Historic Landmark, Recommended Wilderness Areas, some designated wild and scenic river corridors, some of the suitable and eligible wild and scenic river corridors, some designated and proposed research natural areas. For example, there are some lands that are both Idaho Roadless Rule and Designated Wild and Scenic River. In some cases, there are more than two land designations. In cases where there are overlapping land management allocations, actions would have to follow Idaho Roadless Rule direction and the direction for any overlapping land allocations. The plan specifies that the more restrictive direction would prevail in cases where there is conflict. Similarly, the plan specifies that where the plan is inconsistent with the Idaho Roadless Rule, direction in the rule prevails. The lands that have overlapping land allocations are further protected and would contribute to conservation of secure habitat and connectivity. These areas overlap Idaho Roadless Rule Areas and provide additional protections on about 366,900 acres or about 24.8 percent of Idaho Roadless Rule lands. Overlapping areas contain about 288,758 acres of secure habitat.

Most of the Idaho Roadless Rule Areas are managed under Management Area 2 direction, but there is also Idaho Roadless Rule areas within Management Area 1 because of overlapping designations such as the National Historic Landmark and Designated Wild and Scenic Rivers which are both under Management Area 1. In some cases, more than two land designations occur. For example, there are places that are Idaho Roadless Rule areas, designated wild and scenic river, and a research natural area (Table 261). The additional designations and land allocations that overlap Idaho Roadless Rule Areas are shown in table 261. Designated wilderness areas do not overlap with Idaho Roadless Rule Areas.

Table 261. The acres of Idaho Roadless Rule Areas overlapped by other land area allocations or designations

Designation or Allocations	Acres
Designated Wild and Scenic River Corridor	26,115
Suitable Wild and Scenic River Corridor	53,490
Designated National Historic Landmark	28,391
Designated Research Natural Area	14,338
Proposed or Candidate Research Natural Areas	1,685
Eligible Wild and Scenic River Corridor	711
Recommended Wilderness	258,197

Note that because some areas have more than two overlapping management areas, the area of protection is less than the total overlapping acres

Plan direction for Idaho Roadless Rule areas constrain activities that could impact secure habitat and will provide the ecological conditions to provide connectivity and even host a population of grizzly bears.

Consequences from Research Natural Areas

Research Natural Areas (RNAs) are areas that the Forest Service has designated to be permanently protected and maintained in natural conditions. The plan area contains several designated and proposed research natural areas under the 1987 Forest Plans. The plan also identifies and proposes additional research natural areas as part of the Preferred Alternative. The areas identified do not vary by alternative. RNAs are permanently established to maintain areas of natural ecosystems and areas of special ecological significance. These protected natural areas include unique ecosystems or ecological features; rare or sensitive species of plants and animals and their habitat; or high-quality examples of widespread ecosystems. These areas form a long-term network of ecological reserves established as baseline areas for non-manipulative research and the maintenance of biodiversity. Table 262 shows the acres of designated and proposed Research Natural areas and the acres of secure habitat as proposed in the plan.

Table 262 The acres of designated and proposed or Candidate Research Natural Areas in the Existing Condition compared to the Preferred Alternative and the amount of secure habitat contained within designated, proposed, and candidate Natural Research Areas

Research Natural Area	Preferred Alternative Acres	Acres of Secure Habitat
Designated	29,499	21,121
Proposed or Candidate	2,947	2048
Total	**32,446**	**23,169**

Except for RNAs located within Management Area 1 land types, Research Natural Areas are managed as Management Area 2 and have their own set of forest plan components. The management of research natural areas emphasizes maintaining them in a natural condition. The plan manages proposed and designated research natural areas the same. Desired condition MA2-DC-RNA-01 expresses how these areas should be managed. It states that designated and proposed research natural areas maintain a representation of natural systems found on the Nez Perce-Clearwater as a baseline for research, monitoring, and education by the agency, academia, and public interests. Wildfire, insects, and pathogens, along with other processes and disturbances, continue to affect vegetation, reflecting the dynamic nature of the systems they represent. Research Natural Areas contribute to ecological sustainability and biological diversity.

The plan includes two standards and suitability components that dictate the types of activities allowed within these areas. MA2-STD-RNA-01 prohibits the authorization of the collection of forest products for commercial purposes and personal use purposes, including firewood within designated and proposed research natural areas. MA2-STD-RNA-02 prohibits uses that threaten or interfere with the objectives or purposes for which a Research Natural Area is established. Suitability plan components in the Research Natural Areas section of the Plan identify the actions that are suitable and unsuitable within research natural areas. Suitability components find many activities that impact grizzly bear secure habitat as unsuitable including motorized travel, permanent roads, and temporary roads unsuitable.

Research Natural Areas combine for only 32,446 acres, and consist of small, scattered areas, so their contribution to grizzly bear habitat is relatively small but they do add protections to maintain some habitats and contribute to connectivity. They contribute to the protection of 23,169 acres of secure habitat and secure habitats make up 71 percent of Research Natural Areas. They often overlap with other land allocations and plan direction for research natural areas provides additional protection to those areas.

Consequences That Vary by Alternative

The distribution of management areas and overarching direction within each would strongly influence the ecological conditions for grizzly bears across broad areas related to developments and human-bear conflicts. The revised Forest Plan framework allocates the entire national forest into one of three management areas that would have distinctive management. As described in the existing condition section above, this is a substantial change compared to the 1987 plans developed under the 1982 Planning Rule where there were many management areas each with distinct emphasis. Under the Preferred Alternative, the Nez Perce-Clearwater lands are divided into three broad management areas identified as Management Area 1, Management Area 2, and Management Area 3. These broad management areas are arranged from a suite of designated, proposed, and non-designated lands. Each management area follows a broad theme with lands in Management Area 1 being composed of areas designated by congress. Management Area 2 lands are composed of lands set aside by the Idaho Roadless Areas and lands recommended for congressional designation or other designations, while Management Area 3 is made up of lands managed sustainably for multiple uses. However, some lands have more than one designated or proposed area where more than one set of management direction would apply. In cases where multiple designated or proposed land allocations overlap, management direction for all land types applies. According to the plan, where management direction of the different management areas conflicts, the more restrictive direction prevails. The acres of each management area and sub-management area, as well as the acres of secure habitat are shown in Table 263.

Table 263. The acres of area and secure habitat within each Management Area and land allocation in the forest plan*

Management and Sub-management Areas	Acres Within Each Management and Sub-management Area	Acres of Secure Habitat Within Each Management Area and Sub-management Area
1A Designated Wilderness	1,107,131	1,094,558
1A2C: Suitable Wild and Scenic River (WSR) within Designated Wilderness	2,996	2,996
1A2E: Designated Research Natural Area (RNA) within designated wilderness	8,081	7,925
1A2F Candidate Research Natural Area within Designated Wilderness	603	603
1A2I Eligible Wild and Scenic River within Designated Wilderness Area	531	47

Management and Sub-management Areas	Acres Within Each Management and Sub-management Area	Acres of Secure Habitat Within Each Management Area and Sub-management Area
1AB: designated wild and scenic river within designated wilderness	19,029	17,248
1AB2E: established RNA within WSR within designated wilderness	689	689
1B—Designated Wild and Scenic River	11,336	2,257
1B2A: Idaho Roadless Rule area within designated wild and scenic river	24,838	6,872
1B2AE: Idaho Roadless Rule area within designated Research Natural Area within designated Wild and Scenic River	644	32
1BC: WSR within National Historic Landmark (NHL)	721	0
1BC2A: Idaho Roadless Rule (IRR) area within designated Wild and Scenic River and the National Historic Landmark	633	128
1C: National Historic Landmark (Lolo Trail)	25,887	1,325
1C2A: Idaho Roadless Rule area within National Historic Landmark	24,050	7,727
1C2AC: Suitable Wild and Scenic River within Idaho Roadless Rule area within National Historic Landmark	3,504	2,694
1C2AE: Idaho Roadless Rule area within a Designated Research Natural Area within the National Historic Landmark	74	0
1C2AG Candidate Research Natural Area within the National Historic Landmark within Idaho Roadless Rule.	130	0
1C2C: Suitable Wild and Scenic River within the National Historic Landmark	539	5
1C2E: Designated Research Natural Area within the National Historic Landmark	222	35
2A: Idaho Roadless Rule Area without any other overlapping designated or proposed areas	1,114,736	822,955
2AB: Recommended Wilderness within Idaho Roadless Rule Areas	243,773	225,094
2ABC: Suitable Wild and Scenic River within recommended wilderness and within Idaho Roadless Rule area	13,580	12,157
2ABCF: Suitable WSR within recommended wilderness within a Proposed Research Natural Area and within an Idaho Roadless Rule area	122	122
2ABE: Recommended wilderness within a Designated Research Natural Area within an Idaho Roadless Rule area	537	537
2ABF: Recommended wilderness within a proposed Research Natural Area and within an Idaho Roadless Rule area	185	185
2AC: Suitable Wild and Scenic River within an Idaho Roadless Rule area	39,788	22,307

Management and Sub-management Areas	Acres Within Each Management and Sub-management Area	Acres of Secure Habitat Within Each Management Area and Sub-management Area
2AE: Designated Research Natural Area within an Idaho Roadless Rule area	13,083	9,399
2AG Proposed Research Natural within Idaho Roadless Rule area	1,248	793
2AI Eligible Wild and Scenic River within Idaho Roadless Rule area	711	711
2B: Recommended wilderness without any other designation or proposed area.	13	0
2C: Suitable Wild and Scenic River Corridor without any other proposed or designated area	1,319	138
2D: Gospel-Hump Multi-Purpose Area 2 lands within MA2	28,498	25,871
2E: Designated Research Natural Areas outside of any other proposed or designated areas	6,169	2,504
2G Proposed Research Natural Area outside of any other designated or proposed areas	658	345
2I Eligible Wild and Scenic River outside of any other proposed or designated area.	2,658	15
3A All Other Areas	1,182,903	166,300
3B Gospel-Hump Multi-Purpose Area Geographic Area within Management Area 3	57,437	28,505
Subtotal 1A Lands—Designated Wilderness including those with other designated and proposed areas	1,139,059	1,124,066
Subtotal 1B Lands-Designated as Wild and Scenic Rivers outside of designated wilderness but including those with other overlapping designated or proposed areas.	38,173	9,290
Subtotal 1C Lands—National Historic Landmark including those with other overlapping designated or proposed areas	54,406	11,786
Subtotal 2A Lands—(2A through 2AI) Primary Idaho Roadless Rule Areas but includes lands with other overlapping designated or proposed areas.	1,427,763	1,094,259
Subtotal 2B through 2I- Other designated or proposed MA2 lands outside of Idaho Roadless Rule Areas.	39,316	28,875
3A- General Forest Areas	1,182,903	166,300
3B Gospel-Hump Multi-Purpose Areas	57,437	28,505
Total MA1 Lands	**1,231,638**	**1,145,141**
Total MA2 Lands	**1,467,078**	**1,123,133**
Total MA3 Lands	**1,240,340**	**194,805**
Grand Total	**3,939,056**	**2,463,080**

*Management areas are indicated by the first number in the alphanumeric codes and begin with 1, 2, or 3 to indicate the Management Area. In some areas, more than one designation or proposed designation can be found and are indicated by the labels. Each unique combination of land allocation is separated out. Alphanumeric codes that start with 1A are designated Wilderness, if they start with 1B they are designated Wild and Scenic River but not wilderness, if they start with 1C they are Lolo Trail National Historic Landmark and not wilderness nor wild and scenic rivers. Alphanumeric codes that start with 2A are Idaho Roadless Rule areas and may include other overlapping designations. If they start with 2B, 2C, 2D, 2E, 2G, or 2I they are

Management Area 2 lands outside of Idaho Roadless Rule Areas. Management Area 3 consists of lands with alphanumeric codes of 3A and 3B.

There is little flexibility in changing the distribution of these three broad management areas because they are identified by already established boundaries such as Designated Areas and Roadless Rule Areas. While the distribution of the three management areas is relatively static, the suitability of uses and intensity of allowed uses are discretionary. For example, suitability, Recreation Opportunity Spectrum designations, pace of vegetation restoration, wild and scenic suitability, amount of fuel treatments, objectives, and intensity of use are established in the plan and vary between the different management areas. They differ slightly because of alternatives for Suitable Wild and Scenic Rivers where some are located in areas in the Managed Front, and if found suitable, would be managed as Management Area 2 rather than Management Area 3. The differences in acres are shown in Table 264. Alternatives that have more land within Management Area 1 and 2 would be better from a grizzly bear conservation perspective. The No Action Alternative in is an estimate to compare against alternatives, but the 1987 plans had dozens of management areas with different emphasis. The action alternative would be Alternative Y from a grizzly bear perspective.

Table 264. The allocation of management areas in acres by alternative

Management Area (MA)	No Action Alternative	Alternative W	Alternative X	Alternative Y	Alternative Z	Preferred Alternative
MA1	1,231,638	1,231,638	1,231,638	1,231,638	1,231,638	1,231,638
MA2	1,489,736	1,468,505	1,463,081	1,487,434	1,472,364	1,467,078
MA3	1,217,683	1,238,913	1,244,337	1,219,984	1,235,055	1,240,340

There is little flexibility in changing the distribution of these three broad management areas because they are identified by already established boundaries such as Designated Areas and Roadless Rule Areas. While the distribution of the three management areas is relatively static, the suitability of uses and intensity of allowed uses are discretionary. For example, suitability, Recreation Opportunity Spectrum designations, pace of vegetation restoration, wild and scenic suitability, amount of fuel treatments, objectives, and intensity of use are established in the plan and vary between the different management areas.

The effects of management area allocation combined with their respective restrictions on suitability of uses, and management area specific plan components forms the basis for broad protections across the much of landscape for grizzly bear habitat. The effects of management area allocation are described here and analyzed to provide a big picture overview of the effects of management area allocations. Additional detailed analysis specific to each type of land allocation are presented individually and in detail in the analysis of the individual land allocations.

Management Area 1 is composed of three areas designated by congress for specific uses and that have restrictions or special management direction prescribed by law. These include designated wilderness, designated wild and scenic rivers, and the congressionally designated Lolo Trail National Historic Landmark. These designations offer high levels of land protections against developments. Plan components or direction specific to these areas in the plan are labeled with Management Area 1. The effects of the direction in these areas were analyzed above. Plan direction within Management Area 1 includes specific areas of the plan with plan components directing the management of designated wilderness, designated wild and scenic rivers, and the National Historic Landmark. There are also management area specific plan components scattered throughout the plan that also apply to these management areas. They include desired conditions, standards, guidelines, and suitability of uses that would maintain and protect these areas in a condition for connectivity and even a future population of grizzly bears in these areas. Under the plan, the amount of secure habitat would be expected to change only slightly in Management Area 1.

The Bitterroot Recovery Zone is nearly all Management Area 1 lands. Existing roads in these areas can be seen in Figure 102 and Figure 103 below. Management Area 1 provides high levels of protection against the loss of secure habitat with the limited exceptions of areas within Designated Wild and Scenic Rivers where motorized uses are suitable, and within the National Historic Landmark. Designated wild and scenic rivers and the National Historic Landmark areas make up about 92,579 acres or about 7.5 percent (1B and 1C lands in Table 263) of Management Area 1.

These areas are almost all secure habitats and will largely remain secure into the foreseeable future. The result of this management direction is that the 1,231,638 acres of Management Area 1 lands are highly protected for the future establishment and recovery of grizzly bears. Management Area 1 lands are currently composed of 1,145,141 acres or 93 percent secure habitat and wilderness management in the plan will continue to maintain these secure habitats into the future. The bulk of Management Area 1 is designated wilderness at 1,139,059 acres, thus 92.4 percent of Management Area 1 lands are managed and protected as designated wilderness areas. A total of approximately 1,124,066 acres of wilderness or 98.6 percent is secure habitat.

Management Area 2 consists of lands composed of backcountry areas with moderately restrictive management because they are either proposed for designation, roadless areas, or were set aside legislatively as restrictive land management types. Management Area 2 consists of Idaho Roadless Rule Areas; proposed areas such as recommended wilderness, or rivers proposed as suitable or eligible for congressional consideration as wild and scenic rivers; designated and proposed Research Natural Areas, and the Gospel-Hump Multi-Purpose area. The Gospel-Hump Multi-Purpose Area was established by legislation for specific management when the Gospel-Hump Wilderness was established. Management Area 2 is composed mostly of lands within Idaho Roadless Areas, but also includes significant acreage of recommended wilderness areas, and smaller amounts of eligible and suitable wild and scenic rivers, proposed and designated research natural areas, and the Gospel-Hump Geographic Area. This management area is made up of relatively large areas, generally without roads, few motorized trails, and provides a variety of recreation opportunities. Existing roads and motorized trails in Management Area 2 can be viewed in Figure 102 and Figure 103. In many cases the different land allocation types overlap each other. Table 263 shows the acres of land allocations within Management Area 2 including those with overlapping land allocations.

Revised Forest Plan direction for Management Area 2 would apply to projects within any and all land allocation types they occurred in. In many areas, more than one set of set of plan direction would apply. For example, if a project fell within a sub-management area that had Idaho Roadless Rule areas, suitable Wild and Scenic River corridor and Research Natural Area, then all of the plan direction including suitability from each sub-management area would apply to that project. In recommended wilderness, both Idaho Roadless Rule Area restrictions apply, and recommended wilderness area restrictions apply. If conflicting plan guidance is discovered, the direction from the more restrictive management area would apply. Generally, the following order is presumed to be in order from most restrictive to least and generally will be used to determine which plan components shall be applied, though the final decision will be made during project level analysis:

- Designated Wilderness and Designated Wild and Scenic Areas—Management Area 1

- Lolo National Historic Trail
- Designated Research Natural Areas
- Proposed Research Natural Areas, Suitable Wild and Scenic Rivers, and Recommended Wilderness
- Idaho Roadless Rule, unless directed by the rule itself, which supersedes a Land Management Plan
- Geographic Area Plan Components
- Management Area Plan Components for Management Area 3
- Forestwide Plan Components

Plan direction for Management Area 2 is found in Section 6.6 of the revised Forest Plan and includes broad direction for recommended wilderness, eligible and suitable wild and scenic rivers, Idaho Roadless Rule areas, proposed natural research areas, and designated natural research areas. Specific direction includes desired conditions, guidelines, standards, and suitability that would mostly conserve these areas for the future use of grizzly bears. Additional management area specific plan components are also scattered throughout the plan and would also apply in this management area. In the revised Forest Plan, components specific to this management area begin with Management Area 2. Generally, plan components would direct managers to maintain wilderness character within recommended wilderness areas, maintain roadless characteristics in roadless rule areas, and maintain outstandingly remarkable values within suitable within wild and scenic rivers.

Activities are restricted to various degrees in Idaho Roadless Rule Areas, consistent with the Idaho Roadless Rule. The plan components that restrict various activities across broad areas are primarily the suitability plan components specified for each Management Area 2 land allocation, though there are also standards and guidelines that also restrict activities. Depending on location, activities that are constrained to various extents include timber production, timber harvest, permanent road construction, temporary road construction, some mineral extraction activities, construction of new buildings or facilities, over-snow vehicle travel, motorized travel, and mechanized travel. Vegetation management emphasis is to restore and provide variety in size classes, dominance types and density as informed by the natural range of variation for vegetation conditions under natural disturbance regimes. While timber production is generally prohibited, timber harvest can be used to treat vegetation for restoration purposes but must generally be conducted from existing roads. Additional analysis of how plan components contribute to recovery of grizzly bears can be found within the section of this analysis below called “Plan components that contribute to ecological conditions for grizzly bear recovery.”

Management Area 2 has mechanisms to restrict loss of secure habitat. First, in recommended wilderness, road and motorized trails are not suitable uses and are prohibited. Second, the plan restricts road building with only limited exceptions consistent with the Idaho Roadless Rule, but motorized trails are allowed. However, the plan also contains plan components for elk and grizzly bear in MA2-GDL-WL-05 would provide restrictions on the amount and location of motorized trail construction that would be allowed. For example, this guideline requires there to be areas of 5,000 acres without motorized access remaining when constructing motorized trails. These measures help ensure that areas of potential dispersal would largely be maintained because they greatly restrict the construction of new roads and constrains construction of motorized trails. Additionally, it would ensure that grizzly bears could pass through these areas and even occupy them because these minimum sized areas are larger than areas identified by Wakkinen and Kasworm (1997) who suggested that areas 1,280 acres and larger were used more by grizzly bears than smaller blocks.

The direction for these areas would provide connectivity and while there are more roads and motorized trails than in Management Area 1, these areas also provide abundant secure habitats. The amount of secure habitat in this management area would be expected to decline some due to development of future motorized trails, though the amount and location is unknown at this time. Grizzly bears in this management areas would find habitat conditions that support female survival but a higher probability of human-bear conflicts than in Management Area 1. This is because most of this management area is composed of secure habitat that would largely be retained under the plan. While use by the public is expected to increase over time. The probability of human-bear conflict would be far lower than in Management Area 3. This direction would help to maintain ecological conditions to support a future grizzly bear population within Management Area 2 and support connectivity into the Bitterroot Recovery Zone from other ecosystems. This direction would help to maintain ecological conditions to support a future grizzly bear population.

Collectively, Management Areas 2 lands result in a block of land 1,467,078 acres where the plan direction constrains roads and motorized trails, of which 1,124,882 acres or approximately 76.6 percent is currently secure habitat. Most of this management area would remain as secure habitats into the future due to the collective constraints mentioned above. However, they are not completely protected against new motorized roads and trails as some Management Area 2 lands are suitable for motorized uses and have the potential to be impacted by new motorized trails. A map of existing roads and motorized trails are shown in Figure 102 and Figure 103. These areas provide conditions to facilitate connectivity and even occupancy of grizzly bears outside of the recovery zone.

The combined effects of Management Area 1 and 2 direction is that 2,698,716 acres of habitat is either fully protected or partially protected by either the highly restrictive plan direction for Management Area 1 lands or the constraining direction of Management Area 2. Combined these lands have 2,268,274 acres of secure habitat currently or are 84 percent secure. The size and the amount of secure habitats protected by the combined amount of secure habitat, and the percent of the landscape that is secure habitat (or secure core) is comparable to those within other grizzly bear ecosystems Table 265. The condition of the Nez Perce-Clearwater compares favorably to other ecosystems and will remain that way because of constraints in the plan in wilderness and roadless rule management area direction.

Table 265. A comparison of the Nez Perce-Clearwater acres, amount of secure habitat, and percent secure habitat compared to other grizzly bear ecosystems

Grizzly Bear Ecosystem	Total Acres	Secure Core	Percent Secure
Selkirk Ecosystem[1]	1,307,525 total 688,642 in US	298,176	43%
Cabinet Yak[1]	1,693,248	628,543	37%
GYE[2]	3,413,000	2,827,000	83%
NCDE[3]	5,712,862	3,941,874	69%
Nez Perce-Clearwater Protected Lands Alone (MA1 and MA2 Combined)	2,698,716	2,268,274	84%
Nez Perce-Clearwater Plus Rest of BE recovery Zone	5,465,401	Not Available	Not Available

Areas outside of designated and proposed areas are managed for multiple uses and are identified as Management Area 3. These are lands that have no other restrictions or special management imposed by designation or regulation and are not identified as areas recommended for congressional designation. These areas are commonly referred to as the managed front or front country. They are managed to provide for integrated social, economic, and ecological sustainability, and ecosystem integrity and diversity while providing for ecosystem services and multiple uses. The managed front typically includes more roads, most of the campgrounds and infrastructure, more human use, and in many cases are managed for timber production.

Management Area 3 includes lands managed for multiple uses, with emphasis on vegetation management, timber production, road, or motorized access, developed recreation, and wildfire prevention, especially within the Wildland Urban Interface, among other uses. This management area currently has more intensive recreational use, many roads and little secure habitat. There are very few constraints on activities within Management Area 3 in the plan. Existing roads in relation to Management Area 3 are shown in Figure 102 and Figure 103 below.

Grizzly bears in this management area would be expected to have lower survival and a higher probability for human-bear conflicts. The amount of secure habitat by management area is shown in Table 266 below. The road system accesses most of this management area currently and it is anticipated that additional roads would be developed to provide for recreation opportunities and to harvest timber. Therefore, the already low amounts of secure habitat could decline some. Only 16 percent of the secure habitats in the plan area occur in this management area, and secure habitats total only 194,805 acres in this management area. Of note, most of the roads closed to the public but open to administrative uses occur in this management area and as was mentioned above in the existing condition if administrative roads were not counted towards secure habitat, an additional 258,525 acres would be secure, most of which would be within Management Area 3. Management Area 3 is not biologically suitable for grizzly bear occupancy because it represents a risk to grizzly bear survival because if grizzly bears move into this management area, they would experience a higher probability of human-bear conflict because of conditions there.

Table 266. The amount in acres and percentage (rounded) of secure habitat within each management area (MA)

Management Area	Total Acres of Secure Habitat	Percent Secure Habitat Within MA
Management Area 1	1,145,141	93%
Management Area 2	1,123,133	76%
Management Area 3	194,805	16%

Management Area 3 contains some lands where management direction was established by the Endangered American Wilderness Act (1978) which created the Gospel-Hump Wilderness Area. Three areas totaling 92,000 acres were established for multiple resource development and is referred to as the Gospel-Hump Multi-Purpose Area. A portion of these areas occurs within Management Area 2 and another portion occurs within Management Area 3. The plan established these areas as The Gospel-Hump Multipurpose geographic area. The plan contains specific plan components for the geographic area including desired conditions, objectives, and guidelines. The desired condition is for the area to provide quality fish and wildlife habitat, motorized and non-motorized recreation opportunities, areas available for timber harvest to meet social and economic demand, and opportunities for research. The areas within Management Area 3 are emphasized for multiple uses.

The grizzly observations near Whitebird, Fish Creek, and Newsome Creek were within this future Management Area 3 without incident. Bear 927 passed through portions of Management Area 3 in the Lolo Pass area. Bear 927 even used the area of checkerboard ownership within Management Area 3 during his time here. However, these observations suggest that these areas may still be permeable to grizzly bears to some extent. These areas are not managed to emphasize grizzly bears. Management Area 3 would still be somewhat permeable to dispersing bears because even though it has more motorized access, most roads are low speed, gravel forest roads with comparably low amounts of traffic compared to highways. These conditions should not prevent grizzly bears from passage. Of note is the checkerboard ownership near Lolo Pass, which has mixed Forest Service and private ownership and many roads. While that area has more roads, the private lands are owned and managed by a commercial timber company and thus are managed in mostly an undeveloped state that still provides passage for dispersing grizzly bears.

The greatest impacts or changes to secure habitat would most likely occur within the 16 percent of secure habitats in Management Area 3 and to a lesser extent in some secure habitat in Management Area 2. The secure habitat within Management Area 1 is expected to change very little under the Preferred Alternative.

Roads and motorized trails within each management area are shown in Figure 102 and Figure 103 below. These maps illustrate that Management Area 1 has very few roads and motorized trails, Management Area 2 has more than Management Area 1 but fewer than Management Area 3, while Management Area 3 has high amounts of road and motorized trails. This is why most of the secure habitat currently present is within Management Areas 1 and 2 while little exists in Management Area 3. The plan direction for Management Areas 1 and 2 and associated suitability plan components reinforce roadless rule regulations and the Wilderness Act restrictions that have protected, and will continue to protect, these lands from motorized uses. Suitability plan components restrict many activities associated with these management areas across broad areas of the Nez Perce-Clearwater as outlined in other sections below.

The breakdown of the management area allocation in the Preferred Alternative is shown in Figure 101 below. It should be noted that several protective land allocations overlap in a substantial portion of the plan area. The figure also shows the amount of secure habitat present in the management areas.

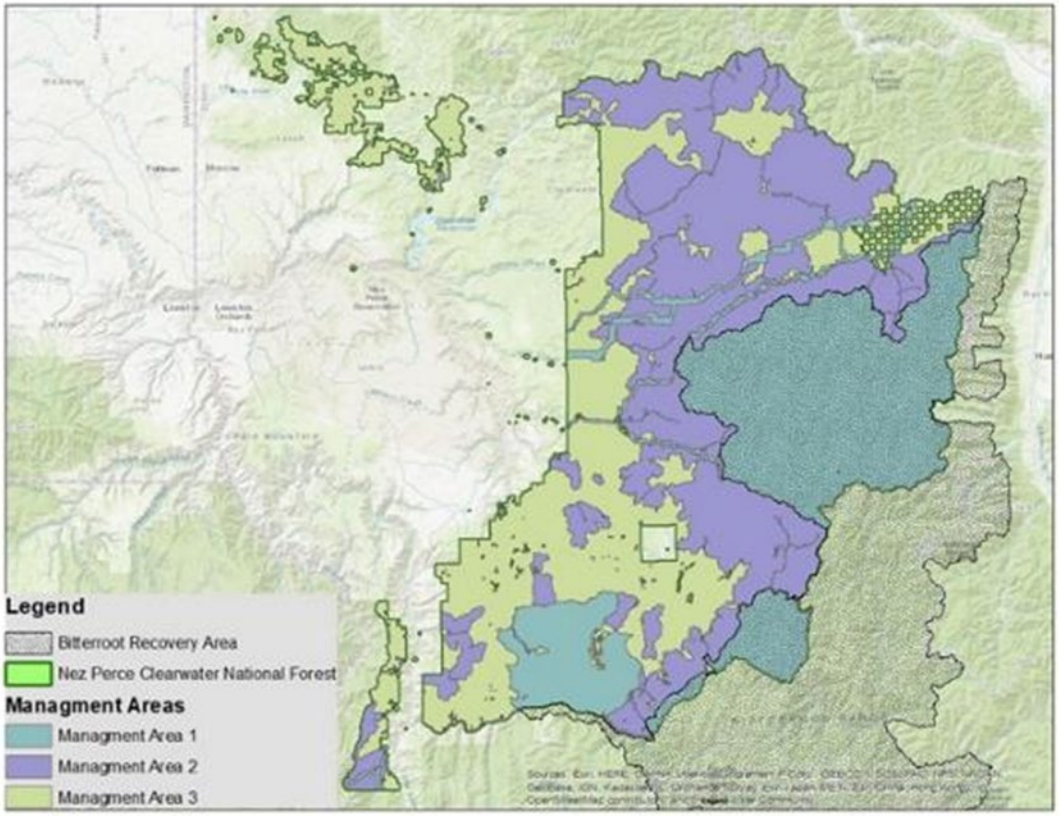

Figure 101. The management areas under the Preferred Alternative

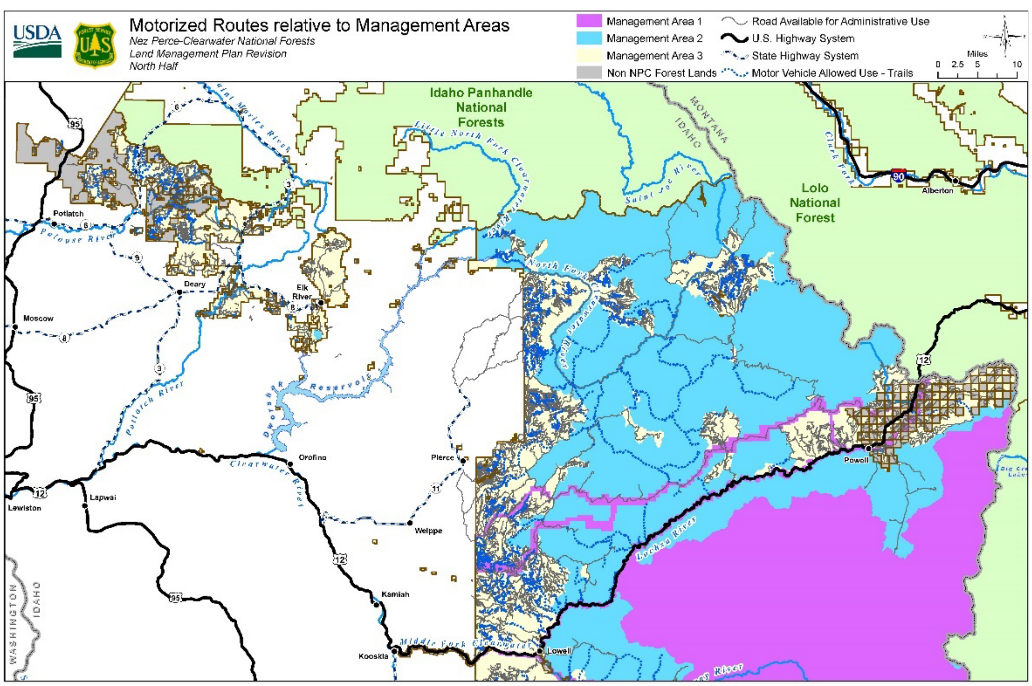

Figure 102. Current motorized roads (gray) and motorized trails (shown in dotted dark blue) in relation to the three management areas of the Preferred Alternative in the northern portion of the plan area

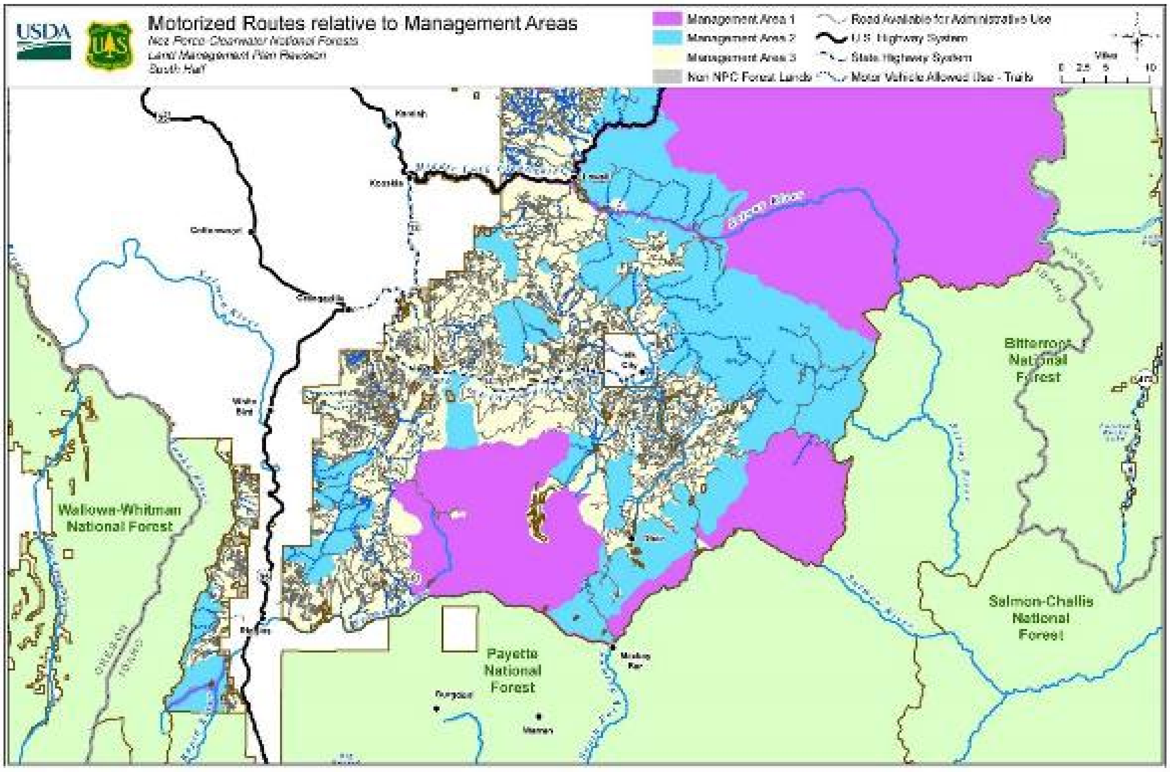

Figure 103. Current motorized roads (gray) and motorized trails (shown in dotted dark blue) in relation to the three management areas of the Preferred Alternative in the southern portion of the plan area

Consequences for Recommended Wilderness Allocation

For dispersing grizzly bears, the amount and location of recommended wilderness may have a beneficial effect on connectivity from the other grizzly bear recovery zones. The recommended wilderness areas in the northern portion of the Nez Perce-Clearwater would contribute to connectivity for dispersing bears heading for the Bitterroot Recovery Zone from the Cabinet Yak, Selkirk, or Northern Continental Divide ecosystem recovery zones.

The existing condition includes recommended wildernesses as described in the 1987 Clearwater Forest Plan and includes 197,693 acres. Recommended wilderness under the 1987 Forest Plan contributes to grizzly bear connectivity which includes the Hoodoo, Mallard-Larkins, and portions of North Fork Spruce-White Sand, and Sneakfoot Meadows.

The alternatives propose various amounts of recommended wilderness. The No Action Alternative would retain the recommended wilderness as described in the 1987 Clearwater Forest Plan. The action alternatives vary the amount of recommended wilderness. Alternative W provides the most acres of recommended wilderness while Alternative X proposes no recommended wilderness and instead all current recommended wilderness areas would be managed as Idaho Roadless Rule areas. Alternative Y proposes similar amounts as the No Action Alternative but modifies and reduces some of those areas currently recommended as wilderness under the No Action Alternative. Alternative Z proposes some of the same areas as recommended wilderness as the No Action Alternative but adds Pot Mountain, Meadow Creek-Upper North Fork, and Rawhide. Regardless of alternative, recommended wilderness areas that best provide for grizzly bear connectivity include Mallard-Larkin, Meadow Creek North-Upper North Fork, Rawhide, Hoodoo, Sneakfoot, and Northfork Spruces White Sand. These areas would provide opportunities for bears to travel from the north into the Bitterroot Ecosystem. From a grizzly bear conservation perspective, the best alternative would be the one that proposes the most recommended wilderness which would be Alternative W. The Preferred Alternative would include Hoodoo, the Mallard Larkin, and Meadow Creek as a new recommended wilderness area but with boundary changes compared to the No Action Alternative.

The Preferred Alternative retains the Mallard Larkin and Hoodoo area albeit with modified boundaries and drops the North Fork Spruce-White Sands and Sneakfoot Meadows. Two of these areas, the Hoodoo and Mallard Larkin areas, are currently managed as recommended wilderness. It includes a newly created Meadow Creek Recommended Wilderness Area, which would be a new Recommended Wilderness Area compared to the previous plan and is located adjacent to the Bitterroot Recovery Zone (Figure 104). The modified boundaries of the Hoodoo recommended wilderness area included both additions and a few areas that will not be recommended wilderness in the Preferred Alternative. The overall results is a reduction in area of that recommended wilderness of about 3,712 acres (Table 268),, however it also resulted in slightly more secure habitat of about 5,401 acres being included in recommended wilderness because of the additions (Table 268). Note that the 3,712 acres will remain unsuitable for summer motorized uses but will be suitable for winter motorized uses. The change in the boundaries of the Mallard Larkin recommended wilderness area results in an increase of about 10,762 acres in that recommended wilderness area (Table 267). The addition of the Meadow Creek recommended wilderness area adds additional new recommended wilderness. The total amount in the Preferred Alternative increases to 258,210 acres (Table 267), an increase of about 60,517 acres. The beneficial effects of this would be to ensure additional area of secure habitat adjacent to the Bitterroot Recovery Zone. The Hoodoo and Mallard Larkin areas would contribute to opportunities for bears to travel from the north into the Bitterroot Recovery Zone and land within a recommended wilderness area. Bears coming from the north or east could arrive within these recommended wilderness areas, providing a gateway into the plan area.

The extent to which recommended wilderness improves or maintains ecological conditions for grizzly bear use and connectivity over Idaho Roadless Rule management depends upon suitability of uses allowed, plan direction for recommended wilderness and, and the roadless rule theme. The wildland recreation theme is the most restrictive while the Primitive theme is slightly less restrictive, and the Backcountry Restoration Theme is the least restrictive. A description of activities allowed and prohibited within roadless rule themes is presented above.

Under the Idaho Roadless Rule, the Hoodoo area is managed as Wildland Recreation Theme, and most of the Mallard Larkin is managed Wildland Recreation but a small portion is managed as Primitive theme. The third, the Meadow Creek Area, is managed as Idaho Roadless Rule Area in part under the Primitive theme and in part and under the Backcountry Restoration them. It is foreseeable that the roadless rule may be amended through the rule making process to align recommended wilderness with the Wildland Recreation theme, however, that process would be outside of revision. Generally, speaking recommended wilderness management is only slightly more restrictive than Idaho Roadless Rule Themes. One primary change that would most affect grizzly bears is the use of summer motorized travel which is restricted in recommended wilderness. Though road building is also restricted within the Idaho Roadless Rule area management, motorized trails are allowed. Under the Preferred Alternative, motorized travel, mechanized travel, motorized and mechanized tools for public use, and aircraft landing for recreational use are prohibited in recommended wilderness. Motorized and mechanized tools may be used administratively and aircraft landing for administrative uses would be allowed. Within the Idaho Roadless Rule areas in the Wildland Recreation Theme, the cutting, sale, or removal of timber is prohibited, except for personal or administrative use, as provided for in 36 CFR Part 223 or where incidental to the implementation of a management activity not otherwise prohibited by the Idaho Roadless Rule.

Areas that were formerly recommended wilderness, and that will no longer be recommended wilderness such as the areas formerly in the Hoodoo recommended wilderness area, will still be managed as Idaho Roadless Rule areas within the Wildland recreation theme. MA2-SUIT-IRA-03 specifies that roads are suitable in these areas only under strict conditions specified in the Idaho Roadless Rule. Furthermore, these areas are mapped as Semi-Primitive Non-motorized in the Summer Recreation Opportunity Spectrum settings so summer motorized uses would not be suitable in these formerly recommended wilderness areas. The primary difference between recommended wilderness and Idaho Roadless Rule wildland recreation theme areas is suitability of winter motorized uses wherein some formerly recommended wilderness areas would be suitable for winter motorized uses where they are mapped as semi-primitive motorized for winter recreational opportunity spectrum. Specific effects from this change are that future potential grizzly bear dens may be disturbed by winter recreation in limited circumstances. Furthermore, allowing winter motorized access in these areas potentially increases the chance of illegal winter motorized uses in adjacent recommended wilderness by the public. However, the public use of adjacent recommended wilderness areas these areas is not authorized and restrictions on this illegal use will be reduced through law enforcement.

The primitive theme includes very limited permissions and exceptions for timber cutting, sale or removal, road construction or reconstruction, and mineral activities. Exceptions include to improve threatened, endangered, proposed, or sensitive species habitat; to maintain or restore the characteristics of ecosystem composition, structure, and processes; and to reduce the risk of uncharacteristic wildland fire effects to an at-risk community or municipal water supply system. Management is primarily to maintain roadless characteristics.

The Backcountry Restoration theme allows limited permissions and exceptions for timber cutting, sale, or removal; road construction and reconstruction; and mineral activities. This includes the following exceptions: to reduce hazardous fuel conditions within or outside of a community protection zone with conditions; to reduce the risk of uncharacteristic wildland fire effects; to improve threatened, endangered, proposed, or sensitive species habitat; and to maintain or restore the characteristics of ecosystem composition, structure, and processes.

Table 268 shows the amount of secure habitat within recommended wilderness areas among alternatives compared to the Preferred Alternative. The Preferred Alternative would add additional secure habitat of about 50,088 acres that will be protected by recommended wilderness compared to the No Action Alternative. Alternatives that have more area in recommended wilderness would be better for grizzly bears. It should be noted that the areas that were previously recommended wilderness would still be secure habitat even if it is not recommended wilderness. Future management of these former recommended wilderness areas would be determined by their new management area direction and because they are also Idaho Roadless Rule areas, road construction, as well as other restricted activities, would continue to be prohibited by regulation. They would retain the most restrictive Idaho Roadless Rule Wildland Recreation Theme. The Preferred Alternative for recommended wilderness provides protections to maintain areas of potential dispersal in the Hoodoo and Mallard-Larkin for bears arriving from the North or East, and the Meadow Creek for bears moving southeast as they spread through the Bitterroot Recovery Zone. The Preferred Alternative would add 60,517 total acres and 50,088 acres of secure habitat to recommended wilderness.

An important note is that about 85.4 miles of existing roads or motorized trails will be unsuitable as a result of the change in recommended wilderness in the Preferred Alternative and will need to be closed in a future travel management decision as a result of the change. This will result in additional secure habitat once this happens. Also, about 80.9 miles of trail open to mechanical travel, such as bicycles, will also be unsuitable as a result of the change in recommended wilderness under the Preferred Alternative.

Suitability of some uses within recommended wilderness also varies by alternative. Suitability of uses considered included whether or not to allow winter motorized travel, mechanized and motorized tools allowed for the public, mechanized and motorized tools allowed to be used administratively, aircraft landings for recreation allowed, and aircraft landings for administrative uses allowed. Of these uses, the winter motorized travel allowed in Alternative Z would have regular and repeated occurrences in recommended wilderness which could disturb or displace grizzly bears during denning season. An in-depth discussion on the effects of winter motorized uses is included in the evaluation of the winter recreation opportunity spectrum alternatives presented below. Aircraft landings have been reported as a disturbance effect. Recreational aircraft landing would have greater potential for effects because it would be more regular and repeated aircraft use that could result in disturbance. While administrative aircraft use could also disturb grizzly bears, this use would be uncommon, and only used for special purposes like wildfire operations, or wildlife related activities of State Agencies. Mechanized travel would be suitable in Alternative Z. Mechanized travel, such as on bicycles, could disturb grizzly bears, and could also result in human bear conflicts if grizzly bears perceive cyclists as a threat or as prey. Mechanized and motorized tools for admin use would be allowed in alternative is allowed in the No Action Alternative and would be allowed in Alternative Z. These would be used to administer land management like clearing trails or maintaining structures. This use could have minor, uncommon, and limited disturbances on grizzly bears. Mechanized and motorized tools are suitable in Alternative Z, and handheld motorized tools would be suitable within Alternative W. This use would be a more common and potentially used more widely than administrative uses and could lead to disturbance effects. Alternative X has no recommended wilderness so all these activities could occur and result in the most disturbance effects. The Preferred Alternative would allow motorized and mechanized tool use for administrative uses and aircraft landings for administrative uses. These would have minor and limited disturbance effects.

Eligible and Suitable Wild and Scenic Rivers

In the 1987 Forest Plans, rivers were identified as eligible based on their outstandingly remarkable values and management direction is to maintain those values until congressional designation. Forest Service policy requires the protection of the outstandingly remarkable values within a one-quarter mile distance from the river called the river corridor. A decision made while revising a Forest Plan is whether other rivers would be identified as suitable or eligible to be considered for future wild and scenic river designation. Grizzly bears are not identified as outstandingly remarkable values for any river identified in the Preferred Alternative because they were not identified as river dependent species.

The plan varies whether various rivers with outstandingly remarkable values are suitable for wild and scenic designation. The plan must protect the outstandingly remarkable values, which would help protect grizzly bear habitat use of these rivers. The general management areas in Management Area 3 do not change between alternatives, except for where wild and scenic rivers are found suitable. Suitable wild and scenic rivers would provide only slight benefits to grizzly bear connectivity. Those rivers that provide the most connectivity for grizzly bears are the North Fork Clearwater River, Lake Creek, North Fork Kelly Creek, Middle Fork Kelly Creek, South Fork Kelly Creek, Crooked Fork, and Colt Killed Creek. These rivers are identified because they are located near where grizzly bears may cross into the Nez Perce-Clearwater and some of them run either away from or towards the Bitterroot Ecosystem which may provide some corridors towards the Bitterroot Ecosystem. Crooked Fork is perhaps the most important proposed suitable wild and scenic river for grizzly bears because it crosses the checkerboard area near Lolo Pass, which could potentially be the most challenging place for grizzly bear passage because of the amount of private land and roads in that area. Alternatives W and Z would select many of these rivers as suitable to be wild and scenic rivers. The Preferred Alternative identified 10 rivers as suitable for wild and scenic consideration. Suitable rivers under the Preferred Alternative include Cayuse Creek, Fish Creek, Hungery Creek, Weitas Creek, Kelly Creek, North Fork Kelly Creek, Middle Fork Kelly Creek, South Fork Kelly Creek, Colt Killed Creek, and Meadow Creek. Most of these rivers are found within roadless rule, recommended wilderness, or designated wilderness and would already be relatively protected as provided by that management. Overall, wild and scenic river management would have minor or discountable effects.

The acres of wild and scenic rivers that are either suitable or eligible by alternative are shown below. Alternative Z would have the most acres of secure habitat within suitable wild and scenic river corridors, while the No Action Alternative has the most as eligible. The Preferred Alternative retains some rivers as eligible and identifies some as suitable. The suitable wild and scenic rivers under Alternative W and Alternative Y are similar or slightly higher than the Preferred Alternative. While grizzly bears are not identified as outstandingly remarkable values, suitable wild and scenic river identification would benefit grizzly bear habitat. Some wild and scenic river classifications restrict actions, like road and trail building within the quarter mile river corridor. The amount of secure habitat within each of the wild and scenic river types are shown below. The No Action Alternative has the most acres within the wild classification compared to the other alternatives. The Preferred Alternative has the most acres under the action alternatives.

Under the action alternatives, rivers were identified as eligible based on a new evaluation of outstandingly Remarkable Values and then, in the final decision, would be determined to be suitable for congressional designation based on a variety of factors. Therefore, the alternatives would change whether rivers with outstandingly remarkable values are suitable for wild and scenic designation or remain eligible.

The acres of secure habitat within eligible or suitable wild and scenic river in the No Action Alternative and the action alternatives are shown in Table 270. The existing condition has many eligible rivers and none that are suitable, while the Preferred Alternative identifies some as suitable. The acres of secure habitat within eligible or suitable wild and scenic river in the existing condition and the Preferred Alternative are shown in Table 271.

Table 270. Acres of grizzly bear secure habitat within the wild and scenic river (WSR) classifications by alternative

Secure Habitat within Suitable/Eligible WSR	No Action Alternative	Alternative W	Alternative Y	Alternative Z	Preferred Alternative
Eligible - Total Secure Habitat	103,465	n/a	n/a	n/a	773
Recreational	3,726	n/a	n/a	n/a	62
Scenic	7,684	n/a	n/a	n/a	711

Wild and Scenic Rivers Type	No Action Alternative	Alternative W	Alternative Y	Alternative Z	Preferred Alternative
Eligible	103,465	n/a	n/a	n/a	773
Suitable	n/a	40,512	43,501	115,316	40,419
Grand Total	103,465	40,512	43,501	115,316	41,192

1 - Alternative X does not have any suitable wild and scenic rivers, so it not included in the table

The revised Forest Plan will set management direction for suitable rivers and their corridors, through plan components and suitability of uses. Like designated wild and scenic rivers, eligible and suitable wild and scenic rivers are classified as either wild, recreational, or scenic and are managed accordingly. Effects of plan components and suitability of uses are included in Table 272 and Table 273. The management of these rivers is to maintain their free-flowing characteristics and outstandingly remarkable values until a designation decision is reached by congress.

Table 272. The new additions as suitable wild and scenic rivers along with the acres of secure habitat within the river corridor

New Rivers Added via Suitability	Acres of Secure Habitat
Middle Fork Kelly Creek	1,423
North Fork Kelly Creek	1,746
South Fork Kelly Creek	1,769
Weitas Creek	309
Total	**5,247**

Table 273. The rivers that will not be eligible wild and scenic rivers under the Preferred Alternative, the acres of secure habitat and whether there is potential to reduce secure habitat because of the change in eligibility

Formerly Eligible River Name	Location and New land allocation	Acres of Secure Habitat	Potential to Reduce Secure Habitat Because of the Change from Eligible?
Bargamin Creek	MA[1] 1-Frank Church-River of No Return Wilderness and MA 2 Meadow Creek recommended Wilderness Area	5,805	No

Formerly Eligible River Name	Location and New land allocation	Acres of Secure Habitat	Potential to Reduce Secure Habitat Because of the Change from Eligible?
Bear Creek	MA 1- Selway Bitterroot Wilderness	6,949	No
Brushy Fork Creek	MA 1 - Selway Bitterroot Wilderness	2,443	No
Cub Creek	MA1- Selway Bitterroot Wilderness	4,964	No
East Fork Moose Creek	MA1- Selway Bitterroot Wilderness	10,578	No
Johns Creek	MA1-Gospel-Hump Wilderness, MA2 -Gospel-Hump Multi-Purpose Area, and MA3	5,497	Yes- Some portions of the river corridor are within Recreation Opportunity Spectrum Settings that allow motorized uses.
Lake Creek	MA 3 and MA 1 - Gospel-Hump Wilderness	3,192	Yes—While the majority of the stream passes through the Gospel-Hump Wilderness, approximately 3.6 miles of the headwaters pass through private lands and portions of MA3 where motorized uses are suitable. These areas are mostly within areas that are not secure habitat.
Moose Creek	MA 1 - Selway Bitterroot Wilderness	1,008	No
North Fork Moose Creek	MA 1 - Selway Bitterroot Wilderness	67	No
Paradise Creek	MA 1 - Selway Bitterroot Wilderness	4,190	No
Rhoda Creek	MA 1 - Selway Bitterroot Wilderness	4,637	No
Running Creek	Mostly MA 2 Meadow Creek Recommended Wilderness Area/IRR-Wildland Recreation, and some MA1- Selway Bitterroot Wilderness	4,439	No, the river corridor falls entirely within non-motorized ROS settings.
Slate Creek	MA1 Gospel-Hump Wilderness Area, MA2 - IRR Backcountry Restoration, and MA3	1,973	Yes, some of the river corridor flows through the areas that are suitable for motorized uses. However, most of the secure habitat within this river corridor falls within the Gospel-Hump Wilderness and would still be unsuitable for motorized uses.
South Fork Clearwater River	MA3	3	Yes because it would all be suitable for motorized uses, but results in little change to secure habitat because there is little secure habitat in the river corridor.
Three Links Creek	MA1 Selway Bitterroot Wilderness	4,269	No, would be managed as designated wilderness.

Formerly Eligible River Name	Location and New land allocation	Acres of Secure Habitat	Potential to Reduce Secure Habitat Because of the Change from Eligible?
Wahoo Creek	MA1 - Selway Bitterroot Wilderness	2,920	No, would be managed as designated wilderness.
West Fork Gedney Creek	MA1-Selway-Bitteroot Wilderness, and MA2 -IRR Backcountry Restoration	1,507	Yes, about half the river corridor would be in an area suitable for motorized uses so could have motorized trails constructed.
West Fork Three Links Creek	MA1- Selway Bitterroot Wilderness	1,689	No, would be managed as designated wilderness.
West Moose Creek	MA1 - Selway Bitterroot Wilderness	2,623	No, would be managed as designated wilderness.
North Fork Clearwater	MA 3, MA2—IRR Primitive, and Backcountry Restoration. River corridor also occurs in semi-primitive non-motorized, roaded natural, and semi-primitive motorized.	67	Yes- occurs in several management areas, roadless rule themes and motorized ROS settings. While this is one of the longer rivers in the plan area, there is currently little secure habitat within the corridor.

1 - MA = management area

The plan components for suitable or eligible wild and scenic rivers are found in direction for Management Area 2 in the revised Forest Plan. The plan components emphasize retaining free-flowing condition, preliminary classification, and the outstandingly remarkable values. MA2-STD-E&SWSR-01 prohibits actions that would change their classification. Other plan direction emphasizes maintain their scenic character.

Activities are also restricted by suitability of uses based on their classification. The plan identifies suitability of uses for Eligible and Suitable wild and scenic rivers which are shown in Table 32 of the revised Forest Plan. Some wild and scenic river classifications restrict actions like road and trail building within the one-quarter mile river corridor. Restrictions in suitability of uses would help maintain grizzly bear habitat and habitat security. The amount of secure habitat within each of the eligible and suitable wild and scenic river classification types are shown in Table 270 and Table 271. The existing condition has the most acres within the wild classification compared to the Preferred Alternative.

Forest Service Handbook (FSH) 1909.12 outlines the activities allowed within the different wild and scenic river classifications. Wild rivers restrict timber cutting, new mineral leases, roads, motorized travel and allows only minimal recreation developments. Scenic Rivers allow timber activities provided there is no substantial impact on the river and its immediate environment but with an emphasis in maintaining visual quality. Mineral operations must minimize surface disturbance, sediment and pollution, and visual impairment. Roads may occasionally bridge the river and short stretches of screened roads may be permitted. Public use facilities are permitted within the river corridor if screened from the river. Motorized travel may be permitted, restricted, or prohibited to protect river values. For recreational rivers timber harvest is permitted but the immediate river environment will be protected and emphasizes maintaining visual quality. New mining claims and new mineral leases must minimize surface disturbance, sedimentation, pollution, and visual impairments. Paralleling roads may be constructed along the river, and there may be several bridges and access points to the river. Campgrounds and recreational facilities may be established. Motorized travel may be permitted, restricted, or prohibited to protect river values. These measures afford some levels of protection for the rivers and may benefit grizzly bears.

Eligible and suitable wild and scenic river management would generally indirectly benefit grizzly bears. Suitable wild and scenic rivers would also provide some benefits to grizzly bear connectivity especially certain rivers that lie between the northern boundary of the Nez Perce-Clearwater and the Bitterroot Recovery Zone. The Preferred Alternative identified 10 rivers as suitable for wild and scenic consideration. Most of these rivers are found within roadless rule, recommended wilderness or designated wilderness and would already be relatively protected by that management. Where land allocations overlap, all plan components would apply, and eligible and suitable wild and scenic river management would add additional protections to these lands. While the total acres of suitable wild and scenic rivers are relatively modest, they will provide some measures for the conservation of secure habitat and contribute to connectivity. This is especially true within the Wild classification which is the most restrictive in terms of suitability plan components and actions that affect secure habitat.

Where land allocations overlap, all plan components would apply, and eligible and suitable wild and scenic river management would add additional protections to these lands. For example, an area might be suitable wild and scenic river and fall within designated wilderness areas. Therefore, plan components guiding management in both areas would apply. The overlap in land allocations of suitable wild and scenic rivers is shown in table 263. While the total acres of suitable wild and scenic rivers are relatively modest, they will provide some measures for the conservation of secure habitat and contribute to connectivity. This is especially true within the Wild classification which is the most restrictive in terms of suitability plan components and actions that affect secure habitat (see Table 32 in the Forest Plan). Wherever they occur, all plan components would apply, and eligible and suitable wild and scenic river management would add additional protections to these lands.

There will be new additions that would be found suitable for inclusion into the wild and scenic river system via suitability (see Eligible and Suitable Wild and Scenic River). These will add a total of 5,247 acres of secure habitat within the wild and scenic river system. The new rivers include the Middle Fork Kelley Creek, North Fork Kelly Creek, and South Fork Kelly Creek are in the northern portion of the plan area which could contribute habitat for dispersing bears coming from the north.

Some rivers that are eligible under the 1987 Forest Plans will no longer be eligible as Wild and Scenic Rivers and would no longer be managed as wild and scenic rivers. Once a suitability determination is made, management to maintain outstandingly remarkable values on eligible rivers is no longer required. Therefore, the Preferred Alternative will result in fewer rivers being managed as eligible for Wild and scenic rivers. In this case, the river corridors would revert to being managed within the land allocation or management area within which they are located. For example, river corridors located within Management Area 3 would be managed for multiple uses. River corridors located in Idaho Roadless Rule areas would be managed consistent with Management Area 2 direct and direct for the Idaho Roadless Rule. Similarly, rivers within designated wilderness would be managed consistent with wilderness and Management Area 1. Most of the rivers that were eligible in the 1987 Forest Plans are located within designated wilderness areas or Idaho Roadless Rule areas as shown in Table 273. In the Preferred Alternative, 21 formerly eligible rivers would no longer be managed as eligible rivers managed to protect outstandingly remarkable values and free flow characteristics. Fifteen of these rivers are located within designated wilderness, recommended wilderness, while six river corridors would be located within Idaho Roadless Rule area or Management Area 3 multiple uses areas.

Those 15 rivers that fall within designated wilderness, recommended wilderness would have low potential for impacts because plan components for management area direction would constrain most management that could affect river corridors. These would not be suitable for motorized uses so they would not be at risk for loss of secure habitat or alteration of free-flowing characteristics. Within these rivers, little would be impacted. Technically speaking, wilderness areas do not prohibit building of dams but in reality, dams are highly unlikely in wilderness areas even though they are not expressly prohibited. While there would be a change in management, it would result in little direct impact to secure habitat or grizzly bears because most of it would remain in areas not suitable for motorized uses.

Six river corridors no longer eligible are located within Idaho Roadless Rule areas or within Management Area 3 managed for multiple uses. These rivers have the potential to have free flow characteristics altered or would no longer protect their outstandingly remarkable values as a result of agency actions. The total amount of secure habitat within these six rivers is 12,172 acres. However, four of these rivers have river corridors located within both wilderness areas and Management Areas 2 or 3. These include John's Creek, Lake Creek, Slate Creek, and West Fork Gedney Creek. Therefore, parts of these rivers are protected with those portions falling within wilderness, recommended wilderness, or areas not suitable for motorized uses. Some sections of these rivers could have future projects that might result in a loss of secure habitat, but most of the areas within Management Area 3 are not secure habitat. There are two large rivers that will not be suitable as Wild and Scenic rivers. These include the North Fork of the Clearwater and the South Fork of the Clearwater. While these rivers have more acres of river corridor, they currently have little existing secure habitat with 67 acres within the North Fork and three acres within the South Fork. Free flowing characteristics would no longer be emphasized on these rivers. While the changes would result in less protective management of the rivers, the rivers themselves will still be managed as important resources, with protections from plan components such as those in the Aquatic Ecosystems section of the plan. Essentially, this change will not result in many future activities that could be impactful to secure habitats.

Timber Suitability

The revised plan contains desired conditions for landscape patterns, size classes, vegetation density, structure, dominance type, and composition that are based on the natural range of variation to provide habitat diversity that should contribute to grizzly bear habitat. Plan components in this section are informed by modeling the natural range of variability and should contribute to ecosystem integrity. Desired conditions would be achieved through a variety of vegetation treatments. Vegetation activities could occur through timber harvest, prescribed fires, fuels treatments, planting, wildfire, other forestry or restoration methods, or other mechanical treatments. The plan also includes objectives for timber production which, in many cases, would be produced while taking actions to meet desired vegetation conditions. Generally, the consequences of this direction would be beneficial to grizzly bears over the long term but would require habitat alterations over the short term.

Where timber production and harvest are allowed or prohibited depends on land allocations and associated suitability for these uses. Timber production, harvest, and restoration is not restricted within Management Area 3 except where there are resource concerns such as within riparian habitat conservation areas, steep slopes, landslide prone areas, and so forth.

Timber harvest may occur with or without road construction involved. Roads would be restricted by the Idaho Roadless Rule or Wild and Scenic River suitability plan direction when conducting vegetation treatments in Management Area 2. In Idaho Roadless Rule areas, vegetation management would be primarily prescribed fire or harvest from existing roads. The treatments might draw bears into these areas when harvesting from existing roads. Site specific analysis and project decisions would consider measures to prevent drawing grizzly bears into forage resources created by vegetation treatments and address these concerns at the project level.

In Management Area 3, the benefits of vegetation conditions would be offset by the presences of roads and would have greater chances of effects on grizzly bear survival because some roads would be constructed to achieve desired conditions. We can expect better body condition and better survival in bears where vegetation treatments occur in association with lower road densities, such as in wilderness, recommended wilderness, and Idaho Roadless Rule Areas. Intensity of human use of these areas are lower because of limited access. These alternatives are integrated with the objectives for fire and fuels management under the Revised Forest Plan.

The plan alternatives vary the acres harvested for timber production and the number of acres or pace needed to restore vegetation to achieve desired vegetation conditions. For timber production acres, under the No Action Alternative, the acreage conducted annually is 4,300 acres, or 50 to 60 million board feet. Alternative W proposes 12,600 acres, or 221 to 241 million board feet; Alternative X proposes 14,000 acres, or 241 to 261 million board feet; Alternative Y proposes 7,500, or 120 to 140 million board feet; and Alternative Z proposes 3,700 acres, or 60 to 80 million board feet. The Preferred Alternative proposes a range of between 8,825 and 10,000 acres annually, for a production amount of 190 to 210 million board feet. Nearly all of this timber production would occur within Management Area 3, while Management Area 2 would receive limited timber harvest and Management Area 1 would not receive timber harvest, except as allowed by enabling legislation for designated lands.

Similarly, the amount of disturbance needed to restore the Nez Perce-Clearwater to the desired vegetation conditions were set based on the pace it would take to achieve these desired conditions within a specified time frame in years. The acres of treatment needed would be 40,000 acres under the No Action Alternative and 53,000 to 64,500 acres in all other alternatives. The Preferred Alternative proposes between 53,000 and 64,000 acres. These acres include wildland fire, timber production, fuels treatments, wildlife habitat enhancement, and vegetation treatments designed to restore vegetation characteristics found in desired conditions. These acres include treatments that would occur across all management areas. In Management Area 3, these acres would be achieved with active vegetation management such as timber production, fuels reduction activities including prescribed fire, non-commercial thinning, and mastication, while in Management Area 2 they would include a range of methods other than for timber production and in Management Area 1 they would mostly be through wildfire that achieves land management plan objectives and to a lesser extent prescribed fire. These alternatives are integrated with the objectives for fire management under the Land Management Plan.

In Management Area 3, roads or temporary roads would typically be associated with timber production and may draw human use after treatments. Bears attracted to vegetation treatments within Management Area 3 would likely encounter higher probabilities of human-bear conflicts. Associated roads along with human activity can negatively affect grizzly bears by disturbing or displacing bears during logging activities and by increasing mortality risk (Zager et al. 1983). In the warm moist broad potential vegetation type, many areas would be planted to restore western white pine. Western white pine restoration is most effective after an even aged harvest such as a clear cut and then planted with blister rust resistant white pine seedlings. Therefore, the acres of white pine restoration should be assumed to follow this type of treatment. The plan has objectives to treat 34,440 acres of the warm moist broad potential vegetation type every five years, some of which would be to restore western white pine. The plan also has desired conditions where white pine increases across the warm moist and cool moist broad potential vegetation types. Areas harvested for timber production or timber harvest must be restocked with trees within five years of treatment. In contrast, areas burned by prescribed or managed fires are often left to recover naturally. Restoration of white pine could change the seral stage and dominance type of forested vegetation, which could produce improved forage conditions or increase nutritional resources over the short term but remove mature forest.

The plan does not have components to direct management to consider or restrain where potential grizzly bear foods are promoted or produced from vegetation treatments. For vegetation projects, managers could consider how the arrangement of treatments could potentially produce foods that could attract bears to areas where conflicts may occur during project development and could take measures that could reduce this potential conflict. Each project could be analyzed as to whether an individual project would attract bears into a conflict on a case-by-case basis. In any case, each project would have its own environmental analysis and be consulted on with the U.S. Fish and Wildlife Service for effects to federally listed species.

Grizzly bears use a variety of habitat conditions and variety in vegetation size classes, densities and dominance types would contribute to grizzly bear habitat. Vegetation management may alter the amount and arrangement of cover and forage available to bears. Use tends to be more frequent in areas that offer some type of hiding cover nearby, particularly during daylight hours (Aune and Kasworm 1989b, Mace and Waller 1997). Vegetation management may alter the amount and arrangement of cover and forage available to bears. Waller (1992) reported that grizzly bears avoided lower-elevation, more accessible harvested stands, as well as stands less than 30–40 years old where the vegetation had not recovered enough to provide cover. Timber harvest and fire can locally increase bear foods by stimulating the growth of grasses, forbs, and berry-producing shrubs. Bears that used regenerating forest habitats (mostly due to forest harvesting) containing a diversity of age classes were more likely to see gains in their body condition, whereas bears that used older forests were more likely to see reductions in body condition (Boulanger et al. 2013). However, survival rate was reduced by road densities which in turn were positively correlated with regenerating forest habitat (Boulanger et al. 2013). Human activities which promote young regenerating forests, such as forest harvesting, therefore promotes improved health (increased body condition) in bears but are offset by reductions in survival rates because of higher road densities. Grizzly bears in Management Area 3 would have better body condition because of better nutrition but lower survival due to increased human bear conflicts as a result of more motorized access (Boulanger et al. 2013). All alternatives under the revised plan contain desired conditions for vegetative patterns, size classes, vegetation density, structure, and composition that are based on the natural range of variation to provide habitat diversity that should contribute to grizzly bear habitat.

Management Area 3 currently has higher road densities, more human activities, and more developments than Management Area 2 and 1. Management Area 3 is where most of the timber production and associated road development would occur. A geospatial analysis of the Nez Perce-Clearwater road system, under the1987 Forest Plans, indicates that 1,035,819 acres, or 83.5 percent, of the 1,240,340 acres in Management Area 3 is within 1,600 feet of a roadway and could be harvested from existing roads. Therefore, while some timber is not yet accessed and will require some new road construction, there is limited areas within Management 3 where additional roads are required to access the timber, which naturally limits the addition of new roads. However, additional roads may need to be constructed to access the remaining 204,521 acres for vegetation management. There is currently only 194,805 acres of secure habitat in Management Area 3 and composes about 16 percent of this management area, most of which exists in smaller blocks, and these would be most likely the areas that may be impacted under the Preferred Alternative. Although it is currently where and how many roads would be constructed.

Vegetation management in Management Areas 2 and 1 to meet desired vegetation conditions would mostly be treated with prescribed fire or wildfire. These treatments would produce better body conditions because of more nutritional resources and promote higher survival rates. These two management areas account for most of the Nez Perce-Clearwater and the best areas for habitat conditions for grizzly bears. Vegetation management in these two management areas would not require permanent road construction in most cases, however temporary roads may be needed. In some areas of Management Area 2, temporary roads may be build based on allowances in the Idaho Roadless Rule, recreation opportunity spectrum, and suitability. The effects of temporary roads are short term for grizzly bears. Road building would only be allowed to the extent that the Idaho Roadless Rule allows and is not allowed in designated wilderness. Timber harvest is suitable for other resource reasons within Idaho Roadless Rule area but are limited to areas within reach of existing roads or by helicopter. However, much of the Idaho Roadless Rule areas are outside the reach from existing roads and are not suitable for harvest (Figure 105). The entirety of the Bitterroot Recovery Zone is not suitable for timber harvest of any kind.

Not all temporary roads would likely to be constructed at once. Some of the roads would be consolidated in project areas and be constructed and used at the same time, which would concentrate effects on bears into a smaller area. Temporary roads would be separated by space and time across the Nez Perce-Clearwater, which may affect more individual grizzly bears, but have less intense effects. As temporary roads are usually closed immediately after the completion of harvesting activities, they do not have prolonged impacts. In some cases, they can be open for up to five years if projects are implemented over multiple years.

For ease of discussing the effects, there are essentially three types of timber suitability, 1) Suitable for timber production, 2) Suitable for timber harvest for other resource objectives but not for timber production, and 3) Not suitable for production nor harvest. The acres and percent of the Nez Perce-Clearwater that is suitable for the different types of timber suitability are shown in Table 274. Timber production is unsuitable on about 73.5 percent of the national forest and thus prohibited. Timber harvest of any kind is unsuitable on about 59 percent of the national forest. Timber production is only suitable on about 26.5 percent of the national forest. The different types of timber suitability largely follow the distribution of land allocations such as management areas, designated wilderness, recommended wilderness, wild and scenic rivers, and Idaho Roadless Rule Areas. Relatedly, timber activities will not create the need for new motorized features in areas unsuitable for timber production, and timber activities are less likely to be the cause of new motorized routes in areas suitable for timber harvest but unsuitable for timber production.

Secure habitat would need to be treated in Management Area 2 to achieve vegetation desired conditions. Treatment examples include prescribed fire, wildfire, non-commercial tree cutting, commercial harvest or other methods. In Idaho Roadless Rule areas, which make up the majority of Management Area 2, timber harvest is limited by the Idaho Roadless Rule. For example, the Final Environmental Impact Statement for the Idaho Roadless rule projected that less than 0.01 percent of roadless area per year of the lands managed under the Idaho Roadless Rule would be affected by timber removal or road construction in the first 15 years. For the approximately 1,481,636 acres of roadless areas on the Nez Perce-Clearwater, this would total 1,500 acres over the 15-year period, or approximately 100 acres per year (U.S. Department of Agriculture 2008a). Per the Idaho Roadless Rule, timber harvest activities must be conducted from existing roads or aerial harvest systems. In the 10-year period from October 2008 to September 2018, approximately 1,800 acres have been affected through community protection zone fuels reduction, constructed fuel breaks during wildfires, and removal of post-fire roadside hazard trees. This trend of timber harvest in Idaho Roadless Rule areas is expected to continue. In Idaho Roadless Rule areas, vegetation treatments are likely to be implemented as prescribed fire or wildfire managed to achieve land management plan objectives. Some areas within community protection zones could also be treated to reduce hazardous fuels and may include the construction of temporary roads.

Neither timber harvest, nor production are suitable within recommended wilderness nor in designated wilderness areas. Therefore, it will not be allowed there, which would prevent effects from these activities to habitats within the Bitterroot Recovery Zone. While prescribed fire is suitable within wilderness and recommended wilderness, it is more likely to be treated with wildfire managed to achieve land management plan objectives in these areas to maintain wilderness character.

The amount of currently secure habitat that will occur within the three suitability classes for the existing condition and the Preferred Alternative are shown in Table 274. Overall, in the Preferred Alternative, about 81 percent of currently secure habitat is not suitable for either harvest nor production, 12 percent is suitable for harvest for other resource reasons, and only about 7 percent is suitable for timber production. Under the existing condition, about 82 percent of secure habitat is not suitable, 12 percent is suitable for harvest, and 7 percent is suitable for production. Therefore, the difference is only about 1 percent of secure habitat or about 22,725 acres of area not suitable. About 21,522 acres more are suitable for timber harvest in the Preferred Alternative compared to the existing condition. The amount of secure habitat suitable for timber production varies little, 1,202 acres, between the Preferred Alternative and the existing condition. The reason is because most of the area suitable for timber production currently lacks much secure habitat to begin with and because so much of the Nez Perce-Clearwater is not suitable due to Idaho Roadless Rule and Wilderness Restrictions. It can be expected that much of the 7 percent of secure habitat suitable for timber production would be impacted by timber activities including harvest or additional road development. Furthermore, existing secure habitat in areas suitable for timber production are small and fragmented. Areas suitable for timber production mostly occur within Management Areas 3, which is an area not biologically suitable nor socially acceptable for grizzly bears. Bears that move into Management Area 3, where most timber production would occur, would likely have a lower survival rate under both existing conditions and under the Preferred Alternative. Every vegetation project will undergo site specific environmental analysis and Endangered Species Act consultation prior to approval an implementation.

Under the No Action Alternative, the maximum size of regeneration units allowed before requiring regional forester approval was 40 acres. All the other alternatives would allow regeneration harvest up to 207 acres. The size of openings would influence the arrangement of vegetation patches on the landscape. The size of disturbances has changed as a result of the 40-acre limit on regeneration harvest. Under natural disturbance, the size of regenerating forest was much larger as a result of wildfire, where thousands to hundreds of thousands of acres were set to a regenerating state after burning. The 207-acre maximum opening size would allow more flexibility to restore a landscape pattern that existed under natural disturbance.

The plan varies the amount of area suitable for timber production because of decisions on wild and scenic river suitability and recommended wilderness. There are essentially three types of timber suitability: 1) suitable for timber production, 2) suitable for timber harvest for other resource objectives but not for timber production, and 3) not suitable for production nor harvest. The amount of currently secure habitat that will occur within the three suitability classes by alternative are shown in Table 274 below. Overall, in the Preferred Alternative, about 81 percent of currently secure habitat is not suitable for either harvest or production, 12 percent is suitable for harvest for other resource reasons, and only about 7 percent is suitable for timber production. Under the No Action Alternative, about 82 percent of secure habitat is not suitable, 12 percent for harvest, and 7 percent is suitable for production. Rounding accounts for the difference in percent change in the alternatives, though the change can be seen in the acres. Alternative W has the most secure habitat not suitable for either harvest or production, while Alternative X has the least amount. They vary by about 6 percent total between the highest and lowest alternatives.

The Preferred Alternative has about 21,522 acres more of secure habitat suitable for harvest than the No Action Alternative (Table 274). Alternative X has the most acres suitable whereas Alternative W has the least and they vary by about 137,915 acres. It can be expected that secure habitat would undergo treatments to achieve vegetation desired conditions but, in most cases, it would not involve permanent road construction due to Idaho Roadless Rule restrictions. Temporary road construction may occur as permitted by the Idaho Roadless Rule. Harvest, when used, would be mostly from existing roads.

Table 274. Acres and percent of currently secure grizzly habitat in the three timber suitability types for each alternative (Alt)

Secure Suitability Type	No Action Alt Acres	%	Alt W Acres	%	Alt X Acres	%	Alt Y Acres	%	Alt Z Acres	%	Preferred Alt Acres	%
Not suitable	2,015,555	82	2,117,530	86	1,978,573	80	2,004,082	81	2,039,187	83	1,992,830	81
Suitable for Harvest	285,106	12	182,880	7	320,795	13	296,392	12	261,720	11	306,628	12
Suitable for Production	162,419	7	162,669	7	163,711	7	162,606	7	162,172	7	163,621	7

The alternatives vary little in how much secure habitat is suitable for production. They vary by about 1,202 acres because of variation in the wild and scenic river suitability. The differences between the other alternatives are similar, differing between Alternative Z with the lowest and Alternative X with the highest amount, by about 1,539 acres. The differences between alternatives are negligible. The reason is because most of the area suitable for timber production currently lacks much secure habitat to begin with and because so much of the Nez Perce-Clearwater is not suitable due to Idaho Roadless Rule and wilderness restrictions. It can be expected that much of the 7 percent of secure habitat suitable for production would be impacted by timber activities, including harvest or additional road development. Figure 105 shows the timber suitability for the Preferred Alternative. Note that the majority of the Nez Perce-Clearwater is not suitable for timber production nor harvest.

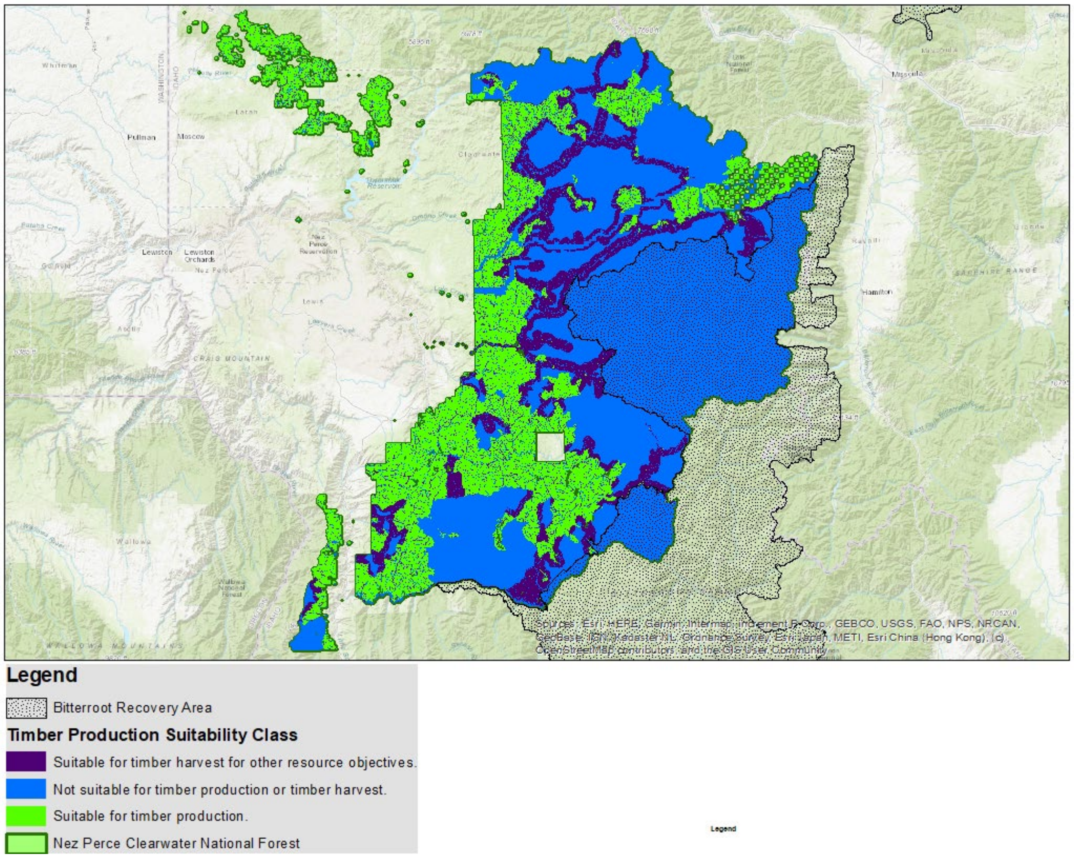

Figure 105. Timber Suitability class distribution in the plan relative to the Bitterroot Recovery Zone. Bright green represents areas suitable for timber production, purple represents areas suitable for harvest to meet other resource objectives such as restoration, and areas in blue are not suitable for harvest nor production.

The National Forest Management Act of 1976 (NFMA) established provisions and limitations on timber harvest activities including limits on the maximum size of regeneration harvest. The 2012 Planning Rule and Forest Service Handbook 1909.12 requires that plan components incorporated into revised plans need to maintain and restore ecosystem integrity. The planning Rule defines Ecosystem Integrity as “the quality or condition of an ecosystem when its dominant ecological characteristics (for example, composition, structure, function, connectivity, and species composition and diversity) occur within the natural range of variation and can withstand and recover from most perturbations imposed by natural environmental dynamics or human influence.”

The 2012 Planning Rule (36 CFR 219_11 Timber requirements) requires that plan components comply with the 40-acre maximum opening size required under NFMA (4)(d). Exceeding the 40-acre maximum is allowed under the NFMA but to do so, the Forest Service must allow a 60-day comment period and must receive approval from the next level above the deciding official, who is usually the forest supervisor, and the next level up is typically the regional forester.

The 2012 Planning Rule permits Forest Plan Standards for opening sizes that exceed the 40-acre maximum required under National Forest Management Act (NFMA) if the responsible official determines that it is necessary to achieve desired ecological conditions as set-fourth in Section 219.11 (d)(4)(i) as follows:

> Plan standards may allow for openings larger than those specified in paragraph (d)(4) of this section to be cut in one harvest operation where the responsible official determines that larger harvest openings are necessary to help achieve desired ecological conditions in the plan area. If so, standards for exceptions shall include the particular conditions under which the larger size is permitted and must set a maximum size permitted under those conditions.

To that end the plan established a plan standard that establishes the size below which a project does not require regional forester approval and the 60-day comment period. The size of openings of regeneration harvests was identified such that they better replicate the size of openings under natural disturbance with the Natural Range of Variation. Under the 1987 Forest Plans, the 40-acre limit was exceeded periodically with regional forester's approval.

The Natural Range of Variation (NRV) is an ecological concept that seeks to describe the landscape conditions that existed before modern forestry practices were adopted (Wiens et al. 2012). Vegetation patch sizes both affects and is affected by disturbance events including wildland fire, insect infestations and tree diseases. Opening size and pattern of vegetation is a major influence on species composition, forest stand structure, ecosystem function and habitat connectivity (Hagmann et al. 2021). Managing forest vegetation within the context of natural disturbance regimes requires an examination of actions implemented at appropriate spatial and temporal scales to address the ecological characteristics that compromise sustainability. The abundance, average size, and range of sizes of early successional forest patches, or "openings" have been identified as the key ecosystem characteristics to represent landscape pattern because this condition is quantifiable and is meaningful for many wildlife and plant species. Openings in the forest are created after a stand-replacing disturbance like wildfire. They are meaningful to many wildlife species because of their distinctive composition and openness, which affects the growth and survival of plants that some wildlife depends on and represent significant ecological contrast to adjacent mid or late successional forest ("edge"). Furthermore, patch size and distribution affect or influence the distribution and habitat selection of some wildlife species. Examples include elk, fisher, and some migratory birds. They also represent the initiation point in forest development, the foundation upon which rests the pattern of the future forest.

The Terrestrial Ecosystem Plan components are founded upon analysis of ecological composition, structure, function, and connectivity. Forest management that focuses restoration at scales within the Natural Range of Variation may support desired conditions focused on maintaining and enhancing ecosystem integrity. Note that the maximum opening size standard only pertains to the size above which requires regional forester approval. It does not preclude creating openings larger than this size by following the proper approval process and comment period, for example regional forester approval and required comment period. Openings smaller than the standard size may also be appropriate.

To inform the maximum size of regeneration units, the Forest Service used a state and transition model known as the SIMulating Patterns and Processes at Landscape scaLEs (SIMPPLLE model) (Chew, Moeller, and Stalling 2012) to inform the patch size distribution under simulated natural disturbance. The spatially interactive model SIMPPLLE incorporates climate data, fire logic, and vegetation growth pathways to estimate forest growth and disturbance for a period of approximately 1,000 years. The model is calibrated with empirical data, expert knowledge, climate data and relevant scientific studies as a basis for model information and assumptions. Model results were compared to the current patch size distribution currently on the Nez Perce-Clearwater.

Model results suggested that the national forest is currently departed from its patch size distribution wherein current average patch sizes are much smaller than the average size of regenerative disturbance under the Natural Range of Variation. This is the result of fire suppression and a number of small mechanical treatments that are the result of timber harvest in recent decades which followed the 40-acre limitation found in National Forest Management Act (NFMA). Additionally, it severely departed relative to the area weighted mean, meaning that many more acres of open or early seral forest were composed of very large early seral patches driven by wildfire disturbance. In the simulation, patch size of openings ranged from 6 to larger than 457,299 acres, and that 25 percent of all openings were from patches between 6 and 1,785 acres and an estimated 75 percent of patch openings were larger than 1,785 acres.

Patch sizes were aggregated using Jenks breaks to facilitate analysis and were used to group patch size classes into 10 bins. The smallest bin size ranged from zero to six acres and was an artifact of the grain size of the model. The second largest bin size, six to 1,785 acres was identified as the bin size most appropriate to replicate the size at which forest vegetation management was most appropriate. The within bin distribution was large so the average within the bin was estimated from the maximum 90th percentile size patch to identify the appropriate maximum patch size for the plan standard. The average patch size was also estimated within each broad potential vegetation type (PVT) because fire behavior can be different within different PVTs.

The forestwide average patch size within bin 2 estimated by maximum 90th percentile was 350 acres. The average size within broad PVTs are as follows: the warm dry was 77, warm moist was 160 acres, cool moist was 188 acres, and within the cold was 95 acres. If forest management is to better reflect the distribution of early seral conditions under natural disturbance, then the patch size of forest management would need to increase. Mechanical treatments would be used to reflect smaller opening size creation through natural processes such as insect infestations and spot fires, while at the same time puts the onus of larger openings on wildfires. The maximum opening size before regional forester approval is established in FW-STD-TBR-06. The Preferred Alternative would allow regeneration harvest up to 207 acres before regional forester approval is required. This number was the average opening size of the second bin. This standard applies to newly created harvest openings from mechanical vegetation treatments on National Forest System lands only and need not consider existing recently created opening on National Forest System lands, adjacent private lands, or other agency lands. The areas where this standard would apply is forestwide and it would only apply to mechanical treatments that regenerate forests, such as clearcutting, seed tree cutting, shelterwood seed cutting, or other cuts designed to regenerate an even-aged stand of timber in a single harvest operation.

The size of openings would influence the arrangement of vegetation patches on the landscape resulting from timber harvest. This patch size would be used most within Management Area 3 as that is where timber harvest is more often going to occur. Nevertheless, the prevailing driver of the patch distribution within the plan area will still be wildfire disturbance as it would continue to be the prevailing agent of change on the landscape.

The 207-acre maximum opening size would allow more flexibility to restore a landscape pattern that existed under natural disturbance. The smaller maximum opening size in the 1987 plan was too small to replicate the patch size and distribution as would have occurred under natural disturbance. As a result, the patch size and distribution characteristics are departed from their historical size because the patch sizes are too small. The plan desired conditions MA1 and MA2- DC-FOR-05 and MA3-DC-FOR-09 would direct forest vegetation to reflect the landscape pattern of natural disturbances. The larger patch size limit would better allow active management to restore conditions more like the patch size present under natural disturbance. Expanding the maximum size of regeneration harvest would allow the Nez Perce-Clearwater to work towards restoration of a landscape pattern consistent with those that existed under natural disturbance from a patch size standpoint. Under the Preferred Alternative, the maximum opening size set by the standard could still be exceeded following a 60-day comment period and regional forester approval. FW-STD-TBR-06 would not apply to openings resulting from natural conditions such as fire, insect and disease attack, or windstorm as specified in FW-STD-TBR-08.

The effects of this direction would be that the Nez Perce-Clearwater would trend towards a vegetation patch size more like the patch size under natural disturbance. A larger maximum patch size would make larger openings on the landscape. As a result of the larger patch size allowance, more patches of larger size would be produced via timber harvest and other mechanical vegetation treatments. Larger opening sizes in some cases would require less road construction than 40-acre cuts because more area could be accessed from a single road to a larger patch opening versus many roads to access smaller spread-out smaller patches. However, the road system would be determined based on-site specific considerations. There would be more nutritional resources for grizzly bears because in many cases, nutritional resources originate from early seral conditions because these are the conditions that facilitate berries, grasses, and prey species. So larger patches would also maintain and facilitate bear nutrition. Larger patch opening sizes are not expected to impact connectivity for grizzly bears as grizzly bears move easily through both forested and early seral conditions.

Research suggested that grizzly bears actively selected for larger cut blocks in British Columbia (Ciarniello et al. 2015). Ciarniello et al., (2015) used location data on 28 (16 females, 12 males) grizzly bears between 1998 and 2003 to determine how bears would respond to the resulting reduction in mature pine forests and increase in the number and size of cut blocks. Grizzly bears used pine stands less than expected and cut blocks more than expected, selecting for cut blocks in spring and summer but not in fall. Cut block size influenced selection by bears during the spring and summer but not in fall with grizzly bears being four times more likely to select for very large cut blocks (16,308 to 17,297 acres) than smaller blocks. In summer, bears selected for larger cut blocks with higher greenness values at higher elevations and where the risk of human-caused mortality was greater. In fall, bears remained closer to block edges and used younger stands. Bears spent a significantly greater fraction of their time in cut blocks during the night than during the day and during “active” versus “resting” periods in all three seasons. Selection for large blocks suggests that bears may respond positively to a harvest regime that mimics the size of natural disturbances. Ciarniello et al. (2015) concluded that following an ecosystem management (that is, natural disturbance) approach to forest harvesting will foster use by grizzly bears inhabiting working forests. They also concluded that the potential benefit of large cut blocks to bears could be outweighed if larger blocks contribute to higher grizzly bear mortality. Attracting grizzly bears via larger openings could potentially result in mortality if larger openings are also associated with increased roads and human access. However, Ciarniello et al., (2015) suggested that grizzly bears accessed large openings more often at night as a strategy to presumably to avoid humans.

From a practical standpoint, the standard would apply more commonly within Management Area 3 but might also be used less often within Management Area 2 within the framework of timber suitability as explained above. It is reasonable to expect that these larger openings would occur across all of Management Area 3 throughout the life of the plan. The standard would also apply to Management Area 2 as well but mechanical treatments in Management Area 2 would be less common and occur only when treatments would best be achieved through mechanical regeneration harvests. More often prescribed fire would be used in Management Area 2 to create large openings because of the practical limitations on timber harvest imposed by the Idaho Roadless Rule. Harvest (to meet other resource objectives) in Management Area 2 is essentially going to be constrained mostly to existing roads or helicopter. Harvesting larger openings from existing roads could in some cases draw grizzly bears into areas accessible to humans in Management Area 2 which might increase the probability of bear-human conflicts. However, because most of the treatments in Management Area 2 are likely going to be via prescribed fire while harvesting from existing roads would be less common. The Forest Plan standard limiting opening size would not apply to prescribed fires. So large openings created by fires or prescribed fires would create large openings to the benefit of grizzly bear selection without the associated motorized system access.

While the plan standard would apply forestwide, many areas of the Nez Perce-Clearwater are not suitable for timber harvest, and because it only applies to mechanical treatments, there is no effects from this plan components in areas not suitable for timber harvest, such as wilderness, recommended wilderness, and Idaho Roadless Rule within the Wildland recreation theme, the Wild classification of designated and suitable Wild and Scenic Rivers, designated Natural Research Areas, and non-forested lands.

Fire Management

Wildland fire management includes all activities for the management of wildland fires to meet land management objectives. Fire management includes the entire scope of activities from planning, prevention, fuels or vegetation modification, prescribed fire, hazard mitigation, fire response, rehabilitation, monitoring, and evaluation. The management of wildland fire influences whether fire effects have beneficial or non-beneficial impacts on resources, such as air and water quality, wildlife habitat, recreation areas, and communities. Wildland fire management incorporates a spectrum of responses ranging from full suppression to managing for resource objectives. Suppression is a management strategy used to extinguish or confine all or a portion of a wildfire. Fuels management is the practice of controlling flammability and reducing resistance to control wildland fuels through mechanical, chemical, biological, or manual means or by fire in support of land management objectives. Fuels treatments result in a change in the amount, configuration, and spacing of live and dead vegetation, creating conditions that result in more manageable fire behavior and reduced intensity during future wildland fire events.

Plan components within the Fire Management section of the plan provides direction for vegetation treatments for fuels reduction, prescribed fire and through the management of vegetation via unplanned ignitions. The plan components would direct future actions related to both the prescribed fires, and direction on when and how fire suppression would be conducted in the future.

Fire management plan components would encourage natural fire or use prescribed fire across the planning area. Fire is likely to play a dominant role in shaping grizzly bear habitat over the life of the plan. Objectives for total disturbance, including wildfire, only vary between the No Action Alternative and the action alternatives, with the No Action Alternative having approximately 40,000 acres of total disturbance annually. FW-OBJ-FIRE-01 in the fire management section would seek to treat vegetation through a combination of managed wildfire or active burning between 530,000 and 645,000 acres every 10 years or an average of 53,000 to 64,500 per year. This objective applies to all the action alternatives including the Preferred Alternative. The objective for total disturbances was calculated based on the distribution of vegetation types and their fire return intervals from fire regime groups. As part of the total disturbance, FW-OBJ-FIRE-02 sets the objectives for fuels treatments on 227,242 per decade under the Preferred Alternative. FW-OBJ-FIRE-03 would encourage fire to play a natural role to reduce uncharacteristic and undesirable wildfire through the management of natural unplanned ignitions on between 360,258 acres per decade under the Preferred Alternative. The amount of total disturbance in FW-OBJ-FIRE-01 also includes all timber production and harvest amounts. Because the amounts of natural disturbances are unpredictable, they are expressed as an amount per decade in the plan.

The plan is integrated among resource areas such that fire is recognized as an important mechanism to achieve desired ecological and vegetation plan direction. The amount of disturbance identified in the objectives, along with the types of disturbance need to achieve desired vegetation conditions, included and accounting for both prescribed fires and natural ignitions. The amounts were modeled with the SIMPPLLE Model, which modeled the vegetative response to timber harvest treatments and stochastic processes like wildfire. Therefore, the plan's fire objectives and other plan components were informed by the model's outcomes for both timber harvest scenarios in alternatives and incorporate the expected amount of future wildfire. Similarly, the plan's ecosystem components for vegetation desired conditions considered the amount of wildfire needed to achieve those desired conditions. Furthermore, they are established to represent our best estimate of the conditions of vegetation within the natural range of variation under natural disturbance. The SIMPPLLE model was calibrated based on the historical amount of wildfire, weather patterns, and the distribution of fire starts. While we do not know where and when a wildfire will start, the model represents a good estimate of the amount of wildfire that can be expected during the life of the plan. Model outcomes suggest that wildfire will still be the predominant driver and agent of change in the vegetation conditions in the plan area despite the increased intensity of timber harvest objectives proposed. Therefore, the objectives within the plan components for Fire Management are paramount to the outcomes of the revised Forest Plan.

While it is impossible to predict when or where wildfire ignitions would start, the Forest Service has discretion on if, when, where, and how suppression activities would be conducted. However, it is reasonably certain that wildfire starts will occur each summer, the estimates of how much fire there will be on the landscape within the life of the plan are reasonable estimates, and it is reasonably certain that wildfire suppression decisions will be based on the guidance in the plan. The intent in the plan is that fire would play a more natural role on the larger landscape compared to the 1987 plans. Some aspects of the 1987 plans required suppression in many cases and had thresholds that limited the amount of prescribed fire allowed in some management areas. The proposed plan allows for more flexible strategic planning and more flexibility during real time fire management decision making that would allow fire to play its natural role across the landscape. In some cases, wildfire is likely to be beyond the agencies' ability to suppress but these types of disturbances have been factored into our vegetation desired conditions and the fire management objectives.

The consequences of fuels treatments and wildfire could be both positive and negative for grizzly bears. These treatments would alter grizzly bear habitat and reduce cover but may enhance food sources. The effects of fuels treatments would be emphasized within the wildland urban interface. Treatments would also occur within Idaho Roadless Rule areas, recommended wilderness, and designated wilderness. Fire has been the dominant agent of change in grizzly bear habitat under natural disturbances, and bears are assumed to be adapted to these conditions. The location, types, size and distribution of fuels treatments and prescribed fires are not yet known. Prescribed fire and fuels treatments are authorized only after site specific environmental analysis, and Endangered Species Act consultation. Activities for fuels treatments and prescribed fires often include establishment of containment lines, mechanical vegetation treatments, and burning conducted under controlled conditions. Existing roads or trails are often used as containment lines. The effects of these treatments could be a change in seral stage and temporary disturbance in the local area. The plan also encourages allowing fires to play a more natural role in forest disturbance through wildfire managed to achieve land management plan objectives. Some but not all wildfire management activities require firefighter personnel to be present near the fire and includes firefighter camps, people using motorized vehicles to access areas to utilize containment lines by removing fuel and constructing fire lines. Aircraft are often used to move people and equipment, monitor burn conditions, and applying fire retardant or water to control the fire intensity and spread rates of fires. Wildfire is the largest disturbance agent within the Nez Perce-Clearwater and will be the driving force for change to the national forest's vegetation conditions. The fire objectives amounts in the action alternatives are more similar to disturbance under natural conditions and would reduce the magnitude of departure from fire return intervals. The amounts in the No Action Alternative are too low to address the departure from the natural fire return intervals and would result in a continued buildup of fuels, leading to potentially larger and more intense fires in the future. In terms of grizzly bear habitat, the action alternatives would create more nutrition for grizzly bears compared to the No Action Alternative. Long term, the No Action Alternative would result in more severe fires that could alter forest vegetation and grizzly bear habitat to greater degree than if they were addressed with a more progressive schedule of disturbance like those in the action alternatives. The action alternatives are better from a grizzly bear conservation perspective.

Consequences of Summer Recreation Opportunity Spectrum Settings and Motorized Suitability

Public access was identified as a significant issue during scoping. The plan does not make site specific decisions on roads, nor motorized trails, nor does it authorize, fund or carryout actions nor decisions on the travel system. Therefore, the plan has only indirect effects on grizzly bears regarding travel management decisions. Instead, forest plans make decisions on the suitability of uses and broad direction under which future decisions for roads and motorized trails could be made. The plan identifies the suitability of motorized uses across the landscape, the extent and amount of which varies by alternative. It should be recognized that identifying lands as suitable does not necessarily mean that these activities would occur on all portions of suitable lands. It only identifies where motorized uses would be suitable to guide future decisions. Motorized uses would not be allowed on lands identified as not suitable for motorized uses in the plan.

The primary mechanism that determines motorized suitability is the Summer and Winter Recreation Opportunity Spectrum settings (ROS). However, the ROS was developed from consideration of the appropriateness of motorized uses within the various land allocations which fed into the identification of Summer and Winter ROS settings. Each land allocation also has its own suitability plan components that must be followed including the suitability of motorized uses. The Summer and Winter ROS settings are consistent with the suitability plan components within the various land allocation suitability components. Furthermore, the types of motorized uses that could occur in some areas suitable for motorized uses are influenced by management area direction. For example, some Idaho Roadless Rule areas are suitable for motorized uses but suitability plan components within the Idaho Roadless Rule section of the plan also provide guidance that can shape the types of motorized uses that occur, for instance roads are restricted but motorized trails are suitable. In addition, even when suitable, the construction of motorized routes would be required to be consistent with forestwide plan components that address the manner in which roads or motorized trails are authorized and constructed.

The ROS has six distinct classes in a continuum that describe settings ranging from highly modified and developed to primitive and undeveloped (Clark and Stankey 1979, U.S. Department of Agriculture 1982b). Five of the ROS classes apply to the Nez Perce-Clearwater: primitive, semi-primitive non-motorized, semi-primitive motorized, roaded natural, and rural. There are no urban ROS classes on the Nez Perce-Clearwater. Allocations of these settings are decisions within the revised Forest Plan that dictate not only where motorized uses are suitable but also the extent of development or “developedness” that are appropriate for an area. Motorized uses within different ROS classes likely have differences in effects because different ROS settings often have different road maintenance levels, which can affect the types of vehicles that can traverse roads and the rate of speed that can be traveled. Table 275 below defines the ROS classes and definitions. See the Sustainable Recreation section for more information about the ROS.

The summer and winter ROS settings influence the suitability of other various activities, in that it sets the level of development that users may anticipate experiencing on roads and within recreation sites. For example, it would not be appropriate to pave a road in a semi-primitive motorized setting as this would be inconsistent with the recreational experience expected. This also applies to recreation sites, a well-developed campsite with hookups would be appropriate in some settings such as rural or roaded natural settings, but not in other settings like semi-primitive motorized where campsites are expected to be more rustic. The motorized settings are the rural, roaded natural, and semi-primitive motorized settings while the non-motorized settings are the primitive and semi-primitive non-motorized.

Summer Recreation Opportunity Spectrum (ROS) settings take into account the suitability of summer motorized uses across all management areas or land allocations. Under the No Action Alternative, the ROS settings were not used as a mechanism to identify motorized suitability. Instead, they were general guides that applied to recreational experiences. The existing condition for motorized uses was that motorized recreation was open unless closed by a site-specific decision such as the Clearwater Travel Plan or specific decisions on closures such as for designated wilderness areas. Because travel planning has not been established within the Nez Perce National Forest, that portion of the national forest is still open to motorized uses except where specific closures were established. Decisions on authorizing motorized routes are guided by plan components like PACFISH and INFISH measures, constraints imposed by elk habitat effectiveness plan components in the 1987 plans, or considerations for other resources. Thus, the action alternatives for summer ROS settings represent the establishment of a new suitability plan component that would identify areas as suitable or not for motorized uses. For comparative purposes in the Draft Environmental Impact Statement, a ROS setting map was delineated for the No Action Alternative based on policy guidance for establishing the ROS settings based on buffered features like roads, but it does not represent any true constraints on motorized uses like those in the action alternatives. The ROS in baseline condition, as mapped for the No Action Alternative, does not represent a decision made in a planning document due to ROS not being used as a suitability plan component prior to the 2012 Planning Rule. Rather, the existing condition maps are a map based on mapping protocols and reflect how other decisions, such as travel plan decisions, have influenced the user's experiences. The 1987 Forest Plans have no provisions to manage consistent with the ROS classifications, the ROS classifications were an effect of other decisions implemented on the ground.

In this revision, under the 2012 Planning Rule, ROS no longer is a mapped existing condition, but rather is a decision made by the responsible official that is tied to both a desired condition and suitability plan components to implement the decision. Thus, direct comparison of the existing condition ROS to the Preferred Alternative ROS is not always equivalent; the Preferred Alternative ROS is binding while the existing condition ROS is solely based on a mapping protocol that takes into account other decisions that have been made.

Plan components within the sustainable recreation section of the plan contains plan components and suitability of uses that direct the national forest to manage recreation consistent with the definitions Table 275. ROS settings are identified for both winter and summer. Plan components in the Sustainable Recreation section of the plan include desired conditions and standards that require management of these settings consistent with their definition.

Table 275. Recreation Opportunity Spectrum classes and definitions[1]

Recreation Opportunity Spectrum	Definition
Primitive (P)	This setting supports large, remote, wild, and predominantly unmodified landscapes. There is no motorized activity and little probability of seeing other people. Primitive settings are managed for quiet solitude away from roads, people, and development. There are few, if any, facilities or developments. Most of the primitive settings coincide with designated wilderness boundaries and recommended wilderness areas.
Semi-Primitive Non-motorized (SPNM)	The semi-primitive non-motorized settings include areas of the Nez Perce-Clearwater managed for non-motorized use. Mechanized transport such as mountain bikes are often present. Rustic facilities are present for the primary purpose of protecting the natural resources of the area. These settings are not as vast or remote as the primitive settings, but they also offer opportunities for exploration, challenge, and self-reliance.
Semi-Primitive Motorized (SPM)	This setting is managed for backcountry motorized use on designated routes. Routes are designed for off-highway vehicles and other high-clearance vehicles. This setting offers visitors motorized opportunities for exploration, challenge, and self-reliance. Mountain bikes and other mechanized transport are also sometimes present. Rustic facilities are present for the primary purpose of protecting the natural resources of the area or providing portals to adjacent primitive or semi-primitive non-motorized areas.
Roaded Natural (RN)	This setting is managed as natural appearing with nodes and corridors of development that support higher concentrations of use, user comfort, and social interaction. The road system is generally well defined in this setting and can typically accommodate passenger car travel. System roads also provide access to other recreation opportunity spectrum settings of semi-primitive motorized, semi-primitive non-motorized, and primitive areas.
Rural ®	This setting represents the most developed recreation sites and modified natural settings on the Nez Perce-Clearwater. Facilities are designed primarily for user comfort and convenience.

1 - Plan area does not have any areas in the urban setting

The percent of the plan area in the summer Recreation opportunity spectrum for the different action alternatives are shown in Table 275. The percentage of areas identified as motorized and non-motorized can be found in the Sustainable Recreation section. The roaded natural and primitive settings are similar across alternatives while the amounts of semi-primitive non-motorized and semi-primitive motorized settings vary. The acres of secure habitat within each recreation opportunity spectrum setting is shown in Table 276 while the amount of secure habitat in motorized and non-motorized settings is shown in Table 277. The recreation opportunity spectrum settings for the No Action Alternative provide guidance on recreational experience but did not include motorized suitability.

Alternatives that identify more secure habitat as suitable for motorized uses would have more consequences for dispersing bears and may impact connectivity more than alternatives that have less areas suitable for motorized uses. Alternative X would have the least amount of secure habitat in a non-motorized setting, while Alternative Y would have the most amount. The other alternatives would be intermediate to these two. The Preferred Alternative would include 69 percent of the secure acres in the two non-motorized settings (primitive and semi-primitive non-motorized) and 31 percent of the secure acres in motorized settings. The alternative with the most area suitable for motorized uses is 14.8 percent more suitable than the alternatives with the least amount of motorized suitability. Several areas in the Preferred Alternative were identified and retained in non-motorized settings to provide for grizzly bear connectivity which are shown in Figure 106.

Table 276. Acres and percent of secure habitat in various summer recreation opportunity spectrum (ROS) classes by alternative (Alt)

ROS Setting	No Action Alt[1]	%	Alt W	%	Alt X	%	Alt Y	%	Alt Z	%	Preferred Alt	%
Primitive	869,480	35	1,151,665	47	1,151,665	47	1,165,043	47	1,165,043	47	1,1240,66	46
Rural	291	0	3,495	0	3,495	0	3,495	0	3,495	0	4,315	0
Roaded Natural	92,237	4	93655	4	116,767	5	106,565	4	99,887	4	158,145	6
Semi-Primitive Motorized	257,358	10	481,867	20	718,410	29	256,611	10	228,730	9	605,122	25
Semi-Primitive Non-Motorized	1,243,714	50	732,397	30	472,741	19	931,365	38	965,925	39	571,432	23

1. The recreation opportunity spectrum settings for the No Action Alternative provide guidance on recreational experience but did not include motorized suitability.

Table 277. Percent of currently secure grizzly bear habitat suitable for motorized uses under the alternatives (Alt)

Secure Habitat	No Action Alt	Alt W	Alt X	Alt Y	Alt Z	Preferred Alt
Motorized	15	23	34	15	14	31
Non-motorized	85	77	66	85	86	69

The recreation opportunity spectrum (ROS) settings do not identify where those motorized uses would occur specifically, rather they identify where those activities could occur after a site-specific travel management decision. However, the ROS settings, in combination with areas identified as recommended wilderness, would largely determine where motorized access could occur under the plan. In the Preferred Alternative, the ROS can be characterized as more summer and winter motorized access with important areas for non-motorized access delineated because of resource concerns, including for grizzly bear connectivity compared to other alternatives. From a grizzly bear conservation perspective, alternatives that have less secure habitat suitable for motorized uses would be better than those with more secure habitat suitable for motorized uses. Future road or motorized trail construction would potentially reduce secure habitats.

Grizzly bear conservation in the 1987 plans relied on constraints in the plan associated with elk habitat effectiveness direction to determine the location and density of motorized roads and trails on the Nez Perce-Clearwater. The elk plan components identified discrete areas called elk analysis units where the plan would maintain 100 percent, 75 percent, 50 percent, and 25 percent elk habitat effectiveness. Elk security was based on road density measures, among other factors, to restrict motorized travel. These measures restricted road building on many areas across the national forest. Once the Idaho Roadless Rule was enacted it imposed restrictions on road building on much of the national forest, representing a new constraint on motorized uses, reducing the need for elk habitat effectiveness measures in much of the national forest.

Under most alternatives, Management Area 3 would mostly consist of roaded natural setting with less in the rural setting. The rural setting represents the most developed recreation sites and modified natural settings on the Nez Perce-Clearwater. Facilities are designed primarily for user comfort and convenience. The roaded natural setting is managed to provide nodes and corridors of development that support higher concentrations of use, user comfort, and social interaction. The road system is generally well defined in this setting and can typically accommodate passenger car travel. In the semi-primitive motorized setting, the Nez Perce-Clearwater is managed for backcountry motorized use on designated routes. Routes are designed for off-highway vehicles and other high-clearance vehicles. This setting offers visitors motorized opportunities for exploration, challenge, and self-reliance. Mountain bikes and other mechanized transport are also sometimes present. Rustic facilities are present for the primary purpose of protecting the natural resources of the area or providing portals to adjacent primitive or semi-primitive non-motorized areas. The changes in Management Area 3 in the action alternatives would allow a more comfortable or higher level of development compared to current conditions. Idaho Roadless Rule areas are typically either semi-primitive motorized or semi primitive non-motorized. These areas would remain relatively rustic, with lower maintenance levels of roads.

As the recreation opportunity spectrum settings move from rural to primitive, the amount of human activity is expected to increase, the amounts and types of developments increase, and these factors would incrementally increase the chance for grizzly-human conflicts. The proximity of the recreation opportunity spectrum settings across the Nez Perce-Clearwater are important as well. Grizzly bears entering the national forest from the north or the east would find recreation opportunity spectrum settings such as primitive and semi-primitive non-motorized. As they move west, they would encounter more semi-primitive motorized and roaded natural settings. Changes in settings also influence the types and intensities of developed recreation sites, trending road development and recreation facilities towards a more developed state.

The non-motorized settings would not be suitable for motorized uses and provide other experiences as well. The semi-primitive non-motorized settings include areas of the Nez Perce-Clearwater managed for non-motorized use. Mechanized transport, such as mountain bikes, is often present. Rustic facilities are present for the primary purpose of protecting the natural resources of the area. These settings are not as vast or remote as the primitive settings, but they also offer opportunities for exploration, challenge, and self-reliance. The primitive setting supports large, remote, wild, and predominantly unmodified landscapes. There is no motorized activity and little probability of seeing other people. Primitive settings are managed for quiet solitude away from roads, people, and development. There are few facilities or developments. Most of the primitive settings coincide with designated wilderness boundaries and recommended wilderness areas. Motorized routes would be prohibited in areas identified as unsuitable for motorized uses.

Several changes would occur in the Preferred Alternative compared to the No Action Alternative. Many areas that were formerly roaded natural in the No Action Alternative, would be identified as rural in the Preferred Alternative. Similarly, many areas currently identified as semi-primitive motorized would become roaded natural under the Preferred Alternative.

Under the Preferred Alternative, secure habitats within motorized settings may experience future road or motorized trail development under the plan after site-specific analysis, though where is yet to be determined. Future new developments would increase the probability of human-grizzly conflict, fragment secure habitat, and could lead to grizzly bear deaths or removal. Roads are allowed in Idaho Roadless Rule Areas in only limited circumstances, but motorized trails are not constrained in these areas and therefore some of them are identified as suitable for these uses. If motorized trails are proposed in the future in Idaho Roadless Rule areas in areas suitable for motorized uses, guideline MA2-GDL-WL-05 apply. Guideline MA2-GDL-WL-05 has three exceptions when the 5,000-acre constraint does not apply as follows:

- Community Protection Zones (CPZs) as defined by the Idaho Roadless Rule.
- Areas with existing motorized access that are currently less than 5,000 acres.

- Existing trails that are relocated or reconstructed to mitigate negative impacts to ecological resources.

According to that guideline, motorized access should not be authorized unless adjacent areas of 5,000 acres or larger can be maintained without motorized access. This guideline would allow limited amounts of motorized trails within secure habitats larger than 10,000 acres within motorized settings within Management Area 2. It would prevent motorized trails from being constructed within secure habitats between 10,000 down to 5,000 acres and then would allow motorized trails within secure habitats smaller than 5,000 acres. This guideline would only apply within Idaho Roadless Rule Areas and that are suitable for motorized uses. It would not apply within areas not suitable for motorized uses because there would not be any motorized trails nor roads allowed. Hypothetically speaking, in secure habitats within Idaho Roadless Rule Areas, only blocks larger than 10,000 acres and those smaller than 5,000 acres could be divided by a motorized road or trail and still meet the conditions of guideline MA2-GDL-WL-05. Blocks of secure habitat larger than 10,000 acres, blocks between 5,000 and 10,000 acres, and blocks smaller than 5,000 acres in Management Area 2 are shown in Figure 108. MA2-GDL-WL-05 would still allow some limited motorized trails to be developed to respond to desires by the public for more access, but it would fragment secure areas, especially those areas of security larger than 10,000 acres. It would not change or fragment habitats within the Bitterroot Recovery Zone as roads are not allowed there, so these are areas outside of the recovery zone.

This guideline would constrain activities that would reduce and fragment secure habitat. The plan area has 27 secure areas that have greater than 10,000 acres each, which includes those in wilderness areas, recommended wilderness areas, and Idaho Roadless Rule areas. There are 20 blocks of secure habitat larger than 10,000 acres that occur outside of wilderness and recommended wilderness areas, ranging in size from 47,849 to 10,250 acres. Most of these large secure areas are located within the Clearwater National Forest in the North Fork of the Clearwater Drainage and all of them have either all or some portion within a motorized setting.

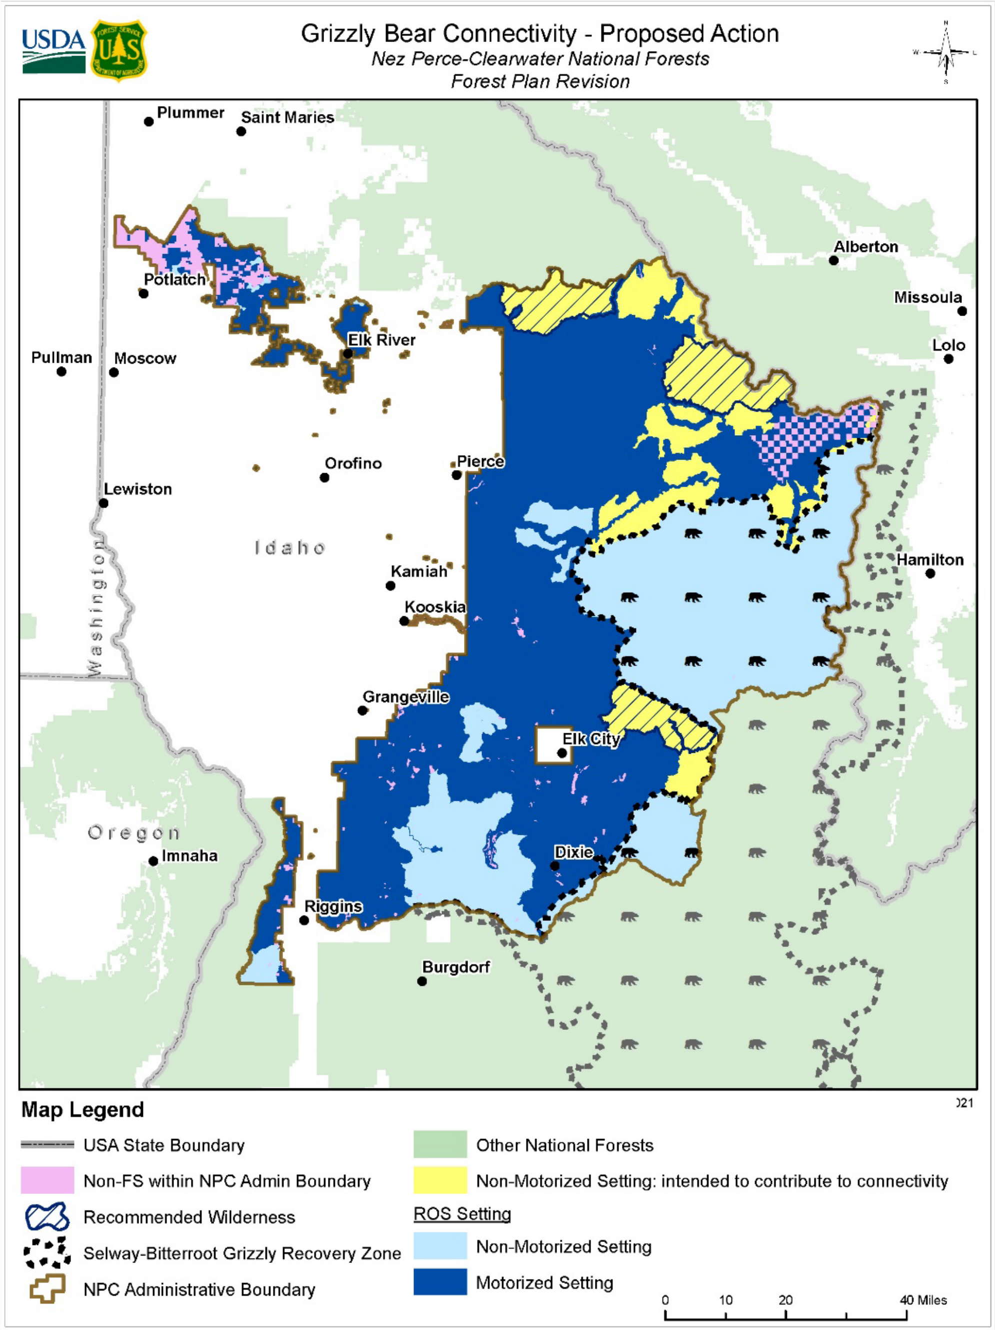

Figure 106. Areas identified as non-motorized in the summer Recreation Opportunity Spectrum Settings in part to provide for grizzly bear connectivity into and through the Bitterroot Recovery Zone

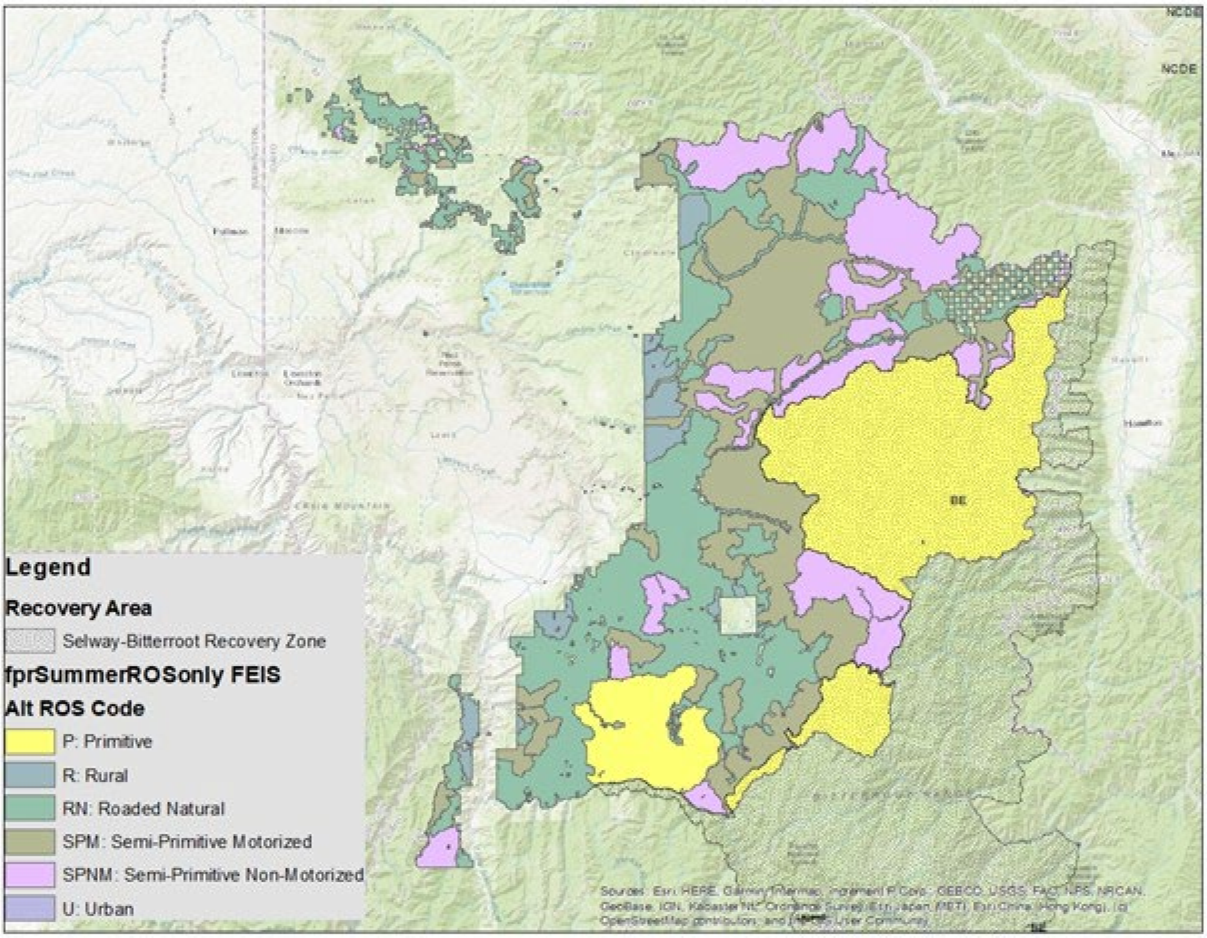

Figure 107. Summer Recreation Opportunity Spectrum under the Preferred Alternative relative to the Bitterroot Recovery Zone. Rural, Roaded Natural, and Semi-Primitive Motorized settings would be suitable for motorized uses while Primitive and Semi-primitive non-motorized are settings not suitable for motorized uses

Table 278. The acres and percent of currently secure grizzly bear habitat suitable for motorized and non-motorized uses in the Preferred Alternative

Secure Habitat	Preferred Alternative acres	Preferred Alternative percent
Motorized	767,582	31%
Non-motorized	1,695,498	69%

A total of approximately 1,111,712 acres of secure habitat are in Idaho Roadless Rule areas. Table 278 shows the acres of secure habitats of different sizes and whether they are suitable for motorized uses or not. Of those, 542,720 acres of secure habitat are totally unsuitable for motorized uses and are protected by suitability plan components. There is a total of 568,992 acres of secure habitat in Idaho Roadless Rule Areas that are in a motorized Recreation Opportunity Spectrum setting. Of those, there are 434,458 acres of secure habitat larger than 10,000 acres, 47,834 acres of secure habitat blocks between 10,000 and 5,000 acres, and 86,699 acres smaller than 5,000 acres to which guideline MA2-GDL-WL-05 would not apply. Therefore, 434,458 acres total blocks of secure habitat larger than 10,000 acres could have a limited number of motorized trails developed, 47,834 would be completely protected, and 86,699 acres that would have no protections under MA2-GDL-WL-05. Unprotected secure habitats smaller than 5,000 acres make up about 3.5 percent of the total secure habitats in the plan area and about 7.7 percent of the secure habitats within Idaho Roadless Rule Areas. Figure 108 shows the areas within Idaho Roadless Rule areas, whether they are in a motorized or non-motorized setting and shows the secure habitats in the various sizes where MA2-GDL-WL-05 apply.

Table 279. The secure habitats within Idaho Roadless Rule Areas that are motorized or non-motorized by secure habitat block size

Secure Habitat in Motorize or Non-Motorized Settings by Block Size	Idaho Roadless Rule that are Not Secure Habitat	Secure Habitat Blocks less than 5000 acres in Idaho Roadless Rule Areas	Secure Habitat Blocks between 5,000 and 10,000 acres in Idaho Roadless Rule Areas	Secure Habitat Blocks greater than 10,000 acres in Idaho Roadless Rule Areas	Total Acres of Secure Habitat	Total Area within Idaho Roadless Rule Areas	Percent of Total Secure Habitat Within Idaho Roadless Rule Areas
Motorized	315,098	86,699	47,834	434,458	568,992	884,090	51.18%
Non-Motorized	54,826	17,273	31,645	493,802	542,720	597,546	48.82%
Grand Total	**369,924**	**103,972**	**79,479**	**928,261**	**1,111,712**	**1,481,636**	**100.00%**

Note, all amounts are estimated by a Geographic Information System and are approximate. The complex overlays involved in calculating secure habitat size, that are within the different

In total, there are 2,463,080 acres of secure habitat, of which 69 percent or 1,695,498 acres of secure habitat are not suitable for motorized uses under the Preferred Alternative and would be protected against motorized uses. A total of approximately 767,582 would be suitable for motorized uses. Approximately 482,292 acres of secure habitat would have constraints imposed by MA2-GDL-WL-05 in Idaho Roadless Rule Areas (Figure 108). A total of 285,290 acres of secure habitat or about 11.5 percent of the total secure habitats are suitable for motorized uses and that would not require the constraints of MA2-GDL-WL-05. Other plan components may exist in those areas to help address motorized uses (see the discussion on how the plan addresses motorized uses below).

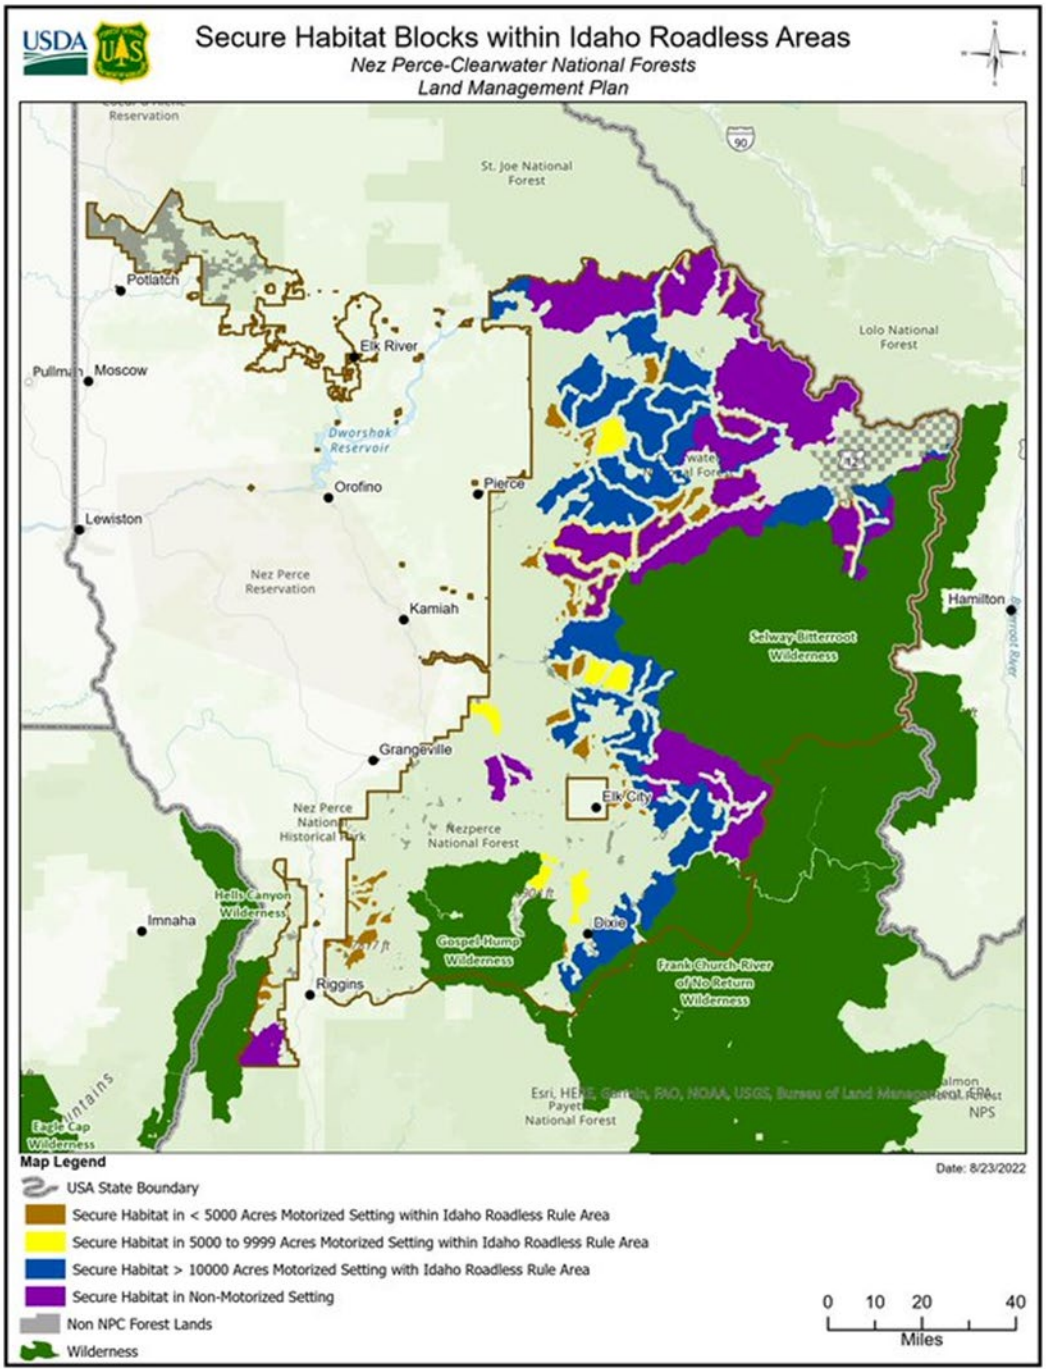

Figure 108. The blocks of secure habitat in Idaho Roadless Rule Areas that are in motorized Recreation Opportunity Settings that are greater than 10,000 acres in blue, between 5000-10000 acres in yellow, and less than 5,000 acres shown as tan. Also shown are Idaho Roadless Rule Areas in non-motorized Recreation Opportunity Spectrum Settings shown in purple. Wilderness areas are shown in dark green. Note, this map does not show secure habitats outside of Idaho Roadless Rule Areas.

The plan area has 26 blocks of secure habitat greater than 10,000 acres (Figure 108). They range in size between 1,102,583 and 10,370 acres and combine for a total of 2,180,362 acres of secure habitat in blocks larger than 10,000 acres. The vast majority of the acres in these large blocks are within Management Area 1 and 2 where there are constraints on new roads and motorized trails.

The four largest blocks of secure habitats are centered over wilderness or recommended wilderness areas and include a block over the Selway Bitterroot Wilderness at 1,102,538 acres and surrounding area, a block over the Gospel-Hump Wilderness and surrounding area at 274,867 acres, one on the Hoodoo Recommended Wilderness Area and surrounding area at 120,423 acres, and one centered over a portion of the Frank Church-River of No Return Wilderness and surrounding area at 108,793 acres for a grand total of 1,606,667 acres. These combined are about 73.6 percent of the secure habitats larger than 10,000 acres. While the majority of these areas are within areas not suitable for motorized uses, some of the secure habitat within these blocks extends over the wilderness boundary into areas suitable for motorized uses. Where they extend is mostly within Idaho Roadless Rule Areas of which some are suitable for motorized uses. This means that, while new roads are not allowed under the Idaho Roadless Rule, these areas could have new motorized trails constructed and still meet MA2-GDL-WL-05 around the periphery of the Wilderness Areas so long as they leave areas 5,000 acres and larger after the construction of the new motorized trails.

A total of 76 percent of secure habitats within blocks over 10,000 acres are in a non-motorized Recreation Opportunity Spectrum Classification. That leaves only 24 percent of secure habitats larger than 10,000 acres suitable for motorized uses. About 2 percent are located partially within Roaded Natural settings within Management Area 3, primarily around the Gospel-Hump Wilderness Area. In these acres, both roads and motorized trails are suitable with no restrictions. Most of the remaining 22 percent suitable for motorized uses are within Idaho Roadless Rule Areas, mostly in the Backcountry Restoration theme, which prohibits roads with only limited exceptions (See description of Idaho Roadless rule themes in the existing condition section above). All of these acres are located within Management Area 2 where MA2-GDL-WL-05 would apply.

The blocks of secure habitat larger than 10,000 acres that occur outside of wilderness and recommended wilderness areas and within areas suitable for motorized uses, range in size from about 32,747 to 10,370 acres. Most of these large secure areas are located within the Clearwater National Forest in the North Fork of the Clearwater drainage, but also occurs within other areas around wilderness areas. In some cases, adding only one or two motorized trails would render them to a size between 5,000 and 10,000 acres wherein they would be unable to accommodate any other motorized trails and still meet MA2-GDL-WL-05, so they would be limited in the total amount of motorized trails that could occur. Figure 108 shows a map of the areas that are suitable for motorized uses in Idaho Roadless Rule where MA2-GDL-WL-05 applies.

Keep in mind that there would still be an additional 47,834 acres more that meet the definition of secure habitat but that are smaller than 10,000 acres but larger than 5,000 acres. These habitats would be protected by MA2-GDL-WL-05. Secure habitats 1,280 acres (or 2 square miles) or larger were identified by Wakkinen and Kasworm (1997) as areas more likely to be used by grizzly bears than smaller areas. Wakkinen and Kasworm (1997) also showed that grizzly bears used areas as small as 141 acres but less frequently. There will be about 70,676 acres of secure habitats less than 5,000 acres but more than 1,280 acres in Management Area 2 that are in a motorized setting and where motorized trails would be allowed. Guideline MA2-GLD-WL-05 would not apply to these secure habitats. This amounts to 2.86 percent of the total secure habitats within the plan area. Guideline MA2-GLD-WL-05 is only required to apply within Management Area 2 and therefore will not protect secure habitats within Management Area 3. Any new motorized roads or trail constructed within 0.31 miles of existing motorized routes would result in a loss of additional secure habitat. Reductions in secure habitat would increase the probability of bear and human conflicts and could increase the probability of bear deaths as they move into the area. While the location, amount and length of new motorized roads and trails are unknown, it is reasonable to expect that new motorized roads and trails would be constructed occasionally throughout the life of the plan. There would likely be new motorized trails constructed within blocks of secure habitat larger than 10,000 acres within motorized Recreation Opportunity Spectrum Settings suitable for motorized uses, but the amount of these would be limited by guideline MA2-GDL-WL-05 in Idaho Roadless Rule Areas. In a worst-case scenario, a portion of the secure habitats in motorized settings in Management Area 2 larger than 10,000 acres could be reduced in size down as small as 5,000 acres. However, these habitats should still remain with low motorized route density overall and would still remain permeable to grizzly bears. Larger secure habitats are more valuable than smaller secure habitats in terms of their ability to provide for grizzly bear dispersal and occupancy and the very largest secure habitats centered around wilderness areas and recommended wilderness areas would mostly remain intact because most of those areas are not suitable for motorized uses.

The location and amount of secure habitat impacted by motorized trails that would be constructed in secure habitats smaller than 5,000 acres in Management Area 2 is not known, and there is no projection as to how much secure habitat would be reduced within the life of the plan. In total the maximum would be determined by the precise alignment and in what manner new motorized trails cross secure habitats. These can only be determined after site specific analysis, which would also include an Endangered Species Act consultation.

While a useful indicator, it should be noted that blocks of secure habitat are delineated based solely on the presence or absence of roads and motorized trails, but are not otherwise delineated as meaningful unit of measure per se. Other factors may also matter to grizzly bears, such the landscape arrangement of blocks of secure habitats, the amount of use and speed of the motorized routes, or habitat conditions such as nutritional resources, or other factors.

It is reasonable to expect that decisions in the plan on motorized suitability will allow a modest potential increase in motorized access and a loss of secure habitat over time within the plan area. Increased motorized access would bring people into proximity with grizzly bears once they move into the plan area. With an increase in people comes an increase in bear attractants that could draw grizzly bears into proximity of people leading to more bear human conflicts as grizzly bears become established. Because grizzly bears avoid motorized routes and smaller secure habitats, a decrease in the size of large secure habitats, and small secure habitats could reduce the permeability of the landscape for grizzly bears to a small degree. However, the distribution of protected secure habitats occurs along the Idaho and Montana border, an area that has been identified as important to grizzly bear connectivity (Peck et al. 2017). The scope of the impacts is within the distribution of secure habitats suitable for motorized uses. Therefore, about 31 percent of the secure habitats within the plan area could be impacted by motorized uses. This represents 767,582 acres of secure habitats. Keep in mind that 1,695,498 acres of secure habitat are protected because they are not suitable for motorized uses.

The addition of a few more motorized trails will still leave these large secure habitats permeable to grizzly bears to provide connectivity. Grizzly bears have been documented moving through and using landscapes with more roads and motorized trails than those in Management Area 2. This guideline, along with the restrictions in the Idaho Roadless Rule would conserve these areas sufficiently to provide connectivity and likely even the ecological conditions to support occupancy of grizzly bears outside of the Recovery Zone. Consider that the total amount of secure habitat in blocks of habitat 10,000 acres and larger (2,180,362 acres) is almost the size of Yellowstone National Park (2,221,766 acres). It is hard to argue that bears could not survive and experience population growth on the Nez Perce-Clearwater landscape with these characteristics, even if more motorized trails are constructed under the constraints of MA2-GDL-WL-05. These areas would clearly allow passage for connectivity. Some might argue that the constraints imposed by this guideline are an overreach because grizzly bears do not currently occupy the Nez Perce-Clearwater, even though some have dispersed through the area.

The Preferred Alternative only identifies where motorized uses are suitable and thus represents only the potential areas where this use could occur. The location, layout, direction, length, and change of secure habitat from new motorized roads or trails is unknown because these decisions have not yet been made and cannot be anticipated. The change in secure habitat from future roads or motorized trails will depend on their layout, where and in which direction they cross the block of secure habitat, their length, and their straightness. Decisions on motorized trails would require site specific analysis on the location, layout, and distribution of future trails, and would undergo site specific National Environmental Policy Act analysis and Endangered Species Act consultation prior to construction.

The effects of motorized trail use on grizzly bears has not been well studied as the focus of most studies are on the effects of roads. There may be differences in effects from motorized trail recreation compared to roads. For example, camping from motorized trails is less common than camping near roads from a full-sized vehicle. Motorized trail users tend to ride loops or paths as the activity of interest itself rather than traveling to a destination as is more common with road use. Therefore, the effects of motorized trails may not have the same impacts as roads from a human-bear conflict standpoint. However, loops are often more attractive to off-highway vehicle (OHV) recreational riders than endpoint destinations because they want to see different scenery across their trek instead of seeing the same landscapes twice. So, loops often become popular attractions for OHV users. In either case, they would still result in displacement and could still potentially result in human-bear conflicts.

A comparison of the elk security measures in the 1987 plans and the suite of suitability plan components coupled with MA2-GDL-WL-05 is needed. Under the 1987 plans, motorized trails and new roads could be constructed so long as they met the requirements of the elk habitat effectiveness measures. So in many areas, they did not prohibit new motorized routes. While the Preferred Alternative does not contain a constraint on road density, it does provide an effective alternative mechanism that would impose considerable constraints on motorized routes. The plan enforces prohibitions on motorized routes within many areas via suitability plan components. Where motorized uses are suitable in management areas, the plan includes a guideline (MA2-GDL-WL-05) designed to maintain secure habitat which places an upper limit on the total amount of motorized trails that could be constructed. So while these are a different mechanism that in the 1987 plans, the suitability plan components in conjunction with guideline MA2-GDL-WL-05 provide a different mechanism to provide the ecological conditions for grizzly bear. The two mechanisms are not directly comparable for a number of reasons:

1. Suitability plan components are a new type of plan component that did not exist in the 1987 Forest Plans. Recreation opportunity spectrum (ROS) was not used as a zoning tool in the 1987 Forest Plans, rather it was a mapping exercise based on other layers of direction, including elk habitat effectiveness and travel plan decisions.
2. The elk habitat effectiveness is based on motorized features within a delineated unit boundary such as an elk analysis unit, while guideline MA2-GDL-WL-05 is unitless and not dependent upon the scale of the delineated unit its measured against. For example, road density is measured as miles of road per square mile within a specified unit like a watershed or bear analysis unit. The calculation results are often dependent on how or where those units are delineated. In contrast, the secure habitat constraints in MA2-GDL-WL-05 is directed at maintaining secure habitat itself as the unit of measure rather than imposing limits on some level of motorized routes within a delineated unit. The secure habitat

guideline does not rely on a delineated unit and is defined only by delineating areas without motorized routes, defined in this case as areas farther than 0.31 miles of a motorized route. Therefore, it is a unitless metric which can be analyzed without somewhat arbitrary delineated units like elk analysis units. The guideline ties instead specifically to the size of the secure habitat rather than being measured relative to a delineated unit. Therefore, is not directly comparable to a unit-based indicator like elk habitat effectiveness.

3. They operate differently. The elk habitat effectiveness standards in the 1987 plans allowed motorized routes so long as at the end of the project, the elk habitat effectiveness within the elk analysis unit remained below the elk habitat effectiveness objective. If the elk habitat effectiveness objective was low enough (25 and 50 percent for example), and the roads were spaced out evenly, it left little to no secure habitat in many cases. A good example of the outcome of this management can be understood by an examination of the current distribution of secure habitat within areas managed for multiple uses wherein Management Area 3 typically had a 25 percent or 50 percent elk habitat effectiveness objective. Baseline conditions in Management Area 3 contain little secure habitat even though most projects would have been required to meet either 25 percent or 50 percent elk habitat effectiveness objectives. In contrast, suitability components completely prohibit motorized routes, and MA2-GDL-WL-05 requires the conserving a specified amount of secure habitat.
4. The two mechanisms operate at different scales. While the elk habitat effectiveness objectives applied across most of the national forest, the requirements for elk habitat effectiveness were applied at the elk analysis unit scale which where delineated to represent area approximately equal to the average size of an elk home range, which were relatively small. For example, the average size of elk analysis units is close to 5,200 acres (based on the elk analysis unit ArcGIS layer).

Comparing the two mechanisms spatially is difficult because they differ in spatial extent, often with different confounding underlying management direction. Management areas direction was more complicated under the 1987 Forest Plan and resource emphasis was different for different areas. The proposed plan simplified the broad management areas into three general types. Furthermore, the boundaries of the land allocations within the Preferred Alternative do not align with the boundaries of the elk habitat effectiveness units. Also, the Idaho Roadless Rule was not established until 2008 which complicates the comparison with the 1987 Forest Plan direction. The distribution of Idaho Roadless Rule does not match the boundaries of habitat effectiveness objectives. So, comparing a spatial overlay of the land allocations within the proposed plan compared with the 1987 elk habitat effectiveness layers would produce complicated alignment problems and topological errors that might not be easy to understand. Such a comparison would result in four categories of elk objectives overlayed on the five categories of Recreation Opportunity Spectrum and the five Idaho Roadless Rule themes resulting in complex overlay combinations of categories, so the overlay was not quantified for this analysis. Suffice it to say the mechanisms are different, and the proposed direction would have more protections for secure habitat in some areas and less in other areas compared to the 1987 Forest Plans. Table 280 below attempts to qualitatively illustrate the differences.

Table 280. A comparison of measures that address motorized access in the revised Forest Plan compared to the direction in the 1987 Forest Plans

Land Allocation in the Preferred Alternative	Whether the protections for secure habitat in the Preferred Alternative are more protective, less protective, or equally protective	Reason	Projected future outcome of the Preferred Alternative
Management Area 3-Managed for Multiple Uses	Less protective	Most of Management Area 3 included some motorized restrictions of either 25 or 50% elk habitat effectiveness objectives in the 1987 plans but have few constraints on motorized uses in the proposed plan.	New roads and motorized trails would be easier to build, and motorized access is expected to increase, however, the need to increase roads is limited because the road system required to effectively administer the Nez Perce-Clearwater already reaches most of Management Area 3 (see travel management in the description of the Preferred Alternative above)
Management Area 2-Recommended Wilderness	More Protective	Motorized uses are not suitable in recommended wilderness. Most were 100% EHE objectives but the meadow creek recommended wilderness area includes areas that were 75% and 50% EHE areas.	Some existing motorized routes will need to be closed because of the new meadow creek recommended wilderness area. No new motorized roads and trails are expected to be constructed in those areas though the plan has limited exceptions to the constraints consistent with Idaho Roadless Rule regulations.
Management Area 2-Idaho Roadless Rule Areas	Some areas less protection, other areas more protection	Roads are suitable only under limited circumstances in most of the Idaho Roadless Rule Areas. However, some Idaho Roadless Rule Areas had standards requiring 100% Elk habitat effectiveness be maintained. Areas with 75% EHE standards still allowed some motorized routes while, 100% EHE objectives heavily restricted or prevented motorized routes. In the proposed plan, some areas with a 100% EHE requirement will be within a motorized setting in the proposed plan. Specifically, these include	New roads would be very limited in Roadless Rule Areas but still possible depending upon theme and exceptions in the Idaho Roadless Rule Regulations. Some new motorized trails are expected to be constructed resulting in some loss of secure habitat. However, they are expected to be limited by MA2-GDL-WL-05 which will help to conserve large secure habitats. Some areas were identified as unsuitable for motorized uses to provide for grizzly bear connectivity and motorized trails would not be allowed.

Land Allocation in the Preferred Alternative	Whether the protections for secure habitat in the Preferred Alternative are more protective, less protective, or equally protective	Reason	Projected future outcome of the Preferred Alternative
		west meadow creek, the Rackliff-Gedney, Moose Mountain, and Bighorn-Weitas Roadless Rule Areas, and as a result will have less protections because of the change. However, guideline MA2-GLD-WL-05 would apply, offering some protections.	
Management Area 2-Research Natural Areas	More protected	Research Natural Areas are not suitable for motorized travel. The plan proposes several new Research Natural Areas.	No new motorized routes are expected within Research Natural Areas.
Management Area 2-Eligible and Suitable Wild and Scenic Rivers	Variable but similarly protective	The plan proposes fewer suitable or eligible wild and scenic rivers. Most formerly eligible rivers that will not be suitable in the Preferred Alternative were wilderness areas or Idaho Roadless Rule Areas which affords them some protections. Plan components that guide suitable and eligible wild and scenic rivers are similarly protective. Many of these river corridors overlap with Idaho Roadless Rule Areas, recommended wilderness or designated wilderness Areas also.	A few new motorized trails or roads could be constructed in scenic or recreational rivers, but not in wild classifications. If the rivers overlap with other land allocations such as Idaho roadless Rule or Wilderness, they would be required to follow suitability components and applicable guidelines for those areas as well.
Management Area 1-Designated Wilderness	Similarly protective	Roads and Motorized Trails are not suitable in Designated wilderness.	No motorized routes are expected to be constructed in designated wilderness.
Management Area 1-Designated Wild and Scenic Rivers	Similarly Protective	While direction specific to Designated Wild and Scenic Rivers is similar in the Preferred Alternative compared to the existing condition, most of the river corridors were winter range that did not have elk habitat effectiveness objectives. Part of the Selway and Salmon River are designated wilderness.	Steep terrain and the protections of the Wild and Scenic River Act and designated wilderness are expected to limit new motorized roads and trails.

Land Allocation in the Preferred Alternative	Whether the protections for secure habitat in the Preferred Alternative are more protective, less protective, or equally protective	Reason	Projected future outcome of the Preferred Alternative
Management Area 1-The National Historic Landmark.	Similarly protective	This management area occurs concurrent with Idaho Roadless Rule areas and so it had 50% and 100% EHE objectives. Idaho Roadless Rule regulation apply, and so would MA2-GDL-WL-05.	Management is similar in the national historic landmark in the Preferred Alternative compared to the existing plans.

The plan must be viewed holistically to understand how the parts of the plan work together to address motorized access. The plan layers land use allocations, management area direction, suitability of uses, desired conditions, standards, and guidelines, which all contribute to manage motorized access to conserve secure habitats. This section provides an overview of how all the parts work together to address motorized access in relation to grizzly bears.

Motorized access is both a habitat related threat and a source of human caused mortality (U.S. Department of the Interior 2021c). The current scope of this threat is the area within 0.31 miles from any road or motorized trail open to the public or closed to the public but open to administrative uses by the Forest Service, which is approximately 37 percent of the total plan area currently. Large areas in the plan are precluded or have substantial restrictions on motorized uses in law, regulation, or policy. Consistent with these, suitability plan components also address motorized access through suitability of uses. Everywhere in the plan area is identified as either suitable, conditionally suitable, or unsuitable for a variety of activities related to motorized access. These include permanent road construction, temporary road construction, motorized over-snow travel, or motorized travel or motorized recreation. Designated areas that prohibit or regulate motorized uses include Designated Wilderness, Idaho Roadless Rule Areas, the National Historic Landmark, and Designated Wild and Scenic River corridors particularly in the wild classification.

The Bitterroot Recovery Zone is highly protected against motorized access because it occurs in designated wilderness and the Wilderness Act prohibits this activity, with only narrow exceptions that are rarely used. Recall only part of the Bitterroot Recovery Zone occurs within the Nez Perce-Clearwater National Forest as it extends across multiple national forests. Additionally, the vast majority of the Bitterroot Recovery Zone outside of the Nez Perce-Clearwater National Forest is also designated wilderness areas and would be similarly protected from motorized access. Furthermore, the wilderness areas within the plan are identified as unsuitable for all of the motorized use categories. In addition, the plan area also has the Gospel-Hump Wilderness Area, which also restricts motorized uses. There are no plans now or in the foreseeable future to have any new motorized roads, nor motorized trails within the Bitterroot Recovery Zone. There is no anticipated future need to have motorized access within the Bitterroot Recovery Zone. The Wilderness Act ensures that this threat will not affect the vast majority of the Bitterroot Recovery Zone. Suitability components ensure that there will be none of these activities under the plan in designated wilderness areas.

Outside of Wilderness, the Idaho Roadless Rule areas address this threat in part because it generally prohibits new road construction except in narrow and limited circumstances. These areas make up

1,481,565 acres of which 1,111,642 acres are secure habitat. Management Area 2 is made up of Idaho Roadless Rule Areas, Eligible and Suitable Wild and Scenic Rivers, Recommended Wilderness, and Research Natural Areas. Each of these constrain roads and motorized access to various extents. They combine to protect for 1,467,078 acres of which 1,124,882 or 76.6 percent is secure habitat currently. The Roadless Rule Area boundaries are often delineated by roads which existed prior to their establishment. So naturally there would be some lack of secure habitats from preexisting roads.

Allen (2011) described secure habitat conditions in the Selkirk and Cabinet Yaak ecosystems based on data from Wakkinen and Kasworm (1997). For context, the entire Selkirk Ecosystem is 1,307,525 acres of which only 688,642 acres occurs within the United States and of which only 298,176 acres of habitat was secure core. The Cabinet Yak Ecosystem is 1,693,248 acres of which 628,543 was secure core. The two ecosystems combined to support secure habitat of approximately 926,719 acres in 1997 (Allen 2011). By comparison, the Idaho Roadless Rule areas within the Nez Perce-Clearwater alone are 1,481,636 acres, not including the wilderness areas, and are larger than the entire Selkirk Ecosystem. The amount of secure habitat within Management Area 2, which is a total of 1,124,882 acres, is larger than the total amount of secure habitats in these two ecosystems combined (926,719 acres). The combined effects of Management Area 1 and 2 direction is that 2,698,716 acres that are either fully protected or partially protected by either the highly restrictive plan direction for Management Area 1 lands or the constraining direction of Management Area 2. These lands have 2,268,274 acres of secure habitat currently. These are in a landscape where roads are either not suitable in the plan, not allowed by law or allowed with only limited exceptions. Some Idaho Roadless Rule Areas are suitable for motorized uses and some are not. There are a total of 1,681,779 acres of secure habitat completely protected as either designated wilderness or Idaho Roadless Rule areas where motorized uses are not suitable. Of the Idaho Roadless Rule Areas, approximately 565,519 acres of secure habitat in Idaho Roadless Rule Areas that are suitable for motorized uses under the Recreation Opportunity Spectrum settings. These areas are protected against new road development by the Idaho Roadless Rule, and new motorized trails are constrained in these areas by MA2-GDL-WL-05. MA2-GDL-WL-05 both allows some limited impacts to 24 percent of the secure habitats in the plan area, while also placing a limit on the amount of secure habitat that motorized trails could impact. A total of 542,720 acres of secure habitats in Idaho Roadless Rule Areas are not suitable for motorized uses within Idaho Roadless Rule Areas. These areas may contribute to grizzly bear connectivity by constraining construction of new roads and other actions related to motorized uses that may affect grizzly bear secure habitats. Table 281 and Table 282 below detail how plan components address or constrain motorized routes.

Table 281 The content of suitability plan components in tables within the revised Forest Plan under the Preferred Alternative

Suitability Plan Component Tables in the Revised Plan	How Motorized access is addressed by the Suitability Plan Components
Table 18—Suitability plan component in Sustainable Recreation	Identifies the activities suitable or not suitable within the Recreation Opportunity Spectrum settings. Permanent road construction, temporary road construction, and motorized travel are unsuitable in Primitive and Semi-primitive Non-motorized settings. Some Recreation Opportunity Spectrum settings were identified as not suitable for motorized uses specifically for grizzly bears.
Table 17—Suitability in Developed Recreation Sites Table 20—Suitability in Administrative Sites Table 26—Suitability in designated wilderness Table 28—Suitability in designated Wild and Scenic River corridors Table 30—Suitability in recommended wilderness	The suitability of uses across all land management allocations in the Forest Plan are contained within land allocation specific tables: Table 17, 20, 26, 28, 30, 32, 33, 35 and 37. Construction of Permanent Roads: Indicates that permanent road construction is

Suitability Plan Component Tables in the Revised Plan	How Motorized access is addressed by the Suitability Plan Components
Table 32—Suitability in eligible and suitable Wild and Scenic River corridors Table 33—Suitability in Idaho Roadless Rule Areas. Table 35—Suitability in Research Natural Areas Table 37—Suitability in the Lolo Trail National Historic Landmark	unsuitable without conditions in Designated Wilderness; Recommended wilderness; Designated Wild and Scenic River -Wild classification; Eligible and Suitable Wild and Scenic River-Wild Classification; Idaho Roadless Rule Areas- Wildland Recreation, Primitive and Special Area Themes; Mass movement areas; and Research Natural Areas. They are conditionally unsuitable in Idaho Roadless Rule Areas with a backcountry restoration theme and in Riparian Management Zones except perpendicular stream crossings. Permanent road construction is conditionally suitable in Designated Wild and Scenic River corridors and in eligible and suitable Wild and Scenic River within Scenic and Recreational classifications as long as it is consistent with the river plan and provided ORV's are protected. They are conditionally suitable within Idaho Roadless Rule Areas within Backcountry Restoration Community Protection Zones in accordance with the Idaho Roadless Rule and in the Lolo Trail National Historic Landmark if the purpose is to benefit the National Register integrity. Construction of Temporary Roads: Not suitable in Lolo Trail National Historic Landmark Corridor, Designated Wilderness, Designated Wild and Scenic River's Wild classification, Suitable Wild and Scenic Rivers Wild Classifications, Recommended Wilderness, Idaho Roadless Rule Wildland Recreation Theme and Primitive and Special areas of Historic or Tribal Significance, Mass Movement Areas, and Research Natural Areas. They are conditionally unsuitable in Idaho Roadless Rule Backcountry/Restoration Themes as permitted by the Idaho Roadless Rule, and Riparian Management Zones prohibited except when they cross perpendicularly to the waterway. Temporary Roads are suitable with conditions in Idaho Roadless Rule Backcountry Restoration Community Protection Zones, Designated Wild and Scenic Rivers within Scenic and Recreation classifications consistent with wild and scenic river management plans, and suitable wild and scenic rivers within scenic and recreation classifications when Outstandingly Remarkable Values are protected. Motorized Recreation: Not suitable in Wilderness nor Recommended Wilderness, Primitive and Semi-primitive non-motorized Recreation Opportunity Spectrum settings, and within designated and proposed Research Natural Areas. Motorized recreation is conditionally suitable within Designated Wild and Scenic River wild classification depending on the Wild and Scenic River Plan and is limited to only motorized uses and unobtrusive trail bridges if ORVs are protected.
Table 26 In the Revised Forest Plan—Suitability plan components in the Forest Plan for Management Actions Suitable within Designated Wilderness.	Indicates that roads, temporary roads, motorized travel, mechanized travel, and motorized over-snow travel is not suitable in designated wilderness areas.

Suitability Plan Component Tables in the Revised Plan	How Motorized access is addressed by the Suitability Plan Components
Table 28 in the Revised Forest Plan—Suitability plan component for management actions in designated wild and scenic rivers.	Indicates permanent and temporary road construction is not suitable within wild classification, but in other classifications they are suitable so long as outstandingly remarkable values are protected. Reconstruction of roads is not suitable within wild classification, but suitable if outstandingly remarkable values are protected. Motorized travel is not suitable in wild classification but is suitable in other classifications as long as outstandingly remarkable values are protected.
Table 30 in the Revised Forest Plan—Suitability plan component in the Revised Forest Plan for Management Actions Suitable within Recommended Wilderness Areas.	Indicates permanent road construction is not suitable, Temporary road construction is conditionally suitable consistent with the Idaho Roadless Rule. Over-snow vehicle use is not suitable, recreational aircraft landings are unsuitable but landings for administrative uses are suitable, and motorized travel is unsuitable,
Table 32—Suitability plan components in the Revised Forest Plan that apply to Eligible and Suitable Wild and Scenic River corridors.	Indicates permanent and temporary road construction is not suitable within wild classification, but in other classifications they are suitable so long as outstandingly remarkable values are protected. Reconstruction of roads is not suitable within wild classification, but suitable if outstandingly remarkable values are protected. Motorized travel is not suitable in wild classification but is suitable in other classifications as long as outstandingly remarkable values are protected.
Table 33 in the Revised Forest Plan—Suitability of Uses within Idaho Roadless Rule Areas.	Indicates that permanent and temporary road construction is not suitable in Wildland Recreation Theme, Primitive and Special Areas of Historic or Tribal Significance theme, and Backcountry Restoration theme areas. Permanent road construction is conditionally suitable in Backcountry Restoration Community Protection Zone areas. Road construction and reconstruction may be allowed only to the extent permitted in the Idaho Roadless Rule (36 CFR 294.23). Motorized travel is suitable as mapped on desired recreation opportunity spectrum maps in the appendix, if mapped as rural, roaded natural, or semi-primitive motorized, motorized use is suitable; if mapped as semi-primitive non-motorized or primitive, motorized use is not suitable. Over-snow vehicle use is a suitable use.
Table 35 in the Forest Plan—Suitability of uses within designated and proposed Research Natural Areas	Motorized travel, permanent road construction and temporary road construction is not suitable within Research Natural Areas. Over-snow vehicle use is suitable in Research Natural Areas.
Table 37 in the Revised Forest Plan—Suitability plan components on lands within the National Historic Landmark	Permanent and temporary road construction is suitable only if the integrity of the National Historic Landmark is maintained, Guideline GA-GDL-NHL-05 further clarifies "New temporary or permanent road and trail construction should not be permitted within the Landmark unless the integrity of the National Historic Landmark is maintained and the purpose of the action is to benefit the National Register integrity of the Landmark."
Table 24 in the Revised Forest Plan—Timber Production Suitability Classification	Identifies which lands or management areas are suitable or not suitable for timber production, timber

Suitability Plan Component Tables in the Revised Plan	How Motorized access is addressed by the Suitability Plan Components
	harvest, and harvest suitable for other resource objectives.

Motorized access is further addressed by plan desired conditions, guidelines, and standards. Plan direction that addresses motorized access includes those within the Aquatic Ecosystem Plan components, multiple uses wildlife plan components, and recreation plan components. The following plan components further address motorized access as described in Table 282.

Table 282. How the plan component contributes to the threat of motorized access

Plan Component Name	Type of Plan component	How the plan component contributes to the threat of motorized access
FW-OBJ-WTR-02	Objective	Seeks to enhance or restore 50-100 miles of stream habitat every 5 years. Specifically mentions streamside road decommissioning as an included activity.
FW-OBJ-WTR-05	Objective	Improve soil and watershed conditions every 5 years in priority watersheds and Conservation Watershed Network watersheds. Specifically mentions non-system road decommissioning.
FW-OBJ-RMZ-01	Objective	Objective to improve 300-700 acres of riparian habitats every five years. Specifically mentions road obliteration and removal of road prisms as part of this restoration.
FW-GDL-RMZ-02	Guideline	Guideline that restricts new road and trail construction, including temporary roads, within riparian management zones except under three conditions: a) necessary for stream crossings, or b) a road or trail relocation contributes to attainment of aquatic and riparian desired conditions, or c) Forest Service authorities are limited by law or regulation (for example, General Mining Act of 1872). Also specifies that temporary roads should be managed to protect aquatic and riparian desired conditions.
FW-STD-ARINF-07	Standard	In the Conservation Watershed Network and HUC12 subwatersheds with Endangered Species Act critical habitat or listed aquatic species, when constructing or reconstructing roads, projects shall result in a net decrease in the hydrologic connectivity of the road system and stream channel network unless no further decreases are needed to meet desired conditions for Water and Aquatic Resources or Conservation Watershed Network. Treatment priority shall be given to roads or road segments that pose the greatest relative ecological risk to riparian and aquatic ecosystems. The net decrease is measured by project area.
FW-DC-ARINF-01	Desired Condition	States: “The transportation system has minimal impacts on aquatic and riparian conditions through reduced hydrologic connectivity of roads to streams, lower sediment delivery to streams, reduced road impact to floodplains, and improved aquatic organism passage, where transportation infrastructure affects these features.” This plan component would direct management to reduce impacts from the transportation system to areas aquatic and riparian conditions. In some cases, it would prevent construction of roads in riparian areas. It may encourage moving existing roads outside of riparian areas.
FW-STD-ARINF-01	Standard	States “Road maintenance and new road construction shall be designed to minimize adverse effects to threatened, endangered, proposed, or candidate aquatic species and their habitat.” This standard would have a chilling effect on roads from being constructed within riparian areas. It would address the manner in which these activities occurred to prevent impacts.
FW-GDL-ARINF-04	Guideline	States: “To reduce road-related mass wasting and sediment delivery to watercourses, new and relocated roads, including skid trails and temporary roads, and other linear features should not be constructed on lands with high mass wasting potential.” This guideline will restrict roads in some areas of the Nez Perce-Clearwater even when suitable for motorized uses. Lands with mass wasting potential would remain free of roads.

Plan Component Name	Type of Plan component	How the plan component contributes to the threat of motorized access
FW-GDL-ARINF-08	Guideline	This plan component states: “To avoid adverse effects to water resources, wetlands and seasonally wet meadows should be avoided when constructing new roads and landings, including temporary roads. For all roads, and where reconstruction of existing roads cannot avoid water courses and wetlands drainage features should maintain wetland functions and characteristics.” This guideline would constrain road construction in aquatic, wetlands, and wet meadow habitats.
FW- GDL-AREM -02	Guideline	Specifies that mineral operations should reuse existing access routes and processing sites from previous entries as long as they are not causing unacceptable impacts to aquatic and riparian dependent resources. Also specifies that when no longer required for mineral activities, roads should be decommissioned.
FW-GL-WL-02	Goal	States: “The Nez Perce-Clearwater cooperates with highway managers, state agencies, tribes, and landowners to implement wildlife and aquatic organism crossings that reduce encounters and contribute to public safety.” This goal would encourage management to address road crossings for wildlife which would also help reduce potential vehicle strikes and enhance connectivity.
FW-DC-WL-06	Desired Condition	States “The grizzly bear Bitterroot Recovery Zone provides the ecological conditions to support recolonization of grizzly bears. Land Management Plan land use allocations provide connectivity to allow secure passage from occupied habitat to the Bitterroot Recovery Zone” This desired condition would direct management to maintain or restore ecological condition to maintain connectivity which might include considerations when constructing or authorizing motorized roads or trails. Although a project does not have to achieve all desired conditions, all projects must be consistent with plan components and cannot preclude achievement of a desired condition.
FW-GDL-WLMU-01	Guideline	States: “When closing routes to motorized use, to ensure benefits to wildlife habitat are realized, include measures to sufficiently exclude motorized use on closed routes.” Guideline intended to ensure that road closures effectively close and prevent unauthorized use by the public. This plan component would minimize the amount of use closed roads or trails would receive. It only requires the deciding official to consider taking actions but does not require actions. All use of these features would not be legal.
FW-DC-WLMU-07	Desired Condition	States: “Elk habitat is distributed throughout the planning area to support elk populations. Motorized access does not preclude use of high-quality nutritional resources or winter ranges.” A desired condition that would guide management to locate motorized access away from high or moderate quality nutrition for elk, and away from winter ranges. This would also indirectly benefit grizzly bears nutritionally by preventing impacts from roads to these important areas. Grizzly bears will find nutritional resources and more elk away from motorized access because of this desired condition.
MA2-DC-WLMU-02	Desired Condition	Desired condition specific to Management Area 2 that states: “Areas at least 5,000 acres in size exist without motorized access open to the public to maintain habitat use by elk.” This desired condition would direct management to maintain large areas without motorized uses. While the plan component focuses on elk, it would also have benefits to grizzly bears because it would maintain non-motorized areas within Management Area 2.

Plan Component Name	Type of Plan component	How the plan component contributes to the threat of motorized access
MA2-GDL-WL-05	Guideline	Plan guideline that states "MA2-GDL-WL-05. To maintain large areas of unfragmented habitat for wide-ranging species, such as elk and grizzly bear, new motorized trails open to the public should not be authorized in Idaho Roadless Areas unless there are adjacent areas of 5000 acres without open motorized system routes. This guideline does not apply to: Community Protection Zones (CPZs) as defined by the Idaho Roadless Rule. Areas with existing motorized access that are currently less than 5,000 acres. Existing trails that are relocated or reconstructed to mitigate negative impacts to ecological resources. This plan guideline acts as a constraint on motorized trails within Idaho Roadless Rule Areas which make up the majority of Management Area 2. It does not constrain motorized routes in other areas of Management Area 2 that are not Idaho Roadless Rule Areas. It would allow some new motorized trails in Idaho Roadless Rule Areas suitable for motorized uses, but these trails would be limited to areas larger than about 10,000 acres and would maintain secure habitats areas in blocks no smaller than 5000 acres or larger without motorized access in Management Area 2. It would not apply to secure habitats smaller than 5000 acres so motorized trails could be constructed without restraint there. It also would not apply to lands outside of Idaho Roadless Rule Areas.
MA3-GDL-WLMU-01	Guideline	States: "Treatments designed to improve elk habitat should focus on one or more of the habitat covariates likely to improve predicted cow elk body fat condition. This plan guideline integrates factors that affect predicted cow elk body fat as a restriction, which could include open motorized routes and nutrition. The four factors that affect predicted elk body fat include the abundance of high quality nutritional resources within a given area such as a watershed, whether those nutritional resources are usable by elk based on whether they occur more than one-half mile from a road, the slope that those resources are located on, and the distribution of those nutritional resources in relation to forage cover edges. The specific factors and how they will be applied are outlined in Management Approaches for elk. This plan component would only apply to projects that aim to improve elk habitats in Management Area 3.
FW-DC-REC-12	Desired condition	Desired condition that states: "Trails (e.g., trails converted from roads, user created trails) not needed to serve management or public needs and purposes are absent." This would direct management to eliminate any unneeded trails including on old roads and user created trails.
FW-STD-REC-01	Standard	Standard that enforces Recreation Opportunity Spectrum Settings as follows: "Construction and reconstruction of recreation facilities and trails shall be compatible with the appropriate recreation opportunity spectrum class and other applicable resource management plans, such as wilderness, recreation corridor, river management, scenic byway, or trail plans." This plan standard would help ensure that trails, including motorized trails, would be managed compatible with Recreation Opportunity settings.

In summary, the plan has significant measures to prevent or address the threat of motorized access within the plan area. They are hierarchal and start with law, regulation, and policy; are reinforced by suitability plan components and summer Recreation Opportunity Spectrum settings; and then are addressed further by desired conditions, standards, and guidelines. There are rigorous measures to restrict the construction of permanent roads, temporary roads, and motorized travel in a substantial portion of the Nez Perce-Clearwater. Measures for roads in riparian areas as noted in the table above (for example, FW-DC-ARINF-01, FW-GDL-RMZ-02) represent a substantial addition because they occur across all management areas and make up approximately 548,284 acres or about 14 percent of the plan area. This includes 233,201 acres of riparian habitats in land allocations otherwise suitable for motorized uses. About 332,862 acres of riparian habitat are secure habitat.

While these measures address motorized access in many areas of the Nez Perce-Clearwater, motorized access is generally not restricted within Management Area 3, and some motorized trails might be constructed in areas suitable for motorized uses in Management Area 2 provided they comply with applicable plan direction. These are activities that could have consequences to grizzly bears because they would result in loss of secure habitat, potential human-bear conflicts, and could result in grizzly bear death. These were analyzed in detail in the Effects of Motorized Suitability and Summer Recreation Opportunity Spectrum section above.

Winter Recreation Opportunity Spectrum Settings and Winter Motorized Suitability

Winter recreation is thought to be less impactful to grizzly bears. There are no known studies that have documented or evaluated the impact of winter recreation on denning or hibernating grizzly bears directly. Instead, researchers and managers have speculated that motorized winter recreation could disturb hibernating grizzly bears and modeled the potential overlap of potential denning areas and snowmobile use as a way to estimate and minimize potential impacts, for example as in Podruzny et al. (2002).

Winter motorized recreation includes snowmobile use, 4-wheelers with winter tracks, snow bikes, and any other motorized vehicles designed for use over-snow. The primary concern for effects would be if recreational activities cause disturbance or abandonment of dens and especially, females with cubs. The other concern would be if recreationalists encounter a female grizzly bear emerging from her den with cubs while recreating leading to conflict. If winter motorized uses are authorized, they could have increased probability that grizzly bears are disturbed in their dens and increase the probability that emerging females could encounter winter recreationalist. However, this type of disturbance is a non-issue without current occupancy and will likely be an uncommon event once occupied based on the infrequent or rarely documented den disturbance in other recovery zones.

Linnell (2000) documented both den abandonment and tolerance of disturbance in brown bears (grizzly bears), and that bears appear to be undisturbed by most activities that occur at distances greater than 1 km. Activity closer than 1 km and especially within 200 m has variable results, with some bears tolerating activity right up to the den.

The revised forest plan would not open areas to winter motorized vehicles; instead, it identifies areas suitable for winter motorized recreation, which could be opened after site specific analysis. Authorization of winter motorized uses would be determined in a future travel management decision under the guidance of the Nez Perce-Clearwater. These types of decisions identify areas open for motorized winter recreation. They may include decisions on specific winter motorized routes, parking lots, and whether routes are groomed as well. Most likely, areas suitable for motorized winter recreation would be opened for motorized winter recreation in the future.

Areas suitable for winter motorized uses are established in the Land Management Plan through Winter Recreation Opportunity Spectrum Settings and Suitability plan components. These decisions dictate not only whether the activity is suitable, but also guides the management of the land to provide a specific recreational experience that is influenced by the level of development. Motorized winter recreation would be suitable in Semi-Primitive motorized, Roaded Natural and Rural settings, while it would be unsuitable in primitive and semi-primitive non-motorized settings The acres of secure habitat within the different winter recreation opportunity spectrum settings by alternative are shown in Table 283.

Table 283. Acres of secure habitat in winter ROS setting by alternative

Secure Habitat in Winter ROS settings	AltP	AltW	AltX	AltY	AltZ
P	1,124,066	1,124,066	1,124,066	1,124,066	1,124,066
R	333	124	124	124	124
RN	31,472	31,983	41,199	39,005	41,199
SPM	923,681	585,308	1,258,382	984,412	1,258,373
SPNM	383,528	721,599	39,309	315,473	39,317

Motorized winter recreation is not suitable within recommended wilderness and designated wilderness in any alternative and would not be allowed under the plan. Therefore, the majority of the Bitterroot Recovery Zone is not suitable for motorized winter recreation and would not be allowed under the plan. Recommended wilderness areas would provide additional areas without winter motorized uses to contribute to connectivity into the Recovery Zone because recommended wilderness areas are outside the recovery zone. Recommended wilderness would provide areas without this activity for dispersing bears and would maintain ecological conditions for a grizzly bear population.

The number of people participating in winter recreation in the plan area is likely to increase in the future as the population in surrounding communities grows, and as more people obtain motorized winter recreation equipment. Most winter motorized recreation is from snowmobiles, but snow bikes and off-highway vehicles (OHVs) equipped with snow tracks are also used. The advent of motorized snow bikes has improved motorized winter recreation technology that could potentially increase the area of use. Snow bikes are narrow, light, and much easier to turn, which lets users go where snowmobiles simply cannot, cutting through dense trees. While more of the Nez Perce-Clearwater will be suitable for winter use under the Preferred Alternative, any new winter motorized recreation will only be authorized after a site specific National Environmental Policy Act analysis and Endangered Species Act consultation. Even where winter uses are authorized, winter recreation would not be distributed evenly on the landscape. There tends to be more use where there are roads for access and groomed trails. Also use would be higher where there is rolling or flatter terrain.

The plan contains FW-STD-WL-01 which requires that the Northern Rockies Lynx Management Direction (NRLMD) would be followed. The NRLMD includes Forest Plan Guideline HU G11 which directs that over-the-snow routes or designated play areas should not expand outside baseline areas of consistent snow compaction. The NRLMD is required to be followed in areas considered to be occupied by lynx which currently includes the Clearwater National Forest. This direction would help prevent new winter motorized uses in lynx habitat within many of the larger secure habitats of the Clearwater National Forest. The Record of Decision for the NRLMD states that "When National Forests are designing management actions in unoccupied mapped lynx habitat they should consider the lynx direction, especially the direction regarding linkage habitat." Because the Nez Perce National Forest is currently considered unoccupied by lynx, the national forest would need to consider the direction in the NRLMD.

This direction would help address impacts from winter motorized recreation to grizzly bear denning habitat.

The Clearwater Travel Plan (U.S. Department of Agriculture 2011e, U.S. Department of Agriculture 2017f) considered and abided by Guideline HU G11, which states over-snow routes should not expand outside baseline areas of consistent snow compaction. The Clearwater National Forest Travel Plan identified 115 miles of baseline motorized snow routes and authorized no expansions in over-snow routes. The Nez Perce National Forest has not yet undergone winter travel planning and is currently open to all winter motorized activities except in areas closed to winter motorized uses.

Some evidence suggests that there may be spatial separation between where winter recreationists choose to recreate and where denning grizzly bears tend to select for dens. Grizzly bears tend to den in areas at high elevations, on steeper slopes, under tree canopy, and relatively far from developed areas or human activity (Linnell et al. 2000, Craighead and Craighead 1972). They avoided valley bottoms, exposed ridge tops and high peaks (Linnell et al. 2000). Linnell (2000) reported that grizzly bear winter dens tend to be located on steep terrain of between 30 and 50 degrees, at higher elevations and under tree canopy. Olson et al. (2017) studied factors selected by GPS-equipped winter recreational users. Snowmobilers riding off trail selected areas for ease of access, reflected in proximity to highways and densities of open forest roads, with lower canopy cover, and smoother, less steep terrain (Olson et al. 2017). On-trail snowmobilers selected for greater forest road density, moderate annual precipitation, and lower terrain variability, and moderate levels of snow, shallow slopes, and higher elevation (Olson et al. 2017). Slopes used averaged between 14.7 and 16.28 degrees for motorized winter users, and canopy cover was between 33.88 to 37.88 percent (Olson et al. 2017). Therefore, winter recreators are less likely to use the same areas as grizzly bear dens because of the avoidance by snowmobilers of steep slopes and tree cover. While overlap of motorized winter recreation and potential grizzly bear den sites undoubtably occurs, the tendencies of both grizzly bears and winter recreational users might provide some partitioning of areas used that reduces overlap.

Snowmobile selection potential was modeled by Lucretia Olson within the Nez Perce-Clearwater National Forest and is shown in Figure 89. This figure estimates where snowmobilers are likely to prefer based on terrain, slope, vegetation, and other factors. It does not reflect where winter recreation is open for use nor where it is actually occurring. The model was created based on parameters obtained from user data from Colorado and applied to Idaho landscapes and standardized to Idaho conditions. Once developed, it was validated by data from user groups from Idaho and Montana. Additional validation was verified by recreation specialists who work on the Nez Perce-Clearwater National Forest and are familiar with known use patterns.

Olson et al. (2017) modeled terrain selection of motorized and non-motorized winter recreationists, including snowmobile, backcountry ski, and snowmobile-assisted hybrid ski. They used GPS systems carried by winter recreationists to determine use selection of remotely sensed environmental characteristics, including topography, vegetation, climate, and road access. Model results indicated that motorized and non-motorized activities select different environmental characteristics. Both motorized and non-motorized winter recreationists selected for ease of access, reflected in proximity to highways, and densities of open forest roads. Areas predicted to have only motorized recreation were more likely to occur further from highways, with greater forest road densities, lower canopy cover, and smoother, less steep terrain, while areas with only non-motorized recreation were closer to highways, with lower forest road densities, more canopy cover and steeper terrain. Snowmobiles using trails selected areas that had greater forest road density, moderate annual precipitation, and lower terrain variability. Off-trail snowmobiles users selected moderate levels of snow, shallow slopes, and higher elevation.

A stronger response to vegetation covariates at a small scale suggests that recreationists select areas in which to recreate at a hierarchical scale, with road access and large topographic features dictating an initial area selection, and finer scale features such as forest density determining where to move within this area. The greater influence of vegetation at a small spatial scale may be related to the differences in movement speed and maneuverability of the different recreation types, since non-motorized recreationists may be better able to safely move through dense trees, while motorized recreationists may select open areas for play and fast travel.

Grizzly bears, in contrast, are known to select steeper slopes with some canopy cover. Linnell (2000) reported that mean slopes of brown bear (grizzly bears) dens were between 30–50-degree slopes (57.73 to 119 percent slope). Mace and Waller (1997) reported that grizzly bear dens averaged 63 percent slope and that grizzly bears denned in open timbered, timbered, and open habitats. According to Olson (2017) the average slope for motorized winter recreational use was about 9 degrees, which is much less steep than grizzly bear den preferences reported by Linnell (2000), and Mace and Waller (1997). While the average is 9-degree slopes, some winter motorized recreationalists seek out steeper areas for hill climbing and high marking, so some overlap occurs.

Generally, bears select dens 1 to 2 km from human activity (roads, habitation, industrial activity) and seemed to tolerate most activities that occurred more than 1 km from the den (Linnell et al. 2000). Olson (2017) in contrast reported that winter motorized users tended to select areas with higher road densities and more access.

Average percent canopy cover reported by Olson (2017) for motorized winter recreational users was about 28 percent. Mace and Waller (1997) classified open canopy cover as less than 40 percent canopy cover, open timbered between 41 and 60 percent canopy cover, and timbered when greater than 60 percent. They found that 40 percent of grizzly bears denned in open, 43 percent denned in open-timbered habitat, and 17 percent denned in timbered habitat. This means that those in open timbered habitats have higher canopy cover than the average amount of canopy cover used by motorized recreationalists, but some grizzly bears use areas with canopy characteristics similar to those preferred by winter motorized users. Based on the preferences, there appears to be some separation in use of space between motorized winter recreationalists and where grizzly bears prefer to den. The differences mostly appear to be in their preferences for slopes wherein there is little overlap in where winter motorized users select and where grizzly bears select. Vegetation characteristics may also prevent some use of motorized winter recreation in areas where grizzly bears den. However, winter recreation is also widespread and overlap of uses probably will occur within potential denning areas once grizzly bears become established. Keep in mind that the Bitterroot Recovery Zone is not suitable for motorized winter recreation and thus it would not be allowed there under the Preferred Alternative. Therefore, the effects from motorized winter recreation are limited to areas outside of the recovery zone.

Concern has been raised that disturbance from winter recreation, and especially motorized over-snow recreation, could potentially adversely affect grizzly bears shortly before or after den emergence of a female with cubs. Females and their cubs remain in the den site area for several weeks after emergence from dens (Mace and Waller 1997). Females with cubs have high energetic needs, and cubs have limited mobility for several weeks after leaving the den. Disturbance levels that cause a female to prematurely leave the den in spring or move from the den area could impair the fitness of the female and safety of the cubs. If cubs attempt to follow their mother, they will likely experience decreased fitness and the family group may be pushed to less suitable habitat. Late season snowmobile use is not restricted under the plan, and extended winter motorized use seasons (after April 1) could occur.

While a conflict like this is possible, it is a low likelihood event for the following reasons. Winter recreation drops off sharply as the snow melts. Winter trail grooming on the Nez Perce-Clearwater begins on around December 1st and ends March 31st and use drops off sharply after grooming ends. Bears in contrast emerge from their dens typically in April in Idaho and Western Montana (Linnell et al. 2000). Females with cubs of the year are the last to leave den sites and some may remain in the vicinity of the den until the snow has disappeared (Linnell et al. 2000, Craighead and Craighead 1972). Snow melts unevenly in spring, leaving patches of snow in some areas while it melts in other areas. People are reluctant to navigate those conditions with motorized over-snow vehicles because they are reluctant to drive across dirt and mud trying to access the next snow patch. While snow melts later in the season at higher elevations, there are often challenges for people accessing those areas because of muddy roads, snow drifts, downed trees across roads, and other seasonal hazards that tend to keep people out of high elevation areas in spring. There are no known grizzly bear denning sites within the action area. To date, litter abandonment by grizzlies due to snowmobiling activity has not been documented in the lower 48 states (Hegg et al. 2010).

The 1987 Forest Plans did not use Winter Recreation Opportunity Spectrum settings to identify whether or where motorized uses are suitable. Instead, Winter Recreation Opportunity Spectrum settings under the existing 1987 Forest Plans were a way to guide management of the land to provide a variety of recreational experiences. Therefore, Winter Recreation Opportunity Spectrum Settings in the existing condition do not reflect suitability of winter motorized uses in the 1987 plans. Prior to the Clearwater Travel Plan, winter motorized uses were allowed across the whole forest unless closed by site specific decisions such as in those that closed designated wilderness areas or other site-specific closures. The Clearwater Travel plan closed winter motorized uses in recommended wilderness but allowed it everywhere outside of recommended wilderness. The existing condition is that motorized winter recreation is currently allowed in most of the Nez Perce-Clearwater where it is not specifically closed, and use is currently occurring in many areas, especially those proximate to the groomed winter recreation features. In contrast, the Revised Forest Plan under the Preferred Alternative does use the Winter Recreation Opportunity Spectrum settings to establish motorized suitability, so it is different than how it was used in the 1987 plans. The alternatives vary the most in which areas are semi-primitive non-motorized versus semi-primitive motorized. The winter recreation opportunity spectrum also identifies the settings under which winter recreation facilities and recreation sites are managed. Alternative W has the least percent of the area suitable for winter motorized uses, while alternatives X and Z have the most area suitable for winter motorized uses with 70 percent of the Nez Perce-Clearwater. For grizzly bear conservation, Alternative W would be best as it would represent the most area not suitable for motorized winter recreation. The Preferred Alternative identifies 60 percent as suitable while 40 percent would be unsuitable for winter motorized uses. Winter motorized recreation under the Preferred Alternative should generally be of low impacts to grizzly bear denning overall. A map of the winter recreation opportunity spectrum for the Preferred Alternative is shown in Figure 109.

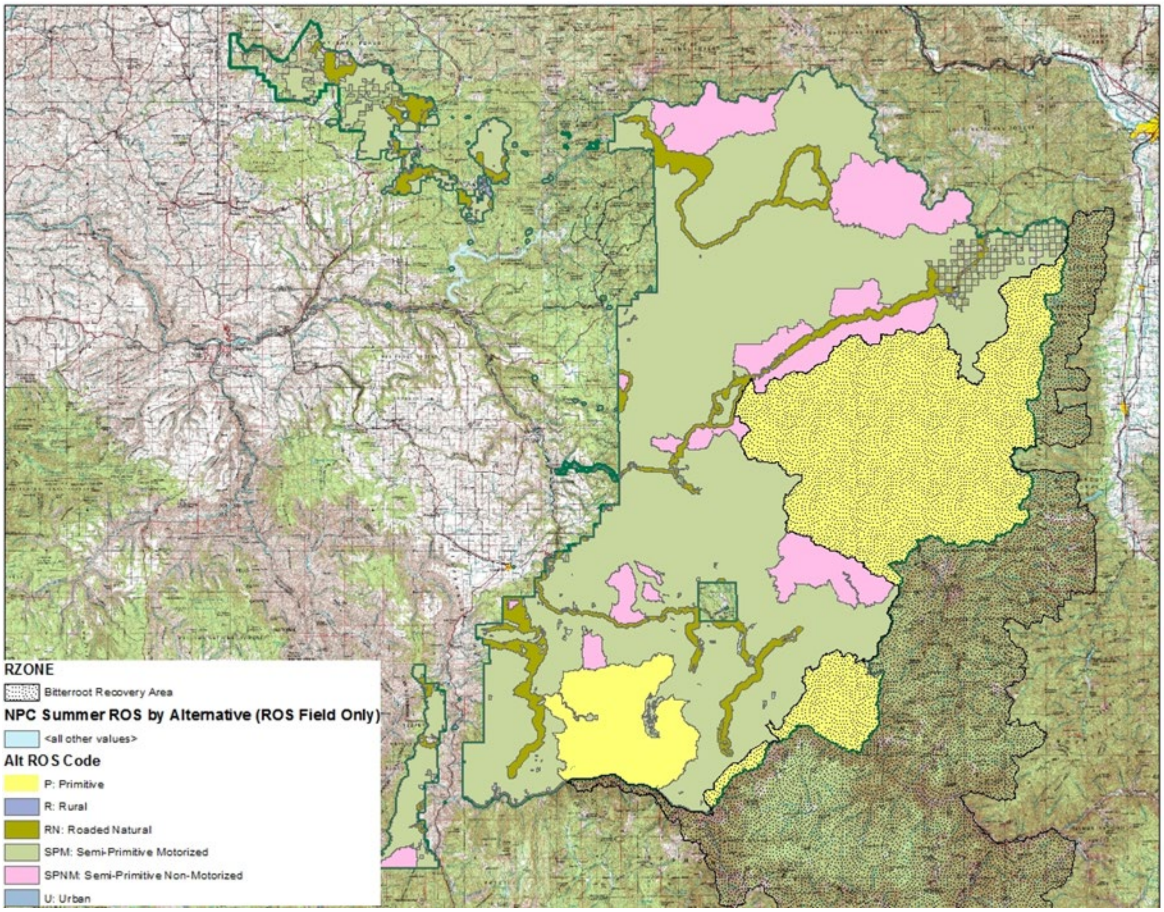

Figure 109. The winter recreation opportunity spectrum settings in relation to the Bitterroot Recovery Zone. Primitive and Semi-Primitive Non-motorized are the Non-motorized settings. Motorized settings include the Urban, Rural, Roaded Natural and Semi-Primitive motorized

Aircraft Use

The Revised Forest Plan will not make any decisions to authorize, nor close aircraft use and does not make decisions to authorize nor close backcountry airstrips. Also, it will not change ongoing aircraft use. Instead, under the Preferred Alternative the Revised Forest Plan will provide plan components to guide future authorization of aircraft and helicopter use. Decisions on the establishment, maintenance, reauthorization or closing of backcountry airstrips would require site specific environmental analysis and Endangered Species Act consultation.

Airplane and helicopters operated by the public and administratively may land at the backcountry airstrips as an ongoing activity. The public typically does not land aircraft anywhere in the Nez Perce-Clearwater outside of these airstrips unless they receive authorization through a permit. The use of backcountry airstrips could have some displacement effects and brings some people into backcountry areas within the Recovery Zone.

The land allocations under the revised Forest Plan influence where aircraft use may occur. Aircraft use within wilderness includes emergency situations or when the agency has undertaken a minimum requirements analysis, National Environmental Policy Act and Endangered Species Act consultation to authorize such use in wilderness areas. State or federal agencies sometimes request authorization to use aircraft in wilderness for research or wildlife management purposes. These also require a minimum requirements analysis and authorization.

The plan identifies aircraft use within Recommended wilderness as suitable and thus allowed for administrative uses, but recreational uses are not suitable and would not be allowed. Administrative uses related to management responsibilities, including by other federal and state agencies in coordination with the Nez Perce-Clearwater and includes research, monitoring, aircraft landing including unmanned aircraft would be suitable in recommended wilderness. Emergency aircraft use and administrative aircraft use is not expected to be recurrent and will occur as dispersed and infrequent disturbances.

Outside of wilderness and recommended wilderness, there are no restrictions on administrative or emergency use of aircraft in the plan. The Forest Service may authorize such uses in response to emergencies or for administrative purposes without environmental analysis or consultation. Aircraft use by other state and federal agencies also can occur after authorization and coordination with the Forest Service.

Aircraft uses may also be authorize for operators or the public. For example, authorizations have occurred for aerial timber harvest, commercial uses, or for any other uses requiring aircraft. Generally speaking, helicopter logging does not pose the same long-term displacement effects and increased mortality risk to grizzly bears as roads do. Helicopter logging is transitory and does not bring additional human use into grizzly bear habitat, whereas roads are generally longer term or permanent features on the landscape and facilitate human access into grizzly bear habitat. Helicopter logging may, however, result in short-term adverse impacts to grizzly bear core habitat because the ability of the area to function as grizzly bear core habitat is compromised, and grizzly bears are likely to be displaced from the area during the time the helicopter logging operations are on-going. Thus, while helicopter logging within grizzly bear secure habitat may not necessarily result in a long-term loss of secure habitat (unlike road construction within grizzly bear secure habitat), the potential temporary adverse displacement effects to grizzly bears associated with helicopter logging within grizzly bear core habitat must be considered. Under the Preferred Alternative, helicopter or aerial logging systems are anticipated to continue to be used within Management Area 3 and within Management Area 2, especially when resource concerns, such as impacts to soils, aquatic resources or wildlife are accounted for in projects. Aerial logging projects are evaluated on a case-by-case basis when analyzing projects and must undergo site specific analysis and Endangered Species Act clearances.

The revised Forest Plan has only a few plan components that guide air travel or helicopter use. Desired condition FW-DC-INF-04 says:

"Airstrips serve the Nez Perce-Clearwater land management and public recreation opportunities. The seven existing public backcountry airstrips for airplane and helicopter access to the Nez Perce-Clearwater's backcountry maintain historical site conditions to provide safe and functioning airstrips for backcountry access."

Desired condition FW-DC-REC-15 states:

"The seven existing public backcountry airstrips provide users the unique opportunities to quickly access vast and remote backcountry and wilderness areas for recreational activities."

These desired conditions would direct management to maintain recreational use of backcountry airstrips and ensure they are maintained for public safety. The backcountry airstrips are expected to continue to receive recurrent use by the public and by the Forest Service. These actions could displace grizzly bears within areas near the three backcountry airstrips within the Bitterroot Recovery Zone once occupied. It could also displace bears from around the four airstrips outside the recovery zone. These effects would be localized around the airstrips. Once bears move into the recovery zone, the airstrips could increase the probability of human bear conflicts.

Administrative or emergency aircraft uses are infrequent and may result in disturbance but not lasting or recurrent effects. Perhaps the most impactful uses are those authorized through special uses permits to the public or operators who then use them for recurrent uses. These can result in longer lasting and repeated disturbances that can displace grizzly bears from important resources. Outside of these effects, aircraft use is expected to be localized, infrequent, and of little consequences to grizzly bears.

Domestic Livestock Grazing

Grazing of domestic livestock is another factor that can affect grizzly bears, in that grizzly bears are known to occasionally depredate on domestic grazing animals such as cattle or sheep. Such conflicts between grizzly bears and domestic livestock can result in the capture, relocation, injury, or removal of grizzly bears. Grizzlies prey more readily upon sheep than cattle, but cattle may compete with grizzlies for forage in key habitats such as riparian sites. The plan only varies whether the only sheep allotment in the plan area is suitable for sheep grazing and varies to consider effects of exposure of bighorn sheep to pathogens from domestic sheep. This allotment would be evaluated for decisions after site specific analysis.

Livestock allotments only overlap a little of the Bitterroot Recovery Zone and most allotments are spatially separated from where grizzly bears would most likely disperse through the Nez Perce-Clearwater. The likelihood of grizzly bear depredation would be low until more grizzly bears enter the analysis area and the bear population grows. The Bitterroot Recovery Zone on the Nez Perce-Clearwater is largely ungrazed, save for a very small portion of one cattle allotment that overlaps about 380 acres of the Recovery Zone near the Big Mallard Creek trailhead. That allotment is currently vacated and is not currently grazed though it is not closed and could again be grazed in the future. Most future potential conflicts, if they occurred, would be outside of the Bitterroot Recovery Zone. The current distribution of allotments maintains the ecological conditions to provide for grizzly bear recovery because most areas where grizzly bears would be expected to occur are separated in space from grazing allotments. For reference and distribution of the allotments (Figure 100).

Grazing is a suitable use on most of the Nez Perce-Clearwater under the Preferred Alternative. Any authorization or reauthorization of grazing allotments would require a site-specific analysis and decision before approval. Livestock grazing is suitable in most of the national forest under the Preferred Alternative. It is conditionally suitable within designated and suitable wild and scenic rivers. Generally, grazing is subject to the wild and scenic river plan and must protect outstandingly remarkable values. Suitability within wilderness areas depends upon the enabling legislation for each wilderness. For the Selway-Bitterroot and Frank Church Wilderness Areas, enabling legislation essentially allows grazing of livestock established prior to the date established and shall be allowed to continue with reasonable regulations. The Wilderness Act and the Central Idaho Wilderness Act does not allow livestock grazing after the dates these wilderness areas were established.

FW-DC-GRZ-01 is a desire to allow range resources to be available for use. Plan direction in the livestock grazing section would potentially have minor environmental consequences for grizzly bear habitat conditions because it could alter vegetation that provides habitat. Desired conditions FW-DC-GRZ-01 outline the desire for grazing to provide for ecosystem services including on transitory forage created after disturbances. Guidelines in the grazing section would ensure that grazing resources are used sustainably because guideline FW-GDL-GRZ-03 specifies that utilization would be limited to between 35 and 55 percent utilization, which is considered moderate grazing. These plan components would help reduce or minimize impacts to vegetation. The range management section of the plan has no specific plan direction related to grizzly bears. Additionally plan components for grazing found in Livestock Grazing (Aquatics and Riparian) would help prevent habitat changes from grazing within riparian areas which should help maintain these habitats for grizzly bear use. Comparatively speaking, the plan direction in the 1987 plans for range management are similar to plan direction in the Preferred Alternative. In the event, that grizzly bears begin residing within the plan area, measures could be taken to minimize potential conflict.

Food Storage and Attractants

The revised Forest Plan does not have direction for management of attractants. The plan area also does not have a food storage order in place; however, food storage orders can be implemented with a forest order outside of the Forest Plan. Instead, it has a desired condition to educate the public about bear safety and food storage, and a desired condition to equip campgrounds with food storage infrastructure in FW-DC-WL-07 and FW-DC-WL-08. These plan components state:

> **FW-DC-WL-07.** The risk of grizzly bear-human conflict is reduced through awareness. The public, Forest Service employees, contractors, volunteers, and permittees are knowledgeable of conflict prevention strategies through education and interpretation.
>
> **FW-DC-WL-08.** Within occupied grizzly bear habitat, developed recreation sites, administrative sites, and dispersed recreation sites where garbage disposal services are provided, facilities are equipped with necessary infrastructure so that food, garbage, and other attractants can be made inaccessible to grizzly bears to reduce the potential of human-bear conflict.

The potential increase of developed and dispersed recreation sites as outlined below could create conditions where conflicts with humans are more probable. See the section below on developed and dispersed sites. In the event, that grizzly bears begin residing within the plan area, measures could be taken to implement a food storage order though a special forest order in coordination with the Bitterroot Interagency Subcommittee.

The plan's Management Strategy and Approaches outlines agency intent related to grizzly bear conservation. They includes the following:

> Interagency Grizzly Bear Committee recommendations for sanitation plans, infrastructure and reducing attractants may be implemented within and outside recovery areas to reduce grizzly bear-human conflict.

This management approach would suggest that the Nez Perce-Clearwater would implement the Interagency Grizzly Bear Committee recommendations for reducing attractants. For more information see the potential management approaches section below.

Consequences of Developed and Dispersed Recreation sites

Since adoption of the forest plans, recreation activities across the Nez Perce-Clearwater have changed and will continue to change. This analysis assumes that changes to recreational use patterns would occur naturally as a result of factors associated with recreation trends, advances in technology, aging population, aging infrastructure, local population increase and decreases, and climatic changes. Recreation trends and use patterns would continue to influence the demand for development, amount, and distribution of developed and dispersed recreation across the Nez Perce-Clearwater. Recreational use is expected to increase in the analysis area over time. Demand for developed and dispersed sites may increase as a result of changing demographics of Nez Perce-Clearwater visitors. Currently, developed campground capacity maxes out during summer weekend peak time periods. The existing 55 developed campgrounds would likely continue to be at or near capacity during the busiest weekends. Use of dispersed recreation overnight sites may increase as these developed sites reach or exceed capacity. The effects from the action alternatives are expected to be similar to those of the No Action Alternative, with a few exceptions based on recreation opportunity spectrum differences by alternative.

The Forest Plan does not authorize any new recreational developments or dispersed sites. Instead, it sets the context under which decisions on future recreation sites and upgrades to existing sites would be developed under the plan. The mechanism to set those contexts in the plan is the Recreation Opportunity Spectrum settings analyzed above. Recall that the recreation opportunity spectrum classes differ in their level of development in addition to whether motorized uses are suitable (table 275). Therefore, it also determines the amount, and types of suitable recreation sites.

Demand for dispersed sites may increase or decrease parallel to the amount of motorized access. As recreation use in general increases, there is likely to be additional demand for dispersed sites. With an increase in motorized access would come an increased number of dispersed sites. These would likely be concentrated along currently open roads and trails, as this use would be less accessible elsewhere in the non-motorized areas. Most of the recreation use on the Nez Perce-Clearwater occurs in dispersed sites rather than developed facilities. Dispersed recreation sites are typically concentrated in the Nez Perce-Clearwater's roaded natural recreation opportunity spectrum settings. There are a total of 1,241 dispersed overnight sites known on the Nez Perce-Clearwater. These features are within the road buffer area and do not reduce secure core area. Demand for dispersed sites may increase or decrease parallel to the amount of motorized access by alternative. As recreation use in general increases, there is likely to be additional demand for dispersed sites. With additional recreation opportunity spectrum motorized settings, such as in Alternatives W and X, some of this demand may be in areas in current non-motorized settings under the No Action Alternative. In Alternatives Y and Z, where less of the Nez Perce-Clearwater is suitable for motorized use, an increased number of dispersed sites would likely be concentrated along currently open roads and trails, as this use would be less accessible elsewhere in the non-motorized areas.

Increasing dispersed and developed sites could cause an increase in the probability of a bear and human conflict. These could be mitigated or reduced through measures to educate the public about bear safety as directed in plan component FW-DC-WL-07 for grizzly bears. Ongoing actions that seek to educate the public include education about the use of bear spray, bear education efforts at events in local communities, information distributed at ranger stations, and signs at recreation facilities. Education materials would probably be more available within developed sites than dispersed sites. Human-bear conflicts could also be minimized through proper storage of attractants. While the plan does not have any direction requiring storage of food or attractants, the intent is that the Nez Perce-Clearwater would initiate efforts to implement food storage orders in the future through a Forest Order as bears become established.

An increase in formerly primitive settings or semi-primitive non-motorized settings would place more people into proximity with secure habitat that potentially has a higher potential for grizzly bear presence. Roadside dispersed sites are more likely in semi-primitive motorized settings and are less likely to have bear food storage infrastructure which could increase the chance of bear-human conflict. Dispersed sites are often established by users in suitable spots, so the Forest Service has less discretion in how they are established. Until a food storage order is in place, grizzly bears in the plan area might be attracted to these sites and have increased probabilities of bear-human conflicts resulting in grizzly bear removal or death. The plan has no components that restrict construction or improvement of development of developed or dispersed sites. The plan contains a desired condition FW-DC-WL-06 to provide the ecological conditions to allow for colonization of and connectivity to the Bitterroot Recovery Zone. This would direct management to maintain areas important to grizzly bear dispersal to maintain these conditions. FW-DC-WL-06 states:

> **FW-DC-WL-06:** The grizzly bear Bitterroot Recovery Zone provides the ecological conditions to support recolonization of grizzly bears. Land Management Plan land use allocations provide connectivity to allow secure passage from occupied habitat to the Bitterroot Recovery Zone.

Roads, motorized trails, non-motorized trails, rivers, and airstrips are present on the Nez Perce-Clearwater for visitors to walk, bike, boat, ride, drive, or fly to their destination. There are about 5,300 miles of system trails on the Nez Perce-Clearwater documented in the national infrastructure database, which is the official database for the Forest Service. There are about 1,300 miles of trails located inside designated wilderness areas. These trail numbers include both motorized and non-motorized trails. The use of hiking trails is expected to increase through time as demographics change. The trails system extends throughout the Nez Perce-Clearwater to provide a variety of experiences for the public. Mountain bikes generally can travel any trail on the Nez Perce-Clearwater outside of designated wilderness and recommended wilderness areas and often use a combination of all maintenance level roads and trails to connect desirable areas to ride. In more developed settings, mountain bikers look for roads that access single-track trails in which they can ride mostly downhill. Mountain biking is restricted in designated wilderness and in most alternatives of recommended wilderness. Mountain biking is generally suitable in all other areas. Recreational use of trails in areas where grizzly bears occur would have the potential for bear human conflicts and potentially bear removal or loss as bears become established. There is no specific direction for trail management related to grizzly bears in the plan. No areas would be precluded from new trail construction or reconstruction as a result of the revised Forest Plan. Plan components provide for increasing connectivity of communities to one another and for increased efficiency of moving people along trails from one location to another.

Motorized trail use is expected to increase as the population grows. Demand for motorized vehicle access and trails is predicted to increase as technology advances. The number of motorized trails is expected to increase some under the plan. New motorized trails would impact or reduce secure habitat. The plan does not authorize, fund, or carry out any new motorized roads or trails. Instead, it sets the conditions under which these features could be authorized in the future. New motorized trail or roads would be authorized or identified during a travel planning project that would require further consultation with the U.S. Fish and Wildlife Service. The plan has few constraints on motorized road or trail building within Management Area 3.

Within Management Area 2, motorized trails would be constrained to be required to leave areas of 5,000 acres or larger without motorized access. This would limit motorized trails to leave secure habitats at least 5,000 acres or larger and would limit the total amount of these features allowed within Management Area 2. Furthermore, some areas were identified within Management Area 2 to be in either semi-primitive non-motorized or primitive recreation opportunity settings where motorized trails would not be suitable. New motorized trails would not be suitable within Recommended nor Designated Wilderness Areas and would not be allowed. Motorized suitability was analyzed in the in the Recreation Opportunity Spectrum section above. Motorized trails were included in the delineation of secure habitat. The miles of various trails, including motorized trails, are shown in table 284 and are the existing condition. Summer motorized trails were accounted for in the calculation of secure habitats. Some existing hiking, pack trails, and bike trails travel through secure habitats. Grizzly bears can be displaced from areas with human foot or bike travel and may react aggressively if surprised by hikers or biking. The Forest Service classifies electric bikes as motorized vehicles, and they must remain on motorized trails or roads and are not allowed on non-motorized trails. The Preferred Alternative does not authorize any new motorized or foot trails. New trails would require site specific National Environmental Policy Act analysis and Endangered Species Act consultation prior to authorization and must comply with the Forest Plan.

Table 284. Miles of trail by designed use managed by Nez Perce-Clearwater ranger districts[1]

District	Hiking Trail	Pack Trail[2]	Bike Trail	Winter Non-Motorized Trail[3]	Winter Motorized Trail	Motorcycle Trail	<50-inch Motorized Trail[4]	>50-inch Motorized Trail[5]	Total
Salmon River	1	454	0	6	88	62	111	0	722
Red River	5	590	0	2	316	20	83	0	1016
Moose Creek	1	739	0	0	24	19	4	0	787
Palouse	1	51	15	20	0	16	172	0	275
NorthFork	3	611	0	14	272	0	426	61	1387
Lochsa-Powell	4	766	0	8	114	4	222	2	1120
Total	**15**	**3211**	**15**	**50**	**814**	**121**	**1018**	**63**	**5307**

1 - Designed use is the use for which the trail was designed, although other uses maybe allowed; for example, a trail designed for pack use may also be used by hikers

2 - Pack type trails are designed for pack and saddle users

3 - Non-motorized winter use includes both Nordic skiing and snowshoeing trails

4 - Motorized vehicles less than 50 inches wide. The Forest Service classifies e-bikes as motor vehicles

5 - Motorized vehicles greater than 50 inches wide

The Nez Perce-Clearwater has approximately 212 recreation facilities serving a variety of different recreational opportunities (Table 285). Most of the recreation facilities on the Nez Perce-Clearwater were developed in the 1960s when highway development expanded access to more of the forest and especially too many of the waterways where facilities are concentrated.

Table 285. Number of recreation facilities by site type[1]

Type	Total Number of Facilities	Of the Total, Facilities that charge Fees	Of the Total, Sites that require a Reservation to Use
Campground (developed)	55	29	6
Camping Area (dispersed)	53	0	0
Group Campground	3	0	1
Visitor Centers	3	0	0
Picnic Day Use Site	12	0	1
Pavilion	3	0	2
Cabin/Lookout	16	11	12
Boat Launch	3	0	0
River Access/Boating Site	5	31	0
Trailheads	40	0	0
Interpretive Sites	12	0	0
Fishing Sites	3	0	0
Snow Park/ Snow Play	4	0	0

Type	Total Number of Facilities	Of the Total, Facilities that charge Fees	Of the Total, Sites that require a Reservation to Use
Total	212	43	22

1 - Fee at boating site is for floating permit on main Salmon River.
Data Source: INFRA

Recreation special use permits are issued to private businesses, individuals, institutions, and nonprofit groups to provide for occupancy and use of the national forest beyond what is normally available to the public. Permitted recreation uses provide specific recreational opportunities to the public and deliver economic benefits to rural economics. Examples of commercial enterprises requiring permits include outfitting and guiding services, resorts, recreation events, and organizational camps. Noncommercial recreation uses are those where the use or activity does not include an entry or participation fee and the purpose is not primarily the sale of a good or service. Examples of noncommercial use include family reunions, weddings, or other similar group gatherings. The Forest Service issues these permits under the authority of a variety of specific laws. About 60 recreational use permits are issued in any given year across the Nez Perce-Clearwater. Recreation use patterns and emerging technologies would continue to influence the need for recreation special use permits across the Nez Perce-Clearwater. The plan has no specific direction for issuing these permits in regard to grizzly bears. However, these permits can provide requirements in special use permits without being required in the Forest Plan. Special use permits often include conditions or measures to protect natural resources and the permittees. A number of measures for grizzly bears could be considered and include as a condition of use for both grizzly bears and human safety based on factors such as the permit duration, location, action, and grizzly bear activity in the area among other factors. Conditions or measures could include food storage requirements, timing restrictions, carcass disposal, prohibitions on firearms and other measures.

FW-DC-REC-04 would direct the management of any new or existing infrastructure to be consistent with the desired recreation opportunity spectrum setting. Timber production, timber harvest, permanent road construction, temporary road construction, construction of new buildings or structures, over-snow vehicle use, and mechanized and motorized travel would be suitable in semi-primitive motorized, roaded natural, and rural recreation opportunity spectrum classes.

FW-DC-REC-10 states: “The Forest’s trail system provides an array of trail classes for a variety of designed uses. Trail systems connect local communities through the Nez Perce-Clearwater, facilitating long-distance travel, as well as loop opportunities to accommodate short-term, day use activities.” This direction would potentially facilitate additional motorized trails and loops, mechanized access, and pedestrian trails potentially where bears may be present or traveling through. Trails, roads, and facilities would be constructed only after site-specific analysis and further consultation with the U. S. Fish and Wildlife Service. These activities would be suitable within about 55 percent of the national forest under the Preferred Alternative, including some areas that currently have high amounts of secure habitat. While these activities may be suitable, and are reasonably likely to occur, the exact location, amount and where is unknown at this time. Non-motorized or foot and horse trails would be suitable across the whole forest under the plan. Mechanized trails, such as bicycle trails, are not suitable within designated wilderness nor recommended wilderness and would not be allowed there but are otherwise a suitable use across the rest of the national forest. The suitability of motorized trails was analyzed above in the effects of motorized suitability and summer recreation opportunity spectrum section and below in the section titled how the plan addresses motorized access.

Similarly, activities found not suitable would be prohibited, such as roads and motorized trails, and recreation facilities would be managed in a more primitive condition consistent with definitions such as those of the primitive and semi-primitive non-motorized settings and would serve to protect bear habitat. Timber production, permanent road construction, temporary road construction, building permanent structures, over-snow vehicle use, and motorize travel are prohibited within primitive and semi-primitive non-motorized recreation opportunity spectrum classes, all of which would help protect grizzly bears. Semi-primitive non-motorized and primitive settings are found on about 45 percent of the Nez Perce-Clearwater under the Preferred Alternative. See the Effects of Motorized Suitability and Summer Recreation Opportunity Spectrum section above for more information on effects of Recreation Opportunity Spectrum settings.

FW-DC-REC-05, FW-DC-REC-10, and FW-DC-REC-12 would direct management to facilitate community connections, which might include motorized routes that connect the Nez Perce-Clearwater to communities and communities to each other. These may result in a reduction in secure habitat and potentially increase the probability of bear-human conflicts. The Grand Exploration Motorized Trail, or GEM Trail, could increase motorized use on some segments of existing roads or trails.

FW-DC-REC-06 could increase use by increasing outfitter and guide activities that bring people into nature. These activities, depending upon where they occur and the terms of special use permits that authorize those activities, could increase the probability of human-bear conflict as bears move in. FW-DC-REC-14 would help ensure that dispersed sites reduce the risks of social and environmental impacts possibly to grizzly bears.

Some plan components would prevent or address effects to grizzly bears. These are included in Table 286 below.

Table 286. Recreation plan components that may be beneficial or prevent effects to grizzly bears

Plan component Name	Type of Plan Component	Description of plan component	Effect of the plan component
FW-DC-REC-04	Desired Condition	Plan component states "The type and level of infrastructure, visitor services, and information are sustainable and consistent with the desired recreation opportunity spectrum settings."	This desired condition would direct management of recreation infrastructure to be consistent with the pertinent recreation opportunity spectrum setting. Broad areas of the Nez Perce-Clearwater would be managed as primitive and semi-primitive non-motorized.
FW-DC-REC-01	Desired Condition	States: "Recreation opportunities are available across a variety of settings that foster quality year-round developed and dispersed experiences, as well as motorized and non-motorized opportunities consistent with the applicable recreation opportunity spectrum (ROS). These settings reflect the integration of other resource values in a sustainable manner with the desired recreation opportunities, facilities, infrastructure, and access provided within those settings. A table of the desired summer recreation opportunity spectrum	This desired condition would direct the amount of development of recreation sites across broad areas of the Nez Perce-Clearwater. Large areas are composed of settings that would be managed for a more remote and rustic recreation experience which would benefit grizzly bears. Other settings may not be as favorable for grizzly bears.

Plan component Name	Type of Plan Component	Description of plan component	Effect of the plan component
		classes is displayed in Table 15 in the Forest Plan and desired winter recreation opportunity spectrum classes in Table 16 of the Forest Plan as well as in maps in Appendix 1.	
FW-DC-REC-13	Desired Condition	States "Dispersed recreation sites are available in desirable locations, are socially and environmentally sustainable, and are consistent with the recreation opportunity spectrum classes and travel management designations."	This desired condition would direct dispersed sites to be consistent with the definitions of the respective summer recreation opportunity spectrum classes. This would serve to maintain many areas in the Nez Perce-Clearwater as a primitive or semi-primitive setting which could help maintain some grizzly bear habitats.
FW-STD-REC-01	Standard	States: "Construction, reconstruction, and maintenance of recreation facilities and trails shall be consistent with the recreation opportunity spectrum classes and specialized plans such as wilderness, recreation corridor, river management, scenic byway, and trail management plans as appropriate."	This would require any new or existing facilities to be consistent and appropriate for the respective area and consistent with the definitions of recreation opportunity spectrum classes.
FW-DC-WL-07	Desired Condition	States: "The risk of grizzly bear-human conflict is reduced through awareness. The public, Forest Service employees, contractors, volunteers, and permittees are knowledgeable of conflict prevention strategies through education and interpretation."	This plan component would direct the Nez Perce-Clearwater to enhance and increase efforts for educating the public of the possibly of bear-human conflicts, the presence of grizzly bears within the plan area and how to stay safe while recreating. This will in turn help prevent bear deaths.
FW-DC-WL-08	Desired Condition	States: "Within occupied grizzly bear habitat, developed recreation sites, administrative sites, and dispersed recreation sites where garbage disposal services are provided, are equipped with necessary infrastructure so that food, garbage, and other attractants can be made inaccessible to grizzly bears to reduce the potential of human-bear conflict.	This plan component would help address attractants at recreation sites to help prevent attracting grizzly bears to recreation sites and prevent conflicts.

Minerals and Energy

Inside the Bitterroot Recovery Zone, mineral rights were withdrawn through wilderness designation, save for any mineral rights at the time in accordance with enabling legislation. The Frank Church-River of No Return, Selway Bitterroot, and Gospel-Hump Wilderness areas are not available for new leases or claims for locatable minerals, mineral materials, or leasable minerals. These withdrawals largely prevent impacts to the Bitterroot Recovery Zone from mineral and energy related activities.

In other areas of the Nez Perce-Clearwater where connectivity is important, mineral activities will be recognized and developed in accordance with existing laws, regulations, and rights of the individuals and companies involved. The laws and regulations largely govern the effects. Plan direction for minerals is within allowed uses under laws and regulations.

There are no plan components that restrict the location of mineral activities except suitability plan components. Mineral activities and their effects on grizzly bears would change very little under the Preferred Alternative. The difference in the influence on mineral, geological, and energy resources are primarily through changes in land allocation and suitability of uses. These would alter the considerations made when approving surface occupancy and developments for mining activities. For example, how mineral activities are approved for surface occupancy and reasonable access managed differ in recommended wilderness compared to Idaho Roadless Rule Areas. However, recommended wilderness areas are not withdrawn from mineral entry and are available for new leases or claims if the social and ecological characteristics that provide a basis for wilderness designation are maintained and protected.

The effects to dispersing bears outside of the Bitterroot Recovery Zone is influenced by how the Idaho Roadless Rule allows mineral activities. The Idaho Roadless Rule does not restrict any authorized mineral activity prior to October 16, 2008. Road construction or reconstruction associated with mining activities within Idaho Roadless Rule areas may only be approved after evaluating other access options. Road construction or reconstruction associated with mining activities within Idaho Roadless Rule areas must be conducted in a manner that minimizes effects on surface resources and must be consistent with land management plan components. Roads constructed or reconstructed within Idaho Roadless Rule areas must be decommissioned upon completion of the project or expiration of the lease, permit, or other authorization.

The Idaho Roadless Rule does not affect mining activities conducted pursuant to the General Mining Law of 1872. The Forest Service will not authorize the sale of common variety mineral materials in Idaho Roadless Areas designated as Wild Land Recreation, Special Areas of Historic or Tribal Significance, or other Primitive themes. The Forest Service may authorize the use or sale of common variety mineral materials and associated road construction or reconstruction to access these mineral materials in Idaho Roadless Areas designated as Backcountry Restoration only if the use of these mineral materials is incidental to an activity otherwise permissible. Overall, mineral activities in roadless rule areas or recommended wilderness areas would have little effect on grizzly bear habitats or connectivity.

The Forest Service may authorize the use or sale of common variety mineral materials and associated road construction or reconstruction to access mineral materials designated as General Forest, Rangeland, and Grassland only if the use of these materials is incidental to an activity otherwise permissible. Currently there are no lands in the planning area designated as General Forest, Rangeland, or Grassland under the Idaho Roadless Rule.

With proper coordination, minerals related activities may be compatible with grizzly bears and their habitat. The effects to grizzly bears include disturbance and displacement from around mining sites. There may be conflicts with bears during operations. Surface occupancy by mining operations will result in a loss of habitat. Energy and minerals management could affect grizzly bears through reductions in secure habitat due to additional road access or through additions of developed sites with associated noise and human presence.

Mineral extraction activities are also managed through suitability plan components. Suitability plan components determine where mineral extraction is suitable based on land allocations. Suitability for mineral-related activities can be found in tables included in the Forest Plan, including all their footnotes.

Activities can be suitable, conditionally suitable, or unsuitable. If an activity is not suitable under the plan in a particular area, the activity would be prohibited within those areas. Similarly, if an activity is conditionally suitable, it can occur only under the circumstances identified in the table footnotes. Suitability for mineral and mining activities addresses some of the threats to grizzly bears because they limit how and where these activities can occur depending upon the area. Areas with restriction include wilderness, designated wild and scenic rivers, and Idaho Roadless Rule Areas, for example.

Mineral activities are divided into three types, locatable minerals, leasable minerals, and mineral activities or saleable minerals. Mineral related activities and their availability are governed by law. Therefore, suitability must be consistent with the laws. Laws like the Wilderness Act, the Idaho Roadless Rule, and the Wild and Scenic River Act, as well as enabling legislation for wilderness and wild and scenic rivers, have withdrawn or modified how and where mineral activities are managed. Suitability differs for the three types of minerals.

Locatable minerals are suitable in most areas of the Nez Perce-Clearwater except wilderness, developed sites, and administrative sites. Locatable minerals are conditionally suitable in recommended wilderness and designated wild and scenic rivers. They are conditionally suitable in recommended wilderness to the extent allowed in the Idaho Roadless Rule Areas and designated wild and scenic rivers under specified conditions on valid mining claims (FSM 2354.42d), depending upon the river management plan.

Leasable minerals are not suitable in the Landmark Historic Corridor, Wilderness, and two Idaho Roadless Rule theme areas including the wildland recreation and primitive and Special Areas of Historic or Tribal Significance theme area. They are also not suitable in riparian management zones, mass movement areas, recreation sites, administrative sites, and research natural areas. They are conditionally suitable within designated and suitable wild and scenic rivers when consistent with river management plan and when protecting outstandingly remarkable values. They are otherwise suitable.

Mineral materials (saleable) are not suitable within Landmark Historic Corridor, Wilderness, designated wild and scenic rivers in the wild classification, and two Idaho Roadless Rule theme areas including the wildland recreation and primitive and Special Areas of Historic or Tribal Significance theme area. They are also not suitable in riparian management zones, mass movement areas, recreation sites, administrative sites, and research natural areas. They are conditionally suitable within designated and suitable wild and scenic rivers when consistent with river management plan or when protecting outstandingly remarkable values. Finally, they are suitable within Idaho Roadless Rule areas to the extent they are allowed in the Idaho Roadless Rule. Otherwise, they are suitable use outside these areas. Thus, vast areas of the Nez Perce-Clearwater receive various levels of protection against impacts from mineral extraction under the plan and would help maintain conditions for grizzly bears.

Plan components in the energy and minerals section may have some environmental consequences to grizzly bear habitats if mining or energy extraction activities occur within secure habitat. These activities would create a footprint representing loss of habitat and human presence at these sites could lead to bear-human conflicts. Reasonable access requirements sometimes would reduce secure habitat when roads are constructed. The desired condition in this section is that mineral resources are available for use. The Forest Service has limited authority to limit these activities. However, the extent of mining or mineral activities would likely be over only a small proportion of grizzly bear habitat so the effects would be minor. FW-STD-EM-01 would require abandoned operations to be returned to a state of site condition comparable to pre-mineral activity and provide comparable form and function based on site potential. This plan direction would help mitigate the loss of habitat after operation are complete. Essentially, management direction in the 1987 Forest Plans is similar to those in the Preferred Alternative.

Land Ownership and Uses

Plan direction in the land ownership and land uses section would have both negative and beneficial consequences on grizzly bears. FW-DC-LND-01 specifically would direct land acquisitions to prioritize habitat for at-risk species, which could have beneficial consequences for grizzly bear connectivity and habitat conservation. On the other hand, FS-DC-LND-04 could facilitate minor impacts to grizzly bear habitat from energy developments because it could encourage development of energy infrastructure. However, grizzly bears are expected to recover in designated wilderness where these facilities would not be allowed. The potential for oil or gas extraction is low to very low on the Nez Perce-Clearwater so there would be little chance to have oil and gas extraction projects. Wind energy potential is also low so there is less likely to be wind energy developments. More likely would be rights-of-way for the electrical grid or oil and gas pipelines for the transportation of these resources. These types of infrastructure usually have temporary impacts during construction but then would have low impacts after completion. The footprint would be limited to only a very small percent of grizzly bear habitat in the plan area. Plan direction in FW-GDL-LND-01 would require using exiting rights of ways before constructing new ones which would serve to minimize the impacts.

Ecosystem Services

The Forest Service balances multiple uses with the conservation of wildlife. Desired condition FW-DC-ES-01 emphasizes a variety of human uses including ecosystem services to area residents and visitors. Key benefits emphasized include clean water; clean air; wood products, including timber and firewood; forage; hunting and fishing; fish; cultural values, including heritage values, subsistence food gathering, and spiritual and inspirational values; scenery; recreation; and flood control and soil stabilization. Management will emphasize these uses as a result of this desired condition for the benefit of people, but there may be some instances when the resulting actions end up impacting grizzly bears. However, this plan component does not authorize these activities, and all projects would require separate consultation and analysis.

FW-GDL-ES-01 is a guideline to provide for social and economic sustainability of rural communities. It states:

> To provide for social and economic sustainability of rural communities, access to activities such as recreation, hunting, fishing, gathering, egress and wildfire management should continue to be provided for on routes or in areas designated as open to motorized use in the summer and winter. If a route is identified as adversely affecting aquatic ecological values, rerouting and route improvement should be considered prior to closure, to preserve motorized access opportunities. If a route or area needs to be closed, alternate motorized access to maintain social and economic sustainability of rural communities should be provided.

It ensures that routes open for motorized use in the summer and areas in the winter should continue to provide access for recreation, hunting, fishing, gathering, egress, and wildfire management. This guideline requires that, in the event of a route closure or relocation, alternate motorized access to maintain social and economic sustainability of rural communities should be provided. In many areas of the Nez Perce-Clearwater, road densities are high or very high locally and may need to be reduced due to resource concerns. In the event that happens, new roads or motorized trails may be required to maintain access. This plan component would also require that any closure of over-snow areas would require consideration to maintain access. This guideline would serve to maintain the baseline travel condition in the plan area, which is consistent with the minimum roads system analysis as the bases for travel planning. The plan component would have a chilling effect on reducing motorized impacts to natural resources through closures. Motorized Routes would be more likely to be moved rather than closed. It could also lead to a redistribution of roads and motorized access when closing areas to motorized access for resource reasons. If the redistribution of motorized access occurs in areas of currently existing secure habitat, secure habitat could be impacted. Any new motorized access would require a separate analysis and Endangered Species Act consultation prior to a travel management decision. New motorized access would be required to be consistent with the entirety of the plan, including wildlife components maintain secure habitat and riparian components greatly limiting new roads within riparian management zones. This plan component works in concert with other plan components, it does not supersede nor loosen requirements of any plan component, and a project must meet all standards and guidelines and not preclude attainment of any desired condition to be consistent with the plan.

FW-GDL-ES-01 would apply to all future travel management projects including forestwide travel decisions and travel decisions made in individual projects. Perhaps the most widespread ramification of FW-GDL-ES-01 would be in its application to conducting a forestwide travel plan, as would occur on the Nez Perce National Forest in the future. In this case FW-GDL-ES-01 would have sweeping influence on travel planning process. It would require careful consideration when closing routes for aquatic resources, and potentially require leaving open or providing alternative motorized access when doing so. The intent of the plan component is that it does not apply to closures needed to achieve the minimum travel system during forestwide travel planning. When closing routes, a responsible official would have to consider leaving routes open, and if a route or area needs to be closed, alternate access to maintain social and economic sustainability of rural communities should be provided. The plan component is not necessarily limited to specific locations or routes per se but could be applied so as to require providing alternative access opportunities or experiences as well. The plan component does not specify whether it would apply to requiring similar maintenance levels, seasons of use, nor whether the alternate access would be applied in the same general area or a new area. These decisions would be made by the responsible official during project development and through Endangered Species Act consultation.

While this plan guideline would not cause an increase in new motorized routes, it would hinder any progress to reducing any baseline conditions existing because of the travel system. In combination with motorized suitability decisions, the overall travel system would most likely trend higher rather than decline as a result of this guideline.

The direction in FW-GDL-ES-01 also applies to winter motorized recreation. If areas previously open to winter motorized recreation were closed, the guideline would require consideration to maintain access or providing alternate winter motorized access in the event areas for winter motorized access are closed. Closure of winter motorized access under in the future is a fairly unlikely event that would potentially occur during the establishment of a travel plan like would occur within the Nez Perce portion of the combined national forest. It would primarily affect potential denning habitat by requiring a maintenance of winter motorized access or the provision of alternate winter motorized access in the event of a closure. This would be essentially a one-time decision made within the scope of the travel plan and it would have a site-specific analysis with associated Endangered Species Act consultation. Effects of winter motorized access was analyzed in more detail above and the scope of the effects would be consistent with the effects detailed in that section. The guideline does not determine where the new area would be and may be located in areas outside of potential grizzly bear denning habitat.

Language in FW-GDL-ES-01 suggests that in order for the guideline to apply the area would need to have been “provided for on routes or in areas designated as open to motorized use.” This language seemingly would not apply to areas in the Nez Perce portion of the planning area that have not yet undergone travel planning and are “open unless designated closed” because they have not yet been designated as open in a travel plan.

These forestwide Travel Planning outcome would typically only occur once mostly within the Nez Perce National Forest portion of the planning area, though it could also apply to any forestwide modifications of the Clearwater Travel Plan. Thereafter, the travel system could be modified through decisions on individual travel routes. Aside from forestwide travel planning, FW-GDL-ES-01 would also apply to decisions regarding the travel system on individual routes or modifications of the travel plan. For example, road or trail system decisions are often made concurrent to support timber operations or individual projects can authorize new road or trails for recreational purpose. Likewise, individual travel decisions can also close individual routes. In these cases, FW-GLD-ES-01 would require consideration of or provision of alternative routes.

Motorized route closures would be more likely to occur where there are already more motorized routes such as within Management Area 3, though this plan component is a forestwide plan component and could occur within Management Area 2 as well. It is unlikely to apply to areas not suitable for motorized uses like in most areas of Management Area 1. The applicability of this plan component is more limited outside of Management Area 3 as described below.

This plan component would not result in new motorized roads nor trails within areas not suitable for motorized uses. These include wilderness areas, recommended wilderness areas, research natural areas, wild classification of suitable and designated wild and scenic rivers, and Idaho Roadless Rule Areas not suitable for motorized uses. The application of FW-GDL-ES-01 would be limited or not applicable to most area of Management Area 1 the vast majority of which is not suitable for motorized uses. Because motorized roads and trails would not be a suitable use in these areas, motorized access would not be allowed within these areas. Therefore, these areas would not have relocations of motorized routes resulting from FW-GDL-ES-01.

Within Idaho Roadless Rule areas that are suitable for motorized uses, which under the Preferred Alternative is mostly within the Backcountry Restoration Theme, road reconstruction or relocations are prohibited unless the regional forester determines that:

> Road is needed for public health and safety for imminent threat of loss of life or property; or in Response to CERCLA, Clean Water Act or Oil Pollution, or Statute, treaty, reserved or outstanding rights or other legal duty of the United States; or Road realignment to prevent irreparable resource damage that can't be mitigate by normal road maintenance for roads essential for public or private access, natural resource management, or public health or safety; or Road reconstruction for road safety on a road determined to be hazardous; or Secretary of Agriculture determines a Federal Aid Highway (Title 23 of the U.S. Code) is warranted.

Some situations might arise where the regional forester makes the determination that roads need to be reconstructed or relocated because of natural resource reasons. Therefore, FW-GDL-ES-01 could apply when system routes are closed for the specific reasons outlined in the Idaho Roadless Rule. Other Idaho Roadless Rule Area Themes do not allow these exceptions and so FW-GDL-ES-01 would not apply there. Furthermore, since they are not suitable for motorized uses, they would not be subject to new motorized routes.

The Idaho Roadless Rule areas suitable for motorized uses would allow relocation or reconstruction of motorized trails. Therefore FW-GDL-ES-01 could be applicable to motorized trails within Idaho Roadless Rule Areas suitable for motorized uses. Any motorized trail that would need to be closed for resource reasons could be relocated within Management Area 2, provided the trail is consistent with all other Forest Plan direction.

FW-GDL-ES-01 specifically identifies that when closing for aquatic resources, rerouting and route improvement should be considered. If routes are closed for aquatic resource reasons, it is reasonable to assume that in most of these cases the routes would be moved into upland areas. In these situations, the species-specific grizzly bear plan component MA2-GDL-WL-05 would not constrain this activity because it specifically states that the guideline does not apply to existing trails that are relocated or reconstructed to mitigate negative impacts to ecological resources.

Management Areas 3 has the highest likelihood of motorized route closures or relocations, simply because it has the most motorized routes, many of which are near important aquatic resources. Management Area 3 has few secure habitats, and most of them are small and scattered. Thus, they have less conservation value to supporting resident grizzly bear populations.

The plan component should not be expected to increase the probability of attractants or increase the probability of conflicts because it seeks to only maintain access so it would not generally result in an increase and would mostly redistribute motorized access. However, it may hinder addressing grizzly bear related conflict or mortality issues related to the distribution and abundance of motorized access because it would require that “alternate motorized access to maintain social and economic sustainability of rural communities should be provided.”

Plan Direction That Contributes to Grizzly Bear Recovery and Effects of Plan Direction from Other Resource Areas

The plan components contain provisions for connectivity. Plan components that express a desire for connectivity include FW-GL-TE-01, FW-DC-TE-04, FW-DC-WL-03, FW-DC-WL-06, MA2-DC-RWILD-03, MA2-DC-IRA-03. The plan does not propose any connectivity areas because the Nez Perce-Clearwater is already a contiguous block of land containing many acres of lands well preserved by management area direction, laws, and rules, such as the Idaho Roadless Rule, designated wilderness, and recommended wilderness. Plan components that express a desire that the land allocations provide for grizzly bear connectivity include FW-DC-WL-06, MA2-DC-RWILD-03, and MA2-DC-IRA-03.

Elk plan components under the action alternatives will continue to contribute to grizzly bear connectivity indirectly. Under the alternatives, the plan components for elk move away from a focus on elk habitat effectiveness and use a more integrated approach at the landscape scale that considers high quality summer forage, probability of use as influenced by roads. This new approach is consistent with new scientific findings that suggest that high quality nutrition and road distribution interact to drive elk distribution and habitat use.

Plan components for aquatic and riparian conservation would help provide both connectivity and forage resources for grizzly bears. Specifically, plan components that provide for riparian management zones would also provide habitat for dispersing bears. Taken as a whole, the aquatics plan components should also help improve fisheries that can provide forage for grizzly bears.

Goals FW-GL-WL-01 and FW-GL-TE-02 contribute to the recovery of federally listed species through cooperation and collaboration with the U.S. Fish and Wildlife Service, other federal agencies, state agencies, and tribes. Desired conditions support this goal, in that all revised plan alternatives include FW-DC-WL-01, which is a goal to have habitat conditions for federally listed threatened, endangered, and candidate plant and animal species that contribute to their recovery to the point at which listing is no longer appropriate and provide conditions to meet their life history needs.

There are three species-specific desired conditions for grizzly bears and one species-specific guideline. They include FW-DC-WL-06, FW-DC-WL-07, FW-DC-WL-08, FW-DC-WL-09, and MA2-GDL-WL-

05. FW-DC-WL-06 is a desired condition that "the grizzly bear Bitterroot Recovery Zone provides the ecological conditions to support recolonization of grizzly bears combined with a desire to have bears able to travel from occupied habitat to the recovery zone through Forest Plan land use allocations." This desired condition would direct management to maintain the conditions to support recolonization and connectivity to the Bitterroot Recovery Zone from other occupied areas. Desired conditions FW-DC-WL-07 and FW-DC-WL-08 would encourage management towards reducing bear-human conflicts through education and providing infrastructure in developed recreation areas to store attractants. Grizzly bear considerations were added to MA2-GDL-WL-05 as a mechanism to limit fragmentation of habitat currently without motorized roads or trails that exist in Management Area 2 and are only applicable in that management area.

As the planning rule directs, the plan provides coarse filter habitat plan components to provide for habitat that contributes to species recovery focused on providing composition, structure, function, and connectivity with the intent to achieve ecological integrity. The plan direction and specific plan components that contribute to ecological conditions for grizzly bears are discussed below.

Terrestrial Ecosystem

Threats Addressed

- Vegetation Management
- Climate change

Plan Component

- FW-DC-TE-04
- FW-DC-TE-05
- FW-GL-TE-02

Plan Component Summary

Provides vegetation conditions that reflect natural disturbances and that the composition, structure, function, and connectivity of native plant communities are appropriate for a given landscape and climatic setting. Includes a goal FW-GL-TE-02 to help meet other agencies goals like federally listed species recovery.

Effect

These should contribute to ecological conditions that should promote diversity of plant and animal communities that should help provide for ecological conditions to support grizzly bears. Would also promote achievement of recovery.

Caves and Karst

Threats Addressed

- Recreation
- Mineral
- Energy Development

Plan Component

- FW-DC-Cave-01
- FW-STD-Cave-01

Plan Component Summary

Includes a desired condition and standard to maintain biological function of caves and karst. The forestwide desired condition FW-DC-CAVE-01 expresses a desire to maintain and protect cave features. The standard FW-STD-BIOPHY-01 specifies that cave environments shall not be altered, except where necessary to protect associated natural resources or to protect health and safety.

Effect

This direction would maintain and protect caves that that might contribute to hibernation sites for grizzly bears. These plan components are a relatively minor contributor to grizzly bear habitats.

Forestlands

Threats Addressed

- Vegetation Management
- Climate change
- Wildfires

Plan Component

- FW-DC-FOR-01
- FW-DC-FOR-02
- MA2 and MA3-DC-FOR-10
- MA3-DC-FOR-11
- MA3-STD-FOR-01
- MA3-GDL-FOR-06
- MA3-GDL-FOR-07
- MA2 and MA3-GDL-FOR-01
- MA2 and MA3-GDL-FOR-02
- MA2 and MA3-GDL-FOR-03
- MA2 and MA3-GDL-FOR-04
- MA2 and MA3-GDL-FOR-05
- MA2 and MA3-DC-FOR-10
- FW-DC-FOR-09

Plan Component Summary

Comprehensive plan components that would direct management to provide a diversity of forest conditions across multiple broad potential vegetation types. The basic premise is that forest will be managed to manage for variation of structure, function, composition, and connectivity of forested habitats, including forest size classes, density, dominance types, and landscape pattern for broad potential vegetation types. Restoring forested habitats back to conditions similar to those under natural disturbances will be the primary driver for management of forested habitats. Forested lands plan components are specific to broad potential vegetation types that provide the physical characteristics that provide for a variety of forest types. The section contains direction to restore western white pine, whitebark pine, and aspen. Several plan components address conditions that describe vegetation patterns that reflect fire regimes, and landscape patterns. These sections also contain plan standards and guidelines to ensure that snags, live leave trees, and downed wood remain distributed across the plan area and provide protections for old growth, which could contribute to hibernation or denning sites. Specific desired conditions and objectives seek to restore whitebark pine which will provide an important source of nutrition at long time periods from now.

Effect

Provide a diversity of forest vegetation conditions to support grizzly bear ecology. These plan components would ensure properly functioning habitat and a variety of dominance types, forest densities, composition, and size classes to provide for the diverse needs of grizzly bears. These plan components would direct forest management towards maintaining or restoring conditions that existed under natural disturbance. These should contribute to ecological conditions like those that grizzly bears evolved with. Early seral conditions would promote bear nutrition while forested lands in mature size classes would promote resting and denning structures. These would seek to restore some bear nutrition through restoration of whitebark pine and perhaps white pine. Desired conditions are such that forests would be more resilient to the effects of climate change and should address vulnerability to uncharacteristic wildfire. Timber production in many cases will be the result of restoration actions to restore ecosystem integrity.

Meadows, Grasslands, and Shrublands

Threats Addressed

- Vegetation Management
- Livestock grazing
- Wildfire

Plan Component

- FW-DC-GS-01
- FW-DC-GS-02
- FW-DC-GS-03
- FW-DC-GS-04
- FW-DC-GS-05
- FW-DC-GS-06
- FW-DC-GS-07
- FW-DC-GS-08
- FW-OBJ-GS-01

Plan Component Summary

Desired conditions describe the desired composition and condition of meadows, grasslands, and shrublands. These plan components represent habitats where these features are persistent rather than a result from disturbance of forested habitats that create early seral forested conditions. These desired conditions are organized by grassland and shrubland types and describe the desired native plant composition. Objectives seek to maintain or expand these habitat features through disturbance.

Effect

Persistent non-forested habitats are relatively uncommon within the plan area as most of the land base is composed of forested habitats. These plan components help ensure that meadows, grasslands, and shrublands maintain composition to function properly and remain in extent to provide foraging resources for bears and their prey. Grazing allotments are often located where these features occur in abundance. Maintaining the composition of these habitats would require proper grazing intensities. Wildfire often maintains these habitats long term.

Fire Management

Threats Addressed

- Wildfire
- Vegetation management
- Climate change

Plan Component

- FW-DC-FIRE-01
- FW-DC-FIRE-02
- FW-OBJ-FIRE-01
- FW-OBJ-FIRE-02
- FW-OBJ-FIRE-02
- FW-GDL-FIRE-01
- FW-GDL-FIRE-02

Plan Component Summary

These are desired conditions and objectives that describe the desired landscape resiliency to fire, desired fuel conditions, spatial pattern, burn intensity, and processes that are a large driver of ecological conditions in the plan area. These conditions emphasize that wildfire plays an integral part of achieving ecosystem sustainability, including interrelated ecological, economic, and social components, such as improved ecosystem resilience and wildlife habitat, protection of property, other values at risk, and public safety. Objective to treat acres of habitat to achieve desired conditions both through prescribed burning and vegetation treatments and wildfire. Guidelines require utilizing opportunity to integrate wildland fires into other disturbances on the landscape. Guidelines require that planned ignitions should be planned and implemented with design features to address the spread of invasive weeds.

Effect

Uncharacteristic wildfire (either too little or too much wildfire) was identified as a threat because it is pervasive and may play a large role in ecosystem changes that could impact productivity of the landscape for grizzly bears. In many areas of the Nez Perce-Clearwater, fire exclusion has contributed to fuels conditions that may cause large, uncharacteristic wildfires. Similarly, fire exclusion has likely substantially reduced grizzly bear nutrition and perhaps carrying capacity. These plan components would serve to ensure that wildfire and prescribed fire continue to play a role to contribute to grizzly bear habitats and food sources. They would also help ensure that wildfire would be restored back to natural intensity and periodicity. Restoration of natural disturbance processes would improve function of forested ecosystems for grizzly bears. Restoring wildfire would help these systems be more resilient to the effects of climate change.

Invasive Species

Threats Addressed

- Wildfire

- Vegetation management
- Invasive species

Plan Component

- FW-DC-INV-01
- FW-OBJ-INV-01
- FW-GDL-INV-01
- FW-GDL-INV-02
- FW-GDL-INV-03

Plan Component Summary

Desired conditions, objectives, and guidelines designed to ensure that invasive species do not significantly increase across the Nez Perce-Clearwater and no new invasive species become established in any of the plant communities or aquatic ecosystems on the Nez Perce-Clearwater.

Effect
