Rapid Assessment Reference Condition Model

The Rapid Assessment is a component of the LANDFIRE project. Reference condition models for the Rapid Assessment were created through a series of expert workshops and a peer-review process in 2004 and 2005. For more information, please visit www.landfire.gov. Please direct questions to helpdesk@landfire.gov.

Geographic Range

This type occupies some of the highest-elevation forested zones in Cascade and Olympic Mountains. Above the elevation of closed forest, the type can exist as tree clumps in a matrix of parkland.

Biophysical Site Description

The lower elevation limit of the type ranges from about 5000' in southern Oregon to about 4000' in northern Washington. Sites are cold and characterized by deep and persistent snowpacks and short growing seasons.

Vegetation Description

Stands are generally dominated by mountain hemlock, though a wide variety of other tree species are present throughout the geographic range of the type. In some areas, lodgepole pine dominates post-disturbance stands. Mature stands may be nearly all mountain hemlock, or may have varying amounts of Pacific silver fir, Alaska yellow cedar, and subalpine fir. Common understory species include Alaska huckleberry, big huckleberry, grouse whortleberry, and beargrass.

Disturbance Description

Wildfire is the major disturbance event of this type, although the frequency of fire tends to be low. Fire is generally stand-replacing, since the major tree species are highly susceptible to fire mortality. Estimates of the return of wildfire range from 500 to over 1500 years. The root rot Phellinus weirii, bark beetles, and other insects can be locally important disturbance agents.

Adjacency or Identification Concerns

The type is immediately upslope from the wet Pacific silver fir types in the north, and the Red Fir type in the south Oregon Cascades. Upslope from this type are subalpine and alpine park lands, and in some cases whitebark pine forest or parkland. Along moisture gradients (i.e., west to east across either the Olympic or Cascade Mountains), this type can grade into the subalpine fir type.

Scale Description

Sources of Scale Data	✓ Literature	Local Data	Expert Estimate
-----------------------	---------------------	------------	-----------------

In areas of continuous forest, fire sizes can range from 10s of acres to at least 10,000 acres. At upper elevation parkland areas, discontinuous fuels can limit fire spread and extent. Root-rot patches can be up to about 100 acres.

Issues/Problems

According to This and Sturrock, Phellinus weirii is distributed from northern California to southern British Columbia, and east to western Montana. So it seems likely that it could affect mountain hemlock anywhere it grows in Oregon or Washington. This part of our model would not be applicable to other parts of the range of mountain hemlock.

Model Evolution and Comments

We assumed that class A can go to class B or class C, with roughly twice the probability of moving to class B.

To start with, we assumed that stand-replacing fire affects all classes with a frequency of 750 years. The insect/disease disturbance of class B is mountain pine beetle, which can thin or destroy the stand. Based on personal communication from Ellen Goheen and Beth Willhite, the effect of Phellinus weirii is to maintain some portion of the landscape in a semi-permanent, semi-open condition with scattered lodgepole pine, western white pine, subalpine fir, and other species. We modeled this as a loop maintaining portions of the landscape in class C.

For classes D and E, we used mixed fire to represent small (e.g., single tree lightning fires) fires that create gaps. (This infrequent fire was modeled in VDDT as 0.0001 probability (~10,000 yrs). The insect/disease for classes D and E represent Phellinus weirii.

Succession Classes** Succession classes are the equivalent of "Vegetation Fuel Classes" as defined in the Interagency FRCC Guidebook (www.frcc.gov). **Dominant Species* and** Structure Data (for upper layer lifeform) Class A 10% **Canopy Position** Min Max Early1 PostRep VACCI 40 % Cover 0% XETE **Description** Height no data no data **PICO** The first few years following stand-Tree Size Class no data **TSME** replacing wildfire are characterized Upper Layer Lifeform by bare ground, herbs, shrubs, and Upper layer lifeform differs from dominant lifeform. ☐ Herbaceous Height and cover of dominant lifeform are: varying densities of tree seedlings Shrub (presumably dependent on seed ∐Tree sources). Dominant species include various huckleberries, Fuel Model no data beargrass, lodgepole pine, and mountain hemlock. [Succession to class B after 50 years. Replacement fire (MFRI about 750 years) sets it back to time zero. Depending on seed source or lack of regeneration success, about one third of the stands develop directly into class C (Alt. Succession, probability 0.33).]

Class B 10%

Mid1 Closed

Description

This class represents rapid regeneration by lodgepole pine. Typical understory species for the type are usually present (i.e., huckleberry species, fool's huckleberry, and various herbs). Trees are in sapling and small pole size. [Succession to class D (open canopy/late) after 150 years. Replacement fire (MFRI about 750 years) resets. Insect and disease could reset to class A at 0.05 probability. Additionally, Insect and disease can maintain these young open stands, or open them up to class C (probability 0.007 for each pathway.)]

Class C 15%

Mid1 Open Description

This class represents delayed tree regeneration and long-term domination by shrubs and herbs. Shrubs include big huckleberry and grouse whortleberry. Herbs include beargrass and sedges. Trees are represented by seedlings and saplings of mountain hemlock and other species. This class can persist for decades, eventually transitioning to class D after 150 years in this class. [Replacement fire MFRI 750-800 years. Insect and disease can maintain it in class C but at a small extent (probability 0.0001).
