Summary: This ecological system is a broadly defined desert grassland, mixed shrub-succulent or xeromorphic oak savanna that is typical of the Borderlands of Arizona, New Mexico and northern Mexico (Apacherian region) but extends west to the Sonoran Desert, north into the Mogollon Rim in Arizona and up the Rio Grande Valley into central New Mexico. It also likely occurs in the southern portions of the Chihuahuan Desert. It is found on gently sloping alluvial erosional fans and piedmonts (bajadas) that lie along mountain fronts of the isolated basin ranges throughout the Sky Island mountain archipelago and on to foothill slopes up to 1670 m elevation in the Chihuahuan Desert. The vegetation in this mixed semi-desert grassland ecosystem is variable. It is characterized by the dominance of a typically diverse layer of perennial grasses with scattered stem succulents and shrubs. Frequent species include the grasses *Aristida ternipes, Bouteloua chondrosioides, Bouteloua curtipendula, Bouteloua eriopoda, Bouteloua gracilis, Bouteloua hirsuta, Bouteloua ramosa, Bouteloua repens, Bouteloua rothrockii, Digitaria californica, Eragrostis intermedia, Heteropogon contortus, Hilaria belangeri, Leptochloa dubia, Muhlenbergia porteri*, with *Muhlenbergia emersleyi, Muhlenbergia setifolia* at upper foothill elevation, rosettophyllous, often succulent species of *Agave, Dasylirion, Nolina, Opuntia*, and *Yucca*, and short-shrub species of *Calliandra*, and *Parthenium*. Tall-shrub/short-tree species of *Acacia, Prosopis, Juniperus, Mimosa*, and various oaks (e.g., *Quercus grisea, Quercus emoryi, Quercus arizonica, Quercus oblongifolia*) may be present with low cover. *Pleuraphis mutica*-dominated semi-desert grasslands often with *Bouteloua eriopoda* or *Bouteloua gracilis* occurring on lowlands and loamy plains in the Chihuahuan Desert are classified as Chihuahuan Loamy Plains Desert Grassland (CES302.061). Many of the historical desert grassland and savanna areas have been converted through intensive grazing and other land uses, some to Apacherian-Chihuahuan Mesquite Upland Scrub (CES302.733) (*Prosopis* spp.-dominated).
Classification Comments: *Dasylirion leiophyllum*, *Dasylirion wheeleri*, and *Fouquieria splendens* foothill shrublands and oak savannas/open woodlands are included in the concept of the this grassland and steppe ecological system. Chihuahuan grassland types that are currently included in this system are: (1) Chino grasslands of mountain slopes on acidic igneous, limestone, or deeper gravelly soils at elevations less than 1070 m (3500 feet). These sites are dominated by *Bouteloua ramosa* with *Euphorbia antisyphilitica, Hechtia texensis (= Hechtia scariosa), Fouquieria splendens, Jatropha dioica*, and *Agave lechuguilla*. (2) Desert mountain grasslands on mountain slopes between 1070 and 1370 m (3500-4500 feet) elevation on acidic igneous substrates, but also sometimes on limestone. *Bouteloua eriopoda* and *Bouteloua curtipendula* are constituents of this system. (3) Gravelly piedmont slope grasslands between 1370 and 1670 m (4500-5500 feet) elevation on Perdiz conglomerate or Tascotal tuff. These grasslands have *Bouteloua eriopoda, Bouteloua gracilis*, and *Dasylirion* as common components. Input from fire ecologist at a Landfire modeling workshop in 2006 suggests a fire-return interval that is generally long (about 10 years), with pluvial periods providing conditions leading to more rapid fuel development.

DESCRIPTION

Environment: It is found on gently sloping alluvial erosional fans and piedmonts (bajadas) that lie along mountain fronts of the isolated ranges throughout the Sky Island mountain archipelago and on to foothill slopes up to 1670 m and possibly to 1800 m elevation in the Chihuahuan Desert. Sites are typically gently sloping mesas and piedmonts (Landfire 2007a).
Dynamics: Semi-desert grasslands are complex with many stands having a shrub or stem succulent component (*Agave* and *Yucca* spp.) under natural conditions (Burgess 1995). This woody component increases in density over time in the absence of disturbance such as fire (Burgess 1995, Gori and Enquist 2003, Schussman 2006a). Under historic natural conditions (also called natural range of variability or NRV), this ecosystem ranges from open perennial grasslands with low cover of shrubs to grasslands with a moderately dense shrub layer and succulent layer (Burgess 1995, Gori and Enquist 2003). An exception is that some stands with deep argillic horizons appear resistant to shrub and tree invasion without disturbance (McAuliffe 1995).

It is well-documented that frequent stand-replacing fire (fire-return interval (FRI) of 2.5 to 10 years) was a key ecological attribute of this semi-desert grassland ecosystem historically before 1890 (Wright 1980, Bahre 1985, McPherson 1995, Kaib et al. 1996). Other evidence of the importance of fire in maintaining desert grasslands includes the widespread conversion of grasslands to shrublands during the century of fire suppression (McPherson 1995) and the results of prescribed burning on decreasing shrub cover and increasing grass cover (Bock and Bock 1992, Robinett 1994). Additional evidence that frequent fire is a key ecological attribute of this ecosystem is that many common invasive shrubs, subshrubs and cacti are fire-sensitive and individuals are killed when top-burned, at least when they are young (<10 years old) (McPherson 1995), while native perennial grasses generally quickly recover from burning (Wright 1980, Martin 1983, Bock and Bock 1992).

Herbivory by native herbivores in the system is varied and ranges from invertebrates and rodents to pronghorn (Parmenter and Van Devender 1995, Whitford et al. 1995, Finch 2004). Soil-dwelling invertebrates include tiny nematodes and larger termites and ants, are important in nutrient cycling and affect soil properties, such as bulk density (Whitford et al. 1995). Above-ground invertebrates such as grasshoppers can significantly impact herbaceous cover when populations are high. Herbivory by native mammals also impacts these grasslands. Historically, populations of large mammals such as pronghorn (*Antilocarpa americana*), mule deer (*Odocoileus hemionus*) and elk (*Cervus elaphus*) were once abundant in this ecosystem (Parmenter and Van Devender 1995). Populations were greatly reduced and, in the case of pronghorn, extirpated during the 1800s and early 1900s, but effective game management has restored many populations, although habitat changes will limit restoration in other areas (Parmenter and Van Devender 1995). The historic impact of large native ungulates on this ecosystem is not known; however, in the case of wintering elk, it may have been significant locally. The current impact is assumed to be relatively small in this ecosystem. Herbivory from native small mammals such as rodents is significant as they are the dominant mammals in the semi-desert grassland ecosystem. There is also high diversity of these rodents, especially ground-dwelling ones such as spotted ground squirrels (*Spermophilus spilosoma*), and bannertail and Ord kangaroo rats (*Dipodomys spectabilis* and *Dipodomys ordii*). These burrowing rodents have a substantial effect on vegetation composition, soil structure and nutrient cycling (Parmenter and Van Devender 1995, Finch 2004). Historically, black-tail prairie dogs (*Cynomys ludovicianus*) had extensive colonies but were greatly reduced or extirpated from semi-desert grasslands in Arizona by 1960s, and their numbers and impacts are still small (Parmenter and Van Devender 1995). Other rodents such as kangaroo rats are still abundant in semi-desert grasslands.

CALIFORNIA CENTRAL VALLEY MIXED OAK SAVANNA (CES206.935)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Woody-Herbaceous; Mediterranean [Mediterranean Xeric-Oceanic]; Deep Soil; Xeric; F-Landscape/Low Intensity; Quercus lobata, Quercus douglasii
Non-Diagnostic Classifiers: Herbaceous; Sideslope; Toeslope/Valley Bottom; Alluvial plain; Alluvial terrace; Eutrophic Soil; Mineral: W/ A-Horizon >10 cm
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Deciduous sparse tree canopy
National Mapping Codes: EVT 2112; ESLF 5401; ESP 1112

CONCEPT

Summary: Historically, these savannas occurred on alluvial terraces and flat plains, often with deep, fertile soils, throughout the California Central Valley from Lake Shasta south to Los Angeles County. This system is found from 10-1200 m (30-3600 feet) elevation; receiving on average 50 cm (range 25-100 cm) of precipitation per year, mainly as winter rain. Variable canopy densities in existing occurrences are likely due to variation in soil moisture regime, natural patch dynamics of fire, and land use (fire suppression, livestock grazing, herbivory, etc.). *Quercus lobata* was the characteristic oak species of these savannas, though other species were present, including *Quercus wislizeni, Quercus agrifolia, Quercus douglasii, Aesculus californica, Cercis canadensis var. texensis (= Cercis occidentalis), Juniperus californica*, and *Nassella pulchra*. There is some evidence that much of the understory prior to the invasion by non-native annual grasses and forbs was composed of native annual herbs such as *Hemizonia, Eriogonum, Trifolium, Gilia, Navarretia, Lupinus, Calycadenia, Lessingia, Lotus, Daucus*, and *Holocarpha* spp. There is considerable seasonal and annual variation in cover of understory species due to phenology and intra-annual precipitation and temperature variation.
Related Concepts:
- Blue Oak Woodland (201) (Shiflet 1994) Broader. Some *Q. lobata-Q. douglasii* Savannas are included in this SRM type.
- Coast Live Oak Woodland (202) (Shiflet 1994) Broader. Where *Q. agrifolia* mixes with *Q. lobata*.

DESCRIPTION

Environment: These savannas historically occurred on alluvial terraces and flat plains, often with deep, well-drained fertile soils, throughout the California Central Valley from Lake Shasta south to Los Angeles County. This system is found from 10-1200 m (30-3600 feet) elevation; receiving on average 50 cm (range 25-100 cm) of precipitation per year, mainly as winter rain. Summers are generally hot and dry. Variable canopy densities in existing occurrences are likely due to variation in soil moisture regime and natural patch dynamics of fire, also intra-annual precipitation and temperature variability result in variability in cover of plants.
Dynamics: Fire regime: frequent surface fires since good fuels of grasses, and carried from adjacent grasslands. Summer to early fall; FRI 5-100+ (Sawyer et al. 2009). Very productive and fire-prone landscape. From Sawyer et al. (2009): Literature describing post-fire natural regeneration and long-term fire recovery of *Quercus lobata* woodlands is minimal. Plants have the ability to survive fire, and stands probably burned frequently and hot with dry grasses and oak litter carrying surface fires. Larger mature trees are usually resistant to moderate-severity fire because of their thick bark. While seedlings and saplings are top-killed by such fire, juveniles sprout from root crowns. However, older mature trees that are top-killed do not have this same ability. Animals such as scrub jays also facilitate regeneration of *Quercus lobata*, because they prefer burned areas as acorn-caching sites, and buried acorns usually survive fire (Howard 1992, Wills 2006). Hot surface fires may kill large trees that have extensive internal rot, and usually kill small trees. Crown fires will kill a large number of valley oak of all size classes (Howard 1992). Herbivory from ungulates winter range; ground burrowers; oak regeneration is dependent upon bare soil and dispersal from birds/small mammals burial of seeds. Valley oak regeneration to replace mature trees is lower than in other deciduous oak species (Landfire 2007a). Some studies indicate that this is due to a rare occurrence of necessary climate conditions, such as a warm summer followed by several wet years.

Component Associations:
- *Quercus douglasii - Quercus wislizeni / Bromus* sp. - *Daucus pusillus* Woodland (CEGL008648, G4?)
- *Quercus douglasii / Bromus* sp. - *Daucus pusillus* Woodland (CEGL008645, G4?)
- *Quercus douglasii / Ceanothus cuneatus* / Poaceae Woodland (CEGL008646, G3G4)
- *Quercus lobata* Woodland (CEGL003096, G2?)

CALIFORNIA COASTAL LIVE OAK WOODLAND AND SAVANNA (CES206.937)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Sideslope; Mediterranean [Mediterranean Xeric-Oceanic]; Xeric; F-Patch/Medium Intensity; Broad-Leaved Evergreen Tree; Quercus agrifolia
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Forest and Woodland (Treed); Ustic; Intermediate Disturbance Interval; Graminoid
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2113; ESLF 5402; ESP 1113

CONCEPT

Summary: These *Quercus agrifolia*-dominated woodlands occur throughout the Pacific coastal areas from Sonoma County, California, south to Baja California. Occurrences vary in canopy cover from dense conditions that support sparse understory vegetation of *Rubus ursinus, Symphoricarpos mollis, Heteromeles arbutifolia*, and *Toxicodendron diversilobum*, to more open conditions with perennial bunchgrass understory. The latter typically occur on south-facing slopes with soils of variable depth. Variable canopy densities in existing occurrences are likely due to variation in soil moisture regime, natural patch dynamics of fire, and land use (fire suppression, livestock grazing, herbivory, etc.).
Related Concepts:
- California Coast Live Oak: 255 (Eyre 1980) Broader
- Coast Live Oak Woodland (202) (Shiflet 1994) Broader

DESCRIPTION

Environment: This system is found mainly below 500 m elevation in foothill environments (but up to 1200 m) on alluvial terraces, canyon bottoms, streambanks, slopes, and flats. It is typically found within 100 km of the coast, largely within the coastal fog belt (Allen-Diaz et al. 2007). Soils are moderately to well-drained, deep, sandy or loamy with high organic matter. More open occurrences with perennial bunchgrass undergrowth are typically on south-facing slopes with soils of variable depth. Annual precipitation is 40-80 cm, with January mean minimum daily temperatures of 5-10 degrees C and July mean maximum daily temperatures of 18-23 degrees C.
Dynamics: From Sawyer et al. (2009): Dominant tree root system contains both roots that tap groundwater and extensive surface-feeding ones (Callaway 1990, as cited in Sawyer et al. 2009). It is the most susceptible of the California oaks to soil drought.

Fire is the dominant disturbance mechanism. Fire severity can range from high in oak woodlands with a high shrub component to moderate or low in open woodlands and savannas with a grass understory. Historically, fire occurred frequently, and the dominant oaks are resistant to low-intensity surface fires (Allen-Diaz et al. 2007). Lightning-ignited fires are uncommon but human-ignited fires may have occurred frequently given the propensity of aboriginal cultures to burn foothill environments (Keeley 2002, Landfire 2007a). Fire history does exert some effect on fire mosaic turnover, although the effect appears to be short-lived. Also, productivity (e.g., high cover of flammable shrubs and grasses) does not seem to be as strong a control on fire occurrence as meteorology (i.e., hot, dry wind events) in these systems (Landfire 2007a).

From Sawyer et al. (2009): Large trees are exceptionally fire-resistant with the thickest bark of any California oak. They generally recover well from a fire, although severely burned crowns, trunks, and root crowns may require several years to sprout. Smaller trees are less resistant, but even low to moderately severe fires often kill seedlings and saplings. Stands may attain 80 to 100% of their pre-fire densities within 10 years after fire, though fire-return intervals in natural conditions vary widely (Steinberg 2002b, Sugihara et al. 2006).

Component Associations:

Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Forest and Woodland (Treed); Sideslope; Toeslope/Valley Bottom; Alluvial plain; Alluvial terrace; Sand Soil Texture; Short Disturbance Interval; Broad-Leaved Deciduous Tree; Broad-Leaved Evergreen Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2114; ESLF 5403; ESP 1114

CONCEPT

Summary: This ecological system is primarily found in the valley margins and foothills of the Sierra Nevada and Coast Ranges of California from approximately 120-1200 m (360-3600 feet) in elevation on rolling plains or dry slopes. Over a century of anthropogenic changes (especially cutting of oak) have altered the density and distribution of woody vegetation. A high-quality occurrence often consists of open park-like stands of *Pinus sabiniana*, with oaks and other various broadleaf tree and shrub species, including *Quercus douglasii, Quercus wislizeni, Quercus agrifolia* (primarily central and southern Coast Ranges), *Quercus lobata, Aesculus californica, Arctostaphylos* spp., *Cercis canadensis var. texensis (= Cercis occidentalis), Ceanothus cuneatus, Frangula californica (= Rhamnus californica), Ribes quercetorum, Juniperus californica*, and *Pinus coulteri* (central and southern Coast Ranges). *Pinus sabiniana* tends to drop out all together in the driest and more southerly sites, which are often dominated by *Quercus douglasii*. The California central coast region may have open stands of just *Juniperus californica*, with a grassy understory. These stands belong here due to proximity to other blue oak and gray pine stands or chaparral, and due to the heavy native or non-native grass cover. This is distinguished from Great Basin pinyon-juniper stands, which have little herbaceous understory, and *Pinus monophylla* rather than *Pinus sabiniana*. These stands of only juniper are caused by repeated removal of the oaks by humans and feral pig populations. Northern extensions of this system include *Quercus garryana* as the dominant oak, where it becomes successional to Mediterranean California Lower Montane Black Oak-Conifer Forest and Woodland (CES206.923). *Pinus sabiniana* density also varies based on intensity or frequency of fire, being less abundant in areas of higher intensity or frequency, hence it is often more abundant on steep, rocky or more mesic north-facing slope exposures. Historically, understory vegetation included mixed chaparral to perennial bunchgrass. Currently, most occurrences have understories dominated by dense cover of annual species, both native and non-native. Variable canopy densities in existing occurrences are likely due to variation in soil moisture regime, natural patch dynamics of fire, and land use (fire suppression, livestock grazing, herbivory, etc.).

- *Quercus douglasii - Pinus sabiniana* / Grass Woodland (CEGL008647, G4?)
- *Quercus wislizeni - Quercus douglasii - Pinus sabiniana* Woodland (CEGL008642, G4?)

DISTRIBUTION

Range: This system occurs primarily in the valley margins and foothills of the Sierra Nevada and Coast Ranges from approximately 120-1200 m (360-3600 feet) elevation, from Shasta County to Kern and northern Los Angeles counties, California. It is unlikely to occur in the southern portion of zone 7 (Modoc Plateau), but this needs to be confirmed with California ecologists.

CENTRAL APPALACHIAN ALKALINE GLADE AND WOODLAND (CES202.602)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Ridge/Summit/Upper Slope; Unglaciated; Alkaline Soil; Shallow Soil
Non-Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Temperate; Mesotrophic Soil; Circumneutral Soil; Ustic; Intermediate Disturbance Interval; F-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2400; ESLF 5416; ESP 1400

CONCEPT

Summary: This system occurs at low to moderate elevations from the Central Appalachians (with a few northward incursions into southernmost New York and New England possible) south to the Ridge and Valley and Piedmont. It consists of woodlands and open glades on thin soils over limestone, dolostone or similar calcareous rock. *Juniperus virginiana* is a common tree, often increasing in the absence of fire, and *Quercus muehlenbergii* is indicative of the limestone substrate. *Rhus aromatica, Cercis canadensis*, and *Ostrya virginiana* may occur. Prairie grasses are the dominant herbs (*Andropogon gerardii, Schizachyrium scoparium, Bouteloua* spp.). Forb richness is often high; characteristic forbs include *Asclepias verticillata, Brickellia eupatorioides, Erigeron pulchellus, Monarda fistulosa, Packera obovata, Salvia lyrata*, and *Symphyotrichum oblongifolium*. Fire is sometimes an important natural disturbance factor, but open physiognomies may also be maintained by drought.

Similar Ecological Systems:

- Central Interior Highlands Calcareous Glade and Barrens (CES202.691)--is a related system to the south and west of CES202.602; ranges do not overlap.
- Laurentian-Acadian Calcareous Rocky Outcrop (CES201.572)--characterized by *Thuja occidentalis* rather than *Juniperus virginiana*.
- North-Central Appalachian Circumneutral Cliff and Talus (CES202.603)
- Southern Ridge and Valley / Cumberland Dry Calcareous Forest (CES202.457)--has a more closed canopy.
- Southern Ridge and Valley Calcareous Glade and Woodland (CES202.024)--occurs in the southern Ridge and Valley south of this system; they meet in southwestern Virginia.

Related Concepts:

- Eastern Redcedar: 46 (Eyre 1980) Finer
- Sugar Maple: 27 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occupies mid-elevation rocky ridges, gentle to steep south- and southwest-facing slopes, and outcrops with thin soils and calcareous bedrock. Large amounts of exposed mineral soils and/or gravel are characteristic. Soils are high in pH and rich in calcium and magnesium. Although these areas are subject to prolonged droughts, local areas of ephemeral vernal seepage occur in microtopographic concavities, and they may have distinctive vegetation (e.g., colonies of Dodecatheon meadia). A series of glades in western Virginia is somewhat distinctive because of the dolostone, which contains a high magnesium content. These glades are located on low dolomite knobs and foothills of Elbrook dolomite that occupy middle to upper slopes and crests of south- or southwest-facing spur ridges at relatively low elevations. In the Allegheny Mountains and along the Allegheny Front of Pennsylvania, the surface geology is primarily sandstone and shale, but the Mauch Chunk formation includes several narrow bands of limestone that outcrop frequently on steep slopes (Berg et al. 1980).

Vegetation: In some cases, the woodlands grade into closed-canopy forests. *Juniperus virginiana* is a common tree, filling in in the absence of fire, and *Quercus muehlenbergii* is indicative of the limestone substrate. *Rhus aromatica, Cercis canadensis*, and *Ostrya virginiana* may occur. Prairie grasses are the dominant herbs (*Andropogon gerardii, Schizachyrium scoparium, Bouteloua* spp.); forb richness is often high. Characteristic forbs include *Asclepias verticillata, Monarda fistulosa, Salvia lyrata, Symphyotrichum oblongifolium*, and *Brickellia eupatorioides* (Braun 1950).

Dynamics: Drought stress appears to drive patch dynamics. Fire is likely to have a somewhat lesser impact due to thin soils and sparse vegetation, although fire scars on woody vegetation of barrens in Virginia suggest that fire may also play a role in maintaining the open character of this system (Ludwig 1999), and fire is also thought to contribute to arresting succession by woody species in Pennsylvania (Laughlin 2004, McPherson 2013). Where this system occurs on steep slopes, debris avalanches may cause periodic disturbance, but this process needs further study (Bartgis 1993); anthropogenic disturbance is thought to have played a role in establishment of some occurrences in Pennsylvania; quarrying has been noted to create habitat for the establishment of species characteristic of limestone prairies, but overall this activity poses a threat through outright destruction or habitat degradation (Laughlin 2004, McPherson 2013).

Component Associations:

- *Acer saccharum - Quercus muehlenbergii / Cercis canadensis* Forest (CEGL006017, G4?)
- *Juniperus virginiana / Bouteloua curtipendula - Carex eburnea* Wooded Herbaceous Vegetation (CEGL006047, G1G2)
- *Quercus muehlenbergii - Cercis canadensis / Packera obovata - Lithospermum canescens* Woodland (CEGL006231, G3G4)
- *Quercus muehlenbergii - Quercus (alba, rubra) - Carya cordiformis / Viburnum prunifolium* Forest (CEGL004793, G3G4)
- *Quercus muehlenbergii / Packera plattensis - Parthenium auriculatum - Schizachyrium scoparium* Woodland (CEGL006030, G2)
- *Quercus rubra - Carya (glabra, ovata) / Ostrya virginiana / Carex lucorum* Forest (CEGL006301, G4)

DISTRIBUTION

Range: This system is known from Pennsylvania and northwestern New Jersey south through the Ridge and Valley to western Virginia, possibly extending to southeasternmost New York and the marble valleys of northwestern Connecticut.

CENTRAL INTERIOR HIGHLANDS CALCAREOUS GLADE AND BARRENS (CES202.691)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades; Alkaline Soil
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Sedimentary Rock; F-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2401; ESLF 5417; ESP 1401

CONCEPT

Summary: This system is found primarily in the Interior Highlands of the Ozark, Ouachita, and Interior Low Plateau regions with scattered occurrences in northern Missouri. It occurs along moderate to steep slopes and steep valleys on primarily southerly to westerly facing slopes. Limestone and/or dolomite bedrock typify this system with shallow, moderately to well-drained soils interspersed with rocks. These soils often dry out during the summer and autumn, and then become saturated during the winter and spring. *Schizachyrium scoparium* dominates this system and is commonly associated with *Andropogon gerardii, Bouteloua curtipendula,* and calcium-loving plant species. Stunted woodlands primarily dominated by *Quercus muehlenbergii* interspersed with *Juniperus virginiana* occur on variable-depth-to-bedrock soils. Fire is the primary natural dynamic, and prescribed fires help manage this system by restricting woody growth and maintaining the more open glade structure.
Classification Comments: In Alabama, this system is found in the Moulton Valley region, which is technically part of TNC Ecoregion 50, but ambiguously placed there. This region is included in the Interior Plateau (71) of EPA (2004). The system is also found in the Western Valley of the Tennessee River (a very limited part of EPA 71f) in Decatur County, Tennessee. Also included here, somewhat uncomfortably, is an unusual series of flatrock glades on Silurian dolomite in Bullitt County, Kentucky (71d of Woods et al. (2002)).
Similar Ecological Systems:
- Alabama Ketona Glade and Woodland (CES202.338)--a similar concept on a very specialized substrate.
- Bluegrass Savanna and Woodland (CES202.888)
- Central Appalachian Alkaline Glade and Woodland (CES202.602)--of central Appalachians, mainly Virginia and north; need to clarify ranges.
- Nashville Basin Limestone Glade and Woodland (CES202.334)--restricted to the Nashville Basin of Tennessee, found on flat terrain instead of slopes.
- Ouachita Shale Glade and Barrens (CES202.343)
- Southern Ridge and Valley / Cumberland Dry Calcareous Forest (CES202.457)--has a more closed canopy.
- Southern Ridge and Valley Calcareous Glade and Woodland (CES202.024)--has a possible overlapping range.

- Xeric Calcareous Forest (Evans 1991) Finer

DESCRIPTION

Environment: This system is found primarily along moderate to steep slopes and steep valleys on primarily southerly to westerly facing slopes. Limestone and/or dolomite bedrock typify this system with shallow, moderately to well-drained soils interspersed with rocks. Soils are affected by the bedrock chemistry and tend to have high levels of calcium and potassium and a relatively high pH. Due to seasonal rainfall patterns and the extremely thin soils, these soils dry out during the summer and autumn and become saturated during the winter and spring. In northern Alabama (Moulton Valley), the stratum on which the system is found is a type of "marl." Seeps may occur where impervious rock strata meet relatively permeable limestone.
Vegetation: *Schizachyrium scoparium* dominates this system and is commonly associated with *Andropogon gerardii, Bouteloua curtipendula,* and calcium-loving plant species. Stunted woodlands primarily dominated by *Quercus muehlenbergii* interspersed with *Juniperus virginiana* occur on variable-depth-to-bedrock soils. The trees typically occur as islands in a wider herbaceous or rocky area. The islands are found in microenvironments where the soil depth and available water are sufficient to support trees (e.g., depressions in the bedrock). Other woody plants associated with this system (within their ranges) include *Quercus shumardii, Cercis canadensis, Ulmus alata, Fraxinus quadrangulata, Juniperus ashei, Acer saccharum,* and *Frangula caroliniana*. Other herbaceous taxa include *Silphium trifoliatum, Silphium terebinthinaceum, Liatris* spp., *Symphyotrichum oblongifolium, Castilleja coccinea, Hedyotis nigricans, Talinum* spp., *Sedum* spp., and *Panicum flexile*. Small-scale stands of annual *Sporobolus* spp. may be prominent in some examples. In some examples, small-scale seepage areas may contain *Eleocharis compressa, Nothoscordum bivalve, Isoetes*

butleri, and *Hypoxis hirsuta*.
Dynamics: The thin, dry soil characteristic of this system dries out during the growing season and much of the vegetation dries, as well. This allows fires to spread easily and these fires restrict the abundance of woody species. In high-quality examples where the natural fire regime operates, small trees and shrubs are limited to the edges of stands or small "islands" of deeper soil that retain more moisture while grasses are the dominant vegetation. Sparsely vegetated areas between the dominant grassy zones contain most of the rare species found in this system (Ware 2002). In the absence of fire, from active suppression or a lack of fuel due to excessive grazing, woody species can increase greatly.

CHIHUAHUAN GYPSOPHILOUS GRASSLAND AND STEPPE (CES302.732)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Alkaline Soil; Gypsiferous; Dwarf-Shrub; Graminoid
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Oligotrophic Soil; Aridic
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2122; ESLF 5451; ESP 1122

CONCEPT

Summary: This ecological system is restricted to gypsum outcrops or sandy gypsiferous and often alkaline soils that occur in basins and slopes in the Chihuahuan Desert. Elevation range is from 1100-2000 m. These typically sparse grasslands, steppes or dwarf-shrublands are dominated by a variety of gypsophilous plants, many of which are endemic to these habitats. Characteristic species include *Tiquilia hispidissima, Atriplex canescens, Calylophus hartwegii, Ephedra torreyana, Frankenia jamesii, Bouteloua breviseta, Mentzelia perennis, Nama carnosum, Calylophus hartwegii (= Oenothera hartwegii), Selinocarpus lanceolatus, Sporobolus nealleyi, Sporobolus airoides*, and *Sartwellia flaveriae* with gypsophilous species diagnostic of this system. This system does not include the sparsely vegetated gypsum dunes that are included in North American Warm Desert Active and Stabilized Dune (CES302.744).

Similar Ecological Systems:
- North American Warm Desert Active and Stabilized Dune (CES302.744)

Related Concepts:

- MLRA 42 - Southern Desertic Basin (SD-3) Gyp Uplands (NRCS 2006a) Broader

DESCRIPTION

Environment: This ecological system is restricted to gypsum outcrops and strongly gypseous soils (Powell and Turner 1974, Henrickson et al. 1985, Meyer 1986, Dick-Peddie 1993). Sites occur in warm, semi-desert and desert regions with hot summers, and occasionally cold winters from the Chihuahuan Desert to eastern Mojave Desert and may extend up into the southern Colorado Plateau (Powell and Turner 1974, Meyer 1986, Dick-Peddie 1993). Elevation range is from 1100-2000 m. Some occurrences may be windswept gypsum "pavement" where much of the gypsum sand has been removed by wind, but these are not open/moving dunes dominated by eolian processes. Substrates are typically fine-textured, alkaline clay soils but include some sandy gypsiferous soils that occur in closed basins in the Chihuahuan Desert, but not gypsum dunes at White Sands National Monument (Reid 1980, Dick-Peddie 1993, Muldavin et al. 2000b). Eolian processes drive the dune system so many of the same common sand scrub plants, e.g., *Atriplex canescens*, may characterize vegetation on both quartz and gypsum active dunes, although some gypsophiles will occur on gypsum dunes (Shields 1956, Reid 1980, 1980, Dick-Peddie 1993).

Vegetation: These typically sparse grasslands, steppes or dwarf-shrublands are dominated by a variety of gypsophilous plants, many of which are endemic to these habitats. Characteristic species include *Tiquilia hispidissima, Atriplex canescens, Calylophus hartwegii, Ephedra torreyana, Frankenia jamesii, Bouteloua breviseta, Mentzelia perennis, Nama carnosum, Calylophus hartwegii (= Oenothera hartwegii), Selinocarpus lanceolatus, Sporobolus nealleyi, Sporobolus airoides*, and *Sartwellia flaveriae*.

Dynamics: Gypsophile endemism is common in the North American deserts, especially the Chihuahuan Desert where much of the region is underlain by limestone, with occasional gypsum exposures. These gypsum deposits are distributed in a discontinuous, island-like fashion that facilitates endemism. Gypsum is a difficult substrate for plants to grow on because it typically forms a hard crust when dry, erodes quickly when wet, and is relatively low in available nutrients. However, a large and diverse group of gypsophilous plants only occur on this substrate, several of which are considered rare and at risk.

This is a substrate-driven ecosystem occurring in extreme environments on chemically harsh substrates. Fire plays little to no role in this ecosystem as vegetation is generally too sparse to carry fire. Normal climate conditions are warm and arid (6-10 inches annually) with drought not uncommon. Climatic fluctuations (precipitation cycles) have been speculated to affect plant vigor and recruitment (Landfire 2007a), but this is not likely significant considering the hardiness of these plants and the harshness of the environments (E. Muldavin pers. comm.). Variation in abundance of subshrubs and grasses is likely more related to fine-scale differences in the soil environment then climatic factors (E. Muldavin pers. comm.). Some occurrences may be windswept, but these are not open/moving dunes with eolian processes. Some occurrences may be gypsum "pavement" or outcrop where much of the gypsum sand has been removed by wind.

Component Associations:
- *Atriplex obovata / Tidestromia carnosa* Dwarf-shrubland (CEGL004575, G2?)
- *Fouquieria splendens / Sporobolus nealleyi* Shrub Herbaceous Vegetation (CEGL001517, GNRQ)

COLUMBIA PLATEAU LOW SAGEBRUSH STEPPE (CES304.080)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Sideslope; Shallow Soil; Silt Soil Texture; Clay Soil Texture; Aridic; W-Landscape/High Intensity; Low Artemisia spp.
Non-Diagnostic Classifiers: Temperate [Temperate Continental]; Alkaline Soil; Dwarf-Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2124; ESLF 5453; ESP 1124

CONCEPT

Summary: This matrix ecological system is composed of sagebrush dwarf-shrub-steppe that occurs in a variety of shallow-soil habitats throughout eastern Oregon, northern Nevada and southern Idaho. *Artemisia arbuscula ssp. arbuscula* and close relatives (*Artemisia arbuscula ssp. longiloba* and occasionally *Artemisia nova*) form stands that typically occur on mountain ridges and flanks and broad terraces, ranging from 1000 to 3000 m in elevation. Substrates are shallow, fine-textured soils, poorly drained clays, shallow-soiled areas, almost always very stony, characterized by recent rhyolite or basalt. Other shrubs and dwarf-shrubs present may include *Purshia tridentata*, *Eriogonum* spp., and other species of *Artemisia*. Common graminoids include *Festuca idahoensis*, *Koeleria macrantha*, *Pseudoroegneria spicata*, and *Poa secunda*. Many forbs also occur and may dominate the herbaceous vegetation, especially at the higher elevations. Isolated individuals of *Juniperus occidentalis* (western juniper) and *Cercocarpus ledifolius* (mountain-mahogany) can often be found in this system.
Related Concepts:
- Antelope Bitterbrush - Bluebunch Wheatgrass (104) (Shiflet 1994) Intersecting. This system may have small inclusions of *Purshia tridentata* shrublands.
- Antelope Bitterbrush - Idaho Fescue (105) (Shiflet 1994) Intersecting. This system may have small inclusions of *Purshia tridentata* shrublands.
- Low Sagebrush (406) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This matrix ecological system is composed of sagebrush dwarf-shrub-steppe that occurs in a variety of shallow-soil habitats throughout eastern Oregon, northern Nevada and southern Idaho. Stands typically occur on mountain ridges and flanks and broad terraces, ranging from 1000 to 3000 m in elevation. Substrates are shallow, fine-textured soils, poorly drained clays, shallow-soiled areas, almost always very stony, characterized by recent rhyolite or basalt.
Vegetation: *Artemisia arbuscula ssp. arbuscula* and close relatives (*Artemisia arbuscula ssp. longiloba* and occasionally *Artemisia nova*) form stands. Other shrubs and dwarf-shrubs present may include *Purshia tridentata, Eriogonum* spp., and other species of *Artemisia*. Common graminoids include *Festuca idahoensis, Koeleria macrantha, Pseudoroegneria spicata*, and *Poa secunda*. Many forbs also occur and may dominate the herbaceous vegetation, especially at the higher elevations. Isolated individuals of *Juniperus occidentalis* (western juniper) and *Cercocarpus ledifolius* (mountain-mahogany) can often be found in this system.

COLUMBIA PLATEAU STEPPE AND GRASSLAND (CES304.083)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Sideslope; Very Shallow Soil; Landslide; Xeromorphic Shrub; Graminoid
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2123; ESLF 5452; ESP 1123

CONCEPT

Summary: These grasslands are similar floristically to Inter-Mountain Basins Big Sagebrush Steppe (CES304.778) but are defined by a more frequent fire regime and the absence or low cover of shrubs over large areas, occasionally entire landforms. These are extensive grasslands, not grass-dominated patches within the sagebrush shrub-steppe ecological system. This system occurs throughout much of the Columbia Plateau and is found at slightly higher elevations farther south. Soils are variable, ranging from relatively deep, fine-textured often with coarse fragments, and non-saline often with a microphytic crust, to stony volcanic-derived clays to alluvial sands. This grassland is dominated by perennial bunch grasses and forbs (>25% cover), sometimes with a sparse (<10% cover) shrub layer; *Chrysothamnus viscidiflorus, Ericameria nauseosa, Tetradymia* spp., or *Artemisia* spp. may be present in disturbed stands. Associated graminoids include *Achnatherum hymenoides, Elymus elymoides, Elymus lanceolatus ssp. lanceolatus, Hesperostipa comata, Festuca idahoensis, Koeleria macrantha, Poa secunda,* and *Pseudoroegneria spicata*. Common forbs are *Phlox hoodii, Arenaria* spp., and *Astragalus* spp. Areas with deeper soils are rare because of conversion to other land uses. The rapid fire-return regime of this ecological system maintains a grassland structure by retarding shrub invasion, and landscape isolation and fragmentation limit seed dispersal of native shrub species. Fire frequency is presumed to be less than 20 years. Through isolation from a seed source, combined with repeated burning, these are "permanently" (more than 50 years) converted to grassland.
Classification Comments: How this differs from Columbia Basin Palouse Prairie (CES304.792) is unclear.
Similar Ecological Systems:
- Inter-Mountain Basins Big Sagebrush Steppe (CES304.778)
- Inter-Mountain Basins Semi-Desert Grassland (CES304.787)

Related Concepts:
- Bluegrass Scabland (106) (Shiflet 1994) Intersecting
- Threetip Sagebrush (404) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: These are extensive grasslands, not grass-dominated patches, within the sagebrush shrub-steppe ecological system. This system occurs throughout much of the Columbia Plateau and is found at slightly higher elevations farther south. Soil depth and soil texture within precipitation zones largely drive the distribution of shrub-steppe and grassland (WNHP 2011). Geographically (climatically), this steppe system is associated with Inter-Mountain Basins Big Sagebrush Steppe (CES304.778), rings the driest portion of the basin that supports the big sagebrush shrubland and the semi-desert shrub-steppe systems and is bounded by montane woodlands and the Palouse prairie. It is found in landscapes that favor frequent ignition sources and fuels that spread fire, and few natural firebreaks. Winter precipitation dominates and promotes cool-season grasses.

Biological soil crust is very important in this ecological system (WNHP 2011). Soils are variable, ranging from relatively deep, fine-textured often with coarse fragments, and non-saline often with a microphytic crust, to stony volcanic-derived clays to alluvial sands. Burrowing animals and their predators likely played important roles in creating small-scale patch patterns (WNHP 2011).
Vegetation: This grassland is dominated by perennial bunch grasses and forbs (>25% cover), sometimes with a sparse (<10% cover) shrub layer; *Chrysothamnus viscidiflorus, Ericameria nauseosa, Tetradymia* spp., or *Artemisia* spp. may be present in disturbed stands. Associated graminoids include *Achnatherum hymenoides, Elymus elymoides, Elymus lanceolatus ssp. lanceolatus, Hesperostipa comata, Festuca idahoensis, Koeleria macrantha, Poa secunda,* and *Pseudoroegneria spicata*. Common forbs are *Phlox hoodii, Arenaria* spp., and *Astragalus* spp.
Dynamics: These grasslands are defined by a more frequent fire regime and the absence or low cover of shrubs over large areas, occasionally entire landforms. The historic frequency was 30-100 years (Landfire 2007a). The natural fire regime of this ecological system likely maintains a patchy distribution of shrubs so the general aspect of the vegetation is a grassland. Post-fire shrub recruitment is limited and rate is estimated to be 25 acres in 50 years under ideal conditions for *Artemisia tridentata* (WNHP 2011). These shrubs produce large quantities of small seeds beginning at age 3-4 years of which 90% of the seed is dispersed within 9 m (30 feet) of the parent and few seeds are carried more than 30 m (100 feet) (Tirmenstein 1999c).

Ecosystems in the Columbia Basin are more sensitive to livestock grazing than grasslands in the Great Plains as they did not evolve with the same duration, seasonality, and severity of large native ungulate grazing (Mack and Thompson 1982, Burkhart 1996). In general, grazing was dispersed and during the winter and spring when forage was available. Shrubs may increase following heavy grazing and/or with fire suppression, particularly in moist portions in the northern Columbia Plateau where it forms a landscape

mosaic pattern with shallow-soil scabland shrublands. Microphytic crust is very important in this ecological system.

DISTRIBUTION

Range: This system occurs throughout the Columbia Plateau region, from north-central Idaho, south and west into Washington, Oregon, southern Idaho, and northern Nevada. Whether it also occurs in northeastern California, in the western ranges of Wyoming, or the central Wyoming Basins is unclear.
Divisions: 304:C; 306:C

CUMBERLAND SANDSTONE GLADE AND BARRENS (CES202.337)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades; Acidic Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2398; ESLF 5414; ESP 1398

CONCEPT

Summary: This system encompasses a complex of sparsely vegetated rock outcrops, perennial grasslands, and woodlands on shallow soils on the Cumberland Plateau of Kentucky, Tennessee, Alabama, and Georgia. Herbaceous plants, including *Diamorpha smallii* and *Minuartia glabra*, are typical of the outcrops in Tennessee. In Alabama, *Bigelowia nuttallii* and *Schizachyrium scoparium* are important. *Pinus virginiana* and *Acer rubrum* are typical of the current condition of many of the woodlands surrounding these outcrops on the Cumberland Plateau. This dominance pattern may be due to lack of disturbance. *Pinus rigida*, *Pinus echinata*, and/or *Quercus prinus* may also occur. Scattered shrubs, such as *Gaylussacia* spp., *Vaccinium arboreum*, and *Chionanthus virginicus*, occur on the margins in patches of deeper soil. Various mosses and fruticose lichens such as *Cladonia* spp. and *Cladina* spp. may be prominent in some examples. To the west, in the Interior Highlands (Ozark, Ouachita, and Interior Low Plateau regions), this system is replaced by Central Interior Highlands Dry Acidic Glade and Barrens (CES202.692) (both are found in Kentucky, with the latter in the Shawnee Hills of the Interior Low Plateau).

Similar Ecological Systems:
- Central Interior Highlands Dry Acidic Glade and Barrens (CES202.692)

Related Concepts:
- Cumberland Mountains xeric pine woodland (Evans 1991) Finer
- Virginia Pine: 79 (Eyre 1980) Finer

DESCRIPTION

Environment: This suite of glade, barren, and rock outcrop communities are found on flat to gently sloping expanses of sandstone and conglomerate (Edwards et al. 2013) on the surface of the Cumberland Plateau and related formations from Virginia south and west to Alabama. As the cement that holds the sand and conglomerate particles together dissolves and is transported away, sandy particles may collect in crevices and depressions to form sandy soil (Quarterman et al. 1993, Edwards et al. 2013). The sites of this system may be saturated for short times after rainfall, but also experience high temperatures in the summer, creating harsh conditions. Some examples of this system may occur adjacent to sandstone cliff faces.

Vegetation: These sandstone glades occur in a matrix of pine-oak forests. *Pinus virginiana* and *Acer rubrum* are typical of the woodlands surrounding these outcrops on the Cumberland Plateau (Perkins 1981). This dominance pattern may be due to lack of disturbance. Other trees may include *Pinus rigida, Pinus echinata*, and/or *Quercus prinus*. A perennial grass zone is typically present, which contains *Schizachyrium scoparium, Andropogon virginicus, Danthonia sericea*, and *Dichanthelium dichotomum*, in varying proportions. Herbaceous plants which are typical of the outcrops in Tennessee include *Diamorpha smallii* and *Minuartia glabra*. In Alabama, *Bigelowia nuttallii* is important, forming stands with other forbs (Perkins 1981, A. Schotz pers. comm.). Other herbaceous plants which may be found include *Liatris microcephala, Coreopsis pulchra, Eurybia surculosa (= Aster surculosus), Hypericum gentianoides, Talinum mengesii, Nuttallanthus canadensis (= Linaria canadensis), Opuntia humifusa var. humifusa, Sporobolus vaginiflorus*, and *Erigeron strigosus*. Nonvascular plants include *Aulacomnium palustre, Campylopus pilifer, Grimmia* spp., *Polytrichum commune, Polytrichum juniperinum*, and fruticose lichens such as *Cladonia* spp. and *Cladina* spp. Scattered shrubs, such as *Gaylussacia* spp., *Vaccinium arboreum*, and *Chionanthus virginicus*, along with oak and hickory regeneration, occur on the margins of more open areas, in patches of deeper soil.

Dynamics: Severe droughts kill tree saplings growing in cracks and potholes, helping to retain the open character of the glades (Quarterman et al. 1993). There is an apparent zonation or patchiness to glade/barren vegetation, with different zones that may be identified by their characteristic plant species (Quarterman et al. 1993). These zones are apparently relatively stable, with woody plant encroachment evident only in relation to the invasion of shrubs and trees into potholes or crevices where soil accumulates more rapidly.

Component Associations:
- *Bigelowia nuttallii - Coreopsis pulchra - Liatris microcephala* Herbaceous Vegetation (CEGL004622, G2)
- *Diamorpha smallii - Minuartia glabra* Sandstone Herbaceous Vegetation (CEGL004343, G2G3)
- *Kalmia latifolia - Gaylussacia (baccata, brachycera)* Cumberland Shrubland (CEGL008470, G3)
- *Pinus virginiana - Pinus (rigida, echinata) - (Quercus prinus) / Vaccinium pallidum* Forest (CEGL007119, G3)
- *Schizachyrium scoparium - Andropogon (gyrans, ternarius, virginicus)* Herbaceous Vegetation (CEGL007707, G3?)
- *Schizachyrium scoparium - Danthonia sericea - Liatris microcephala - (Eurybia surculosa)* Wooded Herbaceous Vegetation (CEGL004061, G3)

DISTRIBUTION

Range: This system is found in the Cumberland Plateau of Kentucky, Tennessee, Virginia, Alabama, and Georgia.

EDWARDS PLATEAU CARBONATE GLADE AND BARRENS (CES303.655)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Diagnostic Classifiers: Herbaceous; Moss/Lichen (Nonvascular); Sedimentary Rock; Limestone; Very Shallow Soil
National Mapping Codes: ESLF 3141

CONCEPT

Summary: This system occurs on thin soils over massive hard-bedded limestone formations in the Edwards Plateau of Texas. This is a sparsely vegetated system, but species such as *Sedum* spp. can form bands of glades that alternate with areas of woodlands and forests. Some of the depressions hold moisture for longer periods than the surrounding landscape, providing for the establishment of a diversity of spring-blooming annuals. Some characteristic plants include *Lesquerella gordonii, Lesquerella ovalifolia, Schizachyrium scoparium, Sedum nuttallianum, Sporobolus vaginiflorus (var. ozarkanus* and *var. vaginiflorus)*, and *Sedum pulchellum*.
Classification Comments: Further field investigation is needed to better develop the association-level information for this system.

DESCRIPTION

Environment: These glades and barrens are found in xeric sites on limestone rock substrates. These include non-slope-forming members of the Glen Rose Formation or areas of massive limestones such as Edwards limestone. Landforms are usually level to gently sloping uplands on plateau tops or level benches between slopes in stairstep topography. Soils are very shallow; there is sometimes very little soil development over rocky substrates (Elliott 2011).
Vegetation: These are generally small-patch occurrences with very sparse herbaceous cover, sometimes with occasional scattered shrubs. These sites generally co-occur with savannas, representing the shallowest soils sites, often on exposed or near-exposed limestone. They may occur as bands with adjacent grasslands, shrublands, or open woodlands (Elliott 2011). The sparse cover of vegetation is usually limited to cracks or depressions in the limestone bedrock where soil has developed and accumulated. Some of the depressions hold moisture for longer periods than the surrounding landscape, providing for the establishment of a diversity of spring annuals. Herbaceous cover may include species such as *Chaetopappa bellidifolia, Evax prolifera, Croton monanthogynus, Sedum nuttallianum, Sedum pulchellum, Sporobolus vaginiflorus (var. ozarkanus* and *var. vaginiflorus), Centaurium texense, Spermolepis inermis, Chamaesyce serpens, Heliotropium tenellum, Lesquerella gordonii, Lesquerella ovalifolia*, and others (Elliott 2011).

A possible outlier (the system occurring well outside the ecoregion within which it is normally found) of this system consists of small-patch occurrences of very sparse herbaceous cover found on very shallow soils over chalk outcrops in isolated locales of northern Texas (Gober, Annona, Austin Chalk, and Pecan Gap formation). Species include *Bouteloua rigidiseta, Sedum pulchellum, Sporobolus vaginiflorus, Nostoc commune, Penstemon cobaea*, and *Lesquerella* spp. Adjacent woodlands or savannas on thin-soiled chalk ridges may contain *Quercus shumardii, Quercus muehlenbergii, Celtis* sp., *Cornus drummondii, Viburnum rufidulum, Fraxinus texensis*, and others (Elliott 2011).
Dynamics: Processes controlling this system are unclear; however, erosion likely plays a major role. Erosion may be exacerbated in some situations by removal of biomass through overgrazing. Erosion mediates the occurrence of this system through its effects on soil depth. As is true for all the systems, there is a gradient from moister representatives of this system in the east to drier representatives in the west.

Component Associations:
- *Lesquerella (gordonii, ovalifolia) - Schizachyrium scoparium* Herbaceous Vegetation (CEGL004917, G2G3)
- *Sedum nuttallianum - Sporobolus vaginiflorus (var. ozarkanus, var. vaginiflorus) - Sedum pulchellum* Herbaceous Vegetation (CEGL004729, G3)
- *Sedum pulchellum - Allium drummondii - Talinum parviflorum - Centaurium texense / Nostoc commune* Herbaceous Vegetation (CEGL004874, G1G2)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Edwards Plateau Cliff (CES303.653)

GREAT LAKES ALVAR (CES201.721)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Laurentian-Acadian (201)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Intermittent Flooding; Flat; Glaciated uplands; Rock Outcrops/Barrens/Glades; Limestone; Extensive Wet Flat [Lakeshore]; Isolated Wetland [Partially Isolated]; Very Shallow Soil
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2409; ESLF 5458; ESP 1409

CONCEPT

Summary: Alvars are natural systems of humid and subhumid climates, centered around areas of glaciated horizontal limestone/dolomite (dolostone) bedrock pavement with a discontinuous thin soil mantle. These communities are characterized by distinctive flora and fauna with less than 60% tree cover that is maintained by associated geologic, hydrologic, and other landscape processes. In particular, all forms of alvar tend to flood each spring, then experience moderate to severe drought in summer months. They include open pavement, grassland, and shrubland/woodland types. Alvar communities occur in an ecological matrix with similar bedrock and hydrologically influenced communities. Almost all of North America's alvars occur within the Great Lakes basin, primarily in an arc along the Niagaran Escarpment from northern Lake Michigan across northern Lake Huron and eastern Ontario and northwestern New York state.

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Northern White-Cedar: 37 (Eyre 1980) Finer

DESCRIPTION

Environment: Alvars are found near Great Lakes shores where flat limestone or dolostone bedrock pavement is exposed. Soils are shallow and discontinuous and tend to accumulate in cracks and shallow depressions in the bedrock. Where present, they are <25 cm deep. In the spring, soils are saturated or even flooded where shallow depressions occur. The thin soils dry quickly and are usually very dry by late summer.

Dynamics: The thin soils and large changes in soil moisture during the growing season shape the vegetation of alvars. These conditions favor herbaceous species over woody species. The composition of alvars varies largely with the soil moisture from seasonal herbaceous wetlands to dry grassy areas to sparsely vegetation bedrock. Small shrublands or stunted woodlands can be found where soil accumulates (Reschke et al. 1998). Fires do not carry well on alvars in most years but they did occur with low frequency (Landfire 2007a). Woody species grow slowly on alvars, so even low frequency fires limited their abundance.

Component Associations:
- *Acer saccharum - Ostrya virginiana - Carya ovata - Quercus rubra* Limestone Woodland (CEGL005059, G3G4)
- *Carya ovata / Zanthoxylum americanum / Panicum philadelphicum - Carex pensylvanica* Wooded Herbaceous Vegetation (CEGL005230, GNR)
- *Danthonia spicata - Poa compressa - (Schizachyrium scoparium)* Herbaceous Vegetation (CEGL005100, G2?)
- *Deschampsia caespitosa - (Sporobolus heterolepis, Schizachyrium scoparium) - Carex crawei - Packera paupercula* Herbaceous Vegetation (CEGL005110, G2)
- *Juniperus communis - (Juniperus virginiana) - Rhus aromatica - Viburnum rafinesquianum / Oligoneuron album* Shrubland (CEGL005212, G3)
- *Juniperus horizontalis - Dasiphora fruticosa ssp. floribunda / Schizachyrium scoparium - Carex richardsonii* Dwarf-shrubland (CEGL005236, G2)
- *Juniperus virginiana / Ranunculus fascicularis* Woodland (CEGL005122, G3?)
- *Picea glauca - Thuja occidentalis - Juniperus communis / Iris lacustris - Carex eburnea* Shrubland (CEGL005211, G1G2)
- *Pinus banksiana - Thuja occidentalis - Picea glauca / Juniperus communis* Woodland (CEGL005126, G2?)
- *Sporobolus heterolepis - Schizachyrium scoparium - (Carex scirpoidea) / (Juniperus horizontalis)* Herbaceous Vegetation (CEGL005234, G2)
- *Sporobolus neglectus - Sporobolus vaginiflorus - Isanthus brachiatus - Panicum philadelphicum - (Poa compressa)* Alvar Herbaceous Vegetation (CEGL005235, G2)
- *Thuja occidentalis - Pinus banksiana / Dasiphora fruticosa ssp. floribunda / Clinopodium arkansanum* Wooded Herbaceous Vegetation (CEGL005132, G1G2)
- *Tortella tortuosa - Cladonia pocillum - Placynthium* spp. Sparse Vegetation (CEGL005192, G2)

DISTRIBUTION

Range: Alvars occur within the Great Lakes basin.

INTER-MOUNTAIN BASINS BIG SAGEBRUSH STEPPE (CES304.778)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Deep Soil; Aridic; Xeromorphic Shrub; Bunch grasses; Artemisia tridentata ssp. tridentata
Non-Diagnostic Classifiers: Lowland [Foothill]; Plain; Plateau; Woody-Herbaceous; Sideslope; Temperate [Temperate Continental]; Alkaline Soil; Forb; Graminoid
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2125; ESLF 5454; ESP 1125

CONCEPT

Summary: This widespread matrix-forming ecological system occurs throughout much of the Columbia Plateau and northern Great Basin, east into the Wyoming Basins, central Montana, and north and east onto the western fringe of the Great Plains in Montana and South Dakota. It is found at slightly higher elevations farther south. In central Montana, this system differs slightly, with more summer rain than winter precipitation, more precipitation annually, and it occurs on glaciated landscapes. Soils are typically deep and non-saline, often with a microphytic crust. This shrub-steppe is dominated by perennial grasses and forbs (>25% cover) with *Artemisia tridentata ssp. tridentata* (this is not at all important in Wyoming occurrences), *Artemisia tridentata ssp. xericensis*, *Artemisia tridentata ssp. wyomingensis*, *Artemisia tripartita ssp. tripartita* (Snake River valley in Wyoming), *Artemisia cana ssp. cana*, and/or *Purshia tridentata* dominating or codominating the open to moderately dense (10-40% cover) shrub layer. *Atriplex confertifolia*, *Chrysothamnus viscidiflorus*, *Ericameria nauseosa*, *Sarcobatus vermiculatus*, *Tetradymia* spp., or *Artemisia frigida* may be common especially in disturbed stands. In Montana and Wyoming, stands are more mesic, with more biomass of grass, have less shrub diversity than stands farther west, and 50 to 90% of the occurrences are dominated by *Artemisia tridentata ssp. wyomingensis* with *Pascopyrum smithii*. In addition, *Bromus japonicus* and *Bromus tectorum* are indicators of disturbance in the Intermountain West. Associated graminoids can include *Achnatherum hymenoides*, *Calamagrostis montanensis*, *Elymus lanceolatus ssp. lanceolatus*, *Koeleria macrantha*, *Poa secunda*, *Pascopyrum smithii*, *Hesperostipa comata*, *Nassella viridula*, *Bouteloua gracilis*, and *Pseudoroegneria spicata*. Important rhizomatous species include *Carex filifolia* and *Carex duriuscula*, which are very common and important in the eastern distribution of this system in both Wyoming and Montana. *Festuca idahoensis* is uncommon in this system, although it does occur in areas of higher elevations/precipitation; *Festuca campestris* is also uncommon. In Wyoming, both *Nassella viridula* and *Pseudoroegneria spicata* rarely occur, with the latter typically found in eastern Wyoming on ridgetops and rocky slopes outside of this system. In Montana, there is an absence of *Festuca* spp., except *Vulpia octoflora*. Common forbs are *Phlox hoodii*, *Arenaria* spp., *Opuntia* spp., *Sphaeralcea coccinea*, *Dalea purpurea*, *Liatris punctata*, and *Astragalus* spp. Areas with deeper soils more commonly support *Artemisia tridentata ssp. tridentata* but have largely been converted for other land uses. The natural fire regime of this ecological system likely maintains a patchy distribution of shrubs, so the general aspect of the vegetation is a grassland. Shrubs may increase following heavy grazing and/or with fire suppression, particularly in moist portions of the northern Columbia Plateau where it forms a landscape mosaic pattern with shallow-soil scabland shrublands. Where fire frequency has allowed for shifts to a native grassland condition, maintained without significant shrub invasion over a 50- to 70-year interval, the area would be considered Columbia Basin Foothill and Canyon Dry Grassland (CES304.993).
Classification Comments: *Artemisia cana ssp. cana* is listed as a component shrub of this system, but this statement needs a bit of review as to whether it is accurate. In addition, in Wyoming and Montana, *Artemisia tripartita ssp. tripartita* associations are not part of this system but occur at higher elevations as components of Inter-Mountain Basins Montane Sagebrush Steppe (CES304.785)%%. Farther west, they are included in this system (CES304.778), but perhaps this should be reviewed by ecologists familiar with the Columbia Basin region.
Similar Ecological Systems:
- Columbia Basin Foothill and Canyon Dry Grassland (CES304.993)
- Columbia Plateau Steppe and Grassland (CES304.083)
- Northern Rocky Mountain Lower Montane, Foothill and Valley Grassland (CES306.040)

- Threetip Sagebrush - Idaho Fescue (324) (Shiflet 1994) Broader. *Artemisia tripartita ssp. tripartita* communities are included in this ecological system.

DESCRIPTION

Environment: This widespread matrix-forming shrub-steppe occurs throughout much of the Columbia Plateau and northern Great Basin, east into the Wyoming Basins and central Montana. In central Montana, there is more summer rain than winter precipitation, more precipitation annually, and it occurs on glaciated landscapes. Soils are typically deep and non-saline, often with a microphytic crust.

Dynamics: The natural fire regime of this ecological system likely maintains patchy distribution of shrubs, so the general aspect of the vegetation is a grassland. Shrubs may increase following heavy grazing and/or with fire suppression, particularly in moist portions of the northern Columbia Plateau where it forms a landscape mosaic pattern with shallow-soil scabland shrublands. Where fire frequency has allowed for shifts to a native grassland condition, maintained without significant shrub invasion over a 50- to 70-year interval, the area would be considered Columbia Basin Foothill and Canyon Dry Grassland (CES304.993).

Response to grazing can be variable depending on the type of grazer and the season in which grazing occurs. *Hesperostipa comata* can decrease in abundance in response to either grazing or fire. In central and eastern Montana (and possibly elsewhere), complexes of prairie dog towns are common in this ecological system. Microphytic crust is very important in this ecological system.

Complex ecological interactions of fire regimes, grazing history, and climate patterns result in equally complex patterns of species structure and composition in *Artemisia tridentata* stands. Prolonged drought on the more xeric sites may reduce shrub cover. Flooding may also cause mortality if the soil remains saturated for an extended period of time. The Aroga moth is capable of defoliating large acreages (i.e., >1000 acres, but usually 10-100 acres). Heavy grazing by wildlife can remove the fine fuels that support mixed-severity fires and result in woody fuel buildup that leads to severe, stand-replacement fires (Landfire BpS 1210800) (Landfire 2007a).

Shrubs in big sagebrush steppe are reduced by fire as *Artemisia tridentata* does not sprout after burning (Tirmenstein 1999c). Excessive grazing may decrease fire frequency due to consumption of herbaceous forage (fine fuels) resulting in increased shrub density. Conversely, increasing fire frequency significantly will eliminate the shrubs from the stands (Daubenmire 1970, Tirmenstein 1999c). With a change in fire frequency, species composition will be altered as well (West 1983c). Locally in areas with a high fire frequency (every 2-5 years), perennial grasses and shrubs are eliminated and non-native annual grasses dominate. At fire-return intervals of 10-30 years, short-lived resprouting shrubs such as *Chrysothamnus* or *Tetradymia* spp. dominate. At fire-return intervals of 30-70 years, a mixture of perennial bunch grasses and non-sprouting shrubs is maintained (Johnson 2000b). Finally, in the complete absence of fire, deep-rooted shrubs such as *Artemisia tridentata* become dominant. At higher-elevation sites with absence of fire (>100 years), *Pinus monophylla* and *Juniperus* spp. trees may invade and eventually dominate sites (Tirmenstein 1999c). Alternatively, Bukowski and Baker (2013) concludes that *Artemisia tridentata* spp. *wyomingensis* steppe fire rotations are 171-342 years (fire regime V). *Artemisia tridentata ssp. wyomingensis* historical fire were longer than *Artemisia tridentata ssp. vaseyana*. Large, contiguous areas of sagebrush with large grass-dominated areas and small mosaics of grass and sagebrush composed the historical landscape. Sagebrush density was a common source of patchiness where "dense" sagebrush made up 24.5% of area and "scattered" sagebrush covered 16.3%. Modern fire rotations are shorter than historical fire rotations. Fire suppression may be advisable, as modern fire rotations are shorter than their historical counterparts (Bukowski and Baker 2013).

Component Associations:
- *Artemisia cana ssp. cana / Pascopyrum smithii* Shrub Herbaceous Vegetation (CEGL001556, G4)
- *Artemisia tridentata (ssp. tridentata, ssp. xericensis) / Pseudoroegneria spicata - Poa secunda* Shrub Herbaceous Vegetation (CEGL001019, G1)
- *Artemisia tridentata (ssp. tridentata, ssp. xericensis) / Pseudoroegneria spicata* Shrub Herbaceous Vegetation (CEGL001018, G1)
- *Artemisia tridentata / Festuca idahoensis* Shrub Herbaceous Vegetation (CEGL001530, G4Q)
- *Artemisia tridentata / Leymus cinereus* Shrub Herbaceous Vegetation (CEGL001458, G2G4)
- *Artemisia tridentata / Sporobolus cryptandrus - Achnatherum hymenoides* Shrub Herbaceous Vegetation (CEGL001545, G2?)
- *Artemisia tridentata ssp. tridentata - Grayia spinosa* Shrubland (CEGL001004, G5)
- *Artemisia tridentata ssp. tridentata / Distichlis spicata* Shrubland (CEGL001000, G5)
- *Artemisia tridentata ssp. tridentata / Festuca idahoensis* Shrubland (CEGL001014, G4?)
- *Artemisia tridentata ssp. tridentata / Hesperostipa comata* Shrubland (CEGL002966, G4?)
- *Artemisia tridentata ssp. tridentata / Leymus cinereus* Shrubland (CEGL001016, G2)
- *Artemisia tridentata ssp. tridentata / Pascopyrum smithii - (Elymus lanceolatus)* Shrubland (CEGL001017, G3?)

- *Artemisia tridentata ssp. tridentata / Pleuraphis jamesii* Shrubland (CEGL001015, G2G4)
- *Artemisia tridentata ssp. tridentata / Poa secunda* Shrubland (CEGL001008, G3G5)

National Mapping Codes: EVT 2115; ESLF 5404; ESP 1115

CONCEPT

Summary: This widespread ecological system occupies dry foothills and sandsheets of western Colorado, northwestern New Mexico, northern Arizona, Utah, and west into the Great Basin of Nevada and southern Idaho. It is typically found at lower elevations ranging from 1500-2300 m. This system is generally found at lower elevations and more xeric sites than Great Basin Pinyon-Juniper Woodland (CES304.773) or Colorado Plateau Pinyon-Juniper Woodland (CES304.767). These occurrences are found on lower mountain slopes, hills, plateaus, basins and flats often where juniper is expanding into semi-desert grasslands and steppe. The vegetation is typically open savanna, although there may be inclusions of more dense juniper woodlands. This savanna is typically dominated by *Juniperus osteosperma* trees with high cover of perennial bunch grasses and forbs, with *Bouteloua gracilis, Hesperostipa comata*, and *Pleuraphis jamesii* being most common. In the southern Colorado Plateau, *Juniperus monosperma* or juniper hybrids may dominate the tree layer. Pinyon trees are typically not present because sites are outside the ecological or geographic range of *Pinus edulis* and *Pinus monophylla*. It has been suggested that all *Juniperus osteosperma* stands in Wyoming be placed in Colorado Plateau Pinyon-Juniper Woodland (CES304.767). This savanna system does not occur in Wyoming.
Classification Comments: *Juniperus californica* savannas in the Central Valley of California and around the fringes of the Mojave Desert are not part of this ecological system. In many cases, they are the result of some disturbance removing an oak component from one of the several oak woodland and savanna systems of California.
Similar Ecological Systems:
- Colorado Plateau Pinyon-Juniper Woodland (CES304.767)
- Great Basin Pinyon-Juniper Woodland (CES304.773)

Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Woody-Herbaceous
Non-Diagnostic Classifiers: Mountainside; Mountain valley; Plateau; Sideslope; Toeslope/Valley Bottom; Temperate [Temperate Continental]; Long Disturbance Interval; F-Patch/Medium Intensity; Broad-Leaved Evergreen Shrub; Graminoid; Bunch grasses; Artemisia tridentata ssp. vaseyana
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2126; ESLF 5455; ESP 1126

CONCEPT

Summary: This ecological system includes sagebrush communities occurring at foothills (in Wyoming) to montane and subalpine elevations across the western U.S. from 1000 m in eastern Oregon and Washington to over 3000 m in the southern Rockies. In Montana, it occurs on mountain "islands" in the north-central portion of the state and possibly along the Boulder River south of Absarokee and at higher elevations. In British Columbia, it occurs between 450 and 1650 m in the southern Fraser Plateau and the Thompson and Okanagan basins. Climate is cool, semi-arid to subhumid. This system primarily occurs on deep-soiled to stony flats, ridges, nearly flat ridgetops, and mountain slopes. In general, this system shows an affinity for mild topography, fine soils, some source of subsurface moisture or more mesic sites, zones of higher precipitation and areas of snow accumulation. Across its range of distribution, this is a compositionally diverse system. It is composed primarily of *Artemisia tridentata ssp. vaseyana, Artemisia cana ssp. viscidula*, and related taxa such as *Artemisia tridentata ssp. spiciformis (= Artemisia spiciformis)*. *Purshia tridentata* may codominate or even dominate some stands. *Artemisia arbuscula ssp. arbuscula*-dominated shrublands commonly occur within this system on rocky or windblown sites. Other common shrubs include *Symphoricarpos* spp., *Amelanchier* spp., *Ericameria nauseosa, Peraphyllum ramosissimum, Ribes cereum*, and *Chrysothamnus viscidiflorus*. *Artemisia tridentata ssp. wyomingensis* may be present to codominant if the stand is clearly montane as indicated by montane indicator species such as *Festuca idahoensis, Leucopoa kingii*, or *Danthonia intermedia*. Most stands have an abundant perennial herbaceous layer (over 25% cover, in many cases over 50% cover), but this system also includes *Artemisia tridentata ssp. vaseyana* shrublands. Common graminoids include *Danthonia intermedia, Festuca arizonica, Festuca idahoensis, Hesperostipa comata, Poa fendleriana, Elymus trachycaulus, Bromus carinatus, Poa secunda, Leucopoa kingii, Deschampsia caespitosa, Calamagrostis rubescens*, and *Pseudoroegneria spicata*. Species of *Achnatherum* are common, including *Achnatherum nelsonii ssp. dorei, Achnatherum nelsonii ssp. nelsonii, Achnatherum hymenoides*, and others. In many areas, wildfires can maintain an open herbaceous-rich steppe condition, although at most sites, shrub cover can be unusually high for a steppe system (>40%), with the moisture providing equally high grass and forb cover.
Classification Comments: In Wyoming and Montana, *Artemisia tripartita ssp. tripartita* associations are part of this system, occurring at higher elevations than Inter-Mountain Basins Big Sagebrush Steppe (CES304.778). Farther west, they are included in that system, but perhaps this should be reviewed by ecologists familiar with the Columbia Basin region.

DESCRIPTION

Environment: This ecological system occurs in many of the western United States, usually at middle elevations (1000-2500 m). The climate regime is cool, semi-arid to subhumid, with yearly precipitation ranging from 25 to 90 cm/year. Much of this precipitation falls as snow. Temperatures are continental with large annual and diurnal variation. In general this system shows an affinity for mild topography, fine soils, and some source of subsurface moisture. Soils generally are moderately deep to deep, well-drained, and of loam, sandy loam, clay loam, or gravelly loam textural classes; soils often have a substantial volume of coarse fragments, and are derived from a variety of parent materials. This system primarily occurs on deep-soiled to stony flats, ridges, nearly flat ridgetops, and mountain slopes. All aspects are represented, but the higher elevation occurrences may be restricted to south- or west-facing slopes.
Vegetation: Vegetation types within this ecological system are usually less than 1.5 m tall and dominated by *Artemisia tridentata ssp. vaseyana, Artemisia cana ssp. viscidula*, or *Artemisia tridentata ssp. spiciformis*. A variety of other shrubs can be found in some

occurrences, but these are seldom dominant. They include *Artemisia rigida, Artemisia arbuscula, Ericameria nauseosa, Chrysothamnus viscidiflorus, Symphoricarpos oreophilus, Purshia tridentata, Peraphyllum ramosissimum, Ribes cereum, Rosa woodsii, Ceanothus velutinus*, and *Amelanchier alnifolia*. *Artemisia tridentata ssp. wyomingensis* may be present to codominant if the stand is clearly montane to subalpine as indicated by montane indicator species such as *Festuca idahoensis, Leucopoa kingii*, or *Danthonia intermedia*. The canopy cover is usually between 20-80%. The herbaceous layer is usually well represented, but bare ground may be common in particularly arid or disturbed occurrences. Graminoids that can be abundant include *Festuca idahoensis, Festuca thurberi, Festuca ovina, Elymus elymoides, Deschampsia caespitosa, Danthonia intermedia, Danthonia parryi, Stipa* spp., *Pascopyrum smithii, Bromus carinatus, Elymus trachycaulus, Koeleria macrantha, Pseudoroegneria spicata, Poa fendleriana*, or *Poa secunda*, and *Carex* spp. Forbs are often numerous and an important indicator of health. Forb species may include *Castilleja, Potentilla, Erigeron, Phlox, Astragalus, Geum, Lupinus*, and *Eriogonum, Balsamorhiza sagittata, Achillea millefolium, Antennaria rosea*, and *Eriogonum umbellatum, Fragaria virginiana, Artemisia ludoviciana, Hymenoxys hoopesii (= Helenium hoopesii)*, etc.
Dynamics: Healthy sagebrush shrublands are very productive, are often grazed by domestic livestock, and are strongly preferred during the growing season (Padgett et al. 1989). Prolonged livestock use can cause a decrease in the abundance of native bunch grasses and increase in the cover of shrubs and non-native grass species, such as *Poa pratensis*. *Artemisia cana* resprouts vigorously following spring fire, and prescribed burning may increase shrub cover. Conversely, fire in the fall may decrease shrub abundance (Hansen et al. 1995). *Artemisia tridentata* is generally killed by fires and may take over ten years to form occurrences of some 20% cover or more. The condition of most sagebrush steppe has been degraded due to fire suppression and heavy livestock grazing. It is unclear how long restoration will take to restore degraded occurrences.

DISTRIBUTION

Range: This system is found at montane and subalpine elevations across the western U.S. from 1000 m in eastern Oregon and Washington to over 3000 m in the southern Rockies. In British Columbia, it occurs in the southern Fraser Plateau and the Thompson and Okanagan basins. This system occurs in mapzone 20 on the Rocky Mountain island ranges and on the western edge with mapzone 19.

INTER-MOUNTAIN BASINS SEMI-DESERT SHRUB-STEPPE (CES304.788)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Woody-Herbaceous; Temperate [Temperate Xeric]; Alkaline Soil; Aridic; Very Short Disturbance Interval; G-Landscape/High Intensity; Graminoid
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Mechanical Disturbance; Broad-Leaved Evergreen Shrub; Xeromorphic Shrub; Thorn Shrub; Evergreen Sclerophyllous Shrub; Succulent Shrub; Dwarf-Shrub; Forb
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2127; ESLF 5456; ESP 1127

CONCEPT

Summary: This ecological system occurs throughout the intermountain western U.S., typically at lower elevations on alluvial fans and flats with moderate to deep soils, and extends into south-central Montana between the Pryor and Beartooth ranges where a distinct rainshadow effect occurs. This semi-arid shrub-steppe is typically dominated by graminoids (>25% cover) with an open shrub to moderately dense woody layer with a typically strong graminoid layer. The most widespread (but not dominant) species is *Pseudoroegneria spicata*, which occurs from the Columbia Basin to the northern Rockies. Characteristic grasses include *Achnatherum hymenoides, Bouteloua gracilis, Distichlis spicata, Poa secunda, Poa fendleriana, Sporobolus airoides , Hesperostipa comata, Pleuraphis jamesii*, and *Leymus salinus*. The woody layer is often a mixture of shrubs and dwarf-shrubs, although it may be dominated by a single species. Characteristic species include *Atriplex canescens, Artemisia tridentata, Chrysothamnus greenei, Chrysothamnus viscidiflorus, Ephedra* spp., *Ericameria nauseosa, Gutierrezia sarothrae*, and *Krascheninnikovia lanata*. *Artemisia tridentata* or *Atriplex canescens* may be present but does not dominate. Annual grasses, especially the exotics *Bromus japonicus* and *Bromus tectorum*, may be present to abundant. Forbs are generally of low importance and are highly variable across the range but may be diverse in some occurrences. The general aspect of occurrences may be either open shrubland with patchy grasses or patchy open herbaceous layers. Disturbance may be important in maintaining the woody component. Microphytic crust is very important in some stands.
Related Concepts:
- Sagebrush - Grass (612) (Shiflet 1994) Intersecting. In southwestern Montana.

DESCRIPTION

Environment: This ecological system occurs throughout the Intermountain West from the western Great Basin to the northern Rocky Mountains and Colorado Plateau at elevations ranging from 300 m up to 2500 m. The climate where this system occurs is generally hot in summers and cold in winters with low annual precipitation, ranging from 18-40 cm and high inter-annual variation. Much of the precipitation falls as snow, and growing-season drought is characteristic. Temperatures are continental with large annual and diurnal variations. Sites are generally alluvial fans and flats with moderate to deep soils. Some sites can be flat, poorly drained and intermittently flooded with a shallow or perched water table often within 1 m depth (West 1983). Substrates are generally shallow, calcareous, fine-textured soils (clays to silt-loams), derived from alluvium; or deep, fine to medium-textured alluvial soils with some source of subirrigation during the summer season. Soils may be alkaline and typically moderately saline (West 1983). Some occurrences occur on deep, sandy loam soils, or soils that are highly calcareous, but not deep sand with active dune fields (Hironaka et al. 1983).
Vegetation: The plant associations in this broadly defined system are characterized by a somewhat sparse to moderately dense (10-70% cover) shrub layer usually with a strong graminoid layer. The typically open woody layer is often a mixture of shrubs and dwarf-shrubs, although it may be dominated by a single species. Characteristic woody species include *Artemisia filifolia, Artemisia tridentata, Atriplex canescens, Ephedra cutleri, Ephedra nevadensis, Ephedra torreyana, Ephedra viridis, Ericameria nauseosa, Chrysothamnus viscidiflorus, Gutierrezia sarothrae, Krascheninnikovia lanata*, and *Sarcobatus vermiculatus*. Other shrubs occasionally present include *Purshia tridentata* and *Tetradymia canescens*. *Artemisia filifolia, Artemisia tridentata, Atriplex canescens*, or *Sarcobatus vermiculatus* may be present but does not dominate as it does in big sagebrush shrublands and steppes, or mixed salt-desert scrub systems. Trees are very rarely present in this system, but some individuals of *Pinus ponderosa, Juniperus scopulorum, Juniperus occidentalis*, or *Cercocarpus ledifolius* may occur. The herbaceous layer is dominated by bunch grasses which occupy patches in the shrub matrix. The most widespread species is *Pseudoroegneria spicata*, which occurs from the Columbia Basin to the northern Rockies. Other locally dominant or important species include *Sporobolus airoides, Leymus cinereus, Festuca idahoensis, Pascopyrum smithii, Bouteloua gracilis, Distichlis spicata, Pleuraphis jamesii, Elymus lanceolatus, Elymus elymoides, Koeleria macrantha, Muhlenbergia richardsonis, Hesperostipa comata*, and *Poa secunda*. Annual grasses, especially the exotics *Bromus japonicus* and *Bromus tectorum*, may be present to abundant. Forbs are generally of low importance and are highly variable across the range, but may be diverse in some occurrences. Species that often occur are *Symphyotrichum ascendens (= Aster adscendens), Collinsia parviflora, Penstemon caespitosus, Achillea millefolium, Erigeron compositus, Senecio* spp., and *Taraxacum officinale*. Other important genera include *Astragalus, Oenothera, Eriogonum*, and *Balsamorhiza*. Mosses and lichens may be

important ground cover. Forbs are common on disturbed weedy sites. Weedy annual forbs may include the exotics *Descurainia* spp., *Helianthus annuus*, *Halogeton glomeratus*, *Lactuca serriola*, and *Lepidium perfoliatum*.

KLAMATH-SISKIYOU XEROMORPHIC SERPENTINE SAVANNA AND CHAPARRAL (CES206.150)

CLASSIFIERS

Classification Status: Standard

Primary Division: Mediterranean California (206)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Serpentine; Mediterranean [Mediterranean Pluviseasonal-Oceanic]; Ultramafic with low Ca:Mg ratio
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2170; ESLF 5425; ESP 1170

CONCEPT

Summary: This ecological system occurs throughout the Klamath-Siskiyou region below 1500 m (4550 feet) on thin rocky soils below winter snow accumulations and typically experiences hot and dry summers. These savannas and shrublands are almost always found on ultramafic soils (gabbro, peridotite, serpentinite), especially on the Josephine Peridotite Formation in the western Klamaths, with very low Ca:Mg ratio. These systems are highly variable and spotty in distribution. This system represents the most xeromorphic of these environments, generally supporting savannas or shrublands in areas with high rainfall amounts (over 130 cm/year) that would usually support closed-canopy forests. Landforms can include rocky ridges and ridgetops, south-facing slopes and river terraces, or gravelly valley bottomlands. These contain mosaics or patches of open-canopy tree-savannas with chaparral understories or shrub-dominated chaparral. Shrubs will often have higher densities than the trees which are more limited due to the rocky/thin soils and are often stunted in growth-form. These can also be short-duration chaparrals in previously forested areas that have experienced crownfires. When present, trees tend to have a scattered, open canopy or can be clustered, over a usually continuous, dense shrub layer, but sometimes with a grassy understory. *Pinus jeffreyi* or occasionally *Pinus attenuata* can form a scattered tree layer over bunch grasses. Dense shrub layers can also be present in some stands, or form their own patches without trees, especially on ridges. *Quercus vacciniifolia, Quercus sadleriana* (coastal and wetter climate but found on xeric sties), *Lithocarpus densiflorus var. echinoides, Quercus garryana var. breweri* (drier, inland), *Ceanothus cuneatus, Ceanothus pumilus, Arctostaphylos viscida, Arctostaphylos X cinerea, Arctostaphylos canescens, Arctostaphylos nevadensis, Frangula californica (= Rhamnus californica),* and *Garrya buxifolia* represent some of the many chaparral shrubs that can be found in these habitats. Perennial grasses such as *Festuca roemeri, Achnatherum lemmonii, Melica,* and *Danthonia californica* may also be characteristic, although a diverse and often endemic forb component (including rare serpentine endemics) is usually present. This system tends to have lower diversity within stands than in the other serpentine woodland and shrubland systems. Locally occurring, stunted and open stands of *Pinus contorta* and *Pinus monticola* on serpentine at low elevation are included in this system. The grassy understory savannas tend to have understory burns, while shrub-dense stands will suffer intense, stand-replacing fires.

Classification Comments: While generally occurring on serpentine soils, these also can be found on rocky or shallow, non-serpentine soils. They are identified by their very dry, open appearance, and hence are distinguished from the similar Klamath-Siskiyou Lower Montane Serpentine Mixed Conifer Woodland (CES206.917) which occurs on less xeric sties and has a woodland physiognomy.

Similar Ecological Systems:
- Klamath-Siskiyou Lower Montane Serpentine Mixed Conifer Woodland (CES206.917)

Related Concepts:

LAURENTIAN ACIDIC ROCKY OUTCROP (CES201.019)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Ridge/Summit/Upper Slope; Rock Outcrops/Barrens/Glades; Glaciated; Acidic Soil
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 5463

CONCEPT

Summary: This Laurentian and near-boreal outcrop system is found across central southern Canada and the upper Midwest of the United States. It is found on ridges or summits of resistant acidic bedrock at low to mid elevations. The vegetation is patchy, often a mosaic of woodlands and open glades. The system is typically dominated by various conifers, including *Pinus banksiana* and *Picea mariana*, with occasional *Picea glauca* or *Populus tremuloides*. Hardwoods include *Quercus rubra, Quercus ellipsoidalis*, and *Populus tremuloides*. Structure can vary from treed to low heath shrubs to open lichen woodland. Exposure and occasional fire are the major factors in keeping the vegetation relatively open.
Classification Comments: See also Northern Appalachian-Acadian Rocky Heath Outcrop (CES201.571), which occurs to the east of this system's primary range and is characterized by granitic bedrock.
Similar Ecological Systems:
- Northern Appalachian-Acadian Rocky Heath Outcrop (CES201.571)--is similar but occurs east of the Great Lakes. *Picea rubens* is often present and *Quercus ellipsoidalis* is absent; *Pinus banksiana* is only rarely present.

LAURENTIAN PINE-OAK BARRENS (CES201.718)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Laurentian-Acadian (201)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2407; ESLF 5423; ESP 1407

CONCEPT

Summary: These pine-oak barrens occur in the northern and western Great Lakes region. They occur on sandplains/outwash habitats, with droughty, infertile sand or loamy sands and frequent fires (every 5-30 years). *Pinus banksiana, Pinus resinosa, Quercus ellipsoidalis*, and *Pinus strobus* are common overstory dominants. Prairie species are common throughout much of the range of the type. Common shrub and ground cover species include *Andropogon gerardii, Carex pensylvanica, Corylus americana, Schizachyrium scoparium*, and *Vaccinium angustifolium*. Oak grubs may be common under frequent burning. Catastrophic burns may create open bracken grasslands.
Classification Comments: his system covers the Great Lakes barrens. The eastern U.S. pine barrens fall into Northeastern Interior Pine Barrens (CES202.590) described under the Central Interior-Appalachian Division (202). The more southern North-Central Oak Barrens (CES202.727) overlaps this type along the "tension zone" of Minnesota and Wisconsin. Northward, this system is differentiated from more boreal systems with *Pinus banksiana* by absence of *Picea mariana* and the presence of many prairie species. Within the pine barrens landscape this system overlaps with Laurentian-Acadian Northern Pine-(Oak) Forest (CES201.719), which may occupy pine barrens sites that have not burned for more than 50 years.
Similar Ecological Systems:
- Laurentian-Acadian Northern Pine-(Oak) Forest (CES201.719)
- North-Central Oak Barrens (CES202.727)
- Northeastern Interior Pine Barrens (CES202.590)

Related Concepts:
- Jack Pine: 1 (Eyre 1980) Finer
- Northern Pin Oak: 14 (Eyre 1980) Finer

DESCRIPTION

Environment: These barrens occur on sandy outwash plains, glacial lakeplains, and broad riverine terraces. Soils are generally infertile, coarse-textured, and acidic sands and loamy sands. The landscape is flat to gently rolling.
Dynamics: Fire and droughty soil conditions maintain the characteristic open tree/shrub canopy and prairie-like understory of this system. The dry, relatively infertile soil limits the rate of tree growth, while periodic fires remove most tree regeneration and, less commonly, canopy trees. Fires are also necessary for regeneration of *Pinus banksiana*. Sites with finer-textured and more fertile soils need greater fire frequency, while sites with coarser-textured, less fertile soils need less frequent fires to maintain this system. The historical fire-return interval is 5-20 years (Landfire 2007a). Fire-return intervals of 20-30 years result in abundant woody cover. Occasional frost during the growing season, sustained drought, and catastrophic winds can kill canopy trees (*Quercus* spp. would be more affected by frost) (Kost et al. 2007).

Component Associations:
- *Pinus banksiana - (Pinus resinosa) - Quercus ellipsoidalis / Carex pensylvanica* Forest (CEGL002478, G4G5)
- *Pinus banksiana - (Quercus ellipsoidalis) / Schizachyrium scoparium* - Prairie Forbs Barrens Woodland (CEGL002490, G2)
- *Pinus banksiana - Pinus resinosa - (Quercus ellipsoidalis) / Carex pensylvanica* Wooded Herbaceous Vegetation (CEGL005124, G3G4)
- *Pinus banksiana / Vaccinium* spp. / *Pleurozium schreberi* Woodland (CEGL002441, G4G5)
- *Pinus strobus - Quercus alba - (Quercus velutina) / Andropogon gerardii* Wooded Herbaceous Vegetation (CEGL005127, G2?)
- *Populus tremuloides - Quercus (ellipsoidalis, macrocarpa) / Andropogon gerardii* Shrubland (CEGL002197, GNR)
- *Pteridium aquilinum - Bromus kalmii* Herbaceous Vegetation (CEGL005142, GNR)
- *Quercus ellipsoidalis - (Quercus macrocarpa)* Forest (CEGL002077, G4?)

DISTRIBUTION

Range: Occurs in the northern and western Great Lakes region.

LAURENTIAN-ACADIAN CALCAREOUS ROCKY OUTCROP (CES201.572)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Rock Outcrops/Barrens/Glades; Glaciated; Alkaline Soil; Circumneutral Soil
Non-Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Ridge/Summit/Upper Slope; Mesotrophic Soil; Very Shallow Soil; Udic; Consolidated; Intermediate Disturbance Interval; F-Patch/Medium Intensity
National Mapping Codes: ESLF 5461

CONCEPT

Summary: This outcrop system occurs in scattered locations from New England west to the Great Lakes. It occurs on ridges or summits of circumneutral to calcareous bedrock. Sites are often exposed and dry; however, there may be local areas of more moist conditions. The vegetation is often a mosaic of woodlands and open glades. This system may also occur on rocks that are primarily acidic but with a local influence of calcium through weathering.

Similar Ecological Systems:
- Central Appalachian Alkaline Glade and Woodland (CES202.602)

Related Concepts:
- Boreal Circumneutral Open Outcrop (Gawler and Cutko 2010) Finer
- Northern White-Cedar: 37 (Eyre 1980) Undetermined

Component Associations:
- *Acer saccharum - Ostrya virginiana - Carya ovata - Quercus rubra* Limestone Woodland (CEGL005059, G3G4)
- *Adiantum aleuticum - Asplenium* spp. *- Cerastium arvense* Sparse Vegetation (CEGL006104, G1G2)
- *Juniperus virginiana - Ostrya virginiana / Carex eburnea* Woodland (CEGL006180, G2G3)
- *Quercus macrocarpa / Danthonia spicata - (Geum triflorum)* Limestone Wooded Herbaceous Vegetation (CEGL005237, G1?)
- *Thuja occidentalis - Fraxinus pennsylvanica / Acer pensylvanicum* Woodland (CEGL006508, GNR)
- *Thuja occidentalis / Carex eburnea* Forest (CEGL006021, GNR)
- *Thuja occidentalis / Gaylussacia baccata - Vaccinium angustifolium* Woodland (CEGL006411, GNR)
- *Thuja occidentalis / Oligoneuron album* Woodland (CEGL006093, GNR)

LLANO ESTACADO CAPROCK ESCARPMENT AND BREAKS SHRUBLAND AND STEPPE (CES303.725)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Canyon
Non-Diagnostic Classifiers: Very Shallow Soil; Flood Scouring
National Mapping Codes: ESLF 3205

CONCEPT

Summary: This ecological system occurs on various surfaces that are sufficiently resistant to erosion to form breaks or escarpments along the eastern edge of the Llano Estacado in Texas. This includes sedimentary deposits such as sandstones, limestones, or shales, or less frequently, igneous formations such as basalt. It is sometimes associated with canyons or drainages, but not always. The system occupies slopes, but may continue over transitions to more level sites upslope and downslope. Soils are variable and this system can occur where there is little soil development. Rough Breaks Ecological Sites are characteristic of this system, but other sites such as Rocky Hill and Gravelly Ecological Sites may also be occupied by this system. The physiognomic character of occurrences ranges from sparsely vegetated to shrubland, to sparse woodland. Bare ground is often conspicuous, and herbaceous cover is usually dominated by mid- to short grasses such as *Aristida purpurea, Bouteloua curtipendula, Bouteloua gracilis, Bouteloua hirsuta,* and *Schizachyrium scoparium*. Forbs, including species such as *Artemisia ludoviciana, Calylophus* sp., *Chaetopappa ericoides, Krameria lanceolata*, and *Melampodium leucanthum*, may also be present. Shrub canopy may be dense, with some species reaching tree stature, and on some sites forming sparse woodland. Shrub and tree species include *Juniperus pinchotii, Juniperus ashei, Quercus mohriana, Rhus trilobata, Dalea formosa, Cercocarpus montanus, Prosopis glandulosa*, and *Gutierrezia sarothrae*.
Classification Comments: This system is differentiated from Southwestern Great Plains Canyon (CES303.664) by its location along the caprock escarpment along the eastern edge of the Llano Estacado in Texas.
Similar Ecological Systems:
- Southwestern Great Plains Canyon (CES303.664)

Related Concepts:
- Mohrs (Shin) Oak: 67 (Eyre 1980) Intersecting
- Rolling Plains: Breaks and Canyon Deciduous Shrubland (2106) (Elliott 2011) Finer
- Rolling Plains: Breaks and Canyon Evergreen Shrubland (2105) (Elliott 2011) Finer

DESCRIPTION

Environment: This system may occur on various surfaces that are sufficiently resistant to erosion to form breaks or escarpments. This includes sedimentary deposits such as sandstones, limestones, or shales, or less frequently, igneous formations such as basalt. Landforms include breaks and escarpments with slopes less than 20% as defined here, sometimes associated with canyons or drainages, but not necessarily. The system occupies slopes but may continue over transitions to more level sites upslope and downslope. The system may occur on various soils, as well as on sites where little soil development has occurred. Rough Breaks Ecological Sites are characteristic of this system, but other sites such as Rocky Hill and Gravelly Ecological Sites may also be occupied (Elliott 2011).
Vegetation: This system is closely related to, and may overlap with, Southwestern Great Plains Canyon (CES303.664), although the currently considered system is not confined strictly to canyons. The physiognomic character of occurrences ranges from sparsely vegetated to shrubland to sparse woodland. Bare ground is often conspicuous, and herbaceous cover is usually dominated by mid- to short grasses such as *Aristida purpurea, Bouteloua curtipendula, Bouteloua gracilis, Bouteloua hirsuta,* and *Schizachyrium scoparium*. Forbs, including species such as *Artemisia ludoviciana, Calylophus* sp., *Chaetopappa ericoides, Krameria lanceolata*, and *Melampodium leucanthum*, may also be present. Shrub canopy may be dense, with some species reaching tree stature and on some sites forming sparse woodland. Shrub and tree species include *Juniperus pinchotii, Juniperus ashei, Quercus mohriana, Rhus trilobata, Dalea formosa, Cercocarpus montanus, Prosopis glandulosa*, and *Gutierrezia sarothrae* (Elliott 2011).

DISTRIBUTION

Range: This system occurs along the escarpment breaks on the east side of the Llano Estacado in Texas.
Divisions: 303:C
Nations: US

MADREAN JUNIPER SAVANNA (CES301.730)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Woody-Herbaceous; Tropical/Subtropical [Tropical Xeric]; Evergreen Sclerophyllous Tree; Succulent Shrub; Juniperus coahuilensis, J. deppeana, J. pinchotii
Non-Diagnostic Classifiers: Alluvial flat; Sideslope; Toeslope/Valley Bottom; Alluvial plain; Alluvial terrace; Sand Soil Texture; F-Patch/Low Intensity; Graminoid
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Evergreen sparse tree canopy
National Mapping Codes: EVT 2116; ESLF 5405; ESP 1116

CONCEPT

Summary: This Madrean ecological system occurs in lower foothills and plains of southeastern Arizona, southern New Mexico extending into west Texas and Mexico. These savannas have widely spaced mature juniper trees and moderate to high cover of graminoids (>25% cover). The presence of Madrean *Juniperus* spp. such as *Juniperus coahuilensis*, *Juniperus pinchotii*, and/or *Juniperus deppeana* is diagnostic. *Juniperus monosperma* may be present in some stands; *Juniperus deppeana* has a broader range than this Madrean system and extends north into southern stands of Southern Rocky Mountain Juniper Woodland and Savanna (CES306.834). Stands of *Juniperus pinchotii* may be short and resemble a shrubland. Graminoid species are a mix of those found in Western Great Plains Shortgrass Prairie (CES303.672) and Apacherian-Chihuahuan Semi-Desert Grassland and Steppe (CES302.735), with *Bouteloua gracilis* and *Pleuraphis jamesii* being most common. In addition, these areas include succulents such as species of *Yucca*, *Opuntia*, and *Agave*. Juniper savanna expansion into grasslands has been documented in the last century.
Similar Ecological Systems:
- Apacherian-Chihuahuan Semi-Desert Grassland and Steppe (CES302.735)
- Western Great Plains Shortgrass Prairie (CES303.672)

Related Concepts:
- Sideoats Grama - Sumac - Juniper (735) (Shiflet 1994) Intersecting

MEDITERRANEAN CALIFORNIA MESIC SERPENTINE WOODLAND AND CHAPARRAL (CES206.928)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Mediterranean [Mediterranean Xeric-Oceanic]; Ultramafic with low Ca:Mg ratio; Shallow Soil; Udic; Broad-Leaved Evergreen Shrub; Cupressus sargentii
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Sideslope; Toeslope/Valley Bottom; Serpentine
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2034; ESLF 4221; ESP 1034

CONCEPT

Summary: This ecological system occurs in Mediterranean California in the north and south Coast Ranges and the northern Sierra Nevada, on cool northerly and concave slopes and toeslopes with thin, rocky, ultramafic (gabbro, peridotite, serpentinite) soils. Not all ultramafic outcrops support distinct vegetation; only those with very low Ca:Mg ratios impact biotic composition. These systems are highly variable and spotty in distribution, and the composition of individual stands can be very diverse, especially the shrubs (often individual species have low cover). *Cupressus sargentii, Pinus sabiniana, Garrya congdonii, Quercus durata, Umbellularia californica*, and *Frangula californica ssp. tomentella (= Rhamnus tomentella ssp. tomentella)* are characteristic. Common associates include *Heteromeles arbutifolia, Adenostoma fasciculatum*, and the California endemics *Arctostaphylos viscida ssp. pulchella* and *Ceanothus jepsonii*. In some settings *Arctostaphylos glauca, Styrax rediviva (= Styrax officinalis)*, or *Cercocarpus montanus var. glaber (= Cercocarpus betuloides)* can be common. Occasionally, *Chamaecyparis lawsoniana* may be present. Common grasses and forbs can include *Melica torreyana, Festuca idahoensis, Iris* spp., and locally endemic serpentine forbs (*Senecio* spp. and others). Structurally, this system is sometimes woodland in character, but it can also be an arborescent chaparral, depending on fire history. Herbaceous-dominated serpentine fens (and bogs) are treated in Mediterranean California Serpentine Fen (CES206.953).
Related Concepts:
- Knobcone Pine: 248 (Eyre 1980) Intersecting
- Pacific Ponderosa Pine: 245 (Eyre 1980) Broader

DESCRIPTION

Environment: This ecological system occurs in Mediterranean California in the northern and southern Coast Ranges and the northern Sierra Nevada, on cool northerly and concave slopes and toeslopes with thin, rocky, ultramafic (gabbro, peridotite, serpentinite) soils. Not all ultramafic outcrops support distinct vegetation; only those with very low Ca:Mg ratios impact biotic composition. Soils on ultramafics are usually shallow and skeletal, with little profile development (Kruckeberg 1984). Ultramafic soils impose the following stresses on plants: imbalance of calcium and magnesium, magnesium toxicity, low availability of molybdenum, toxic levels of heavy metals, sometime high alkalinity, low concentrations of some essential nutrients, and low soil water storage capacity (Kruckeberg 1984, Sanchez-Mata 2007). In some cases, the steepness of the slopes and general sparseness of the vegetation result in continual erosion.
Dynamics: Structurally, this system is sometimes woodland in character, but it can also be an arborescent chaparral, depending on fire history. Landfire (2007)a: Stand-replacing fires occur mostly in the shrub-dominated stages. In the conifer-dominated late-seral closed stage, surface fire is also important. Mean FRI is generally greater than that of the surrounding forested landscape (including the lower elevation California Mesic Chaparral (CES206.926) - perhaps double (Nagel and Taylor 2005) - due to the lack of flammability of many young shrub fields without a long history of fuel accumulation.

Within this system, *Cupressus sargentii* dominates some occurrences as woodlands or as dense shrubby thickets (Griffin and Critchfield 1976). This tree begins bearing cones by 3-7 years of age, and abundant cone crops are produced that require 2 years to mature. The serotinous cones remain closed on the tree until opened by the heat of a fire or from desiccation due to age. Seeds establish best on bare mineral soil. Seedling mortality is high on shaded sites with abundant litter because of damping-off fungi (Esser 1994b, Barbour 2007). *Cupressus sargentii (= Callitropsis sargentii)* has serotinous cones. Burned trees usually release large quantities of seed after fire, and seedlings establish as dense thickets. No information was available on fire-return intervals. To maintain a stand, fire-return intervals of greater than 7 years will allow new cone crops to develop (Esser 1994b).

The mesic chaparral stage of this system generally burns in high-intensity, stand-replacing crown fires that may burn thousands of acres in a single event (Landfire 2007a). However, there is a considerable range in the flammability of shrub species (e.g., *Adenostoma fasciculatum* is "flashier" than *Arctostaphylos* spp.). Large, stand-replacement events can interact with seed availability and, hence, influence post-fire successional pathways differently than for smaller, less severe fires. Mean fire-return intervals are highly variable across the range of this system depending on species composition and other factors. Sediment cores taken from the Santa Barbara Channel in central California dating from the 16th and 17th centuries indicate that large fires burned the Santa Ynez and Santa Lucia mountains every 40-60 years. Season of burning plays a large part in species composition. Occasionally, frost affects mortality and increases fuel buildup.

Quercus durata is an important shrub in this system. Plants sprout from swollen root crowns and root suckers after damage to their trunks; they sprout rapidly following fire (Sawyer et al. 2009). Small mammals and jays cache acorns, which other wildlife also eat.

Component Associations:
- *Cupressus sargentii* Woodland (CEGL003044, G2)
- *Quercus durata - Arctostaphylos glandulosa* Shrubland (CEGL003351, G3)
- *Umbellularia californica - Quercus agrifolia / Toxicodendron diversilobum* Forest (CEGL003175, G4)
- *Umbellularia californica / Polystichum munitum* Forest (CEGL003174, G4)

DISTRIBUTION

Range: This system occurs throughout Mediterranean California except in the Klamath Mountains and possibly into Oregon.
Divisions: 206:C
Nations: US
Subnations: CA, OR?
Map Zones: 2:C, 3:C, 4:C, 6:C, 7:P

NASHVILLE BASIN LIMESTONE GLADE AND WOODLAND (CES202.334)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades; Alkaline Soil; Graminoid
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2397; ESLF 5413; ESP 1397

CONCEPT

Summary: This system encompasses a range of plant communities associated with thin soils on flat areas of Ordovician limestone in the Inner Nashville Basin of Tennessee, with a few disjunct occurrences in Kentucky. The vegetation of this system includes sparsely vegetated rock outcrops, annual *Sporobolus* spp.-dominated grasslands, *Schizachyrium scoparium*-dominated perennial grasslands, seasonally wet herbaceous washes and seeps, shrublands, as well as woodlands dominated by *Juniperus virginiana* and oaks. *Echinacea tennesseensis* and *Astragalus bibullatus* are completely endemic to this system. There are numerous other disjunct and near-endemic plants.

Classification Comments: This system occupies a small portion of the landscape but many associations are only found in this system. The most closely related system is Central Interior Highlands Calcareous Glade and Barrens (CES202.691). Also included here are related disjunct examples in Kentucky on Mississippian limestones (EPA ecoregions 71a, 71e of Woods et al. (2002)).

Similar Ecological Systems:

- Central Interior Highlands Calcareous Glade and Barrens (CES202.691)--is typically found on sloping surfaces, not flatrocks, and has a broader distribution.

Related Concepts:

- Eastern Redcedar: 46 (Eyre 1980) Finer
- Limestone Flat-Rock Glade (Evans 1991) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is associated with thin soils on flat areas of Ordovician limestone in the Inner Nashville Basin of Tennessee (Ecoregion 71i of Griffith et al. 1998 and EPA 2004; Subsection 222Ed of Keys et al. 1995), with a few disjunct occurrences in Kentucky.

Vegetation: The vegetation of this system includes sparsely vegetated rock outcrops, annual *Sporobolus* spp.-dominated grasslands, *Schizachyrium scoparium*-dominated perennial grasslands, seasonally wet herbaceous washes and seeps, shrublands, as well as woodlands dominated by *Juniperus virginiana* and oaks. Other woody plants associated with this system include *Quercus shumardii, Cercis canadensis, Ulmus alata, Fraxinus quadrangulata,* and *Acer saccharum.* Characteristic shrubs include *Forestiera ligustrina, Rhus aromatica, Hypericum frondosum,* and *Frangula caroliniana*. Other herbaceous taxa include *Andropogon gerardii, Bouteloua curtipendula, Silphium trifoliatum, Silphium terebinthinaceum, Helianthus mollis, Grindelia lanceolata, Liatris* spp., *Hedyotis nigricans, Croton capitatus, Heliotropium tenellum, Isanthus brachiatus, Manfreda virginica, Ruellia humilis, Talinum calcaricum, Sedum pulchellum,* and *Panicum flexile*. *Echinacea tennesseensis* and *Astragalus bibullatus* are completely endemic to this system. There are numerous other disjunct and near-endemic plants, including *Astragalus tennesseensis, Dalea gattingeri,* and *Pediomelum subacaule* (Somers et al. 1986). Small-scale seepage areas and washes may contain *Eleocharis compressa, Nothoscordum bivalve, Isoetes butleri,* and *Hypoxis hirsuta*.

Dynamics: There is an apparent zonation or patchiness to glade/barren vegetation, with different zones that may be identified by their characteristic plant species (Quarterman et al. 1993). These zones are apparently relatively stable, with woody plant encroachment evident only in relation to the invasion of shrubs and trees into potholes or crevices where soil accumulates more rapidly.

Periodic droughts, fire, historic grazing, and ice storms all play a role in the dynamics of the system by restricting woody growth and maintaining the more open glade structure. Historic grazing by wild and domestic ungulate species represented a significant disturbance regime in the past. Regionally significant drought cycles lead to death or decline of *Juniperus virginiana*, as well as affecting the severity of other disturbance regimes. Severe droughts kill tree saplings growing in cracks and potholes, helping to retain the open character of the glades (Quarterman et al. 1993). Fire carries best in zones or areas dominated by perennial grasses, which provide the most abundant and consistent fuel. This zone is also the most vulnerable to succession, with *Juniperus virginiana* and various native (and exotic) shrubs occupying these areas in periods without disturbance (Landfire 2007a).

The ecological processes that maintain these open grasslands and glades within a forested matrix are not completely understood. Clearly periodic drought cycles of varying lengths play a role, along with fire and free-ranging grazing livestock, at least until the 1940s, when open range laws were changed (DeSelm 1994). Livestock confinement, habitat fragmentation, and the ingrowth of exotic shrubs have caused many examples of these communities to become more densely covered by woody plants, including the native but weedy *Juniperus virginiana var. virginiana*.

Open range laws and the use of fire to clear native grass pastures worked to keep large parts of the rural Nashville Basin in an open, grass-dominated condition, either as open, prairie-like areas, or as oak woodlands with a native grass and forb understory. This combination of conditions persisted until about 1945 (DeSelm 1994). In a Missouri study of presettlement fire using composite fire scar chronologies, Guyette and McGinnes (1982 as cited in Frost 1998) reconstructed a presettlement fire frequency of 3.2 years in Missouri cedar glade vegetation.

Component Associations:
- *Dalea foliosa - Mecardonia acuminata - Mitreola petiolata* Herbaceous Vegetation (CEGL004292, G2?)
- *Eleocharis (bifida, compressa) - Schoenolirion croceum - Carex crawei - Allium cernuum* Herbaceous Vegetation (CEGL004169, G2?)
- *Juniperus virginiana var. virginiana - Forestiera ligustrina - Rhus aromatica - Hypericum frondosum* Shrubland (CEGL003938, G3G4)
- *Juniperus virginiana var. virginiana - Fraxinus quadrangulata / Polymnia canadensis - (Astranthium integrifolium)* Woodland (CEGL003754, G3)
- *Quercus muehlenbergii - Juniperus virginiana / Schizachyrium scoparium - Manfreda virginica* Wooded Herbaceous Vegetation (CEGL005131, G2G3)
- *Quercus stellata / Viburnum rufidulum - Forestiera ligustrina / Andropogon gerardii* Woodland (CEGL003712, G2?)
- *Sedum pulchellum - Talinum calcaricum - Leavenworthia* spp. / *Nostoc commune* Herbaceous Vegetation (CEGL004346, G3)
- *Sporobolus (neglectus, vaginiflorus) - Aristida longispica - Panicum flexile - Panicum capillare* Herbaceous Vegetation (CEGL004340, G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Southern Interior Low Plateau Dry-Mesic Oak Forest (CES202.898)

DISTRIBUTION

Range: This system is restricted to flat areas of Ordovician limestone in the Inner Nashville Basin of Tennessee (Ecoregion 71i of Griffith et al. (1998); Subsection 222Ed of Keys et al. (1995)), as well as limited and disjunct examples on flat Mississippian limestones in Kentucky.

NORTH-CENTRAL INTERIOR OAK SAVANNA (CES202.698)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Woody-Herbaceous
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Deciduous sparse tree canopy
National Mapping Codes: EVT 2394; ESLF 5410; ESP 1394

CONCEPT

Summary: This system is found primarily in the northern glaciated regions of the Midwest with the largest concentration in the prairie-forest border ecoregion. It is typically found on rolling outwash plains, hills and ridges. Soils are typically moderately well- to well-drained deep loams. This system is typified by scattered trees over a continual understory of prairie and woodland grasses and forbs. *Quercus macrocarpa* is the most common tree species and can range from 10-60% cover. The understory is dominated by tallgrass prairie species such as *Andropogon gerardii* and *Schizachyrium scoparium* associated with several forb species. Historically, frequent fires maintained this savanna system within its range and would have restricted tree canopies to 10-30%. Fire suppression in the region has allowed trees to establish more dense canopies. Periodic, strong wind disturbances and browsing also impact this system. Much of this system has also been converted to urban use or agriculture, and thus its range has decreased considerably.

DESCRIPTION

Environment: This system is typically found on rolling tillplains, hills, and ridges in the glaciated Midwest. Soils are typically moderately well- to well-drained deep loams and fertile. Because fire is critical to maintaining this system, it is not found in fire-protected portions of the landscape.
Vegetation: *Quercus macrocarpa* is the most common tree species and can range from 10-60% cover. The understory is dominated by tallgrass prairie species such as *Andropogon gerardii*, *Calamagrostis canadensis*, and *Schizachyrium scoparium* associated with several forb species.
Dynamics: Historically, frequent fires maintained this savanna system within its range and would have restricted tree canopies to 10-30% cover with some portions having up to 60% tree canopy. On average, surface fires were very frequent (1- to 5-year return intervals) and maintained the open, herbaceous understory. Canopy trees were replaced when periodic longer fire-return intervals, due to chance, multi-year wet climatic cycles, or lack of burning by Native Americans, allowed oak seedlings to grow large enough to survive surface fires when they returned. If fire is absent for more than about 20-40 years, a site will transition to oak woodland/forest (Cottam 1949, Curtis 1959, Grimm 1981). Fire suppression in the region has allowed trees to establish more consistent dense canopies. Periodic, strong wind disturbances and browsing/grazing also impact this system through modification to the herbaceous layer and tree seedlings.

Component Associations:
- *Quercus alba - Quercus macrocarpa - Quercus rubra / Corylus americana* Woodland (CEGL002142, G3G4)
- *Quercus alba - Quercus macrocarpa / Andropogon gerardii* Wooded Herbaceous Vegetation (CEGL005121, G1)
- *Quercus macrocarpa - (Quercus alba, Quercus stellata) / Andropogon gerardii* Wooded Herbaceous Vegetation (CEGL002159, G1)
- *Quercus macrocarpa - (Quercus alba, Quercus velutina) / Andropogon gerardii* Wooded Herbaceous Vegetation (CEGL002020, G1)
- *Quercus macrocarpa - Quercus palustris - Quercus bicolor / Calamagrostis canadensis* Wooded Herbaceous Vegetation (CEGL005120, G1)
- *Quercus macrocarpa* Northern Tallgrass Wooded Herbaceous Vegetation (CEGL002158, G1G2)

DISTRIBUTION

Range: This system is found throughout the northern glaciated regions of the Midwest. Its main concentration, where it was likely the matrix type, is within the Prairie Forest Border of Minnesota, Wisconsin, Iowa, and Illinois. Conversion to urban uses and agriculture and fire suppression have significantly impacted the range of this system.

NORTH-CENTRAL INTERIOR QUARTZITE GLADE (CES202.699)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Woody-Herbaceous; Ridge/Summit/Upper Slope; Metamorphic Rock [Quartzite]; Very Shallow Soil; Cliff (Landform)
National Mapping Codes: ESLF 5459

CONCEPT

Summary: This quartzite woodland is found on rocky, hilly regions in the upper midwestern United States in the Baraboo Hills of Wisconsin. Stands occur on the brow of steep slopes that overlay quartzite or rhyolite bedrock that contains some fractures. Soils are thin (10-30 cm deep) silt loams, acidic (pH of 4.5-5.0), fertile, and rich in organic matter (10-15% organic matter). These glades represent forest openings dominated by relatively even-spaced, small-statured trees and a sparse shrub and sapling layer. The tree canopy is variable. These glades are dominated by *Quercus alba*, *Quercus macrocarpa*, or *Carya ovata* with an understory of herbaceous species such as *Carex pensylvanica*, *Antennaria plantaginifolia*, *Solidago ulmifolia*, and others. Lichens and mosses are common on the exposed bedrock. Drought strongly influences this system, although deer browsing and fire, at least historically, may also play a role in keeping the glade structure.
Classification Comments: This system was originally included with the Minnesota/South Dakota quartzite glades, but further discussion determined that those examples found within the Driftless Area are distinct from those farther west.

DESCRIPTION

Environment: Stands occur on the brow of steep slopes that overlay quartzite or rhyolite bedrock that contains some fractures. Exposed bedrock may average about 15%. The stands themselves have gentle slopes (2-11%), mostly with a southwestern aspect, but range from due east to due west. Glade soils are thin (10-30 cm deep) silt loams, acidic (pH of 4.5-5.0), fertile, and rich in organic matter (10-15% organic matter). The high organic matter content could be a function of low pH and droughtiness that inhibit decomposition of organic matter (West and Welsh 1998).
Vegetation: These glades represent forest openings dominated by relatively even-spaced, small-statured trees and a sparse shrub and sapling layer. The tree canopy is fairly closed, averaging about 75% (range of 57-82%). Either *Quercus alba* or *Carya ovata* dominate the canopy. *Quercus velutina* and *Quercus rubra* are much less common. Shrubs are nearly absent from all glades. Herbaceous species include *Carex pensylvanica*, *Antennaria plantaginifolia*, *Solidago ulmifolia*, and others. The flora is complicated by the fact that the glades likely served as refugia for prairie plants historically and now serve as refugia for woodland and savanna plants (P. West pers. comm. 2000).
Dynamics: Droughts and deer browse may currently interact to keep these glades open. Historically, the surrounding matrix of dry oak forests may have been more likely to burn, and those fires could have spread into the glades (West and Welsh 1998). These glades are thought to be more environmentally controlled, by shallow soils, which suggest that soil depth and the historic extent of the glade community may be positively correlated (P. West pers. comm. 2000). *Juniperus virginiana* was present on some of the glades but in low abundance (P. West pers. comm. 2000).

Component Associations:
- *Quercus alba - Carya ovata / Carex pensylvanica - Heuchera richardsonii* Quartzite Glade Woodland (CEGL005276, G2?)

DISTRIBUTION

Range: This system is known from a very restricted area on quartzite or rhyolite outcrops in the Baraboo Hills region of Wisconsin. Glades, including partially wooded glades, also occur on basalt in northwestern Wisconsin, on rhyolite in central Wisconsin, and at a few sites on various bedrock substrates, including quartzite, in northwestern Wisconsin, e.g., within the Nicolet portion of the Chequamegon-Nicolet National Forest.

NORTH-CENTRAL OAK BARRENS (CES202.727)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Deciduous sparse tree canopy
National Mapping Codes: EVT 2395; ESLF 5411; ESP 1395

CONCEPT

Summary: This system occurs on well-drained, coarse-textured sandy soils derived from glacial outwash, end moraine formations, lakeplain dune systems, and broad sandy river terraces in the north-central U.S. into Ontario, Canada. Soils range from almost pure sand, to loamy sand, to sandy loam. The soils have low fertility, organic matter, and moisture-retention capacity. Factors which affect seasonal soil moisture are strongly related to variation in this type. This oak barrens system is a scrubby, open-treed system dominated by graminoids and shrubs. Canopy structure varies from a dominant herbaceous ground layer with sparse, scattered "savanna" canopy (5-30%), through oak-dominated scrub, to a more closed woodland canopy (30-80%). The canopy layer is dominated by *Quercus velutina*, with some *Quercus ellipsoidalis, Quercus macrocarpa*, and *Quercus alba* (the latter more common eastward and in woodland conditions). Occasional *Pinus banksiana* can occur in the northern parts of the range. Species found in the herb layer include *Ambrosia psilostachya, Amphicarpaea bracteata, Artemisia ludoviciana, Andropogon gerardii, Calamovilfa longifolia, Carex pensylvanica, Carex* spp., *Comandra umbellata, Dichanthelium* spp., *Hesperostipa spartea (= Stipa spartea), Koeleria macrantha, Lupinus perennis, Schizachyrium scoparium, Sorghastrum nutans*, and *Tephrosia virginiana*. Fire was an important factor in maintaining this system. Oak wilt, droughts and, in some northern sites, frosts during the growing season also reduce tree cover.
Classification Comments: Black oak woodland variants may occur in this system, but because *Quercus velutina* and *Quercus ellipsoidalis* can sprout after stems have been killed by fires, stands generally have a somewhat scrubby structure that can vary from 10-60% cover over time. Some stands may occur on fairly mesic sands. In New England and (most of) New York, similar settings are occupied by pitch pine - oak barrens (Northeastern Interior Pine Barrens (CES202.590)) which are characterized by *Quercus ilicifolia*, not *Quercus ellipsoidalis*.
Similar Ecological Systems:
- Laurentian Pine-Oak Barrens (CES201.718)--is a pine-dominated system and lacks *Quercus velutina*.

Related Concepts:
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on well-drained, coarse-textured sandy soils derived from glacial outwash, end moraine formations, lakeplain dune systems, broad sandy river terraces, and sometimes on colluvium below sandstone bluffs. Soils range from almost pure sand, to loamy sand, to sandy loam. The soils have low fertility, organic matter, and moisture-retention capacity. Factors which affect seasonal soil moisture are strongly related to variation in this type.
Vegetation: This oak barrens system is a scrubby, open-treed system dominated by graminoids and shrubs. Canopy structure varies from a dominant herbaceous ground layer with sparse, scattered "savanna" canopy (5-30%), through oak-dominated scrub, to a more closed woodland canopy (30-80%). The canopy layer is dominated by *Quercus velutina*, with some *Quercus ellipsoidalis, Quercus macrocarpa*, and *Quercus alba* (the latter more common eastward and in woodland conditions). Occasional *Pinus banksiana* can occur in the northern parts of the range. Species found in the herb layer include *Ambrosia psilostachya, Amphicarpaea bracteata, Artemisia ludoviciana, Andropogon gerardii, Calamovilfa longifolia, Carex pensylvanica, Carex* spp., *Comandra umbellata, Sorghastrum nutans, Hesperostipa spartea (= Stipa spartea)*, and *Schizachyrium scoparium*.
Dynamics: Fire was an important factor in maintaining this system. Oak wilt and droughts also reduce tree cover. For more fertile sites, surface fires were very frequent (1- to 5-year return intervals) and important for maintaining the open canopy and herbaceous understory. This system was not as fire-dependent as more mesic savannas and woodlands, due to the relatively infertile and often droughty soils on which it occurred. Some examples retained an open canopy without frequent fires (Whitford and Whitford 1971). Canopy trees were replaced when periodic longer fire-return intervals, due to chance, multi-year wet climatic cycles, or lack of burning by Native Americans, allowed oak seedlings to grow large enough to survive surface fires when they returned. If fire is absent for more than about 20-40 years, a site will transition to oak woodland/forest (Curtis 1959).

Component Associations:
- *Quercus alba - (Quercus velutina) / Lespedeza virginica - Eupatorium hyssopifolium* Woodland (CEGL006433, GNR)
- *Quercus macrocarpa - (Quercus ellipsoidalis) / Schizachyrium scoparium - Koeleria macrantha* Wooded Herbaceous Vegetation (CEGL002160, G2)
- *Quercus velutina - (Quercus alba) - Quercus ellipsoidalis / Schizachyrium scoparium - Lupinus perennis* Wooded Herbaceous Vegetation (CEGL002492, G3)
- *Quercus velutina - (Quercus ellipsoidalis) - Quercus alba / Deschampsia flexuosa* Woodland (CEGL005029, GNR)

DISTRIBUTION

Range: This system is found in the north-central U.S. from North Dakota to western New York and westernmost Pennsylvania (mostly historic there) and into Ontario, Canada.

NORTHERN APPALACHIAN-ACADIAN ROCKY HEATH OUTCROP (CES201.571)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Ridge/Summit/Upper Slope; Rock Outcrops/Barrens/Glades; Glaciated; Acidic Soil
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Oligotrophic Soil; Very Shallow Soil; Mineral: W/ A-Horizon >10 cm; Mineral: W/ A-Horizon <10 cm; Loam Soil Texture; Sand Soil Texture; Udic; Consolidated; Long Disturbance Interval; F-Patch/Low Intensity; W-Landscape/Medium Intensity; Needle-Leaved Tree; Broad-Leaved Deciduous Tree; Broad-Leaved Shrub; Dwarf-Shrub; Graminoid; Nonvascular
National Mapping Codes: ESLF 5462

CONCEPT

Summary: This outcrop ecological system ranges across New England and adjacent Canada, and southward at higher elevations to northern Pennsylvania, on ridges or summits of resistant acidic bedrock. Throughout most of its range, it occurs at low to mid elevations (600-1000 m, lower on the coast of eastern Maine and the Maritimes). The vegetation is patchy, often a mosaic of woodlands and open glades. *Quercus rubra* and various conifers, including *Pinus strobus* and *Picea rubens*, or (especially near the coast) *Picea mariana*, are characteristic trees. Low heath shrubs, including *Kalmia angustifolia, Vaccinium angustifolium, Gaylussacia baccata*, and *Photinia melanocarpa*, are typically present. Exposure and occasional fire are the major factors in keeping the vegetation relatively open.
Classification Comments: This system transitions westward and northward into Laurentian Acidic Rocky Outcrop (CES201.019) and southward into Central Appalachian Pine-Oak Rocky Woodland (CES202.600). Where their ranges overlap or abut, this system is distinguished from the latter by the presence of more northern elements such as *Picea, Sorbus, Pinus banksiana*, etc., and lack of *Pinus rigida* and *Quercus ilicifolia* which may be found in the Central Appalachian system. This system overlaps with Laurentian Acidic Rocky Outcrop (CES201.019) only in New York state, where the latter occurs in the St. Lawrence - Champlain ecoregion (an extension of its Great Lakes affinities), and the present type occurs primarily in the Northern Appalachian ecoregion. Northward or at higher elevations, this system is replaced by Acadian-Appalachian Subalpine Woodland and Heath-Krummholz (CES201.568).
Similar Ecological Systems:
- Acadian-Appalachian Subalpine Woodland and Heath-Krummholz (CES201.568)--occurs at higher elevations.
- Central Appalachian Pine-Oak Rocky Woodland (CES202.600)
- Laurentian Acidic Rocky Outcrop (CES201.019)

NORTHERN ROCKY MOUNTAIN FOOTHILL CONIFER WOODED STEPPE (CES306.958)

CLASSIFIERS

Classification Status: Standard

Primary Division: Rocky Mountain (306)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Shallow Soil; Aridic; Short Disturbance Interval; F-Patch/Low Intensity; F-Landscape/Low Intensity; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Evergreen sparse tree canopy
National Mapping Codes: EVT 2165; ESLF 5426; ESP 1165

CONCEPT

Summary: This inland Pacific Northwest ecological system occurs in the foothills of the northern Rocky Mountains in the Columbia Plateau region and west along the foothills of the Modoc Plateau and eastern Cascades into southern interior British Columbia. It also occurs east across Idaho into the eastern foothills of the Montana Rockies. The system may also occur on the lower treeline slopes of the Wyoming Rockies. These wooded steppes occur at the lower treeline/ecotone between grasslands or shrublands and forests and woodlands, typically on warm, dry, exposed sites too droughty to support a closed tree canopy. This is not a fire-maintained system. The "savanna" character results from a climate-edaphic interaction that results in widely scattered trees over shrubs or grasses, and even in the absence of fire, a "woodland" or "forest" structure will not be obtained. Elevations range from less than 500 m in British Columbia to 1600 m in the central Idaho mountains. Occurrences are found on all slopes and aspects; however, moderately steep to very steep slopes or ridgetops are most common. This system can occur in association with cliff and canyon systems. It generally occurs on glacial till, glacio-fluvial sand and gravel, dune, basaltic rubble, colluvium, to deep loess or volcanic ash-derived soils, with characteristic features of good aeration and drainage, coarse textures, circumneutral to slightly acidic pH, an abundance of mineral material, rockiness, and periods of drought during the growing season. These can also occur on areas of sand dunes, scablands, and pumice where the edaphic conditions limit tree abundance. *Pinus ponderosa* (vars. *ponderosa* and *scopulorum*) and *Pseudotsuga menziesii* are the predominant conifers (not always together); *Pinus flexilis* may be present or common in the tree canopy. In interior British Columbia, *Pseudotsuga menziesii* is the characteristic canopy dominant. In transition areas with big sagebrush steppe systems, *Purshia tridentata, Artemisia tridentata ssp. wyomingensis, Artemisia tridentata ssp. tridentata*, and *Artemisia tripartita* may be common in fire-protected sites such as rocky areas. Deciduous shrubs, such as *Physocarpus malvaceus, Symphoricarpos albus*, or *Spiraea betulifolia*, can be abundant in more northerly sites or more moist climates. Important grass species include *Pseudoroegneria spicata, Poa secunda, Hesperostipa* spp., *Achnatherum* spp., and *Elymus elymoides*.
Classification Comments: This is not a fire-maintained system; it occurs on sites too droughty to support a closed tree canopy. It does burn with a high-frequency / low-intensity regime, but fire is not carried because of the sparse vegetation of the edaphically constrained sites (rock outcrops, dunes, super-dry, sparse trees over shrubs and sometimes grasses but widely spaced). True "savannas" with grassy understories and high-frequency / low-intensity fires are now placed into Northern Rocky Mountain Ponderosa Pine Woodland and Savanna (CES306.030). Ponderosa woodlands and "steppes" in eastern Wyoming, eastern and central Montana, including the Missouri River Breaks, are now included in Northwestern Great Plains-Black Hills Ponderosa Pine Woodland and Savanna (CES303.650). Southern Rocky Mountain Ponderosa Pine Woodland (CES306.648) and Southern Rocky Mountain Ponderosa Pine Savanna (CES306.649) mostly contain *Pinus ponderosa var. scopulorum, Pinus ponderosa var. ponderosa (= var. brachyptera),* and *Pinus arizonica var. arizonica (= Pinus ponderosa var. arizonica)*. The FRIS site describes different varieties of *Pinus ponderosa* and associated species. This ecological system of the northern Rockies is primarily *Pinus ponderosa var. ponderosa*. Johansen and Latta (2003) have mapped the distribution of two varieties (*Pinus ponderosa var. scopulorum* and *Pinus ponderosa var. ponderosa*) using mitochondrial DNA. They hybridize along the Continental Divide in Montana backing up the FRIS information.
Similar Ecological Systems:
- Northwestern Great Plains-Black Hills Ponderosa Pine Woodland and Savanna (CES303.650)

Related Concepts:
- Interior Ponderosa Pine: 237 (Eyre 1980) Intersecting
- Limber Pine: 219 (Eyre 1980) Intersecting
- Ponderosa Pine - Grassland (110) (Shiflet 1994) Intersecting. This SRM type includes edaphically-controlled open ponderosa over sparse grasses, corresponding to this system.
- Ponderosa Pine - Shrubland (109) (Shiflet 1994) Intersecting. This SRM type includes edaphically-controlled open ponderosa over shrubs, corresponding to this system.

DESCRIPTION

Environment: These wooded steppes occur at the lower treeline/ecotone between grasslands or shrublands and forests and woodlands, typically on warm, dry, exposed sites too droughty to support a closed tree canopy. The "savanna" character results from a climate-edaphic interaction that results in widely scattered trees over shrubs or grasses, and even in the absence of fire, a "woodland" or "forest" structure will not be obtained. Elevations range from less than 500 m in British Columbia to 1600 m in the central Idaho mountains. Occurrences are found on all slopes and aspects; however, moderately steep to very steep slopes or ridgetops are most

common. This system can occur in association with cliff and canyon systems. It generally occurs on glacial till, glacio-fluvial sand and gravel, dune, basaltic rubble, colluvium, to deep loess or volcanic ash-derived soils, with characteristic features of good aeration and drainage, coarse textures, circumneutral to slightly acidic pH, an abundance of mineral material, rockiness, and periods of drought during the growing season. These can also occur on areas of sand dunes, scablands, and pumice where the edaphic conditions limit tree abundance.

Dynamics: This is not a fire-maintained system. Periodic drought that limits tree establishment is the driving factor in this system. The concept is that of the climate-edaphic interaction that results in widely scattered trees over "shrub-steppe" of sage, bitterbrush, or sparsely distributed grasses. Tree growth is likely episodic, with regeneration episodes in years with available moisture. Tree density is limited in some areas by available growing space due to rocky conditions of the site. The tree canopy in this system will never reach woodland density or close due to the interaction of climate and edaphic factors, even in the absence of fire. This system burns occasionally, but the vegetation is sparse enough that fires are typically not carried through the stand. Fire frequency is speculated to be 30-50 years. This type usually has little surface fuel and replacement fires would be a function of extreme conditions, such as very high winds (Landfire 2007a). Western pine beetle is a significant disturbance and especially affects larger trees, while parasitic mistletoe can cause tree mortality in young and small trees.

Component Associations:

- *Pinus ponderosa - Pseudotsuga menziesii / Purshia tridentata* Woodland (CEGL000214, G3)
- *Pinus ponderosa / Artemisia tridentata - Purshia tridentata* Woodland (CEGL000178, G3)
- *Pinus ponderosa / Artemisia tridentata ssp. wyomingensis / Hesperostipa comata* Woodland (CEGL000179, G1)

- *Pinus ponderosa / Pseudoroegneria spicata* Woodland (CEGL000865, G4)
- *Pinus ponderosa / Purshia tridentata / Achnatherum hymenoides* Woodland (CEGL000196, G1)
- *Pinus ponderosa / Purshia tridentata / Achnatherum occidentale* Woodland (CEGL000198, G2)
- *Pinus ponderosa / Purshia tridentata* Woodland (CEGL000867, G3G5)
- *Pinus ponderosa* Scree Woodland (CEGL000878, G4)
- *Pseudotsuga menziesii / Purshia tridentata* Woodland (CEGL000909, G3Q)

DISTRIBUTION

Range: This system is found in the Fraser River drainage of southern British Columbia south along the Cascades into the Modoc Plateau of California, and the northern Rocky Mountains of Washington and Oregon. In the northeastern part of its range, it extends across the northern Rocky Mountains west of the Continental Divide into northwestern Montana and south to the Snake River Plain in Idaho. In Oregon, it is most common in south-central Oregon, in lands managed by the Lakeview District of the BLM, and by the adjacent Fremont and Deschutes national forests. It also occurs on the marginal lands coming south out of the Blue Mountains, on the edge of the northern Basin and Range.

OUACHITA NOVACULITE GLADE AND WOODLAND (CES202.314)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Ozark/Ouachita; Rock Outcrops/Barrens/Glades
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2505; ESLF 5427; ESP 1505

CONCEPT

Summary: This system represents a mosaic of glades and woodlands found on novaculite geology in the central Ouachita Mountains of western Arkansas and adjacent Oklahoma. Novaculite is a weakly metamorphosed rock of sedimentary origin that is primarily composed of microcrystalline quartz and chalcedony. Examples of this system generally occupy ridgetops at 450-640 m (1476-2100 feet) elevation. They are a mosaic of small woodlands scattered on ridges and upper slopes with outcrops and patches of talus scattered throughout. Some woodland or forest patches may appear as almost linear strips interspersed with grassy openings. Wooded patches have a variable, often patchy, structure with some areas of dense canopy interspersed with more open canopies and open grassy patches. In general, the grassy openings occur on shallow soils with exposed bedrock, while the woodlands occur on somewhat deeper soils. In all cases, these are fairly extreme growing conditions due to droughty, rocky soils.

Similar Ecological Systems:
- Ozark-Ouachita Dry Oak Woodland (CES202.707)
- Ozark-Ouachita Dry-Mesic Oak Forest (CES202.708)
- Ozark-Ouachita Shortleaf Pine-Oak Forest and Woodland (CES202.313)

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: The novaculite formation is of Devonian and Mississippian age and consists of novaculite interbedded with some shale, ranging in thickness from about 76 to 275 m (250-900 feet) (Arkansas Geological Commission 2001, Babcock et al. 2001). Examples of this system are found on ridgetops and south-facing sideslopes over fractured outcrops of novaculite, a hard, siliceous, weakly metamorphosed rock of sedimentary origin as a bedded, virtually pure silica chert deposited under geosynclinal conditions. It is primarily composed of microcrystalline quartz and chalcedony. The Arkansas Novaculite formation is of Devonian and Mississippian age and consists of novaculite interbedded with some shale. These glade openings can range in size from small (less than one hectare) to larger, often linear formations covering as much as 40 hectares.

Vegetation: Several distinct communities may be recognized at a local scale within this system. Open habitats may be characterized by sparse tree cover of dwarfed (1-3 m) *Quercus marilandica var. ashei*, which can sometimes occur in clumps. Herbaceous cover is 100%, except where bare rock is exposed or on talus. Lichens cover 40-70% of the exposed rock surface. Open community components of this system grade into more densely wooded types, with a variable structure, dominated by *Quercus stellata, Ulmus alata, Quercus marilandica, Juniperus virginiana var. virginiana, Pinus echinata*, and *Carya texana*. More submesic areas have *Quercus rubra*-dominated woodlands with *Carya texana* that may approach a forest physiognomy.

Dynamics: The structure of this system is thought to be controlled by edaphic factors, along with a combination of periodic fire and severe drought. Many existing overstory trees have multiple stems indicating past die-back due to severe drought of decades-long intervals. Summer leaf loss is common and snags extant. Minor droughts cause extensive die-backs in smaller stems and appear to maintain shrubby conditions in places and limit the abundance and distribution of shortleaf pine. Historically, fire is thought to have played a more important role than today in maintaining the open canopy. A lack of fire presumably decreases the extent of the glade openings and allows a change in structure through increased coverage by shrubs and trees. The trees, when present, are dwarfed and often multi-stemmed from drought die-back. Summer leaf loss is common.

Component Associations:
- *Quercus marilandica var. ashei / Schizachyrium scoparium - Andropogon gerardii - Monarda fistulosa var. stipitatoglandulosa - Streptanthus maculatus* / Lichens Novaculite Glade Wooded Herbaceous Vegetation (CEGL007825, G3)
- *Quercus rubra / Ostrya virginiana / Ptelea trifoliata - Ribes curvatum / Helianthus divaricatus* Woodland (CEGL007828, G3)
- *Quercus stellata - Ulmus alata - (Juniperus virginiana var. virginiana) / Sporobolus clandestinus - Monarda fistulosa var. stipitatoglandulosa* Woodland (CEGL003756, G2)
- *Toxicodendron radicans / (Polymnia cossatotensis)* Sparse Vegetation (CEGL003889, G1)

DISTRIBUTION

Range: This system is endemic to the central Ouachita Mountains in Arkansas and adjacent Oklahoma.

OUACHITA SHALE GLADE AND BARRENS (CES202.343)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades
National Mapping Codes: ESLF 5432

CONCEPT

Summary: This ecological system is found in scattered locations in the Ouachita Mountains of Arkansas. It occurs on gently sloping to steep south- and west-facing slopes and in broad, flat and gently sloping drainages where shale bedrock outcrops comes near to the surface of the ground. It is characterized by treeless, open glades which grade into open woodlands along gradients of soil depth and moisture. Both glades and woodlands may support exceptionally diverse plant communities and appear to have been maintained in an open condition by a combination of fire and edaphic factors. Vegetation in these barrens is highly heterogeneous and ranges from xeric patches of exposed bedrock with sparse vascular plant cover, to rich mucky seepage meadows, to prairie-like grasslands, to shrub thickets, to open woodlands over a small area. Much of the non-bedrock ground in these barrens lacks organic soil but consists of a soft, friable, dark gray or tan shale residuum that retains moisture in the wet season but becomes very dry in the summer and early fall. Depressions in flat areas may contain thin layers of dark, seasonally-wet, organic-rich soil over bedrock. This system supports more than 600 species of vascular plants including 36 species of state conservation concern in Arkansas and more than 20 globally critically imperiled, imperiled, or vulnerable species (G1-G3).

Similar Ecological Systems:

- Central Interior Highlands Calcareous Glade and Barrens (CES202.691)
- Central Interior Highlands Dry Acidic Glade and Barrens (CES202.692)

DESCRIPTION

Environment: This system can be divided into two subtypes based on slope and hydrology: (1) steep, xeric barrens occurring on slopes above small stream drainages which are exceedingly well-drained, and (2) gently sloping to flat barrens occurring in small erosional valleys, often along intermittent streams. The valley-bottom barrens often have a wet component, at least during the spring. Several of the shale formations that outcrop in these barrens in Arkansas also contain thin interbedded limestones and provide habitat for several species typically associated with calcareous habitat and which are uncommon or rare in the Ouachita Mountains. Examples of these include *Ophioglossum engelmannii, Ratibida pinnata, Pellaea atropurpurea, Sporobolus compositus var. compositus, Nemastylis nuttallii, Carex meadii, Scleria verticillata*, and *Hypericum sphaerocarpum*. In addition, these glades and woodlands provide habitat for a number of plant taxa of conservation concern and are of significant conservation importance. One species, *Sabatia arkansana* Pringle & Witsell, was recently described new-to-science from this habitat and is known only from Saline County, where it is apparently restricted to shale barrens and igneous glades (Pringle and Witsell 2005).

Vegetation: The most extreme areas, with very shallow soils adjacent to bare rock outcrops, are dominated by annual forbs and grasses with a very few extremely drought-tolerant perennials. Characteristic species include *Ptilimnium nuttallii, Ambrosia bidentata, Astranthium integrifolium ssp. ciliatum (= Astranthium ciliatum), Krigia virginica, Hypericum drummondii, Hypericum gentianoides, Croton willdenowii, Phacelia hirsuta, Clinopodium arkansanum (= Calamintha arkansana), Isanthus brachiatus (= Trichostema brachiatum), Oenothera linifolia, Plantago virginica, Polygonum tenue, Diodia teres, Valerianella longiflora, Valerianella nuttallii, Aristida dichotoma var. curtissii, Panicum flexile, Sporobolus vaginiflorus*, and *Vulpia octoflora*.

Seasonally wet microhabitats occur along drainages within flat, open shale glades. These areas include thin, seasonally saturated organic soils in the floodplains of small streams and scattered areas over bedrock where water stands in shallow pools during the wet season. Small seepage zones also occur where water continues to seep out along the bedrock surface into the summer, keeping the thin soil moist. These microhabitats support a distinctive assemblage of species characterized by *Isoetes butleri, Isoetes melanopoda, Selaginella apoda, Selenia aurea, Minuartia patula, Sedum pulchellum, Sabatia arkansana, Clinopodium arkansanum, Talinum calycinum (= Phemeranthus calycinus), Houstonia pusilla (= Hedyotis crassifolia), Allium canadense var. mobilense, Bulbostylis capillaris, Cyperus squarrosus, Fimbristylis autumnalis, Isolepis molesta (= Isolepis pseudosetacea),* and *Agrostis elliottiana*. Wet spots on deeper soils along ephemeral streams and drains within glades support a variety of shrubs, including *Symphoricarpos orbiculatus, Hypericum lobocarpum, Hypericum prolificum, Cornus obliqua, Amorpha nitens, Amorpha ouachitensis*, and *Salix caroliniana*. Herbaceous-dominated areas in drains support *Amsonia hubrichtii, Arnoglossum plantagineum, Mitreola petiolata, Spigelia marilandica, Cuphea viscosissima, Eleocharis wolfii, Juncus secundus*, and *Steinchisma hians*.

Adjacent woodlands are dominated by stunted, open-grown *Pinus echinata, Quercus stellata, Quercus muehlenbergii, Juniperus virginiana, Nyssa sylvatica*, and *Carya texana*, with *Quercus alba, Fraxinus americana, Sideroxylon lanuginosum*, and *Ulmus alata* as locally important species. Shrubs include *Rhus aromatica, Rhus copallinum, Symphoricarpos orbiculatus, Celtis tenuifolia, Hypericum prolificum*, and *Vaccinium arboreum*. The herbaceous layer is diverse and well-developed and is dominated by *Chasmanthium sessiliflorum, Piptochaetium avenaceum, Schizachyrium scoparium, Sporobolus* spp., and *Danthonia spicata*. There is typically a diverse herbaceous layer similar to that of the deeper soil areas of the glades. Without fire, extreme drought, or some other

vegetation management, these sites become encroached by woody vegetation, especially *Juniperus virginiana*.
Dynamics: Fire is the primary natural dynamic and prescribed fires help manage this system by restricting woody growth and maintaining the more open glade structure.

Component Associations:
- *Schizachyrium scoparium - Sporobolus clandestinus - Grindelia lanceolata - Opuntia humifusa - (Eriogonum longifolium)* Dry Shale Glade Herbaceous Vegetation (CEGL007117, G3?)

DISTRIBUTION

Range: This system is endemic to the central Ouachita Mountains in Arkansas and adjacent Oklahoma.

PALEOZOIC PLATEAU BLUFF AND TALUS (CES202.704)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Woody-Herbaceous; Herbaceous; Unglaciated; Bluff
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2517; ESLF 5430; ESP 1517

CONCEPT

Summary: This system is found in the driftless regions of southeastern Minnesota, southwestern Wisconsin, and northern Iowa and Illinois. This region was not glaciated like the surrounding areas and thus is predominated by rolling hills and bluff outcrops. This system is found primarily on blufftops and dry upper slopes along the Upper Mississippi River, although it can range into bordering regions such as the Baraboo Hills in Wisconsin. This system contains a mosaic of woodlands, savannas, prairies and sparsely vegetated limestone, dolomite, and/or sandstone outcrops, with occasional talus, especially algific talus. Soils range from thin to moderately deep and are moderately to excessively well-drained with a high mineral content. Woodlands consist of primarily a mixture of oak species such as *Quercus macrocarpa, Quercus rubra, Quercus muehlenbergii*, and *Quercus alba*. *Acer saccharum, Betula alleghaniensis*, and conifer species such as *Pinus* spp. and *Tsuga canadensis* may occur on more mesic and protected areas within this system. Prairie openings (also called "goat prairies") contain *Schizachyrium scoparium* and *Bouteloua curtipendula* with scattered *Juniperus virginiana*. Historically, fire was the most important dynamic maintaining these systems, however, fire suppression within the region has allowed more canopy cover and thus very few prairie openings remain. Algific talus harbors a number of unusual Pleistocene relict species, including plants and snails.
Classification Comments: This system will need review from Minnesota, Wisconsin and Iowa to make sure it is correctly characterized.
Similar Ecological Systems:
- Central Interior Calcareous Cliff and Talus (CES202.690)

Related Concepts:

- Eastern White Pine: 21 (Eyre 1980) Finer
- Hemlock - Yellow Birch: 24 (Eyre 1980) Finer
- Red Pine: 15 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is found on an unglaciated landscape that is predominated by rolling hills and bluff outcrops. This system is found primarily on blufftops and dry upper slopes along the Upper Mississippi River, although it can range into bordering regions such as the Baraboo Hills in Wisconsin. This system contains limestone, dolomite, and/or sandstone outcrops, with occasional talus, especially algific talus. Soils are primarily loess and range from thin to moderately deep and are moderately to excessively well-drained with a high mineral content.
Dynamics: This is a diverse system with different ecological processes necessary for different aspects. Fire is important for maintaining the prairie and dry oak aspects of the system, but the steep slope and thin soil reduce the suitability for many other species, so fire frequency does not need to be as high as in more fertile prairies and oak woodlands. The prolonged absence of fire will favor shrub and tree invasion of the prairie and an increase in mesophytic trees and shrubs in the oak forests and woodlands (Nowacki and Abrams 2008). The cooler, more mesic aspects of the system with significant conifers (*Pinus strobus, Pinus resinosa,* and *Tsuga canadensis*) occur in protected ravines or on steep slopes with little soil development, and fire is not important in establishing or maintaining these communities (McIntosh 1950, Kline and Cottam 1979). These communities occur where there are cooler summer soil and air temperatures and on this soiled sites over acidic bedrock (McIntosh 1950, Adams and Loucks 1971).

Component Associations:
- *Impatiens pallida - Cystopteris bulbifera - Adoxa moschatellina - (Chrysosplenium iowense, Aconitum noveboracense)* Algific Talus Herb Vegetation (CEGL002387, G2)
- Midwest Maderate Cliff Vegetation (CEGL002293, G3?)
- *Pinus strobus - (Pinus resinosa)* Driftless Bluff Forest (CEGL002378, G2G3)
- *Pinus strobus - Abies balsamea - Betula alleghaniensis* Driftless Forest (CEGL002111, G2?)
- *Quercus muehlenbergii - Quercus (alba, velutina) - (Juniperus virginiana var. virginiana)* Bluff Woodland (CEGL002144, G2G3)
- *Schizachyrium scoparium - Bouteloua curtipendula - Muhlenbergia cuspidata - Symphyotrichum sericeum* Alkaline Herbaceous Vegetation (CEGL002403, G2)
- *Schizachyrium scoparium - Bouteloua curtipendula* Bedrock Bluff Herbaceous Vegetation (CEGL002245, G3G4)
- *Tsuga canadensis - Acer saccharum / (Hepatica nobilis var. acuta)* Driftless Forest (CEGL002597, G2)

DISTRIBUTION

Range: This system is found within the Paleozoic Plateau (aka Driftless Region) of southeastern Minnesota, southwestern Wisconsin and northern Iowa and Illinois.

PANHANDLE FLORIDA LIMESTONE GLADE (CES203.534)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: ESLF 5422

CONCEPT

Summary: This small-patch limestone glade and outcrop system is nearly endemic to the Panhandle of Florida (primarily Gadsden and Jackson counties), and is also found in adjacent Decatur County, Georgia. It includes a range of open limestone outcrops on hillsides and hill crests where soils are either shallow or absent, as well as shaded mesic lower slopes near the floodplain of the Chipola River.

Related Concepts:
- Upland Glade (FNAI 1990) Equivalent
- Upland Glade, Chalky Limestone Glade subtype (FNAI 1992b) Undetermined

DESCRIPTION

Environment: These calcareous glades of the warm temperate Southeastern Coastal Plain are found in rather soft, chalky limestone, in Gadsden and Jackson counties, Florida, and Decatur County, Georgia (Ward and Gholson 1987, FNAI 1990). In Gadsden County, these matrix soils are Binnsville soils or Cuthbert, Boswell, and Susquehanna soils on moderate to steep slopes (Thomas et al. 1961b). In Jackson County, the matrix soils are the Oktibbeha variant rock outcrop complex (Duffee et al. 1979).

Vegetation: On the open calcareous glades, the dominant herbaceous species are *Schoenus nigricans, Hedyotis nigricans var. nigricans, Muhlenbergia capillaris var. capillaris, Andropogon* sp., *Setaria* sp., *Helianthus radula*, and *Dichanthelium* sp. Some additional forbs are *Callirhoe papaver, Rudbeckia fulgida, Aristida* spp., *Delphinium carolinianum ssp. carolinianum, Stachys crenata, Lepuropetalon spathulatum, Solidago discoidea, Liatris squarrosa, Symphyotrichum pratense (= Aster sericeus var. microphyllus), Asclepias viridis, Asclepias viridiflora, Ponthieva racemosa, Carex cherokeensis, Rhynchospora* spp., and *Selaginella ludoviciana*. *Nostoc commune* is abundant on the exposed limestone. Woody species occurring in soil islands and borders of the limestone outcrops are *Berchemia scandens, Cercis canadensis var. canadensis, Sideroxylon* sp., *Morella cerifera (= Myrica cerifera), Diospyros virginiana, Fraxinus americana, Ulmus alata, Acer leucoderme, Rhus copallinum, Crataegus spathulata, Yucca filamentosa (= Yucca flaccida)*, and *Viburnum* sp. Also included here are shaded limestone outcrops with herbaceous vegetation found near the Chipola River; these outcrops are dominated by *Aquilegia canadensis, Polymnia laevigata, Thelypteris kunthii, Asplenium heterochroum, Oxalis* sp., *Pilea pumila, Laportea canadensis, Pachysandra procumbens, Urtica chamaedryoides, Melica mutica, Arenaria lanuginosa, Chaerophyllum tainturieri*, and *Carex willdenowii*. Bryophytes are locally abundant and include *Anomodon attenuatus, Conocephalum conicum*, and *Marchantia* sp. Shrubs and woody vines, such as *Decumaria barbara, Hydrangea quercifolia, Ptelea trifoliata*, and *Acer barbatum*, are sometimes rooted in solution pockets in the tops and sides of the outcrops and can be locally abundant. The alien *Lonicera japonica* may also be rooted in these solution pockets and may dominate parts of lower quality examples.

Dynamics: Although the ecology of the upland glade community has not been studied, it seems a reasonable working hypothesis that soil depth prevents woody colonization on the rockier portions of the glades, such as those areas dominated by *Hedyotis nigricans (= Stenaria nigricans)* and *Sporobolus vaginiflorus*, as has been proposed for herbaceous portions of limestone glades in Tennessee and Alabama (Quarterman 1950, Quarterman et al. 1993, Baskin and Baskin 1999). A small study measuring soil depth and pH on transects across three of the Gadsden County glades (Coultas 1983) lends support to this hypothesis for the Florida upland glades (FNAI 2010c). Portions of the glades supporting taller grasses such as *Muhlenbergia capillaris* and *Schizachyrium scoparium* may be more susceptible to woody encroachment, since increases in cover of *Juniperus virginiana* have been observed at some glades over the course of several decades. Fire may have swept through upland glades at irregular intervals, especially those that were bordered by longleaf pine-dominated upland or sandhill communities that would have naturally tended to burn frequently. These fires would play a role in preventing woody species from shading out the characteristic graminoid dominants (FNAI 2010c). Casual observation of one burn on a glade indicated that the herbaceous species recovered to pre-burn levels of cover within a year or two, but the question of natural fire interval for this community needs more research. Growing season burns on experimental plots on a glade in Georgia also showed little effect on 14 herbaceous species of conservation concern two years later, but did result in a dramatic decline in populations of young trees on the glade (Duncan et al. 2008). Occasional droughts may also play a similar role in retarding woody growth on the glade. An additional environmental factor in glades is the alternation between wet and dry soils. Soils on the herbaceous portion of the glades are often wet and "mushy" in early spring and become nearly completely dry by fall.

Component Associations:
- *Aquilegia canadensis - Asplenium heterochroum - Polymnia laevigata - Urtica chamaedryoides* Herbaceous Vegetation (CEGL004268, G1?)

- *Schoenus nigricans - Hedyotis nigricans* Wooded Herbaceous Vegetation (CEGL004081, G1)

SPATIAL CHARACTERISTICS

Size: Glades occur in very small areas, <1.0 hectare.

DISTRIBUTION

Range: This system is nearly endemic to the Panhandle of Florida (primarily Gadsden and Jackson counties), and is also found in adjacent Decatur County, Georgia.

SOUTH-CENTRAL SALINE GLADE (CES203.291)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades; Very Shallow Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: ESLF 5418

CONCEPT

Summary: This system occurs in portions of the Gulf Coastal Plain west of the Mississippi River on soils with high saline content, which in the most extreme examples are generally not conducive to woody plant growth. Thus, the vegetation forms a mosaic primarily consisting of open herbaceous or shrubby plant communities. This type is most common and best documented in Arkansas and western Louisiana, but also occurs in eastern Texas. At least one high-ranked plant species, *Geocarpon minimum*, occurs in this system. In some cases, this system may be associated with inland salt domes when the proximity of such a structure to the surface produces high salinity in the surface soils. Otherwise, surface geology of various formations may contain sufficient alkalinity such that leaching from particular members of these formations gives rise to such conditions.
Classification Comments: In Arkansas, the forested examples of this system are called "Alkali Post Oak Flat," and the herbaceous examples are called "Alkali Wet Prairie" (Arkansas Multi-Agency Wetland Planning Team 2001).
Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Pineywoods: Saline Glade (4207) [CES203.291] (Elliott 2011) Equivalent
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on soils with high saline content, including Glossic Natraqualfs, which in the most extreme examples are generally not conducive to woody plant growth. The soils on which this system is found have high pH and high levels of sodium or magnesium salts in or near the surface layer. They typically have very poor drainage and a shallow hardpan. The combination of impeded drainage and unusual soil chemistry restricts the potential plant communities and provides habitat for certain rare species. The forested community apparently occurs on soils with deeper hardpans than the prairie communities. These sites are often associated with streams or drainages, sometimes occurring on terraces (Elliott 2011). Most sites with alkali soils are believed to be former (Pleistocene) lakebeds (Arkansas Multi-Agency Wetland Planning Team 2001). In some cases, this system may be associated with inland salt domes when the proximity of such a structure to the surface produces high salinity in the surface soils. Otherwise, surface geology of various formations may contain sufficient alkalinity such that leaching from particular members of these formations gives rise to such conditions (Elliott 2011).
Vegetation: Some characteristic plants in examples of this system include (in stands with trees) *Quercus stellata, Quercus marilandica, Quercus similis*, as well as shrubs *Baccharis halimifolia, Crataegus berberifolia, Iva angustifolia*; grasses and graminoids include *Aristida dichotoma, Aristida longispica, Aristida oligantha, Aristida purpurascens, Distichlis spicata, Eleocharis* spp., *Fimbristylis* spp., *Juncus* spp., *Muhlenbergia capillaris, Schoenoplectus* spp., *Schizachyrium scoparium, Tridens strictus*, and forbs *Krigia occidentalis, Houstonia rosea, Ambrosia artemisiifolia, Diodia teres, Euthamia leptocephala,* and *Bigelowia nuttallii*.
Dynamics: Edaphic factors are the most important in maintaining and limiting this system. The influence of fire is variable depending on the density of the vegetation, with a greater influence where the fuels are adequate to carry a fire. Some areas may support relatively frequent fire, and others are too thinly vegetated to carry one. The topsoil is thin silt with toxic levels of sodium and/or magnesium salts in the subsoil, and in some areas is often exposed as "slick spots," which are denuded of vegetation, except for a "cryptogamic lip" dominated by lichens, algae and very small flowering plants (Pittman 1988, Baker and Witsell 2013, T. Foti pers. comm.). Although the subsoil is silt, it is essentially cemented into an impervious hardpan by calcium or other minerals. Sites therefore alternate between extremely dry and extremely wet, a condition that has been described as xerohydric. The genesis of the slicks is uncertain, but salts may be "wicked" to the surface through evaporation. The "slicks" appear to be somewhat ephemeral features, appearing, disappearing, and migrating around a site over time. This migration has been observed in the process of collecting transect data in an effort to monitor *Geocarpon minimum*. It was reported that "experimental transects [to monitor *Geocarpon* populations over time] were set up in saline prairie areas. The project was a miserable failure because the plants disappeared from the transects. Then someone noticed that there were unrecorded, apparently new, slicks nearby that had *Geocarpon*" (T. Foti pers. comm.). It was observed that "Â…not only did the *Geocarpon* disappear from the transects, but many of the slicks themselves disappeared. First they were encroached by lichens, then by *Aristida, Ambrosia bidentata*, and mosses, some of them [being] no longer even discernible as having been slicks in the past" (T. Witsell pers. comm.).

Component Associations:
- *Aristida longispica - Schizachyrium scoparium - Diodia teres* Saline Herbaceous Vegetation (CEGL008419, G1G2)
- *Baccharis halimifolia - Crataegus berberifolia / Eleocharis* sp. *- Tridens strictus - Euthamia leptocephala* Shrubland

(CEGL003904, G1)
- *Bigelowia nuttallii - Aristida dichotoma - Houstonia rosea / Cladonia* spp. Herbaceous Vegetation (CEGL004274, G1)
- *Eleocharis* sp. - *Iva angustifolia - Distichlis spicata* Herbaceous Vegetation (CEGL004171, G1)
- *Eleocharis* spp. - *Schoenoplectus* spp. - *Fimbristylis* spp. - *Juncus* spp. Southeastern Coastal Plain Inland Salt Flat Sparse Vegetation (CEGL007803, G1?)
- *Quercus stellata - Quercus similis - Quercus marilandica* Saline Woodland (CEGL008418, G2G3)

DISTRIBUTION

Range: This system is found in isolated areas of the Upper West and West Gulf Coastal Plain ecoregions, and along the boundary of the Gulf Coast Prairies and Marshes. It is also known from the Mississippi River Alluvial Plain (T. Foti pers. comm. 2005). It does not occur in Oklahoma.

SOUTHERN AND CENTRAL APPALACHIAN MAFIC GLADE AND BARRENS (CES202.348)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades; Shallow Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: ESLF 5415

CONCEPT

Summary: This Southern and Central Appalachian system consists of vegetation associated with shallow soils over predominantly mafic bedrock, usually with significant areas of rock outcrop. Bedrock includes a variety of igneous and metamorphic rock types such as greenstone and amphibolite. These areas support a patchy mosaic of open woodland and grassy herbaceous vegetation sometimes with a predominant woody short-shrub community present.
Classification Comments: These glades and barrens are intermediate between other rock outcrop and forest systems, with less dense vegetation than the closed forests supported by the region's climate but with more vegetation than bare rock cover. They may grade very gradually into both kinds of systems. Systems of similar physiognomy and setting but on acidic substrates are generally included in Central Appalachian Pine-Oak Rocky Woodland (CES202.600).
Similar Ecological Systems:
- Appalachian Shale Barrens (CES202.598)
- Southern Appalachian Granitic Dome (CES202.297)
- Southern Appalachian Montane Cliff and Talus (CES202.330)
- Southern Appalachian Rocky Summit (CES202.327)
- Southern Piedmont Glade and Barrens (CES202.328)

DESCRIPTION

Environment: Occurs on upper to mid slopes, usually on gentle to moderate slopes but occasionally steeper. The ground is mostly shallow soil over bedrock, usually with significant areas of rock outcrop. The rock usually has few fractures but may have a pitted or irregular surface. This rock structure supports more extensive and deeper soil development than in Southern Appalachian Granitic Dome (CES202.297), but has few of the crevices and deeper rooting sites available in Southern Appalachian Rocky Summit (CES202.327). Micro-scale soil depth and presence of seepage are important factors in determining the vegetation patterns. Shallow soil, unable to support a closed tree canopy, separates this system from forest systems. Bedrock includes a variety of igneous and metamorphic rock types. Some examples are on mafic substrates such as amphibolite, some are on felsic rock such as granitic gneiss but have flora that suggests a basic influence, and a few occur on felsic rocks and are clearly acidic. Rock or soil chemistry appears to be the most important factor affecting different associations on sites that have the physical structure to belong to this system. Elevation may also be an important factor causing variation.
Vegetation: Vegetation is a fine mosaic of different physiognomies, with open woodland and grassy herbaceous vegetation or short shrubs predominating. Some instances may have closed canopies of small trees or large shrubs, but no examples have large canopy trees with a closed canopy. Bare rock outcrops are usually present in a minority of the area. The canopy species are species tolerant of dry, shallow soils, most commonly *Quercus prinus, Pinus* spp., and *Juniperus virginiana*. Basic examples may also have *Carya glabra, Fraxinus americana,* and other species abundant. Shrubs may be dense, with species determined by soil chemistry. The herb layer is usually fairly dense and dominated by grasses, both in treeless areas and beneath open canopy. An abundant forb component is also usually present, especially in the more basic examples. The forbs include species characteristic of other rock outcrops and grassland species, with a smaller number of forest species present.
Dynamics: The dynamics of this system are not well known. The occurrence of the system appears to be primarily determined by site physical properties, with physical and chemical properties determining vegetational variation. Fire may be an important influence on vegetation, and may in the long run be important for keeping the vegetation structure open, though the patchy distribution of vegetation might limit fire intensity. Periodic drought and windstorms may also be important factors limiting canopy density and stature. These sites, with their shallow soil, would likely be affected by fire, drought, and windstorms. Severe droughts kill tree saplings growing in cracks and potholes, helping to retain the open character of the glades (Quarterman et al. 1993). These glades do not appear to be undergoing the kind of cyclic succession that has been described for granitic domes, but some balance of soil accumulation and destruction may be occurring on a longer term or coarser scale. There may be a zonation or patchiness to glade/barren vegetation, with different zones that may be identified by their characteristic plant species (Quarterman et al. 1993). These zones are apparently relatively stable, with woody plant encroachment evident only in relation to the invasion of shrubs and trees into potholes or crevices where soil accumulates more rapidly. It is possible that the slightly irregular curved surface of some examples represents a late stage in the weathering of old exfoliation surfaces that once supported granitic domes, but most known examples are not spatially associated with existing granitic domes.

Component Associations:

- (*Kalmia latifolia, Physocarpus opulifolius) / Schizachyrium scoparium - Thalictrum revolutum - Sibbaldiopsis tridentata* Shrub Herbaceous Vegetation (CEGL004238, G1)
- *(Pinus palustris) / Prunus umbellata - Rhus aromatica / Piptochaetium avenaceum - Schizachyrium scoparium* Herbaceous Vegetation (CEGL007014, G1)

SPATIAL CHARACTERISTICS

Spatial Summary: Small-patch system, most examples covering a few acres.
Size: Most examples naturally cover a few acres, with a few examples up to 10 or more acres.
Adjacent Ecological Systems:
- Southern Appalachian Granitic Dome (CES202.297)
- Southern Appalachian Oak Forest (CES202.886)
- Southern Appalachian Rocky Summit (CES202.327)

Adjacent Ecological System Comments: This system is surrounded by forest systems on deeper soils less influenced by bedrock, most typically Southern Appalachian Oak Forest (CES202.886). It is rarely associated with Southern Appalachian Granitic Dome (CES202.297) or Southern Appalachian Rocky Summit (CES202.327).

DISTRIBUTION

Range: This system occurs in scattered clusters in the Southern Blue Ridge and adjacent portions of the upper Piedmont and Central Appalachians.
Divisions: 202:C
Nations: US
Subnations: GA?, MD, NC, PA?, SC?, TN, VA
Map Zones: 54:C, 57:C, 59:C, 61:C
USFS Ecomap Regions: 221D:CC, M221D:CC
TNC Ecoregions: 51:C, 52:C, 59:C

SOUTHERN CALIFORNIA OAK WOODLAND AND SAVANNA (CES206.938)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Mediterranean [Mediterranean Desertic-Oceanic]; Broad-Leaved Evergreen Tree; Evergreen Sclerophyllous Shrub; Quercus agrifolia, Q. wislizeni, Q. engelmannii
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Sideslope; F-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2118; ESLF 5407; ESP 1118

CONCEPT

Summary: These oak woodlands and savannas occur in coastal plains, intermountain valleys, and low mountains (such as the San Jacinto Mountains) from Ventura County, California, south into Baja California, Mexico. *Quercus agrifolia, Quercus wislizeni, Quercus engelmannii, Quercus kelloggii*, and/or *Juglans californica* dominate a mixed closed or open canopy. Southern chaparral species such as *Adenostoma fasciculatum, Artemisia californica, Rhus integrifolia, Rhus ovata, Rhus trilobata, Ceanothus* spp., *Ribes* spp., and *Arctostaphylos* spp. are also characteristic. These woodlands may occur as remnant patches on offshore islands, where they include endemic species such as *Quercus tomentella* and *Lyonothamnus floribundus*. The California central coast region may have open stands of just *Juniperus californica*, with a grassy understory. These stands belong here due to proximity to other oak stands or chaparral, and due to the heavy native or non-native grass cover. This is distinguished from Great Basin pinyon-juniper stands, which have little herbaceous understory, and *Pinus monophylla* mixed with *Juniperus californica*. These stands of only juniper are caused by repeated removal of the oaks by humans and feral pig populations. Variable canopy densities in existing occurrences are likely due to variation in soil moisture regime, natural patch dynamics of fire, and land use (fire suppression, livestock grazing, herbivory, etc.). Most of these woodlands and savannas have been heavily altered through urban and agricultural development throughout southern California.

Related Concepts:
- California Coast Live Oak: 255 (Eyre 1980) Intersecting
- Coast Live Oak Woodland (202) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This system occurs in coastal plains, intermountain valleys, and low mountains (such as the San Jacinto Mountains). Soils are moderately to well-drained, deep, sandy or loamy with high organic matter. Elevation ranges from sea level to 2200 m, but generally at less than 1500 m elevation. It is found on variable aspects and topography with rainfall between 13-102 cm (5-40 inches).
Dynamics: Variable canopy densities in existing occurrences are likely due to variation in soil moisture regime and natural patch dynamics of fire. Fire reduces the survivorship and growth of juvenile *Quercus engelmannii*, with seedlings especially sensitive. Stands with grassy understories tend to suffer minimal damage, but those with shrubby understories tend to top-kill the trees, which may sprout and survive (Sawyer et al. 2009). Natural fire-return intervals are 30-100 years, and occur primarily in summer to early fall. From Landfire (2007a): Typical regime is frequent, low-severity fire that likely exert positive influences on overstory productivity and canopy resilience to fire damage. Infrequent isolated areas of stand-replacement fire create gaps of grasslands that require patch-gap recruitment and edge recolonization over time. Grass fuels allow very frequent fire, up to annually. A high proportion of seedlings and saplings are top-killed in low- to moderate-severity fires. Mortality rates of different size trees decrease with increasing height and dbh. Mortality may be as much as 50-60% for trees less than 40 cm (15.7 inches) dbh. In plants that survive fires, there is a significant amount of resprouting (Lathrop and Osborne 1991, Lawson 1993, Steinberg 2002b).

Component Associations:
- *Quercus tomentella* Forest (CEGL003098, G2?)

DISTRIBUTION

Range: This system occurs in coastal plains and intermountain valleys from Ventura County, California, south into Baja California, Mexico.

SOUTHERN PIEDMONT GLADE AND BARRENS (CES202.328)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: ESLF 5412

CONCEPT

Summary: This glade and barrens system of the southern Piedmont consists of gently to moderately sloping areas with mostly shallow soil over bedrock. Examples usually have significant areas of exposed rock evident. The bedrock potentially includes a variety of igneous and metamorphic rock types, including diabase, mudstone, and shale. Examples support open vegetation of patchy, mixed physiognomy with a significant woody component. Trees may be stunted and/or more widely spaced than in the more typical forests of the region. The shallow soils which impede tree growth help distinguish this system from forest systems of the Piedmont. This system is structurally intermediate between other rock outcrop systems and the more common and typical forest systems. The canopy species are those tolerant of dry, shallow soils, most commonly *Juniperus virginiana* and various oaks and pines, but also including *Fraxinus americana, Ulmus alata*, and *Cercis canadensis* on basic examples. Shrubs may be dense, with species determined by soil chemistry. The herb layer is usually fairly dense and may be dominated by grasses or by a mix of grasses and forbs, both in treeless areas and beneath open canopy. The forbs include species characteristic of other rock outcrops and grassland species, with a smaller number of forest species present. Plant species richness may be fairly high in communities of this system.
Classification Comments: The southern Piedmont as defined here consists of TNC Ecoregion 52 (ECOMAP 231A, EPA 45), but within this region, this system is not expected to occur north of about the James River in Virginia. This system is intermediate between other rock outcrops and forest systems, with less dense vegetation than the closed forests supported by the region's climate but with more vegetation than bare rock cover. They may grade very gradually into both kinds of systems. They are analogous to Southern and Central Appalachian Mafic Glade and Barrens (CES202.348), but are distinguished by their climate, flora, and landscape setting. Southern and Central Appalachian Mafic Glade and Barrens (CES202.348) occurs in the hilly upper Piedmont, whereas this system is confined to the eastern and central Piedmont.

This system represents a collection of several different kinds of communities related primarily by structure, and could be further subdivided. The rare diabase glades are flat and have a very distinctive flora. The examples on meta-mudstone are less well known. Other kinds may occur.

Similar Ecological Systems:
- Southern and Central Appalachian Mafic Glade and Barrens (CES202.348)
- Southern Appalachian Rocky Summit (CES202.327)
- Southern Piedmont Cliff (CES202.386)
- Southern Piedmont Granite Flatrock and Outcrop (CES202.329)

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Shortleaf Pine - Oak: 76 (Eyre 1980) Finer
- Shortleaf Pine: 75 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on upper to midslopes, usually on moderate slopes but occasionally flat. The ground is mostly shallow soil over bedrock, usually with significant areas of rock outcrop. The rock usually has few fractures but may have a pitted or irregular surface. This rock structure supports more extensive and deeper soil development than in Southern Piedmont Granite Flatrock and Outcrop (CES202.329) or Southern Piedmont Cliff (CES202.386), but has few of the crevices and deeper rooting sites available in Southern Appalachian Rocky Summit (CES202.327). Micro-scale soil depth and presence of seepage are important factors in determining the vegetation patterns. Shallow soil, unable to support a closed tree canopy, separates this system from forest systems. Bedrock potentially includes a variety of igneous and metamorphic rock types, including diabase, mudstone, and shale. Rock or soil chemistry appears to be the most important factor affecting different associations on sites that have the physical structure to belong to this system.
Vegetation: Vegetation is a fine mosaic of different physiognomies, with open woodland and grassy herbaceous vegetation or short shrubs predominating. Bare rock outcrops are usually present in a minority of the area. The canopy species are species tolerant of dry, shallow soils, most commonly *Juniperus virginiana* and various oaks and pines, but also including *Fraxinus americana, Ulmus alata*, and *Cercis canadensis* on basic examples. Shrubs may be dense, with species determined by soil chemistry. The herb layer is usually fairly dense and may be dominated by grasses or by a mix of grasses and forbs, both in treeless areas and beneath open canopy. The forbs include species characteristic of other rock outcrops and grassland species, with a smaller number of forest species present. Plant species richness may be fairly high in communities of this system.

Dynamics: The dynamics of this system are not well known. The occurrence of the system appears to be primarily determined by site physical properties, with physical and chemical properties determining vegetational variation. Fire may be an important influence on vegetation, and may in the long run be important for keeping the vegetation structure open, though the patchy distribution of vegetation might limit fire intensity. It is possible that fire would have allowed glade structure and vegetation to extend onto slightly deeper soils and therefore allowed for more extensive glades. Periodic drought and wind storms may also be an important factor limiting canopy density and stature. The shallow soil would make these sites particularly prone to all three. These glades do not appear to be undergoing the kind of cyclic succession that has been described for granitic flatrocks, but some balance of soil accumulation and destruction may be occurring on a longer term or coarser scale.

SOUTHERN RIDGE AND VALLEY CALCAREOUS GLADE AND WOODLAND (CES202.024)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades
National Mapping Codes: ESLF 5464

CONCEPT

Summary: This ecological system consists of open glades and surrounding woodlands on shallow, high pH soils of the Ridge and Valley region from southwestern Virginia southward. These glades occur in broad valley bottoms, rolling basins, and adjacent slopes where soils are shallow over flat-lying limestone strata. The flat to rolling terrain and locally xeric soils may have been especially conducive to periodic fires that helped maintain the prairielike openings and savannalike woodlands. Today, much of the system is currently somewhat more closed and brushy, suggesting fire suppression. *Quercus muehlenbergii* and *Quercus stellata* are typical where the canopy is present. Dominant or abundant *Juniperus virginiana var. virginiana* is probably a result of the lack of fire.
Classification Comments: This system formerly embodied a narrower concept, being restricted to glades of "valley bottoms," and thereby, at least by implication, not those of slopes. The current concept includes glades in the southern Ridge and Valley on a variety of landforms and slope positions, as they are all sufficiently similar in floristic components and ecological processes to be grouped together. These processes and factors include erosional processes, zonal vegetation patterns, and general ecological dynamics.
Similar Ecological Systems:
- Central Appalachian Alkaline Glade and Woodland (CES202.602)--of central Appalachians, Virginia and north.
- Central Interior Highlands Calcareous Glade and Barrens (CES202.691)--is related, generally to the west in the Interior Low Plateau.
- Southern Ridge and Valley / Cumberland Dry Calcareous Forest (CES202.457)--is a more closed-canopy system with a similar range.

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Limestone and Dolomite Barrens (Fleming et al. 2005) Undetermined
- Sugar Maple: 27 (Eyre 1980) Finer

DESCRIPTION

Environment: Examples occur on shallow, high pH soils, in broad valley bottoms, rolling basins, and adjacent slopes over limestone strata.
Vegetation: The vegetation of typical examples could range from open woodlands of *Quercus muehlenbergii* and *Juniperus virginiana*, with interspersed grasslands dominated by perennial *Schizachyrium scoparium*, to patches dominated by annual grasses such as varieties of *Sporobolus vaginiflorus* (e.g., var. *ozarkanus*, var. *vaginiflorus*). Some other trees that may occur in stands include *Quercus falcata, Quercus shumardii, Quercus stellata*, as well as the understory woody plants *Cercis canadensis, Salix humilis*, and *Viburnum rufidulum*. Some characteristic herbs include *Eryngium yuccifolium, Manfreda virginica*, and *Hypericum dolabriforme*. Dominant or abundant *Juniperus virginiana var. virginiana* is probably a result of the lack of fire.
Dynamics: The flat to rolling terrain and locally xeric soils may have been especially conducive to periodic fires that helped maintain the grass-dominated openings and open woodlands. In addition to occasional fire, periodic drought may also be important in regulating woody plant encroachment into native grasslands. It is believed that these native glade-grassland systems have evolved under a combined system of grazing, drought, and periodic fire (Duffey et al. 1974, Estes et al. 1979, Noss 2013).

Component Associations:
- *Andropogon gerardii - Bouteloua curtipendula - Echinacea simulata* Coosa Valley Barren Herbaceous Vegetation (CEGL004045, G1)
- *Fraxinus americana - Carya ovata / Frangula caroliniana / Helianthus hirsutus* Woodland (CEGL008458, G1?)
- *Quercus muehlenbergii - Juniperus virginiana / Schizachyrium scoparium - Manfreda virginica* Wooded Herbaceous Vegetation (CEGL005131, G2G3)
- *Quercus muehlenbergii - Quercus (falcata, shumardii, stellata) / Cercis canadensis / Viburnum rufidulum* Forest (CEGL007699, G3)
- *Rhus aromatica - Celtis tenuifolia / Carex eburnea* Shrubland (CEGL004393, G3)
- *Sporobolus vaginiflorus (var. ozarkanus, var. vaginiflorus) - Hypericum dolabriforme* Herbaceous Vegetation (CEGL004339, G2G3)

DISTRIBUTION

Range: This system occurs from southwestern Virginia (roughly Roanoke) south through the southern Ridge and Valley into Georgia.

SOUTHERN ROCKY MOUNTAIN JUNIPER WOODLAND AND SAVANNA (CES306.834)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Woody-Herbaceous; Shallow Soil; Mineral: W/ A-Horizon <10 cm; Aridic; Needle-Leaved Tree; Graminoid; Juniperus monosperma and grasses
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Lowland [Lowland]; Temperate [Temperate Continental]; Unglaciated; Intermediate Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Evergreen sparse tree canopy
National Mapping Codes: EVT 2119; ESLF 5408; ESP 1119

CONCEPT

Summary: This ecological system occupies the lower and warmest elevations, growing from 1370 to 1830 m in a semi-arid climate, primarily along the east and south slopes of the southern Rockies and Arizona-New Mexico mountains. It is best represented just below the lower elevational range of ponderosa pine and often intermingles with grasslands and shrublands. This system is best described as a savanna that has widely spaced, mature (>150 years old) juniper trees and occasionally *Pinus edulis*. *Juniperus monosperma* and *Juniperus scopulorum* (at higher elevations) are the dominant tall shrubs or short trees. These savannas may have inclusions of more dense juniper woodlands and have expanded into adjacent grasslands during the last century. Graminoid species are similar to those found in Western Great Plains Shortgrass Prairie (CES303.672), with *Bouteloua gracilis* and *Pleuraphis jamesii* being most common. In addition, succulents such as species of *Yucca* and *Opuntia* are typically present.
Similar Ecological Systems:
- Western Great Plains Shortgrass Prairie (CES303.672)

Related Concepts:
- Pinyon - Juniper: 239 (Eyre 1980) Intersecting

FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Evergreen sparse tree canopy
National Mapping Codes: EVT 2117; ESLF 5406; ESP 1117

CONCEPT

Summary: This ecological system is found predominantly in the Colorado Plateau region, west into scattered locations in the Great Basin, and north along the eastern front of the southern Rocky Mountains into southeastern Wyoming. These savannas occur at the lower treeline/ecotone between grassland/or shrubland and more mesic coniferous forests typically in warm, dry, exposed sites. Elevations range from less than 1900 m in central and northern Wyoming to 2800 m in the New Mexico mountains to well over 2700 m on the higher plateaus of the Southwest. It is found on rolling plains, plateaus, or dry slopes usually on more southerly aspects. This system is best described as a savanna that has widely spaced (<25% tree canopy cover) (>150 years old) *Pinus ponderosa* (primarily *var. scopulorum* and *var. ponderosa (= <i>var. brachyptera)*) as the predominant conifer. It is maintained by a fire regime of frequent, low-intensity surface fires. A healthy occurrence often consists of open and park-like stands dominated by *Pinus ponderosa*. Understory vegetation in the true savanna occurrences is predominantly fire-resistant grasses and forbs that resprout following surface fires; shrubs, understory trees and downed logs are uncommon. Important and often dominant species include *Festuca arizonica, Koeleria macrantha, Muhlenbergia montana, Muhlenbergia virescens,* and *Pseudoroegneria spicata*. Other important grasses, such as *Andropogon gerardii, Bouteloua gracilis, Elymus elymoides, Festuca idahoensis, Piptatherum micranthum,* and *Schizachyrium scoparium,* dominate less frequently. A century of anthropogenic disturbance and fire suppression has resulted in a higher density of *Pinus ponderosa* trees, altering the fire regime and species composition. Presently, many stands contain understories of more shade-tolerant species, such as *Pseudotsuga menziesii* and/or *Abies* spp., as well as younger cohorts of *Pinus ponderosa*. Northern Rocky Mountain Ponderosa Pine Woodland and Savanna (CES306.030) in the eastern Cascades, Okanogan, and northern Rockies regions receives winter and spring rains, and thus has a greater spring "green-up" than the drier woodlands in the Central Rockies.
Classification Comments: The Pine Escarpment regions of northwestern and central Nebraska are no longer included within this system; they have been lumped into Northwestern Great Plains-Black Hills Ponderosa Pine Woodland and Savanna (CES303.650). Because this ecological system has undergone some important changes in its concept, the original system (CES306.826) was archived, and this new system was created to account for the new concept of ponderosa pine savannas in the southern Rocky Mountains.

The FRIS site describes different varieties of *Pinus ponderosa* and associated species. This system is mostly *Pinus ponderosa var. scopulorum* and *Pinus ponderosa (= var. brachyptera)*. Johansen and Latta (2003) have mapped the distribution of two varieties (vars. *scopulorum* and *ponderosa*) using mitochondrial DNA. Hybridization along the Continental Divide in Montana backs up the FRIS information.

Similar Ecological Systems:

DESCRIPTION

Environment: These savannas occur at the lower elevation ecotone between pinyon conifer woodlands, grassland/or shrubland and upper elevation, more mesic coniferous forests typically in warm, dry, exposed sites. Elevations range from less than 1900 m in central and northern Wyoming to 2800 m in the New Mexico mountains to well over 2700 m on the higher plateaus of the Southwest. It is found on rolling plains, plateaus, or dry slopes usually on more southerly aspects; however, it can occur on all slopes and aspects. Stands occur on soils derived from igneous, metamorphic, and sedimentary material, including basalt, andesite, intrusive granitoids and porphyrites, and tuffs (Youngblood and Mauk 1985). Characteristic soil features include good aeration and drainage, coarse textures, circumneutral to slightly acidic pH, an abundance of mineral material, and periods of drought during the growing season. Surface textures are highly variable in this ecological system ranging from sand to loam and silt loam. Exposed rock and bare soil consistently occur to some degree in all the associations. Annual precipitation is 25-60 cm (8-24 inches), mostly through winter storms and some monsoonal summer rains. Typically a seasonal drought period occurs throughout this system as well.
Dynamics: *Pinus ponderosa* is a drought-resistant, typically open-grown conifer, which usually occurs at lower treeline in the major ranges of the western United States. Mature trees have thick bark that protects the cambium layer from fire. Historically, fires and drought were influential in maintaining open-canopy conditions in these woodlands. Low-intensity surface fire would burn through these stands every 5-15 year, killing young trees, but not the fire-resistant mature ponderosa pine trees or grass understory maintaining

an open park-like stand (Harrington and Sackett 1992, Mehl 1992, Swetnam and Baisan 1996). Infrequent stand-replacement fire on the order of a few hundred years (300-500 years) is possible (Landfire 2007a). Drought and other weather events (e.g., blowdown), parasites and disease may play a minor role, and have very long rotations (Landfire 2007a). Impacts from insects such as mountain pine beetles (*Dendroctonus ponderosae*) may be significant during outbreaks, but infrequent in occurrence (Landfire 2007a). Beetles attack less vigorously growing trees, e.g., old, crowded, diseased, damaged, or growing on poor sites) especially during droughts (Leatherman et al. 2013). Winter mortality of beetles is a significant factor; however, a severe freeze of at least -30 degrees F is necessary for at least five days during midwinter (Leatherman et al. 2013).

Component Associations:
- *Pinus ponderosa / Bouteloua gracilis* Woodland (CEGL000848, G4)
- *Pinus ponderosa / Cercocarpus montanus / Andropogon gerardii* Wooded Herbaceous Vegetation (CEGL000852, G2)
- *Pinus ponderosa / Cornus sericea* Woodland (CEGL000853, G3)
- *Pinus ponderosa / Crataegus douglasii* Woodland (CEGL000855, G1)
- *Pinus ponderosa / Festuca arizonica* Woodland (CEGL000856, G4)
- *Pinus ponderosa / Festuca idahoensis* Woodland (CEGL000857, G4)
- *Pinus ponderosa / Poa fendleriana* Woodland (CEGL005507, GNR)
- *Pinus ponderosa / Purshia stansburiana* Woodland (CEGL000854, G3)
- *Pinus ponderosa* / Sparse Understory Woodland (CEGL002384, GNR)

DISTRIBUTION

Range: This ecological system is found predominantly in the Colorado Plateau region, west into scattered locations of the Great Basin, and north along the eastern front of the Rocky Mountains of Colorado and Wyoming. Pine woodlands and savannas of the Black Hills and central Montana are now included in Northwestern Great Plains-Black Hills Ponderosa Pine Woodland and Savanna (CES303.650), as are woodlands and savannas in Nebraska and northeastern Colorado.

WEST GULF COASTAL PLAIN CATAHOULA BARRENS (CES203.364)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades; Very Shallow Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2403; ESLF 5419; ESP 1403

CONCEPT

Summary: This system is confined to the Catahoula geologic formation of eastern Texas and western Louisiana. It includes a vegetational mosaic ranging from herbaceous-dominated areas on shallow soil and exposed sandstone to deeper soils with open woodland vegetation. Woodlands include a post oak-dominated overstory grading into longleaf pine-dominated areas. Seasonal droughtiness, shallow soils, aluminum toxicity, and periodic fires are important factors that influence the composition and structure of this system. Vegetation associated with thin soils over the tuffaceous sandstone of the Catahoula Formation is primarily herbaceous. But where the soil is deeper, or fire is excluded for long periods, it can display significant woody cover, with usually stunted representatives of species such as *Pinus palustris, Pinus taeda, Pinus echinata, Quercus stellata, Quercus marilandica*, and *Carya texana* dominating the canopy. Shrubs may form a patchy, discontinuous layer. Open sites may have significant herbaceous cover, usually dominated by graminoid species.
Classification Comments: The western boundary of this system is unclear. The Catahoula Formation extends into the Crosstimbers region as well as the Pineywoods, but it is not clear whether these areas should be considered the same system.
Related Concepts:

- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer

DESCRIPTION

Environment: The habitat of this system includes shallow soil and exposed sandstone, which tend to an herbaceous-dominated vegetation expression, as well as zones of deeper soils with open woodland vegetation. Examples of this system are restricted to surface outcrops of the Oligocene Catahoula geologic formation, an often tuffaceous sandstone. Sites are generally level to gently undulating (but sometimes steep), with surface or near-surface exposure of the underlying sandstone bedrock. Soils are shallow loams, such as Browndell-Rock outcrop. Soils may contain montmorillonitic clays. These thin soils can be extremely xeric during dry periods, but can also be saturated during wetter months (Elliott 2011).
Vegetation: Vegetation associated with thin soils over the tuffaceous sandstone of the Catahoula Formation is primarily herbaceous. But where the soil is deeper, or fire is excluded for long periods, it can display significant woody cover, with usually stunted representatives of species such as *Pinus palustris, Pinus taeda, Pinus echinata, Quercus stellata, Quercus marilandica*, and *Carya texana* dominating the canopy. Shrubs may form a patchy, discontinuous layer with species such as *Ilex vomitoria, Morella cerifera, Vaccinium arboreum, Forestiera ligustrina, Gelsemium sempervirens*, and *Crataegus* spp. commonly encountered. Maintenance of fire in the landscape will reduce woody cover in these sites, with herbaceous-dominated sites displaying increased species richness. On open sites, there may be exposed patches of bedrock or mineral soils, or areas of patchy cover of foliose and/or fruticose lichens. Open sites may have significant herbaceous cover, usually dominated by graminoid species such as *Schizachyrium scoparium, Sporobolus clandestinus, Sporobolus silveanus, Schizachyrium tenerum, Tridens strictus, Scleria* spp., and/or *Aristida* spp. Forbs, including *Bigelowia nuttallii, Plantago* spp., *Minuartia drummondii, Chaetopappa asteroides, Lechea san-sabeana, Sabatia campestris, Croton michauxii, Croton monanthogynus, Krameria lanceolata, Selaginella arenicola ssp. riddellii, Talinum parviflorum (= Phemeranthus parviflorus)*, and a variety of other herbaceous species, may also be present. Lack of fire tends to lead to closing of the woody canopy and a reduction in diversity in the herbaceous layer. More wooded sites may have an herbaceous cover that contains species such as *Chasmanthium sessiliflorum, Ranunculus fascicularis*, and *Piptochaetium avenaceum* (Elliott 2011). Undisturbed examples are dominated by *Bigelowia nuttallii, Aristida longispica, Schizachyrium scoparium, Croton michauxii (= Crotonopsis linaris)*, and *Sporobolus silveanus* (Marietta and Nixon 1984). Woodlands include a *Quercus stellata*-dominated overstory grading into *Pinus palustris*-dominated areas.
Dynamics: Seasonal droughtiness, shallow soils, aluminum toxicity, and periodic fires are important factors that influence the maintenance of this system as one with primarily herbaceous composition and structure. This ecological system is maintained by a combination of edaphic factors and natural disturbances including severe drought and fire. The outcrops themselves are relatively extreme environments for plant growth due to mild alkalinity, exfoliation of rock surfaces, and surface moisture and temperature fluctuations. Severe droughts kill tree saplings growing in cracks and potholes, helping to retain the open character of the glades (Quarterman et al. 1993). There is an apparent zonation or patchiness to glade/barren vegetation, with different zones that may be

identified by their characteristic plant species (Quarterman et al. 1993). These zones are apparently relatively stable, with woody plant encroachment evident only in relation to the invasion of shrubs and trees into potholes or crevices where soil accumulates more rapidly.

Component Associations:
- *(Pinus palustris) / Schizachyrium scoparium - Bigelowia nuttallii / Cladonia* spp. Herbaceous Vegetation (CEGL003600, G1G2)
- *Bigelowia nuttallii - Krameria lanceolata - Aristida dichotoma - Sporobolus silveanus* Herbaceous Vegetation (CEGL002276, G1)
- *Quercus stellata - Carya texana - (Pinus palustris) / Chasmanthium sessiliflorum - Ranunculus fascicularis* Woodland (CEGL007868, G1)

DISTRIBUTION

Range: This system is endemic to areas where sandstones of the Catahoula Formation occur near and at the surface in western Louisiana and eastern Texas. Sandstone glades are estimated to have historically covered less than 2000 acres in Louisiana and today 50-75% of that historic distribution is thought to remain (Smith 1993).

WEST GULF COASTAL PLAIN NEPHELINE SYENITE GLADE (CES203.371)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades; Very Shallow Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2405; ESLF 5421; ESP 1405

CONCEPT

Summary: This glade system is present only in Saline and Pulaski counties, Arkansas, on distinctive, massive outcrops of igneous substrate ("nepheline syenite"). Zonal vegetation communities are present around the outcrops. Interior herbaceous-dominated zones can be mesic to wet as springs and small ephemeral streams flow across the rock outcrops and water pools in flat areas. Deeper, more heavily wooded vegetation develops along the flat or slightly sloping outcrop edges.

DESCRIPTION

Environment: This ecological system is found where the igneous rock nepheline syenite occurs at or near the surface in the Upper West Gulf Coastal Plain of Arkansas. This glade system is characterized by patches of bare rock interspersed with areas of shallow soil imbedded within a matrix of deeper soil supporting forested ecosystems. Slope varies from gentle to flat. Gently sloping areas are often extremely xeric whereas flatter areas can accumulate moisture, creating seasonally wet microhabitats. Exposed bedrock may have abundant lichen and moss cover and limited vascular plants. At the edges of the rock outcrops, areas with shallow soils support grasslands with scattered stunted trees. As soils become deeper, grasslands grade into open woodlands (Witsell 2007).
Vegetation: Some examples will have open stands of *Quercus stellata*, but trees may be absent. Some typical dominant grasses include *Schizachyrium scoparium, Piptochaetium avenaceum, Aristida purpurascens*, and *Sporobolus clandestinus*. Other herbs may include *Delphinium carolinianum, Clinopodium arkansanum, Camassia scilloides, Sabatia campestris*, and *Talinum calycinum.* Lichens are common on the rocky substrate of some examples.
Dynamics: This ecological system is maintained by a combination of edaphic factors and natural disturbances, including severe drought and fire (Witsell 2007). The outcrops themselves are relatively extreme environments for plant growth due to mild alkalinity, exfoliation of rock surfaces, and surface moisture and temperature fluctuations. Severe droughts kill tree saplings growing in cracks and potholes, helping to retain the open character of the glades (Quarterman et al. 1993). There is an apparent zonation or patchiness to glade/barren vegetation, with different zones that may be identified by their characteristic plant species (Quarterman et al. 1993). These zones are apparently relatively stable, with woody plant encroachment evident only in relation to the invasion of shrubs and trees into potholes or crevices where soil accumulates more rapidly.

Component Associations:
- *(Quercus stellata) / Schizachyrium scoparium - Piptochaetium avenaceum - Aristida purpurascens - Delphinium carolinianum* Nepheline Syenite Wooded Herbaceous Vegetation (CEGL008422, G1)
- *Sporobolus clandestinus - Clinopodium arkansanum - Camassia scilloides - Sabatia campestris - Talinum calycinum* - Lichens Nepheline Syenite Herbaceous Vegetation (CEGL008421, G1)

DISTRIBUTION

Range: This system is present only in the Upper West Gulf Coastal Plain of Saline and Pulaski counties, Arkansas. It may have existed historically in Garland and Hot Spring counties (and thereby at least partly in the Ouachita region). Less than 10 occurrences of this ecological system are known to persist.

WEST GULF COASTAL PLAIN WECHES GLADE (CES203.277)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades; Alkaline Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2404; ESLF 5420; ESP 1404

CONCEPT

Summary: This small-patch system is endemic to outcrops of marine sediment and glauconitic clays of the Weches Formation in central eastern Texas, where it occurs primarily in San Augustine, Nacogdoches, and Sabine counties. These outcrops are exposed by natural erosion of hillsides. Soils are shallow, rocky and basic, factors which tend to inhibit growth of woody vegetation, although as soil depth increases, so does woody plant development. Outcrops are seepy and saturated during winter and early spring but become hard and dry in the summer. Enormous seasonal variations in species dominance can occur, but a number of herbaceous species are characteristic of this system, including the narrowly endemic annuals *Lesquerella pallida (= Physaria pallida)* and *Leavenworthia aurea var. texana (= Leavenworthia texana)*. Characteristic species include *Sedum pulchellum, Clinopodium arkansanum,* and *Sporobolus vaginiflorus*. A scattered shrub layer, including *Cercis canadensis, Cornus drummondii, Juniperus virginiana,* and *Sideroxylon lanuginosum*, may be present on some sites.
Classification Comments: There is probably a woodland association from this geology that should also be described.
Related Concepts:
- Pineywoods: Weches Herbaceous Glade (4107) [CES203.277.7] (Elliott 2011) Finer
- Pineywoods: Weches Shrub Glade (4106) [CES203.277.6] (Elliott 2011) Finer

DESCRIPTION

Environment: This system is associated with outcrops of glauconitic (green-stone) clays, marls, mudstone, and ironstone of the Eocene Weches Formation. Outcrops of the Weches Formation are often found on slopes as a result of erosion, therefore this ecological system typically occupies slopes within rolling to relatively steep uplands, and sometimes on minor scarp slopes of ironstone outcrops. Surficial outcrops of the Weches Formation form the core of this ecological system but it extends to areas where the Weches is near the surface supporting shallow soils. Soils in this ecological system have high levels of calcium, magnesium, and potassium as a result of the marine-based parent material, and are mapped as the Trawick-Bub complex or the Trawick series (Mollic Hapludalfs). It is known from Texas and may extend into Louisiana and Arkansas (T. Witsell pers. comm. 2012, USFWS 2013b). Soils are often shallow but have been measured as deep as 50 cm (20 inches) (George and Nixon 1990). Outcrops of the Weches are generally 5-20 m wide and <100 m long and occur within a band averaging 8 km (5 miles) wide paralleling Texas State Highway 21 (George and Nixon 1990, USFWS 2013a, 2013b).The Weches Formation forms an impermeable layer that transports shallow groundwater to surface seeps and springs occurring on outcrop ledges along slopes. This moisture forms small pools and saturates shallow soils during the winter and spring, but the system can quickly become parched and droughty in the summer. The seasonal wet-dry pattern and alkaline soils are important characteristics to the maintenance of this system. In addition, the lack of woody canopy and corresponding leaf litter is important for the heliophytic flora (George and Nixon 1990, USFWS 2012a, 2013b). Calciphilic woody species may occur along the margins of outcrops where deeper soils have formed. The naturally fragmented distribution of this small-patch ecosystem over rock outcrops and thin alkaline soils in a region dominated by acidic sandy soils has become more isolated as areas are converted to other uses and encroachment by invasive species and off-site natives degrades the system (USFWS 2013b).
Vegetation: Characteristic species include *Sedum pulchellum, Clinopodium arkansanum,* and *Sporobolus vaginiflorus*. Other species include *Valerianella radiata, Galium virgatum, Minuartia patula (= Arenaria patula), Allium drummondii, Anemone caroliniana, Opuntia* spp., *Croton monanthogynus, Chamaesyce nutans (= Euphorbia nutans), Arnoglossum plantagineum (= Cacalia plantaginea),* and *Ipomopsis rubra*. A scattered shrub layer, including *Cercis canadensis, Cornus drummondii, Juniperus virginiana,* and *Sideroxylon lanuginosum*, may be present on some sites.
Dynamics: This ecological system is maintained by a combination of edaphic factors and natural disturbances, including severe drought and fire (Geroge and Nixon 1990, TNC 2003a, USFWS 2013a, 2013b). The outcrops themselves are relatively extreme environments for plant growth due to shallow soils, high levels of calcium, magnesium, and potassium, and extreme fluctuations in moisture and temperature. Severe droughts and a suggested fire frequency of 5-10 years can kill tree saplings, helping to retain the open character of glades (Quarterman et al. 1993, TNC 2003a). There is an apparent zonation or patchiness to glade/barren vegetation, with different zones that may be identified by their characteristic plant species (Quarterman et al. 1993). These zones are apparently relatively stable, with woody plant encroachment evident only in relation to the invasion of shrubs and trees into potholes or crevices where soil accumulates more rapidly. The open physiognomy and wet-dry hydrology play important roles in the dynamics of this system which supports heliophytic herbaceous species, some of which depend on the seasonal pattern of saturated and droughty soils (Baskin and Baskin 1988, USFWS 2013a, 2013b). This system supports two federally endangered endemic species, *Leavenworthia*

aurea var. texana (= Leavenworthia texana) and *Lesquerella pallida (= Physaria pallida)*.

Component Associations:
- *Sedum pulchellum - Clinopodium arkansanum - Sporobolus vaginiflorus* Herbaceous Vegetation (CEGL007797, G1)

DISTRIBUTION

Range: This system is endemic to a localized region of eastern Texas, primarily in San Augustine, Nacogdoches, and Sabine counties. More information is needed on possible extension into Arkansas and Louisiana.

WESTERN NORTH AMERICAN BOREAL DRY ASPEN-STEPPE BLUFF (CES105.109)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Slope; Sideslope; Boreal [Boreal Subcontinental]; Shallow Soil; Xeric; Bluff; Low Artemisia spp.
Non-Diagnostic Classifiers: Montane; Montane [Upper Montane]; Slump and topple prone slope; Soil creep slope; Ridge/Summit/Upper Slope; Populus tremuloides
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Deciduous sparse tree canopy
National Mapping Codes: EVT 2606; ESLF 5431; ESP 1606

CONCEPT

Summary: This ecological system occurs commonly on moderately steep to very steep, south-facing slopes and windswept bluffs throughout the boreal and boreal transition regions of Alaska. Generally, the substrate is steep, unstable, dry mineral soil. This system is common above major rivers and is often associated with river bluffs above treeline. Soils are typically well-drained to excessively well-drained and develop on glacial, loess, or fluvial deposits or residual material. Soils are often unstable and rocky; outcrops are common. The system is a mosaic of open forests or woodlands, low shrub-dominated patches, or dry meadows. At increasing elevation, trees become less important, and at subalpine or low alpine locations, shrubs are the dominant lifeform. Tree patches are dominated by *Populus tremuloides*, but *Picea glauca* may also be present. Patches of low-shrub and dry herbaceous communities are interspersed within the aspen forest, where it occurs. Common shrubs include *Artemisia frigida, Artemisia alaskana, Juniperus communis*, and *Arctostaphylos uva-ursi*. Important grasses include *Pseudoroegneria spicata (= Agropyron spicatum), Bromus inermis var. pumpellianus (= Bromus pumpellianus), Calamagrostis purpurascens, Festuca altaica*, and *Poa* spp.
Classification Comments: This system combines those known as Boreal Dry Aspen and Steppe Bluff and Boreal Subalpine Steppe Bluff by the Alaska Natural Heritage Program.
Similar Ecological Systems:
- Western North American Boreal Dry Grassland (CES105.115)

- III.A.1.d - Midgrass-herb (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: This system occurs from the low alpine down through low elevations on south-facing slopes and windswept bluffs and ridges. Substrates are steep, unstable, dry mineral soils that are typically excessively well- to well-drained and develop on glacial, loess, or fluvial deposits or residual material. Rocky outcrops are common.
Vegetation: This system is a mosaic of *Populus tremuloides* forest, low-shrub and dry herbaceous communities. The vegetation cover in this system is typically open and discontinuous with much exposed mineral soil. Where trees dominate, *Populus tremuloides* is typically the dominant species, and *Picea glauca* may also be present at low cover values. The *Populus tremuloides* understory is typically open, and common species include *Vaccinium vitis-idaea, Rosa acicularis, Shepherdia canadensis*, and *Chamerion angustifolium* (Boggs and Sturdy 2005). The unforested portion features steppe vegetation, including species such as *Juniperus communis, Arctostaphylos uva-ursi, Artemisia frigida, Artemisia alaskana, Calamagrostis purpurascens, Pseudoroegneria spicata (= Agropyron spicatum), Bromus inermis var. pumpellianus (= Bromus pumpellianus), Festuca altaica*, and *Poa* spp. (Viereck et al. 1992, Chapin et al. 2006).
Dynamics: The aspen component can be self-replacing. Stages in model represent the mosaic within the system (sagebrush-juniper, aspen, spruce, grass-dominated).

DISTRIBUTION

Range: This system is found in the boreal and boreal transition (low elevation through alpine) regions of Alaska. It probably occurs further east into the Yukon Territories of Canada.
Divisions: 105:C
Nations: CA? , US
Subnations: AK, YT?
Map Zones: 69:C, 70:C, 71:C, 73:C, 74:C, 75:C

WILLAMETTE VALLEY UPLAND PRAIRIE AND SAVANNA (CES204.858)

CLASSIFIERS

Conf.: 1 - Strong
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Short Disturbance Interval; F-Landscape/Low Intensity
Non-Diagnostic Classifiers: Lowland [Lowland]; Temperate [Temperate Oceanic]
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2120; ESLF 5409; ESP 1120

CONCEPT

Summary: This grassland system is endemic to the Puget Trough and Willamette Valley. It formed a complex mosaic of varying patch sizes with wet prairies and riparian forests over much of the Willamette Valley during the pre-European settlement era. In parts of the Puget Trough, it occurred as large patches in more forested landscapes, usually associated with deep, coarse outwash deposits. Historically, it also occurred as large patches on glacially associated soils of variable texture in localized portions of the Georgia Basin in both Washington and British Columbia. It occurs on well-drained deep soils and was maintained historically by frequent anthropogenic burning. Landforms are usually flat, rolling, or gently sloping, and often part of extensive plains. Dominant vegetation is perennial bunch grasses, especially *Festuca roemeri (= Festuca idahoensis var. roemeri)* and, to a lesser degree, *Danthonia californica*, with abundant and diverse forbs. Scattered deciduous (*Quercus garryana*) and/or coniferous (*Pseudotsuga menziesii*, *Pinus ponderosa*) trees are rarely found now, but such savannas historically covered about one-third of the total acreage. In the absence of disturbance, many of them have succeeded to forest and others continue to do so.

DESCRIPTION

Environment: This ecosystem occurs on well-drained deep soils and was maintained historically by frequent anthropogenic burning. Landforms are usually flat, rolling, or gently sloping, and often part of extensive plains.
Dynamics: Fires are thought to have occurred every few years (Chappell and Kagan 2001, as cited in WNHP 2011). Annual soil drought during the summer made it difficult for woody species (especially trees) to establish in these grasslands. However, occasionally *Quercus garryana* and *Pseudotsuga menziesii* would establish and survive long enough to be resistant to frequent fires thereby creating savanna conditions (Chappell and Kagan 2001, as cited in WNHP 2011). Following European settlement of the region, anthropogenic fire became less frequent resulting in widespread encroachment of the prairies and savannas by woody vegetation, especially conifers (WNHP 2011).

Component Associations:
- *Danthonia californica* Valley Grassland Herbaceous Vegetation (CEGL001598, G1Q)
- *Elymus caninus - Festuca roemeri - (Koeleria macrantha)* Herbaceous Vegetation (CEGL001744, G1)
- *Festuca roemeri - Sericocarpus rigidus* Herbaceous Vegetation (CEGL001608, G1)
- *Pinus ponderosa / Carex inops - Festuca roemeri* Woodland (CEGL003348, G1)
- *Quercus garryana / Festuca (roemeri, rubra)* Wooded Herbaceous Vegetation (CEGL001714, G1)

DISTRIBUTION

Range: This system is endemic to the Puget Trough and Willamette Valley.

UPLAND GRASSLAND AND HERBACEOUS

ALASKA ARCTIC LICHEN TUNDRA (CES104.178)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Montane]; Moss/Lichen (Nonvascular); Polar [Polar Oceanic]; Acidic Soil; Lichen
Non-Diagnostic Classifiers: Ridge; Slope; Summit
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Nonvascular, Lichen
National Mapping Codes: EVT 2687; ESLF 7166; ESP 1687

CONCEPT

Summary: This is a common ecological system in the hills and mountains of arctic Alaska. Common slope positions include sideslopes, summits and ridges. Sites are typically acidic and dry to mesic. It is especially common on recent volcanic deposits with little soil development. Patch size is small to large. Lichen cover is >25%, and vascular plant species cover is <25%. Foliose and fruticose lichens dominate and include *Umbilicaria* spp., *Rhizocarpon geographicum, Cladina stellaris (= Cladonia stellaris), Racomitrium lanuginosum, Flavocetraria* spp., and *Alectoria ochroleuca*. Common dwarf-shrubs include *Loiseleuria procumbens, Betula nana, Ledum palustre ssp. decumbens, Empetrum nigrum*, and *Vaccinium uliginosum*.
Classification Comments: This system is known as Lichen by the Alaska Natural Heritage Program.
Related Concepts:
- III.C.1.b - Dry bryophyte (Viereck et al. 1992) Finer
- III.C.2.a - Crustose lichen (Viereck et al. 1992) Finer

ALASKA ARCTIC MARINE BEACH AND BEACH MEADOW (CES102.207)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Coastal Grass/Shrub/Barren Mosaic; Lowland; Herbaceous; Dune (Substrate); Beach (Substrate); Polar [Polar Hyperoceanic]; Salt Spray; Salt-tolerant Forbs
Non-Diagnostic Classifiers: Dune (Landform); Sand Soil Texture; Beach (Landform)
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2709; ESLF 7167; ESP 1709

CONCEPT

Summary: This system consists of coastal beaches, beach dunes, and vegetation that has stabilized sand or cobble deposits. Soils are dry to mesic and typically sandy. Patch size is small to moderate and often linear. Two different physiognomic structures are found in the system: *Leymus mollis* grasslands and dwarf-shrublands; bare sand or cobble are also common. Salt-tolerant forb communities occur just above mean high tide and are dominated or codominated by *Cochlearia groenlandica*, *Achillea millefolium var. borealis*, *Honckenya peploides*, and/or *Mertensia maritima*. As dune height and distance from the ocean increase, sites are dominated by *Leymus mollis* communities that may include near-monocultures of *Leymus mollis* to more species-rich associations including *Leymus mollis*, *Lathyrus japonicus var. maritimus (= Lathyrus maritimus)*, and *Poa eminens*. Older dunes support dwarf-shrubs (primarily *Empetrum nigrum*) mixed with herbaceous species which often grow in narrow stringers on the older beach ridges behind the *Leymus mollis* zone. *Lathyrus japonicus var. maritimus*, *Conioselinum chinense*, and *Cnidium cnidiifolium* are uncommon east of Cape Lisburne. The *Leymus mollis* and *Empetrum nigrum* zones are above the high tide line but still experience storm surges, high winds and salt spray.
Classification Comments: This system is known as Sandy Beach and Beach Meadow by the Alaska Natural Heritage Program. This is very similar to the Aleutian beach and beach meadow system; for now they are maintained as two distinct systems, but may be merged in the future.
Similar Ecological Systems:
- Alaskan Pacific Maritime Coastal Dune, Beach and Beach Meadow (CES204.166)
- Aleutian Marine Beach and Beach Meadow (CES105.239)

Related Concepts:
- III.A.1.a - Elymus (Viereck et al. 1992) Intersecting
- III.A.1.e - Hair-grass (Viereck et al. 1992) Intersecting
- III.B.2.a - Mixed herbs (Viereck et al. 1992) Intersecting
- III.B.2.b - Fireweed (Viereck et al. 1992) Intersecting
- III.B.2.c - Large umbel (Viereck et al. 1992) Intersecting
- III.B.3.d - Halophytic herb wet meadow (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: Processes that define the system include sand deposition, wind erosion, long-shore transport, dune formation, and water erosion such as overwash from storm surges. Herbaceous species stabilize the sand deposits (dunes, beaches), and the older deposits support dwarf-shrubs mixed with herbaceous species.

DISTRIBUTION

Range: This system occurs along Alaska's arctic coastline, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.

ALASKA ARCTIC MESIC HERBACEOUS MEADOW (CES102.186)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Polar [Polar Oceanic]
Non-Diagnostic Classifiers: Sideslope; Toeslope/Valley Bottom
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Perennial forb grassland
National Mapping Codes: EVT 2699; ESLF 7168; ESP 1699

CONCEPT

Summary: This mesic herbaceous system occurs throughout arctic Alaska on hill and mountain slopes, upper drainages, and lowlands including drained lake basins. It typically occurs as small patches and is more common in the western arctic. This system occurs on mesic sites with >25% cover of herbaceous species. Species include *Carex microchaeta ssp. nesophila* (dominant sedge in higher elevations), *Alopecurus alpinus, Artemisia arctica, Polygonum bistorta, Valeriana capitata, Pedicularis* spp., *Polemonium acutiflorum, Salix rotundifolia*, and *Salix reticulata*. Collapsed acidic lowland snowbeds that support *Phippsia algida* and *Alopecurus alpinus* and drained lake basins dominated by *Calamagrostis canadensis* (western Alaska) are also included in this system.
Classification Comments: This system is known as Mesic Herbaceous by the Alaska Natural Heritage Program.
Related Concepts:

ALASKA SUB-BOREAL AND MARITIME ALPINE MESIC HERBACEOUS MEADOW (CES204.145)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Slope; Herbaceous; Soil creep slope; Boreal [Boreal Oceanic]; Avalanche
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Perennial forb grassland
National Mapping Codes: EVT 2645; ESLF 7169; ESP 1645

CONCEPT

Summary: These are mesic subalpine and alpine herbaceous meadows that occur on mountain sideslopes in the boreal transition and maritime regions of Alaska. The slope position is often above the tall-shrub zone and below alpine dwarf-shrub tundra, and the slope shape is usually straight to concave. The substrate is colluvium, residuum, or glacial till. This system often occurs as a continuous band above or mixed with subalpine and alpine shrublands on moderate to steep slopes underlain by colluvium, talus, or bedrock. Species composition is diverse and species richness is often very high, typically no single species is dominant. Vegetation is dominated by herbaceous species, including *Carex macrochaeta, Geranium erianthum, Sanguisorba canadensis, Valeriana sitchensis, Lupinus nootkatensis, Veratrum viride, Aconitum delphiniifolium, Anemone narcissiflora, Polemonium acutiflorum, Chamerion angustifolium (= Epilobium angustifolium), Chamerion latifolium, Senecio triangularis, Nephrophyllidium crista-galli, Calamagrostis canadensis* (often present but not dominant), *Castilleja unalaschcensis, Artemisia arctica, Fritillaria camschatcensis*, and *Athyrium filix-femina*. The dominant disturbances are snow avalanche, soil creep and freeze-thaw action.
Classification Comments: This system combines those known as Boreal Transition Alpine Herbaceous Meadow and Maritime Alpine Mesic Herbaceous Meadow by the Alaska Natural Heritage Program.
Similar Ecological Systems:
- Western North American Sub-boreal Mesic Bluejoint-Forb Meadow (CES105.114)

Related Concepts:

ALASKAN PACIFIC MARITIME COASTAL DUNE, BEACH AND BEACH MEADOW (CES204.166)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Coastal Grass/Shrub/Barren Mosaic; Lowland; Herbaceous; Dune (Substrate); Beach (Substrate); Salt Spray; Salt-tolerant Forbs
Non-Diagnostic Classifiers: Dune (Landform); Temperate [Temperate Oceanic]; Sand Soil Texture; Beach (Landform)
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2666; ESLF 7170; ESP 1666

CONCEPT

Summary: This system consists of coastal sandy beaches, meadows, beach dunes, and sand spits. Processes that define the system include sand deposition, wind and water erosion, long-shore transport, and overwash from storm surges. Soils are usually sandy and well-drained, though dune slacks may be poorly drained. Beaches and dunes are dominated by a mosaic of barren sands and herbaceous vegetation. Common species include *Leymus mollis*, *Hordeum brachyantherum*, *Poa eminens*, *Festuca rubra*, *Deschampsia* spp., *Calamagrostis canadensis*, *Achillea millefolium var. borealis (= Achillea borealis)*, *Angelica lucida*, *Angelica genuflexa*, *Ligusticum scoticum*, *Heracleum maximum*, *Senecio pseudoarnica*, *Lupinus nootkatensis*, *Fragaria chiloensis*, and *Lathyrus japonicus var. maritimus*. Tidally flooded dune slacks may be colonized by herbaceous communities dominated by *Equisetum variegatum* and may eventually succeed to shrub communities with *Myrica gale* and *Salix* spp.
Classification Comments: This system is known as Maritime Coastal Dune, Beach, and Beach Meadow by the Alaska Natural Heritage Program.
Similar Ecological Systems:
- Alaska Arctic Marine Beach and Beach Meadow (CES102.207)
- Aleutian Marine Beach and Beach Meadow (CES105.239)

ALASKAN PACIFIC MARITIME MESIC HERBACEOUS MEADOW (CES204.163)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Temperate [Temperate Oceanic]
Non-Diagnostic Classifiers: Montane; Lowland; Sideslope; Toeslope/Valley Bottom
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Perennial forb grassland
National Mapping Codes: EVT 2653; ESLF 7171; ESP 1653

CONCEPT

Summary: This ecological system includes a wide variety of herbaceous vegetation types and occurs below subalpine shrublands on sideslopes, rolling hills, and alluvial deposits. Soils are typically mesic, well-drained, and underlain by colluvium, alluvium, glacial till or residuum. Vegetation may be dominated by forbs, graminoids, or ferns. The most common dominant species are *Calamagrostis canadensis* and *Chamerion angustifolium*. One or more of the following species can also be dominant: *Veratrum viride, Athyrium filix-femina*, or *Heracleum maximum*. Other common species may include *Lupinus nootkatensis, Aconitum delphiniifolium, Sanguisorba canadensis, Senecio triangularis*, and *Nephrophyllidium crista-galli*.
Classification Comments: This system is known as Mesic Herbaceous Meadow by the Alaska Natural Heritage Program. On Kodiak Island, mesic herbaceous meadows are placed into Aleutian Mesic Herbaceous Meadow (CES105.232). The transition between maritime and Aleutian mesic meadows, as well as north into the boreal transition region is not clearly defined.
Similar Ecological Systems:

DESCRIPTION

Environment: This ecological system includes a wide variety of herbaceous vegetation types and occurs below subalpine shrublands on sideslopes, rolling hills, and alluvial deposits. Soils are typically mesic, well-drained, and underlain by colluvium, alluvium, glacial till or residuum.
Vegetation: Vegetation may be dominated by forbs, graminoids, or ferns. The most common dominant species are *Calamagrostis canadensis* and *Chamerion angustifolium*. One or more of the following species can also be dominant: *Veratrum viride, Athyrium filix-femina*, or *Heracleum maximum*. Other common species may include *Lupinus nootkatensis, Aconitum delphiniifolium, Sanguisorba canadensis, Senecio triangularis*, and *Nephrophyllidium crista-galli* (Shephard 1995, DeVelice et al. 1999).

DISTRIBUTION

Range: This system occurs from Prince William Sound through southeastern Alaska. Its southern boundary has yet to be determined.
Divisions: 204:C
Nations: US
Subnations: AK
Map Zones: 77:C, 78:C
TNC Ecoregions: 69:C, 70:C

ALEUTIAN AMERICAN DUNEGRASS GRASSLAND (CES105.233)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Dune (Landform); Herbaceous; Boreal [Boreal Oceanic]
Non-Diagnostic Classifiers: Dune (undifferentiated); Dune field; Colluvial slope
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2671; ESLF 7172; ESP 1671

CONCEPT

Summary: Sites are level to steep. The substrates are commonly dunes or shallow to deep eolian sand deposits over bedrock, sometimes 2 km inland. This system is not subjected to typical coastal processes such as overwash. The sites may be unstable, including eroding coastal bluffs and isolated blowouts. Other sites have loamy soils on colluvium that are nutrient-enriched by seabirds. Sites may or may not receive salt spray. Patch size is small to large. *Leymus mollis* cover is >25%, and the sites are not part of Aleutian Marine Beach and Beach Meadow (CES105.239). Other dominant or codominant species include *Festuca rubra, Heracleum maximum, Ligusticum scoticum, Angelica lucida,* and *Claytonia sibirica*. Some sites have 1- to 2-foot tall tussocks. Recent research has shown that the abundance of graminoids in the Aleutian Islands has been significantly reduced due to a reduction in nutrient inputs from seabird colonies; where seabirds have been impacted by introduced predators, the cover of graminoid species is lower.
Classification Comments: This system is known as *Leymus mollis* by the Alaska Natural Heritage Program.
Similar Ecological Systems:

ALEUTIAN MARINE BEACH AND BEACH MEADOW (CES105.239)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Coastal Grass/Shrub/Barren Mosaic; Lowland; Herbaceous; Dune (Substrate); Beach (Substrate); Boreal [Boreal Oceanic]; Salt Spray; Empetrum nigrum; Salt-tolerant Forbs
Non-Diagnostic Classifiers: Dune (Landform); Sand Soil Texture; Beach (Landform)
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2725; ESLF 7173; ESP 1725

CONCEPT

Summary: This ecological system consists of coastal beaches, beach dunes, and vegetation that has stabilized sand deposits. Cobble beaches are also included. Soils are dry to mesic (occasionally tidally inundated) and typically sandy. Patch size is small to moderate and often linear. This system sometimes grades into sandy loess deposits on rolling hills dominated Aleutian American Dunegrass Grassland (CES105.233). Three different vegetation types occur in this system: salt-tolerant forb communities, *Leymus mollis* grasslands, and *Empetrum nigrum* shrublands. Bare sand or cobble are also common. Salt-tolerant forb communities occur just above mean high tide and are dominated or codominated by *Cochlearia groenlandica, Achillea millefolium var. borealis, Honckenya peploides*, and/or *Mertensia maritima*. As dune height and distance from the ocean increase, sites are dominated by *Leymus mollis* communities that may include near-monocultures of *Leymus mollis* to more species-rich associations, including *Leymus mollis, Lathyrus japonicus var. maritimus, Achillea millefolium var. borealis, Festuca rubra, Fragaria chiloensis, Senecio pseudoarnica, Deschampsia beringensis, Heracleum maximum*, and *Poa eminens*. *Empetrum nigrum*-dominated communities often grow in narrow stringers on the older beach ridges behind the *Leymus mollis* zone. Herbaceous species are common, including *Cornus suecica*. The *Leymus mollis* and *Empetrum nigrum* existing vegetation types are above the high tide line but still experience storm surges, high winds and salt spray.
Classification Comments: This system is known as Marine Beach and Beach Meadow by the Alaska Natural Heritage Program. This system should probably be merged with other coastal dune and beach systems in Alaska; it's unlikely that coastal dunes and beaches in the Aleutians are significantly different from those in the southern arctic or maritime regions.
Similar Ecological Systems:
- Alaska Arctic Marine Beach and Beach Meadow (CES102.207)

ALEUTIAN MESIC HERBACEOUS MEADOW (CES105.232)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Matrix, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Herbaceous; Temperate [Temperate Oceanic]
Non-Diagnostic Classifiers: Ravine; Slope; Talus (Landform); Alluvial fan; Sideslope; Toeslope/Valley Bottom; Bluff
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Perennial forb grassland
National Mapping Codes: EVT 2651; ESLF 7174; ESP 1651

CONCEPT

Summary: This ecological system occurs on all slopes and aspects with a mesic moisture regime, including windswept coastal headlands, coastal bluffs, old beach ridges, hillside slopes, stabilized talus, alluvial fans, and ravine sideslopes, and commonly forms a mosaic with alder patches. Patch size is small to matrix-forming. Herbaceous cover is >25%, *Leymus mollis* cover is <25%. This system includes four predominant vegetation types: (1) The *Athyrium filix-femina* meadow type is dominated by *Athyrium filix-femina* with *Veratrum viride, Heracleum maximum, Streptopus amplexifolius*, *Angelica lucida*, and *Calamagrostis canadensis*; (2) The *Chamerion angustifolium ssp. angustifolium* meadow type is dominated by *Chamerion angustifolium ssp. angustifolium*, usually with ferns, *Calamagrostis canadensis,* and often *Heracleum maximum*; (3) The *Calamagrostis canadensis* meadow type is dominated by *Calamagrostis canadensis*, usually with ferns and scattered forbs. It is common on disturbed sites (human or natural) that are in early stages of recovery; and (4) The mixed herbaceous meadow type includes mesic herbaceous meadows not dominated by *Athyrium filix-femina, Chamerion angustifolium ssp. angustifolium*, or *Calamagrostis canadensis*; these species, however, often codominate. Common forbs include *Lupinus nootkatensis, Solidago canadensis var. lepida, Polemonium acutiflorum, Castilleja unalaschcensis, Sanguisorba canadensis, Veratrum viride, Valeriana capitata, Antennaria dioica, Cardamine oligosperma var. kamtschatica, Achillea millefolium var. borealis, Arnica unalaschcensis, Dendranthema arcticum ssp. arcticum, Claytonia sibirica, Geum calthifolium, Ranunculus occidentalis, Dryopteris expansa,* and *Angelica lucida*. Graminoids include *Carex macrochaeta, Festuca rubra, Agrostis exarata, Agrostis scabra,* and *Deschampsia beringensis*. *Empetrum nigrum* may also be common.
Classification Comments: This system is known as Mesic Herbaceous by the Alaska Natural Heritage Program.

ARKANSAS VALLEY PRAIRIE AND WOODLAND (CES202.312)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Graminoid
Non-Diagnostic Classifiers: Lowland
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2415; ESLF 7128; ESP 1415

CONCEPT

Summary: This system of prairies and associated woodlands is found in the Arkansas River Valley region of Arkansas and adjacent Oklahoma. This region is distinctly bounded by the Boston Mountains to the north and the Ouachita Mountains to the south, although it has been considered part of the Ouachita Ecoregion. The valley is characterized by broad, level to gently rolling uplands derived from shales and is much less rugged and more heavily impacted by Arkansas River erosional processes than the adjacent mountainous regions. In addition, the valley receives annual precipitation total of 5-15 cm (2-6 inches) less than the surrounding regions due to a rainshadow produced by a combination of prevailing western winds and mountain orographic effects. The shale-derived soils associated with the prairies are thin and droughty. The combined effect of droughty soils, reduced precipitation, and prevailing level topography create conditions highly conducive to the ignition and spread of fires. Stands are typically dominated by *Andropogon gerardii, Sorghastrum nutans, Panicum virgatum*, and *Schizachyrium scoparium*. Some extant examples of this system remain, but most are small and isolated. They were common on the western edge of the region bordering or possibly included in the Crosstimbers and Southern Tallgrass Prairie where precipitation and agriculture conversion were lowest.
Classification Comments: There is little floristic and environmental overlap with the Grand Prairie and calcareous prairies of southern Arkansas. There may be stronger overlap with Southeastern Great Plains Tallgrass Prairie (CES205.685), and further review is needed to clarify the distinction between these two systems.
Similar Ecological Systems:
- Southeastern Great Plains Tallgrass Prairie (CES205.685)
- Texas Blackland Tallgrass Prairie (CES205.684)

DESCRIPTION

Environment: This region is distinctly bounded by the Boston Mountains to the north and the Ouachita Mountains to the south, although it has been considered part of the Ouachita Ecoregion (TNC Ecoregion 39). The valley is characterized by broad, level to gently rolling uplands derived from shales and is much less rugged and more heavily impacted by Arkansas River erosional processes than the adjacent mountainous regions. In addition, the valley receives annual precipitation total of 5-15 cm (2-6 inches) less than the surrounding regions due to a rainshadow produced by a combination of prevailing western winds and mountain orographic effects (T. Foti pers. comm. 2003). The shale-derived soils associated with the prairies are thin and droughty. The combined effect of droughty soils, reduced precipitation, and prevailing level topography create conditions highly conducive to the ignition and spread of fires. Some extant examples of this system remain, but most are small and isolated. They were common on the western edge of the Arkansas Valley region, bordering (or possibly included in) the Crosstimbers (TNC Ecoregion 32) where precipitation and agriculture conversion were lowest (T. Foti pers. comm. 2003). This western portion of the Arkansas Valley region is labeled as part of 231Gc by Cleland et al. (2005) and 37d, 37e by EPA (EPA 2013).
Vegetation: These prairies are typically dominated by *Schizachyrium scoparium, Andropogon gerardii, Sorghastrum nutans*, and *Panicum virgatum*. Other grasses include *Koeleria macrantha, Sporobolus heterolepis, Sphenopholis obtusata, Dichanthelium* spp., *Aristida purpurascens, Panicum brachyanthum*, and *Coelorachis cylindrica*. A rich forb diversity is commonly present and includes *Helianthus mollis, Echinacea pallida, Rudbeckia grandiflora, Silphium laciniatum, Symphyotrichum* spp., *Solidago* spp., *Callirhoe digitata, Asclepias hirtella, Eryngium yuccifolium, Delphinium carolinianum, Castilleja coccinea, Calopogon oklahomensis, Buchnera americana, Dodecatheon meadia, Tephrosia virginiana, Baptisia alba, Baptisia bracteata, Liatris pycnostachya*, and *Liatris squarrosa var. hirsuta*. Wetter areas support a rich diversity of rushes and sedges, including *Carex bicknellii var. opaca (= Carex opaca), Carex oklahomensis, Carex complanata*, and *Eleocharis wolfii* (T. Witsell pers. comm. 2006).
Dynamics: These prairies and woodlands were historically maintained by frequent fire. Drought cycles and grazing were also likely important ecosystem processes. Fires were frequent, primarily autumnal and of human origin. As *Quercus-Carya* regeneration becomes established, individuals of these species become largely fire-resistant with age. Surface fires within woodland and forest

types occurred every 12 to 15 years, reducing duff layers and allowing recruitment of young individuals of *Quercus* and *Carya* species (Landfire 2007a).

Component Associations:

BLUEGRASS SAVANNA AND WOODLAND (CES202.888)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Deep Soil; Very Short Disturbance Interval; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2413; ESLF 7126; ESP 1413

CONCEPT

Summary: This system represents deep soil savannas and woodlands of the Inner Bluegrass Basin of Kentucky (EPA Ecoregion 71l and "S. Fork Licking River arm" of EPA Ecoregion 71d). Only remnants or stands undergoing restoration are currently extant. The original woodland-savanna aspect, especially on drier uplands, is believed to have been dominated by fire-resistant oaks, especially *Quercus muehlenbergii* and *Quercus macrocarpa*, but also with a variety of other species such as *Fraxinus quadrangulata, Robinia pseudoacacia, Gleditsia triacanthos, Acer saccharum, Fraxinus americana, Fraxinus pennsylvanica, Carya cordiformis, Juglans nigra*, and the rare *Gymnocladus dioicus*. The understory is composed of cool-season grasses, as far as known (e.g., *Elymus, Dichanthelium*) with *Arundinaria gigantea* (extensive canebrakes). Settlers referred to a "buffalo grass" of unknown identity (possibly *Dichanthelium clandestinum* or *Dichanthelium scoparium*). The fire regime is unknown. Characteristic remnant trees (e.g., *Fraxinus quadrangulata, Quercus macrocarpa*) are fire-tolerant.
Classification Comments: This system may, in part, be related to mesic woodland variants of Central Interior Highlands Calcareous Glade and Barrens (CES202.691). The mesic barrens and woodlands in the Interior Low Plateau have all but disappeared from the landscape, making regional assessments difficult. For information elsewhere on mesic barrens/woodlands in the Interior Highlands, see description for *Quercus stellata - Quercus alba - (Quercus falcata) / Schizachyrium scoparium* Woodland (CEGL004217).

- Bluegrass Mesophytic Cane Forest (Evans 1991) Finer
- Bluegrass Savanna-Woodland (Evans 1991) Finer
- Bur Oak: 42 (Eyre 1980) Finer

DESCRIPTION

Environment: These savannas or woodlands occur on deep fertile soils of the Inner Bluegrass Basin of Kentucky (Ecoregion 71l and "S. Fork Licking River arm" of Ecoregion 71d of EPA (EPA 2004) and Woods et al. (2002)).
Vegetation: The original woodland-savanna aspect, especially on drier uplands, is believed to have been dominated by fire-resistant oaks, especially *Quercus muehlenbergii* and *Quercus macrocarpa*, but also with a variety of other species such as *Fraxinus quadrangulata, Robinia pseudoacacia, Gleditsia triacanthos, Acer saccharum, Fraxinus americana, Fraxinus pennsylvanica, Carya cordiformis, Juglans nigra*, and the rare *Gymnocladus dioicus*. The understory is composed of cool-season grasses, as far as known (e.g., *Elymus, Dichanthelium*) with *Arundinaria gigantea* (extensive canebrakes). Settlers referred to a "buffalo grass" of unknown identity (possibly *Dichanthelium clandestinum* or Dichanthelium scoparium). Historical descriptions also mention "pea vine," two or three species of nettles, Vernonia species, Ageratina altissima, and *Trifolium stoloniferum*.
Dynamics: Central Kentucky grasslands were maintained by a combination of grazing, periodic drought, and fire, but one would expect that woody succession was also retarded by the heavy, clayey soils originating from the limestone substrate (Landfire 2007a). The first approximation map of presettlement fire regimes of the U.S. indicated fire regimes of 4-6 and 7-12 years in the model area (Frost 1998). Anthropogenic burning by Native Americans was probably an important part of the presettlement fire regime. This would have resulted in an expansion of these savannas and woodlands into otherwise forested areas. Native American population decline after the 1500s may have led to a decrease in the amount and frequency of burning in these savannas. Characteristic remnant trees (e.g., *Fraxinus quadrangulata*, *Quercus macrocarpa*) are fire-tolerant. Grazing by native herbivores (white-tailed deer and bison) may have been an important factor in maintaining the open character of these savannas.

In the gently rolling limestone regions, large expanses of land without significant firebreaks lie between the major firebreak streams. The large size of fire compartments in these areas suggests that fire frequency should have been high, perhaps 4-6 years where understory species were conducive to fire spread. Areas dominated by *Elymus* species may have experienced lower fire frequency because of the reduced capacity of this fuel type to carry fire (J. Campbell pers. comm.). Some writers think that these cool-season grasses (e.g., *Elymus*) predominated in preference to warm-season grasses such as *Schizachyrium*. In contrast, a fire frequency of 7-12 years could be expected in areas with broken topography such as the more rugged parts of the Outer Bluegrass and other limestone margin regions (Landfire 2007a). Lightning and Native Americans likely provided roughly equal influence as ignition sources in presettlement Kentucky, with Indian influence being the dominant factor locally near population concentrations and around fall and winter hunting camps. U.S. Weather Service lightning ground flash monitoring stations indicate a lightning strike density of 4-8 strikes per square kilometer per year in the limestone regions. While only a tiny fraction of strikes result in ignitions, this rate would

have produced a fire regime sufficient to support canebrakes and woodlands even in the absence of man (C. Frost pers. comm.).

Component Associations:
- *Acer (nigrum, saccharum) - Carya cordiformis* Forest (CEGL004411, G1)
- *Fraxinus quadrangulata - Quercus macrocarpa - Quercus muehlenbergii / Arundinaria gigantea ssp. gigantea / Elymus* spp. Woodland (CEGL004436, G1)
- *Fraxinus quadrangulata - Quercus macrocarpa / Arundinaria gigantea ssp. gigantea* Wooded Shrubland (CEGL003835, GH)
- *Juglans nigra - Aesculus glabra var. glabra - Gymnocladus dioicus / Arundinaria gigantea ssp. gigantea - (Asimina triloba)* Forest (CEGL004437, G1)

DISTRIBUTION

Range: This system is restricted to the Inner Bluegrass Basin of Kentucky (Ecoregion 71l and "S. Fork Licking River arm" of Ecoregion 71d of EPA (2004) and Woods et al. (2002)). Only remnants or stands undergoing restoration are currently extant.

BOREAL ALPINE FESCUE DWARF-SHRUBLAND AND GRASSLAND (CES105.320)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino; Boreal
National Mapping Codes: ESLF 7184

CONCEPT

Summary: This ecological system encompasses alpine grasslands and dwarf-shrubs characterized by *Festuca altaica* common in the Skeena and Ominega mountains.
Classification Comments: This system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. The system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).
Related Concepts:
- no data (BAFAunp/) (BCMF 2006) Intersecting

DISTRIBUTION

Range: This ecological system is found in northern boreal British Columbia and fingers down into the interior regions of British Columbia.

CALIFORNIA CENTRAL VALLEY AND SOUTHERN COASTAL GRASSLAND (CES206.942)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Valley; Toeslope/Valley Bottom; Mediterranean [Mediterranean Xeric-Oceanic]; Eutrophic Soil; Clay Soil Texture; F-Landscape/Low Intensity; Graminoid; Nassella pulchra
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Plateau; Woody-Herbaceous; Valley bottom; Valley floor; Valley side; Alluvial plain; Deep Soil; Mineral: W/ A-Horizon >10 cm; Udic; Short Disturbance Interval; Coastal plain
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2129; ESLF 7101; ESP 1129

CONCEPT

Summary: This system is found from 10-1200 m (30-3600 feet) elevation, in the Great Central Valley and along the southern coastal regions of California. It receives on average 50 cm (range 25-100 cm) of precipitation per year, mainly as winter rain. It is found with fine-textured soils, moist or even waterlogged in winter, but very dry in summer. Historically, these grasslands were common among oak savanna and woodland and probably experienced similar frequent fire regimes. Characteristic plant species include *Nassella pulchra, Aristida* spp., *Achillea millefolium var. borealis (= Achillea borealis), Achyrachaena mollis, Agoseris heterophylla, Bloomeria crocea, Triteleia ixioides (= Brodiaea lutea), Chlorogalum pomeridianum, Clarkia purpurea, Dodecatheon jeffreyi, Elymus glaucus, Leymus triticoides, Festuca californica, Melica californica, Castilleja attenuata (= Orthocarpus attenuatus),* and *Poa secunda (= Poa scabrella).*
Related Concepts:
- Coastal Prairie (214) (Shiflet 1994) Broader. Only small portions of this systems correspond to this SRM type (coastal grasslands between San Francisco Bay and Monterey).
- Valley Grassland (215) (Shiflet 1994) Intersecting. The SRM Valley grassland is described as predominantly annual grasslands and vernal pool communities.

DESCRIPTION

Environment: This ecosystem occurs from 10 to 1200 m (30-3600 feet) in elevation; receiving on average 50 cm (range 25-100 cm) of precipitation per year, mainly as winter rain. It is found with deep fine-textured soils, moist or even waterlogged in winter, but very dry in summer (Sawyer et al. 2009).
Dynamics: These grasslands have evolved to survive fire and long seasonal droughts (Keeley 2006). Invasion of non-native annual grasses out-compete natives through prolific seed production and the ability to re-seed quickly after fires, which generally means they maintain themselves at the expense of the native grasses and forbs (Sawyer et al. 2009).

DISTRIBUTION

Range: Found from in California from 10-1200 m (30-3600 feet) elevation, in the Great Central Valley and along the southern coastal region.
Divisions: 206:C
Nations: US

CALIFORNIA MESIC SERPENTINE GRASSLAND (CES206.943)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Mediterranean [Mediterranean Xeric-Oceanic]; Ultramafic with low Ca:Mg ratio; Deep Soil; Udic; Calamagrostis ophitidis
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Woody-Herbaceous; Serpentine
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2130; ESLF 7102; ESP 1130

CONCEPT

Summary: These grasslands are of very limited distribution in California within the Coast Ranges, Sierra Nevada, and Transverse Ranges on deep soils with serpentine-rich parent material. Not all serpentinite outcrops support distinct vegetation; only those with very low Ca:Mg ratios impact biotic composition. In this system, native bunchgrass dominates, though typically in less dense cover than other perennial bunchgrass types. Characteristic species include *Calamagrostis ophitidis*, *Eschscholzia californica*, *Vulpia microstachys var. ciliata (= Festuca grayi)*, *Poa secunda (= Poa scabrella)*, *Hemizonia congesta ssp. luzulifolia (= Hemizonia luzulifolia)*, *Nassella cernua*, and *Nassella pulchra*. Historic fire regimes in this system are not well known.
Related Concepts:
- Valley Grassland (215) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This ecosystem occurs on deep soils with serpentine-rich parent material. Not all serpentinite outcrops support distinct vegetation; only those with very low Ca:Mg ratios impact biotic composition.
Dynamics: Serpentine soils are relatively infertile soils and mycorrhizal relationships are considered important to plant survival (Jimerson et al. 1995). Hopkins 1986 (as cited in Jimerson et al. 1995) found that 98% of the herbaceous plants in the serpentine grassland communities of the Santa Cruz Mountains were mycorrhizal. Ectomycorrhizae are often associated with members of the Ericaceae family, a well-represented family in the serpentine flora (Jimerson et al. 1995).

DISTRIBUTION

Range: This system is found in the Coast Ranges, Sierra Nevada, and Transverse Ranges of California on deep soils with serpentine-rich parent material. It may also occur on serpentine in the Klamath Mountains of southern Oregon.
Divisions: 206:C
Nations: US

CALIFORNIA NORTHERN COASTAL GRASSLAND (CES206.941)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Herbaceous; Terrace; Mediterranean [Mediterranean Xeric-Oceanic]; Very Short Disturbance Interval [Periodicity/Nonrandom Disturbance]; F-Patch/Low Intensity; Graminoid
Non-Diagnostic Classifiers: Hillslope bedrock outcrop; Woody-Herbaceous
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2131; ESLF 7103; ESP 1131

CONCEPT

Summary: This ecological system is found in discontinuous patches below 300 m (1000 feet) elevation from San Francisco Bay north into Oregon, on coastal terraces and ridgeline balds in the Coast Ranges and Klamath Mountains. Small patches have been documented as far south as Santa Barbara and San Luis Obispo counties. It has a similar distribution to coastal shrublands (Northern California Coastal Scrub (CES206.932)) in areas that receive more rainfall than other California grasslands of the interior or southern coastal California. In recent centuries, these were fire-dominated systems, and there is a known history of Native American use of fire in these areas. While still present, annual grasses and forbs are not as prevalent in these grasslands as elsewhere in California. With fire suppression, *Baccharis pilularis* and other shrub components of north coastal scrub often invade and can replace these grasslands with scrub-dominated systems. *Agrostis* spp., *Bromus carinatus, Calamagrostis nutkaensis, Danthonia californica, Festuca rubra, Festuca idahoensis, Deschampsia caespitosa, Koeleria macrantha, Trisetum canescens*, and perennial forbs such as *Iris douglasiana, Sisyrinchium bellum, Grindelia hirsutula*, and *Sanicula arctopoides* are characteristic.
Similar Ecological Systems:
- North Pacific Hypermaritime Shrub and Herbaceous Headland (CES204.088)

Related Concepts:
- Coastal Prairie (214) (Shiflet 1994) Broader. Most of the SRM Coastal Prairie type corresponds to this system.

DESCRIPTION

Environment: This ecosystem occurs on coastal terraces and ridgeline balds in the Coast Ranges in small patches in areas that receive more rainfall than the Central Valley grasslands or those of southern coastal California (south of Santa Barbara County), and wherever the cooling influence of the Pacific Ocean moderates summer drought (Ford and Hayes 2007). Soils are rich and moist, on terraces on the coast line and balds on inland ridges and hilltops (Sawyer et al. 2009).
Dynamics: Coastal prairies are maintained by salt spray that limits woody growth, and burning, likely annual ignitions by Native Americans (Stuart and Stephens 2006). Historical frequent fire, salt-laden wind, and windy ridgetops inhibit forest development in these areas (Franklin and Dyrness 1973, as cited in Sawyer et al. 2009). Fire is a useful management tool for control of non-native invasive species (Sawyer et al. 2009).

Component Associations:
- *Calamagrostis nutkaensis - Carex* spp. - *Juncus* spp. Herbaceous Vegetation (CEGL003378, G2)
- *Calamagrostis nutkaensis - Elymus glaucus* Herbaceous Vegetation (CEGL001564, G2)
- *Danthonia californica - Aira caryophyllea* Herbaceous Vegetation (CEGL003474, G3)
- *Danthonia californica - Festuca rubra* Herbaceous Vegetation (CEGL001597, G2)
- *Deschampsia caespitosa - Danthonia californica* Coastal Herbaceous Vegetation (CEGL003325, G2)
- *Empetrum nigrum - Gaultheria shallon* Dwarf-shrubland (CEGL000971, G2)

DISTRIBUTION

Range: This system is found below 300 m (1000 feet) elevation from San Francisco Bay (and possibly farther south) north into Oregon, on coastal terraces and ridgeline balds in the Coast Ranges and Klamath Mountains.
Divisions: 206:C
Nations: US

CENTRAL MIXEDGRASS PRAIRIE (CES303.659)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Lowland [Lowland]; Herbaceous; Temperate [Temperate Continental]; Shallow Soil; Loam Soil Texture; Silt Soil Texture; Ustic; F-Landscape/Medium Intensity; G-Landscape/High Intensity; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2132; ESLF 7104; ESP 1132

CONCEPT

Summary: This mixedgrass prairie system ranges from South Dakota into the Rolling Plains and the western Edwards Plateau of Texas. It is bordered by the shortgrass prairie on its western edge and the tallgrass prairie to the east. The loessal regions in west-central Kansas and central Nebraska, the Red Hills region of south-central Kansas and northern Oklahoma are all located within this system. Because of its proximity to other ecoregions, this system contains elements from both shortgrass and tallgrass prairies, which combine to form the mixedgrass prairie ecological system throughout its range. The distribution, species richness and productivity of plant species within the mixedgrass ecological system is controlled primarily by environmental conditions, in particular soil moisture and topography. Grazing and fire are important dynamic processes in this system. The relative dominance of the various grass and forb species within different associations in the system also can strongly depend on the degree of natural or human disturbance. This system can contain grass species such as *Bouteloua curtipendula, Schizachyrium scoparium, Andropogon gerardii, Hesperostipa comata, Sporobolus heterolepis*, and *Bouteloua gracilis*, although the majority of the associations within the region are dominated by *Pascopyrum smithii* or *Schizachyrium scoparium*. Numerous forb and sedge species (*Carex* spp.) can also occur within the mixedgrass system in the Western Great Plains. Although forbs do not always significantly contribute to the canopy, they can be very important. Some dominant forb species include *Ambrosia psilostachya, Echinacea angustifolia*, and *Lygodesmia juncea*. Oak species such as *Quercus macrocarpa* can occur also in areas protected from fire due to topographic position. This can cause an almost oak savanna situation in certain areas, although fire suppression may allow for a more closed canopy and expansion of bur oak beyond those sheltered areas. In those situations, further information will be needed to determine if those larger areas with a more closed canopy of bur oak should be considered part of Western Great Plains Dry Bur Oak Forest and Woodland (CES303.667). Likewise, within the mixedgrass system, small seeps may occur, especially during the wettest years. Although these are not considered a separate system, the suppression of fire within the region has enabled the invasion of both exotics and some shrub species such as *Juniperus virginiana* and also allowed for the establishment of *Pinus ponderosa* in some northern areas.
Classification Comments: This system is found primarily in the Central Mixed-grass Prairie (TNC Ecoregion 33); it becomes more restricted to mesic lowlands sites to the west and southwest in the shortgrass prairie region of Texas (S. Menard pers. comm. 2005). This is probably a reference to the Llano Estacado region rather than the Southern Shortgrass Prairie (TNC Ecoregion 28) (J. Teague pers. obs. 2005). The Central Mixed-grass Prairie (TNC Ecoregion 33) should be extended south to include the Rolling Plains of Texas; being separated from the Southern Shortgrass Prairie (TNC Ecoregion 28) by the Caprock Escarpment (L. Elliott pers. comm. 2005).
Similar Ecological Systems:
- Northwestern Great Plains Mixedgrass Prairie (CES303.674)
- Western Great Plains Dry Bur Oak Forest and Woodland (CES303.667)
- Western Great Plains Mesquite Woodland and Shrubland (CES303.668)
- Western Great Plains Sand Prairie (CES303.670)

Related Concepts:
- Blue Grama - Western Wheatgrass (704) (Shiflet 1994) Finer
- Bluestem - Grama (709) (Shiflet 1994) Broader
- Bluestem - Grama Prairie (604) (Shiflet 1994) Finer
- Central Mixed-Grass Prairie (Rolfsmeier and Steinauer 2010) Equivalent
- Eastern Redcedar: 46 (Eyre 1980) Finer. Only on really degraded sites.
- Rolling Plains: Mixedgrass Prairie (307) [CES303.659.9] (Elliott 2011) Equivalent

DESCRIPTION

Environment: Differences in topography and soil characteristics occur across the range of this system. It is often characterized by gently rolling to extremely hilly landscapes with soils developed from loess, shale, limestone or sandstone parent material, including Pennsylvanian formations of the Red Rolling Plains (Elliott 2011). Mollisol soils are most prevalent and range from silt loams and silty clay loams with sandy loams possible on the western edge of the range. The Red Hills region of Kansas and Oklahoma, which contains examples of this system, contains somewhat unique soil characteristics and has developed from a diversity of sources including red shale, red clay, sandy shale, siltstone, or sandstone. These soils have developed a characteristic reddish color from the primary material. These soils can consist of silt, loam, clay loam, or clay and can have textures ranging from a fine sandy loam to a

more clayey surface. Ecological Sites include Clay Slopes, Loamy Prairie, Clayey Upland, Claypan Prairie, Sandy Loam, and Clay Loam (Elliott 2011).

Vegetation: This system contains elements from both Western Great Plains Shortgrass Prairie (CES303.672) and Western Great Plains Tallgrass Prairie (CES303.673). This system typically contains grass species such as *Bouteloua curtipendula, Schizachyrium scoparium, Andropogon gerardii, Hesperostipa comata, Sporobolus heterolepis,* and *Bouteloua gracilis*, although the majority of the associations within the region are dominated by *Pascopyrum smithii* or *Schizachyrium scoparium.* Isolated patches of *Quercus macrocarpa* also can occur. Central Mixedgrass Prairie (CES303.659) represents the common prairie type in the Rolling Plains of Texas (Elliott 2011). This prairie often has *Schizachyrium scoparium* as a dominant, with *Bouteloua curtipendula, Bouteloua hirsuta, Bouteloua gracilis, Buchloe dactyloides, Andropogon gerardii, Pascopyrum smithii,* and *Nassella leucotricha* also commonly encountered. Grazing tends to favor shortgrass species such as *Buchloe dactyloides* and *Bouteloua gracilis.* This system is frequently invaded by juniper (primarily *Juniperus pinchotii*) and *Prosopis glandulosa* (Elliott 2011).

Dynamics: Fire, grazing, and drought are the primary processes occurring within the system. The diversity in this mixedgrass system likely reflects both the short- and long-term responses of the vegetation to these often concurrent disturbance regimes (Collins and Barber 1985). Fire is not as common as in more fertile, well-watered tallgrass prairies further east but is still important. Fire-return intervals have been estimated at 15-25 years (Landfire 2007a), but fires burn patchily across the landscape, consuming vegetation in some areas and missing others. This combined with the differential responses of species to burning results in greater diversity across the landscape (Wright 1974). Grazing by native ungulates, primarily bison (*Bison bison*) and small mammals, principally prairie dogs (*Cynomys* spp.) added a further degree of patchy disturbance to the mixedgrass prairie (Whicker and Detling 1988, Weltzin et al. 1997). Long-term precipitation variance affects diversity of the mixedgrass prairie, creating conditions more favorable to shortgrass species during droughts while allowing mixedgrass species to spread during wetter years (Albertson and Tomanek 1965).

CENTRAL TALLGRASS PRAIRIE (CES205.683)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Eastern Great Plains (205)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Glaciated plains; Herbaceous; Temperate; Glaciated; Deep Soil; Loam Soil Texture
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2421; ESLF 7134; ESP 1421

CONCEPT

Summary: This system is found primarily in the Central Tallgrass Prairie ecoregion ranging from eastern Kansas and Nebraska to northwestern Indiana. This system differs from other prairie systems to the north and south by being the most mesic with primarily deep, rich Mollisol soils. These soils are usually greater than 1 meter deep. This system is dominated by tallgrass species such as *Andropogon gerardii*, *Sorghastrum nutans*, and *Panicum virgatum*. These species typically grow to 1-2 m tall in the rich soils found in this system. Other mid- and shortgrass species, such as *Bouteloua curtipendula*, *Hesperostipa spartea*, and *Schizachyrium scoparium*, are usually present and can be common or locally dominant on patches of this system, particularly slopes or other areas with drier habitats. Several forb species are also associated with this system making it one of the most diverse grassland systems. As many as 300 herbaceous plant species could occur in this system across its range. The environment and habitat of this system do not prevent invasion by shrubs and trees. High-quality examples of this system have trees and shrubs widely scattered or clustered in areas that are wetter and/or more sheltered from fire than the surrounding grassland. Fire, drought, and grazing are the primary natural dynamics influencing this system and help prevent woody species from invading. However, conversion to agriculture has been the prime disturbance since post-European settlement. The rich soils and long growing season make this an ideal location for farming row crops, and as a result very few examples of this system remain.

Similar Ecological Systems:
- Northern Tallgrass Prairie (CES205.686)
- Southeastern Great Plains Tallgrass Prairie (CES205.685)
- Texas Blackland Tallgrass Prairie (CES205.684)

Related Concepts:
- Central Tall-Grass Prairie (Rolfsmeier and Steinauer 2010) Equivalent

DESCRIPTION

Environment: This system differs from other prairie systems to the north and south by being the most mesic with primarily deep, rich Mollisol soils. These soils are usually greater than 1 m deep and organic matter is high. Litter can build up if sites are not burned or grazed for several years. This system occurs in a climate that allows the growth of trees and shrubs. These are kept out of the prairies largely by fires and periodic drought, so the prairies tended to be on flat to rolling topography with fewer firebreaks (wetlands, rivers, or steeply dissected topography).

Vegetation: This system is dominated by tallgrass species such as *Andropogon gerardii*, *Sorghastrum nutans*, and *Panicum virgatum*. These species typically grow to 1-2 m tall in the rich soils found in this system. Other mid- and shortgrass species, such as *Bouteloua curtipendula*, *Hesperostipa spartea*, and *Schizachyrium scoparium*, are usually present and can be common or locally dominant on patches of this system, particularly slopes or other areas with drier habitats. Several forb species are also associated with this system making it one of the most diverse grassland systems. As many as 300 herbaceous plant species could occur in this system across its range. The environment and habitat of this system do not prevent invasion by shrubs and trees. High-quality examples of this system have trees and shrubs widely scattered or clustered in areas that are wetter and/or more sheltered from fire than the surrounding grassland.

Dynamics: Fire, drought, and grazing are the primary natural dynamics influencing this system and help prevent woody species from invading. This system is found in a climate that can support trees and shrubs but woody vegetation is inhibited by frequent fires. Historically, fire-return intervals were short, estimated at between 2 and 5 years (Stambaugh et al. 2006, Landfire 2007a). The frequent but unpredictable fires created a patchwork of habitats across the landscape, with recently burned sites having less litter and forb cover and sites with infrequent fires possibly having more woody species and dense stands of grasses (Kucera and Koelling 1964). This system developed in an area with large numbers of native ungulates, notably bison (*Bison bison*) but including other species, and the grazing of these species affected species composition and the patchwork of habitat. Bison were likely more numerous and thus had more effect in the western portion of this system's range. Bison preferentially favor newly burned areas and graminoids over forbs (Vinton et al. 1993, Coppedge and Shaw 1998). Their grazing, trampling, and wallowing were important in creating habitat diversity across the landscape (Knapp et al. 1999). On unburned sites, grazing removes live and dead vegetation, allowing more light and heat to the soil surface and increasing available moisture thus favoring species, forbs or woody plants, in the case of bison grazing, that were resilient to the effects of grazing or avoided by the grazers (Damoureyeh and Hartnett 1997).

CHIHUAHUAN LOAMY PLAINS DESERT GRASSLAND (CES302.061)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Warm Desert (302)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Plain; Valley; Alluvial flat
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2503; ESLF 7164; ESP 1503

CONCEPT

Summary: This ecological system occurs in the northern Chihuahuan Desert and extends into limited areas of the southern Great Plains on alluvial flats, loamy plains, and basins sometimes extending up into lower piedmont slopes. Sites are typically flat or gently sloping so precipitation does not run off and may be somewhat mesic if they receive runoff from adjacent areas, but these are not wetlands or mesic, bottomland grassland. Soils are non-saline, finer textured loams or clay loam. Vegetation is characterized by perennial grasses and is typically dominated by *Pleuraphis mutica* or with *Bouteloua eriopoda* codominant (more historically) or *Bouteloua gracilis*. In degraded stands, *Scleropogon brevifolius, Dasyochloa pulchella (= Erioneuron pulchellum)*, or *Aristida* spp. may codominate. *Pleuraphis jamesii* may become important in northern stands and *Bouteloua gracilis* in the Great Plains and on degraded stands. If present, mesic graminoids such as *Pascopyrum smithii, Panicum obtusum*, *Sporobolus airoides*, and *Sporobolus wrightii* typically have low cover and are restricted to drainages and moist depressions (inclusions). Scattered shrubs such as *Ephedra torreyana, Flourensia cernua, Gutierrezia sarothrae, Larrea tridentata, Opuntia imbricata, Prosopis glandulosa*, and *Yucca* spp. may be present, especially on degraded sites.
Classification Comments: NRCS Ecological Site Description MLRA 42 SD-2 Loamy Ecological Site (NRCS 2006) describes this system on the Jornada Experimental Range with State-and-Transition Model showing shifts in species composition with land use. Degraded stands often have scattered desert scrubs such as *Larrea tridentata, Flourensia cernua,* and *Prosopis glandulosa* present.

This upland grassland is similar to the bottomland/depressional wetland system Chihuahuan-Sonoran Desert Bottomland and Swale Grassland (CES302.746) and grades into Apacherian-Chihuahuan Semi-Desert Grassland and Steppe (CES302.735) in the foothills and piedmont desert grasslands. In similar loamy plains land positions in the Great Plains, *Bouteloua gracilis, Buchloe dactyloides*, or *Pleuraphis jamesii* are dominant grasses in Western Great Plains Shortgrass Prairie (CES303.672).

Similar Ecological Systems:
- Chihuahuan-Sonoran Desert Bottomland and Swale Grassland (CES302.746)

Related Concepts:
- MLRA 42 - Southern Desertic Basin (SD-1) Loamy (NRCS 2006a) Broader
- MLRA 42 - Southern Desertic Basin (SD-2) Loamy (NRCS 2006a) Broader
- MLRA 42 - Southern Desertic Basin (SD-3) Loamy (NRCS 2006a) Broader

DESCRIPTION

Environment: These upland grasslands occur at approximately 1450-2320 m (4750-7610 feet) elevation and are found on alluvial flats, loamy plains, and desert basins sometimes extending up into lower piedmont slopes including mesatops. Sites are typically flat or gently sloping so precipitation does not run off and may be somewhat mesic if they receive runoff from adjacent areas, but these are not wetlands or bottomland grasslands described in Chihuahuan-Sonoran Desert Bottomland and Swale Grassland (CES302.746). Annual precipitation is usually from 20-40cm (7.9-15.7 inches). Soils are non-saline, finer-textured loams or clay loam that are often derived from sedimentary parent materials but are quite variable and may include fine-textured soils derived from igneous and metamorphic rocks. These grasslands can occur on a variety of aspects and slopes ranging from flat to moderately steep. When they occur near foothill grasslands, they will be at lower elevations (Landfire 2007a).

Vegetation: The vegetation in examples of this system is characterized by perennial grasses and is typically dominated by *Pleuraphis mutica* (tobosa) or with *Bouteloua eriopoda* codominant (more historically) or *Bouteloua gracilis*. In degraded stands, *Scleropogon brevifolius, Dasyochloa pulchella (= Erioneuron pulchellum)*, or *Aristida* spp. may codominate. *Pleuraphis jamesii* may become important in northern stands and *Bouteloua gracilis* in the Great Plains and on degraded stands. If present, mesic graminoids such as *Pascopyrum smithii, Panicum obtusum, Sporobolus airoides*, and *Sporobolus wrightii* typically have low cover and are restricted to drainages and moist depressions (inclusions). Scattered shrubs such as *Ephedra torreyana, Flourensia cernua, Gutierrezia sarothrae, Larrea tridentata, Opuntia imbricata, Prosopis glandulosa*, and *Yucca* spp. may be present, especially on degraded sites.

Dynamics: Historic fire frequency in this ecosystem is not known, but is likely less frequent than other denser desert grasslands because of less fuel in this typically open grassland ecosystem (Humphrey 1963). The effects of burning tobosa-dominated grasslands is variable depending upon soil moisture and plant phenology at the time of the fire, precipitation in the months following the fire, and site characteristics that influence soil moisture availability, and fire intensity based on research in the Great Plains (Innes 2012). However, the dominant grass *Pleuraphis mutica* is likely to survive most fires and can sprout from rhizomes and grow quickly after top-kill by fire (Britton and Steuter1983).

These grasslands are prone to flooding during high precipitation events because of slow infiltration. This may result in overland flow

and erosion of topsoil and some short-term loss of vegetative cover. Landfire (2007a) modeled this system and predicted that during a >500-year flooding event in a swale or stream channel, sites could downcut, thus lowering the water table, and favor woody species in an altered state. Drought cycles likely resulted in a reduction in vegetative cover and production of these sites (Landfire 2007a). Annual growth of woody vegetation depends on annual rainfall; drought negatively affected woody species. Cyclic drought impacts vegetation growth two to three years out of every 10 years, and vegetation-killing drought has a mean return interval of 100 years (Landfire 2007a).

Some grasslands with deep argillic horizons in the San Rafael valley in Arizona and Animas valley in New Mexico have not shown shrub or tree encroachment and/or conversion in the absence of fire or presence of livestock grazing (McAuliffe 1995, Muldavin et al. 2012c). These deep-soil systems have maintained open grassland characteristics despite fire suppression, drought, and livestock grazing. However, there are other valley bottom areas that once supported grasslands, such as the San Simon valley, that have been converted to shrublands due to soil erosion. It is unclear exactly what mechanisms are responsible for the resilience seen in some areas and not in others. McAuliffe (1995) highlighted research on the Santa Rita Experimental Range in Arizona that shows sites of the mid-Pleistocene fan remnants with strongly developed argillic horizons that have not been significantly invaded by deep-rooted shrubs when compared to nearby younger substrates with weakly developed or absent argillic horizons. McAuliffe (1995) suggested these impermeable argillic layers restrict deep percolation of soil-water and may favor the shallower-rooted grasses like tobosa. These soil - water - vegetation relationships may apply to these grasslands in the Chihuahuan Desert.

Component Associations:
- *Pleuraphis mutica - Bouteloua gracilis* Herbaceous Vegetation (CEGL001638, GNRQ)
- *Pleuraphis mutica - Buchloe dactyloides* Herbaceous Vegetation (CEGL002272, G4?)
- *Pleuraphis mutica - Scleropogon brevifolius* Herbaceous Vegetation (CEGL001640, G5)
- *Pleuraphis mutica* Monotype Herbaceous Vegetation (CEGL001637, G5?)

DISTRIBUTION

Range: This grassland system is found from the northern to central Chihuahuan Desert and extends across the Trans-Pecos and into areas of the southwestern Great Plains. It extends from western Texas across New Mexico and into southeastern Arizona. Stands are described from Jornada del Muerto Basin, Marfa grasslands and Marathon Basin, south to central Chihuahua and Coahuila, Mexico.

CHIHUAHUAN SANDY PLAINS SEMI-DESERT GRASSLAND (CES302.736)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Sand Soil Texture; Graminoid
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Mesa; Plain; Toeslope/Valley Bottom; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Continental]; Temperate [Temperate Xeric]; Aridic; Xeromorphic Shrub; Succulent Shrub
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2133; ESLF 7105; ESP 1133

CONCEPT

Summary: This ecological system occurs across the Chihuahuan Desert and extends into the southern Great Plains where soils have a high sand content. These dry grasslands or steppe are found on sandy plains and sandy mesatops. The graminoid layer is typically dominated or codominated by *Bouteloua eriopoda* and *Sporobolus flexuosus*. Other common species are *Aristida purpurea, Bouteloua gracilis, Hesperostipa neomexicana* (minor), *Muhlenbergia arenicola, Pleuraphis jamesii, Sporobolus airoides, Sporobolus contractus*, and *Sporobolus cryptandrus*. Typically, there are scattered desert shrubs and stem succulents present, such as *Ephedra torreyana, Ephedra trifurca, Opuntia imbricata, Yucca baccata, Yucca elata*, and *Yucca torreyi*, that are characteristic of the Chihuahuan Desert. The widespread shrub *Artemisia filifolia* is also frequently present along with *Atriplex canescens*, especially in the northern extent.
Classification Comments: When degraded, this grassland will convert to open to dense shrublands frequently dominated by *Prosopis glandulosa* or *Artemisia filifolia* (in its northern extent where it is too cold for *Prosopis glandulosa* to be abundant) (S. Yanoff pers. comm. 2006). This degraded type is classified as Chihuahuan Stabilized Coppice Dune and Sand Flat Scrub (CES302.737).

DESCRIPTION

Environment: This grassland system occurs on gently sloping, undulating piedmont slopes or plains at elevations ranging from 1065-1525 m (3500-5000 feet). Mean annual precipitation ranges from 20-27 cm (8-10.5 inches), although rainfall is highly variable ranging from 5-50 cm (2-20 inches). Half of the precipitation or more typically falls during summer monsoonal events. Annual frost-free season exceeds 200 days. Spring southwesterly winds are an important factor for soil/sand distribution (Landfire 2007a).

Historically the grassland type was widespread in the northern Chihuahuan Desert occupying sandy sites and dominated by *Bouteloua eriopoda* and other grasses, especially *Sporobolus flexuosus* and *Sporobolus cryptandrus*. Natural spatial variation in the vegetation of this ecological system may be governed by slight variations in soil texture. For example, dropseeds may dominate on loamy sands. Variation in the depth to a restrictive horizon, such as caliche, may also drive variation in grass cover (Landfire 2007a). Frequently, mesquite shrublands have invaded former black grama grassland sites, including the development of coppice dunes (Landfire 2007a).
Dynamics: Wind is an important disturbance agent in this grassland system. The grassland is highly sensitive to grazing and frequent drought. Fire is relatively infrequent, but can result in a significant change of dominant vegetation (Landfire 2007a). The role of fire in New Mexico's black grama-dominated grasslands is unclear, as studies of historical records do not document fires in these grasslands (Wright 1960, Buffington and Herbal 1965). However, in contrast to other desert grasslands, fire has been shown to decrease black grama cover (Buffington and Herbel 1965, Drewa and Havstad 2000). Several other New Mexico studies have shown that black grama decreases with other disturbances, such as drought, livestock grazing, and clipping, recovering slowly, if at all, after such events (Buffington and Herbel 1965, Gibbens and Beck 1988, Gosz and Gosz 1996, Whitford et al. 1999, Drewa and Havstad 2000, Gibbens et al. 2005). While drought was a conflicting factor in many of these studies, it is important to note that studies in Arizona were also conducted during times of drought and resulted in longer recovery times, not a lack of recovery in perennial grasses (Schussman 2006a).

Bouteloua eriopoda is a key plant due to its dominance under pristine conditions, its high forage value and its consequent sensitivity to grazing. Shifts away from black grama dominance are thought to be due to overgrazing and/or multi-year periods of summer or spring drought, or due to the introduction of *Prosopis glandulosa* seeds with or without grazing. With continuous heavy grazing, the proportional representation of black grama declines because it is preferred by cattle over species of *Sporobolus, Aristida*, and *Gutierrezia* (Paulsen and Ares 1962). *Sporobolus* spp. are more palatable than *Aristida* spp., so dropseeds may also decline relative to threeawns and *Gutierrezia* spp. Under climatic conditions that are not conducive to black grama reproduction, or due to the loss of components of the soil biota, demographic limitations may lead to persistent absence of black grama, even without shrub invasion. Shrub invasion is, however, very common. Loss of soil stability and/or a reduction in black grama cover may permit either the survival or establishment mesquite seedlings due to reduced competition or fire frequency. These grasslands have been shown to trend

towards shrublands over the last 100 years (Buffington and Herbel 1965, Gibbens et al. 2005). Subsequent grazing by livestock and native herbivores, competition from shrubs, erosion, and concentration of nutrients under adult shrubs eventually lead to persistent reductions of grass cover and mesquite-dominated coppice dunes with bare or snakeweed-dominated interdunal areas. A substantial number of studies document states and potential causes of transitions. There are multiple competing and complementary explanations for individual transitions that have not been formally tested. If the operation of these mechanisms is case-contingent, it may be especially problematic to define the causes of transitions quantitatively (e.g., a threshold cover of black grama). Nonetheless, careful monitoring of black grama health should be a key feature of management. Overall, the high palatability of black grama during times of year when most other species are less palatable, coupled with the limited capacity of this grass to regenerate under current climatic conditions (Neilson 1986), leads to a relatively high probability of transition with poor range management. It is also possible that changes in climate over the last several hundred years have created an transition from the presumed historic plant community type and that good management can only delay the inevitable shift to shrubland (Landfire 2007a).

Component Associations:

COLUMBIA BASIN FOOTHILL AND CANYON DRY GRASSLAND (CES304.993)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Sideslope; Very Shallow Soil; Landslide; Graminoid
Non-Diagnostic Classifiers: Herbaceous; Temperate [Temperate Continental]; Unconsolidated; Succulent Shrub
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2134; ESLF 7106; ESP 1134

CONCEPT

Summary: These grasslands are similar floristically to Columbia Basin Palouse Prairie (CES304.792) but are distinguished by landform, soil, and process characteristics. They occur in the canyons and valleys of the Columbia Basin, particularly along the Snake River canyon, the lower foothill slopes of the Blue Mountains, and along the main stem of the Columbia River in eastern Washington. Occurrences are found on steep open slopes, from 90 to 1525 m (300-5000 feet) elevation. Annual precipitation is low, ranging from 10 to 25 cm (4-10 inches). Settings are primarily long, steep slopes of 100 m to well over 400 m, with soils derived from residuum and having patchy, thin, wind-blown surface deposits. Slope failures are a common process. Fire frequency is presumed to be less than 20 years. The vegetation is dominated by patchy graminoid cover, cacti, and some forbs. *Pseudoroegneria spicata, Festuca idahoensis*, and *Opuntia polyacantha* are common species. Deciduous shrubs *Symphoricarpos* spp., *Physocarpus malvaceus, Holodiscus discolor*, and *Ribes* spp. are infrequent native species that may increase with fire exclusion.

Similar Ecological Systems:
- Columbia Basin Palouse Prairie (CES304.792)
- Inter-Mountain Basins Big Sagebrush Steppe (CES304.778)
- Northern Rocky Mountain Lower Montane, Foothill and Valley Grassland (CES306.040)

Related Concepts:
- Bluebunch Wheatgrass (101) (Shiflet 1994) Intersecting
- Idaho Fescue (102) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: These dry grasslands are distinguished by landform, soil, and process characteristics. Annual precipitation is low, ranging from 12-25 cm (5-10 inches) that occurs mostly in the winter, primarily as rain. They occur in the canyons and valleys of the Columbia Basin, particularly along the Snake River canyon, the lower foothill slopes of the Blue Mountains, and along the main stem of the Columbia River in eastern Washington. Occurrences are found on steep open slopes, from 90 to 1525 m (300-5000 feet) elevation. Landform settings of this grassland are primarily long, steep slopes of 100 m to well over 400 m in length, with colluvial soils derived from residuum and having patchy, thin, wind-blown surface deposits. Bare ground, gravel and rock between bunches are common features due to frequent soil movement and sun exposure. Biological soil crust cover is usually present but generally decreases with increasing vascular plant cover, elevation, loose surface rock, and coarseness of soil. Elk, deer and bighorn sheep are native large grazers in the canyon who used these grasslands, particularly in winter and spring (Tisdale 1986).

Vegetation: The vegetation is dominated by patchy graminoid cover, cacti, and some forbs. *Pseudoroegneria spicata, Festuca idahoensis*, and *Opuntia polyacantha* are common species. Deciduous shrubs *Symphoricarpos* spp., *Physocarpus malvaceus, Holodiscus discolor*, and *Ribes* spp. are infrequent native species that may increase with fire exclusion.

Dynamics: This grassland primarily occurs on long, steep slopes. Surface disturbances from slope failure are a common process. Most slips result from saturated soil layers over frozen ground (Tisdale 1986). Fire is the primary disturbance factor. Historically, fire resulted in top-kill and some mortality, although the overall grassland was not changed. Fires were low intensity due to limited fuel and significant internal spacing between fuel patches. Currently, cheatgrass and other introduced grasses often invade these habitats after fire. The historic frequency was 5-20 years. Fire frequency is presumed to be less than 20 years; the return interval may have been as low as 5-10 years (Landfire 2007a).

Biological soil crust cover diminishing or eliminated alters the composition of perennial species and increases the establishment of native disturbance-increasers and annual grasses, particularly *Bromus tectorum* and other exotic annual bromes (WNHP 2011). Crust cover and diversity are greatest where not impacted by trampling, other soil surface disturbance and fragmentation (Belnap et al. 2001, Rosentreter and Eldridge 2002, Tyler 2006).

Component Associations:
- *Aristida purpurea var. longiseta - Poa secunda* Herbaceous Vegetation (CEGL001781, G3)

COLUMBIA BASIN PALOUSE PRAIRIE (CES304.792)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Long (>500 yrs) Persistence; Loess deposit (undifferentiated); Herbaceous; Deep Soil; Mineral: W/ A-Horizon >10 cm; Graminoid; Cool-season bunch grasses
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Temperate [Temperate Continental]; Glaciated
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2142; ESLF 7115; ESP 1142

CONCEPT

Summary: This once-extensive grassland system occurs in eastern Washington and Oregon, and west-central Idaho, though in very small patches there. In much of its range it is characterized by rolling topography composed of loess hills and plains over basalt plains. The climate of this region has warm-hot, dry summers and cool, wet winters. Annual precipitation is high, 38-76 cm (15-30 inches). The soils are typically deep, well-developed, and old. The cool-season bunch grasses that dominate the vegetation are adapted to this winter precipitation. Characteristic species are *Pseudoroegneria spicata* and *Festuca idahoensis* with *Hesperostipa comata, Achnatherum scribneri, Leymus condensatus, Leymus cinereus, Koeleria macrantha, Pascopyrum smithii*, or *Poa secunda*. Shrubs commonly found include *Amelanchier alnifolia, Rosa* spp., *Eriogonum* spp., *Symphoricarpos albus*, and *Crataegus douglasii*. Excessive grazing, past land use and invasion by introduced annual species have resulted in a massive conversion to agriculture or shrub-steppe and annual grasslands dominated by *Artemisia* spp. and *Bromus tectorum* or *Poa pratensis*. Remnant grasslands are now typically associated with steep and rocky sites or small and isolated sites within an agricultural landscape.
Similar Ecological Systems:
- Columbia Basin Foothill and Canyon Dry Grassland (CES304.993)
- Northern Rocky Mountain Lower Montane, Foothill and Valley Grassland (CES306.040)

Related Concepts:

DESCRIPTION

Environment: This once-extensive grassland system occurs in eastern Washington and Oregon, and west-central Idaho, though in very small patches there. In much of its range it is characterized by rolling topography composed of loess hills and plains over basalt plains. The climate of this region has warm-hot, dry summers and cool, wet winters. Annual precipitation is high, 38-76 cm (15-30 inches). The soils are typically deep, well-developed, and old. The cool-season bunch grasses that dominate the vegetation are adapted to this winter precipitation.
Vegetation: Characteristic species are *Pseudoroegneria spicata* and *Festuca idahoensis* with *Hesperostipa comata, Achnatherum scribneri, Leymus condensatus, Leymus cinereus, Koeleria macrantha, Pascopyrum smithii*, or *Poa secunda*. Shrubs commonly found include *Amelanchier alnifolia, Rosa* spp., *Eriogonum* spp., *Symphoricarpos albus*, and *Crataegus douglasii*.
Dynamics: Fire is the primary disturbance factor. Fires were low intensity due to limited fuel and significant internal spacing between fuel patches. Currently, *Bromus tectorum* and other introduced grasses often invade these habitats after fire, building up a dense fuelbed that creates frequent, high-intensity fires that are lethal to native perennial grasses (Landfire 2007a). The historic frequency was 50 years to maintain this grassland (Landfire 2007a). Extending fires frequency to >50 years leads to increased shrub cover and shrub regeneration (Landfire 2007a).

CUMBERLAND WET-MESIC MEADOW AND SAVANNA (CES202.053)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 7165

CONCEPT

Summary: This system consists of open, prairie-like vegetation of the undissected portions of the Cumberland Plateau of Kentucky and adjacent Tennessee in EPA Ecoregion 68a [Cumberland Plateau]; this is part of Subsection 221Hc. Stands are dominated by grasses and forbs with scattered shrubby vegetation and, occasionally, trees. The scattered trees are mainly *Quercus bicolor, Quercus falcata, Quercus palustris, Nyssa sylvatica, Liquidambar styraciflua*, and *Acer rubrum var. trilobum*. The primary dominant grass in the wetter phase is *Chasmanthium laxum*. This vegetation was the predominant type here in the early 1800s and earlier and probably was maintained from burning by Native Americans.

Similar Ecological Systems:
- Eastern Highland Rim Prairie and Barrens (CES202.354)
- North-Central Interior Wet Meadow-Shrub Swamp (CES202.701)
- Pennyroyal Karst Plain Prairie and Barrens (CES202.355)
- Western Highland Rim Prairie and Barrens (CES202.352)

DESCRIPTION

Environment: This system is found in an open, flat to gently rolling landscape which easily carries fire if maintained in a grassy condition. It is endemic to the undissected portions of the Cumberland Plateau of Kentucky and adjacent Tennessee (EPA Ecoregion 68a [Cumberland Plateau] of Griffith et al. (1998) and Woods et al. (2002); this is part of Subsection 221Hc of Keys et al. (1995)).
Vegetation: Stands are dominated by grasses and forbs with scattered shrubby vegetation and, occasionally, trees. The scattered trees are mainly *Acer rubrum var. trilobum, Liquidambar styraciflua, Nyssa sylvatica, Quercus bicolor, Quercus falcata*, and *Quercus palustris* (Braun 1937). The primary dominant grass in the wetter phase is *Chasmanthium laxum* (Braun 1937). Other common grasses include *Andropogon glomeratus, Calamagrostis coarctata (= Calamagrostis cinnoides)* (southern), *Dichanthelium sphaerocarpon var. isophyllum (= Panicum polyanthes)*, and *Dichanthelium scoparium (= Panicum scoparium)*, plus, in drier transitions, *Panicum anceps, Schizachyrium scoparium, Sorghastrum nutans*, and locally *Andropogon gerardii*. Sedges are common, especially *Carex atlantica* (with *var. capillacea*), *Carex debilis* (with vars.), *Carex lurida* (with *var. gracilis*), *Rhynchospora capitellata, Rhynchospora glomerata, Scirpus cyperinus, Scirpus polyphyllus*, etc. Rushes are also common, especially *Juncus canadensis* and *Juncus marginatus* on drier sites (?); *Juncus effusus* (with *var. pylaei*) and *Juncus coriaceus* on wetter sites (?). Common ferns are *Lygodium palmatum, Thelypteris noveboracensis* and, in wetter places, *Athyrium filix-femina ssp. asplenioides (= Athyrium asplenioides)* and *Osmunda cinnamomea*. The most abundant herbs often include *Eupatorium fistulosum* and *Solidago rugosa*. Other typical species include *Agalinis purpurea, Aletris farinosa, Apios americana, Symphyotrichum dumosum (= Aster dumosus), Doellingeria umbellata (= Aster umbellatus), Eupatorium pilosum, Eupatorium rotundifolium, Eupatorium perfoliatum* (richer soil?), *Linum striatum, Lobelia puberula, Lycopus virginicus, Platanthera ciliaris* (often in drier sites), *Potentilla simplex, Rhexia mariana* (less *Rhexia virginica*), *Viola X primulifolia*, and *Vernonia noveboracensis* (southern). The subshrubby vine *Rubus hispidus* is also common. Regionally rare species (mostly increasing to the south) include *Bartonia paniculata, Gratiola pilosa, Helianthus angustifolius, Hypericum crux-andreae, Lobelia nuttallii, Dichanthelium dichotomum var. ensifolium (= Panicum ensifolium), Panicum rigidulum var. pubescens (= Panicum longifolium)* (locally abundant on finer soils), *Platanthera cristata* (typically in boggy forest transitions), *Polygala cruciata, Pycnanthemum verticillatum*?, *Rhynchospora globularis, Sabatia campanulata*?, *Stenanthium gramineum, Xyris torta*, etc. The most abundant woody species include *Acer rubrum var. trilobum* and *Rhus copallinum*; others include *Alnus serrulata, Photinia* spp. (*Photinia pyrifolia (= Aronia arbutifolia), Photinia melanocarpa (= Aronia melanocarpa)*), *Ilex opaca, Liriodendron tulipifera, Liquidambar styraciflua, Lyonia ligustrina, Nyssa sylvatica, Oxydendrum arboreum, Pinus echinata, Quercus alba, Rhododendron* sp. (*Rhododendron cumberlandense*? (= *Rhododendron bakeri*?)), *Rubus* spp. (*Arguti* group), *Salix* spp. (*Salix humilis, Salix nigra, Salix sericea*), *Spiraea tomentosa* (local on finer textured soil?), and *Smilax glauca* (J. Campbell unpubl. data).
Dynamics: This vegetation was the predominant type of the undissected portions of the Cumberland Plateau of Kentucky and adjacent Tennessee in the early 1800s and earlier and probably was maintained by burning by Native Americans, and subject to natural fire as well. There are very few examples extant. It is the subject of some restoration efforts at Catoosa Wildlife Management Area, Tennessee. Data are lacking on the details of its exact fire and disturbance regime.

Component Associations:
- *Andropogon gerardii - (Sorghastrum nutans)* Kentucky Herbaceous Vegetation (CEGL004677, G1G2)

DISTRIBUTION

EAST GULF COASTAL PLAIN JACKSON PLAIN PRAIRIE AND BARRENS (CES203.353)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2427; ESLF 7140; ESP 1427

CONCEPT

Summary: This ecological system was locally dominant in the Jackson Purchase area of western Kentucky, extending into limited areas of adjacent Tennessee. This central region, called "the Barrens," has been historically subdivided from the rest of the Coastal Plain region of Kentucky. A number of early reports mentioned extensive prairies in this region and also emphasized the importance of annual fires in maintaining these grasslands. Interspersed among the extensive grasslands were likely scattered groves of oaks, especially those tolerant of frequent fires. Among the most frequent trees historically present in the entire region were *Quercus stellata, Quercus velutina*, and *Quercus marilandica*. With fire suppression, groves of trees rapidly expanded and largely replaced the prairies. In general, this system was found on "poorly consolidated Tertiary deposits," which are capped by loess, in the northern part of the Upper East Gulf ecoregion. High-quality examples would support a dense herbaceous layer dominated by tall grasses such as *Andropogon gerardii* and *Schizachyrium scoparium*, but the floristic composition of this type is poorly known since so few extant examples remain. *Sassafras albidum* and *Diospyros virginiana* are present in current sample data from stands attributed to this type, but their presence at higher cover values is probably a symptom of fire suppression.
Classification Comments: The component associations of this system are poorly known since so few extant examples remain. The best remaining examples may be found in the West Kentucky Wildlife Management Area (M. Evans pers. comm.). This system extends, at least historically, into adjacent Henry County, TN, interpreted from the occurrence of several barrens plant species (M. Pyne pers. obs.). Related systems are known from Cretaceous gravels in the Western Highland Rim of Tennessee and from flat uplands of the Southeastern Highland Rim (this latter one includes wetter (xerohydric) barrens). It is classed as a "large-patch" system today, but larger examples are rare if they exist at all, primarily due to its fragmentation by agriculture and fire suppression.
Similar Ecological Systems:
- Western Highland Rim Prairie and Barrens (CES202.352)

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer
- Tallgrass Prairie (Evans 1991) Intersecting
- Wet Prairie (Evans 1991) Intersecting
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: These grassy barren communities occur on soils are predominantly thin, well-drained, and gravelly, lying atop flat upland terrain in the Jackson Purchase area of western Kentucky, extending into limited areas of adjacent Tennessee. The former barrens were on flat to gently rolling lands just to the dry side of the moisture gradient (Bryant and Held 2001). These lands are flat and composed of drought-prone materials whose structure and composition serve to retard woody plant growth and reproductive success. The topography is flat to gently sloping. This system likely did not develop on the deeper loess soils of the region.
Vegetation: The exact floristic composition of this type is poorly known since so few extant examples remain. Interspersed among the extensive grasslands were likely scattered groves of oaks, especially those tolerant of frequent fires (M. Evans pers. comm.). Among the most frequent trees historically present in the entire region were *Quercus marilandica, Quercus stellata*, and *Quercus velutina* (Bryant and Martin 1988). With fire suppression, groves of trees rapidly expanded and largely replaced the prairies. In general, this system was found on "poorly consolidated Tertiary deposits" (Evans 1991), which are capped by loess, in the northern part of the Upper East Gulf ecoregion. High-quality examples would support a dense herbaceous layer dominated by tall grasses such as *Andropogon gerardii* and *Schizachyrium scoparium*, but the floristic composition of this type is poorly known since so few extant examples remain (M. Evans pers. comm.). Some stands sampled by Bryant and Held (2001) were recognized by them as perhaps representing "the former barrens of the JPR" (Jackson Prairie Region). *Diospyros virginiana, Quercus falcata, Quercus stellata*, and *Sassafras albidum* were generally present in the stands sampled, which were located in those portions of Ballard, Graves and Calloway counties mapped as barrens by Davis (1923). *Andropogon gerardii*, *Schizachyrium scoparium*, and *Sorghastrum nutans*, characteristic prairie grasses, and several scrub oaks were located together in Graves County near the stands sampled (Bryant and Held 2001). Some possible shrub species include *Rosa setigera* and *Rhus copallinum*. Wetter swales dominated by *Panicum virgatum* are probably imbedded within these predominantly dry-mesic barrens. *Sassafras albidum* and *Diospyros virginiana* are present in current sample data from stands attributed to this type (Bryant and Held 2001), but their presence at higher cover values is probably a symptom of fire suppression.

Dynamics: Past fire and grazing constitute the major dynamic processes for the "barrens" region of the Jackson Purchase area of western Kentucky and adjacent Tennessee. Fires were probably frequent (potentially on a five-year return interval), primarily of human origin, and are thought to have occurred in late summer to early autumn prior to European settlement. Some proposed factors which have functioned to maintain the openness of this system following the reduction of fire frequency include the droughty, gravelly soils and resulting stresses to vegetation, as well as more occasional fire. Other factors include natural and managed grazing, and modern anthropogenic factors such as mowing for hay, etc. (Landfire 2007a). Fralish et al. (1999) noted that both post oak and chestnut oak woodlands are essentially the result of fire suppression in the barrens and historic savannas. In some areas, where the soils are particularly harsh (droughty, nutrient-poor, rocky), stands may retain an open aspect in the absence of fire. Some of the extant examples are largely dependent on contemporary management regimes. A number of early reports mentioned extensive prairies in this region and also emphasized the importance of annual fires in maintaining these grasslands [see references in Bryant and Martin (1988)].

Component Associations:

EAST-CENTRAL TEXAS PLAINS XERIC SANDYLAND (CES205.897)

CLASSIFIERS

Classification Status: Standard

Primary Division: Eastern Great Plains (205)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Sand Soil Texture; Xeric; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2424; ESLF 7137; ESP 1424

CONCEPT

Summary: This xeric system of east-central Texas is found primarily on the Carrizo geologic formation, but also on other Eocene sandy strata such as Queen City and Sparta. The combination of these very droughty soils with low levels of rainfall create extreme edaphic conditions and a locally unique environment which supports a number of endemic plant taxa. The vegetational component of this system includes open herbaceous-dominated sand "prairies" or "barrens" to open oak-dominated woodlands, with *Quercus incana* and *Quercus margarettiae*. A large number of narrowly distributed, endemic species are associated with this system, including *Abronia macrocarpa, Allium elmendorfii, Brazoria truncata var. pulcherrima (= Brazoria pulcherrima), Brazoria truncata var. truncata, Chaetopappa imberbis, Cryptantha texana, Dalea obovata, Galactia canescens, Hymenopappus carrizoanus, Lechea san-sabeana, Lesquerella grandiflora, Liatris elegans var. carizzana, Liatris elegans var. bridgesii, Polanisia erosa ssp. breviglandulosa, Polygonella parksii, Prunus texana, Rhododon ciliatus, Senecio ampullaceus, Sphaeralcea lindheimeri, Tephrosia lindheimeri*, and *Tetragonotheca repanda*.
Classification Comments: The endemism associated with this system has been well-documented (Sorrie and Weakley 2001, MacRoberts et al. 2003).
Similar Ecological Systems:
- East-Central Texas Plains Post Oak Savanna and Woodland (CES205.679)
- Western Great Plains Sandhill Steppe (CES303.671)

Related Concepts:
- Post Oak Savanna: Sandylands Grassland (707) [CES205.897.9] (Elliott 2011) Finer
- Post Oak Savanna: Sandylands Woodland and Shrubland (706) [CES205.897.6] (Elliott 2011) Finer

DESCRIPTION

Environment: This xeric system is found primarily on the Carrizo geologic formation, but also on other Eocene strata such as Queen City and Sparta. The combination of these very droughty soils with low levels of rainfall create extreme edaphic conditions and a locally unique environment which supports a number of endemic plant taxa. It is found on high topographic positions, and this, along with rapidly draining soils, results in conditions that only briefly retain surface moisture. Deep sandy soils typify this system (Elliott 2011).
Vegetation: This small-patch system is typically an open, herbaceous-dominated sand "prairie," sometimes with open, oak-dominated woodlands. Species such as *Quercus incana, Quercus margarettiae, Quercus stellata,* and *Carya texana* (often stunted) occur in the usually sparse overstory. Invasion by *Ilex vomitoria* is frequent in the absence of fire. Other woody plants that may be encountered include *Juniperus virginiana, Rhus aromatica, Vaccinium arboreum, Viburnum rufidulum, Rhus copallinum,* and *Cornus florida*. The herbaceous layer may be sparse, often with exposed sand, and includes *Cladonia* spp., and species such as *Aristida desmantha, Brazoria truncata var. truncata, Cnidoscolus texanus, Dichanthelium* spp., *Sporobolus junceus, Froelichia floridana, Hymenopappus artemisiifolius, Lechea* spp., *Loeflingia squarrosa, Opuntia humifusa, Paronychia drummondii, Polanisia erosa, Schizachyrium scoparium, Monarda punctata, Senecio ampullaceus, Sorghastrum elliottii, Stylisma pickeringii, Tetragonotheca* spp., *Gaillardia amblyodon, Rhynchosia americana, Zornia bracteata*, and *Triplasis purpurea*. Species such as *Cyperus grayoides, Penstemon murrayanus, Selaginella arenicola ssp. riddellii, Tradescantia reverchonii*, and *Yucca louisianensis* may be present, but primarily to the east, while *Tephrosia lindheimeri* and *Rhynchosia americana* are frequently encountered to the south. Texas endemics, such as *Brazoria truncata var. pulcherrima, Rhododon ciliatus*, and *Hymenopappus carrizoanus* may be found in this system (Elliott 2011). Some other narrowly distributed, endemic species that may be associated with this system include *Abronia macrocarpa, Allium elmendorfii, Chaetopappa imberbis, Cryptantha texana, Dalea obovata, Galactia canescens, Lechea san-sabeana, Lesquerella grandiflora, Liatris elegans var. carizzana, Polanisia erosa ssp. breviglandulosa, Polygonella parksii, Prunus texana, Sphaeralcea lindheimeri*, and *Tetragonotheca repanda*.
Dynamics: This small-patch system is associated higher topographic positions that shed water, and it is underlain by loose sandy soils that are rapidly drained resulting in xeric surface conditions. Fire maintains this system in an open condition with increased cover of herbaceous species. Woody species such as *Ilex vomitoria* tend to encroach in the absence of fire, leading to a loss of diversity.

Component Associations:
- *Schizachyrium scoparium - Lechea tenuifolia - Acalypha radians* Herbaceous Vegetation (CEGL004913, G2G3)

EASTERN HIGHLAND RIM PRAIRIE AND BARRENS (CES202.354)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Herbaceous; Very Short Disturbance Interval; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2417; ESLF 7130; ESP 1417

CONCEPT

Summary: This system represents "The Barrens" of the Southeast Highland Rim of Tennessee. This is a distinctive part of the state and ecoregion and includes a series of plant communities with open canopies, ranging from herbaceous-dominated barrens (some of which are maintained today by mowing instead of fire and grazing) through savanna and woodland types. Open ponds and other wetlands are scattered throughout the landscape. The variety of relatively open habitats which are present here include prairie-like areas, as well as savanna woodlands and upland depression ponds.
Classification Comments: Western Highland Rim Prairie and Barrens (CES202.352), Eastern Highland Rim Prairie and Barrens (CES202.354), Pennyroyal Karst Plain Prairie and Barrens (CES202.355), and Southern Ridge and Valley Patch Prairie (CES202.453) form a series of similar systems in the eastern Interior Highlands and adjacent Ridge and Valley.
Similar Ecological Systems:
- Cumberland Wet-Mesic Meadow and Savanna (CES202.053)
- Pennyroyal Karst Plain Prairie and Barrens (CES202.355)
- Southern Ridge and Valley Patch Prairie (CES202.453)
- Western Highland Rim Prairie and Barrens (CES202.352)

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer
- Sweetgum - Willow Oak: 92 (Eyre 1980) Finer
- Willow Oak - Water Oak - Diamondleaf (Laurel) Oak: 88 (Eyre 1980) Finer

DESCRIPTION

Environment: These various barren communities occur on Fragiudult soils formed in Pleistocene loess over karstic Mississippian Limestone. Their topography is flat to gently sloping. Some proposed factors which have functioned to maintain their openness include the hardpan soils and fire (as well as natural and managed grazing, and modern anthropogenic factors such as mowing for hay, etc.). These barrens include a variety of systems whose primary presettlement environmental factors were specialized soils and extremes of hydrology, as influenced by fire and grazing. The prevalent soils within the polygon labeled "Dickson-Mountview-Guthrie" (D32 of Elder and Springer (1978), Springer and Elder (1980)) are generally flatter, wetter, and more likely to have fragipans than adjoining units. Average conditions in the area of The Barrens can be summarized as follows (Wolfe 1996): January is typically the coldest month, with average high and low temperatures of 8.8Âº C (47.8Âº F) and 1.9Âº C (35.4Âº F), respectively. July is the warmest month, with average high and low temperatures of 31.3Âº C (88.3Âº F) and 18.9Âº C (66.0Âº F), respectively. Monthly mean temperatures range from 3.5Âº C (38.3Âº F) in January to 25.11Âº C (77.2Âº F) in July. The mean annual precipitation is 1438 mm (56.6 inches) (Wolfe 1996, Pyne 2000). Precipitation is heaviest from November through May, averaging between 113 and 171 mm (4.4 to 6.7 in) per month. Rainfall is lightest during the months of June through October, with averages ranging from 83 mm (3.3 inches) per month to a minor peak of 122 mm (4.8 inches) in July.
Vegetation: Stands may vary in physiognomy from savanna-grasslands to oak-dominated woodlands and forests. Many stands are in a forested condition today due to lack of fire. Typical mesic grassland vegetation of the barrens of the southeastern Highland Rim of Tennessee is dominated by *Andropogon gerardii* along with *Schizachyrium scoparium* and *Sorghastrum nutans*. Other graminoid species present include *Andropogon glomeratus, Calamagrostis coarctata,* and *Panicum virgatum*. Other dominants may include *Eurybia hemispherica (= Aster paludosus ssp. hemisphericus), Symphyotrichum dumosum (= Aster dumosus), Helianthus angustifolius, Potentilla simplex, Solidago odora, Solidago rugosa, Pteridium aquilinum,* and *Polytrichum commune*; found to a lesser extent are *Aristida purpurascens var. virgata (= Aristida virgata), Chasmanthium laxum, Dichanthelium aciculare (= Dichanthelium angustifolium), Dichanthelium dichotomum, Gymnopogon brevifolius, Panicum anceps, Panicum rigidulum*, and *Panicum verrucosum*. Woody species may include *Quercus alba, Quercus stellata, Quercus falcata, Quercus marilandica, Carya* spp., *Acer rubrum, Rhus copallinum, Rosa setigera, Salix humilis, Diospyros virginiana, Rubus argutus*, and *Smilax glauca*. The Barrens contains a variety of natural, semi-natural, and managed openings which provide habitat for plants and animals which are unusual in the ecoregion, rare in the state, or globally rare. These include a variety of plants more at home in other ecoregions, most notably the Coastal Plain and the western prairies, including carnivorous plants and other specialized plants of ponds and other wetlands. In addition, globally rare endemic fish and disjunct amphibians and invertebrates call The Barrens their home.
Dynamics: Past fire and grazing constitute the major dynamic processes for this system. Fires were frequent (potentially on a

five-year return interval (Guyette et al. 2006), documented over approximately the last 370 years), primarily of human origin, occurring in late summer to early autumn. Forestry activities (including planting of off-site *Pinus taeda*, which is not truly native to the region) and fire suppression have led to the current forested condition with solar intensity as low as 10%. The current persistence of prairies, shrublands, and grassy-woodland/savannas is largely dependent on contemporary management regimes. The woodlands, savannas and prairies are often grown up in woody vegetation (e.g., *Acer rubrum, Liquidambar styraciflua*, as well as *Quercus* spp. and *Carya* spp.) due to fire suppression. Woodlands dominated by *Quercus alba, Quercus stellata*, and to a lesser extent *Quercus marilandica* often "fill in" with less fire-tolerant species (e.g., *Acer rubrum, Liquidambar styraciflua, Nyssa sylvatica, Quercus coccinea, Quercus falcata*, etc.) resulting in a closed-canopy forest.

Component Associations:
- *Andropogon gerardii - (Andropogon glomeratus, Panicum virgatum, Sorghastrum nutans)* Herbaceous Vegetation (CEGL007705, G2?)
- *Andropogon gerardii - Schizachyrium scoparium - (Calamagrostis coarctata, Panicum virgatum)* Herbaceous Vegetation (CEGL007706, G2?)
- *Andropogon gerardii - Schizachyrium scoparium - Dichanthelium scoparium - Rhynchospora glomerata* Herbaceous Vegetation (CEGL004006, G1)
- *Quercus (falcata, stellata) / Quercus marilandica / Gaylussacia (baccata, dumosa)* Woodland (CEGL004922, G2G3)
- *Quercus phellos - Quercus alba / Vaccinium fuscatum - (Viburnum nudum) / Carex (barrattii, intumescens)* Forest (CEGL007364, G2)
- *Quercus phellos - Quercus nigra - (Nyssa biflora)* Forest (CEGL007405, G1?)
- *Quercus stellata - (Quercus coccinea) / Quercus marilandica / Vaccinium pallidum - (Vaccinium stamineum)* Woodland (CEGL004709, G2G3)
- *Schizachyrium scoparium - Andropogon (gyrans, ternarius, virginicus)* Herbaceous Vegetation (CEGL007707, G3?)
- *Schizachyrium scoparium - Calamagrostis coarctata* Herbaceous Vegetation (CEGL007708, GNRQ)
- *Schizachyrium scoparium - Panicum anceps - Panicum virgatum - Lespedeza capitata - Scleria* spp. Herbaceous Vegetation (CEGL004063, G1)

SPATIAL CHARACTERISTICS

Spatial Summary: This system was the historic matrix system in a large region of five Tennessee counties of the southeastern Highland Rim. It is classed as a "large patch" system primarily due to its fragmentation by fire suppression, tree plantations, agriculture, and suburban development.

Adjacent Ecological Systems:
- Central Interior Highlands and Appalachian Sinkhole and Depression Pond (CES202.018)

Adjacent Ecological System Comments: The depression ponds which occur within the landscape of Eastern Highland Rim Prairie and Barrens (CES202.354) are examples of the Central Interior Highlands and Appalachian Sinkhole and Depression Pond (CES202.018); several depression pond associations particular to the Eastern Highland Rim are described. Small wet depressions in the Eastern Highland Rim Prairie and Barrens (CES202.354), which are not distinguished physiognomically or by canopy species, are included in the concept of Eastern Highland Rim Prairie and Barrens (CES202.354). These are akin to vernal pools or wet streamheads. These small wet depressions with extensive herbaceous vegetation (e.g., *Carex, Juncus*, and *Panicum* species) certainly would have burned during drier periods.

DISTRIBUTION

Range: This system is restricted to "The Barrens" of the southeastern Highland Rim of Tennessee (today primarily extant in Coffee, Franklin, and Warren counties, Tennessee). This is a small part of Subsection 223Eb (USFS) and EPA Level IV Ecoregion 71g.

FLORIDA DRY PRAIRIE (CES203.380)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Short Disturbance Interval; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2425; ESLF 7138; ESP 1425

CONCEPT

Summary: This system, which is endemic to subtropical Florida, is characterized by nearly treeless plains with dense cover of grasses and low shrubs, primarily *Serenoa repens*. Examples occur on flat, low-lying terrain over moderately to poorly drained soils with sandy surfaces overlying organic hardpans or clayey subsoil. The original extent has been heavily reduced by clearing for agriculture and conversion for forage production. Intact examples have been further altered by fire suppression which changes the proportion of grasses and shrubs and may further alter species composition. It is found on the plains near the Myakka River, Kissimmee River, as well as north of Lake Okeechobee and near Fisheating Creek (west of Lake Okeechobee).
Classification Comments: This system grades into mesic pine flatwoods and may have nearly identical composition except for the absent or nearly absent overstory layer (Abrahamson and Hartnett 1990, FNAI 1990, Huffman and Judd 1998).

The Florida Gap program recognizes a single map unit which is apparently analogous to this type.
Similar Ecological Systems:
- South Florida Pine Flatwoods (CES411.381)

Related Concepts:
- Cabbage Palmetto: 74 (Eyre 1980) Finer
- Dry Prairie (FNAI 1990) Equivalent

DESCRIPTION

Environment: The climate where this ecological system occurs is subtropical, characterized by hot, wet summers and mild, dry winters. Average annual rainfall is about 127 cm and occurs mostly in June through September. It occurs on flat, moderately to poorly drained sandy soils with sandy surfaces overlying organic hardpans or clayey subsoil (FNAI 1990). These extensive flat prairies are seldom inundated but may flood with several centimeters of water in the wet summer. Frequent spring fires followed by summer flooding may have limited the survival of *Pinus elliottii var. densa* (Platt et al. 2006a). The normal water table is several centimeters (in summer and fall) to several meters (in winter and spring) below the ground surface (Duever and Brinson 1984a, Abrahamson and Hartnett 1990, Hardin 1990). Soils consist of 0.1-0.9 m of undifferentiated quartz sand with a spodic horizon or clayey subsoil 30-107 cm below the surface. These acidic, nutrient-poor sands have few weatherable minerals and low clay nutrients in the surface soil (Abrahamson and Hartnett 1990). Soils supporting these sparse shrublands are classified as Arenic Haplaquods and include such series as Smyrna; types are Myakka (sandy, siliceous, hyperthermic Aeric Alaquod), Wabasso (sandy, siliceous, hyperthermic Alfic Alaquod), Oldsmar (sandy, siliceous, hyperthermic Alfic Arenic Alaquod), Immokalee (sandy, siliceous, hyperthermic Arenic Alaquod), Leon, Adamsville, and Keri sands (Moore and Swindel 1981, Duever and Brinson 1984a).
Vegetation: Intact examples of this system are generally open and essentially treeless areas dominated by *Serenoa repens* and low shrubs (*Quercus minima, Lyonia lucida, Lyonia fruticosa, Vaccinium darrowii, Vaccinium myrsinites, Ilex glabra,* and *Befaria racemosa*), as well as a variety of grasses (*Aristida beyrichiana, Schizachyrium scoparium var. stoloniferum, Sorghastrum secundum, Andropogon ternarius, Aristida spiciformis, Dichanthelium dichotomum var. ensifolium, Dichanthelium strigosum, Paspalum setaceum,* and others) (Huffman and Judd 1998). At least 5 fairly discrete phases or "states" of this system can be identified (Huffman and Werner 2000): good conditions are typified by abundant herbaceous cover and relatively low (<40%) cover of shrubs, especially *Serenoa repens*, degraded conditions resulting from long fire-free intervals result in reduced herbaceous cover and increased shrub coverage, to the eventual exclusion of all herbaceous cover.
Dynamics: Like the floristically and ecologically related pine flatwoods, the open structure and species composition of dry prairies is maintained by frequent fire. Frequent fires were an important natural process in this system, with an estimated frequency of every 1-2 years (FNAI 2010a). The natural fire frequency is thought to be greater than in the surrounding mesic pine flatwoods (Duever et al. 1982, Abrahamson and Hartnett 1990, Hardin 1990). Dry prairie is readily invaded by woody vegetation in the absence of frequent fire, especially in the absence of fires which occur during the dry portions of early spring. In "good condition" this system has abundant herbaceous cover and relatively low cover (<40%) of *Serenoa repens*; degraded conditions are indicated by reduced herbaceous cover and increased cover of *Serenoa repens* (Huffman and Werner 2000). Florida dry prairie occurs on extensive flat areas with few creeks. Due to the lack of landscape dissection, wildfires in the past may have been larger and more frequent than in pineland areas which had more creeks (Bridges 2006). Also, summer flooding, even for short durations, may have been another stress which limited the survival of pines (Platt et al. 2006a). With lack of fire, outright replacement of dry prairies by stands of *Quercus laurifolia, Quercus virginiana,* and *Serenoa repens* has been well-documented at Myakka River State Park (Huffman and Blanchard 1990). Most dry prairie has a long history of human use as native range for cattle (Penfield 2006).

Component Associations:
- *Sabal palmetto / Serenoa repens* Woodland (CEGL003796, G1G2)
- *Serenoa repens / Aristida beyrichiana* Shrubland (CEGL004236, G2)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Central Florida Herbaceous Pondshore (CES203.890)
- Central Florida Wet Prairie and Herbaceous Seep (CES203.491)
- South Florida Depression Pondshore (CES411.054)

DISTRIBUTION

Range: This system occurs in southern Florida mainly north of the Everglades and Big Cypress area. It is found on the plains near the Myakka River, Kissimmee River, as well as north of Lake Okeechobee and near Fisheating Creek (west of Lake Okeechobee). Early surveyors noted large expanses of this system on the plains near the Kissimmee River, north from Lake Okeechobee, and in the area west of Lake Okeechobee (Fisheating Creek) (Huffman and Judd 1998). The presettlement extent of dry prairie has been mapped based on historical sources (Bridges 2006). Areas of dry prairie included the Kissimmee River region (in Osceola, Okeechobee, Polk, and Highlands counties), the Big Prairie (in Desoto, Glades, and Charlotte counties), and the Myakka Prairie (in Manatee and Sarasota counties) in southern Florida (Bridges 2006). The Kissimmee River dry prairie region was determined to be about 2000 km2 (500,000 acres) prior to settlement (Bridges 2006). The original extent has been heavily reduced by clearing for agriculture and conversion for forage production (FNAI 2010a).

HAWAI'I FUMAROLE (CES412.415)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lava; Acidic Soil; Volcanic Sulphur Dioxide Fumes; Alga
Non-Diagnostic Classifiers: Herbaceous; Cinder; Basalt; Tropical/Subtropical
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Nonvascular, Bryophyte
National Mapping Codes: EVT 2830; ESLF 7178; ESP 1830

CONCEPT

Summary: This ecological system is restricted to areas of ongoing volcanic activity on the island of Hawai'i from near sea level to the summit of Mauna Loa, especially near and leeward of the Kilauea summit caldera. Steam from the relatively permanent vents has varying amounts of chemical output (largely sulphur dioxide or other sulphur-rich compounds), which is a driving variable for this system. Substrates are recent volcanics, whether pÃ¢hoehoe, 'a'Ã¢ or overlain with cinder or ash. Fumarole communities are vegetated by blue-green algae and bryophytes, with zonal distribution apparently related to temperature and chemical concentrations. In the hottest, sulphur-rich areas, a slimy aggregate of blue-green algae may be the only vegetation, but outward from the vent, various species of bryophytes (mosses and liverworts) ring the vent in a manner analogous to algae in the intertidal zone. Finally, ferns and angiosperms from communities surrounding the vent appear at a variable distance from the vent, marking the transition out of the fumarole community.
Classification Comments: Fumarole communities are poorly understood biological communities currently restricted to habitats directly in and around volcanic steam vents. Should the concept be expanded to include broader areas generally downwind of vents affected by volcanic sulphur dioxide fumes/fog? Vegetation in these sulphur dioxide-affected areas is significantly sparser both in cover and diversity, and sites often appear barren. Volcanic areas can be active for long periods of time, maintaining the depauperate community. The animal portion of fumarole communities includes mites and springtails (*Collembola*), some of which are known (to date) only from fumaroles. However, as only a very small portion of existing fumaroles have been sampled, the full distribution of fumarole animals can not be predicted. In addition, the plants and animals of Hawaiian fumaroles can not yet be compared to fumaroles in other volcanic areas of the world, because of inadequate biological sampling.
Related Concepts:
- Hawaiian Fumarole Communities (Gon 1988) Equivalent

DESCRIPTION

Environment: This volcanic ecological system occurs independently of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007) and likely occurs in most of the zones. Moisture in the vent is generally saturated where steam is escaping, but the overriding limiting features are high temperatures (on a gradient from above boiling to near ambient) and the presence of volcanic chemical compounds (generally sulphur-containing). Both of these features strongly limit all but a small set of adapted or tolerant plants and animals.

Component Associations:
- Hawaiian Fumarole Herbaceous Vegetation (CEGL008095, G3)

DISTRIBUTION

Range: This ecological system is only known from the Big Island of Hawai'i.

HAWAI'I LOWLAND DRY GRASSLAND (CES412.410)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Tropical/Subtropical [Tropical Xeric]; Short Disturbance Interval; Graminoid
Non-Diagnostic Classifiers: Herbaceous
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2819; ESLF 7179; ESP 1819

CONCEPT

Summary: This lowland grassland ecological system mostly occurs on dry leeward sides of the larger islands of Hawai'i and Maui and on relatively dry smaller islands of LÃ¢na'i and Kaho'olawe. This ecological system also includes coastal dry grasslands that occur beyond the immediate coastal effects of the sea with wind, salt spray and salinity. Elevations range from 30-1000 m (100-3280 feet). Annual precipitation is generally between 100 and 1750 mm. Substrates are variable. Dominant native species are *Heteropogon contortus* (pili) which was fairly widespread. These stands were maintained and expanded by ancient Hawaiians by regular burning. Other species include low scattered shrubs such as *Dodonaea viscosa, Sida fallax*, and *Waltheria indica*. Woody plants invade in the absence of regular fire. Other native dry lowland grasslands are composed of *Eragrostis variabilis, Fimbristylis* spp., *Lepturus repens*, or *Sporobolus virginicus* which were more common near coasts. Many dry grasslands have been replaced by exotic grass species or converted to exotic shrublands.
Classification Comments: This dry grassland system grades into the dry coastal strand system near the leeward coasts. Coastal dry grasslands that are affected by immediate sea coast processes (salt spray and salinity) are classified in the dry coastal strand ecological system.
Similar Ecological Systems:
- Hawai'i Dry Coastal Strand (CES412.418)
- Hawai'i Lowland Dry Shrubland (CES412.409)
- Hawai'i Montane-Subalpine Dry Shrubland (CES412.403)

DESCRIPTION

Environment: This lowland ecological system occurs over a broad moisture range within the arid, very dry, moderately dry, and seasonally mesic zones (Zones 1, 2, 3 and 4) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This lowland grassland ecological system mostly occurs on dry leeward sides of the larger islands of Hawai'i and Maui and on relatively dry smaller islands of LÃ¢na'i and Kaho'olawe. This ecological system also includes coastal dry grasslands that occur beyond the immediate coastal effects of the sea with wind, salt spray and salinity. Elevations range from 30-1000 m (100-3280 feet). Annual precipitation is generally between 100 and 1750 mm (Gagne and Cuddihy 1990). Substrates are variable.
Vegetation: Vegetation in this ecological system is characterized by native dry grass species such as *Heteropogon contortus* (pili) which was fairly widespread. Stands were maintained and expanded by ancient Hawaiians by regular burning (Gagne and Cuddihy 1990). Other species include low scattered native shrubs such as *Dodonaea viscosa, Sida fallax*, and *Waltheria indica*. Woody plants invade in the absence of regular fire (Stone and Pratt 1994). Other native dry lowland grasslands were composed of *Eragrostis variabilis, Fimbristylis* spp., *Lepturus repens*, or *Sporobolus virginicus* which were more common near coasts. Many dry grasslands have been replace by exotic grass species such as *Andropogon virginicus, Cymbopogon refractus, Hyparrhenia hirta, Pennisetum setaceum, Melinis repens (= Rhynchelytrum repens),* and *Schizachyrium condensatum*, or been converted to exotic shrublands dominated by *Acacia farnesiana, Lantana camara, Leucaena leucocephala, Schinus terebinthifolius*, or *Prosopis pallida* (coastal only).
Dynamics: *Heteropogon contortus* is a fire-adapted grass. Ecologically stable *Heteropogon contortus*-dominated stands may occur on dry lowland cliffs where woody plants can not form dense canopies (Gagne and Cuddihy 1990).

Component Associations:
- *Eragrostis variabilis* Coastal Dry Herbaceous Vegetation (CEGL008087, G3)
- *Fimbristylis* spp. Coastal Dry Herbaceous Vegetation (CEGL008089, G3)
- *Heteropogon contortus* Lowland Dry Herbaceous Vegetation (CEGL008090, G4)
- *Lepturus repens* Annual Herbaceous Vegetation (CEGL008105, G3?)
- *Sporobolus virginicus* Coastal Dry Shrub Herbaceous Vegetation (CEGL008094, G4)

DISTRIBUTION

HAWAI'I LOWLAND MESIC GRASSLAND (CES412.413)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Tropical/Subtropical [Tropical Pluviseasonal]; Shallow Soil; Graminoid
Non-Diagnostic Classifiers: Herbaceous
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2820; ESLF 7180; ESP 1820

CONCEPT

Summary: Lowland mesic grasslands can be found on most of the islands from 300 to 2000 m (1000-6500 feet) elevation. Annual rainfall is 750-1000 mm (30-40 inches) and falls mostly from November to March. Soils are generally shallow. On the younger islands, it can occur on young pÃ¢hoehoe that is beginning to form a thin mantel of soil. These communities are floristically poor, dominated by *Eragrostis variabilis*, on moderate to steep slopes of Kaua'i, O'ahu, Moloka'i and Maui. These grasslands form a near-continuous dense ground cover, about 1.2 m (1.5 feet) tall, that may extend downslope to coastal dry slopes. Associated species include *Metrosideros tremuloides*, *Bidens* spp., *Dodonaea viscosa*, and *Gouania hillebrandii*. Most examples of this system have been invaded by alien species. Lowland mesic grasslands grade into mesic shrublands and forests where *Metrosideros polymorpha* is frequently a dominant species.

HAWAI'I MONTANE-SUBALPINE DRY GRASSLAND (CES412.405)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Herbaceous; Tropical/Subtropical [Tropical Xeric]
Non-Diagnostic Classifiers: Mountainside; Saddle
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2822; ESLF 7181; ESP 1822

CONCEPT

Summary: This ecological system occurs on dry montane to subalpine saddles and slopes of Mauna Kea, Mauna Loa, Hualalai, Hawai'i, from near 1615 to 2300 m (5295-7540 feet) elevation. An inversion layer of warmer air forms 50-70% of the time between 1600 and 3000 m that dramatically reduces precipitation at higher elevations. This is because the wet trade winds generally do not rise above 1900 m (6230 feet) and are deflected around the mountains, leaving upper slopes too dry to support rain forests. Stands also occur at lower elevations on leeward sides of islands where there is a strong rainshadow effect. Annual rainfall is generally 400-500 mm. Many sites are wind-exposed. Substrates include well-drained, sandy loam soils derived from volcanic ash or cinder and weathered basaltic lava with little soil development. Edaphic properties tend to suppress woody lifeforms. Vegetation is characterized by a moderate to dense bunchgrass layer (<1 m tall) dominated by *Eragrostis atropioides* and sometimes codominated by *Panicum tenuifolium*. Other grass species include *Agrostis sandwicensis, Eragrostis deflexa*, and *Trisetum glomeratum*. Scattered shrubs may be present such as *Bidens menziesii, Chenopodium oahuense, Dodonaea viscosa, Dubautia linearis, Pseudognaphalium sandwicensium (= Gnaphalium sandwicensium), Osteomeles anthyllidifolia, Myoporum sandwicense*, and *Sophora chrysophylla*. Fire-adapted exotic grass *Pennisetum setaceum* has not significantly invaded and is only occasionally present. Weedy exotic forbs are common. *Heterotheca grandiflora, Senecio madagascariensis, Verbascum thapsus*, and *Verbesina encelioides* are common in disturbed stands (Shaw and Castillo 1997, J. Jacobi pers. comm.).

Similar Ecological Systems:
- Hawai'i Montane-Subalpine Dry Shrubland (CES412.403)

Related Concepts:
- *Eragrostis* Grassland (Shaw and Castillo 1997) Equivalent
- Lovegrass/Mountain Pili (*Eragrostis/Panicum*) Grassland (Gagne and Cuddihy 1990) Equivalent

DESCRIPTION

Environment: This montane to subalpine ecological system occurs within the arid, very dry, and moderately dry zones (Zones 1, 2 and 3) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This ecological system occurs on dry montane to subalpine saddles and slopes of Mauna Kea, Mauna Loa, Hualalai, Hawai'i, from near 1615 to 2300 m (5295-7540 feet) elevation. An inversion layer of warmer air forms 50-70% of the time between 1600 and 3000 m that dramatically reduces precipitation at higher elevations (Gagne and Cuddihy 1990). This is because the wet trade winds generally do not rise above 1900 m (6230 feet) and are deflected around the mountains, leaving upper slopes too dry to support rain forests (Mueller-Dombois and Fosberg 1998). Stands also occur at lower elevations on leeward sides of islands where there is a strong rainshadow effect. Annual rainfall is generally 400-500 mm. Many sites are wind-exposed. Substrates include well-drained, sandy loam soils derived from volcanic ash or cinder and weathered basaltic lava with little soil development. Edaphic properties tend to suppress woody lifeforms.
Vegetation: Vegetation is characterized by a moderate to dense bunchgrass layer (<1 m tall) dominated by *Eragrostis atropioides* and sometimes codominated by *Panicum tenuifolium* (Gagne and Cuddihy 1990). Other grass species include *Agrostis sandwicensis, Eragrostis deflexa*, and *Trisetum glomeratum*. FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2823; ESLF 7182; ESP 1823

CONCEPT

Summary: This ecological system occurs on cool windward subalpine slopes of east Maui and Mauna Loa, Hawai'i. Elevation ranges from 2100 m on Maui and 1680-1980 m on Hawai'i. Sites are relatively mesic as annual rainfall is generally 1300-2500 mm. Soils are shallow over rock, retaining soil moisture, or much deeper ash deposits. Vegetation is characterized by a moderate to dense bunchgrass layer (<1 m tall) dominated by *Deschampsia nubigena* with *Pteridium aquilinum var. decompositum* frequently codominate. Other herbaceous species include *Carex macloviana, Uncinia* cf. *uncinata, Luzula hawaiiensis, Plantago* spp., *Ranunculus hawaiensis,* and *Sanicula sandwicensis*. Scattered shrubs may be also present such as *Coprosma montana, Dubautia* spp., *Sophora chrysophylla,* and *Styphelia tameiameiae*. Several exotic species are common in disturbed stands.

DESCRIPTION

Environment: This montane to subalpine ecological system occurs within the seasonally mesic and moist mesic zones (Zones 4 and 5) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This ecological system occurs on cool windward subalpine slopes of east Maui and Mauna Loa, Hawai'i. Elevation ranges from 2100 m on Maui and 1680-1980 m on Hawai'i. Sites are relatively mesic as annual rainfall is generally 1300-2500 mm. Soils are shallow over rock, retaining soil moisture, or much deeper ash deposits.
Vegetation: Vegetation is characterized by a moderate to dense bunchgrass layer (<1 m tall) dominated by *Deschampsia nubigena* with *Pteridium aquilinum var. decompositum* frequently codominant (Gagne and Cuddihy 1990). Other herbaceous species include *Carex macloviana, Uncinia* cf. *uncinata, Luzula hawaiiensis, Plantago* spp., *Ranunculus hawaiensis,* and *Sanicula sandwicensis*. Scattered shrubs may be also present such as *Coprosma montana, Dubautia* spp., *Sophora chrysophylla*, and *Styphelia tameiameiae*. Several exotic species are common in disturbed stands.
Dynamics: Natural fires are extremely rare, though evidence exists as charcoal layers of past fire at Kalapawili, associated with lava flows on Hawai'i Island, and lightning throughout range. Storms might expand its range by opening tree canopies in adjacent forest and forming new alluvial pans, taking stands back to primary succession.

Component Associations:
- *Deschampsia nubigena* Montane and Subalpine Mesic Herbaceous Vegetation (CEGL008085, G1)

INTER-MOUNTAIN BASINS SEMI-DESERT GRASSLAND (CES304.787)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Herbaceous; Temperate [Temperate Xeric]; Alkaline Soil; Aridic; Graminoid
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Intermediate Disturbance Interval; F-Landscape/Medium Intensity; G-Landscape/Low Intensity; Forb
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2135; ESLF 7107; ESP 1135

CONCEPT

Summary: This widespread ecological system includes the driest grasslands throughout the intermountain western U.S. It occurs on xeric sites over an elevation range of approximately 1450 to 2320 m (4750-7610 feet) on a variety of landforms, including swales, playas, mesas, alluvial flats, and plains. This system may constitute the matrix over large areas of intermountain basins, and also may occur as large patches in mosaics with shrubland systems dominated by *Artemisia tridentata ssp. tridentata, Artemisia tridentata ssp. wyomingensis, Atriplex* spp., *Coleogyne* spp., *Ephedra* spp., *Gutierrezia sarothrae*, or *Krascheninnikovia lanata*. Grasslands in areas of higher precipitation, at higher elevation, typically belong to other systems. Substrates are often well-drained sandy or loam soils derived from sedimentary parent materials but are quite variable and may include fine-textured soils derived from igneous and metamorphic rocks. The dominant perennial bunch grasses and shrubs within this system are all drought-resistant plants. Dominant or codominant species are *Achnatherum hymenoides, Aristida* spp., *Bouteloua gracilis, Hesperostipa comata, Muhlenbergia* spp., *Pleuraphis jamesii*, or *Sporobolus* spp.,. Scattered shrubs and dwarf-shrubs often are present, especially *Artemisia tridentata ssp. tridentata, Artemisia tridentata ssp. wyomingensis, Atriplex* spp., *Coleogyne* spp., *Ephedra* spp., *Ericameria* spp., *Gutierrezia sarothrae*, and *Krascheninnikovia lanata*. Grasslands in the basins of south-central and southwestern Wyoming, dominated by *Pseudoroegneria spicata* and *Poa secunda* and containing cushion-form forbs and other species typical of dry basins, are included in this system.

Classification Comments: In the relatively high-elevation basins of Wyoming and south-central Montana, grass vegetation dominated or codominated by *Pseudoroegneria spicata* and *Poa secunda* seems to be transitional between more typical Inter-Mountain Basins Semi-Desert Grassland (CES304.787) as found farther west and south in the intermountain region and Northern Rocky Mountain Lower Montane, Foothill and Valley Grassland (CES306.040) common on the foothills of the surrounding mountains. That grass vegetation is placed into this semi-desert grassland system, instead of into the foothill grassland system, for two reasons. The first is composition of the vegetation: *Pseudoroegneria*- and *Poa*-rich vegetation often contains shrubs (*Artemisia tridentata ssp. wyomingensis, Krascheninnikovia lanata*), other grasses (*Achnatherum hymenoides, Hesperostipa comata*), and cushion-form forbs common in drier vegetation of the same basins, while the species common in the foothills, especially *Festuca idahoensis* and *Leucopoa kingii*, are absent. The second is the setting: patches of the *Pseudoroegneria*- and *Poa*-rich vegetation occur in a mosaic with other basins systems, especially Inter-Mountain Basins Big Sagebrush Steppe (CES304.778), with which it often merges.

In the Columbia Plateau, this semi-desert ecological system does not include *Pseudoroegneria spicata*-dominated or -codominated associations such as *Pseudoroegneria spicata - Achnatherum hymenoides* Herbaceous Vegetation (CEGL001674) or *Pseudoroegneria spicata - Poa secunda* Herbaceous Vegetation (CEGL001677). Additionally, *Poa cusickii* Herbaceous Vegetation (CEGL001655) is restricted to relatively mesic sites there and does not occur in this semi-desert system as it occurs in the Columbia Plateau, but may be found in this system in Wyoming.

Similar Ecological Systems:
- Columbia Plateau Steppe and Grassland (CES304.083)
- Northern Rocky Mountain Lower Montane, Foothill and Valley Grassland (CES306.040)

Related Concepts:
- Grama - Galleta (502) (Shiflet 1994) Finer

DESCRIPTION

Environment: Low-elevation grasslands in the Intermountain West region occur in semi-arid to arid climates at approximately 1450 to 2320 m (4750-7610 feet) elevation. These grasslands occur in lowland and upland areas and may occupy swales, playas, mesa tops, plateau parks, alluvial flats, and plains. These grasslands typically occur on xeric sites. This system experiences cold temperate conditions. Hot summers and cold winters with freezing temperatures and snow are common. Annual precipitation is usually from 20-40 cm (7.9-15.7 inches). A significant portion of the precipitation falls in July through October during the summer monsoon storms, with the rest falling as snow during the winter and early spring months. Because of this monsoonal aspect, there is a strong gradient of warm-season/cool-season grass dominance from southeast to northwest. One could almost accept two different grassland systems because of this. These grasslands occur on a variety of aspects and slopes. Sites may range from flat to moderately steep.

Soils supporting this system also vary from deep to shallow, and from sandy to finer-textured. The substrate is typically derived from sandstone or shale. Some occurrences on sandy soils have a high cover of cryptogams on the soil surface. These cryptogams tend to increase the stability of the highly erodible sandy soils of these grasslands during torrential summer rains and heavy wind storms (Kleiner and Harper 1977). Muhlenbergia-dominated grasslands which flood temporarily, combined with high evaporation rates in this dry system, can have accumulations of soluble salts in the soil. Soil salinity depends on the nature of the parent material and on the amount and timing of precipitation and flooding. Growth-inhibiting salt concentrations are diluted when the soil is saturated, allowing the growth of less salt-tolerant species. As the saturated soils dry, the salt concentrates until it precipitates out on the soil surface (Dodd and Coupland 1966, Ungar 1968).

Vegetation: The dominant perennial bunch grasses and shrubs within this system are all drought-resistant plants. Dominant or codominant species are *Achnatherum hymenoides, Aristida* spp., *Bouteloua gracilis, Hesperostipa comata, Muhlenbergia* spp., or *Pleuraphis jamesii*. Scattered shrubs and dwarf-shrubs often are present, especially *Artemisia tridentata ssp. tridentata, Artemisia tridentata ssp. wyomingensis, Atriplex* spp., *Coleogyne* spp., *Ephedra* spp., *Gutierrezia sarothrae*, and *Krascheninnikovia lanata*. Grasslands in the basins of south-central and southwestern Wyoming, dominated by *Pseudoroegneria spicata* and *Poa secunda* and containing cushion-form forbs and other species typical of dry basins, are included in this system.

Dynamics: Disturbance dynamics in this semi-arid grassland system are variable because of variation in the compositions; however, most are dominated by perennial bunch grasses that are adapted to low- to medium-frequency (<30 to <100 years) and low- to medium-intensity fires (Howard 1997a, 1997b, Tirmenstein 1999e, Zlatnik 1999a, 1999b, Johnson 2000c, Simonin 2000a, 2000b, 2000c, Anderson 2003, Sawyer et al. 2009). Most of the species are classified as resistant or tolerant of fire, with the exception of *Bouteloua eriopoda*, which is classified as sensitive, but will recover quickly if there is adequate summer moisture (Simonin 2000a). Season of burn is also important for predicting post-burn recovery.

The majority of characteristic grass species, such as *Achnatherum hymenoides, Aristida* spp., *Bouteloua eriopoda, Bouteloua gracilis, Hesperostipa comata, Pleuraphis jamesii, Poa secunda, Pseudoroegneria spicata, Sporobolus airoides*, and *Sporobolus cryptandrus*, will be top-killed after burning, then resprout from rootcrowns unless the fire was very severe (Howard 1997a, 1997b, Tirmenstein 1999e, Zlatnik 1999a, 1999b, Johnson 2000c, Simonin 2000a, 2000b, 2000c, Anderson 2003, Sawyer et al. 2009). This grassland system is maintained by fires that kill or reduce cover of the more fire-sensitive shrub species.

Achnatherum hymenoides is one of the most drought-tolerant grasses in the western U.S. (USFS 1937, Tirmenstein 1999e). It is also a valuable forage grass in arid and semi-arid regions. Improper grazing by ungulates decreases cover of this palatable plant species and increases weedy species and soil erosion (USFS 1937, Tirmenstein 1999e). *Hesperostipa comata* is a deep-rooted grass that uses soil moisture below 0.5 m during the dry summers. It is prone to litter accumulations at plant bases, which can increase intensity of fire, making it more susceptible to mortality (Zlatnik 1999a). *Bouteloua gracilis* is drought- and very grazing-tolerant, and generally forms a short sod. *Pleuraphis jamesii* is only moderately palatable to livestock, but decreases when heavily grazed during drought and in the more arid portions of its range where it is the dominant grass (West et al. 1972). This grass reproduces extensively from scaly rhizomes, which make the plant resistant to trampling by large wildlife or livestock and have good soil-binding properties (Weaver and Albertson 1956, West et al. 1972).

Semi-desert grassland can be large (>10,000 acres) when associated with extensive sandsheet systems. Historic disturbance (fire) likely ranged from small (<10 acres) to large (>10,000 acres) depending on conditions, time since last ignition and fuel loading. It is assumed that the average patch size of fire is 250 acres (Landfire 2007a). Drought cycles likely resulted in a reduction in vegetative cover, production and acreage of these sites (mean return interval of 100 years) (Landfire 2007a). During severe droughts there is a tendency for increased soil erosion primarily from wind processes, forming inter-canopy blowouts and coppice dunes where shrubs stabilize and prevent soil movement.

Component Associations:

- *Achnatherum hymenoides - Sporobolus contractus* Herbaceous Vegetation (CEGL001652, G2G4)

- *Sporobolus cryptandrus* Shrub Herbaceous Vegetation (CEGL001514, G2)

DISTRIBUTION

Range: This system occurs throughout the intermountain western U.S. on dry plains and mesas, at approximately 1450 to 2320 m (4750-7610 feet) elevation. In the Bighorn Basin of north-central Wyoming, there may be some desert grasslands, but this is uncertain.

LOWER MISSISSIPPI ALLUVIAL PLAIN GRAND PRAIRIE (CES203.549)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Deep Soil
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2432; ESLF 7145; ESP 1432

CONCEPT

Summary: This system of prairies and woodlands occurs on the oldest land surfaces in the Mississippi River Alluvial Valley and the highest land surface in the river deposited portions of the ecoregion (EPA Ecoregion 73). It occupies a very flat region up to 20 miles wide and 60 miles long bounded by present day rivers, especially the Arkansas and White, which are much lower in elevation than the Grand Prairie terrace (Subsection 234Ae). This terrace is covered with thin soils underlain be deep layers of impervious clay. The surface soils have been considered to be loess by some sources but are more likely silts and silty clays (T. Foti pers. comm.). Although productive, these soils are droughty due to the impervious clay subsoils. The combination of droughty soils, very flat topography, and the lack of major stream corridors in the region create conditions suitable to the ignition and spread of fires. Almost annual fires would have been necessary to maintain these prairies, and anthropogenic influences have been critical for probably 5000 years. Typical examples are dominated by *Panicum virgatum* and *Andropogon gerardii*. The vegetation includes both wet and dry prairies as well as "slashes" dominated by *Fraxinus pennsylvanica* and *Crataegus* spp.
Classification Comments: There is little floristic and environmental overlap between the Grand Prairie and calcareous prairies of southern Arkansas and the Arkansas River Valley (Ecoregion 39) manifestations of Southeastern Great Plains Tallgrass Prairie (CES205.685).
Similar Ecological Systems:
- Lower Mississippi River Flatwoods (CES203.193)
- Southeastern Great Plains Tallgrass Prairie (CES205.685)
- Texas Blackland Tallgrass Prairie (CES205.684)

DESCRIPTION

Environment: This system occupies a very flat region up to 20 miles wide and 60 miles long bounded by present day rivers, especially the Arkansas and White, which are much lower in elevation than the Grand Prairie terrace (Subsection 234Ae). This terrace is covered with thin soils underlain be deep layers of impervious clay. The surface soils have been considered to be loess by some sources but are more likely silts and silty clays (T. Foti pers. comm.). Although productive, these soils are droughty due to the impervious clay subsoils. It occurs on the oldest land surfaces in the Mississippi River Alluvial Valley and the highest land surface in the river deposited portions of the ecoregion (EPA Ecoregion 73) (T. Foti pers. comm.).
Vegetation: Typical examples are dominated by *Panicum virgatum* and *Andropogon gerardii*. The vegetation includes both wet and dry prairies, as well as "slashes" dominated by *Fraxinus pennsylvanica* and *Crataegus* spp.
Dynamics: The combination of droughty soils, very flat topography, and the lack of major stream corridors in the region create conditions suitable to the ignition and spread of fires. Almost annual fires would have been necessary to maintain these prairies, and anthropogenic influences have been critical for probably 5000 years. The region is characterized by frequent surface fires, both lightning and anthropogenic in origin (Higgins 1986). Mixed fires occurred frequently in this BpS. Natural fires were possible during the dormant season through spring and during the late-growing season dependent on the availability of dry fine fuels sufficient to carry a fire. Prior to extirpation of bison, the fire-return interval was estimated to have been from 1 to 3 years based on observations of travelers through the region (Gregg 1844, Olmstead 1855). Historic accounts from later in the 1800s often depict very large landscape-scale burns where an entire landscape was described as burning (Irving 1935, Jackson 1965).

Component Associations:
- *Panicum virgatum - Andropogon gerardii* Grand Prairie Herbaceous Vegetation (CEGL007911, G2)
- *Panicum virgatum - Tripsacum dactyloides* Grand Prairie/Big Barrens Herbaceous Vegetation (CEGL004624, G2?)

MEDITERRANEAN CALIFORNIA ALPINE DRY TUNDRA (CES206.939)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Alpine Mosaic; Herbaceous; Temperate [Temperate Oceanic]; Udic; W-Landscape/High Intensity; Graminoid
Non-Diagnostic Classifiers: Late-lying snowpack; Ridge/Summit/Upper Slope; Sideslope; Glaciated; Shallow Soil; Forb
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2136; ESLF 7108; ESP 1136

CONCEPT

Summary: These dry meadows typically occur between 3200 and 4500 m (9700-13,600 feet) elevation in the northern Sierra Nevada, Klamath Mountains and Cascade Mountains. They are typically found on gentle to steep slopes, flat ridges and upper basins where the soil is thin and the water supply is constant and strongly regulated by snowpatch patterns. These sites are generally very well-drained and xeric once the snow melts. The system is commonly comprised of a mosaic of small-patch plant communities that are dominated by sedges, grasses and forbs. Characteristic species include *Phlox diffusa*, *Phlox covillei*, *Erigeron pygmaeus*, *Podistera nevadensis*, *Carex congdonii*, *Calamagrostis purpurascens*, *Eriogonum incanum*, *Raillardiopsis muirii (= Raillardella muirii)*, *Castilleja nana*, *Erigeron compositus*, *Eriogonum ovalifolium*, *Eriogonum gracilipes*, etc. There is a rocky mesic version of this system with *Hulsea algida*, *Saxifraga tolmiei*, *Carex helleri*, *Ranunculus eschscholtzii*, *Polemonium eximium*, *Salix reticulata* (rarely), *Oxyria digyna*, *Sibbaldia procumbens*, etc. that could be found near snowmelt patches generally on sheltered, steep, rocky slopes. Alpine dry tundra typically intermingles with alpine bedrock and scree, ice field, fell-field, alpine dwarf-shrubland, and alpine/subalpine wet meadows.

Related Concepts:
- Alpine Grassland (213) (Shiflet 1994) Broader. SRM type 213 includes all alpine communities in Sierra, Klamath and California Cascades, both herbaceous and shrub dominated, and wet meadows.

Component Associations:
- *Calamagrostis purpurascens - Leptodactylon pungens* Herbaceous Vegetation (CEGL008658, GNR)
- *Carex helleri - Eriogonum incanum - Raillardella argentea* Herbaceous Vegetation (CEGL003138, G3?)
- *Carex helleri - Saxifraga tolmiei - Luzula spicata* Herbaceous Vegetation (CEGL003139, G3?)

DISTRIBUTION

Range: This system occurs between 3200 and 4500 m (9700-13,600 feet) elevation in the northern Sierra Nevada, Klamath Mountains, and Cascade Mountains of California, Nevada and Oregon.

MEDITERRANEAN CALIFORNIA SUBALPINE MEADOW (CES206.940)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Late-lying snowpack; Montane [Upper Montane]; Herbaceous; Ustic; W-Landscape/High Intensity
Non-Diagnostic Classifiers: Alpine Mosaic; Sideslope; Temperate [Temperate Oceanic]; Shallow Soil; Udic; Forb; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2137; ESLF 7109; ESP 1137

CONCEPT

Summary: This ecological system occurs at subalpine and montane elevations where finely textured soils, snow deposition, or windswept dry conditions limit tree establishment. It is typically found above 3000 m (9100 feet) elevation in California, western Nevada and Oregon. The soils in these sites can be seasonally moist to saturated in the spring but, if so, will dry out later in the growing season, and overall these are mesic to dry meadows, not wet. Characteristic plant species include *Achillea millefolium var. occidentalis (= Achillea lanulosa)*, *Artemisia rothrockii*, *Oreostemma alpigenum (= Aster alpigenus)*, *Calamagrostis breweri*, *Cistanthe umbellata (= Calyptridium umbellatum)*, *Carex exserta*, *Eriogonum incanum*, *Horkeliella purpurascens (= Ivesia purpurascens)*, and *Trisetum spicatum*. Burrowing mammals can increase the forb diversity. Herbs can include *Carex subnigricans*, *Carex vernacula*, *Calamagrostis breweri*, *Antennaria media*, *Potentilla drummondii*, *Lewisia pygmaea*, *Erigeron algidus*, *Lupinus lepidus*, *Dodecatheon alpinum*, and *Solidago multiradiata*. Wet meadows of *Carex*, *Calamagrostis*, *Camassia*, *Eleocharis*, *Juncus*, *Veratrum*, etc. from montane to subalpine are treated in Temperate Pacific Subalpine-Montane Wet Meadow (CES200.998).
Related Concepts:

NORTH PACIFIC ALPINE AND SUBALPINE DRY GRASSLAND (CES204.099)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Montane [Upper Montane]; Herbaceous; Deep Soil; Ustic; Intermediate Disturbance Interval; Graminoid; Tussock-forming grasses
Non-Diagnostic Classifiers: Temperate [Temperate Continental]; Mineral: W/ A-Horizon <10 cm; F-Patch/Low Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2171; ESLF 7157; ESP 1171

CONCEPT

Summary: This high-elevation, grassland system is dominated by perennial grasses and forbs found on dry sites, particularly south-facing slopes, typically imbedded in or above subalpine forests and woodlands. Disturbance such as fire also plays a role in maintaining these open grassy areas, although drought and exposed site locations are primary characteristics limiting tree growth. It is most extensive in the eastern Cascades, although it also occurs in the Olympic Mountains. Alpine and subalpine dry grasslands are small openings to large open ridges above or drier than high-elevation conifer trees. In general, soil textures are much finer, and soils are often deeper under grasslands than in the neighboring forests. These grasslands, although composed primarily of tussock-forming species, do exhibit a dense sod that makes root penetration difficult for tree species. Typical dominant species include *Festuca idahoensis*, *Festuca viridula*, and *Festuca roemeri* (the latter species occurring only in the Olympic Mountains). This system is similar to Northern Rocky Mountain Subalpine-Upper Montane Grassland (CES306.806), differing in its including dry alpine habitats, more North Pacific floristic elements, greater snowpack, and higher precipitation.

NORTH PACIFIC HERBACEOUS BALD AND BLUFF (CES204.089)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Ridge/Summit/Upper Slope; Bluff
National Mapping Codes: ESLF 7162

CONCEPT

Summary: This system consists of mostly herbaceous-dominated areas located primarily on shallow soils from eastern Vancouver Island and the Georgia Basin south to at least the southern end of the Willamette Valley and adjacent slopes of the Coast Ranges and western Cascades, excluding areas adjacent to the outer coastline (hypermaritime climate). They are largely, if not completely, absent from the windward side of Vancouver Island, the Olympic Peninsula, and the Coast Ranges of Washington and Oregon. Due to shallow soils, steep slopes, sunny aspect, and/or upper slope position, these sites are dry and marginal for tree establishment and growth except in favorable microsites. Rock outcrops are a typical small-scale feature within balds and are considered part of this system. Sites with many favorable microsites can have a "savanna" type structure with a sparse tree layer of *Pseudotsuga menziesii* or, less commonly, *Quercus garryana*. The climate is relatively dry to wet (20 to perhaps 100 inches annual precipitation), always with a distinct dry summer season when these sites usually become droughty enough to limit tree growth and establishment. Seeps are a frequent feature in many balds and result in vernally moist to wet areas within the balds that dry out by summer. Vegetation differences are associated with relative differences in soil moisture. Most sites have little snowfall, but sites in the *Abies amabilis* zone (montane *Tsuga heterophylla* in British Columbia) can have significant winter snowpacks. Snowpacks would be expected to melt off sooner on these sunny aspect sites than surrounding areas. Fog and salt spray probably have some influence (but less than in the hypermaritime) on exposed slopes or bluffs adjacent to saltwater shorelines in the Georgia Basin, where soils on steep coastal bluffs sometime deviate from the norm and are deep glacial deposits. Slightly to moderately altered serpentine soils occur rarely. Fires, both lightning-ignited and those ignited by Native Americans, undoubtedly at least occasionally burn all these sites. Lower elevation sites in the Georgia Basin, Puget Trough, and Willamette Valley probably were burned somewhat more frequently and in some cases intentionally. Because of this fire history, the extent of this system has declined locally through tree invasion and growth, as areas formerly maintained herbaceous by burning have filled in with trees.

Grasslands are the most prevalent vegetation cover, though forblands are also common especially in the mountains. Dwarf-shrublands occur commonly, especially in mountains or foothills, as very small patches for the most part, usually in a matrix of herbaceous vegetation, most often near edges. Dominant or codominant native grasses include *Festuca roemeri, Danthonia californica, Achnatherum lemmonii, Festuca rubra* (near saltwater), and *Koeleria macrantha*. Forb diversity can be high. Some typical codominant forbs include *Camassia quamash, Camassia leichtlinii, Triteleia hyacinthina, Mimulus guttatus* (seeps), *Plectritis congesta, Lomatium martindalei, Allium cernuum*, and *Phlox diffusa* (can be considered a dwarf-shrub). Important dwarf-shrubs are *Arctostaphylos uva-ursi, Arctostaphylos nevadensis*, and *Juniperus communis*. Small patches and strips dominated by the shrub *Arctostaphylos columbiana* are a common feature nested within herbaceous balds. Significant portions of some balds, especially on rock outcrops, are dominated by bryophytes (mosses) and to a lesser degree lichens.

Component Associations:
- *Achnatherum lemmonii / Racomitrium canescens* Herbaceous Vegetation (CEGL001800, G1)
- *Danthonia californica* Valley Grassland Herbaceous Vegetation (CEGL001598, G1Q)
- *Festuca roemeri - Cerastium arvense - Koeleria macrantha* Herbaceous Vegetation (CEGL003349, G1)
- *Festuca rubra - (Camassia leichtlinii, Grindelia stricta var. stricta)* Herbaceous Vegetation (CEGL003347, G1)
- *Festuca rubra* Montane Herbaceous Vegetation (CEGL001568, G2Q)
- *Lomatium martindalei* Herbaceous Vegetation (CEGL001972, G2)

DISTRIBUTION

Range: This system occurs in the Willamette Valley, Puget Trough, Georgia Basin, eastern and northern Olympic Mountains, eastern side of Vancouver Island, western and northwestern Cascades of Washington, probably on the leeward side of the Coast Mountains in British Columbia (submaritime climates)?, Old Cascades of western Oregon, and Oregon Coast Ranges (but not the coast itself).

NORTH PACIFIC HYPERMARITIME SHRUB AND HERBACEOUS HEADLAND (CES204.088)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Ridge/Summit/Upper Slope; Bluff
National Mapping Codes: ESLF 7161

CONCEPT

Summary: This system consists of herbaceous- and shrub-dominated areas directly adjacent to the outer Pacific Coast from central Oregon north to Vancouver Island. These are very windy sites where wind and salt spray combine to limit tree growth. The climate is very wet, relatively warm in winter, and cool and foggy. In Oregon, fires apparently set by Native Americans also contributed to the open character of many of these sites. The relative prevalence of grasslands versus shrublands increases to the south. Steep slopes on coastal bluffs, headlands, or small islands are typical, though sometimes this system occurs on relatively level tops of headlands or islands. Soils can be shallow to bedrock or of glacial or marine sediment origin. Vegetation is dominated by perennial bunch grasses or shrubs. Dominant species include *Vaccinium ovatum, Gaultheria shallon, Rubus spectabilis, Calamagrostis nutkaensis,* and *Festuca rubra*. Scattered stunted trees, especially *Picea sitchensis*, are often present.
Classification Comments: California Northern Coastal Grassland (CES206.941) is somewhat similar to the grassland part of this but is more extensive (larger patches) and extends further inland and higher in elevation. In southern Oregon, the climate gets warmer and drier and the grasslands start climbing well up into the hills, picking up some southern elements of vegetation. Probably corresponds with where Northern California Coastal Scrub (CES206.932) starts also, somewhere south of Coos Bay.
Similar Ecological Systems:

NORTH PACIFIC INTERIOR DRY GRASSLAND (CES207.389)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
National Mapping Codes: ESLF 7183

CONCEPT

Summary: This ecological system encompasses grasslands of the central, dry interior of British Columbia, dominated by *Pseudoroegneria spicata*, *Elymus trachycaulus*, *Calamagrostis purpurascens*, *Calamagrostis rubescens*, and *Koeleria macrantha*. *Pulsatilla occidentalis* may be codominant in some areas, other areas may have significant shrub cover, such as *Artemisia* spp. or *Amelanchier alnifolia*. Stunted *Populus tremuloides* and *Pinus contorta* are often present. These grasslands are common on south-facing slopes, and are maintained by a combination of dry and nutrient rich soils and frequent fire.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC MONTANE GRASSLAND (CES204.100)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Temperate [Temperate Oceanic]; Mesotrophic Soil; Shallow Soil; Intermediate Disturbance Interval; F-Patch/Low Intensity
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Ustic
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2138; ESLF 7110; ESP 1138

CONCEPT

Summary: This ecological system includes open dry meadows and grasslands on the west side of the Cascades Mountains and northern Sierra Nevada. They occur in montane elevations up to 3500 m (10,600 feet). Soils tend to be deeper and more well-drained than the surrounding forest soils. Soils can resemble prairie soils in that the A-horizon is dark brown, relatively high in organic matter, slightly acidic, and usually well-drained. Dominant species include *Elymus* spp., *Festuca idahoensis*, and *Nassella cernua*. These large-patch grasslands are intermixed with matrix stands of red fir, lodgepole pine, and dry-mesic mixed conifer forests and woodlands.
Classification Comments: Upon review, Washington Heritage ecologists determined this system does not occur in Washington. Review in November 2008 suggests this ecological system should be lumped with Mediterranean California Subalpine Meadow (CES206.940) and that system be redefined to include the small patches of dry montane grasslands found in the Sierras and southern Cascades. For now, we've retained this as a system pending further review and comment from California ecologists.
Related Concepts:
- Idaho Fescue (102) (Shiflet 1994) Intersecting

NORTH-CENTRAL INTERIOR SAND AND GRAVEL TALLGRASS PRAIRIE (CES202.695)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Esker; Kame; Lakeplain; Moraine; Outwash plain; Outwash terrace; Herbaceous; Glaciated; Sand Soil Texture; F-Patch/High Intensity; W-Patch/High Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2412; ESLF 7125; ESP 1412

CONCEPT

Summary: This system is found in the northern Midwest, particularly in Minnesota, Wisconsin, Michigan, and possibly ranging into Ontario. It is often found on glacial features such as kames, eskers, moraines, lakeplains (though excluding the Great Lakes lakeplain) and sandplains, and along eolian dunes. In contrast to the deeper, richer soils supporting other tallgrass systems in the region, the underlying soils in this system tend to be more shallow, sandy, rocky, and/or gravelly outwash soils. Organic content is significantly lower. Grassland species such as *Schizachyrium scoparium*, *Andropogon gerardii*, and *Bouteloua* spp., varying in cover from sparse to moderately dense, dominate this system. *Hesperostipa spartea* and *Sporobolus heterolepis* are also common components of this system. Woody species more tolerant of droughty conditions may be found in some examples. The most common trees are *Pinus banksiana*, *Quercus ellipsoidalis*, *Quercus macrocarpa*, and *Populus tremuloides*. Fire and drought are the major dynamics influencing this system. If fire and periodic drought are not present, woody species begin to invade this system, especially in the eastern parts of its distribution. Wind can also play a role, especially on examples found on sandplains and/or eolian dunes.

DESCRIPTION

Environment: This system is often found on glacial features such as kames, eskers, moraines, lakeplains (though excluding the Great Lakes lakeplain), and sandplains, and along eolian dunes and river deltas. In contrast to the deeper, richer soils supporting other tallgrass systems in the region, the underlying soils in this system tend to be more shallow, sandy, rocky, and/or gravelly soils. Soil texture is sand or sandy loam. Organic content and soil moisture retention are significantly lower than the more mesic grasslands.
Vegetation: Grassland species such as *Schizachyrium scoparium*, *Andropogon gerardii*, and *Bouteloua* spp., varying in cover from sparse to moderately dense, dominate this system. *Hesperostipa spartea* and *Sporobolus heterolepis* are also common components of this system. Woody species more tolerant of droughty conditions may be found in some examples. The most common trees are *Pinus banksiana*, *Quercus ellipsoidalis*, *Quercus macrocarpa*, and *Populus tremuloides*.
Dynamics: Fire and drought are the major dynamics influencing this system. If fire and periodic drought are not present, woody species begin to invade this system, especially in the eastern parts of its distribution. Fire-return intervals were likely 1-8 years (Landfire 2007a). Drier examples of this system likely could not be maintained in the presence of long-term short fire-return intervals due to the lower fertility of the soils. The typical dominant perennial grasses would not have time to recover from repeated burning and shorter-lived opportunistic species could dominate (Loucks et al. 1985). These sites were maintained as grasslands by the dry soil conditions possibly supplemented by low-frequency fires, while other areas required fire to eliminate invasion by woody species. Wind can also play a role, especially on examples found on sandplains and/or eolian dunes or during droughts when vegetation cover is low. Blowouts can form, exposing bare sand (Burgess 1965). Productivity is lower on this system than on other tallgrass prairies, so vegetation responds more slowly to disturbance. This system can not persist with the same frequency of reductions in vegetation cover by fire, grazing, drought, or mowing as richer prairies can.

Component Associations:
- *Andropogon gerardii - Calamagrostis canadensis* Sand Herbaceous Vegetation (CEGL005177, G2G3)
- *Andropogon gerardii - Sorghastrum nutans - Schizachyrium scoparium - Aletris farinosa* Herbaceous Vegetation (CEGL005096, G2)
- *Schizachyrium scoparium - Bouteloua curtipendula* Gravel Herbaceous Vegetation (CEGL002215, G3)
- *Schizachyrium scoparium - Bouteloua* spp. - *Hesperostipa spartea* Gravel Herbaceous Vegetation (CEGL002499, G2G3)
- *Schizachyrium scoparium - Danthonia spicata - Carex pensylvanica - (Viola pedata)* Herbaceous Vegetation (CEGL002318, G2G3)
- *Schizachyrium scoparium - Hesperostipa spartea - Bouteloua (curtipendula, gracilis)* Sand Herbaceous Vegetation (CEGL005204, G2G3)
- *Schizachyrium scoparium - Sorghastrum nutans - Andropogon gerardii - Lespedeza capitata* Sand Herbaceous Vegetation (CEGL002210, G3)

NORTHERN ROCKY MOUNTAIN LOWER MONTANE, FOOTHILL AND VALLEY GRASSLAND (CES306.040)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Herbaceous; Sideslope; Very Shallow Soil; Loam Soil Texture; Silt Soil Texture; Ustic; Landslide; Graminoid; Cool-season bunch grasses
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2139; ESLF 7112; ESP 1139

CONCEPT

Summary: This ecological system of the northern Rocky Mountains is found at lower montane to foothill elevations in the mountains and large valleys of northeastern Wyoming and western Montana, west through Idaho into the Blue Mountains of Oregon, and north into the Okanagan and Fraser plateaus of British Columbia and the Canadian Rockies. They also occur to the east in the central Montana mountain "islands," foothills, as well as the Rocky Mountain Front and Big and Little Belt ranges. These grasslands are floristically similar to Inter-Mountain Basins Big Sagebrush Steppe (CES304.778), Columbia Basin Foothill and Canyon Dry Grassland (CES304.993), and Columbia Basin Palouse Prairie (CES304.792), but are defined by shorter summers, colder winters, and young soils derived from recent glacial and alluvial material. These northern lower montane and valley grasslands represent a shift in the precipitation regime from summer monsoons and cold snowy winters found in the southern Rockies to predominantly dry summers and winter precipitation. In the eastern portion of its range in Montana, winter precipitation is replaced by a huge spring peak in precipitation. They are found at elevations from 300 to 1650 m, ranging from small meadows to large open parks surrounded by conifers in the lower montane, to extensive foothill and valley grasslands below the lower treeline. In the southern extent, some of these valleys may have been primarily sage-steppe with patches of grassland in the past, but because of land-use history post-settlement (herbicide, grazing, fire, pasturing, etc.), they have been converted to grassland-dominated areas. Soils are relatively deep, fine-textured, often with coarse fragments, and non-saline, often with a microphytic crust. The most important species are cool-season perennial bunch grasses and forbs (>25% cover), sometimes with a sparse (<10% cover) shrub layer. *Pseudoroegneria spicata, Festuca campestris*, *Festuca idahoensis*, or *Hesperostipa comata* commonly dominate sites on all aspects of level to moderate slopes and on certain steep slopes with a variety of other grasses, such as *Achnatherum hymenoides, Achnatherum richardsonii, Hesperostipa curtiseta, Koeleria macrantha, Leymus cinereus, Elymus trachycaulus, Bromus inermis ssp. pumpellianus (= Bromus pumpellianus), Achnatherum occidentale (= Stipa occidentalis), Pascopyrum smithii*, and other graminoids such as *Carex filifolia* and *Danthonia intermedia*. Other grassland species include *Opuntia fragilis, Artemisia frigida, Carex petasata, Antennaria* spp., and *Selaginella densa*. Important exotic grasses include *Phleum pratense, Bromus inermis*, and *Poa pratensis*. Shrub species may be scattered, including *Amelanchier alnifolia*, *Rosa* spp., *Symphoricarpos* spp., *Juniperus communis, Artemisia tridentata*, and in Wyoming *Artemisia tripartita ssp. rupicola*. Common associated forbs include *Geum triflorum, Galium boreale, Campanula rotundifolia, Antennaria microphylla, Geranium viscosissimum*, and *Potentilla gracilis*. A soil crust of lichen covers almost all open soil between clumps of grasses; *Cladonia* and *Peltigera* are the most common lichens. Unvegetated mineral soil is commonly found between clumps of grass and the lichen cover. The fire regime of this ecological system maintains a grassland due to rapid fire return that retards shrub invasion or landscape isolation and fragmentation that limits seed dispersal of native shrub species. Fire frequency is variable, but is presumed to be generally less than 20 years to reduce shrub cover and maintain grassland. These are extensive grasslands, not grass-dominated patches within the sagebrush shrub-steppe ecological system. *Festuca campestris* is easily eliminated by grazing and does not occur in all areas of this system.
Classification Comments: This is the same as the Interior Plateau Grassland also called "Northern Plateau Grassland" of the Okanagan Ecoregional Plan. In Wyoming, this is distinguished from Northwestern Great Plains Mixedgrass Prairie (CES303.674) by the presence of *Festuca idahoensis* or *Carex rossii*, the lack of *Bouteloua gracilis* (which is common in CES303.674), or the presence of *Artemisia nova* or *Artemisia tripartita ssp. rupicola*, neither of which occur in CES303.674.
Similar Ecological Systems:
- Columbia Basin Foothill and Canyon Dry Grassland (CES304.993)
- Columbia Basin Palouse Prairie (CES304.792)
- Inter-Mountain Basins Big Sagebrush Steppe (CES304.778)
- Inter-Mountain Basins Semi-Desert Grassland (CES304.787)
- Northern Rocky Mountain Subalpine-Upper Montane Grassland (CES306.806)

DESCRIPTION

Environment: This system is found at lower montane to foothill elevations in the mountains and large valleys of northeastern Wyoming and western Montana, west through Idaho into the Blue Mountains of Oregon, and north into the Okanagan and Fraser plateaus of British Columbia and the Canadian Rockies. They also occur to the east in the central Montana mountain "islands" and foothills, as well as the Rocky Mountain Front Range and Big and Little Belt ranges. These grasslands are floristically similar to Inter-Mountain Basins Big Sagebrush Steppe (CES304.778), Columbia Basin Foothill and Canyon Dry Grassland (CES304.993), and Columbia Basin Palouse Prairie (CES304.792), but are defined by shorter summers, colder winters, and young soils derived from recent glacial and alluvial material. These lower montane and valley grasslands represent a shift in the precipitation regime from summer monsoons and cold snowy winters found in the Southern Rockies to predominantly dry summers and winter precipitation. In the eastern portion of its range in Montana, winter precipitation is replaced by a huge spring peak in precipitation. They are found at elevations from 300 to 1650 m, ranging from small meadows to large open parks surrounded by conifers in the lower montane, to extensive foothill and valley grasslands below the lower treeline. In the southern extent some of these valleys may have been primarily sage-steppe with patches of grassland in the past, but because of land-use history post-settlement (herbicide, grazing, altered fire regime, pasturing, etc.), they have been converted to grassland-dominated areas. Soils are relatively deep, fine-textured, often with coarse fragments, and non-saline, often with a microphytic crust.

Dynamics: These are extensive grasslands, not grass-dominated patches within the sagebrush shrub-steppe ecological system. *Festuca campestris* is easily eliminated by grazing and does not occur in all areas of this system. The most droughty sites produce little and discontinuous fuel and likely have much longer fire regimes. Isolation of grassland patches by fragmentation may also limit seed dispersal of native shrubs leading to persistence of the grassland. Soil drought and herbivory retard shrub and tree invasion resulting in a patchy distribution of shrubs and trees when present.

The high-frequency fire regime of this ecological system maintains a grassland due to rapid fire return that retards shrub invasion or landscape isolation and fragmentation that limits seed dispersal of native shrub species. Fire frequency is presumed to be less than 20 years generally. Johnson and Swanson (2005) presumed fire frequency to be less than 35 years in the Blue and Ochoco mountains of Oregon. Wikeem and Wikeem (2004) compiled average fire intervals for interior grasslands in British Columbia which range from 5-20 years. Klenner et al. (2008) research supports a fire regime of predominantly mixed-severity fires that maintain grasslands in the dry forest and grasslands ecotone in the southern interior of British Columbia.

Biological soil crust cover is important in these grasslands. It alters the composition of perennial species and increases the establishment of native disturbance-increasers and annual grasses, particularly *Bromus tectorum* and other exotic annual bromes (WNHP 2011). Crust cover and diversity are greatest where not impacted by trampling, other soil surface disturbance and fragmentation (Belnap et al. 2001, Rosentreter and Eldridge 2002, Tyler 2006).

DISTRIBUTION

Range: This lower montane, foothill and valley grassland system occurs throughout the southern interior and southern portion of the Fraser Plateau, as well as the valleys around the Fraser River in the Pavilion Ranges, the Nicola River and the Similkameen River in British Columbia. It also occurs in the mountains and large valleys of northwestern Wyoming and western Montana, east to the central Montana Rocky Mountain Front and mountain "island" ranges, west through Idaho into the Blue Mountains of Oregon.

NORTHERN ROCKY MOUNTAIN SUBALPINE-UPPER MONTANE GRASSLAND (CES306.806)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Herbaceous; Deep Soil; Ustic; Intermediate Disturbance Interval; Graminoid; Tussock-forming grasses
Non-Diagnostic Classifiers: Temperate [Temperate Continental]; Mineral: W/ A-Horizon <10 cm; F-Patch/Low Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2140; ESLF 7113; ESP 1140

CONCEPT

Summary: This is an upper montane to subalpine, high-elevation, lush grassland system dominated by perennial grasses and forbs on dry sites, particularly south-facing slopes. It is most extensive in the Canadian Rockies portion of the Rocky Mountain cordillera, extending south into western Montana, eastern Oregon, eastern Washington and Idaho. Subalpine dry grasslands are small meadows to large open parks surrounded by conifer trees but lack tree cover within them. In general, soil textures are much finer, and soils are often deeper under grasslands than in the neighboring forests. Grasslands, although composed primarily of tussock-forming species, do exhibit a dense sod that makes root penetration difficult for tree species. Disturbance such as fire also plays a role in maintaining these open grassy areas. Typical dominant species include *Leymus innovatus (= Elymus innovatus), Koeleria macrantha, Festuca campestris, Festuca idahoensis, Festuca viridula, Achnatherum occidentale (= Stipa occidentalis), Achnatherum richardsonii (= Stipa richardsonii), Bromus inermis ssp. pumpellianus (= Bromus pumpellianus), Elymus trachycaulus, Phleum alpinum, Trisetum spicatum*, and a variety of Carices, such as *Carex hoodii, Carex obtusata*, and *Carex scirpoidea*. Important forbs include *Lupinus argenteus var. laxiflorus, Potentilla diversifolia, Potentilla flabellifolia, Fragaria virginiana*, and *Chamerion angustifolium (= Epilobium angustifolium)*. This system is similar to Northern Rocky Mountain Lower Montane, Foothill and Valley Grassland (CES306.040) but is found at higher elevations and is more often composed of species of *Festuca, Achnatherum*, and/or *Hesperostipa* with additional floristic components of more subalpine taxa. Occurrences of this system are often more forb-rich than Southern Rocky Mountain Montane-Subalpine Grassland (CES306.824).

Similar Ecological Systems:
- North Pacific Alpine and Subalpine Dry Grassland (CES204.099)
- Northern Rocky Mountain Lower Montane, Foothill and Valley Grassland (CES306.040)

NORTHERN TALLGRASS PRAIRIE (CES205.686)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Eastern Great Plains (205)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Glaciated plains; Herbaceous; Glaciated; Deep Soil; Loam Soil Texture; F-Landscape/Low Intensity; G-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2420; ESLF 7133; ESP 1420

CONCEPT

Summary: This system is found primarily in the Northern Tallgrass ecoregion ranging along the Red River basin in Minnesota and the Dakotas to Lake Manitoba in Canada. It constitutes the northernmost extension of the "true" prairies. Similar to Central Tallgrass Prairie (CES205.683), this system is dominated by tallgrass species such as *Andropogon gerardii*, *Sorghastrum nutans*, and *Panicum virgatum*. However, the soils in this region are not as rich nor deep, and thus this system does not have as much species diversity as grasslands to the south. This system is often found on well-drained, drier soils and can grade into Eastern Great Plains Tallgrass Aspen Parkland (CES205.688) to the north and east. Grazing and fire influenced this system historically. Much of this system has been converted to agriculture with very few unaltered and highly fragmented examples remaining.

Similar Ecological Systems:
- Central Tallgrass Prairie (CES205.683)

DESCRIPTION

Dynamics: Fire plays an important role in the maintenance of this prairie system. Fire promotes seed production and flowering necessary for plant regeneration. Because environmental conditions are suitable for tree growth, without recurrent fire (every 2-10 years), succession to forest or woodland will occur rapidly (Minnesota DNR 2005b). From Landfire BpS: Frequent fires impacted this prairie system every 1-3 years, maintaining grass and forb vegetation. Insect and small mammal herbivory impacts composition and dominance. Large mammals were present in low densities; main grazers were elk and deer, but impacts were likely minimal. Fire played an important role in the maintenance of the tallgrass prairie (Curtis 1959, Vogl 1964, Anderson 1990b). Fire could occur throughout the year with larger, less frequent fires occurring during the dormant season and smaller, more frequent fires occurring during the growing season. Native American burning, essential to maintaining the eastern tallgrass prairie, was bimodal in distribution, peaking in April and October with lightning ignition occurring primarily during July and August (Higgins 1986).

Bison grazing as a major disturbance was likely much more limited than prairies further west. Elk probably contributed to the impact of grazing and browsing as well, but it is assumed that the total contributions of these two species was still considerably less than to the west. The elk may have contributed to the reduction of young woody saplings invading prairie adjacent to protected woody areas. Prior to European settlement, episodic grazing by large, native mammals was common and encouraged the persistence of several native grass and forb species (Minnesota DNR 2005b). From Landfire BpS: Bison, with peripheral help from grasshoppers, elk, antelope and a myriad of smaller animals made herbivory one of the dominating factors of the northern tallgrass prairie (Severson and Sieg 2006). With estimates of 30-60 million bison in the Northern Great Plains (Isenberg 2000), herbivory by large mammals also was a significant disturbance to the grasslands. Bison herbivory occurred in a mob-grazing or flash-grazing method, with extensive herds migrating across the prairie as they graze. Modern rotational grazing systems simulate this by resting areas after intensive grazing. Elk, too, may have played an important role than generally believed, particularly in the eastern portion of the zone. Whether bison or elk, large mammals preferentially grazed recently burned sites.

Component Associations:

NORTHWESTERN GREAT PLAINS MIXEDGRASS PRAIRIE (CES303.674)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Herbaceous; Glaciated; Shallow Soil; Loam Soil Texture
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2141; ESLF 7114; ESP 1141

CONCEPT

Summary: This system extends from northern Nebraska into southern Canada and westward through the Dakotas to the Rocky Mountain Front in Montana and probably Wyoming, on both glaciated and non-glaciated substrates. Soil texture (which ultimately effects water available to plants) is the defining environmental descriptor; soils are primarily fine and medium-textured and do not include sands, sandy soils, or sandy loams. This system occurs on a wide variety of landforms (e.g., mesatops, stream terraces) and in proximity to a diversity of other systems. Most usually it is found in association with Western Great Plains Sand Prairie (CES303.670) which occupies the coarser-textured substrates. In various locales the topography where this system occurs is broken by many glacial pothole lakes, and this system may be proximate to Great Plains Prairie Pothole (CES303.661). On the eastern Montana plains, mixedgrass prairie is by far the predominant system. Here it occurs continuously for hundreds of square kilometers, interrupted only by riparian areas or sand prairies, which are associated with gentle rises, eroded ridges or mesas derived from sandstone. Historically, this system covered approximately 38 million ha in Nebraska, North and South Dakota, and Canada; now it covers approximately 270,000 square km in this region. The growing season and rainfall are intermediate to drier units to the southwest and mesic tallgrass regions to the east. Graminoids typically comprising the greatest canopy cover include *Pascopyrum smithii*, *Nassella viridula*, and *Festuca* spp. In Montana these include *Festuca campestris* and *Festuca idahoensis*. Other commonly dominant species in Montana are *Bouteloua gracilis*, *Hesperostipa comata*, and *Carex filifolia*, while *Festuca campestris* and *Festuca idahoensis* may be more abundant in the north and foothill/montane grassland transition areas. Remnants of *Hesperostipa curtiseta*-dominated vegetation are found in northernmost Montana and North Dakota associated with the most productive sites (largely plowed to cereal grains); this species, usually in association with *Pascopyrum smithii*, is much more abundant in Canada. Sites with a strong component of *Nassella viridula* indicate a more favorable moisture balance and perhaps a favorable grazing regime as well because this is one of the most palatable of the mid-grasses. *Hesperostipa comata* is also an important component and becomes increasingly so as improper grazing regimes favor it at the expense of (usually) *Pascopyrum smithii*; progressively more destructive grazing can result in the loss of *Pascopyrum smithii* from the system followed by drastic reduction in *Hesperostipa comata* and ultimately the dominance of *Bouteloua gracilis* (or *Poa secunda* and other short graminoids) and/or a lawn of *Selaginella densa*. *Koeleria macrantha*, at least in Montana and southern Canada, is the most pervasive grass; if it has high cover, past intensive grazing is the presumed reason. Shrub species such as *Symphoricarpos* spp. and *Artemisia frigida* and *Artemisia cana* also occur. Fire and grazing constitute the primary dynamics affecting this system. Drought can also impact this system, in general favoring the shortgrass component at the expense of the mid-grasses. With intensive grazing, cool-season exotics such as *Poa pratensis*, *Bromus inermis*, and *Bromus japonicus* can increase in dominance; both of the rhizomatous grasses have been shown to markedly depress species diversity. Shrub species such as *Juniperus virginiana* can also increase in dominance with fire suppression. This system is one of the most disturbed grassland systems in Nebraska, North and South Dakota, and Canada.

Classification Comments: This system was edited to expand the concept for central Montana mixedgrass prairie and to exclude specifically sandy soil grasslands, which are placed into Western Great Plains Sand Prairie (CES303.670). This system is similar to Central Mixedgrass Prairie (CES303.659) and can contain elements of Great Plains tallgrass and shortgrass systems. However, it differs from Central Mixedgrass Prairie (CES303.659) in that the cooler climate in this region allows natural cool-season grasses to be more important (greater than 50% cover). Cover of native, nongrazing-induced shrubs typically does not exceed 25% in conjunction with topographic relief (breaks); otherwise the stand would be considered part of Northwestern Great Plains Shrubland (CES303.662). Additional review and commentary by Canadian, Dakotan, and Nebraskan ecologists is needed to flesh out the compositional variation and range of distribution for this important grassland system. In Wyoming, this system transitions into Northern Rocky Mountain Lower Montane, Foothill and Valley Grassland (CES306.040) in the foothills of the northern Wyoming mountains where *Pascopyrum smithii* communities finger up into foothills. If *Festuca idahoensis*, *Carex rossii*, *Artemisia nova*, or *Artemisia tripartita ssp. rupicola* occur, then the example is not this system.

DESCRIPTION

Environment: Given the system's rather extensive geographic range, it not surprising to find it occurring on a wide variety of landforms (e.g., mesatops, stream terraces) and in proximity to a diversity of other systems. Climate and growing season length for the region this system occurs are intermediate to the shortgrass regions to the west and southwest and the tallgrass regions to the east with a shorter growing season and less humid climate compared to the range of Central Mixedgrass Prairie (CES303.659). Moisture conditions are semi-arid. This system occurs on soils derived primarily from fine-textured sedimentary rocks and deposits, but other rock types are included so long as their weathering products are not coarse-textured, namely not sands, sandy soils, or sandy loams and relatively stable. It is found primarily on planar to gently rolling topography but is found on broken topography hillslopes as well.
Vegetation: This system contains greater than 50% cover of natural, cool-season grasses such as *Festuca* spp., *Pascopyrum smithii, Elymus lanceolatus, Hesperostipa comata*, *Hesperostipa curtiseta*, and *Nassella viridula*. *Hesperostipa comata* becomes increasingly important where improper grazing regimes have favored it at the expense of (usually) *Pascopyrum smithii*; progressively more destructive grazing can result in the loss of *Pascopyrum smithii* from the system followed by drastic reduction in *Hesperostipa comata* and ultimately the dominance of *Bouteloua gracilis* (or *Poa secunda* and other short graminoids) and/or a lawn of *Selaginella densa*. *Koeleria macrantha*, at least in Montana and southern Canada, is the most pervasive grass; if it has high cover, past intensive grazing is the presumed reason. Shrub species such as *Symphoricarpos* spp. and *Artemisia frigida* also occur. Cover of native, nongrazing-induced shrubs typically does not exceed 25% in conjunction with topographic relief (breaks); otherwise the stand would be considered part of Northwestern Great Plains Shrubland (CES303.662). Cool-season exotics such as *Poa pratensis, Bromus inermis*, and *Bromus japonicus* can increase in dominance with overgrazing; both of the above-named rhizomatous grasses are sufficiently aggressive to outcompete natives regardless of disturbance regime. Likewise, shrub species such as *Juniperus virginiana* can also increase in dominance with fire suppression.
Dynamics: Fire and grazing constitute the primary dynamics affecting this system. Drought can also impact this system. It should be acknowledged that this system occurs within the very same biotope as Inter-Mountain Basins Big Sagebrush Steppe (CES304.778) or Inter-Mountain Basins Big Sagebrush Shrubland (CES304.777), the only difference being that fire has not been present where the sagebrush systems occur, a purely stochastic outcome. Heavy grazing causes cool-season exotics such as *Poa pratensis* and *Bromus inermis* to increase in dominance. Conversion to agriculture also impacts this system; however, the degree of agricultural alteration of this system is highly variable by geographic region with Montana (and Wyoming??) having experienced much less impact than the estimated 75% percent of the Nebraska-Dakota-south-central Canada region, where this system has been heavily altered. In Montana, this system is the major sustainer of livestock grazing with overall far less than half of it having been lost to agriculture; several Montana counties have more than 90% of this system remaining intact, though impacted by grazing to varying degrees.

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Great Plains Prairie Pothole (CES303.661)
- Northwestern Great Plains Shrubland (CES303.662)
- Western Great Plains Sand Prairie (CES303.670)
- Western Great Plains Shortgrass Prairie (CES303.672)
- Western Great Plains Tallgrass Prairie (CES303.673)

Adjacent Ecological System Comments: Across much of the western portion of its range, this system exists intimately associated with Western Great Plains Sand Prairie (CES303.670), at least as we have redefined Western Great Plains Sand Prairie). This system may be proximate to Great Plains Prairie Pothole (CES303.661) at various locations across its distribution.

DISTRIBUTION

Range: This system extends from northern Nebraska into southern Canada, and west to central Montana. The U.S. range corresponds to Bailey et al. (1994) sections 331D, 331E, 331F (mostly), 331G, 332A, 332B, and perhaps minor extensions into 251B, and in Canada to the Moist Mixed Grassland and Fescue Grassland.
Divisions: 205:P; 303:C
Nations: CA, US

OZARK PRAIRIE AND WOODLAND (CES202.326)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Graminoid
Non-Diagnostic Classifiers: Lowland
FGDC Crosswalk: Vegetated
National Mapping Codes: EVT 2508; ESLF 5429; ESP 1508

CONCEPT

Summary: This system of prairies and associated woodlands is found in the undissected portions of the Springfield Plateau region of Arkansas, Oklahoma, and Missouri (EPA Ecoregion 39a). This region is characterized by broad, level to gently rolling uplands derived from limestone and chert. It is much less rugged than the adjacent mountainous regions and more dissected portions of the Springfield Plateau. In addition, this region receives an annual precipitation total of 5-15 cm (2-6 inches) less than the surrounding regions due to a rainshadow produced by a combination of prevailing western winds and orographic effects. The limestone and chert-derived soils associated with the prairies are thin and droughty. The combined effect of droughty soils, reduced precipitation, and prevailing level topography create conditions highly conducive to the ignition and spread of fires. Stands are typically dominated by *Andropogon gerardii, Sorghastrum nutans, Panicum virgatum,* and *Schizachyrium scoparium*. Few extant examples of this system remain and most are small and isolated.

Classification Comments: There is little floristic and environmental overlap with the Grand Prairie and calcareous prairies of southern Arkansas. There may be stronger overlap with Southeastern Great Plains Tallgrass Prairie (CES205.685), and further review is needed to verify the distinction between these two systems.

Similar Ecological Systems:

- Southeastern Great Plains Tallgrass Prairie (CES205.685)
- Texas Blackland Tallgrass Prairie (CES205.684)

DESCRIPTION

Environment: This system of prairies and associated woodlands is found in the undissected portions of the Springfield Plateau region, which is distinctly bounded by the Boston Mountains to the south. This region is characterized by broad, level to gently rolling uplands derived from limestone and chert. It is much less rugged than the adjacent mountainous regions and more dissected portions of the Springfield Plateau. In addition, this region receives an annual precipitation total of 5-15 cm (2-6 inches) less than the surrounding regions due to a rainshadow produced by a combination of prevailing western winds and orographic effects. The limestone and chert-derived soils associated with the prairies are thin and droughty. The combined effect of droughty soils, reduced precipitation, and prevailing level topography create conditions highly conducive to the ignition and spread of fires. Few extant examples of this system remain and most are small and isolated.

The alternating shale plains are separated by limestone scarps that in a broad sense decrease in elevation in a stairstep pattern, from northwest to southeast. The flatter plains were formerly nearly continuous tallgrass prairie, while the scarped limestone areas were more dissected with bedrock outcrops and a mixture of prairie and savanna (Nigh and Schroeder 2002). Because of the presence of the rocky substrate close to the surface and the rolling topography, this area is relatively unsuitable for agriculture. Most occurrences of this system are on gently to moderately rolling terraces developed predominately in sandstones and shales of Pennsylvanian age. Soils are moderately fertile to sterile and well-drained. In addition, this region receives an annual precipitation total of 5-15 cm (2-6 inches) less than the adjacent regions due to a rainshadow produced by a combination of prevailing western winds and orographic effects (Landfire 2007a).

Vegetation: These prairies are typically dominated by *Schizachyrium scoparium, Andropogon gerardii, Sorghastrum nutans,* and *Panicum virgatum*. Other grasses include *Koeleria macrantha, Sporobolus heterolepis, Sphenopholis obtusata, Dichanthelium* spp., *Aristida purpurascens, Panicum brachyanthum, Phalaris caroliniana, Tripsacum dactyloides,* and *Spartina pectinata*. A rich forb diversity is commonly present and includes *Helianthus mollis, Helianthus grosseserratus, Rudbeckia subtomentosa, Silphium laciniatum, Symphyotrichum* spp., *Solidago* spp., *Camassia scilloides, Echinacea pallida, Callirhoe digitata, Asclepias hirtella, Eryngium yuccifolium, Delphinium carolinianum, Castilleja coccinea, Calopogon oklahomensis, Buchnera americana, Dodecatheon meadia, Amorpha canescens, Tephrosia virginiana, Orbexilum pedunculatum, Baptisia alba, Baptisia bracteata, Liatris pycnostachya,* and *Liatris squarrosa var. hirsuta (= Liatris hirsuta)*. Wetter areas support a rich diversity of rushes and sedges, including *Carex bicknellii var. opaca (= Carex opaca), Carex oklahomensis, Carex buxbaumii, Carex scoparia, Carex conjuncta, Carex davisii, Carex arkansana, Eleocharis tenuis var. verrucosa, Eleocharis wolfii,* and *Rhynchospora macrostachya*.

Dynamics: These prairies and woodlands were historically maintained by frequent fire. Drought cycles and grazing were also likely important ecosystem processes. Fires were frequent, primarily autumnal and of human origin. As *Quercus-Carya* regeneration becomes established, individuals of these species become largely fire-resistant with age. Surface fires within woodland and forest types occurred every 12 to 15 years, reducing duff layers and allowing recruitment of young individuals of *Quercus* and *Carya* species

(Landfire 2007a).

Component Associations:
- *Andropogon gerardii - Panicum virgatum - Helianthus grosseserratus* Herbaceous Vegetation (CEGL002024, G2G3)
- *Andropogon gerardii - Sorghastrum nutans* Unglaciated Herbaceous Vegetation (CEGL002204, G3)
- *Juncus (acuminatus, brachycarpus) - Panicum virgatum - Bidens aristosa - Hibiscus moscheutos ssp. lasiocarpos* Herbaceous Vegetation (CEGL004782, G2G3)
- *Schizachyrium scoparium - Bothriochloa laguroides ssp. torreyana - Croton willdenowii* Herbaceous Vegetation (CEGL008564, G1?)
- *Schizachyrium scoparium - Dichanthelium* spp. - *Buchnera americana - Echinacea pallida* Herbaceous Vegetation (CEGL007827, G2G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Interior Highlands Unglaciated Flatwoods (CES202.454)

DISTRIBUTION

Range: This system is found in the Springfield Plateau subsection of the Ozark Plateau region of Arkansas, Oklahoma, and Missouri, possibly ranging into a limited area of Kansas.

PENNYROYAL KARST PLAIN PRAIRIE AND BARRENS (CES202.355)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2418; ESLF 7131; ESP 1418

CONCEPT

Summary: This system consists of open, prairielike vegetation of the northwestern Highland Rim (Pennyroyal Plateau) of Tennessee and adjacent Kentucky (EPA Ecoregion 71e; part of Subsection 222Eh). Stands are dominated by grasses and forbs with scattered shrubby vegetation and, occasionally, trees. The scattered trees are mainly *Quercus falcata* and *Quercus imbricaria*. *Quercus alba* and *Quercus marilandica* would also be expected. The primary dominant grass is *Schizachyrium scoparium*, with some *Sorghastrum nutans* present. Other more mesic grasses (*Andropogon gerardii, Tripsacum dactyloides*) are restricted to ditches. The largest extant examples are presently found on Fort Campbell Military Reservation, Tennessee, where ecological burning and fires from live munitions use result in open herbaceous-dominated landscapes. This vegetation was the predominant type here in the early 1800s and probably originated from burning by Native Americans.
Classification Comments: Western Highland Rim Prairie and Barrens (CES202.352), Eastern Highland Rim Prairie and Barrens (CES202.354), Pennyroyal Karst Plain Prairie and Barrens (CES202.355), and Southern Ridge and Valley Patch Prairie (CES202.453) form a series of similar systems in the eastern Interior Highlands and adjacent Ridge and Valley.
Similar Ecological Systems:
- Cumberland Wet-Mesic Meadow and Savanna (CES202.053)
- Eastern Highland Rim Prairie and Barrens (CES202.354)
- Southern Ridge and Valley Patch Prairie (CES202.453)
- Western Highland Rim Prairie and Barrens (CES202.352)

Related Concepts:
- Limestone Prairie (Evans 1991) Finer
- Tallgrass Prairie (Evans 1991) Finer
- Wet Prairie (Evans 1991) Finer

DESCRIPTION

Environment: This system occurs in an open rolling Karst Plain landscape which easily carries fire if maintained in a grassy condition. Bedrocks are the St. Louis or Ste. Genevieve, Upper MiIan limestones of the Meramecian Series including some of the area which forms the base of the Dripping Springs Escarpment. Sinkholes mostly range up to 200 m wide and 10 m deep, with some areas nearly sinkhole-free while other areas have sinkholes up to 1600 m wide and 60 m deep with some sinkhole ponds and lakes. One sinkhole covers 1261 ha (3114 acres). Some sinkhole ponds were created by sinkhole plugging via agricultural erosion or human disturbance. The area exhibits well-developed underground drainage, low stream density, and soils quick to dry. Most upland streams have limited discharge with intermittent or ephemeral flow.

The barrens of this area exhibit two types of uncharacteristic conditions. Agricultural changes converted much of the landscape for use as fields and for grazing. With fire suppression they grew up with woody vegetation. Today in many areas, old pastures or agricultural fields have succeeded into areas dominated by *Juniperus virginiana*. It is not likely this would have been common in presettlement times. However, with fencerow habitats that encourage *Juniperus* survival being created in recent history, this has become the most common successional pathway (Landfire 2007a).
Vegetation: Stands of this system are dominated by grasses and forbs with scattered shrubby vegetation trees. The scattered trees are mainly *Quercus falcata* and *Quercus imbricaria*. The primary dominant grass is *Schizachyrium scoparium*, with some *Sorghastrum nutans* present. Other more mesic grasses (*Andropogon gerardii*, *Tripsacum dactyloides*) are restricted to ditches. Other herbaceous components may include *Andropogon gyrans, Andropogon ternarius, Lespedeza capitata, Lespedeza virginica, Symphyotrichum novae-angliae (= Aster novae-angliae), Sericocarpus linifolius (= Aster solidagineus), Coreopsis major, Coreopsis tripteris, Helianthus angustifolius, Helianthus hirsutus, Helianthus mollis, Helianthus occidentalis, Silphium trifoliatum, Solidago juncea, Pycnanthemum tenuifolium, Pycnanthemum verticillatum var. pilosum (= Pycnanthemum pilosum)*, and *Lobelia puberula*. In addition, *Rudbeckia subtomentosa, Prenanthes barbata*, and *Agalinis auriculata (= Tomanthera auriculata)* are rare plants found in some examples. Other typical woody species include *Cornus florida, Cercis canadensis, Prunus angustifolia, Ilex decidua, Rhus copallinum, Rosa carolina*, and *Symphoricarpos orbiculatus*.
Dynamics: This vegetation was the predominant type here in the early 1800s and probably originated from burning by Native Americans. The largest extant examples are presently found on Fort Campbell Military Reservation, Tennessee, where ecological burning and fires from live munitions use result in open herbaceous-dominated landscapes. Much of the area supports crops and livestock production. Very few "original" presettlement barrens exist. These barrens originated by burning of forests by Native

Americans. If not grazed or farmed, these barrens quickly grew into oak-dominated forests after settlement by Europeans and occur on soil that developed under forest vegetation (Landfire 2007a).

Component Associations:
- *Andropogon gerardii - (Sorghastrum nutans)* Kentucky Herbaceous Vegetation (CEGL004677, G1G2)
- *Schizachyrium scoparium - (Helianthus mollis, Helianthus occidentalis, Silphium trifoliatum)* Herbaceous Vegetation (CEGL007805, G2G3)

DISTRIBUTION

Range: This system is found in the northern Highland Rim (Pennyroyal Plateau) of Tennessee and adjacent Kentucky (EPA Ecoregion 71e [Western Pennyroyal Karst Plain] of Griffith et al. (1998) and Woods et al. (2002); part of Subsection 222Eh of Keys et al. (1995)).

ROCKY MOUNTAIN ALPINE FELL-FIELD (CES306.811)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine Slopes; Alpine/AltiAndino [Alpine/AltiAndino]; Herbaceous; Ridge/Summit/Upper Slope; Oligotrophic Soil; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Very Short Disturbance Interval; W-Patch/High Intensity; Cushion plants
Non-Diagnostic Classifiers: Patterned ground (undifferentiated); Saddle; Temperate [Temperate Continental]; Glaciated; Ustic; W-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2143; ESLF 7116; ESP 1143

CONCEPT

Summary: This ecological system is found discontinuously at alpine elevations throughout the Rocky Mountains, west into the mountainous areas of the Great Basin, and north into the Canadian Rockies. Small areas are represented in the west side of the Okanagan Ecoregion in the eastern Cascades. These are wind-scoured fell-fields that are free of snow in the winter, such as ridgetops and exposed saddles, exposing the plants to severe environmental stress. Soils on these windy unproductive sites are shallow, stony, low in organic matter, and poorly developed; wind deflation often results in a gravelly pavement. Most fell-field plants are cushioned or matted, frequently succulent, flat to the ground in rosettes and often densely haired and thickly cutinized. Plant cover is 15-50%, while exposed rocks make up the rest. Fell-fields are usually within or adjacent to alpine tundra dry meadows. Common species include *Arenaria capillaris, Geum rossii, Kobresia myosuroides, Minuartia obtusiloba, Myosotis asiatica, Paronychia pulvinata, Phlox pulvinata, Sibbaldia procumbens, Silene acaulis, Trifolium dasyphyllum*, and *Trifolium parryi*.
Classification Comments: Alpine fell-fields in the Cascades occur at a very small-scale spatial pattern not mappable (recognizable) at landscape levels. These small-scale fell-fields are conceptually included here.
Related Concepts:

ROCKY MOUNTAIN ALPINE TURF (CES306.816)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine Slopes; Alpine/AltiAndino [Alpine/AltiAndino]; Oligotrophic Soil; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Aridic; Very Long Disturbance Interval; Graminoid
Non-Diagnostic Classifiers: Long (>500 yrs) Persistence; Herbaceous; Temperate [Temperate Continental]; Glaciated; Periglacial
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2144; ESLF 7117; ESP 1144

CONCEPT

Summary: This widespread ecological system occurs above upper treeline throughout the Rocky Mountain cordillera, including alpine areas of ranges in Utah and Nevada, and isolated alpine sites in the northeastern Cascades. It is found on gentle to moderate slopes, flat ridges, valleys, and basins, where the soil has become relatively stabilized and the water supply is more or less constant. Vegetation in these areas is controlled by snow retention, wind desiccation, permafrost, and a short growing season. This system is characterized by a dense cover of low-growing, perennial graminoids and forbs. Rhizomatous, sod-forming sedges are the dominant graminoids, and prostrate and mat-forming plants with thick rootstocks or taproots characterize the forbs. Dominant species include *Artemisia arctica*, *Carex elynoides*, *Carex siccata*, *Carex scirpoidea*, *Carex nardina*, *Carex rupestris*, *Festuca brachyphylla*, *Festuca idahoensis*, *Geum rossii*, *Kobresia myosuroides*, *Phlox pulvinata*, and *Trifolium dasyphyllum*. Many other graminoids, forbs, and prostrate shrubs can also be found, including *Calamagrostis purpurascens*, *Deschampsia caespitosa*, *Dryas octopetala*, *Leucopoa kingii*, *Poa arctica*, *Saxifraga* spp., *Selaginella densa*, *Sibbaldia procumbens*, *Silene acaulis*, *Solidago* spp., and *Trifolium parryi*. Although alpine dry tundra is the matrix of the alpine zone, it typically intermingles with alpine bedrock and scree, ice field, fell-field, alpine dwarf-shrubland, and alpine/subalpine wet meadow systems.

ROCKY MOUNTAIN SUBALPINE-MONTANE MESIC MEADOW (CES306.829)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Herbaceous; Silt Soil Texture; Clay Soil Texture; Udic; Forb
Non-Diagnostic Classifiers: Sideslope; Temperate [Temperate Continental]; Shallow Soil; Mineral: W/ A-Horizon >10 cm; W-Patch/Medium Intensity; W-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2145; ESLF 7118; ESP 1145

CONCEPT

Summary: This Rocky Mountain ecological system is restricted to sites from lower montane to subalpine where finely textured soils, snow deposition, or windswept dry conditions limit tree establishment. Many occurrences are small patch in spatial character, and are often found in mosaics with woodlands, more dense shrublands, or just below alpine communities. It is typically found above 2000 m in elevation in the southern part of its range and above 600 m in the northern part. These upland communities occur on gentle to moderate-gradient slopes and relatively moist habitats. The soils are typically seasonally moist to saturated in the spring, but if so will dry out later in the growing season. These sites are not as wet as those found in Rocky Mountain Alpine-Montane Wet Meadow (CES306.812). Vegetation is typically forb-rich, with forbs often contributing more to overall herbaceous cover than graminoids. Some stands are comprised of dense grasslands, these often being taxa with relatively broad and soft blades, but where the moist habitat promotes a rich forb component. Important taxa include *Erigeron* spp., Asteraceae spp., *Mertensia* spp., *Penstemon* spp., *Campanula* spp., *Lupinus* spp., *Solidago* spp., *Ligusticum* spp., *Thalictrum occidentale, Valeriana sitchensis, Rudbeckia occidentalis, Balsamorhiza sagittata*, and *Wyethia* spp. Important grasses include *Deschampsia caespitosa, Koeleria macrantha*, perennial *Bromus* spp., and a number of *Carex* species. *Dasiphora fruticosa ssp. floribunda* and *Symphoricarpos* spp. are occasional but not abundant. Burrowing mammals can increase the forb diversity.
Classification Comments: There are probably quite a number of *Carex*- and *Calamagrostis*-dominated types that could be cited as constituent associations.
Similar Ecological Systems:
- Rocky Mountain Alpine-Montane Wet Meadow (CES306.812)

Related Concepts:

SOUTHEASTERN GREAT PLAINS TALLGRASS PRAIRIE (CES205.685)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Eastern Great Plains (205)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Graminoid
Non-Diagnostic Classifiers: Lowland; Unglaciated; Shallow Soil; F-Landscape/Medium Intensity; G-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2423; ESLF 7136; ESP 1423

CONCEPT

Summary: This system is found primarily within the Flint Hills and Osage Plains of Kansas and Oklahoma. Small patches can be found in the Ozarks of Missouri and the Arbuckle Mountains of Oklahoma. In southern Oklahoma and Texas, this is the primary natural system of the "Grand Prairie" or "Fort Worth Prairie," ranging south into the Lampasas Cutplain of Texas (EPA 29d and 29e, respectively). It is distinguished from Central Tallgrass Prairie (CES205.683) by having more species with southwestern geographic affinities and the presence of a thin soil layer over limestone beds ranging to more acidic substrates, although some areas of deeper soil are found within the region, especially on lower slopes, draws, and terraces. Because of the presence of the rocky substrate close to the surface and the rolling topography, this area is relatively unsuitable for agriculture. The Flint Hills contain one of the largest remaining, relatively intact pieces of tallgrass prairie. The vegetation in this system is typified by tallgrass species such as *Andropogon gerardii, Panicum virgatum, Schizachyrium scoparium*, and *Sorghastrum nutans* forming a dense cover. A moderate to high density of forb species also occurs. Species composition varies geographically, with *Oligoneuron rigidum (= Solidago rigida), Liatris punctata, Symphyotrichum ericoides, Lespedeza capitata*, and *Viola pedatifida* occurring in some localities. Areas of deeper soil, especially lower slopes along draws, slopes and terraces, can include *Baptisia alba var. macrophylla, Liatris pycnostachya*, and *Vernonia missurica*. Shrub and tree species are relatively infrequent and, if present, constitute less than 10% cover in the area. Fire and grazing constitute the major dynamic processes for this region. Although many of the native common plant species still occur, grazing does impact this region. Poor grazing practices can lead to soil erosion and invasion by cool-season grasses such as *Bromus inermis* within its range.
Classification Comments: This includes the Flint Hills, in addition to prairies in Oklahoma and Missouri south of the glacial line (including Ozarks of Missouri). There may need to be further review concerning the prairies in Missouri and Oklahoma. Southeastern Great Plains Tallgrass Prairie (CES205.685) lies to the west of the floristically related Texas Blackland Tallgrass Prairie (CES205.684), and is more widespread, ranging from Texas north to Kansas.
Similar Ecological Systems:
- Arkansas Valley Prairie and Woodland (CES202.312)
- Central Tallgrass Prairie (CES205.683)
- Lower Mississippi Alluvial Plain Grand Prairie (CES203.549)
- Ozark Prairie and Woodland (CES202.326)
- Texas Blackland Tallgrass Prairie (CES205.684)
- West Gulf Coastal Plain Northern Calcareous Prairie (CES203.377)

Related Concepts:

- Eastern Redcedar: 46 (Eyre 1980) Finer. Only on really degraded sites.
- Flint Hills Tallgrass Prairie (Lauver et al. 1999) Finer
- Grand Prairie: Tallgrass Prairie (2007) [CES205.685.9] (Elliott 2011) Equivalent

DESCRIPTION

Environment: This system is typified by a thin soil layer over limestone beds or acidic substrates such as chert or granite, although areas of deeper soils are possible along lower slopes, draws, and terraces. The topography is rolling and mostly unsuitable for agriculture. The typical geology is Lower Cretaceous formations, including various limestones, sands (such as from the Paluxy and Antlers formations), and clays (such as from the Walnut Formation). In contrast to Blackland Prairie, landform surfaces are flat rather than undulating, and valley slopes are angular rather than rounded. The "cuesta" landforms with gentle slopes leading up to relatively abrupt escarpments are characteristic of this portion of the Southeastern Great Plains Tallgrass Prairie. Soils of the Southeastern Great Plains Tallgrass Prairie in Texas differ from those of the Southern Blackland Prairie in being browner in color and containing more rock fragments, though much of the region occupied by this prairie is included in the Blackland Ecological Site. Clay Loam, Sandy Loam, Shallow, and Claypan Prairie are also significant Ecological Sites for this system. Soils of this area are more frequently characterized as Mollisols, as opposed to the Vertisols more characteristic of the Blackland Prairie. Calcareous clays are commonly encountered (Elliott 2011).
Vegetation: *Schizachyrium scoparium* tends to dominate examples of this system, with *Bouteloua curtipendula* as another significant component. Other grasses that are frequently present include *Nassella leucotricha, Bothriochloa laguroides ssp. torreyana, Aristida*

spp., *Andropogon gerardii, Andropogon ternarius, Aristida dichotoma, Buchloe dactyloides, Sporobolus compositus, Bouteloua eriopoda, Bouteloua gracilis, Bouteloua hirsuta, Sorghastrum nutans, Muhlenbergia reverchonii, Chloris verticillata*, and *Erioneuron pilosum*. Forbs species such as *Symphyotrichum ericoides, Ambrosia psilostachya, Tragia ramosa, Amphiachyris dracunculoides, Dyschoriste linearis, Salvia texana, Oenothera* spp., *Hedyotis nigricans var. nigricans (= Stenaria nigricans var. nigricans), Lindheimera texana, Thelesperma* spp., *Dalea* spp., and *Psoralidium* spp. may be encountered (Elliott 2011). Occurrences often contain, and are sometimes dominated by, the non-native grass *Bothriochloa ischaemum var. songarica* and/or *Cynodon dactylon*. Other forb species that can occur include *Oligoneuron rigidum (= Solidago rigida), Liatris punctata, Lespedeza capitata, Viola pedatifida, Coreopsis grandiflora, Danthonia spicata, Helianthus grosseserratus, Mentzelia oligosperma, Rudbeckia missouriensis, Silene regia, Croton willdenowii*, and *Tradescantia bracteata*. In areas of deeper soils, *Baptisia alba var. macrophylla, Liatris pycnostachya*, and *Vernonia missurica* can also occur within their ranges. Significant areas of this system remain within the Grand Prairie of Texas (Elliot 2011).

Dynamics: Fire and grazing are the prevalent dynamic processes in examples of this system. This system is found in a climate that can support trees and shrubs but woody vegetation is inhibited by frequent fires. Historically, fire-return intervals were short, estimated at between 2 and 15 years (Abrams 1986, Landfire 2007a). The frequent but unpredictable fires created a patchwork of habitats across the landscape, with recently burned sites having less litter and forb cover, and sites with infrequent fires possibly having more woody species and dense stands of grasses. This system developed in an area occupied by vast numbers of native ungulates, notably bison (*Bison bison*) but including other species, and the grazing of these species affected species composition and the patchwork of habitat. Bison preferentially favor newly burned areas and graminoids over forbs (Vinton et al. 1993, Coppedge and Shaw 1998). Their grazing, trampling, and wallowing were important in creating habitat diversity across the landscape (Knapp et al. 1999). On unburned sites, grazing removes live and dead vegetation, allowing more light and heat to the soil surface and increasing available moisture thus favoring species, forbs or woody plants, in the case of bison grazing, that were resilient to the effects of grazing or avoided by the grazers (Damoureyeh and Hartnett 1997).

Component Associations:

- *Andropogon gerardii - Panicum virgatum - Helianthus grosseserratus* Herbaceous Vegetation (CEGL002024, G2G3)
- *Andropogon gerardii - Sorghastrum nutans - Schizachyrium scoparium* Flint Hills Herbaceous Vegetation (CEGL002201, G4?)
- *Andropogon gerardii - Sorghastrum nutans* Unglaciated Herbaceous Vegetation (CEGL002204, G3)
- *Bouteloua curtipendula - Bouteloua (eriopoda, gracilis)* Herbaceous Vegetation (CEGL002250, G4)
- *Juniperus ashei / Bouteloua (curtipendula, hirsuta)* Woodland (CEGL002125, G2G3)
- *Muhlenbergia reverchonii - Croton monanthogynus* Herbaceous Vegetation (CEGL004785, G2G3)
- *Schizachyrium scoparium - (Sorghastrum nutans) - Sporobolus compositus var. compositus - Liatris mucronata* Herbaceous Vegetation (CEGL004211, GNR)
- *Schizachyrium scoparium - Aristida dichotoma - Croton willdenowii* / Lichens Wooded Herbaceous Vegetation (CEGL002242, G3)
- *Schizachyrium scoparium - Bouteloua curtipendula - Rudbeckia missouriensis - Mentzelia oligosperma* Wooded Herbaceous Vegetation (CEGL002251, G2)
- *Schizachyrium scoparium - Sorghastrum nutans - Andropogon ternarius - Coreopsis grandiflora* Sandstone - Shale Herbaceous Vegetation (CEGL002212, G3)
- *Schizachyrium scoparium - Sorghastrum nutans - Danthonia spicata - Silene regia* Chert Herbaceous Vegetation (CEGL002211, G3)
- *Schizachyrium scoparium - Sorghastrum nutans - Tradescantia bracteata* Alkaline Bedrock Herbaceous Vegetation (CEGL005280, G1G2)

DISTRIBUTION

Range: This system is found primarily within the Flint Hills and Osage Plains of Kansas and Oklahoma. Small patches can be found in the Ozarks of Missouri and the Arbuckle Mountains of Oklahoma. In southern Oklahoma and Texas, this is the primary natural system of the "Grand Prairie" or "Fort Worth Prairie," ranging south into the Lampasas Cutplain of Texas (EPA 29d and 29e, respectively). In Missouri, it is attributed to EPA 40c, 40d, and possibly 39k.

SOUTHERN APPALACHIAN GRASS AND SHRUB BALD (CES202.294)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Herbaceous; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2414; ESLF 7127; ESP 1414

CONCEPT

Summary: This ecological system consists of dense herbaceous and shrubland communities in the highest elevational zone of the Southern Appalachians, generally above 1524 m (5000 feet) but occasionally to 1220 m (4000 feet), and at slightly lower elevations at its northern limit in Virginia and West Virginia, and in the Cumberland Mountains along the Virginia-Kentucky border. Vegetation consists either of dense shrub-dominated areas (heath balds) or dense herbaceous cover dominated by grasses or sedges (grassy balds). Heath balds are most often dominated by *Rhododendron catawbiense*, but substantial examples are also dominated by *Rhododendron carolinianum, Kalmia latifolia*, or a mixture of shrubs. One large example, dominated by *Alnus viridis ssp. crispa*, has been regarded as related to the heath balds, but is better treated separately due to much greater herbaceous diversity and coverage which is clearly different from typical heath balds. Grassy balds are characteristically dominated by *Danthonia compressa, Deschampsia flexuosa*, or *Carex* spp. Large areas have also become dominated by *Rubus allegheniensis* and/or *Rubus canadensis*, and by mixtures of native grasses with exotic pasture grasses. Most examples of grassy balds have some invading shrubs and trees, often dense enough to threaten the herbaceous vegetation. Heath balds may contain sparse stunted trees barely larger than the shrub canopy. The combination of high-elevation, non-wetland sites and dense herbaceous or shrub vegetation without appreciable rock outcrop conceptually distinguishes this system from all others in the Southern Appalachians. However, the widespread areas of degraded spruce-fir with grass and shrub cover and the invasion of grassy balds by trees blur the distinction somewhat.
Classification Comments: Grassy balds and heath balds differ in a number of ways and are often recognized as distinct entities. Whether these need to be split out at the system level, rather than just at the association level, has been questioned (M. Schafale pers. comm.). This system occurs in settings similar to Southern Appalachian Rocky Summit (CES202.327) and might be broadened to encompass that system.

DESCRIPTION

Environment: This system generally occurs at elevations above 1524 m (5000 feet) but may range as low as 1220 m (4000 feet) in the Southern Blue Ridge, with most examples from 1600-1780 m (5200-5800 feet) elevation (Mark 1958). It is also of limited extent above 1035 m (3400 feet) in the Cumberland Mountains along the Virginia-Kentucky border. It occurs on broad ridgetops and narrow spur ridges. Elevation and orographic effects (winds cooling as they rise to create increased condensation) make the climate cool and wet, with heavy moisture input from fog and cloud interception as well as high rainfall and snowfall. Convex slopes and exposure to wind offset the moisture input to some extent. The high peaks of the Southern Appalachians are not above the treeline; balds occur well below the elevation which would be a treeline today. Concentration of air pollutants has been implicated as an important anthropogenic stress in this elevational range in recent years. Soils range from shallow and rocky to fairly deep residual soils. Any kind of bedrock may be present, but most sites have erosion-resistant felsic igneous or metamorphic rocks, with slate and quartzite particularly frequent. Alder bald tends to occur on areas with thinner and rockier soils than nearby grassy bald (Brown 1941, J. Donaldson pers. comm. 2013), and is distinct from heath bald (Harshberger 1903b, Schafale 2012). The sites that support balds are not obviously different from similar sites that support spruce-fir forests, so the origin of the balds continues to be fodder for debate. Grazing and/or exposure to the elements may help maintain balds. Grass balds occur on less than one percent of the sites suitable for them (White and Sutter 1999b), and heath balds occur on 4-9% of the sites suitable for them (White et al. 2001). Forests occur on most of these sites, such as northern hardwood, high-elevation oak, or spruce-fir forests.
Vegetation: Vegetation consists either of dense shrubs (heath balds or blackberry) or dense herbaceous cover dominated by grasses or sedges (grassy balds). Heath balds are most often dominated by *Rhododendron catawbiense*, but substantial examples are also dominated by *Rhododendron carolinianum, Kalmia latifolia*, or a mixture of other shrubs, including *Prunus pensylvanica, Sorbus americana, Corylus cornuta, Gaylussacia baccata, Pieris floribunda, Vaccinium corymbosum*, and *Leiophyllum buxifolium*. One large example, dominated by *Alnus viridis ssp. crispa*, is generally also regarded as being related to the heath balds. Grassy balds are characteristically dominated by *Danthonia compressa, Carex pensylvanica*, or other *Carex* spp. with forbs including *Minuartia groenlandica, Paronychia argyrocoma, Saxifraga michauxii, Solidago glomerata, Solidago rugosa ssp. aspera, Sibbaldiopsis tridentata*, and others. Large areas have also become dominated by *Rubus allegheniensis*, possibly with other brambles (*Rubus canadensis, Rubus idaeus ssp. strigosus*) and by mixtures of native grasses with exotic pasture grasses (e.g., *Phleum pratense*). Most examples of grassy balds have some invading shrubs and trees, often dense enough to threaten the herbaceous vegetation. Heath balds may contain sparse stunted trees barely larger than the shrub canopy.
Dynamics: The dynamics that maintain and that created the communities in this system have been a major topic of debate, so far without resolution. Most grassy bald occurrences show a strong tendency to succeed to shrub or forest vegetation under present

conditions, suggesting that some important maintenance process has been lost. Northern hardwood, high-elevation oak, or spruce-fir forests may occur adjacent to balds. Grazing by native herbivores (elk and bison) and periodic fire have both been suggested as natural mechanisms to keep out woody vegetation. Others have suggested that all grassy balds are of anthropogenic origin and were never ecologically stable. The most definitive grassy balds have been documented as present at the time of the first European settlement, making documentation of their origin impossible. The presence of shade-intolerant endemic or disjunct herbaceous plant species in some suggests even greater age. These include *Lilium grayi, Geum radiatum, Packera schweinitziana*, and *Houstonia purpurea var. montana*. Some areas of the spruce-fir system degraded by a combination of logging, slash fires, and grazing resemble grassy balds, but most do not. The common practice of cattle grazing in grassy balds by early settlers has further obscured their presettlement character and evidence of presettlement disturbance processes.

Heath balds (not including alder balds) are more prone to disturbance by fire (Conkle 2004). However, heavy organic accumulations in the soil suggest great age for some. Most heath balds show limited tendency to succeed to forest, suggesting that the dense heath shrub layer is very competitive with tree seedlings. Spruce-fir forest stands which burned in historical times have not usually developed vegetation identical to heath balds.

Component Associations:
- *Alnus viridis ssp. crispa / Carex pensylvanica* Shrubland (CEGL003891, G1)
- *Carex pensylvanica* Herbaceous Vegetation (CEGL004094, G1)
- *Danthonia compressa - (Sibbaldiopsis tridentata)* Herbaceous Vegetation (CEGL004242, G1)
- *Kalmia latifolia - Gaylussacia (baccata, brachycera)* Cumberland Shrubland (CEGL008470, G3)
- *Kalmia latifolia - Rhododendron catawbiense - (Gaylussacia baccata, Pieris floribunda, Vaccinium corymbosum)* Shrubland (CEGL003814, G2G3)
- *Leiophyllum buxifolium* Dwarf-shrubland (CEGL003951, G1)
- *Photinia melanocarpa - Gaylussacia baccata / Carex pensylvanica* Shrubland (CEGL008508, G1?)
- *Rhododendron carolinianum - Rhododendron catawbiense - Leiophyllum buxifolium* Shrubland (CEGL007876, G1)
- *Rhododendron carolinianum* Shrubland (CEGL003816, G2)
- *Rhododendron catawbiense - Pieris floribunda* Shrubland (CEGL004516, G1)
- *Rhododendron catawbiense* Shrubland (CEGL003818, G2)

Spatial Characteristics

Spatial Summary: Small-patch to large-patch system, sometimes occurring as single patches, sometimes as complexes of small patches.
Size: Individual patches of both grassy bald and heath bald range from 10 acres or less, to occasional expanses of hundreds of acres. Heath balds sometimes occur as complexes of small patches on spur ridges. Separation rules will have a strong effect on the aggregate acreage of defined occurrences in these situations, but the largest occurrences are fairly contiguous.
Adjacent Ecological Systems:
- Central and Southern Appalachian Spruce-Fir Forest (CES202.028)
- Southern Appalachian Montane Pine Forest and Woodland (CES202.331)
- Southern Appalachian Northern Hardwood Forest (CES202.029)
- Southern Appalachian Rocky Summit (CES202.327)
- Southern Appalachian Seepage Wetland (CES202.317)

Adjacent Ecological System Comments: This system is virtually always bordered by Southern Appalachian Northern Hardwood Forest (CES202.029) or Central and Southern Appalachian Spruce-Fir Forest (CES202.028). It may also contain embedded small patches of Southern Appalachian Rocky Summit (CES202.327) and Southern Appalachian Seepage Wetland (CES202.317).

Distribution

Range: This system ranges from the Balsam Mountains and Great Smoky Mountains of North Carolina and Tennessee northward to Virginia and West Virginia. The system is also of limited extent in the Cumberland Mountains along the Virginia-Kentucky border. The current status in Georgia is open to question and the ecological system was apparently never extensive in any case. The distribution and classification of grassy balds and high-elevation pastures has been documented (Gersmehl 1970). Heath balds could be mapped separately from grassy balds as has been done for the Great Smoky Mountains (White et al. 2001). Alder bald can also be mapped separately, but it requires more field verification to map correctly.
Divisions: 202:C

SOUTHERN ATLANTIC COASTAL PLAIN DUNE AND MARITIME GRASSLAND (CES203.273)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Herbaceous; Graminoid; Coast
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2426; ESLF 7139; ESP 1426

CONCEPT

Summary: This ecological system consists primarily of grasslands and related shrublands of Atlantic Coastal Plain barrier islands and related coastal areas from North Carolina south to northern and central Florida. On the Florida coast from south of Cape Canaveral to the sandy portions of the Florida Keys, this system occurs in a more attenuated fashion. This ecological system includes upland dune grasslands and maritime wet grasslands and shrublands, which are not tidal, but may be flooded for short periods of time from storm surge or heavy rain. The environment of this system is highly dynamic. Reworking of sand by storms or by slower eolian processes may completely change the local environment. Vegetation responds to these natural coastal processes through primary succession. The combined effects of chronic and extreme salt spray and periodic ocean overwash by seawater prevent or dramatically inhibit woody plant growth.
Classification Comments: This system was separated from Northern Atlantic Coastal Plain Dune and Swale (CES203.264) to parallel broad-scale biogeographic and climatic differences believed to be important in this environment. The northern part of this broad transition was labeled by Cowardin et al. (1979) as the Virginian Province and the southern region as the Carolinian Province, although the demarcated boundary differs somewhat from that used here. A primary indicator of this transition is the shift in vegetation dominance on the dunes from *Uniola paniculata* in the south to *Ammophila breviligulata* in the north. Although the location of this shift itself is somewhat imprecise because of widespread planting of both species on artificially enhanced dunes, this boundary appears to be well approximated by Omernik Ecoregion 63g vs. 63d (EPA 2004).
Similar Ecological Systems:
- Central Atlantic Coastal Plain Maritime Forest (CES203.261)
- Northern Atlantic Coastal Plain Dune and Swale (CES203.264)--occurs to the north.
- Southeastern Coastal Plain Interdunal Wetland (CES203.258)
- Southern Atlantic Coastal Plain Maritime Forest (CES203.537)
- Southwest Florida Dune and Coastal Grassland (CES203.539)

- Coastal Grassland (FNAI 1990) Intersecting
- Coastal Strand (FNAI 1992b) Intersecting
- Live Oak: 89 (Eyre 1980) Finer

DESCRIPTION

Environment: Occurs on barrier islands and similar coastal strands, on sand dunes and sand flats. Strong salt spray is an important influence on vegetation in many parts. Overwash by sea water during storms is important on sand flats not protected by continuous dunes. On dunes, present or recent sand movement is an important factor. The combination of these factors prevents the dominance of woody vegetation. Sites may be either dry or saturated by freshwater from rainfall and local water table. Areas connected to tidal influence and areas with ponded freshwater are placed in other ecological systems. Soils are sandy, with little organic matter and little or no horizon development. Soils may be excessively drained on the higher dunes. Soils are low in nutrient-holding capacity, but aerosol input of sea salt provides a continuous source of nutrients. North of the Sea Islands region of coastal Georgia and South Carolina, barrier islands that face south tend to have better developed dune fields, and often have extensive maritime forest systems, and east-facing barrier islands naturally have less continuous dunes and more overwash flats. On islands that face east, the northern portion tends to experience shoreline and dune erosion and the south end may experience accretion. Many of Georgia's barrier islands (known as Sea Islands) show this pattern.
Vegetation: Vegetation consists of a set of grassland and other herbaceous associations. *Uniola paniculata* is the characteristic dominant on the youngest dunes and those most exposed to salt spray and less commonly *Panicum amarum* (Pinson 1973). *Spartina patens* or *Schizachyrium littorale* tend to dominate older dunes and sand flats. Component communities tend to be low in plant species richness, but have a characteristic set of forbs and occasional low shrubs associated with them. Wetter sand flats and dune swales may be dominated by a variety of herbs and sometimes have fairly high species richness. Also included in this system are patches of transition shrub communities or shrub thickets.
Dynamics: The environment of this system is one of the most dynamic in existence for terrestrial vegetation. Reworking of sand by storms or by slower eolian processes may completely change the local environment in a short time, changing one association to

another or changing this system into a different system. Many of these sites are fairly early in the process of primary succession on recent surfaces. Chronic salt spray is an ongoing stress. Overwash and extreme salt spray in storms is a frequent disturbance. Vegetation interacts strongly with geologic processes; the presence of dune grass is an important factor in the development of new dunes. Artificial enhancement of dunes by sand fencing or planting off-site species, including *Ammophila breviligulata*, can alter the dynamic processes of the dunes. Fire is probably not a major natural factor in this system, but may have been important locally. Most vegetation is too sparse to carry fire well.

Component Associations:
- *Iva imbricata / Uniola paniculata - Helianthus debilis ssp. debilis* Herbaceous Vegetation (CEGL004001, G2G3)
- *Morella cerifera / Spartina patens* Shrubland (CEGL003839, G3G4)
- *Morella pensylvanica / Diodia teres* Shrubland (CEGL003881, G2)
- *Muhlenbergia filipes - Spartina patens - Eustachys petraea* Herbaceous Vegetation (CEGL004051, G2)
- *Quercus virginiana - (Ilex vomitoria)* Shrubland (CEGL003833, G3)
- *Sabal palmetto / Glyceria septentrionalis - Carex stipata - Woodwardia virginica* Woodland (CEGL007784, G3?)
- *Salix caroliniana / Hibiscus grandiflorus / Polygonum punctatum* Woodland (CEGL004272, G3G4)
- *Salix caroliniana / Sacciolepis striata - Boehmeria cylindrica* Woodland (CEGL004222, G2?)
- *Serenoa repens - Sabal palmetto - Ilex vomitoria - Sideroxylon tenax* Scrub (CEGL003812, G1)
- *Smilax auriculata - Toxicodendron radicans* Vine-Shrubland (CEGL003885, GNRQ)
- *Smilax auriculata / Heterotheca subaxillaris - Strophostyles helvula - (Uniola paniculata)* Herbaceous Vegetation (CEGL004234, G2G3)
- *Spartina patens - Schoenoplectus pungens - Solidago sempervirens* Herbaceous Vegetation (CEGL004097, G2G3)
- *Uniola paniculata - Hydrocotyle bonariensis* Herbaceous Vegetation (CEGL004040, G3?)
- *Uniola paniculata - Schizachyrium littorale - Panicum amarum* Herbaceous Vegetation (CEGL004039, G3)
- *Vitis rotundifolia / Triplasis purpurea - Panicum amarum - Schizachyrium littorale* Mid-Atlantic Coastal MedaÃ±o Sparse Vegetation (CEGL004397, G1)

SPATIAL CHARACTERISTICS

Spatial Summary: Occurs as a large-patch or local matrix system.
Size: Occurs in narrow to broad bands, up to several miles wide, extending along the length of barrier islands. Individual patches may cover a thousand or more acres. However, some of the best remnants are naturally small, occurring on smaller islands.
Adjacent Ecological Systems:
- Central Atlantic Coastal Plain Maritime Forest (CES203.261)

DISTRIBUTION

Range: This system ranges on the Atlantic Coast from northern North Carolina (Omernik ecoregion 63g, Carolinian Barrier Islands and Coastal Marshes) to central Florida. The northern limit is a transition zone from around Kitty Hawk, North Carolina, to the Virginia-North Carolina border.

SOUTHERN COASTAL PLAIN BLACKLAND PRAIRIE AND WOODLAND (CES203.478)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Circumneutral Soil; Deep Soil; Clay Soil Texture; Graminoid
Non-Diagnostic Classifiers: Herbaceous
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2430; ESLF 7143; ESP 1430

CONCEPT

Summary: This system includes natural grassland vegetation and associated wooded vegetation found primarily in two relatively small natural regions in the southeastern Coastal Plains, primarily in Alabama and Mississippi (with one of these extending barely into southern Tennessee), and a related area of southern Georgia. The larger of these, the so-called Black Belt, is approximately 480 km (300 miles) long and 40-50 km (25-30 miles) wide, and is delineated as the Black Belt Subsection 231Ba and the Blackland Prairie EPA Ecoregion 65a. The smaller and more southerly one of the two is known as the Jackson Prairie region, is found on younger geologic strata and is delineated as the Jackson Hills Subsection (231Bj) and as the Jackson Prairie EPA Ecoregion (65r). The vegetation of this system is comprised of natural grasslands and associated wooded vegetation (woodlands and savannas). The Black Belt region derives its name from the nearly black, rich topsoil that developed over Selma Chalk, and has long been noted as a distinct topographic region in the state of Mississippi. In Alabama, the formations on which this system primarily occurs are Demopolis Chalk and Mooreville Chalk (members of the Selma Group). In Tennessee, only Demopolis Chalk is mapped. Examples occur over relatively deep soils (as opposed to "glades and barrens" on or adjacent to rock outcrops), with circumneutral surface soil pH. Vegetation of this ecological system includes evergreen *Juniperus virginiana*-dominated forests and deciduous *Quercus*-dominated woodlands of varying densities, interspersed with native prairielike grasslands. Much of the natural vegetation of the region has been converted to pasture and agricultural uses, but even old-field vegetation reflects the distinctive composition of the flora and ecological dynamics. In most cases individual prairie openings are small and isolated from one another, but were formerly more extensive prior to European settlement, forming a mosaic of grasslands and woodlands under frequent fire regimes. The flora has much in common with other prairies of the East Gulf Coastal Plains, as well as the classic Midwestern prairies. Within this natural region, there are pockets of acidic soils which produce more typical pine-oak woodland or forest vegetation. The Jackson Prairie component of the system includes natural grassland vegetation and associated wooded vegetation in the Jackson Hills Subsection (231Bj), also called the Jackson Prairie EPA Ecoregion (65r), a relatively small natural region of Mississippi and adjacent Alabama. This system occurs on montmorillonitic Vertisols, which are deep, slowly permeable soils formed in residuum weathered from marl or chalk. Examples occur in a larger matrix of primarily acidic soils and of generally *Pinus taeda*-dominated forest vegetation. In most cases individual prairie openings are small and isolated from one another but were formerly more extensive prior to European settlement, forming a mosaic of grassland and woodland under frequent fire regimes. Much of the natural vegetation of the region has been converted to pasture and agricultural uses, with concomitant destruction of most prairie remnants.
Classification Comments: "Blackland Prairies" occur primarily in two discrete areas of the East Gulf Coastal Plain: Jackson Prairie and the Black Belt. There is also an area in the Atlantic Coastal Plain of Georgia which is included here. It is a "blackland" but not a "black belt" prairie. Much of the natural vegetation of the region has been converted to pasture and agricultural uses, with concomitant destruction of most prairie remnants (DeSelm and Murdock 1993). Of the approximately 100,000 acres of Blackland Prairies mapped during the general land surveys of the early and mid 1800s in Mississippi, probably less than 500 acres of Jackson Prairie vegetation exists today, even if one considers grazed areas and vacant agricultural lands with a semblance of prairie species (R. Wieland pers. comm.). Almost all of the lands were converted to agriculture. Some of the lands are now reverting back to prairie after being abandoned. More recently, lands are being converted to fescue pasture; other abandoned lands have become stands of eastern red-cedar. The number of acres in good condition is probably less than 100. The flora has much in common with other prairies of the East Gulf Coastal Plains as well as the classic Midwestern prairies.
Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer

DESCRIPTION

Environment: The Black Belt component of this system generally occurs on Cretaceous age chalk, marl and calcareous clay. This includes calcareous soils of the Sumter, Binnsville, and Demopolis series, described as beds of marly clay over Selma Chalk (including the Demopolis and Mooreville formations). The area has an average annual precipitation of 130-140 cm and a frost-free period of 200-250 days. The soils of the Jackson Prairie openings are presently mapped as the Maytag Series, a fine montmorillonitic, thermic Entic Chromudert. This deep slowly permeable soil has formed in residuum weathered from marl of chalk of the Blackland Prairies (Wieland 1995). Examples occur in a larger matrix of primarily acidic soils and of generally Pinus taeda-dominated forest vegetation (Jones 1971).

Vegetation: Vegetation of this ecological system includes evergreen *Juniperus virginiana*-dominated forests and deciduous *Quercus*-dominated woodlands of varying densities, interspersed with native prairie-like grasslands. Much of the natural vegetation of the region has been converted to pasture and agricultural uses, but even old-field vegetation reflects the distinctive composition of the flora and ecological dynamics. The oak woodlands of the Black Belt component typically contain *Quercus stellata, Quercus muehlenbergii*, and *Quercus marilandica*. Other woody components include *Quercus falcata, Carya alba, Carya glabra, Fraxinus americana, Celtis laevigata, Cercis canadensis var. canadensis, Crataegus engelmannii, Diospyros virginiana, Ilex decidua, Prunus angustifolia, Frangula caroliniana, Sideroxylon lycioides*, and *Ulmus alata*. Prairie forbs and grasses may persist in small openings and in edge situations in the more heavily forested areas of the Black Belt. The presence of *Juniperus virginiana*-dominated zones may represent invasion by this species in the absence of sufficiently frequent or intense fire (DeSelm and Murdock 1993). Pines are generally absent, being inhibited by the higher surface soil pH. In the grass-dominated areas of the Black Belt, *Schizachyrium scoparium* and *Sorghastrum nutans* are the principal herbs. Other herbaceous taxa include *Andropogon glomeratus, Andropogon virginicus, Bouteloua curtipendula, Panicum virgatum*, and *Schizachyrium scoparium*, with lesser amounts of *Paspalum floridanum, Setaria parviflora*, and *Sporobolus indicus* (exotic). Other common species include *Arnoglossum plantagineum, Symphyotrichum dumosum (= Aster dumosus), Symphyotrichum patens (= Aster patens), Crotalaria sagittalis, Dalea candida, Dalea purpurea, Desmanthus illinoensis, Desmodium ciliare, Dracopis amplexicaulis, Liatris aspera, Liatris squarrosa, Liatris squarrulosa, Neptunia lutea, Ratibida pinnata, Ruellia humilis, Silphium terebinthinaceum, Silphium trifoliatum var. latifolium*, and *Solidago nemoralis*. In depressions and drainages, *Andropogon gerardii* and/or *Panicum virgatum* will have greater importance (DeSelm and Murdock 1993). At this more mesic end of the continuum, invasion by woody plants is a more serious threat to the system. Moist, seepy inclusions within this system are often dominated by *Rhynchospora colorata* and *Scleria verticillata*; *Rhynchospora divergens, Lythrum alatum var. lanceolatum, Mitreola petiolata*, and *Mecardonia acuminata* also occur but much less frequently (A. Schotz pers. comm.). The most prominent tall grasses of the Jackson Prairie component are *Andropogon gerardii, Schizachyrium scoparium, Sorghastrum nutans*, and *Panicum virgatum*. Additional tall grasses include *Tripsacum dactyloides, Andropogon glomeratus*, and *Paspalum floridanum*. Along with *Schizachyrium scoparium*, two other species provide over 50% cover in prairie openings: *Carex cherokeensis* and *Helenium autumnale*. Other plants closely affiliated with less disturbed prairie openings include *Dalea purpurea, Dalea candida, Sporobolus compositus var. macer, Muhlenbergia capillaris, Penstemon laxiflorus (= Penstemon australis ssp. laxiflorus), Symphyotrichum novae-angliae (= Aster novae-angliae), Echinacea purpurea, Manfreda virginica, Ruellia purshiana, Desmanthus illinoensis*, and *Spiranthes magnicamporum* (Wieland 1995).

Dynamics: In the presettlement landscape and throughout the nineteenth century, a combination of fire and grazing (first by native ungulates and then by free-ranging cattle) kept these sites open and grass-dominated (DeSelm and Murdock 1993).

Blackland prairie and woodland occurs on eponymous rich, black, circumneutral topsoils formed over clayey, heavy, usually calcareous subsoils with carbonatic or montmorillonitic mineralogy. The system occurs in association with formations of the Tertiary Jackson (Yazoo Clay), Claiborne (Cook Mountain) and Fleming groups, and the Cretaceous Selma group (Selma, Mooreville or Demopolis chalks). The matrix around the blackland prairies is pine-oak forests growing in acidic, sandier soils with less clay (recent STATSGO soils maps).

Floristic similarity among sites across this geographic range generally appears to be 50% or greater, although a number of different alliances within this type have been recognized according to dominant, codominant, and diagnostic species. Extant prairies occur in single patches as well as mosaics less than one acre to over several hundred acres in response to soil depth, slope and fire. Mosaics may include virtually treeless patches associated with other patches of widely scattered trees, open deciduous woodlands and evergreen thickets (eastern red-cedar "balds"). This vegetation is a mosaic of *Juniperus virginiana* woodland, *Quercus stellata - Quercus marilandica* woodland, and *Schizachyrium scoparium - Sorghastrum nutans* herbaceous alliances. It is a rare and imperiled vegetation type consisting of scattered remnants. Most of the original cover has been destroyed or altered by conversion to agriculture and the exclusion of fire (Landfire 2007a).

For the last 500-1000 years, fires were probably annual in most of the system, many if not most set by Native Americans. Fires were probably used to clear prairies for agricultural planting, to eliminate woody growth, and to aid in hunting. The modern landscape shows a tendency toward erosion, creating shallow-soil areas known as "cedar balds" where soil erosion, presumably from historic agriculture or overgrazing, has reduced topsoil. These areas often show exposures of underlying chalk. Such areas may have resulted (albeit at much lower frequencies) from aboriginal agriculture or overgrazing by native herbivores (Landfire 2007a).

Component Associations:

- *(Quercus sinuata) / Sorghastrum nutans - Ratibida pinnata - Hedyotis nigricans var. nigricans - (Glandularia bipinnatifida)* Georgia Chalk Prairie Herbaceous Vegetation (CEGL004247, G1)
- *Crataegus crus-galli - Ilex decidua - Crataegus viridis* Shrubland (CEGL004532, GNR)
- *Juniperus virginiana var. virginiana - (Celtis laevigata, Prunus angustifolia, Sideroxylon lycioides)* Woodland (CEGL007747, G2)
- *Quercus stellata - Quercus muehlenbergii / Schizachyrium scoparium - Sorghastrum nutans* Black Belt Woodland (CEGL004670, G2G3)
- *Schizachyrium scoparium - Sorghastrum nutans - Dalea candida - Liatris squarrosa - (Silphium terebinthinaceum)* Black Belt Herbaceous Vegetation (CEGL004664, G1)
- *Schizachyrium scoparium - Sorghastrum nutans - Dalea purpurea - Silphium integrifolium* Jackson Prairie Herbaceous Vegetation (CEGL004020, G1)

DISTRIBUTION

Range: This system has several distinct components. The Black Belt Prairie component is primarily restricted to the Black Belt

(Subsection 231Ba of Keys et al. 1995) or Blackland Prairie area (EPA Ecoregion 65a) and Flatwoods/Blackland Prairie Margins area (EPA Ecoregion 65b) of Griffith et al. (2001). This region is primarily in Alabama and Mississippi, ranging north in a depauperate form to southern Tennessee (McNairy County) (DeSelm 1989b). The Jackson Prairie component of this system is found in a relatively small natural region of Mississippi, known as the Jackson Hills Subsection 231Bj of Keys et al. (1995) and the Jackson Prairie Ecoregion 65r of EPA (EPA 2004). There is also a recently recognized component found in limited parts of Georgia (e.g., on both sides of the Ocmulgee River on the Fort Valley Plateau of Bleckley, Houston, Peach, and Twiggs counties). There are also outlying occurrences southward in the Chunnenuggee Hills and Red Hills (both of these parts of the Southern Hilly Coastal Plain -EPA Ecoregion 65d), and Buhrstone/Lime Hills (EPA Ecoregion 65q) of southern Alabama (in Washington, Wilcox, Monroe, and Clark counties). There are some limited examples in EPA Ecoregion 65i (Fall Line Hills; e.g., Jones Bluff in Alabama).

SOUTHERN RIDGE AND VALLEY PATCH PRAIRIE (CES202.453)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2419; ESLF 7132; ESP 1419

CONCEPT

Summary: This system is a collection of deep soil prairies and barrens found historically in the Coosa Valley of northwestern Georgia and adjacent Alabama and related areas including barrens at Oak Ridge, Tennessee. This system was formerly widespread, but is now found only in scattered and isolated remnants. Vegetation is typically prairie-like and may have supported scattered trees depending upon fire-return interval. Some typical species found in examples of this system include *Andropogon gerardii, Sorghastrum nutans, Panicum anceps, Panicum virgatum, Tripsacum dactyloides, Schizachyrium scoparium, Helianthus mollis, Helianthus occidentalis, Silphium trifoliatum*, and *Silphium terebinthinaceum*.
Classification Comments: Western Highland Rim Prairie and Barrens (CES202.352), Eastern Highland Rim Prairie and Barrens (CES202.354), Pennyroyal Karst Plain Prairie and Barrens (CES202.355), and Southern Ridge and Valley Patch Prairie (CES202.453) form a series of similar systems in the eastern Interior Highlands and adjacent Ridge and Valley.
Similar Ecological Systems:
- Eastern Highland Rim Prairie and Barrens (CES202.354)
- Pennyroyal Karst Plain Prairie and Barrens (CES202.355)
- Western Highland Rim Prairie and Barrens (CES202.352)

DESCRIPTION

Environment: See DeSelm (1993) for an extensive discussion.
Vegetation: Some typical species found in examples of this system include *Andropogon gerardii, Sorghastrum nutans, Panicum anceps, Panicum virgatum, Tripsacum dactyloides, Schizachyrium scoparium, Helianthus mollis, Helianthus occidentalis, Silphium trifoliatum*, and *Silphium terebinthinaceum*.
Dynamics: This system was formerly widespread, but is now found only in scattered and isolated remnants (DeSelm and Murdock 1993). Vegetation is typically prairie-like and may have supported scattered trees depending upon fire-return interval. With prolonged lack of fire (and grazing) areas may succeed to forested vegetation, becoming indistinguishable from adjacent hardwood forests.

Component Associations:
- *Andropogon gerardii - Bouteloua curtipendula - Echinacea simulata* Coosa Valley Barren Herbaceous Vegetation (CEGL004045, G1)
- *Andropogon gerardii - Panicum (anceps, virgatum)* Herbaceous Vegetation (CEGL007931, G2?)
- *Schizachyrium scoparium - Andropogon gerardii - Silphium terebinthinaceum* Coosa Valley Barren Herbaceous Vegetation (CEGL004757, G1)
- *Schizachyrium scoparium - Sorghastrum nutans - Silphium* spp. Herbaceous Vegetation (CEGL007932, G2?)

DISTRIBUTION

Range: This system occurs in the Coosa River valley of northwestern Georgia, Tennessee, and northeastern Alabama, and related areas of the Ridge and Valley physiographic province, including barrens at Oak Ridge, Tennessee.
Divisions: 202:C
Nations: US
Subnations: AL, GA, TN

SOUTHERN ROCKY MOUNTAIN MONTANE-SUBALPINE GRASSLAND (CES306.824)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Acidic Soil; Mineral: W/ A-Horizon >10 cm; Loam Soil Texture; Silt Soil Texture; Aridic; Short Disturbance Interval; Graminoid; Cool-season bunch grasses
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Montane [Montane]; Montane [Lower Montane]; Sideslope; Temperate [Temperate Continental]; Shallow Soil; F-Patch/Low Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2146; ESLF 7119; ESP 1146

CONCEPT

Summary: This Rocky Mountain ecological system typically occurs between 2200 and 3000 m elevation on flat to rolling plains and parks or on lower sideslopes that are dry, but it may extend up to 3350 m on warm aspects. Soils resemble prairie soils in that the A-horizon is dark brown, relatively high in organic matter, slightly acidic, and usually well-drained. An occurrence usually consists of a mosaic of two or three plant associations with one of the following dominant bunch grasses: *Danthonia intermedia*, *Danthonia parryi*, *Festuca idahoensis*, *Festuca arizonica*, *Festuca thurberi*, *Muhlenbergia filiculmis*, or *Pseudoroegneria spicata*. The subdominants include *Muhlenbergia montana*, *Bouteloua gracilis*, and *Poa secunda*. These large-patch grasslands are intermixed with matrix stands of spruce-fir, lodgepole pine, ponderosa pine, and aspen forests. In limited circumstances (e.g., South Park in Colorado), they form the "matrix" of high-elevation plateaus. Small-patch representations of this system do occur at high elevations of the Trans-Pecos where they present as occurrences of *Festuca arizonica - Blepharoneuron tricholepis* Herbaceous Vegetation (CEGL004508). These occurrences often occupy sites adjacent to Madrean Oriental Chaparral (CES302.031).
Classification Comments: Montane grasslands are very similar and intergrade with their subalpine counterparts, but are separated here to represent those species that do not occur at higher altitudes.

Component Associations:
- *Agrostis variabilis* Herbaceous Vegetation (CEGL001846, G2G3)
- *Carex duriuscula* Herbaceous Vegetation (CEGL001874, GUQ)
- *Carex siccata - Carex rossii* Herbaceous Vegetation (CEGL005388, GNR)
- *Danthonia intermedia - Solidago multiradiata* Herbaceous Vegetation (CEGL001879, G3G4)
- *Danthonia intermedia* Herbaceous Vegetation (CEGL001794, G2G3)
- *Danthonia parryi* Herbaceous Vegetation (CEGL001795, G3)
- *Deschampsia caespitosa* Herbaceous Vegetation (CEGL001599, G4)
- *Elymus lanceolatus* Herbaceous Vegetation (CEGL002588, GNR)
- *Festuca (calligera, arizonica, brachyphylla)* Herbaceous Vegetation (CEGL005500, GNR)
- *Festuca arizonica - Blepharoneuron tricholepis* Herbaceous Vegetation (CEGL004508, G1G2)
- *Festuca arizonica - Muhlenbergia filiculmis* Herbaceous Vegetation (CEGL001605, GU)
- *Festuca arizonica - Muhlenbergia montana* Herbaceous Vegetation (CEGL001606, G3)
- *Festuca idahoensis - Danthonia intermedia* Herbaceous Vegetation (CEGL001612, G3?Q)
- *Festuca idahoensis - Festuca thurberi* Herbaceous Vegetation (CEGL001617, G3G4)
- *Festuca idahoensis - Geranium viscosissimum* Herbaceous Vegetation (CEGL001618, G2G3)
- *Festuca idahoensis - Pseudoroegneria spicata* Herbaceous Vegetation (CEGL001624, G4)
- *Festuca thurberi* - (*Lathyrus lanszwertii var. leucanthus, Potentilla* spp.) Herbaceous Vegetation (CEGL001630, G4)
- *Festuca thurberi - Danthonia parryi / Potentilla hippiana* Herbaceous Vegetation (CEGL005377, GNR)
- *Festuca thurberi* Subalpine Grassland Herbaceous Vegetation (CEGL001631, G3)
- *Leymus cinereus* Herbaceous Vegetation (CEGL001479, G2G3Q)
- *Muhlenbergia filiculmis* Herbaceous Vegetation (CEGL001780, G2)
- *Muhlenbergia montana - Hesperostipa comata* Herbaceous Vegetation (CEGL001647, G1G2)
- *Muhlenbergia montana - Schizachyrium scoparium* Herbaceous Vegetation (CEGL005381, GNR)
- *Muhlenbergia montana* Herbaceous Vegetation (CEGL001646, G3G4)
- *Muhlenbergia pungens* Herbaceous Vegetation (CEGL002363, GNR)
- *Pascopyrum smithii - Bouteloua gracilis* Herbaceous Vegetation (CEGL001578, G5)
- *Pascopyrum smithii* Herbaceous Vegetation (CEGL001577, G3G5Q)
- *Poa fendleriana* Herbaceous Vegetation (CEGL001925, GU)
- *Poa secunda* Herbaceous Vegetation (CEGL001657, G4?)
- *Pseudoroegneria spicata - Hesperostipa comata* Herbaceous Vegetation (CEGL001679, G4)
- *Pseudoroegneria spicata - Poa fendleriana* Herbaceous Vegetation (CEGL001676, G1G2)

- *Pseudoroegneria spicata* Herbaceous Vegetation (CEGL001660, G2)

DISTRIBUTION

Range: This system occurs between 2200 and 3000 m elevation in the Colorado Rockies. Where it transitions in Wyoming to Northern Rocky Mountain Subalpine-Upper Montane Grassland (CES306.806) still needs to be clarified.

SOUTHWEST FLORIDA DUNE AND COASTAL GRASSLAND (CES203.539)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Graminoid; Coast
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2431; ESLF 7144; ESP 1431

CONCEPT

Summary: This system occurs along the southwest coast of Florida, one of the four distinctive coastal regions of Florida. It includes herbaceous vegetation on dunes and just inland of the dunes, often on recently deposited sands. These are generally upland plant communities and less commonly non-flooded dune swale wetlands. Although the vegetation is mostly herbaceous, there are typically scattered shrubs of various heights present. The dune vegetation includes *Uniola paniculata*, *Panicum amarum var. amarulum*, and *Iva imbricata*. *Scaevola plumieri*, *Chamaesyce mesembrianthemifolia*, and *Coccoloba uvifera* help distinguish this system from similar dune and coastal grasslands found farther north.
Classification Comments: The spatial boundary between this system and Florida Panhandle Beach Vegetation (CES203.266) is clearly separated by the Big Bend region (see Tanner 1960, Johnson and Muller 1993a). Within this system, there is a large amount of variation along a north-to-south gradient. A finer distinction could be made in the future.
Similar Ecological Systems:
- Florida Panhandle Beach Vegetation (CES203.266)
- Southern Atlantic Coastal Plain Dune and Maritime Grassland (CES203.273)

Related Concepts:
- Beach Dune (FNAI 1990) Intersecting
- Coastal Grassland (FNAI 1990) Intersecting

DESCRIPTION

Environment: The vegetation consists largely of herbaceous vegetation and patches of shrublands on barrier islands and other coastal areas where salt spray, saltwater overwash, and sand movement are important ecological forces. Soils are sandy, with little organic matter and little or no horizon development. Soils may be excessively drained on the higher dunes. Soils are low in nutrient-holding capacity, but aerosol input of sea salt provides a continuous source of nutrients. Winter low temperatures are warmer along the southwest coast of Florida, than along the coast further north. Killing frosts are more unusual further south along the coast of the Florida Peninsula.
Vegetation: Although the vegetation is mostly herbaceous, there are typically scattered shrubs of various heights present. Although the vegetation may overlap in species composition with other Florida coastal regions, there are important differences based on plant species composition, vegetation structure, and physical site characteristics (Johnson and Muller 1993a). The dune vegetation, like that of other Florida regions, includes *Uniola paniculata*, *Panicum amarum var. amarulum*, and *Iva imbricata*. *Scaevola plumieri*, *Chamaesyce mesembrianthemifolia*, and *Coccoloba uvifera* help distinguish this system from those to the north. However, while all other dune communities in Florida have frequently occurring distinctive species which help distinguish them, such species are lacking in this system. However, more inland coastal grassland components of this system sometimes include *Schizachyrium sanguineum (= Schizachyrium semiberbe)* and *Bouteloua hirsuta*, among other species not found in coastal grasslands elsewhere in Florida (Johnson and Muller 1993a).
Dynamics: The natural coastal dynamics include the movement of sand from wind, tides, and storm surge along this low-energy coastline. This includes transport of sand along the coast, and movement of sand by wind or water between the dunes, beach and subtidal areas, and the movement of sand from the foredunes to the interior. If not restricted by infrastructure or engineered hard structures, beaches and dunes can migrate as coastlines change over time in response to the action of wind and water. The Gulf of Mexico coast is affected by one tide per day. Coastal grassland develops as a barrier island builds seaward, developing new dune ridges along the shore which protect the inland ridges from sand burial and salt spray, or as a beach recovers after storm overwash and a new foredune ridge builds up along the shore, protecting the overwashed area behind it from sand burial and salt spray (FNAI 2010a). Wrack and seaweed deposited along the shore is an important source of nutrients for the coastal ecosystem, and helps promote revegetation in newly disturbed areas. Fire is rare and local to small areas.

Component Associations:
- *Bouteloua hirsuta - (Muhlenbergia filipes)* Herbaceous Vegetation (CEGL004093, G1)
- *Cladium mariscus ssp. jamaicense - Fimbristylis castanea - Symphyotrichum tenuifolium* Herbaceous Vegetation (CEGL003968, G2?)
- *Ernodea littoralis / Uniola paniculata - Muhlenbergia filipes* Herbaceous Vegetation (CEGL004000, G1G2)
- *Schizachyrium sanguineum var. sanguineum - Muhlenbergia filipes - Cirsium horridulum - (Waltheria indica)* Herbaceous Vegetation (CEGL003964, G1)

DISTRIBUTION

Range: Found along the western coast of Florida south of the Big Bend region to the Florida Keys, one of the four distinctive coastal regions of Florida.

TAMAULIPAN CALICHE GRASSLAND (CES301.989)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Caliche Layer; Lowland [Lowland]; Plain; Herbaceous; Tropical/Subtropical [Tropical Xeric]; Alkaline Soil; Calcareous; Very Shallow Soil; Sand Soil Texture
Non-Diagnostic Classifiers: Toeslope/Valley Bottom; Oligotrophic Soil
National Mapping Codes: ESLF 9410

CONCEPT

Summary: This ecological system is restricted to the Loreto Plain in Tamaulipas, Mexico. It occurs on shallow sandy loam soils with a caliche hardpan subhorizon. These small-patch grasslands are less than 40 ha in area and are dominated by perennial grasses often with sparse low shrubs within a mosaic of thornscrub. Dominant grasses may include *Aristida purpurea, Bouteloua hirsuta, Bouteloua radicosa, Cenchrus spinifex, Paspalum setaceum*, and *Tridens muticus*. Perennial forbs may be abundant such as *Boerhavia coccinea, Chamaecrista flexuosa, Heliotropium confertifolium*, or *Rhynchosia americana*. Low shrubs are *Calliandra conferta* and *Krameria ramosissima*.

Related Concepts:
- South Texas: Caliche Grassland (6707) [CES301.989] (Elliott 2011) Equivalent

DESCRIPTION

Environment: This system is described from the vicinity of Loreto in Tamaulipas, Mexico, but the conditions of sand veneer over caliche outcrop may also be present on the edge of the sandsheet where it passes over the Goliad Formation in northern Hidalgo and Starr counties (Elliott 2011). Soils are a reddish sandy loam about 0.3 m in depth or less. These grasslands occur on relatively level sites atop the Goliad Formation. These are areas that have a relatively thin veneer of eolian sand over caliche substrate. Such sites occur on the edge of the South Texas Sand Sheet where it overlies caliche of the Goliad Formation. Soils are shallow sands and sandy loams, sometimes red sandy loams, over caliche substrate. This Tamaulipan ecological system occurs on clay prairies near the Gulf Coast and drier sites further inland. Substrates are fine calcareous clays and clay loam. Occasional fires and root-pruning from montmorillonitic clay limit shrub invasion, if the grassland is not overgrazed. If overgrazed, the land will convert to stable thornscrub dominated by *Prosopis glandulosa* and *Celtis pallida*.

Vegetation: Sites may currently be occupied by non-native grasses such as *Pennisetum ciliare* and *Bothriochloa ischaemum var. songarica*, though invasion by these species is not observed in Mexican occurrences (Chris Best pers. obs.). These grasslands are known to occur within a mosaic of calcareous shrublands. Johnston (1963) describes them as grassland patches (the largest of which are 50 to 100 acres in extent) within a matrix of shrubland. Grasses often dominate sites, including species such as *Schizachyrium littorale, Aristida purpurea, Bouteloua hirsuta, Elionurus tripsacoides, Trachypogon spicatus, Heteropogon contortus, Bouteloua curtipendula, Tridens texanus*, and *Tridens muticus*. *Brachiaria ophryodes* and *Bouteloua radicosa* are also noted from occurrences in Mexico. Shrubs and subshrubs are scattered and sometimes coalesce into larger areas, and include species such as *Calliandra conferta, Krameria ramosissima, Calliandra biflora, Chamaecrista greggii*, and *Macrosiphonia lanuginosa*. Perennial forbs are conspicuous and include species such as *Heliotropium confertifolium, Melampodium cinereum, Simsia calva, Acalypha radians, Cnidoscolus texanus, Galphimia angustifolia, Hermannia texana, Croton capitatus, Rhynchosia americana*, and *Dalea nana*. Scattered shrubs that may be present include *Prosopis glandulosa, Zanthoxylum fagara, Cordia boissieri*, and *Condalia hookeri* (Elliott 2011).

Dynamics: Occurrences are naturally small with the larger brush-free stands only 50-100 acres in extent. Larger areas occur as mosaics of grassland mixed with brush mottes (Johnston 1963). Fire is a key process that limits invasion by brush (Landfire 2007a). Fire occurs on a frequent 2- to 5-year return interval. The fire regime has frequent replacement fires, both lightning and anthropogenic in origin (Stewart 1951, Lehmann 1965, Drawe 1980, Stewart 2002, Jurney et al. 2004). Fire was dependent on the availability of dry fine fuel sufficient to carry a fire. Both native grazing and wet/dry periods would have dictated whether sufficient dry fine fuels were present to carry a burn and strongly influenced the probable size of burns. Drought may shift composition and cause minor changes in herbaceous cover (Landfire 2007a).

DISTRIBUTION

Range: This system is restricted to the Loreto Plain in Tamaulipas, Mexico. It may also be present in Texas on the edge of the sandsheet where it passes over the Goliad Formation in northern Hidalgo and Starr counties (Elliott 2011).

TAMAULIPAN SAVANNA GRASSLAND (CES301.985)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Herbaceous; Tropical/Subtropical [Tropical Xeric]
Non-Diagnostic Classifiers: Toeslope/Valley Bottom
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2438; ESLF 7151; ESP 1438

CONCEPT

Summary: This Tamaulipan ecological system is dominated by perennial grasses with sparse overstory of mesquite or oak trees and thornscrub. Stands of the system are typically dominated by *Prosopis glandulosa* in the overstory, which may be sparse, giving the aspect of an open grassland with scattered trees and shrubs. Or, more commonly, the system occurs as shrub-dominated patches within a grassy matrix. There will typically be an emergent canopy ranging to about 6 or more meters in height, composed of *Prosopis glandulosa* sometimes with *Ebenopsis ebano* and/or *Celtis pallida (= Celtis ehrenbergiana)*. Sometimes the overstory canopy is well-developed and would be considered woodland. These patches often coalesce to form significant expanses of shrubland. Dominant grasses are *Cynodon* spp. This system was once a common matrix system, but has largely been converted to desert scrub and exists as remnant patches. Degraded subtropical forests and woodlands may have similar structure but are not included in this system because different ecological processes maintain them.

Similar Ecological Systems:
- Tamaulipan Mixed Deciduous Thornscrub (CES301.983)
- Tamaulipan Saline Thornscrub (CES301.711)

Related Concepts:

- South Texas: Sandy Live Oak Motte and Woodland (7102) [CES301.985.2] (Elliott 2011) Finer
- South Texas: Sandy Mesquite / Evergreen Woodland (7103) [CES301.985.3] (Elliott 2011) Finer
- South Texas: Sandy Mesquite Dense Shrubland (7105) [CES301.985.5] (Elliott 2011) Finer
- South Texas: Sandy Mesquite Savanna Grassland (7107) [CES301.985.7] (Elliott 2011) Finer
- South Texas: Sandy Mesquite Woodland and Shrubland (7104) [CES301.985.4] (Elliott 2011) Finer

DESCRIPTION

Environment: Examples of the system are found on thinner eolian sands on the western side of the South Texas Sand Sheet, as well as other sandy sites such as those of the Eocene sands of the Carrizo, Queen City, and Sparta formations. It may also be found associated with other formations, such as Oakville sandstone and other formations producing sandy residuum. Typical sites are level to gently rolling. This system occurs on sandy soils, including sandy, sandy loam, and loamy sands. Ecological Sites include sandy to sandy loam sites, such as those of the Sandy, Loamy Sand and Sandy Loam Ecological Sites (Elliott 2011).

Vegetation: This system is typically dominated by *Prosopis glandulosa* in the overstory, which may be sparse, giving the aspect of an open grassland with scattered trees and shrubs. Or, more commonly, the system occurs as shrub-dominated patches within a grassy matrix. There will typically be an emergent canopy ranging to about 6 or more meters in height, composed of *Prosopis glandulosa* sometimes with *Ebenopsis ebano* and/or *Celtis pallida (= Celtis ehrenbergiana)*. Sometimes the overstory canopy is well-developed and would be considered woodland. These patches often coalesce to form significant expanses of shrubland. Sites with somewhat tighter soils tend to have a denser shrub stratum, while deep sands and sandy sites tend to be more open, often with sizeable areas lacking significant shrub cover and dominated by a primarily graminoid herbaceous layer. The shrub component of woody patches or shrublands is commonly dominated by species such as *Zanthoxylum fagara, Condalia hookeri, Celtis pallida, Opuntia engelmannii var. lindheimeri, Diospyros texana, Colubrina texensis, Opuntia leptocaulis (= Cylindropuntia leptocaulis),* and *Acacia farnesiana* (Elliott 2011). *Prosopis glandulosa* is almost always present, and is often dominant to codominant and occupies the highest canopy position (sometimes sharing that position with few other species), sometimes to 6 m in height. Numerous other species may also occur in the shrub layer, including but not limited to *Schaefferia cuneifolia, Mahonia trifoliolata, Forestiera angustifolia, Lycium berlandieri, Aloysia gratissima, Salvia ballotiflora,* and *Ziziphus obtusifolia*. The diversity of the shrub layer is significantly influenced by land-use history, with recently cleared areas sometimes being represented by a near monoculture of *Prosopis glandulosa* in the overstory, *Pennisetum ciliare* in the herbaceous layer, and *Opuntia engelmannii var. lindheimeri* as the most conspicuous component of the shrub layer. The herbaceous layer is typically dominated by graminoids and may be quite dense (60-100% cover). Grasses, such as *Schizachyrium scoparium, Schizachyrium littorale, Chloris cucullata, Paspalum monostachyum, Paspalum plicatulum, Elionurus tripsacoides, Bouteloua rigidiseta, Urochloa ciliatissima, Heteropogon contortus, Eragrostis secundiflora, Bothriochloa laguroides ssp. torreyana, Chloris pluriflora (= Trichloris pluriflora), Aristida* spp., *Sporobolus cryptandrus,* and/or *Dichanthelium* spp., commonly dominate or codominate the herbaceous layer. Forbs are also common, including species such as *Gaillardia pulchella, Eriogonum multiflorum, Croton* spp., *Cnidoscolus texanus, Aphanostephus skirrhobasis, Rudbeckia hirta,*

Verbesina encelioides, Clematis drummondii, Cynanchum barbigerum, Thymophylla pentachaeta, Siphonoglossa pilosella (= Justicia pilosella), Nama jamaicense, Monarda punctata, Palafoxia texana, Florestina tripteris, Zornia bracteata, Croptilon divaricatum, Rhynchosia americana, and *Wedelia texana*, though some of these species are restricted to the sandiest sites (Elliott 2011).
Dynamics: Fire and drought are key ecological processes in this system. This system was modeled by Landfire (2007a) using three classes: early-, mid- and late-seral. The early-seral class (1-20 years) is dominated by perennial grasses. This class was maintained by frequent replacement fire (MFRI = 5 years) as the dominant disturbance type in this class. Droughts slow progression of this class to mid-seral class. This class is modeled to last 20 years; this duration is extended due to limited mesquite seed dispersal mechanisms historically (prior to livestock introduction) (Landfire 2007a).

Mid-seral class (21-50 years) is the early development of shrub patches, often surrounding a mesquite trees. Tree canopy is sparse, but shrub cover is dense. Herbaceous cover is declining due to increased shrub and overstory canopy. Replacement fire is modeled to occur with a 20-year return interval. A mixed fire is modeled to occur with a 7-year return interval. Twenty-year drought is modeled to slow successional progression to late-seral class. The mechanism for drought effect may be an enhanced effect of fire. This class is modeled to last 30 years (Landfire 2007a).

The late-seral class (51+ years) is a closed-canopy, late-development stage that represents the continued development of shrub patches as they coalesce into more well-developed woodlands of *Prosopis glandulosa* (Archer 1989). In these late stages other species begin to colonize into woodlands and shrublands. Species present in mid-seral class are still present in late-seral class, but other species begin to colonize, such as *Mahonia trifoliolata*, *Schaefferia cuneifolia*, and *Lycium berlandieri*. Replacement fire is modeled to occur with a 200-year return interval. A mixed fire is modeled to occur with a 20-year return interval. Twenty-year drought is modeled and may slow increase in patch size but does not cause transition (Landfire 2007a).

Component Associations:
- *Bothriochloa barbinodis - Chloris pluriflora* Herbaceous Vegetation (CEGL002236, G2?)
- *Prosopis glandulosa var. glandulosa - Parkinsonia texana var. macra - (Cordia boissieri, Koeberlinia spinosa)* Shrubland (CEGL007762, G4)

Spatial Characteristics

Adjacent Ecological Systems:
- Tamaulipan Closed Depression Wetland (CES301.197)

Distribution

Range: Examples of the system are found on thinner eolian sands on the western side of the South Texas Sand Sheet in Texas and related areas of Mexico.

TEXAS BLACKLAND TALLGRASS PRAIRIE (CES205.684)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Eastern Great Plains (205)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Mima mound; Herbaceous; Unglaciated; Loam Soil Texture; G-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2422; ESLF 7135; ESP 1422

CONCEPT

Summary: This grassland system is found primarily in the Blackland Prairie region of Texas but may range into southern Oklahoma. It is typified by the presence of dark alkaline Vertisol soils over calcareous parent material, although substantial belts of acidic, sandy clay loam Alfisols and loamy or clay loam Mollisols also occur. These soil types relate directly to the underlying surface geology. Microtopography such as gilgai occurs over Vertisols, and mima mounds occur over Alfisols. These create important microhabitats that increase plant diversity in this system. *Schizachyrium scoparium, Sorghastrum nutans,* and *Andropogon gerardii* are the most common dominants. *Tripsacum dactyloides* and *Panicum virgatum* are common associates on the Vertisol soils, especially on the gilgai microtopography. Fire, drought, and possibly grazing were the major natural dynamics influencing this system.
Classification Comments: This system (CES205.684) lies to the east of the floristically related Southeastern Great Plains Tallgrass Prairie (CES205.685), and is primarily, if not entirely, found in Texas (and possibly Oklahoma).
Similar Ecological Systems:
- Arkansas Valley Prairie and Woodland (CES202.312)
- Central Tallgrass Prairie (CES205.683)
- Lower Mississippi Alluvial Plain Grand Prairie (CES203.549)
- Ozark Prairie and Woodland (CES202.326)
- Southeastern Great Plains Tallgrass Prairie (CES205.685)
- West Gulf Coastal Plain Northern Calcareous Prairie (CES203.377)

Related Concepts:
- Blackland Prairie: Disturbance or Tame Grassland (207) [CES205.684.9] (Elliott 2011) Finer

DESCRIPTION

Environment: This system is typified by the presence of dark alkaline Vertisol soils over calcareous parent material interspersed with patches of acidic, sandy loam Alfisols and Mollisols. The detailed geology includes Cretaceous shales, marls and limestones, such as those of the Pecan Gap Chalk, Marlbrook Marl, Eagle Ford, Gober Chalk, Annona Chalk, and Austin Chalk formations, and Taylor and Navarro groups, as well as portions of the Eocene Midway Group and Wilcox Formation. Also, Miocene formations (Fleming and Oakville Sandstone formations) underlie the southern outlier of Blackland prairie recognized as the Fayette Prairie. Landforms are flat to gently rolling and dissected by drainages, with the most significant ridges associated with harder chalk formations. Microtopography such as gilgai and mima mounds can occur and are important microhabitats that lead to an increase in plant diversity in this system (Diamond and Smeins 1990). Soils are typically Vertisols, but this system may occupy Mollisols or Alfisols with the latter more common. The system generally occurs on calcareous clays, but may also occur on loams, clay loams, or even sandy clay loams or silt loams. Annual rainfall averages 890mm, wettest seasons are spring and fall (Harmel et al. 2003).
Vegetation: Currently, only remnants of this system exist, with most of the historical distribution replaced by crop production or improved pasture. *Schizachyrium scoparium* is the most ubiquitous component of occurrences of this system. *Andropogon gerardii* and *Sorghastrum nutans* are also common dominants. Other species commonly encountered include *Bouteloua curtipendula, Carex microdonta, Sporobolus compositus, Nassella leucotricha, Bothriochloa laguroides ssp. torreyana, Eriochloa sericea, Paspalum floridanum,* and *Tridens strictus*. Forbs commonly encountered in this system include *Symphyotrichum ericoides, Hedyotis nigricans var. nigricans (= Stenaria nigricans var. nigricans), Helianthus maximiliani, Rudbeckia hirta, Bifora americana, Acacia angustissima var. hirta, Desmanthus illinoensis,* and many more. Perhaps more commonly encountered species include *Croton monanthogynus, Amphiachyris dracunculoides,* and *Asclepias* spp. Lowland sites and swales are often dominated by *Tripsacum dactyloides* and *Panicum virgatum* (Elliott 2011). Heavy grazing has allowed species such as *Buchloe dactyloides* and *Bouteloua rigidiseta* to invade. *Tripsacum dactyloides* and *Panicum virgatum* are common associates on the Vertisols, especially on the gilgai microtopography.
Dynamics: Fire, drought and possibly and grazing constitute the major natural dynamics influencing this system. Frequent fires (mean fire-return interval of 2.5 years) prevent woody species from establishing and favor grassland species adapted to fire for reproduction and vigor (Landfire 2007a) prevent woody species from establishing and favor grassland species adapted to fire for reproduction and vigor. Bison and other ungulates possibly played an important role in the vegetation composition and structure of this system (Eidson and Smeins 1999). Fire suppression and overgrazing have allowed woody species to invade. Heavy grazing has also altered the floristic composition by allowing species such as *Buchloe dactyloides (= Bouteloua dactyloides)* and *Bouteloua rigidiseta* to invade. This system is important for a suite of wildlife, many of which are declining, that are dependent on native grasslands (TPWD 2012a).

Component Associations:
- *Schizachyrium scoparium - Andropogon gerardii - Sorghastrum nutans - Bifora americana* Mollisol Herbaceous Vegetation (CEGL004025, G1G2)
- *Schizachyrium scoparium - Sorghastrum nutans - Andropogon gerardii - Bifora americana* Vertisol Herbaceous Vegetation (CEGL004027, G1G2)
- *Schizachyrium scoparium - Sorghastrum nutans - Bifora americana* Alfisol Herbaceous Vegetation (CEGL004026, G1G2)
- *Sporobolus silveanus - Carex meadii* Herbaceous Vegetation (CEGL004521, G1)
- *Sporobolus silveanus - Tridens strictus* Herbaceous Vegetation (CEGL002216, G2)
- *Tripsacum dactyloides - Panicum virgatum - Sorghastrum nutans - Helianthus maximiliani* Herbaceous Vegetation (CEGL002217, G1)
- *Tripsacum dactyloides - Sporobolus compositus var. compositus* Herbaceous Vegetation (CEGL004036, G1)

DISTRIBUTION

Range: This system is restricted to the Blackland Prairie region, part of the Crosstimbers and Southern Tallgrass Prairie Ecoregion, in Texas and possibly adjacent southern Oklahoma.

TEXAS SALINE INLAND PRAIRIE (CES301.720)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Herbaceous; Saline Substrate Chemistry
National Mapping Codes: ESLF 9443

CONCEPT

Summary: This non-coastal saline system is found along floodplains in south-central Texas. It is typically herbaceous and usually occurs within floodplains on soils of relatively high salinity. It is often comprised of *Spartina spartinae* as the single dominant, but some occurrences may have a significant cover of salt-tolerant shrubs.

Similar Ecological Systems:

- Texas Saline Coastal Prairie (CES203.543)

Related Concepts:

- Texas Saline Inland Flat (2400) (Elliott 2011) Finer
- Texas Saline Inland Prairie (2407) (Elliott 2011) Finer
- Texas Saline Inland Prairie Shrubland (2406) (Elliott 2011) Finer

DESCRIPTION

Environment: This system often occurs on relatively level sites, typically within floodplains on Quaternary-aged alluvium, sometimes juxtaposed with Eocene deposits of the Jackson Group or Yegua Formation. Soils that support this system are often mapped as the Salty Prairie Ecological Site type. Salts are leached from the surrounding landscape and deposited into these alluvial settings where repeated flooding and evaporation brings the salts to the surface.

Vegetation: *Spartina spartinae* typically dominates these sites, sometimes to the near exclusion of other species. Other species that may be encountered include *Sporobolus virginicus, Distichlis spicata, Monanthochloe littoralis, Paspalidium geminatum, Chloracantha spinosa, Coreopsis tinctoria, Heliotropium curassavicum, Isocoma drummondii, Borrichia frutescens*, and *Helianthus ciliaris*. Shrubs such as *Prosopis glandulosa, Prosopis reptans, Lycium carolinianum*, and *Opuntia engelmannii var. lindheimeri* may be present. Occasionally shrubs, particularly *Prosopis glandulosa*, may gain sufficient cover. Dense stands of *Chloracantha spinosa, Isocoma drummondii*, or *Borrichia frutescens* may also occur, and these sites may also have a sparse overstory of *Prosopis glandulosa*.

DISTRIBUTION

Range: This system is found along floodplains in south-central Texas.

WEST GULF COASTAL PLAIN NORTHERN CALCAREOUS PRAIRIE (CES203.377)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; West Gulf Coastal Plain; Circumneutral Soil; Deep Soil; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2428; ESLF 7141; ESP 1428

CONCEPT

Summary: This is one of two described calcareous prairie ecological systems which occur within the pine-dominated portions of the Coastal Plain west of the Mississippi River. This type is the more northerly ranging of the two [compare against West Gulf Coastal Plain Southern Calcareous Prairie (CES203.379)]. This system includes natural grassland vegetation and associated wooded vegetation in a relatively small natural region of the Upper West Gulf Coastal Plain of Arkansas and adjacent Oklahoma. Although other calcareous prairies are found west of the Mississippi River, this system represents some of the largest known and highest quality remaining examples. Plant communities in this system occur over relatively deep soils (as well as shallow soils over chalk and limestone) with circumneutral surface soil pH, which is unusual given the predominance of acidic, generally forested soils in the region. In most cases individual prairie openings are small and isolated from one another, but were formerly more extensive prior to European settlement, forming a mosaic of grassland and woodlands under frequent fire regimes. The flora has much in common with other prairie systems of the East Gulf Coastal Plains as well as classic Midwestern prairies.

Similar Ecological Systems:
- Southeastern Great Plains Tallgrass Prairie (CES205.685)
- Texas Blackland Tallgrass Prairie (CES205.684)
- West Gulf Coastal Plain Southern Calcareous Prairie (CES203.379)

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is characterized by deep to shallow soils with circumneutral surface soil pH that have developed over Cretaceous-aged calcareous substrates. Soils vary from well-drained to poorly drained clays, silty clays, silty clay loams, and fine sandy loams, and are typically excessively dry in summer exhibiting high shrink-swell potential. Within this general landscape, fine-scale abiotic characteristics in conjunction with ecological processes, frequent fire in particular, supported a mosaic of grasslands and short-statured woodlands comprising the ecological system.

Vegetation: Dominant plants in stands of this system vary from example to example; there are several subtypes and associations with variability among these. Typical trees include *Quercus stellata, Quercus muehlenbergii, Quercus shumardii, Quercus pagoda, Quercus sinuata, Carya illinoinensis, Carya myristiciformis, Juniperus virginiana var. virginiana,* and *Maclura pomifera*. Some typical shrubs include *Forestiera ligustrina, Symphoricarpos orbiculatus, Ilex decidua,* and *Rhus aromatica*. Herbs may include *Sorghastrum nutans, Bouteloua curtipendula, Andropogon glomeratus, Leersia virginica, Panicum anceps, Panicum flexile, Sporobolus compositus, Fimbristylis puberula var. puberula, Carex cherokeensis, Carex microdonta, Echinacea pallida, Liatris aspera, Marshallia caespitosa, Silphium integrifolium, Silphium laciniatum, Solidago auriculata, Symphyotrichum lanceolatum, Packera tampicana, Thelesperma filifolium, Nemastylis geminiflora, Dalea purpurea, Lythrum alatum, Allium canadense var. mobilense,* and *Zigadenus nuttallii*.

Dynamics: The composition and structure of this grassland and open woodland ecological system are primarily maintained by edaphic conditions, fire, and climate. Fires less than every four or so years are necessary to maintain the grassland and open woodland states. Under normal weather conditions, eight to ten years without fire will result in a shrub-dominated physiognomy. Continued fire suppression under normal climate conditions will result in a closed-canopy condition. Tight soils provide a barrier to root penetration and limit water availability during dry periods, thereby also inhibiting the establishment and growth of woody plants, but soils alone cannot limit woody growth. Historically, native grazers or browsers also played a role in the maintenance of this system.

Component Associations:
- *Crataegus crus-galli - Ilex decidua - Crataegus viridis* Shrubland (CEGL004532, GNR)
- *Juniperus virginiana - Maclura pomifera / Bouteloua curtipendula - Thelesperma filifolium - Packera tampicana* Wooded Herbaceous Vegetation (CEGL007812, G1?)
- *Quercus falcata - Carya illinoinensis / Silphium integrifolium - Panicum anceps - (Carex cherokeensis)* Mesic Wooded Herbaceous Vegetation (CEGL007963, G1)
- *Quercus muehlenbergii - Quercus sinuata / Rhus aromatica / Liatris aspera - Allium canadense var. mobilense - Schizachyrium scoparium* Woodland (CEGL007968, G2)
- *Quercus shumardii - Carya myristiciformis - (Quercus muehlenbergii) / Carex cherokeensis - Sorghastrum nutans* Woodland

(CEGL007775, G1)
- *Quercus sinuata / Solidago auriculata - Zigadenus nuttallii* Mixed Herb Dry-mesic Blackland Ravine Woodland (CEGL007966, G1)
- *Quercus stellata / Forestiera ligustrina - Symphoricarpos orbiculatus / Carex cherokeensis - Schizachyrium scoparium* Woodland (CEGL007777, G1G2)
- *Schizachyrium scoparium - Sorghastrum nutans - Bouteloua curtipendula* Herbaceous Vegetation (CEGL002214, G2G3)
- *Schizachyrium scoparium - Sorghastrum nutans - Echinacea pallida - Dalea purpurea* Herbaceous Vegetation (CEGL007769, G2G3)
- *Schizachyrium scoparium - Sporobolus compositus - Fimbristylis puberula var. puberula* Wooded Herbaceous Vegetation (CEGL007768, G1G2)
- *Sorghastrum nutans - Andropogon glomeratus - Silphium laciniatum* Herbaceous Vegetation (CEGL007774, G1?)
- *Typha latifolia - Thalia dealbata* Herbaceous Vegetation (CEGL004526, GNR)

DISTRIBUTION

Range: This system is known only from a relatively small natural region of the Upper West Gulf Coastal Plain of Arkansas and adjacent Oklahoma.

WEST GULF COASTAL PLAIN SOUTHERN CALCAREOUS PRAIRIE (CES203.379)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Herbaceous; West Gulf Coastal Plain; Circumneutral Soil; Deep Soil; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2429; ESLF 7142; ESP 1429

CONCEPT

Summary: This is one of two described calcareous prairie ecological systems which occur within the pine-dominated portions of the West Gulf Coastal Plain west of the Mississippi River. This type is the more southerly-ranging of the two [compare against West Gulf Coastal Plain Northern Calcareous Prairie (CES203.377)]. Examples include natural grassland vegetation and adjacent wooded vegetation in a relatively small natural region of Arkansas, Louisiana and Texas. Although most examples are typically upland, some include small stream bottoms or riparian areas that bisect the prairies. Plant communities in this system occur over relatively deep soils that are unusual in the local landscape because they are much less acidic than the soils of the surrounding forests. Stands are dominated by perennial grasses and graminoids, including *Carex cherokeensis, Carex microdonta, Muhlenbergia expansa, Schizachyrium scoparium, Schizachyrium tenerum, Sorghastrum nutans*, and *Sporobolus silveanus*. Historically, this system is thought to have occupied large patches (up to a couple thousand acres), but currently, most individual prairie openings are small and isolated from one another.

Similar Ecological Systems:
- West Gulf Coastal Plain Northern Calcareous Prairie (CES203.377)

- Jackson Calcareous Prairie (LNHP 2004) Finer
- Longleaf Pine: 70 (Eyre 1980) Finer
- Morse Clay Calcareous Prairie (LNHP 2004) Finer
- Pineywoods: Southern Calcareous Mixedgrass Prairie (4407) [CES203.379] (Elliott 2011) Equivalent
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer
- Swamp Chestnut Oak - Cherrybark Oak: 91 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is best documented from the Fleming geologic formation, but is also known from the Cook Mountain Formation in Louisiana. Examples from the Jackson Group (in Louisiana) are also included here, as well as the Morse Clay Calcareous Prairie of northwestern Louisiana and adjacent Arkansas. It occupies deep vertic soils with circumneutral surface pH, a condition uncommon in a region of predominantly acidic, forested soils. It typically occurs on upper slopes and broad uplands in gently undulating landscapes. Soils are circumneutral to moderately alkaline, including vertic soils such as Ferris, Houston Black, or Wiergate clays (Elliott 2011). Occurrences may reflect a relationship to the Blackland Prairie further to the west (including the Fayette Prairie), and some consider these small-patch prairies to be outliers of the Blackland Tallgrass Prairie. In Arkansas, it also occurs on the Gore silt loam and McKamie silt loam, as well as the Morse clay (Foti 1987). Within this general landscape, fine scale abiotic characteristics in conjunction with ecological processes, frequent fire in particular, supported a mosaic of grasslands and short stature woodlands comprising the ecological system. Prior to European settlement this system is believed to have occupied patches up to a couple thousand acres.

Vegetation: The flora has much in common with that of other prairie systems of the East Gulf Coastal Plain as well as that of classic Midwestern prairies, although there is variability among examples. Stands are dominated by perennial grasses and graminoids, including *Schizachyrium scoparium, Schizachyrium tenerum, Muhlenbergia expansa, Sorghastrum nutans, Bothriochloa laguroides ssp. torreyana, Bouteloua curtipendula, Andropogon gerardii, Nassella leucotricha, Paspalum pubiflorum, Panicum virgatum, Carex cherokeensis*, and *Carex microdonta*. Much of the typical flora are species uncommon in the rest of the Pineywoods region, such as *Dalea compacta var. compacta, Rudbeckia hirta, Rudbeckia missouriensis, Acacia angustissima, Croton monanthogynus, Liatris mucronata, Eustoma exaltatum ssp. russellianum (= Eustoma russellianum), Grindelia lanceolata, Agalinis heterophylla, Stenosiphon linifolius, Neptunia lutea, Indigofera miniata (= Indigofera miniata var. leptosepala), Palafoxia reverchonii, Indigofera miniata, Arnoglossum plantagineum, Coreopsis tinctoria, Symphyotrichum* spp., *Onosmodium molle ssp. occidentale (= Onosmodium occidentale)*, and *Euphorbia bicolor*. Some of these species are found either most commonly or exclusively in the more western examples of this system when compared with those in Louisiana. Arkansas examples may contain *Mimosa nuttallii (= Mimosa quadrivalvis var. nuttallii), Dalea purpurea, Neptunea lutea, Baptisia nuttalliana, Arnoglossum plantagineum, ryngium yuccifolium,*

Manfreda virginica, Silphium laciniatum, Nemastylis geminiflora, and other prairie species (Foti 1987). Various woody species from the surrounding landscape, including *Pinus taeda, Ulmus alata, Liquidambar styraciflua, Juniperus virginiana, Crataegus spathulata, Crataegus crus-galli, Sideroxylon lanuginosum*, and others, may invade these prairies. Non-native woody species such as *Rosa bracteata* may also invade, this presumably being a result of long-term fire suppression (Elliott 2011). Non-native grasses such as *Bothriochloa ischaemum var. songarica, Bromus arvensis, Cynodon dactylon*, and/or *Lolium perenne* may be conspicuous to dominant (Elliott 2011).

Dynamics: The composition and structure of this grassland and open woodland ecological system are primarily maintained by edaphic conditions, fire, and climate. Examples historically formed a mosaic of grassland and open woodlands under frequent fire regimes. With fire suppression, trees invade from surrounding pine forests. As a result, some evidence suggests that soil properties are modified, especially the surface pH and nutrient dynamics. Fires every four or so years are necessary to maintain the grassland and open woodland states. Under normal weather conditions, 15 to 20 years without fire will result in a shrub-dominated physiognomy. Continued fire suppression under normal climate conditions will result in a closed-canopy condition. Tight soils provide a barrier to root penetration and limit water availability during dry periods, thereby also inhibiting the establishment and growth of woody plants.

Component Associations:

- *Celtis laevigata - Gleditsia triacanthos - Sapindus saponaria var. drummondii / Lithospermum tuberosum - Carex willdenowii* Forest (CEGL007318, G1)
- *Crataegus spathulata - Cornus drummondii - Berchemia scandens* Shrubland (CEGL003879, G2)
- *Juniperus virginiana var. virginiana - Pinus taeda - Quercus sinuata var. sinuata* Woodland (CEGL007799, G1)
- *Pinus palustris / Quercus marilandica / Schizachyrium tenerum - Muhlenbergia expansa - Bigelowia nuttallii - Packera obovata* Woodland (CEGL003597, G1)
- *Quercus shumardii - Fraxinus americana - Carya myristiciformis / Viburnum dentatum / Carex cherokeensis* Forest (CEGL007194, G1Q)
- *Quercus similis - Quercus pagoda - Carya (glabra, myristiciformis, ovata)* Temporarily Flooded Forest (CEGL007360, G1)
- *Quercus sinuata var. sinuata - Fraxinus americana - Quercus muehlenbergii / Rhus aromatica - Cornus drummondii* Forest (CEGL007256, G1)
- *Quercus stellata / Forestiera ligustrina - Symphoricarpos orbiculatus / Carex cherokeensis - Schizachyrium scoparium* Woodland (CEGL007777, G1G2)
- *Schizachyrium scoparium - Marshallia caespitosa - Nemastylis geminiflora* Herbaceous Vegetation (CEGL004022, G1G2)
- *Schizachyrium scoparium - Panicum flexile - Carex microdonta* Herbaceous Vegetation (CEGL004021, G1)
- *Schizachyrium scoparium - Rudbeckia missouriensis - Grindelia lanceolata - (Liatris mucronata)* Herbaceous Vegetation (CEGL007930, G1)
- *Schizachyrium scoparium - Sorghastrum nutans* Jackson Prairie Herbaceous Vegetation (CEGL004721, G1)

SPATIAL CHARACTERISTICS

Size: A very few extant examples may range into the large-patch size category, but most are small. Historical patch size is hard to estimate. Small patch is the best attribute for this system, fide Jason Singhurst (TPWD).

DISTRIBUTION

Range: This system is restricted to a relatively small natural region of Arkansas, Louisiana and Texas.
Divisions: 203:C
Nations: US
Subnations: AR, LA, TX
Map Zones: 37:C
USFS Ecomap Regions: 231E:CC, 232F:CC

WESTERN CANADIAN BOREAL DRY GRASSLAND AND BLUFF (CES103.864)

CLASSIFIERS

Conf.: 3 - Weak
Classification Status: Standard
Primary Division: Boreal (103)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous
Non-Diagnostic Classifiers: Montane [Montane]; Lowland [Lowland]
National Mapping Codes: ESLF 7160

CONCEPT

Summary: This grassland and shrub-steppe system occurs throughout the boreal regions of western Canada including Yukon Territory, British Columbia, Alberta and probably Saskatchewan. This system consists of communities dominated by herbaceous vegetation on dry to mesic sites, such as ridgetops, rolling foothills, steep south-facing river bluffs, or openings in predominantly upland forest. Soils are well-drained to excessively drained, and permafrost is absent. These sites are typically dominated by grasses, though forbs may codominate on some sites. Shrub cover is less than 25%. Dominant species include *Leymus innovatus, Calamagrostis purpurascens, Koeleria macrantha, Elymus trachycaulus (= Agropyron pauciflorum), Elymus lanceolatus (= Elymus dasystachya), Piptatherum pungens (= Oryzopsis pungens), Festuca hallii, Festuca saximontana, Danthonia californica, Hesperostipa spartea*, and *Hesperostipa curtiseta*. Sagebrushs also occur, predominantly *Artemisia frigida* and *Artemisia ludoviciana*. The steep, dry south-facing bluffs along the Peace and Smoky rivers in western Alberta and eastern British Columbia have communities dominated by *Artemisia frigida*, dryland *Carex* spp., *Koeleria macrantha, Hesperostipa comata, Hesperostipa spartea*, and *Hesperostipa curtiseta* interspersed with bare mineral soil. On less pronounced slopes where moisture is in greater supply, *Elymus lanceolatus, Elymus trachycaulus*, and *Opuntia fragilis* are more abundant.
Classification Comments: The dry bluffs of interior boreal Alaska (Western North American Boreal Dry Aspen-Steppe Bluff (CES105.109)) are compositionally very similar to this system, but without the suite of Great Plains mixedgrass species found in Alberta and British Columbia. But certainly the environmental setting of south-facing steep bluffs above major boreal rivers is very similar, and some species are shared between the two types. Upon review, Oregon and Washington ecologists determined that this system does not occur in those states. However, it is a poorly defined system and needs further review and a better definition of its concept. In Alaska, dry boreal meadows are placed into Western North American Boreal Dry Grassland (CES105.115), which perhaps should be merged into this system. Undoubtedly, dry meadows occur across subarctic Canada.
Similar Ecological Systems:
- Western North American Boreal Dry Grassland (CES105.115)

WESTERN GREAT PLAINS FOOTHILL AND PIEDMONT GRASSLAND (CES303.817)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Toeslope/Valley Bottom; Clay Soil Texture; Aridic; Short Disturbance Interval [Periodicity/Irregular Disturbance]; F-Patch/Low Intensity; Graminoid
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Herbaceous; Temperate [Temperate Continental]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2147; ESLF 7120; ESP 1147

CONCEPT

Summary: This ecological system typically occurs between 1600 and 2200 m in elevation. It is best characterized as a mixedgrass to tallgrass prairie on mostly moderate to gentle slopes, usually at the base of foothill slopes, e.g., the hogbacks of the Rocky Mountain Front Range where it typically occurs as a relatively narrow elevational band between montane woodlands and shrublands and the shortgrass steppe and mixedgrass prairie, but extends east on the Front Range piedmont alongside the Chalk Bluffs near the Colorado-Wyoming border, out into the Great Plains on the Palmer Divide, and on piedmont slopes below mesas and foothills in northeastern New Mexico. A combination of increased precipitation from orographic rain, temperature, and soils limits this system to the lower elevation zone with approximately 40 cm of precipitation/year. It is maintained by frequent fire and associated with well-drained clay soils. Usually occurrences of this system have multiple plant associations that may be dominated by *Andropogon gerardii, Schizachyrium scoparium, , Nassella viridula, Pascopyrum smithii, Sporobolus cryptandrus, Bouteloua gracilis, Hesperostipa comata*, or *Hesperostipa neomexicana*. In Wyoming, typical grasses found in this system include *Pseudoroegneria spicata, Schizachyrium scoparium, Hesperostipa neomexicana, Hesperostipa comata*, and species of *Poa*. Typical adjacent ecological systems include foothill shrublands, ponderosa pine savannas, juniper savannas, as well as shortgrass prairie.
Classification Comments: Need to incorporate northern Rockies information. How does this differ from Northwestern Great Plains Mixedgrass Prairie (CES303.674) which seems pretty similar? In southeastern Wyoming, it is mostly in mapzone 33, along bluffs.
Related Concepts:
- Bluestem - Grama Prairie (604) (Shiflet 1994) Intersecting. This ecological system overlaps this SRM type along the Wyoming-Colorado-New Mexico eastern foothills of the Rocky Mtns.
- Grama - Feathergrass (716) (Shiflet 1994) Finer
- Sideoats Grama - New Mexico Feathergrass - Winterfat (724) (Shiflet 1994) Finer
- Sideoats Grama - Sumac - Juniper (735) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This ecological system occurs between 1600 and 2200 m in elevation. It is best characterized as a mixedgrass to tallgrass grassland on mostly moderate to gentle slopes, usually at the base of foothill slopes, e.g., the hogbacks of the Rocky Mountain Front Range where it typically occurs as a relatively narrow elevational band between montane woodlands and shrublands and the shortgrass steppe and mixedgrass prairie, but extends east on the Front Range piedmont alongside the Chalk Bluffs near the Colorado-Wyoming border, out into the Great Plains on the Palmer Divide, and on piedmont slopes below mesas and foothills in northeastern New Mexico. This mixed grassland receives more precipitation than shortgrass steppe or occurs on coarser-textured substrates allowing for increased infiltration and water storage (Noy-Meir 1973). A combination of increased precipitation from orographic rain, temperature, and soils limits this system to the lower elevation zone with approximately 40 cm of precipitation/year. It is maintained by frequent fire and associated with well-drained clay soils. Typical adjacent ecological systems include foothill shrublands, ponderosa pine savannas, juniper savannas, as well as shortgrass prairie.
Dynamics: Relatively frequent surface fire (FRI = 20 years -15 years in the southern extent) maintains this ecosystem by reducing seedling survival of shrubs such as *Cercocarpus montanus* and *Rhus trilobata* and trees such as *Pinus ponderosa, Pinus edulis*, and *Juniperus* spp. thus preventing conversion to shrublands and woodlands (Landfire 2007a). There is little information on this natural frequency, size, intensity, or severity of fire in this ecosystem. Ungulate grazing (Landfire 2007a) and herbivory are a key process that includes grazing and browsing by large and small mammals and insects. Soils are naturally disturbed by burrowing mammals such as prairie dogs, rabbits, pocket gophers, ground squirrels, and badgers providing habitat for disturbance-dependent species. Drought occurs periodically (approximately every 20-50 years) and can cause shifts in species compositions to more drought-tolerant species (Landfire 2007a).

Component Associations:

- *Yucca glauca / Pseudoroegneria spicata* Shrub Herbaceous Vegetation (CEGL001499, G4Q)

DISTRIBUTION

Range: This mixed grassland ecological system occurs in a transitional band between the Rocky Mountains and the Shortgrass Steppe where increased soil moisture from orographic lifting and local topography favor tall and mid-height grasses. The band is restricted to the Rocky Mountain foothills and piedmont and adjacent plains, extending farther east on the Palmer Divide, north alongside the Chalk Bluffs near the Colorado-Wyoming border, and south on and below mesas and escarpments in southeastern Colorado, northeastern New Mexico, and the panhandles of Oklahoma and Texas. These grasslands also occur around the edges of the Black Hills uplift, where Schizachyrium scoparium is the dominant grass.

WESTERN GREAT PLAINS SAND PRAIRIE (CES303.670)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Lowland [Lowland]; Herbaceous; Sand Soil Texture; Ustic; G-Landscape/Low Intensity; W-Patch/High Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2148; ESLF 7121; ESP 1148

CONCEPT

Summary: The sand prairies constitute a very unique system within the western Great Plains. These sand prairies are often considered part of the tallgrass or mixedgrass regions in the western Great Plains but can contain elements from Western Great Plains Shortgrass Prairie (CES303.672), Central Mixedgrass Prairie (CES303.659), and Northwestern Great Plains Mixedgrass Prairie (CES303.674). The largest expanse of sand prairies (approximately 5 million ha) can be found in the Sandhills of north-central Nebraska and southwestern South Dakota. These areas are relatively intact. The primary use of this system has been grazing (not cultivation), and areas such as the Nebraska Sandhills can experience less degeneration than other prairie systems. Although greater than 90% of the Sandhills region is privately owned, the known fragility of the soils and the cautions used by ranchers to avoid poor grazing practices have allowed for fewer significant changes in the vegetation of the Sandhills compared to other grassland systems. The unifying and controlling feature for this system is that coarse-textured soils predominate and the dominant grasses are well-adapted to this condition. Soils in the sand prairies can be relatively undeveloped and are highly permeable. Soil texture and drainage along with a species' rooting morphology, photosynthetic physiology, and mechanisms to avoid transpiration loss are highly important in determining the composition of the sand prairies. In the northwestern portion of its range, stand size corresponds to the area of exposed caprock sandstone, and small patches predominate, but large patches are also found embedded in the encompassing Northwestern Great Plains Mixedgrass Prairie (CES303.674). Another important feature is their susceptibility to wind erosion. Blowouts and sand draws are some of the unique wind-driven disturbances in the sand prairies, particularly the Nebraska Sandhills. In most of eastern Montana, substrates supporting this system have weathered in place from sandstone caprock; thus the solum is relatively thin, and the wind-sculpted features present further east, particularly in Nebraska, do not develop. Graminoid species dominate the sand prairies, although relative dominance can change due to impacts of wind disturbance. *Andropogon hallii* and *Calamovilfa longifolia* are the most common species, but other grass and forb species such as *Hesperostipa comata, Carex inops ssp. heliophila*, and *Panicum virgatum* may be present. Apparently only *Calamovilfa longifolia* functions as a dominant throughout the range of the system. In the western extent, *Hesperostipa comata* becomes more dominant, and *Andropogon hallii* is less abundant but still present. Communities of *Artemisia cana ssp. cana* are included here in central and eastern Montana. Patches of *Quercus havardii* can also occur within this system in the southern Great Plains. Fire and grazing constitute the other major dynamic processes that can influence this system.
Classification Comments: This system was edited to expand the concept to include sandy portions of the mixedgrass prairie of the Montana plains. Although in terms of potentially dominant graminoids there is virtually a complete overlap between the eastern and western extremities of the system, there is a distinct shift from west to east from midgrass species dominance, most notably *Hesperostipa comata*, to tallgrass species dominance, including prominently *Andropogon gerardii* and *Andropogon hallii*. Prevailing patch size also shifts from smaller to larger moving west to east. Current thinking is to include this variation within this system, but with more information and input from other Great Plains ecologists in the U.S. and Canada, this concept is subject to change, including the possibility of creating a new system.

DESCRIPTION

Environment: The distribution, species richness and productivity of plant species within the sand prairie ecological system are controlled primarily by environmental conditions, in particular the temporal and spatial distribution of soil moisture and topography. Soils in the sand prairies can be relatively undeveloped and are highly permeable. Soil texture and drainage along with a species' rooting morphology, photosynthetic physiology, and mechanisms to avoid transpiration loss are highly important in determining the composition and distribution of communities/associations within the sand prairies. Another important aspect of soils in the sand prairies is their susceptibility to wind erosion. Blowouts and sand draws are some of the unique wind-driven disturbances in the sand prairies, particularly the Nebraska Sandhills, which can profoundly impact vegetation composition and succession within this system. This tallgrass system is found primarily on sandy and sandy loam soils that can be relatively undeveloped and highly permeable as compared to Western Great Plains Tallgrass Prairie (CES303.673), which occurs on deeper loams. This system is usually found in areas with a rolling topography and can occur on ridges, midslopes and/or lowland areas within a region. It often occurs on moving sand dunes, especially within the Sandhills region of Nebraska and South Dakota. In Montana, occurrences are intimately associated with Northwestern Great Plains Mixedgrass Prairie (CES303.674), usually occupying higher positions in local landscapes due to the fact that sandy members of some formations (that are predominantly marine shales) constitute the highest (and most weathering-resistant) points in the landscape.

Vegetation: This system is distinguished by the dominance of graminoids such as *Andropogon hallii* and *Calamovilfa longifolia*. Other graminoids such as *Hesperostipa comata, Carex inops ssp. heliophila*, and *Panicum virgatum* may be present. Characteristic forbs differ by region, but species of *Psoralidium* and *Pediomelum* are a common feature. *Penstemon haydenii* is endemic to the sand prairie system and of special conservation concern because of its probable decline due to grazing and fire suppression. Very diffuse patches of *Rhus trilobata* are found on shallow sandy soils, often associated with breaklands; other shrubs occasionally occurring include *Artemisia cana ssp. cana, Betula occidentalis, Juniperus horizontalis*, and *Yucca glauca*. Many of the warm-season graminoids extend at least to the Rocky Mountain Front as dominant components on appropriate sites or as a response to disturbance. All the characteristic species mentioned for Nebraska and South Dakota are also found in Montana stands (and possibly Wyoming and perhaps the rest of the states cited). Some of the communities cited as part of the concept in Nebraska and South Dakota are only marginally present in Montana, but others are found throughout Montana's Great Plains region. In the southern range of this system, patches of *Quercus havardii* can also occur.

Dynamics: The distribution, species richness and productivity of plant species within the sand prairie ecological system are controlled primarily by environmental conditions, in particular the temporal and spatial distribution of soil moisture and topography. Another important aspect of this system is its susceptibility to wind erosion. Blowouts and sand draws are some of the unique wind-driven disturbances in the sand prairies, particularly the Nebraska Sandhills, which can profoundly impact vegetation composition and succession within this system. Fire and grazing constitute the other major disturbances that can influence this system. Overgrazing, fire and trampling that leads to the removal of vegetation within those areas susceptible to blowouts can either instigate a blowout or perpetuate one already occurring. Overgrazing can also lead to significant erosion.

Component Associations:

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:

- Northwestern Great Plains Mixedgrass Prairie (CES303.674)

DISTRIBUTION

Range: This system is found throughout the Western Great Plains Division. The largest and most intact example of this system is found within the Sandhills region of Nebraska and South Dakota. However, it is also common (though occurring in predominantly small patches) farther west into central and eastern Montana. Its western extent in Wyoming is still to be determined, but it does occur in mapzone 29 on weathered-in-place sandy soils, where *Calamovilfa longifolia* is found, along with *Artemisia cana*.

WESTERN GREAT PLAINS SHORTGRASS PRAIRIE (CES303.672)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Herbaceous; Loam Soil Texture; Ustic; F-Landscape/Low Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2149; ESLF 7122; ESP 1149

CONCEPT

Summary: This system is found primarily in the western half of the Western Great Plains Division in the rainshadow of the Rocky Mountains and ranges from the Nebraska Panhandle south into Texas and New Mexico, although grazing-impacted examples may reach as far north as southern Canada where it grades into Northwestern Great Plains Mixedgrass Prairie (CES303.674). This system occurs primarily on flat to rolling uplands with loamy, ustic soils ranging from sandy to clayey. In much of its range, this system forms the matrix system with *Bouteloua gracilis* dominating this system. Associated graminoids may include *Aristida purpurea, Bouteloua curtipendula, Bouteloua hirsuta, Buchloe dactyloides, Hesperostipa comata, Koeleria macrantha (= Koeleria cristata), Pascopyrum smithii (= Agropyron smithii), Pleuraphis jamesii, Sporobolus airoides*, and *Sporobolus cryptandrus*. Although mid-height grass species may be present, especially on more mesic land positions and soils, they are secondary in importance to the sod-forming short grasses. Sandy soils have higher cover of *Hesperostipa comata*, and *Sporobolus cryptandrus*. Scattered shrub and dwarf-shrub species such as *Artemisia filifolia, Artemisia frigida, Artemisia tridentata, Atriplex canescens, Eriogonum effusum, Gutierrezia sarothrae, Lycium pallidum*, and *Yucca glauca* may also be present. Also, because this system spans a wide range, there can be some differences in the relative dominance of some species from north to south and from east to west. Large-scale processes such as climate, fire and grazing influence this system. High variation in amount and timing of annual precipitation impacts the relative cover of cool- and warm-season herbaceous species.

In contrast to other prairie systems, fire is less important, especially in the western range of this system, because the often dry and xeric climate conditions can decrease the fuel load and thus the relative fire frequency within the system. However, historically, fires that did occur were often very extensive. Currently, fire suppression and more extensive grazing in the region have likely decreased the fire frequency even more, and it is unlikely that these processes could occur at a natural scale. A large part of the range for this system (especially in the east and near rivers) has been converted to agriculture. Areas of the central and western range have been impacted by the unsuccessful attempts to develop dryland cultivation during the Dust Bowl of the 1930s. The short grasses that dominate this system are extremely drought- and grazing-tolerant. These species evolved with drought and large herbivores and, because of their stature, are relatively resistant to overgrazing. This system in combination with the associated wetland systems represents one of the richest areas for mammals and birds. The endemic bird species of the shortgrass system may constitute one of the fastest declining bird populations in North America.

Classification Comments: In Texas, this system occurs on the Llano Estacado and ranges to but does not include the Stockton Plateau.

DESCRIPTION

Environment: This system occurs on various geologic formations, primarily on flat to rolling uplands. Soils typically are loamy and ustic but can range from sandy to clayey. Climate is continental with mean annual precipitation generally about 300 mm ranging to 500 mm to the south in Texas. Most of the annual precipitation occurs during the growing season as thunderstorms. Precipitation events are mostly <10 cm with occasional larger events. High variation in amount and timing of annual precipitation impacts the relative cover of cool- and warm-season herbaceous species. This is the driest of the Great Plains grasslands ecosystems. In the southeasternmost expression of the system in Texas, it occurs on sites with soils providing relatively dry conditions such as Rough Breaks, Shallow Clay, Very Shallow, and Very Shallow Clay Ecological Sites (Elliott 2011).
Vegetation: Vegetation: This system spans a wide range and thus there can be some differences in the relative dominance of some species from north to south and from east to west. This system is primarily dominated by *Bouteloua gracilis* throughout its range with various associated graminoid species depending on precipitation, soils and management. Associated graminoids may include *Achnatherum hymenoides, Aristida purpurea, Bouteloua curtipendula, Bouteloua hirsuta, Buchloe dactyloides, Carex filifolia, Hesperostipa comata, Koeleria macrantha (= Koeleria cristata), Muhlenbergia torreyana, Pascopyrum smithii (= Agropyron smithii), Pleuraphis jamesii, Sporobolus airoides*, and *Sporobolus cryptandrus*. In addition, *Bouteloua rigidiseta, Erioneuron pilosum*, and *Hilaria belangeri* may occur in Texas examples (Elliott 2011). Although mid-height grass species may be present especially on more mesic land positions and soils, they are secondary in importance to the sod-forming short grasses. Sandy soils have higher cover of *Hesperostipa comata, Sporobolus cryptandrus*, and *Yucca elata*. Scattered shrub and dwarf-shrub species such as *Artemisia filifolia, Artemisia frigida, Artemisia tridentata, Atriplex canescens, Eriogonum effusum, Gutierrezia sarothrae*, and *Lycium pallidum* may also be present. In Texas examples, shrub cover is generally low but may include species such as *Acacia greggii, Rhus microphylla, Rhus trilobata, Dalea formosa, Mahonia trifoliolata, Juniperus* sp., and *Prosopis glandulosa*. Forbs such as *Calylophus* sp., *Melampodium leucanthum, Krameria lanceolata*, and others are often present. *Gutierrezia sarothrae* may be present with significant cover, especially on sites with intense and continuous grazing (Elliott 2011). High annual variation in amount and timing of precipitation impacts relative cover of herbaceous species. Cover of cool-season grasses is dependant on winter and early spring precipitation.
Dynamics: Large-scale processes such as climate, fire and grazing constitute the primary processes impacting this system. The short grasses that dominate this system are extremely drought- and grazing-tolerant (Lauenroth and Milchunas 1992, Lauenroth et al. 1994a). These species evolved with large herbivores and drought (Milchunas and Lauenroth 2008) and adapted to historical heavy grazing with their low stature making them relatively resistant to overgrazing (Lauenroth et al. 1994a). The return intervals for grazing varied with areas distant from water sources likely grazed less heavily as those near water. However, the shortgrass steppe is probably the system with the highest intensity of grazing than other systems historically (Lauenroth et al. 1994a, Milchunas 2006). This is a drought-tolerant system. However, extended drought (over 3-4 years) will reduce cover (Landfire 2007a). Many shortgrass species are drought-tolerant and have root systems that extend up near the soil surface where they can utilize low precipitation events (Salas and Lauenroth 1982). If blue grama is eliminated from an area by extended drought (3-4 years) or disturbance such as plowing, regeneration is slow because of very slow tillering rates (Samuel 1985), low and variable seed production (Coffin and Lauenroth 1992), minimal seed storage in soil (Coffin and Lauenroth 1989) and limited seedling germination and establishment due to particular temperature and extended soil moisture requirements for successful seedling establishment (Hyder et al. 1971, Briske and Wilson 1978, 1980). Patterns and scales of heterogeneity related to historic natural grazing and fire regimes within the system are not well understood, but are assumed to be important to biodiversity (Fuhlendorf et al. 2006).

In contrast to other prairie systems, fire is less frequent, especially in the western range of this system, because the often dry and xeric climate conditions can decrease the fuel load and thus the relative fire frequency within the system. However, historically, fires that did occur were often very extensive. Wright and Bailey (1982c) suggest that in semiarid areas, big prairie fires usually occurred during drought years that followed one to three years of above average precipitation, because of the abundant and continuous fuel. Consequently, these wildfires could travel far when the winds and air temperatures were high and relative humidity was low. There is debate as to the mean fire-return interval (MFRI) for this shortgrass system. Because of the lack of long-lived trees, and trees that do exist are in relatively productive sites, there is absolutely no way to reconstruct a reliable historic fire-return interval. All estimates of historic fire-return intervals must be based on those for surrounding vegetation types that do have means for reconstruction, and then extrapolating based on differences in primary production and herbivore removal of fuel loads. Therefore, there is no means to directly obtain the estimate, and the range is varied. It depends on many factors: portions will be drier, and portions will vary in frequency over time and there will be decadal variation. Anderson (2003) reports a broad fire-return interval (FRI) of <35 years for shortgrass prairie. There is a wide variability of MFRI across this system, based on precipitation, fuel and ignition sources (Landfire 2007a).

Component Associations:
- *Aristida purpurea* Herbaceous Vegetation (CEGL005800, GNR)
- *Bouteloua curtipendula - Bouteloua (eriopoda, gracilis)* Herbaceous Vegetation (CEGL002250, G4)
- *Bouteloua eriopoda - Bouteloua gracilis* Herbaceous Vegetation (CEGL001748, G2)
- *Bouteloua gracilis - Bouteloua curtipendula* Herbaceous Vegetation (CEGL001754, G5)

WESTERN GREAT PLAINS TALLGRASS PRAIRIE (CES303.673)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Herbaceous; Deep Soil; Loam Soil Texture; Ustic; F-Patch/Low Intensity; G-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2150; ESLF 7123; ESP 1150

CONCEPT

Summary: This system can be found throughout the Western Great Plains Division. It is found primarily in areas where soil characteristics allow for mesic conditions more typical of the Eastern Great Plains Division and thus are able to sustain tallgrass species. This system may be small patches interspersed within Northwestern Great Plains Mixedgrass Prairie (CES303.674) or Western Great Plains Shortgrass Prairie (CES303.672) and may also be associated with upland terraces above a floodplain system where these more mesic conditions persist. Soils are primarily loamy Mollisols that are moderately deep and rich. Those areas that contain more sandy soils should be considered part of Western Great Plains Sand Prairie (CES303.670). This system is dominated primarily by *Andropogon gerardii* and may also include *Sorghastrum nutans, Schizachyrium scoparium, Pascopyrum smithii, Hesperostipa spartea*, and *Sporobolus heterolepis*. *Andropogon gerardii* often dominates the lowland regions, although *Pascopyrum smithii* can be prolific if conditions are favorable. Forbs in varying density may also be present. The primary dynamics for this system include fire, climate and grazing. Fire suppression in these areas has allowed for the invasion of woody species such as *Juniperus virginiana* and *Prunus* spp. Grazing also has contributed to these changes and likewise led to a decrease of this system as overgrazing favors shortgrass and mixedgrass systems. Conversion to agriculture likewise has probably decreased the range of this system. Thus, this system likely only occurs in small patches and in scattered locations throughout the division. Large-patch occurrences are mostly isolated to slopes and swales of rolling uplands where either grazing or cultivation are more problematic.
Classification Comments: A granitic woodland association of the Wichita Mountains of Oklahoma (*Quercus fusiformis - (Quercus stellata) / Schizachyrium scoparium* Granite Woodland (CEGL004937)), formerly included here, now is included in Crosstimbers Oak Forest and Woodland (CES205.682).

- Wheatgrass - Bluestem - Needlegrass (606) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This system is found primarily on loam, moderately deep, and rich Mollisols throughout the Western Great Plains Division. These soils tend to be more mesic and deep than the majority of soils within the Western Great Plains and are more typical of the Eastern Great Plains Division. This system requires more moisture than is available from precipitation in the Western Great Plains so it occurs in valleys, on lower slopes, and sometimes on floodplains (Albertson 1937, Heitschmidt et al. 1970). Occurrences are usually medium to small.
Vegetation: The mesic, deep soils of this system allow for dominance by *Andropogon gerardii*. Other species, such as *Sorghastrum nutans, Schizachyrium scoparium, Pascopyrum smithii, Hesperostipa spartea*, and *Sporobolus heterolepis*, can also be present. In more lowland areas, *Pascopyrum smithii* can become more prevalent. Fire suppression can lead to the invasion of these areas by woody species such as *Juniperus virginiana* and *Prunus* spp.
Dynamics: Fire, climate and grazing constitute the primary dynamic processes impacting this system. Fire may have occurred as often as every 5 years, especially in the wetter eastern portions of this system's range (Landfire 2007a). This system occurred in a landscape dominated by mixedgrass and shortgrass vegetation. These systems do not have the rapid build up of litter that occurs in tallgrass prairies further east and thus do not carry fire as readily so there were fewer fires that could affect this system.

This system developed in an area occupied by vast numbers of native ungulates, notably bison (*Bison bison*) but including other species, and the grazing of these species affected species composition and the patchwork of habitat. Bison preferentially favor newly burned areas and graminoids over forbs (Coppedge and Shaw 1998, Vinton et al. 1993). On unburned sites, grazing removes live and dead vegetation, allowing more light and heat to the soil surface and increasing available moisture thus favoring species, forbs or woody plants, in the case of bison grazing, that were resilient to the effects of grazing or avoided by the grazers (Damoureyeh and Hartnett 1997).

WESTERN HIGHLAND RIM PRAIRIE AND BARRENS (CES202.352)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Deep Soil; Graminoid
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2416; ESLF 7129; ESP 1416

CONCEPT

Summary: This system includes open, fire-maintained vegetation (often called "barrens") on uplands in western middle Tennessee (USFS Subsection 223Eg and EPA Level IV Ecoregion 71f). Although parts of the region are highly dissected, extensive interfluvial areas formerly supported fire-adapted "barrens" vegetation. These barrens occur, at least in part, on Cretaceous gravels which cap Mississippian limestone strata on hills in the Tennessee counties of Dickson, Hickman, Lewis, and Lawrence. The general terrain is flat to gently sloping. Some proposed factors which have functioned to maintain the openness of this system include the droughty, gravelly soils and resulting stresses to vegetation, as well as fire. The same gravels are mapped in Land Between the Lakes, and this vegetation could be expected there (if all examples have not succeeded to woody vegetation due to lack of fire). There may be similar habitats in Kentucky, including relatively extensive areas of Tertiary age material in eastern Calloway and Marshall and southern Livingston counties. The areas are transitional between Highland Rim and Coastal Plain, but they are included in EPA Ecoregion 71f.
Classification Comments: Western Highland Rim Prairie and Barrens (CES202.352), Eastern Highland Rim Prairie and Barrens (CES202.354), Pennyroyal Karst Plain Prairie and Barrens (CES202.355), and Southern Ridge and Valley Patch Prairie (CES202.453) form a series of similar systems in the eastern Interior Highlands and adjacent Ridge and Valley.
Similar Ecological Systems:
- Cumberland Wet-Mesic Meadow and Savanna (CES202.053)
- East Gulf Coastal Plain Jackson Plain Prairie and Barrens (CES203.353)
- Eastern Highland Rim Prairie and Barrens (CES202.354)
- Pennyroyal Karst Plain Prairie and Barrens (CES202.355)
- Southern Ridge and Valley Patch Prairie (CES202.453)

Related Concepts:
- Chestnut Oak: 44 (Eyre 1980) Finer
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer

DESCRIPTION

Environment: As noted by Shanks (1958) and described by DeSelm (1989a), these barrens occur, at least in part, on Cretaceous gravels which cap Mississippian limestone strata on hills in the Tennessee counties of Dickson, Hickman, Lewis, and Lawrence; these are mapped in Miller et al. (1966). The general terrain is flat to gently sloping. An example on slopes in northwestern Davidson County (Ridgetop Barrens) is also included here (DeSelm and Chester 1993). Shanks (1958) also specifically refers to barrens on "cherty residuum, elsewhere characterized by Planosols with impeded drainage." Haywood (1959) noted extensive prairie in the southern portion of Land Between the Lakes, and DeSelm (1988) noted the existence of barrens remnants in the region, describing the substrate for non-limestone barrens of the Western Highland Rim of Tennessee as "upland over loess. silty clay loam or silty clay soils."
Vegetation: Some stands may be in a woodland or fire-suppressed forest condition, dominated by dry-site oaks such as *Quercus marilandica*, *Quercus prinus*, and/or *Quercus stellata*. These trees would become more scattered under an appropriate fire regime. In the herbaceous layer of well-managed examples of this system, *Schizachyrium scoparium* is codominant along with a variable mixture of *Andropogon gyrans*, *Andropogon ternarius*, and/or *Andropogon virginicus*. Other dominant grasses may include *Dichanthelium aciculare (= Dichanthelium angustifolium)*, *Gymnopogon brevifolius*, and *Dichanthelium dichotomum var. dichotomum (= var. ramulosum)*. Other common species may include *Symphyotrichum dumosum (= Aster dumosus)*, *Sericocarpus linifolius (= Aster solidagineus)*, *Coreopsis major*, *Eupatorium hyssopifolium*, *Eupatorium rotundifolium*, *Helianthus angustifolius*, *Liatris microcephala*, *Liatris spicata*, *Packera anonyma (= Senecio anonymus)*, *Solidago juncea*, *Solidago odora*, *Chamaecrista fasciculata*, *Chamaecrista nictitans*, *Stylosanthes biflora*, *Lobelia puberula*, *Diodia teres*, *Potentilla simplex*, *Aristida longispica*, *Calamagrostis coarctata*, *Dichanthelium dichotomum*, *Sorghastrum nutans*, *Pteridium aquilinum*, and *Smilax glauca*.
Dynamics: Past fire and grazing constitute the major dynamic processes for this region. Fires were frequent (potentially on a 5-year return interval), primarily of human origin, and are thought to have occurred in late summer to early autumn prior to European settlement. Some proposed factors which have functioned to maintain the openness of this system following the reduction of fire frequency include the droughty, gravelly soils and resulting stresses to vegetation, as well as more occasional fire. Fralish et al. (1999) noted that both post oak and chestnut oak woodlands are essentially the result of fire suppression in the barrens and historic savannas. In some areas, where the soils are particularly harsh (droughty, nutrient-poor, rocky), stands may retain an open aspect in the absence

of fire. Shanks (1958) also specifically refers to barrens on "cherty residuum, elsewhere characterized by Planosols with impeded drainage." Some of the extant examples are largely dependent on contemporary management regimes.

Component Associations:
- *Quercus marilandica / Schizachyrium scoparium - (Helianthus mollis, Silphium asteriscus, Liatris aspera)* Woodland (CEGL004756, G2)
- *Quercus prinus / Smilax* spp. Forest (CEGL005022, G4)
- *Quercus stellata / Viburnum rufidulum / Schizachyrium scoparium - (Sorghastrum nutans, Helianthus eggertii)* Woodland (CEGL004686, G2G3)
- *Schizachyrium scoparium - Andropogon (gyrans, ternarius, virginicus)* Herbaceous Vegetation (CEGL007707, G3?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506)

DISTRIBUTION

Range: This system is restricted to the Western Highland Rim of Tennessee and equivalent landforms in adjacent Alabama and Kentucky. Examples (good-condition examples are limited and of small size) are found in Dickson. Hickman, Lawrence, and Lewis counties of Tennessee (DeSelm 1988, NatureServe unpubl. data). These areas are scattered across Subsection 223Eg (Cleland et al. 2005) and EPA Level IV Ecoregion 71f (EPA 2004).

WESTERN NORTH AMERICAN BOREAL ALPINE MESIC HERBACEOUS MEADOW (CES105.131)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino; Herbaceous; Boreal [Boreal Subcontinental]; Carex bigelowii
Non-Diagnostic Classifiers: Sideslope; Toeslope/Valley Bottom
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Perennial forb grassland
National Mapping Codes: EVT 2633; ESLF 7175; ESP 1633

CONCEPT

Summary: This ecological system occurs throughout boreal Alaska on gentle slopes in subalpine and alpine environments. *Carex bigelowii* is the dominant species. Other common species may include *Luzula confusa* and lichens. Dwarf-shrubs such as *Arctostaphylos alpina, Empetrum nigrum, Salix pulchra,* and *Betula nana* are usually present, but contribute less than 25% to the canopy cover. This system may form a mosaic with dwarf- and low-shrub systems.
Classification Comments: This system is known as Boreal Alpine Herbaceous Meadow by the Alaska Natural Heritage Program. There is no species overlap between boreal and boreal transition herbaceous alpine meadow types. Slope position may also be different: *Carex macrochaeta* types usually occur on sites just above subalpine alder on straight or concave slopes.
Related Concepts:

WESTERN NORTH AMERICAN BOREAL DRY GRASSLAND (CES105.115)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Aridic; Graminoid
Non-Diagnostic Classifiers: Sideslope; Toeslope/Valley Bottom; Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2612; ESLF 7176; ESP 1612

CONCEPT

Summary: This system occurs across the boreal and boreal transition regions of Alaska on dry sideslopes or well-drained lowland sites. Soils are well-drained to excessively drained and permafrost is absent. These sites are typically dominated by grasses, though forbs may codominate on some sites. Shrub cover is less than 25%. Common species include *Festuca altaica, Festuca rubra, Calamagrostis purpurascens, Leymus innovatus (= Elymus innovatus), Artemisia frigida,* and *Achillea* spp.
Classification Comments: This system is known as Boreal Dry Meadow by the Alaska Natural Heritage Program. It does not include coastal *Leymus*-forb meadows that occur in the Aleutians, southwestern, south-central, and southeastern Alaska.
Similar Ecological Systems:

WESTERN NORTH AMERICAN SUB-BOREAL MESIC BLUEJOINT-FORB MEADOW (CES105.114)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Montane [Upper Montane]; Herbaceous
Non-Diagnostic Classifiers: Flat; Slope; Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2611; ESLF 7177; ESP 1611

CONCEPT

Summary: This ecological system occurs throughout the boreal and boreal transition regions of Alaska, and extends south and east into western Canada. Soils are typically fine-textured mineral and may be poorly drained (on flats) to well-drained (on sideslopes). In the boreal transition region, mesic *Calamagrostis canadensis* meadows often occur near treeline interspersed with subalpine tall shrub. Its elevational limit is just above the limit of tall shrubs (within 100 m). This system appears to be less common north of the Alaska Range. Mesic meadows also occur as seral stages in drained lakebeds, or after disturbance such as fire or logging. The vegetation is usually dense, with canopy height of 0.8 to 1.4 m, occasionally reaching 2 m. Species composition ranges from nearly pure stands of *Calamagrostis canadensis* to mixtures of *Calamagrostis canadensis* with forbs, such as *Chamerion angustifolium*. Forb- or fern -dominated patches also occur. Common forbs and ferns include *Heracleum maximum, Thalictrum* spp., *Veratrum viride, Angelica lucida, Athyrium filix-femina, Dryopteris expansa,* and *Equisetum arvense*. Short-term mesic meadow seral stages, such as post-fire *Chamerion angustifolium,* are considered seral stages of the forested system they replaced and not included in this description.
Classification Comments: This system is known as Boreal Transition Mesic Meadow by the Alaska Natural Heritage Program. While it undoubtedly occurs in many areas of boreal Canada, its exact distribution remains to be sorted out.
Similar Ecological Systems:
- Alaska Sub-boreal and Maritime Alpine Mesic Herbaceous Meadow (CES204.145)
- Alaskan Pacific Maritime Mesic Herbaceous Meadow (CES204.163)

Related Concepts:

- III.B.2.d - Ferns (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: This system occurs throughout the boreal and boreal transition regions of Alaska, as well as throughout western boreal Canada. Soils are typically fine-textured mineral and may be poorly drained (on flats) to well-drained (on sideslopes). In the boreal transition region, mesic *Calamagrostis canadensis* meadows often occur near treeline interspersed with subalpine tall shrub. Its elevational limit is just above the limit of tall shrubs (within 100 m). This system appears to be less common north of the Alaska Range. Mesic meadows also occur as seral stages in drained lakebeds, or after disturbance such as fire or logging.
Vegetation: The vegetation is usually dense, with canopy height of 0.8 to 1.4 m, occasionally reaching 2 m (Viereck et al. 1992). Species composition ranges from nearly pure stands of *Calamagrostis canadensis* to mixtures of *Calamagrostis canadensis* with forbs, such as *Chamerion angustifolium*. Forb- or fern -dominated patches also occur. Common forbs and ferns include *Heracleum maximum, Veratrum viride, Angelica lucida, Athyrium filix-femina, Dryopteris expansa,* and *Equisetum arvense* (Viereck et al. 1992).

DISTRIBUTION

Range: This systems occurs in the upland, lowland, and subalpine zones of the boreal transition and, less commonly, boreal regions of Alaska. It also occurs in scattered locations throughout western Canada.
Divisions: 103:C; 105:C
Nations: CA, US
Subnations: AB, AK, BC, YT
Map Zones: 68:?, 69:C, 70:C, 71:C, 72:?, 73:C, 74:C, 75:C, 76:?

WOODY WETLANDS AND RIPARIAN

ACADIAN MARITIME BOG (CES201.580)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Maritime Climate; Organic Peat (>40 cm); Dwarf-Shrub; Graminoid
Non-Diagnostic Classifiers: Oligotrophic Water; Acidic Water; Saturated Soil; >180-day hydroperiod; Moderate (100-500 yrs) Persistence; Shrubland (Shrub-dominated); Extensive Wet Flat; Depressional; Bryophyte
National Mapping Codes: ESLF 9301

CONCEPT

Summary: These ombrotrophic acidic peatlands occur along the north Atlantic Coast from downeast Maine east into the Canadian Maritimes. When these form in basins, they develop raised plateaus with undulating sedge and dwarf-shrub vegetation. *Trichophorum caespitosum* may form sedge lawns on the raised plateau. The system may also occur as "blanket bogs" over a sloping rocky substrate in extreme maritime settings; here, dwarf-shrubs and *Sphagnum* are the dominant cover. Species characteristic of this maritime setting include *Empetrum nigrum* and *Rubus chamaemorus*. Typical bog heaths such as *Kalmia angustifolia, Kalmia polifolia, Gaylussacia baccata, Ledum groenlandicum*, and *Gaylussacia dumosa* are also present. Morphological characteristics and certain coastal species distinguish these from more inland raised bogs. The distribution is primarily Canadian, and these peatlands are rare in the U.S.
Similar Ecological Systems:
- Boreal-Laurentian Bog (CES103.581)

ACADIAN-APPALACHIAN CONIFER SEEPAGE FOREST (CES201.576)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Mesotrophic Water; Seepage-Fed Sloping; Picea (glauca, mariana, rubens) - Abies; Thuja occidentalis - Fraxinus nigra
Non-Diagnostic Classifiers: Circumneutral Water; Acidic Water; Saturated Soil; Moderate (100-500 yrs) Persistence; Forest and Woodland (Treed); Isolated Wetland [Partially Isolated]; Mineral: W/ A-Horizon >10 cm; Mineral: W/ A-Horizon <10 cm; Needle-Leaved Tree
National Mapping Codes: ESLF 9344

CONCEPT

Summary: These forests occur as large-patch landscape features near the southern periphery of the boreal forest in the northeastern U.S. and adjacent Canada. They are found on gentle to moderate slopes in the colder regions of the Northern Appalachians, often adjacent to (but above) drainage channels, in settings where groundwater seepage provides constant moisture. *Thuja occidentalis* and *Picea rubens* are the typical dominants; some areas may have a prominent deciduous component. The herbaceous and bryophyte flora is typically extensive. Because of their setting, these are often not mapped as wetlands.
Classification Comments: This system may have application in other parts of the Laurentian-Acadian Division, depending on how the break is made between "wet-mesic" lowland white-cedar forests (with subsurface gleyed soils) and the white-cedar seepage forests described here.
Related Concepts:
- Cedar - Spruce Seepage Forest (Gawler and Cutko 2010) Finer
- Northern White-Cedar: 37 (Eyre 1980) Finer
- Red Spruce: 32 (Eyre 1980) Finer

Component Associations:
- *Thuja occidentalis - (Picea rubens) / Tiarella cordifolia* Forest (CEGL006175, GNR)

DISTRIBUTION

Range: Northernmost parts of New England, north and east into Canada.

ALASKA ARCTIC COASTAL SEDGE-DWARF-SHRUBLAND (CES102.211)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Polar [Polar Hyperoceanic]; Tidal / Estuarine [Haline]; Tidal / Estuarine [Oligohaline]
Non-Diagnostic Classifiers: Herbaceous; Aquic; Dwarf-Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2701; ESLF 9357; ESP 1701

CONCEPT

Summary: This system typically occurs immediately above coastal brackish meadows or tidal marshes in arctic Alaska. These are tidal deposits that are only periodically tidally flooded and typically have permafrost. It is a dominant system on the Yukon-Kuskokwim Delta, but occurs elsewhere along the arctic Alaska coast. It has >25% dwarf- and low-shrub cover and >25% herbaceous cover. Dominant dwarf-shrubs are *Empetrum nigrum, Salix fuscescens, Salix ovalifolia,* and sometimes *Betula nana*. Diagnostic herbaceous species are *Carex rariflora, Calamagrostis deschampsioides, Deschampsia caespitosa,* and *Puccinellia andersonii*. Additional species include *Dupontia fisheri, Arctagrostis latifolia, Alopecurus alpinus, Tanacetum bipinnatum (= Chrysanthemum bipinnatum),* and *Petasites frigidus*.
Classification Comments: This system is known as Dwarf Shrub by the Alaska Natural Heritage Program.

DESCRIPTION

Dynamics: This system's disturbance processes and succession have not been described.

DISTRIBUTION

Range: This system occurs along Alaska's arctic coastline, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: US
Subnations: AK
Map Zones: 67:C, 68:C, 72:C, 76:C
TNC Ecoregions: 73:C, 74:C, 75:C, 79:C

ALASKA ARCTIC DWARF-SHRUB-SPHAGNUM PEATLAND (CES102.201)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Permafrost; Lowland [Lowland]; Shrubland (Shrub-dominated); Polar [Polar Oceanic]; Acidic Soil; Organic Peat (>40 cm); Bog; Dwarf-Shrub; Sphagnum spp.
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2703; ESLF 9358; ESP 1703

CONCEPT

Summary: This ecological system occurs primarily on the Yukon-Kuskokwim Delta and the Kotzebue Sound lowlands ecoregions on flat permafrost plateaus and raised bogs. Soils are poorly drained and acidic, typically with a well-developed peat layer. Permafrost is present. Patch size is small to large. Dwarf- and low shrub cover is >25%, *Sphagnum* spp. cover is >25%, and lichen cover is <25%. The dominant dwarf-shrubs are *Betula nana* and *Ledum palustre ssp. decumbens*. Other species include *Empetrum nigrum, Chamaedaphne calyculata, Vaccinium uliginosum, Salix pulchra, Spiraea stevenii (= Spiraea beauverdiana), Vaccinium vitis-idaea, Arctostaphylos* spp., *Eriophorum* spp., *Carex aquatilis*, and *Carex microchaeta*.
Classification Comments: This system is known as Lowland Dwarf Shrub Sphagnum by the Alaska Natural Heritage Program.
Related Concepts:
- III.A.3.g - Subarctic lowland sedge-shrub wet meadow (Viereck et al. 1992) Intersecting
- III.A.3.j - Subarctic lowland sedge bog meadow (Viereck et al. 1992) Intersecting
- III.A.3.k - Subarctic lowland sedge-moss bog meadow (Viereck et al. 1992) Intersecting
- III.C.1.a - Wet bryophyte (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: This system occurs as a late-seral stage created by permafrost uplift within the thaw-pond cycle and on raised bogs due to organic matter buildup, but could also develop due to permafrost uplift outside the thaw-pond cycle. It likely persists for more than 100 years. Thaw pond succession starts with the collapse of a permafrost plateau, resulting in a wet depression often with open water. This is colonized by marsh species or *Sphagnum* spp. or a combination of both. Sedges eventually invade, and Alaska Arctic Wet Sedge-Sphagnum Peatland (CES102.200) develops. If organic matter buildup or permafrost uplift the surface, then this system may be seral to Alaska Arctic Dwarf-Shrub-Sphagnum Peatland (CES102.201). In turn, this system may be seral to Alaska Arctic Permafrost Plateau Dwarf-Shrub Lichen Tundra (CES102.202). The seral sequence may not be unidirectional, and the timeframe is unclear, possibly taking hundreds of years.

DISTRIBUTION

Range: This system occurs on the Yukon-Kuskokwim Delta and the Kotzebue Sound lowlands ecoregions of Alaska.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK
Map Zones: 68:C, 72:C, 76:C
TNC Ecoregions: 74:C, 75:C

ALASKA ARCTIC FLOODPLAIN (CES102.227)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riparian Mosaic [Trees, shrublands, meadows]; Polar [Polar Oceanic]; Riverine / Alluvial; Braided channel or stream
Non-Diagnostic Classifiers: Lowland [Lowland]; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Alluvial terrace
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2715; ESLF 9359; ESP 1715

CONCEPT

Summary: This ecological system includes active and inactive glacially- and non-glacially-fed floodplains. It is mosaiced with various floodplain wetland systems and is widespread and common. The rivers are typically braided, and floodplain terraces may be short-lived (<100 years) or last for more than a 1000 years. Soils develop on alluvium and are typically shallow and well-drained; barren alluvium is common. Permafrost is usually absent. The low- and tall-willow-dominated communities may be absent at higher elevations. Common existing vegetation types include mesic herbaceous meadow, low-tall willow shrublands, *Dryas* dwarf-shrubland, ericaceous dwarf-shrublands, and patches of *Populus balsamifera* or *Betula papyrifera*. Herbaceous species include *Chamerion latifolium* and *Lupinus* spp. Common willows include *Salix alaxensis, Salix arbusculoides, Salix richardsonii (= Salix lanata), Salix glauca*, and *Salix pulchra*. *Dryas integrifolia* dominates the *Dryas* communities, but other species may also be common, such as *Lupinus* spp., *Cassiope tetragona, Vaccinium uliginosum, Salix* spp., and *Arctostaphylos rubra*.
Classification Comments: This system is known as Floodplain by the Alaska Natural Heritage Program.

DESCRIPTION

Dynamics: Frequent river channel migration and associated flooding and fluvial processes constitute the major disturbances. *Dryas* terraces, if not eroded, eventually (possibly over 1000+ years) develop into systems no longer part of the floodplain**.**

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US

ALASKA ARCTIC LARGE RIVER FLOODPLAIN (CES102.213)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval [Short interval, Spring Flooding]; Riparian Mosaic [Trees, shrublands, meadows]; Floodplain; Lowland [Lowland]; Polar [Polar Oceanic]; Riverine / Alluvial
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2714; ESLF 9360; ESP 1714

CONCEPT

Summary: This system includes floodplains associated with two of Alaska's high-volume arctic rivers: the Yukon and Kuskokwim. It includes active (flooded frequently) and inactive floodplains (flooded infrequently) and is mosaiced with the various floodplain wetland ecological systems. The flooding regime is characterized by large spring floods at ice break-up. The active flooding zone is often several kilometers wide. Permafrost is usually absent. Patch size is matrix-forming and linear, following the river courses. These floodplains are beyond the distribution of *Picea glauca*, which is a major component of interior boreal floodplains. Species composition is diverse, as are structural characteristics. Some of the predominant vegetation types include mesic herbaceous meadows, alder and alder-willow shrublands, tall and low willow shrublands, and *Populus balsamifera*. Some of the common woody species can include *Populus balsamifera, Alnus viridis, Alnus incana ssp. tenuifolia, Salix* spp., and a number of other shrubs.
Classification Comments: This system is known as Large River Floodplain by the Alaska Natural Heritage Program.

- III.B.1.a - Seral herbs (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: Ice-scour and ice dams are important dynamics. This causes regeneration of willow carrs where scoured by ice. Some mesic sites may eventually become wetlands due to silt deposition from overbank flooding.

DISTRIBUTION

Range: This system occurs along the Yukon and Kuskokwim rivers in Alaska.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK
Map Zones: 72:C
TNC Ecoregions: 75:C

ALASKA ARCTIC PERMAFROST PLATEAU DWARF-SHRUB LICHEN TUNDRA (CES102.202)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Permafrost; Lowland [Lowland]; Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Acidic Soil; Dwarf-Shrub; Lichen
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2704; ESLF 9361; ESP 1704

CONCEPT

Summary: This system occurs on the Yukon-Kuskokwim Delta and the Kotzebue Sound lowlands ecoregions but not on the Beaufort Coastal Plain. It occurs on flat permafrost plateaus and gently sloping terrain. Soils are poorly drained and acidic, typically with a well-developed peat layer. Permafrost is present. Patch size is small to large. Dwarf- and low-shrub cover is >25% and lichen cover is >25%. Fruticose lichen species (*Cladina* and *Cladonia*) codominate with *Betula nana* and *Ledum palustre ssp. decumbens*. Other possible shrubs include *Empetrum nigrum*, *Chamaedaphne calyculata*, *Vaccinium uliginosum*, *Salix pulchra*, *Spiraea stevenii (= Spiraea beauverdiana)*, *Vaccinium vitis-idaea*, and *Arctostaphylos* spp. Graminoids usually have <10% cover and may include *Eriophorum* spp., *Carex aquatilis*, and *Carex microchaeta*.
Classification Comments: This system is known as Lowland Dwarf Shrub Lichen by the Alaska Natural Heritage Program.
Related Concepts:

- II.D.2.c - Crowberry tundra (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: This system occurs as a late-seral stage created by permafrost uplift within the thaw-pond cycle, but could also develop due to permafrost uplift outside the thaw-pond cycle. Thaw pond succession starts with the collapse of a permafrost plateau, resulting in a wet depression often with open water. This is colonized by marsh species or *Sphagnum* spp. or a combination of both. Sedges eventually invade, and Alaska Arctic Wet Sedge-Sphagnum Peatland (CES102.200) develops. If organic matter buildup or permafrost uplift the surface, then this system may be seral to Alaska Arctic Dwarf-Shrub-Sphagnum Peatland (CES102.201). In turn, this system may be seral to Alaska Arctic Permafrost Plateau Dwarf-Shrub Lichen Tundra (CES102.202). The seral sequence may not be unidirectional, and the timeframe is unclear, possibly taking hundreds of years.

DISTRIBUTION

Range: This system occurs on the Yukon-Kuskokwim Delta and the Kotzebue Sound lowlands ecoregions of Alaska.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK

ALASKA ARCTIC POLYGONAL GROUND MESIC SHRUB TUNDRA (CES102.206)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Ice-Wedge Polygons; Shrubland (Shrub-dominated); Polar [Polar Oceanic]; Dwarf-Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2700; ESLF 9362; ESP 1700

CONCEPT

Summary: Ice-wedge polygons and the thaw-lake cycle dominate the Beaufort Coastal Plain ecoregion. The ice-wedge polygons generally occur on level surfaces (0- to 2-degree slopes), and the ice wedges may be 2 m wide at the top. Polygon diameter ranges from several to more than 30 m. In addition to the Beaufort Coastal Plain, ice-wedge polygons are a common feature on level ground within foothills and mountains, on terraces, glacial drift, and lacustrine surficial deposits. This mesic shrub tundra system occurs on high-center polygons, raised areas along drainages, terraces and other mesic flat to slightly sloping sites. The combined cover of dwarf-shrubs and low shrubs is >25%, and sedge cover is typically <25%. Some tussocks may occur but are often degenerating. The open to closed shrub canopy has *Salix pulchra, Betula nana, Vaccinium vitis-idaea, Ledum palustre ssp. decumbens*, and *Cassiope tetragona*. Common herbaceous species include *Eriophorum angustifolium, Carex aquatilis*, and *Eriophorum vaginatum* (the latter is often dead). Common mosses include *Sphagnum* spp., *Hylocomium splendens*, and *Aulacomnium turgidum*. Lichens are common.

- II.D.3.a - Willow tundra (Viereck et al. 1992) Intersecting
- Moist shrub tundra on high-centered polygons map class (Jorgenson et al. 1994) Equivalent

DESCRIPTION

Dynamics: Ice-wedge polygons are formed by large ice wedges which grow in thermal contraction cracks in permafrost. High-center polygons indicate that erosion, deposition, or thawing are more prevalent than the up-pushing of the sediments along the sides of the wedge. Ice-wedge polygons are typically part of a spatially coarser thaw-lake cycle.

Most of the land on the Beaufort Coastal Plain (Nowacki et al. (2001) ecoregion 1) is polygonal ground and pond complexes. To be able to model and map polygonal ground systems in this region, first mask out lakes, ponds, floodplains and tidal marshes. Then, use only land with less than a 2-degree slope as being polygonal ground.

DISTRIBUTION

Range: This system is typically found in the lowland regions of arctic Alaska, particularly on the Beaufort Coastal Plain in northern Alaska, and the Kotzebue Sound lowlands of west-central Alaska, but it also occurs in other scattered locations of arctic Alaska where there ice-wedge processes occur.
Divisions: 102:C; 104:C

ALASKA ARCTIC POLYGONAL GROUND SHRUB-TUSSOCK TUNDRA (CES102.205)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Ice-Wedge Polygons; Shrubland (Shrub-dominated); Woody-Herbaceous; Polar [Polar Oceanic]; Shallow Soil; Silt Soil Texture; Dwarf-Shrub; Graminoid; Tussock-forming grasses
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2708; ESLF 9363; ESP 1708

CONCEPT

Summary: Ice-wedge polygons and the thaw-lake cycle dominate the Beaufort Coastal Plain ecoregion. The ice-wedge polygons generally occur on level surfaces (0- to 2-degree slopes), and the ice wedges may be 2 m wide at the top. Polygon diameter ranges from several to more than 30 m. In addition to the Beaufort Coastal Plain, ice-wedge polygons are a common feature on level ground within foothills and mountains, on glacial drift, lacustrine and floodplain terrace surficial deposits. These sites are cold, poorly drained, and underlain by mesic, silty mineral soils with a shallow surface organic layer surrounding the tussocks. Permafrost is present. Patch size is small to large. This tundra ecological system occurs primarily on high-center polygons. Their centers are mesic and dominated by tussocks and shrubs, and their perimeters are commonly wet, supporting wet sedges. *Betula nana* and *Salix pulchra* dominate the shrub layer. Other species include *Ledum palustre ssp. decumbens, Vaccinium vitis-idaea, Vaccinium uliginosum*, and *Empetrum nigrum*. *Eriophorum vaginatum* is the primary tussock-former in most sites, but *Carex bigelowii* may dominate some sites. *Calamagrostis canadensis, Arctagrostis latifolia*, and *Chamerion latifolium* may be common. Common mosses include *Sphagnum* spp., *Polytrichum strictum*, and *Hylocomium splendens*. The wet perimeters typically support *Carex aquatilis* and *Eriophorum angustifolium*.

ALASKA ARCTIC SHRUB-TUSSOCK TUNDRA (CES102.180)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Woody-Herbaceous; Polar [Polar Oceanic]; Shallow Soil; Silt Soil Texture; Dwarf-Shrub; Graminoid; Tussock-forming grasses
Non-Diagnostic Classifiers: Eriophorum vaginatum
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2693; ESLF 9364; ESP 1693

CONCEPT

Summary: Tussock shrub tundra is common in valleys and slopes throughout arctic Alaska. These sites are cold, poorly drained, and underlain by mesic, silty mineral soils with a shallow surface organic layer surrounding the tussocks. Permafrost is present. Patch size is small to matrix-forming. Tussock shrub tundra has >35% cover of sedges in a tussock growth form, and the combined cover of dwarf- and low shrubs is >25%. *Eriophorum vaginatum* is the primary tussock-former in most stands, but *Carex bigelowii* may dominate some sites. *Betula nana* and *Salix pulchra* dominate the low-shrub layer. Other species include *Ledum palustre ssp. decumbens*, *Vaccinium vitis-idaea*, *Vaccinium uliginosum*, *Empetrum nigrum*, and *Carex* spp. There are also distinctions between acidic and non-acidic tussock tundra. Acidic sites have more ericaceous shrubs and *Sphagnum* and less *Eriophorum* spp., *Betula nana*, and *Carex bigelowii*. Acidic sites also have more organic matter buildup and the tussocks tend to be larger.
Classification Comments: This system is known as Tussock Shrub Tundra by the Alaska Natural Heritage Program.
Similar Ecological Systems:
- Western North American Boreal Low Shrub-Tussock Tundra (CES105.126)

Related Concepts:
- II.C.2.a - Mixed shrub-sedge tussock tundra (Viereck et al. 1992) Intersecting
- II.C.2.b - Mixed shrub-sedge tussock bog (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: Tussock shrub tundra is common in valleys and slopes throughout arctic Alaska. These sites are cold, poorly drained, and underlain by mesic, silty mineral soils with a shallow surface organic layer surrounding the tussocks (Viereck et al. 1992). Permafrost is present. Patch size is small to matrix-forming.
Vegetation: Tussock shrub tundra has >35% cover of sedges in a tussock growth form, and the combined cover of dwarf- and low shrubs is >25%. *Eriophorum vaginatum* is the primary tussock-former in most stands, but *Carex bigelowii* may dominate some sites. *Betula nana* and *Salix pulchra* dominate the low-shrub layer. Other species include *Ledum palustre ssp. decumbens*, *Vaccinium vitis-idaea*, *Vaccinium uliginosum*, *Empetrum nigrum*, and *Carex* spp. There are also distinctions between acidic and non-acidic tussock tundra. Acidic sites have more ericaceous shrubs and *Sphagnum* and less *Eriophorum* spp., *Betula nana*, and *Carex bigelowii*. Acidic sites also have more organic matter buildup and the tussocks tend to be larger.
Dynamics: According to lake-core records, the fire-return interval is approximately 240 years on the Seward Peninsula and 1000+ years on the Beaufort Coastal Plain (J. Allen pers. comm.). These figures may apply to acidic more than non-acidic tussock tundra. Fires typically burn-off the shrub layer resulting in an herbaceous-dominated tussock system, but the shrubs often recover to their pre-fire cover within 15 years.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US

ALASKAN PACIFIC MARITIME DWARF-SHRUB-SPHAGNUM PEATLAND (CES204.165)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Permafrost; Lowland [Lowland]; Shrubland (Shrub-dominated); Temperate [Temperate Oceanic]; Acidic Soil; Organic Peat (>40 cm); Bog; Dwarf-Shrub; Sphagnum spp.
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2658; ESLF 9365; ESP 1658

CONCEPT

Summary: This ecological system is a mosaic of dwarf-shrub- and herbaceous-dominated peatlands. It includes well-developed peatlands (bogs and poor fens) in basins or on flat to gently sloping terrain. Soils are acidic and are usually saturated throughout the growing season. *Sphagnum* spp. (especially *Sphagnum fuscum*) dominate the ground layer. Shrub cover is typically low and may include *Ledum* spp., *Andromeda polifolia, Kalmia polifolia, Vaccinium oxycoccos (= Oxycoccus microcarpos), Empetrum nigrum*, and *Vaccinium uliginosum*. Other common species include *Drosera* spp., *Carex livida, Carex pluriflora, Carex pauciflora, Carex aquatilis var. dives (= Carex sitchensis), Trichophorum caespitosum*, and *Eriophorum angustifolium*. This system includes raised bogs.
Classification Comments: This system is known as Dwarf-Shrub-Sphagnum Peatland by the Alaska Natural Heritage Program. Need criteria to differentiate from fen/wet meadow for mapping.
Similar Ecological Systems:

ALASKAN PACIFIC MARITIME FLOODPLAIN FOREST AND SHRUBLAND (CES204.154)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riparian Mosaic; Floodplain; Temperate [Temperate Oceanic]
Non-Diagnostic Classifiers: Montane; Lowland; Alluvial plain; Alluvial terrace; Bank; Broad-Leaved Deciduous Tree; Braided channel or stream; Broad-Leaved Deciduous Shrub
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2655; ESLF 9366; ESP 1655

CONCEPT

Summary: This system includes glacially- and non-glacially-fed rivers and streams along the Gulf Coast of Alaska. It includes the active and inactive portions of the floodplain but not abandoned floodplains. Frequent flooding, shifting channels, and sediment deposition characterize the system. This system includes large and small channels as well as proximal outwash. Glacially-fed rivers occur primarily on the mainland, while non-glacially-fed rivers occur on both the mainland and large islands in the Gulf of Alaska. Since glacial and non-glacial floodplain types can not be mapped confidently as separate systems, they are considered one ecological system. However, vegetation composition and disturbance cycle vary depending on type of input (glacial vs. non-glacial) and proximity to the glacier, so descriptions that follow retain these distinctions. Two floodplain types are described below: glacial floodplains and non-glacial floodplains. (It may be possible to apply different successional models by region or proximity to glacier terminus.)

Classification Comments: This system is known as Floodplain Forest and Shrub by the Alaska Natural Heritage Program. Add other indicator species if possible. Model is similar to glacial floodplain, but the frequency and severity of flooding are lower. Possibly have higher percent of landscape in late-seral stages. May need different models for systems with red alder (southern vs. mid to northern). On Kodiak Island, floodplains are placed into Aleutian Floodplain Forest and Shrubland (CES105.295).

DESCRIPTION

Environment: Glacial Floodplains: These are glacially-fed rivers and streams along the Gulf Coast of Alaska; this type is uncommon on islands in the Gulf of Alaska. Frequent flooding, shifting channels, and sediment deposition characterize this type. Both large and small channels and short and long (such as the Copper River) rivers are included. Glacial outwash occurs near the terminus of the glacier. This is active proximal outwash with high flood frequency and high sediment input. Channels are scoured and braided, and the substrate is well-drained to excessively well-drained gravel or cobble.

Non-glacial Floodplains: These are non-glacially-fed floodplains occurring along the Gulf Coast of Alaska. They are common on the Alexander Archipelago but also occur on the mainland of southeast Alaska. *Picea sitchensis* is the dominant conifer. These floodplains tend to be smaller than the glacially-fed systems.

Vegetation: Glacial Floodplains: Vegetation classes are the same as early- to mid-seral floodplains, but with a lower proportion in mature forest and a higher proportion in barren and early-seral stages. Wetland development is minimal. Further downstream (distal outwash), vegetation dominance on the floodplain depends on seral stage and frequency of flooding. Low benches are dominated by shrub, seedling, and herbaceous species such as *Alnus viridis ssp. sinuata, Salix alaxensis,* and *Salix* spp. Mid-bench vegetation features shrub types and early-seral forests (*Picea sitchensis, Alnus rubra, Populus balsamifera*). High bench types include mature forests with a more diverse shrub understory (*Picea sitchensis, Tsuga heterophylla, Oplopanax horridus, Rubus spectabilis,*

Vaccinium ovalifolium, Menziesia ferruginea, and *Lysichiton americanus* (in poorly drained inclusions)). Extensive wetlands may develop on the low-angle floodplains. *Populus balsamifera* does not occur commonly on the islands of southeast Alaska, and is more closely linked with larger rivers with at least some glacial input.

Non-glacial Floodplains: *Populus balsamifera* is not common (as it is on the glacially-fed systems). *Alnus rubra* or *Alnus viridis ssp. sinuata* may be common in early-seral stands. Floodplain wetlands are common, but small patch compared to those on large, distal outwash plains. *Alnus rubra* is more common on the outer islands of southeast Alaska than it is on the mainland.

Component Associations:
- *Picea sitchensis - Alnus rubra / Rubus spectabilis* Woodland (CEGL003253, G3)
- *Picea sitchensis - Populus balsamifera ssp. trichocarpa / Oplopanax horridus* Forest (CEGL003278, G3)
- *Picea sitchensis - Populus balsamifera ssp. trichocarpa / Orthilia secunda* Woodland (CEGL003280, G3)
- *Picea sitchensis - Populus balsamifera ssp. trichocarpa* Woodland (CEGL003281, G4Q)
- *Picea sitchensis / Oplopanax horridus - Rubus spectabilis* Forest (CEGL003256, G4)
- *Picea sitchensis / Oplopanax horridus* Temporarily Flooded Forest (CEGL003258, G5)
- *Populus balsamifera ssp. trichocarpa / Oplopanax horridus* Woodland (CEGL003284, G3)
- *Populus balsamifera ssp. trichocarpa / Rubus spectabilis* Woodland (CEGL003283, G3)

DISTRIBUTION

Range: This system occurs from along the Gulf Coast of Alaska, but not on Kodiak Island, south through southeastern Alaska.
Divisions: 204:C
Nations: US
Subnations: AK
Map Zones: 77:C, 78:C
TNC Ecoregions: 69:C, 70:C

ALASKAN PACIFIC MARITIME MOUNTAIN HEMLOCK PEATLAND (CES204.156)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Bog and Fen Mosaic; Sideslope; Temperate [Temperate Oceanic]; Organic Peat (>40 cm); Tsuga mertensiana
Non-Diagnostic Classifiers: Picea sitchensis; Chamaecyparis nootkatensis
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2659; ESLF 9367; ESP 1659

CONCEPT

Summary: This ecological system is a mosaic of dwarf-tree dominated communities (*Tsuga mertensiana* (more common), *Cupressus nootkatensis*, or *Picea sitchensis*), and dwarf-shrub- and herbaceous-dominated peatland communities. It typically occurs on sloping terrain and may develop on fairly steep sideslopes in areas with very high rainfall and low permeability (such as Prince William Sound and Kenai Fjords). Stunted *Tsuga mertensiana* (more common), *Chamaecyparis nootkatensis (= Cupressus nootkatensis)*, or *Picea sitchensis* may be present. Shrubs include *Vaccinium uliginosum, Vaccinium caespitosum*, and *Empetrum nigrum*. Common herbaceous species include *Nephrophyllidium crista-galli, Trichophorum caespitosum, Dodecatheon pulchellum, Geum calthifolium, Cornus canadensis, Carex pauciflora, Carex anthoxanthea*, and *Eriophorum angustifolium*. *Sphagnum* spp. are usually abundant in the ground layer. This system occurs at higher elevations (usually above 500 m) in the southern portion of its range (southeastern Alaska and British Columbia).
Classification Comments: This system is known as Mountain Hemlock Peatland by the Alaska Natural Heritage Program.
Similar Ecological Systems:
- North Pacific Bog and Fen (CES204.063)

ALASKAN PACIFIC MARITIME POORLY DRAINED CONIFER WOODLAND (CES204.315)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Forest and Woodland (Treed); Temperate [Temperate Oceanic]; Organic Peat (>40 cm); Needle-Leaved Tree; Tsuga mertensiana
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2681; ESLF 9368; ESP 1681

CONCEPT

Summary: This ecological system occurs on low to mid elevations on rolling terrain, benches, and gentle slopes with restricted drainage from Kenai Fjords through southeast Alaska. Soils may be shallow to deep, are poorly drained, and usually have a thick organic layer or some peat development. In some places, stands are often a fine mosaic of peatlands and better-drained inclusions. These are low-productivity sites that are intermediate between shore pine or mountain hemlock peatland sites and productive forest systems. The forest canopy is open (less than 45% cover), and trees often show signs of stress such as spike-top (especially cedar) or chlorotic foliage (especially spruce). Standing dead trees are common. In the north, paludification on these sites may lead to conversion from mountain hemlock to mountain hemlock peatland over long time scales. Overstory trees may include several of the following species: *Tsuga heterophylla, Tsuga mertensiana* (often alone or with *Picea sitchensis* in the subpolar rainforest zone), *Thuja plicata* (southern portion of the Alaska distribution only), and *Chamaecyparis nootkatensis (= Cupressus nootkatensis). Picea sitchensis* and *Pinus contorta* may also be present but are not dominant. Common shrubs include *Vaccinium ovalifolium, Gaultheria shallon* (southern portion of the Alaska distribution only), and *Elliottia pyroliflorus*. Common understory species include *Nephrophyllidium crista-galli, Thelypteris quelpaertensis, Phegopteris connectilis, Trichophorum caespitosum, Carex anthoxanthea, Carex pluriflora, Carex stylosa, Eriophorum* spp., *Lysichiton americanus*, and *Sphagnum* spp.
Classification Comments: This system combines those known as Poorly Drained Mountain Hemlock and Poorly Drained Conifer by the Alaska Natural Heritage Program. This system includes all mixed conifer types and low-productivity forests in the Western Hemlock - Redcedar and Western Hemlock - Alaska Cedar types. We combined open-canopied *Tsuga mertensiana - Cupressus nootkatensis* in this system. This system may be a good fit for both red-cedar and yellow-cedar types that are classified as "unproductive; volume class 4 and under."
Similar Ecological Systems:
- North Pacific Hardwood-Conifer Swamp (CES204.090)

Related Concepts:
- I.A.1.c - Sitka spruce-western hemlock (Viereck et al. 1992) Intersecting
- I.A.2.c - Mountain hemlock (open) (Viereck et al. 1992) Intersecting
- I.A.2.d - Mixed conifer (Viereck et al. 1992) Finer

DESCRIPTION

Environment: This system is common on rolling terrain, benches, and gentle slopes with restricted drainage. Soils are poorly drained and usually have a thick organic layer.
Dynamics: This system represents a topoedaphic climax which is relatively stable over time. Short-term succession occurs from single tree mortality from a variety of causes. Tree regeneration frequently occurs on raised organic microsites on the remains of previous trees. Tree growth is generally very slow. Longer term succession is probably influenced by climatic patterns that dictate drainage, either favoring poorer drainage, increased tree mortality, and more open canopy; or, improved drainage, greater tree growth, and a more closed canopy. These patterns can also favor individual tree species based on their tolerance or intolerance of wet soils. The widespread yellow-cedar decline, which covers 200,000 ha of this system in southeastern Alaska, is an example of a climate-induced tree death that has resulted in a composition shift away from yellow-cedar due to this mortality (Hennon et al. 2008).

Component Associations:
- *Tsuga heterophylla - Chamaecyparis nootkatensis / Vaccinium ovalifolium / Lysichiton americanus* Forest (CEGL003240, G3)
- *Tsuga heterophylla - Thuja plicata / Vaccinium ovalifolium / Lysichiton americanus* Forest (CEGL003223, G5)

ALASKAN PACIFIC MARITIME SHORE PINE PEATLAND (CES204.164)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Bog and Fen Mosaic; Temperate [Temperate Oceanic]; Deep Soil; Organic Peat (>40 cm); Pinus contorta
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2657; ESLF 9369; ESP 1657

CONCEPT

Summary: This ecological system is a mosaic of shore pine-, dwarf-shrub- and herbaceous-dominated peatland communities. It includes well-developed peatlands on flat, rolling, or sloping terrain. Soils are poorly drained with deep organic layers. Trees are usually stunted and the tree canopy typically has less than <30% cover. Common species include *Pinus contorta, Chamaecyparis nootkatensis (= Cupressus nootkatensis), Empetrum nigrum, Kalmia, Ledum* spp., *Vaccinium uliginosum, Carex aquatilis var. dives (= Carex sitchensis), Carex pluriflora, Carex pauciflora, Carex livida, Trichophorum caespitosum, Eriophorum angustifolium, Sanguisorba menziesii*, and *Cornus canadensis*. *Sphagnum* spp. dominate the moss layer. This system includes a range of canopy structures and compositions from mixed conifer peatlands on sideslopes and benches with *Chamaecyparis nootkatensis, Tsuga mertensiana, Tsuga heterophylla*, and *Pinus contorta*, to peatlands on level ground with scrub *Pinus contorta*.
Classification Comments: This system is known as Shore Pine Peatland by the Alaska Natural Heritage Program. We discussed splitting out forest and non-forest phases in Juneau, but decided to keep as one type. Do we still need to describe a sedge bog for southeast (we have one in north)? Use 10% trees to get here, but can have non-forested inclusions. Banner et al. (1988) describe this *Pinus contorta* peatland type as a "slope bog."
Similar Ecological Systems:
- North Pacific Bog and Fen (CES204.063)

ALASKAN PACIFIC MARITIME SHRUB AND HERBACEOUS FLOODPLAIN WETLAND (CES204.155)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Bog and Fen Mosaic; Floodplain; Temperate [Temperate Oceanic]
Non-Diagnostic Classifiers: Montane; Lowland; Alluvial plain; Alluvial terrace; Bank; Braided channel or stream; Broad-Leaved Deciduous Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2656; ESLF 9370; ESP 1656

CONCEPT

Summary: Floodplain wetlands occur within the active and inactive portions of floodplain systems. Wetlands develop on poorly drained deposits, oxbows, and abandoned channels and are often mosaiced with well-drained floodplain vegetation. Frequent river channel migration and associated flooding and fluvial processes constitute the major disturbances. Wetland succession and species composition are variable due to diverse environmental conditions such as water depth, substrate, and nutrient input. Floodplain wetland vegetation includes the following classes: aquatic bed, freshwater marsh, fen, wet low shrub, and tall-shrub swamp. These have been described as unique systems in this classification, but because floodplain wetland dynamics are different from wetland dynamics outside the floodplain, we will consider floodplain wetlands a distinct system, and model succession accordingly.
Classification Comments: This system is known as Floodplain Wetland by the Alaska Natural Heritage Program.

ALASKAN PACIFIC MARITIME WET LOW SHRUBLAND (CES204.157)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Lowland; Shrubland (Shrub-dominated); Temperate [Temperate Oceanic]; Organic Peat (>40 cm); Muck; Myrica gale, Vaccinium uliginosum
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2660; ESLF 9371; ESP 1660

CONCEPT

Summary: This wetland system typically occurs as a ring on the outer edge of peatlands or on uplifted tidal marshes that are relatively wet but no longer tidally influenced. It is a minor yet widespread system wherever mature peatlands and uplifted tidal marshes occur, such as the Copper River Delta and Yakutat Forelands. It also occurs on old lakebeds, drained beaver ponds, wet depressions, and the edge of tidal marshes. Soils are saturated for at least a portion of the growing season, and generally have a wet organic layer of variable depth (8 cm to 1 m deep) over silt, sand or gravel. The shrub layer is dominated by *Myrica gale* and/or *Vaccinium uliginosum*. In Katmai National Park and Preserve, *Myrica gale* is the dominant shrub, but *Betula nana* or *Salix barclayi* may also codominate. Species richness is often high and composition is variable. Common associated species may include *Alnus viridis ssp. sinuata, Kalmia microphylla, Carex pauciflora, Carex livida, Carex aquatilis var. dives (= Carex sitchensis), Carex pluriflora, Carex viridula ssp. viridula, Trichophorum caespitosum, Eriophorum angustifolium, Equisetum variegatum, Drosera rotundifolia, Sanguisorba canadensis, Sanguisorba officinalis, Calamagrostis canadensis*, and *Rubus arcticus*. *Sphagnum* spp. may be abundant in the ground layer.
Classification Comments: This system is known as Wet Low Shrub by the Alaska Natural Heritage Program. Not seen in the Stikine valley, not in Kenai Fjords.
Related Concepts:
- *Myrica gale* (Boggs et al. 2003) Finer
- II.C.2.e - Ericaceous shrub bog (Viereck et al. 1992) Intersecting
- II.C.2.i - Willow-graminoid shrub bog (Viereck et al. 1992) Intersecting
- II.C.2.j - Sweetgale-graminoid bog (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: This wetland system typically occurs as a ring on the outer edge of peatlands or on uplifted tidal marshes that are relatively wet but no longer tidally influenced. It is a minor yet widespread system wherever mature peatlands and uplifted tidal marshes occur, such as the Copper River Delta and Yakutat Forelands. It also occurs on old lakebeds, drained beaver ponds, wet depressions, and the edge of tidal marshes. Soils are saturated for at least a portion of the growing season, and generally have a wet organic layer of variable depth (8 cm to 1 m deep) over silt, sand or gravel.
Vegetation: The shrub layer is dominated by *Myrica gale* and/or *Vaccinium uliginosum*. In Katmai National Park and Preserve, *Myrica gale* is the dominant shrub, but *Betula nana* or *Salix barclayi* may also codominate. Species richness is often high and composition is variable. Common associated species may include *Alnus viridis ssp. sinuata, Kalmia microphylla, Carex pauciflora, Carex livida, Carex aquatilis var. dives (= Carex sitchensis), Carex pluriflora, Carex viridula ssp. viridula, Trichophorum caespitosum, Eriophorum angustifolium, Equisetum variegatum, Drosera rotundifolia, Sanguisorba canadensis, Sanguisorba officinalis, Calamagrostis canadensis*, and *Rubus arcticus*. *Sphagnum* spp. may be abundant in the ground layer.

Component Associations:
- *Myrica gale / Carex (aquatilis var. dives, utriculata)* Shrubland (CEGL003376, G3)

DISTRIBUTION

Range: This system occurs from the region of the eastern Alaska Peninsula, Katmai National Park and Preserve, east and south throughout southeastern Alaska. However it does not occur on Kodiak Island.
Divisions: 204:C
Nations: US
Subnations: AK
Map Zones: 76:C, 77:C, 78:C
TNC Ecoregions: 69:C, 70:C, 72:C

ALEUTIAN FLOODPLAIN FOREST AND SHRUBLAND (CES105.295)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riparian Mosaic [Trees, shrublands, meadows]; Boreal [Boreal Oceanic]; Unconsolidated; Populus balsamifera
Non-Diagnostic Classifiers: Very Short Flooding Interval [Short interval, Spring Flooding]; Floodplain; Outwash plain
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2728; ESLF 9372; ESP 1728

CONCEPT

Summary: This floodplain system includes active and inactive forested floodplains and outwash plains, and is mosaiced with Aleutian Floodplain Wetland (CES105.296). Forested floodplains and outwash plains are widespread on Kodiak Island and the eastern Alaska Peninsula, but absent from the Aleutian Islands. The substrate is typically well-drained sand or cobble alluvium, although finer silts and clays are found on higher terraces, on distal floodplains, and in lower energy systems. Permafrost is absent. Patch size is small to large and often linear. These are rivers that always have a tree-dominated component. The primary existing vegetation types are: tall willow, alder (*Alnus viridis ssp. sinuata*), mesic herbaceous meadows on the younger deposits, and cottonwood-poplar (*Populus balsamifera* or *Populus balsamifera ssp. trichocarpa*) on the older sites. The cottonwood-poplar stands often have an understory of tall willow, *Calamagrostis canadensis*, ferns and scattered forbs. Floodplains dominated by volcanic ash deposits, the largest being the Katmai River floodplain, are included.
Classification Comments: This system is known as Floodplain Forest and Shrub by the Alaska Natural Heritage Program. This system does not go much farther west than Katmai National Park and Preserve which is about 75 miles into ecoregion 27 (Nowacki et al. 2001). Smaller rivers and streams farther west where the trees are no longer found are classified into Aleutian Shrub and Herbaceous Meadow Floodplain (CES105.283). Consider merging into maritime floodplain system.

ALEUTIAN FLOODPLAIN WETLAND (CES105.296)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Bog and Fen Mosaic; Boreal [Boreal Oceanic]
Non-Diagnostic Classifiers: Very Short Flooding Interval [Short interval, Spring Flooding]; Floodplain; Oxbow; Pond; Backswamp; Broad-Leaved Deciduous Shrub; Forb; Aquatic Herb; Graminoid
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2729; ESLF 9373; ESP 1729

CONCEPT

Summary: Floodplain wetlands occur within the active and inactive portions of the floodplain systems ("floodplain forest and shrub" and "floodplain herbaceous meadow and shrub"). Wetlands develop on poorly drained deposits, oxbows, and abandoned channels, and are often mosaiced with well-drained floodplain vegetation. River channel migration, flooding and other fluvial processes constitute the major disturbance in this system. Wetland succession and species composition is variable due to diverse environmental conditions such as water depth, substrate, and nutrient input. This floodplain wetland system includes the following existing vegetation types: freshwater aquatic beds, freshwater marshes, wet meadow and herbaceous peatland - complex, and Aleutian Mesic-Wet Willow Shrubland (CES105.148). These have been described as unique systems in this classification, but because floodplain wetland dynamics are different from wetland dynamics outside the floodplain, floodplain wetlands are considered a distinct system, and model succession accordingly. Each type, however, has the same species composition as its correspondingly named system.
Classification Comments: This system is known as Floodplain Wetland by the Alaska Natural Heritage Program.

ALEUTIAN SHRUB AND HERBACEOUS MEADOW FLOODPLAIN (CES105.283)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riparian Mosaic; Boreal [Boreal Oceanic]
Non-Diagnostic Classifiers: Floodplain; Outwash plain
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2727; ESLF 9374; ESP 1727

CONCEPT

Summary: This ecological system includes active and inactive unforested floodplains and outwash plains, and is mosaiced with Aleutian Floodplain Wetland (CES105.296). Small unforested floodplains and outwash plains are widespread in the Aleutian Islands and Alaska Peninsula. The substrate is typically well-drained sand or cobble alluvium, although finer silts and clays are found on higher terraces, on distal floodplains, and in lower energy systems (capped by an organic mat). Permafrost is absent. Patch size is small to large and often linear. These floodplains have several different kinds of plant communities, including shrublands dominated by tall or low willow, or alder (*Alnus viridis ssp. sinuata*), and mesic herbaceous meadows, or *Leymus mollis* grasslands. The tall willow, alder and mesic herbaceous types tend to dominate low-elevation floodplains on Kodiak Island and the Alaska Peninsula. The mesic herbaceous and *Leymus mollis* existing vegetation types dominate the Aleutian Island floodplains. *Calamagrostis* spp. is the dominant mesic herbaceous species, and others include *Athyrium filix-femina, Leymus mollis, Gymnocarpium dryopteris, Geranium richardsonii, Fritillaria camschatcensis, Heracleum maximum,* and *Chamerion angustifolium ssp. angustifolium*. Floodplains dominated by volcanic ash deposits are included.
Classification Comments: This system is known as Floodplain Herbaceous Meadow and Shrub by the Alaska Natural Heritage Program.

ATLANTIC COASTAL PLAIN BLACKWATER STREAM FLOODPLAIN FOREST (CES203.247)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial [Blackwater]
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9322

CONCEPT

Summary: This Atlantic Coastal Plain system, which is apparently most abundant in the Carolinas, occurs in floodplains of small streams that carry little mineral sediment (blackwater streams). These streams have their headwaters in sandy portions of the Coastal Plain. The water is usually strongly stained by tannins but has little suspended clay and is not turbid. Depositional landforms may be absent or present only in limited variety and of small size. Soils are usually strongly acidic. Periodicity of flooding ranges from long (semipermanent) in the wettest portions to short in higher gradient streams. Some small blackwater streams have most of their flow from sandhill seepage and have limited fluctuation in water levels. Vegetation varies from north to south, but generally consists almost entirely of forests of wetland trees, but occasional, small shrubby sloughs may also be present. A variety of tree species may be present; wetter examples (especially toward the northern range limits of this system) are often strongly dominated by *Taxodium distichum* and *Nyssa biflora*. Other examples have mixtures of these species with *Quercus* spp. and other bottomland hardwoods tolerant of blackwater conditions. Species richness ranges from low to moderate, but is lower than in comparable brownwater systems. Flooding is an important ecological factor in this system and may be the most important factor separating it from adjacent systems. Flooding brings nutrients and excludes non-flood-tolerant species. Unlike river systems, flooding tends to be variable and of shorter duration.

Classification Comments: The distinction between brownwater and blackwater streams is sometimes problematic. A number of plant species are characteristic of brownwater floodplains and not blackwater. Well-developed blackwater streams may be confined to areas with primarily sandy soils. The boundary between systems based on river/stream size is necessarily somewhat arbitrary, but is based on significant differences which correspond with river size. Small streams have small watersheds, which tend to lead to more irregular flooding. Depositional landforms are small enough that they do not differentiate communities well, and communities tend to have more of a mixture of species that are segregated on the larger floodplains. The boundary between this system and Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252) may be somewhat gradual. It should be based on the predominance of seepage influence over flooding influence, but vegetational differences may also be partly determined by fire regime. Southern Coastal Plain Spring-run Stream Aquatic Vegetation (CES203.275) shares many characteristics with this system, but differs in having calcareous water and more steady flows.

DESCRIPTION

Environment: Examples of this system occur in floodplains of small streams of the Atlantic Coastal Plain that carry little mineral sediment (blackwater streams). These streams occur in low areas within sandy portions of the Coastal Plain (Smock and Gilinsky 1992). The water is usually strongly stained by tannins but has little suspended clay and is not turbid. Depositional landforms may be absent or may be present in limited variety and of small size. Soils are generally sandy in drier portions of the floodplain, mucky in wetter portions, or may be uniform organic soils. Soils are usually strongly acidic, but spring-fed rivers or streams may have local components with calcareous water and non-acidic soils. Flooding ranges from semipermanent in the wettest floodplains to intermittent and short in slightly higher areas and along higher gradient streams. Some small blackwater streams near the Fall-line Sandhills have most of their flow from sandhill seepage and have limited fluctuation in water levels, but other blackwater stream channels may dry out during the late summer. In these cases, water tables are not far below the channel, and are high enough that the deeper depressions

may still hold water (Smock and Gilinsky 1992). Sediment oxygen demand is high in blackwater swamp areas which have long-duration flooding and high amounts of total organic carbon in the soil and sediments. Evidence suggests that blackwater streams may naturally be low in dissolved oxygen (Todd et al. 2010).

The fluvial features of riverine floodplains occur less frequently along small streams. These features, such as river terraces, oxbows, alluvial flats, point bars, and streamside levees, may occur but on a smaller scale and sometimes poorly developed. Fine-scale alluvial floodplain features may be abundant. In pre-European settlement forests, community diversity in these streamside systems was much more complex than in the modified landscapes of today. Fire and beaver activity created a mosaic whose elements included canebrakes, beaver ponds and grass-sedge meadows in abandoned beaver clearings, as well as the streamside zones and mixed hardwood and/or *Pinus* spp. forests that make up more than 95% of the cover that exists today. The most prominent evergreen south of Virginia is the shade-intolerant *Pinus taeda*, which manages to maintain itself by reproducing in larger (multi-tree) treefall gaps.
Vegetation: Vegetation consists almost entirely of forests of wetland trees. Wetter examples are strongly dominated by *Taxodium distichum* and *Nyssa biflora*. Other examples have mixtures of these species with *Quercus* spp. and other bottomland hardwoods tolerant of blackwater conditions. Except in the very wet examples, understory, shrub, and herb layers are generally well-developed, and woody vines are also prominent. Species richness ranges from low to moderate but is lower than in comparable brownwater systems.
Dynamics: Flooding is an important ecological factor in this system and may be the most important factor separating it from adjacent systems. Flooding brings nutrients and excludes non-flood-tolerant species. Unlike river systems, flooding tends to be variable and of shorter duration. It is unclear how important aquatic fauna are when the system is flooded, but they may be important. The small flows, low gradient, and binding of sediment by vegetation limit channel shifts and sediment movement, but floods may cause local disturbance by scouring. The areas flooded for the longest durations tend to have accumulations of organic sediments which deplete levels of aquatic dissolved oxygen (Todd et al. 2010). Most of these forests would exist naturally as multi-aged old-growth forests driven by gap-phase regeneration. Windthrow is probably the most important cause of canopy gaps. Fire is probably more important than in larger river systems, because distances to uplands are short and because stream channels and sloughs are smaller and less effective as firebreaks. However, most of the vegetation is not very flammable and usually will not carry fire. Some of these areas apparently were once canebrakes, which presumably were maintained by periodic fire.

Fire-return interval varied highly in this system. Except in canebrakes, most fires were very light surface fires, creeping in hardwood or pine litter with some thin, patchy cover of bottomland grasses such as *Chasmanthium laxum* and *Chasmanthium latifolium*. Flame lengths are typically 15 to 30 cm (6-12 inches) (Landfire 2007a). Even so, fire-scarred trees can be found in most small stream sites except in the wettest microsites. Stand-replacement fires are unknown in this type. Except where Native American burning was involved, fires likely occurred primarily during drought conditions and then often only when fire spread into bottomlands from more pyrophytic uplands. Trees may be partially girdled by fire in duff, followed by bark sloughing. While fire rarely killed the tree, this allowed entry of rot, which, in the moist environment, often resulted in hollow trees, providing nesting and denning habitat for many species of birds and animals. Surface fires occurred on a frequency ranging from about 3 to 8 years in streamside canebrake, streamside hardwood/canebrake, or pine, to 25 years or more in hardwood litter. Low areas having a long hydroperiod, islands, and areas protected from fire by backswamps and oxbows were virtually fire-free. Fire effects were largely limited to top-kill of shrubs and tree saplings less than 5 cm (2 inches) diameter, and the formation of hollow trees.

The distinctive dynamics of stream flooding and protected topographic position dominate the distinctive vegetation of this system. The small watersheds and sometimes higher gradients on these streams may limit floods to fairly short duration. Flooding is most common in the winter, but may occur in other seasons. The sorting of plants by depositional landforms of different heights suggest that wetness or depth of flood waters has significance. In higher gradient streams, flood waters have significant energy. Scouring and reworking of sediment make up an important factor on the streambanks, and channels may occasionally change course. In addition to disturbance, floods bring nutrient input, deposit sediment and disperse plant seeds. However, because of the limited sediment transport, nutrient input is less in blackwater stream systems than in other floodplains. Stream flooding rarely leads to canopy tree mortality.

Component Associations:
- *Betula nigra - Quercus laurifolia - Taxodium (distichum, ascendens) / Crataegus aestivalis* Forest (CEGL004282, G2G3)
- *Chamaecyparis thyoides - (Liriodendron tulipifera) / Lyonia lucida* Forest (CEGL007563, G2)

- *Taxodium distichum - Nyssa biflora / Fraxinus caroliniana / Lyonia lucida* Forest (CEGL004733, G3G4)
- *Taxodium distichum - Nyssa ogeche* Forest (CEGL003841, G3G4)

Spatial Characteristics

Spatial Summary: Generally a small-patch system, with narrow bands or dendritic patches interspersed with other systems.
Size: Occurs in narrow bands, from a few hundred feet to possibly as much as a mile in width, and often several to many miles long. Natural limitations on development and conversion often result in contiguous patches that may be hundreds or even thousands of acres. However, because of relatively easy accessibility compared to larger floodplains, patches of mature vegetation are often small.
Adjacent Ecological Systems:
- Atlantic Coastal Plain Small Brownwater River Floodplain Forest (CES203.250)
- Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252)
- Southeastern Coastal Plain Cliff (CES203.398)
- Southern Atlantic Coastal Plain Tidal Wooded Swamp (CES203.240)

Adjacent Ecological System Comments: May be associated with a variety of systems, especially upland or wetland longleaf pine systems and Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252). Most naturally connect downstream to Atlantic Coastal Plain Small Brownwater River Floodplain Forest (CES203.250) or to Southern Atlantic Coastal Plain Tidal Wooded Swamp (CES203.240).

Distribution

Range: This system is potentially found throughout the Atlantic Coastal Plain north to about the James River in Virginia, but it is most abundant in North Carolina and South Carolina.
Divisions: 203:C
Nations: US
Subnations: FL, GA, NC, SC, VA

ATLANTIC COASTAL PLAIN BROWNWATER STREAM FLOODPLAIN FOREST (CES203.248)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial [Brownwater]
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9320

CONCEPT

Summary: This Atlantic Coastal Plain ecological system ranges from southern Virginia (south of the James River) to Georgia on floodplains of smaller streams that carry significant mineral sediment (brownwater or redwater streams). These streams have their headwaters in the Piedmont, Blue Ridge, or other interior regions, or in portions of the Coastal Plain where fine-textured sediment predominates. The water generally carries substantial amounts of silt and clay. Depositional landforms, at least a natural levee, are often distinctly present but are fairly small relative to the scale of communities and help create some variation in duration of flooding and nutrient input. Soils are generally fertile and not strongly acidic. Flooding is generally seasonal but may range to nearly semipermanent. Vegetation consists almost entirely of forests of wetland trees. Wetter examples are strongly dominated by *Taxodium distichum* and *Nyssa* spp. Other examples have mixtures of these species with *Quercus* spp. and other bottomland hardwoods. Except in the very wet examples, understory, shrub and herb layers are generally well-developed and woody vines are also prominent. Flooding is an important ecological factor in this system and may be the most important factor separating it from adjacent systems. Flooding brings nutrients and excludes non-flood-tolerant species. In contrast to larger river systems, the flooding in this system tends to be variable and of shorter duration.
Classification Comments: The distinction between brownwater and blackwater streams is sometimes problematic. A number of plant species are characteristic of brownwater floodplains and not blackwater. Well-developed blackwater streams may be confined to areas with primarily sandy soils. The boundary between systems based on river/stream size is necessarily somewhat arbitrary, but is based on significant differences which correspond with river size. Small streams have small watersheds, which tend to lead to more irregular flooding. Depositional landforms are small enough that they do not differentiate communities well, and communities tend to have more of a mixture of species that are segregated on the larger floodplains.

This system as defined covers a large geographic range. There are some significant biogeographic differences across this range, leading to a large number of associations. However, more plant species are shared across the region in this system than in most other systems in the region.
Similar Ecological Systems:
- Northern Atlantic Coastal Plain Riverine Peat Swamp (CES203.070)
- Southern Atlantic Coastal Plain Large River Floodplain Forest (CES203.066)
- Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242)

DESCRIPTION

Environment: Occurs on floodplains of smaller streams that carry significant mineral sediment (brownwater or redwater streams). These streams have their headwaters in the Piedmont, Blue Ridge, Interior Plateaus, or in portions of the Coastal Plain where fine-textured sediment predominates. The water generally carries substantial amounts of silt and clay. Depositional landforms, at least a natural levee, are often distinctly present but are fairly small relative to the scale of communities. They create some variation in duration of flooding and nutrient input. Soil texture varies from sandy to clayey, often in a fine mosaic. Soils are generally fertile and not strongly acidic. Flooding is generally seasonal, but may range to nearly semipermanent.
Vegetation: Vegetation consists almost entirely of forests of wetland trees. Wetter examples are strongly dominated by *Taxodium distichum* and *Nyssa* spp. Other examples have mixtures of these species with *Quercus* spp. and other bottomland hardwoods. Except in the very wet examples, understory, shrub, and herb layers are generally well-developed, and woody vines are also prominent. Some canopy trees may include *Acer rubrum, Acer saccharinum, Betula nigra, Carya illinoinensis, Celtis laevigata, Liquidambar styraciflua, Liriodendron tulipifera, Nyssa aquatica, Nyssa biflora, Pinus taeda, Platanus occidentalis, Quercus laurifolia, Quercus*

michauxii, Quercus phellos, Salix caroliniana, and *Taxodium distichum*. Some shrubs and small trees may include *Alnus serrulata, Arundinaria gigantea ssp. tecta, Carpinus caroliniana, Fraxinus caroliniana, Ilex opaca, Itea virginica, Leucothoe racemosa, Sabal minor*, and *Serenoa repens*. Herbs may include *Boehmeria cylindrica, Commelina virginica, Leersia lenticularis*, and *Onoclea sensibilis*.

Dynamics: Flooding is the most important ecological factor in this system. Frequency and duration of flooding determines the occurrences of different associations and separates the system from other kinds of wetlands. Flooding brings nutrients and excludes non-flood-tolerant species. When flooded, the system has a substantial aquatic faunal component, with high densities of invertebrates, and may play an important role in the life cycle of fish in the associated river. Unusually long or deep floods may stress vegetation or act as a disturbance for some species. Larger floods cause local disturbance by scouring and depositing sediment along channels, and occasionally causing channel shifts. However, the low gradient and binding of sediment by vegetation generally makes these processes much slower and less frequent than in river systems of most other regions. Except for primary successional communities such as bars, most forests exist naturally as multi-aged old-growth forests driven by gap-phase regeneration. Windthrow is probably the most important cause of gaps. Fire is probably more important than in larger river systems, because distances to uplands are short and because stream channels and sloughs are smaller and less effective as firebreaks. However, most of the vegetation is not very flammable and usually will not carry fire. Some of these areas apparently were once canebrakes, which presumably were maintained by periodic fire.

Component Associations:

- *Acer saccharinum / Leersia lenticularis - Commelina virginica* Forest (CEGL007727, G3?)
- *Betula nigra - Platanus occidentalis / Alnus serrulata / Boehmeria cylindrica* Forest (CEGL007312, G4G5)
- *Liquidambar styraciflua - Liriodendron tulipifera / Onoclea sensibilis* Forest (CEGL007329, G4)
- *Nyssa aquatica* Forest (CEGL002419, G4G5)
- *Pinus taeda - Quercus hemisphaerica / Osmanthus americanus / Ilex glabra* Woodland (CEGL003619, G2)
- *Quercus (phellos, palustris, michauxii) - Liquidambar styraciflua / Cinna arundinacea* Forest (CEGL006605, G3G4)
- *Quercus michauxii / Carpinus caroliniana - Ilex opaca / Leucothoe racemosa* Forest (CEGL007737, G2G3)
- *Quercus pagoda - Quercus nigra / Halesia diptera - Ilex decidua / Chasmanthium sessiliflorum - Dicliptera brachiata* Forest (CEGL007354, G4?)
- *Quercus phellos - Quercus laurifolia - Nyssa biflora - Liquidambar styraciflua / Arundinaria gigantea ssp. tecta - Sabal minor* Forest (CEGL007846, G4?)
- *Quercus virginiana - (Pinus taeda) / (Sabal minor, Serenoa repens)* Forest (CEGL007039, G3G4)
- *Salix caroliniana* Temporarily Flooded Forest (CEGL007373, G4)
- *Taxodium distichum - Nyssa aquatica - Nyssa biflora / Fraxinus caroliniana / Itea virginica* Forest (CEGL007432, G3G4)
- *Taxodium distichum - Nyssa aquatica / Fraxinus caroliniana* Forest (CEGL007431, G5?)

Spatial Characteristics

Spatial Summary: Generally a linear system, with narrow bands or dendritic patches interspersed with other systems.

Size: Occurs in narrow bands, from a few hundred feet to possibly as much as a mile in width, and often several to many miles long. ATLANTIC COASTAL PLAIN CLAY-BASED CAROLINA BAY WETLAND (CES203.245)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Depressional; Graminoid
Non-Diagnostic Classifiers: Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2459; ESLF 9128; ESP 1459

CONCEPT

Summary: This system consists of mineral soil wetlands associated with ovoid, shallow depressions with nearly flat bottoms in parts of the Atlantic Coastal Plain. Often called clay-based Carolina bays, these areas are most numerous and extensive in South Carolina but are also present in adjacent Georgia and the Inner Coastal Plain of North Carolina. The depressions have mineral soils with a clay hardpan or some other layer in the soil that traps and retains water from a combination of rainfall and the exposure of a high regional water table. Some examples are essentially permanently flooded, while others are seasonally flooded but have water levels that vary substantially from year to year and over longer climatic cycles. Vegetation includes a series of primarily herbaceous and woodland associations, which have high herbaceous plant diversity. The wettest sites have open water and floating-leaved aquatic vegetation, or marsh vegetation of tall graminoids. Drier sites often have an open canopy of *Taxodium ascendens*, with a dense, often fairly species-rich herbaceous layer beneath. A few occurrences are shrubby, but none contain the dense shrub layers of characteristic pocosin species that occur in the bays with organic rather than mineral soils. Vegetation composition often varies substantially from year to year, in response to differences in water levels and drawdown times. Variation in hydroperiod is the most important dynamic, causing rapid major changes in the herbaceous vegetation. Unlike the steeper-sided solution depressions, where many different hydroperiods are present within a short distance and vegetation zones simply shift, the flat-bottomed Carolina bays experience drastic yearly changes in hydroperiod over most of their extent. Fire periodically spreads into the bays from adjacent uplands when conditions are dry, helping prevent invasion by less water-tolerant trees during dry periods, and this interacts with flooding to affect vegetation composition. In the absence of fire, *Pinus taeda* often invades the bays. Fire may also be important in preventing buildup of organic matter on the soil surface.

Classification Comments: The distinction between the central concepts of this system and Southern Atlantic Coastal Plain Depression Pondshore (CES203.262) is well marked, with basin morphology, geographic range, and prevailing communities differing. However, there is a common set of plant species, including some rare ones, that occur in both systems. Thus, there may be difficulty in defining the local boundary, and some atypical depressions may have to be placed in one system or the other based on the preponderance of evidence. This system is related to Northern Atlantic Coastal Plain Pond (CES203.518) which occurs farther north in the Coastal Plain, and to some of the flat-bottomed basin wetlands of Florida which occur outside the range of this system to the south.

Similar Ecological Systems:
- East Gulf Coastal Plain Depression Pond (CES203.558)
- Northern Atlantic Coastal Plain Pond (CES203.518)
- Southeastern Coastal Plain Natural Lakeshore (CES203.044)
- Southern Atlantic Coastal Plain Depression Pond (CES203.262)

- Pondcypress: 100 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in Carolina bays with mineral soils and with seasonal to permanent standing water. Carolina bays are oriented, oval, shallow depressions with nearly flat bottoms, which range from North Carolina through South Carolina, and into adjacent Georgia. Most Carolina bays in the Outer Coastal Plain occur in sandy sediments and are filled with peat, while most Carolina bays in the Inner Coastal Plain occur in loamy sediments and have mineral soils with a clay hardpan or some other layer in the soil that traps water. These depressions hold water, due to a combination of rainfall and exposure of a high regional water table. Some are essentially permanently flooded. Others contain water well into the growing season in most years, but water levels vary substantially from year to year and over longer climatic cycles. Fire is an important natural influence in dry times.

Vegetation: Vegetation includes a series of primarily herbaceous and woodland associations. The wettest sites have open water and floating-leaved aquatic vegetation, or marsh vegetation of tall graminoids. Drier sites often have an open canopy of *Taxodium*

ascendens, with a dense, often fairly species-rich herbaceous layer beneath. A large number of annual species are present. Showy, characteristic plants include species of *Symphiotrichum, Boltonia, Xyris, Ludwiga*, and *Solidago* (Bennett and Nelson 1991). Some sites have similar herbaceous vegetation without trees. A few occurrences are shrubby, but none contain the dense shrub layers of characteristic pocosin species that occur in the bays with organic soils. Vegetational composition often varies substantially from year to year, in response to differences in water levels and drawdown times. Seed banking plays an important role in component communities. The system is also important as amphibian breeding habitat and may support a distinctive aquatic invertebrate community.

Dynamics: Variation in hydroperiod is the most important dynamic, causing rapid major changes in the herbaceous vegetation. Unlike the steeper-sided solution depressions, where many different hydroperiods are present within a short distance and vegetation zones simply shift, the flat-bottomed Carolina bays experience drastic yearly changes in hydroperiod over most of their extent. Many plants persist in seed banks for periods of years when conditions are not suitable. Fire is also an important process, spreading into the bays from adjacent uplands when conditions are dry. Fire prevents invasion by less water-tolerant trees during dry periods, and interacts with flooding to affect vegetational composition. In the absence of fire, *Pinus taeda* often invades the bays. Fire may also be important in preventing buildup of organic matter on the soil surface. Seed banking is a very important process in this system. The drastic variation in species composition in response to varying water levels is made possible by a long-persistent seed bank for most of the herbaceous species. Species can be unseen for many years, but reappear quickly when conditions are favorable for them.

Animal migration is also potentially an important dynamic. These wetlands are often important breeding sites for frogs and salamanders, including a number of rare species. Movement of these amphibians transfers nutrients to and from the system, and ties it closely to the surrounding upland systems, and locally in some cases to connected riparian wetlands.

Component Associations:
- *Leersia hexandra - (Panicum verrucosum, Scleria reticularis)* Herbaceous Vegetation (CEGL004047, G2G3)
- *Taxodium ascendens / Cyrilla racemiflora - Zenobia pulverulenta* Woodland (CEGL003734, G2)
- *Taxodium ascendens / Panicum hemitomon - Polygala cymosa* Woodland (CEGL003733, G2G3)
- *Taxodium ascendens / Woodwardia virginica* Woodland (CEGL004441, G2?)

Spatial Characteristics

Spatial Summary: Small-patch system, occurring alone or in closely associated complexes.

Size: Most clay-based Carolina bays are Â½ mile or less long. Some are isolated, while in places several bays may be close enough together to be considered part of the same occurrence.

Adjacent Ecological Systems:
- Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281)
- Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265)

Adjacent Ecological System Comments: Most occurrences were naturally associated with or embedded within Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265) and Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281). Most are now surrounded by heavily altered systems.

Distribution

Range: This system is found in the Inner to Middle Coastal Plain, from southern North Carolina, through South Carolina, and into adjacent Georgia. It is most numerous and extensive in South Carolina.

Divisions: 203:C

Nations: US

Subnations: GA, NC, SC

ATLANTIC COASTAL PLAIN NORTHERN BOG (CES203.893)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Acidic Water; Shrubland (Shrub-dominated); Depressional; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9189

CONCEPT

Summary: This system is comprised of dwarf-shrub sphagnum bogs dominated by *Chamaedaphne calyculata* occurring on Cape Cod (Massachusetts), Long Island (New York), and the Coastal Plain and near-coastal areas of northern New Jersey. North of the glacial border, this system typically occurs in isolated glacial kettleholes and in New Jersey in similar isolated basins, generally in regions of deep sands. The system is characterized by acidic, tannic water supporting a floating or grounded *Sphagnum* mat over which *Chamaedaphne calyculata, Gaylussacia dumosa*, and other dwarf-shrubs have rooted. Taller shrubs such as *Vaccinium corymbosum* may occur at the periphery of the bog, and *Decodon verticillatus* often forms a distinct zone adjacent to open water. Scattered individuals of *Pinus rigida, Pinus strobus*, or less often *Chamaecyparis thyoides* or *Picea mariana* may form a partial and stunted tree layer. Rooted hydromorphic plants such as *Nymphaea odorata* occur in open water.
Classification Comments: This system is separated from Northern Atlantic Coastal Plain Pitch Pine Lowland (CES203.374) based on the different landscape setting of the latter (pine barrens) and the implications for a different fire regime.
Similar Ecological Systems:
- North-Central Interior and Appalachian Acidic Peatland (CES202.606)--occurs inland from the Coastal Plain.
- Northern Atlantic Coastal Plain Pitch Pine Lowland (CES203.374)--may be similar in some instances, but is restricted to the New Jersey Pine Barrens region southward to Maryland, where the bogs occur in a contiguous pine barrens landscape.

Related Concepts:
- Pitch Pine Bog (Gawler and Cutko 2010) Finer
- Pitch Pine: 45 (Eyre 1980) Finer

Component Associations:
- *Chamaecyparis thyoides / Chamaedaphne calyculata* Woodland (CEGL006321, G3G4)
- *Chamaedaphne calyculata - (Gaylussacia dumosa) - Decodon verticillatus / Woodwardia virginica* Dwarf-shrubland (CEGL006008, G5)
- *Myrica gale - Chamaedaphne calyculata / Carex exilis* Shrub Herbaceous Vegetation (CEGL006392, GNR)
- *Nuphar advena - Nymphaea odorata* Herbaceous Vegetation (CEGL002386, G4G5)
- *Pinus rigida / Chamaedaphne calyculata / Sphagnum* spp. Woodland (CEGL006194, G3G5)
- *Sphagnum cuspidatum* Nonvascular Vegetation (CEGL004384, G2?)

DISTRIBUTION

Range: This system occurs on Cape Cod (Massachusetts), Long Island (New York), and possibly on the Coastal Plain of New Jersey north of the Pine Barrens region.

ATLANTIC COASTAL PLAIN PEATLAND POCOSIN AND CANEBRAKE (CES203.267)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Shrubland (Shrub-dominated); Extensive Wet Flat
Non-Diagnostic Classifiers: Organic Peat (>40 cm)
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2452; ESLF 9121; ESP 1452

CONCEPT

Summary: This system includes wetlands of organic soils, occurring on broad flats or gentle basins, primarily on the outer terraces of the Atlantic Coastal Plain of the Carolinas and southeastern Virginia. Under current conditions, the vegetation is predominantly dense shrubland and very shrubby open woodlands. A characteristic suite of primarily evergreen shrubs, greenbriars, and *Pinus serotina* dominates. These shrubs include *Cyrilla racemiflora, Ilex coriacea, Ilex glabra, Lyonia lucida,* and *Zenobia pulverulenta,* along with *Smilax laurifolia*. *Pinus serotina* is the characteristic tree, along with *Gordonia lasianthus, Magnolia virginiana,* and *Persea palustris*. Herbs are scarce and largely limited to small open patches. Under pre-European settlement fire regimes, stands of *Arundinaria gigantea ssp. tecta* (canebrakes) would have been more common and extensive. Soil saturation, sheet flow, and peat depth create a distinct zonation, with the highest stature woody vegetation on the edges and lowest in the center. Catastrophic fires are important in this system, naturally occurring at moderate frequency. Fires generally kill all above-ground shrubs in large patches. Mortality of *Pinus serotina* varies, creating a shifting mosaic. Vegetation structure and biomass recover rapidly in most of the burned areas, primarily by sprouting. *Pinus serotina* can regenerate from serotinous cones if killed.
Classification Comments: Related vegetation occurs in Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252), which may share many plant species but which has hydrology driven by seepage. This system ((CES203.267) has three recognizable landscape patterns within it: domed peatlands, peat-filled Carolina bays, and small swales. Vegetational and ecological differences between these have not been demonstrated but may warrant further investigation. There are differences in landscape pattern among them. The "small swale" manifestation of this exists in smaller patches.
Similar Ecological Systems:
- Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252)
- Southern Atlantic Coastal Plain Nonriverine Swamp and Wet Hardwood Forest (CES203.304)

- Sweetbay - Swamp Tupelo - Redbay: 104 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on broad interfluvial flats and in small to large, very gentle basins and swales, largely on the outermost terraces of the Outer Coastal Plain. Some occurrences are in large to small peat-filled Carolina bays (Bennett and Nelson 1991, Nifong 1998). Smaller patches occur in shallow swales associated with relict coastal dune system or other irregular sandy surfaces. Soils range from wet mineral soils with mucky surface layers to peats several meters deep. Most of the largest occurrences are domed peatlands with the deepest peat associated with topographic highs in the center, but deep peats are also associated with buried drainage channels. Hydrology is driven by rainfall and sheet flow. The low hydraulic conductivity of the organic material limits interaction with the groundwater. The raised center of domed peatlands is fed only by rainwater and is therefore a true ombrotrophic bog. More peripheral portions are fed by sheet flow from the center, and so receive only acidic water low in nutrients. Occurrences in Carolina bays and other basins appear to be similarly isolated from surface or groundwater inflow from adjacent areas. Soils are normally saturated throughout the winter and well into the growing season, though the organic material may dry enough to burn during droughts. Standing water is limited to local depressions and disturbed areas. Soil saturation and peat depth, with its corresponding nutrient limitation, are the primary drivers of vegetational zonation as well as the distinction between this system and adjacent ones, but their effect may be modified by drainage patterns.
Vegetation: Vegetation is a series of distinctive associations known as pocosins. Under current conditions, the vegetation is predominantly dense shrubland and very shrubby open woodlands, ranging to nearly closed forests. Herbaceous associations are present only as small patches. Vegetation is typically zoned. The lowest stature vegetation occurs in the center of the system, with woodlands on the edges and in the smaller occurrences. The communities have in common a dense shrub layer of wetland shrubs tolerant of the organic soils, low nutrient conditions, and fire. *Ilex glabra, Lyonia lucida, Lyonia mariana, Cyrilla racemiflora, Ilex coriacea,* and *Zenobia pulverulenta* are characteristic and usually dominant in some combination, along with *Smilax laurifolia*. *Pinus serotina* is the characteristic tree, and it along with a set of evergreen hardwoods, including *Gordonia lasianthus, Magnolia*

, and *Persea palustris*, are generally the only trees present. Under pre-European settlement fire regimes, stands of *Arundinaria gigantea ssp. tecta* (canebrakes) would have been more common and extensive. Component communities tend to be low in plant species richness, and woody species richness exceeds herbaceous in most associations, with herbs being limited to small open patches. These areas would have formerly been more extensive under pre-European settlement fire regimes. The dominance of pond pine and evergreen shrubs as opposed to a canopy of deciduous hardwoods distinguishes this system from nonriverine swamp forests (CES203.304).

Dynamics: Fire is an important factor in these systems, with the pre-settlement fire regime probably being very different from that observed under current conditions. Natural fire-return intervals are not well known, but are probably on the order of a decade or two in the wettest areas. Peripheral areas may be subject to fire as often as the surrounding vegetation burns, which may naturally have been an average of 3 years. Fires are typically intense due to density and flammability of the vegetation; all above-ground vegetation is often killed, though *Pinus serotina* are resilient to fire and may survive. Fires are followed by vigorous root sprouting by shrubs and hardwoods, leading to recovery of standing biomass within a few years. *Pinus serotina* recovers by epicormic sprouting or by regeneration from seeds released from serotinous cones. Fires during droughts may ignite peat, forming holes that take longer to recover. Herb-dominated openings in pocosins may depend on peat fires for their creation, though this is not well documented. Natural fires occur in large patches, creating a shifting patch structure in the system that interacts with the vegetational zonation created by peat depth. The intensity of fire in these systems makes fire control difficult; prescribed burning is seldom done, and wild fires during drought continue to be a significant influence. The larger peatlands are believed to have been created by paludification following natural blocking of drainage (Otte 1981). Peat buildup raises the water table in the center, creating the domed structure of the largest peatlands and allowing the wetland to spread out as wetness is increased at the edges. Many of the deeper pocosin peats contain fossil logs that indicate dominance by a swamp forest in past millennia. Otte (1981) noted that peat fires likely limit the height to which the peat can accumulate, in proportion to how high it can raise the local water table.

Component Associations:
- *Arundinaria gigantea ssp. tecta* Shrubland (CEGL003843, G1)
- *Chamaedaphne calyculata - Vaccinium macrocarpon / Carex striata var. striata - Woodwardia areolata* Dwarf-shrubland (CEGL004165, G1)
- *Chamaedaphne calyculata / Carex striata var. striata - Sarracenia (flava, purpurea, rubra ssp. rubra)* Dwarf-shrubland (CEGL004164, G1)
- *Chamaedaphne calyculata / Carex striata var. striata - Woodwardia virginica* Dwarf-shrubland (CEGL004163, G1G2)
- *Cyrilla racemiflora - Persea palustris - Magnolia virginiana* Shrubland (CEGL004449, G2)
- *Cyrilla racemiflora - Zenobia pulverulenta* Shrubland (CEGL003943, G2G3)
- *Gordonia lasianthus - Magnolia virginiana - Persea palustris / Sphagnum* spp. Forest (CEGL007044, G4)
- *Ilex glabra - Lyonia lucida - Zenobia pulverulenta* Shrubland (CEGL003944, G2)
- *Magnolia virginiana - Persea palustris / Lyonia lucida* Forest (CEGL007049, G3?)
- *Pinus serotina - Gordonia lasianthus / Lyonia lucida* Woodland (CEGL003671, G3)
- *Pinus serotina / Arundinaria gigantea ssp. tecta* Wooded Shrubland (CEGL003851, G1)
- *Pinus serotina / Arundinaria gigantea ssp. tecta* Woodland (CEGL004433, G1)
- *Pinus serotina / Cyrilla racemiflora - Lyonia lucida - Ilex glabra* Woodland (CEGL003670, G3)
- *Pinus serotina / Ilex glabra / Woodwardia virginica* Woodland (CEGL004652, G2?)
- *Pinus serotina / Lyonia lucida - Ilex glabra - (Cyrilla racemiflora)* Shrubland (CEGL003846, G3)
- *Pinus serotina / Morella cerifera / Osmunda regalis var. spectabilis* Woodland (CEGL003669, G2?)
- *Pinus serotina / Zenobia pulverulenta - Cyrilla racemiflora - Lyonia lucida* Wooded Shrubland (CEGL004458, G2?)

Spatial Characteristics

Spatial Summary: This system occurs both as large patches in domed peatlands and large Carolina bays, and as complexes or isolated individual small patches in swales. Large patches tend to be homogeneous systems, while small patches often occur in mosaics with other systems. Large patches are usually zoned, with large patches of different associations.

Size: Occurs as both large patches, a few up to 10,000 acres or more, and also as small patches. Small patches are often in complexes, with many in close proximity.

Adjacent Ecological Systems:
- Atlantic Coastal Plain Small Blackwater River Floodplain Forest (CES203.249)
- Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281)
- Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265)
- Southern Atlantic Coastal Plain Nonriverine Swamp and Wet Hardwood Forest (CES203.304)
- Southern Atlantic Coastal Plain Wet Pine Savanna and Flatwoods (CES203.536)
- Southern Atlantic White-cedar Peatland Forest (CES203.068)

Adjacent Ecological System Comments: Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281) and Southern Atlantic Coastal Plain Wet Pine Savanna and Flatwoods (CES203.536) may be the most adjacent systems in the southern part of the range, and in swale and Carolina bay occurrences. Nonriverine swamp systems are the most frequently associated in the northern half of the range.

Distribution

Range: This system is found primarily in North Carolina, extending into Georgia and southeastern Virginia.

ATLANTIC COASTAL PLAIN SMALL BLACKWATER RIVER FLOODPLAIN FOREST (CES203.249)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial [Blackwater]
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9318

CONCEPT

Summary: This ecological system encompasses the floodplains of small to medium blackwater rivers in the Atlantic Coastal Plain which are intermediate in size between the smaller streams and the largest rivers. Blackwater rivers originate in the sandy areas of the Coastal Plain, carry little sediment, and have less well-developed depositional alluvial landforms. The water is usually strongly stained by tannins but has little suspended clay and is not turbid. Soils are sandy or mucky, acidic, and infertile. Vegetation is a mosaic of cypress and gum swamps and bottomland hardwoods dominated by a limited set of oaks and other species. The lowest, wettest areas have some combination of *Taxodium distichum*, *Taxodium ascendens*, and *Nyssa biflora*. *Nyssa aquatica* is generally scarce or absent. Higher portions of the floodplain have forests with combinations of a small set of wetland oaks and other species, including *Quercus laurifolia*, *Quercus lyrata*, *Quercus nigra*, *Liquidambar styraciflua*, *Pinus taeda*, *Magnolia virginiana*, and other species. In general, vegetation is low in species richness.

Classification Comments: The distinction between brownwater and blackwater rivers is sometimes problematic. A number of plant species are characteristic of brownwater floodplains and not blackwater. Well-developed blackwater rivers may be confined to areas with primarily sandy soils. The boundary between systems based on river/stream size is necessarily somewhat arbitrary, but is based on significant differences which correspond with river size. Smaller streams have smaller watersheds, which tend to lead to more variable water levels and irregular flooding. Depositional landforms are small enough that they do not differentiate communities well, and communities tend to have more of a mixture of species that are segregated on the larger floodplains. Large rivers have greater variation in water levels and have flood regimes that integrate the effects of very large watersheds. Depositional landforms are larger, and communities can be more segregated.

DESCRIPTION

Environment: Examples of this system occur in floodplains of medium to small coastal plain rivers that carry little mineral sediment (blackwater rivers). These rivers have their headwaters in sandy portions of the Atlantic Coastal Plain. The water is usually strongly stained by tannins but has little suspended clay and is not turbid. Depositional landforms such as natural levees and backswamps are usually not well-developed, but point bars, ridge-and-swale systems (scrollwork), and sloughs caused by river meandering may be prominent. Soils are generally sandy in drier portions of the floodplain, mucky in wetter portions, and are very acidic (Smock and Gilinsky 1992). Spring-fed rivers may have calcareous water and non-acidic soils. Flooding ranges from semipermanent in the wettest areas to intermittent and short on the higher portions of the floodplain. Sediment oxygen demand is high in blackwater swamp areas which have long duration flooding and high amounts of total organic carbon in the soil and sediments. Evidence suggests that blackwater streams may naturally be low in dissolved oxygen (Todd et al. 2010). The sandy soils may make some higher areas within the floodplain well-drained and dry when not flooded.

Saturation and flooding by acidic water, high in tannins is a key process. These waters carry very little sediment and are the color of dark tea (Wharton 1978). This is a linear to large-patch ecological system; stands may be contiguous over thousands of acres. Examples are by nature linear and most tend to be narrow The largest ones, such as the Satilla River of Georgia, could be called matrix examples. The Satilla could be the largest example; it is about 375 km in length. Its lower floodplain is about 2 km across, so in its entirety it could be up to 750 square km in size. Stands that have not had extensive timber removal will probably have more woody debris and constitute better habitat for component animal and plant species (Wharton 1978).

Vegetation: Vegetation consists largely of forests dominated by wetland trees species. Non-forested vegetation is present only on recently deposited bars and in oxbow lakes. The lowest, wettest areas have some combination of *Taxodium distichum, Taxodium ascendens*, and *Nyssa biflora*. *Nyssa aquatica* is generally scarce or absent. Higher portions of the floodplain have forests with combinations of a small set of wetland oaks and other species, including *Quercus laurifolia, Quercus lyrata, Quercus nigra, Liquidambar styraciflua, Pinus taeda, Magnolia virginiana*, and other species. Overall canopy species richness in a given site and over the system as a whole is lower than in comparable brownwater river systems. The distinctive levee assemblage of trees in brownwater river systems is largely lacking, though *Betula nigra, Salix nigra, Salix caroliniana*, and *Planera aquatica* may dominate banks and bars. The wettest forests are sometimes simple in structure, with an understory but little shrub or herb layer, but the other communities tend to have well-developed understories, shrub, and herb layers. Woody vines are usually prominent.

Dynamics: Flooding is the most important ecological factor in this system. Frequency and duration of flooding determine the occurrences of different associations and separate the system from other kinds of wetlands. Flooding brings nutrients and excludes non-flood-tolerant species. When flooded, the system may have a substantial aquatic faunal component, with high densities of invertebrates, and may play an important role in the life cycle of fish in the associated river. Unusually long or deep floods may stress vegetation or act as a disturbance for some species. Larger floods cause local disturbance by scouring and depositing sediment along channels, and occasionally causing channel shifts. However, the low gradient and binding of sediment by vegetation generally makes these processes much slower and less frequent than in river systems of most other regions. The areas flooded for the longest durations tend to have high amounts of total organic carbon in the soil and sediments which deplete levels of aquatic dissolved oxygen (Todd et al. 2010).

Except for primary successional communities such as bars, most forests exist naturally as multi-aged old-growth forests driven by gap-phase regeneration. In addition to periodic flooding, the formation of windfall gaps is a dominant ecological process in bottomland hardwood forests. Windfall gaps range from small (a single mature canopy tree) to patches up to a hectare or occasionally more, due to the effects of tornadoes and hurricanes. When canopy trees fall, seedlings in the understory are released and compete for a spot in the canopy. This leads to dense areas of herbaceous and woody vegetation in windfall gaps of all sizes. This is the major process in forest regeneration in bottomland hardwood forests.

Flooding is more frequent on the lower terraces but frequently floods higher terraces (Wharton et al. (1982) zones IV and V). Duration of flooding varies with the placement of a site in the landscape and is a dominant process affecting vegetation on a given site. Flooding can deposit alluvium or scour the ground, depending on the landscape position of a site and the severity of the flood event.

Fire is not believed to be important, due to low flammability of much of the vegetation, wetness, and abundance of natural firebreaks. Some areas of bottomlands apparently were once occupied by canebrakes, which presumably were maintained through deliberate fall burning by Native Americans. Infrequent, mild surface fires would occur in the system; however, they would not alter species composition or structure.

Component Associations:

- *Betula nigra - Quercus laurifolia - Taxodium (distichum, ascendens) / Crataegus aestivalis* Forest (CEGL004282, G2G3)
- *Eragrostis hypnoides - Micranthemum umbrosum - Lipocarpha micrantha - (Juncus repens)* Herbaceous Vegetation (CEGL004341, G2)
- *Fraxinus caroliniana - Sabal palmetto - Ulmus americana / Cephalanthus occidentalis* Forest (CEGL008592, G3?)
- *Fraxinus pennsylvanica - Ulmus americana - Celtis laevigata / Ilex decidua* Forest (CEGL002427, G4G5)
- *Nuphar sagittifolia* Herbaceous Vegetation (CEGL004328, G3?)
- *Panicum rigidulum - Hibiscus moscheutos* Herbaceous Vegetation (CEGL004273, G2G3)

- *Salix caroliniana* Temporarily Flooded Coastal Plain Shrubland (CEGL007052, G4?)
- *Taxodium ascendens / Fraxinus caroliniana - Cephalanthus occidentalis - (Planera aquatica)* Woodland (CEGL004289, G2G3)
- *Taxodium distichum - Nyssa aquatica - Nyssa biflora / Fraxinus caroliniana / Itea virginica* Forest (CEGL007432, G3G4)
- *Taxodium distichum - Nyssa biflora / Fraxinus caroliniana / Lyonia lucida* Forest (CEGL004733, G3G4)

SPATIAL CHARACTERISTICS

Spatial Summary: Large-patch system, often contiguous over thousands of acres. Could potentially be regarded as matrix.

Size: This system occurs in broad linear bodies that are usually at least a mile wide, sometimes several miles wide, and may be dozens of miles long. The natural limitations on development and conversion often result in contiguous patches of tens of thousands of

acres in natural or semi-natural condition. Areas of vegetation in good condition are more likely to be hundreds of acres, bordered by young forests, clearcut areas, or pine plantations.

Adjacent Ecological Systems:

- Atlantic Coastal Plain Fall-line Sandhills Longleaf Pine Woodland (CES203.254)
- Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267)
- Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265)
- Southeastern Coastal Plain Cliff (CES203.398)
- Southern Atlantic Coastal Plain Nonriverine Swamp and Wet Hardwood Forest (CES203.304)
- Southern Atlantic White-cedar Peatland Forest (CES203.068)

Adjacent Ecological System Comments: Generally bordered by upland hardwood systems on bluffs, by longleaf pine or Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267). Riverine aquatic systems are closely associated.

DISTRIBUTION

Range: This system is potentially found throughout the Atlantic Coastal Plain from Georgia north to about the James River in Virginia, but it is most abundant in North Carolina and South Carolina.

ATLANTIC COASTAL PLAIN SMALL BROWNWATER RIVER FLOODPLAIN FOREST (CES203.250)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial [Brownwater]
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9315

CONCEPT

Summary: This ecological system encompasses the floodplains of small to medium brownwater rivers of the Atlantic Coastal Plain which are intermediate in size between the smaller streams and the largest rivers. Brownwater rivers originate in clayey areas and carry substantial amounts of mineral sediment, creating well-developed deposition alluvial landforms and fertile soils. These rivers have their headwaters in the Piedmont, Blue Ridge, Interior Plateaus, or in portions of the Coastal Plain where fine-textured sediment predominates. Vegetation is a mosaic of cypress and gum swamps, oak-dominated bottomland hardwoods, and mixed levee forests, with only local examples of embedded non-forested communities. The lowest, wettest areas are dominated by a combination of *Taxodium distichum* and *Nyssa aquatica*. Natural levees and riverfronts have a diverse mixture of trees, including *Platanus occidentalis, Celtis laevigata, Fraxinus pennsylvanica, Acer negundo,* and others. Moderate to high parts of the floodplain away from the levee are usually dominated by bottomland hardwoods, including wetland oaks such as *Quercus laurifolia, Quercus michauxii, Quercus pagoda,* and sometimes a number of other species including *Liquidambar styraciflua*.
Classification Comments: The distinction between brownwater and blackwater rivers is sometimes problematic. A number of plant species are characteristic of brownwater floodplains and not blackwater. Well-developed blackwater rivers may be confined to areas with primarily sandy soils. The boundary between systems based on river/stream size is necessarily somewhat arbitrary, but is based on significant differences which correspond with river size. Smaller streams have smaller watersheds, which tend to lead to more variable water levels and irregular flooding. Depositional landforms are small enough that they don't differentiate communities well, and communities tend to have more of a mixture of species that are segregated on the larger floodplains. Large rivers have greater variation in water levels and have flood regimes that integrate the effects of very large watersheds. Depositional landforms are larger, and communities can be more segregated.

This system as defined covers a large geographic range. There are some significant biogeographic differences across this range, leading to a large number of associations. However, more plant species are shared across the region in this system than in most other systems in the region.

DESCRIPTION

Environment: Examples of this system occur in floodplains of medium to small Coastal Plain rivers that carry significant mineral sediment (brownwater or redwater rivers). These rivers have their headwaters in the Piedmont, Blue Ridge, Interior Plateaus, or in portions of the Coastal Plain where fine-textured sediment predominates. The water generally carries substantial amounts of silt, clay, and sometimes sand. Depositional landforms such as point bars, natural levees, backswamps, and ridge-and-swale systems (scrollwork) are well-developed and form patterns of significant variation in flooding duration and nutrient input. Soil texture varies from sandy to clayey. Soils are generally fertile and not strongly acidic. Flooding ranges from semipermanent in the wettest areas to intermittent and short on the higher portions of the floodplain. The highest terraces may no longer flood at all and belong to a different system.

Vegetation: Vegetation consists largely of forests dominated by wetland tree species. Non-forested vegetation is present only on recently deposited bars and in oxbow lakes. Three distinct groups of associations can be recognized. The lowest, wettest areas have

some combination of *Taxodium distichum* and *Nyssa aquatica* dominating. Natural levees and riverfronts have a diverse mixture of trees that typically includes *Platanus occidentalis, Celtis laevigata, Fraxinus pennsylvanica, Acer negundo*, and other species that benefit from the high light levels and heavy alluvial deposition of these sites. Moderate to high parts of the floodplain away from the levee are usually dominated by bottomland hardwoods, various mixtures of wetland oaks, including *Quercus laurifolia, Quercus michauxii, Quercus pagoda*, and sometimes a number of other oak species, along with *Liquidambar styraciflua*, but other species are sometimes codominant. The wettest forests are sometimes simple in structure, with an understory but little shrub or herb layer, but the other communities tend to have well-developed understories, shrub, and herb layers. Woody vines are usually prominent.
Dynamics: Flooding is the most important ecological factor in this system. Frequency and duration of flooding determines the occurrences of different associations and separates the system from other kinds of wetlands. Flooding brings nutrients and excludes non-flood-tolerant species. When flooded, the system has a substantial aquatic faunal component, with high densities of invertebrates, and may play an important role in the life cycle of fish in the associated river. Unusually long or deep floods may stress vegetation or act as a disturbance for some species. Larger floods cause local disturbance by scouring and depositing sediment along channels, and occasionally causing channel shifts. However, the low gradient and binding of sediment by vegetation generally makes these processes much slower and less frequent than in river systems of most other regions. Except for primary successional communities such as bars, most forests exist naturally as multi-aged old-growth forests driven by gap-phase regeneration. Windthrow is probably the most important cause of gaps. Fire is not believed to be important, due to low flammability of much of the vegetation, wetness, and abundance of natural firebreaks. However, some areas of bottomlands apparently were once canebrakes, which presumably were maintained by periodic fire.

Component Associations:

SPATIAL CHARACTERISTICS

Spatial Summary: Linear system, often contiguous over thousands of acres. Could potentially be regarded as matrix.
Size: This system occurs in broad linear bodies that are usually several miles wide and may be hundreds of miles long. The natural limitations on development and conversion often result in contiguous patches of tens of thousands of acres in natural or semi-natural condition. Areas of vegetation in good condition are more likely to be hundreds to possibly thousands of acres, bordered by young forests, clearcut areas, or pine plantations.
Adjacent Ecological Systems:
- Atlantic Coastal Plain Blackwater Stream Floodplain Forest (CES203.247)
- Atlantic Coastal Plain Brownwater Stream Floodplain Forest (CES203.248)
- Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265)

Adjacent Ecological System Comments: Generally bordered by upland hardwood systems on bluffs or adjacent high terraces. Riverine aquatic systems are closely associated.

DISTRIBUTION

Range: This ranges throughout the Atlantic Coastal Plain from Georgia, north to about the James River in Virginia.
Divisions: 203:C
Nations: US
Subnations: GA, NC, SC, VA
Map Zones: 55:C, 58:C, 60:C
USFS Ecomap Regions: 232A:CC, 232C:CC, 232H:CC, 232I:CC, 232J:CC
TNC Ecoregions: 56:C, 57:C

ATLANTIC COASTAL PLAIN STREAMHEAD SEEPAGE SWAMP, POCOSIN AND BAYGALL (CES203.252)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Mid and Southern Atlantic Coastal Plain; Seepage-Fed Sloping
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2468; ESLF 9137; ESP 1468

CONCEPT

Summary: This ecological system encompasses seepage-fed wetlands in dissected landscapes of the Atlantic Coastal Plain, from southeastern Virginia south through South Carolina and into the Inner Coastal Plain of Georgia. Examples are usually associated with ravines or along headwater streams. Overbank flooding is a negligible influence. Fire may be an important force in some associations and not in others. Vegetation consists of open to closed forests or woodlands of acid-tolerant wetland hardwoods or pine. Generally there is a dense shrub layer consisting primarily of species shared with Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267).

Classification Comments: This system is very heterogeneous in vegetation and in the role of fire, as well as extensive in geographic range. It might be appropriate to split it into two or even three systems. The streamhead pocosins of the Fall-line Sandhills region of North Carolina and northern South Carolina (EPA 65c), as well as related areas of Georgia and southern Virginia are distinctive in being strongly fire-dominated, having pine as a major canopy dominant, and having a flora consisting largely of pocosin species. The closely related white-cedar- and cane-dominated associations would also fit into this system. A second set of associations ranging from South Carolina through the Gulf Coastal Plain has vegetation that suggests less influence by fire, including hardwood canopies and shrub layers that are primarily pocosin species but share some other wetland species. A third set, from a wider variety of topographic settings throughout the region, has hardwood canopies and shrub and herb layers with less peatland affinities, more closely related to floodplain communities. Their flora suggests a minor role for fire.

This system is distinguished from Atlantic Coastal Plain Sandhill Seep (CES203.253) by the predominance of woody vegetation indicative of less frequent fire. Where the two co-occur, it occurs in larger and topographically lower patches. This system is distinguished from Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267), which may have fairly similar flora, by having seepage-dominated hydrology and occurring in dissected landscapes.

Similar Ecological Systems:
- Atlantic Coastal Plain Blackwater Stream Floodplain Forest (CES203.247)
- Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267)
- Atlantic Coastal Plain Sandhill Seep (CES203.253)
- Piedmont Seepage Wetland (CES202.298)
- Southern Coastal Plain Seepage Swamp and Baygall (CES203.505)

DESCRIPTION

Environment: This system occurs in dissected Coastal Plain terrain on sites saturated by seepage of shallow groundwater. Seasonal to permanent saturation combined with fire of only moderate to low frequency and woody vegetation are the unifying characteristics of this system. A stream is often present draining the site, but it is small, and overbank flooding is a negligible influence. Most examples are in bottoms of ravines, but some are on sideslopes or flats at the base of slopes. Most examples are in sandy areas where rapid soil drainage in the surrounding landscape supplies the seepage. Soils within the system itself are generally mucky sands or clays, or deeper organic soils. This system occurs in landscapes that had frequent fire under natural conditions.

Vegetation: Vegetation is dominated by woody plants. An open to closed tree canopy is usually present and consists of a mixture of acidic-tolerant wetland trees such as *Nyssa biflora, Acer rubrum, Pinus serotina, Magnolia virginiana, Liriodendron tulipifera,* and *Chamaecyparis thyoides*. There is generally a dense shrub layer that is dominated by species shared with pocosins or baygalls, such as *Cyrilla racemiflora, Leucothoe axillaris, Lyonia lucida, Lyonia ligustrina, Clethra alnifolia, Cliftonia monophylla, Ilex glabra,* and *Arundinaria gigantea ssp. tecta,* but includes some species of other saturated wetlands, such as *Toxicodendron vernix, Morella caroliniensis, Persea palustris,* and *Viburnum nudum*. *Smilax laurifolia* may be abundant. The herb layer, if well-developed at all, generally consists of large wetland ferns, such as *Osmunda cinnamomea, Osmunda regalis var. spectabilis, Woodwardia virginica,* and *Woodwardia areolata*, with *Carex* spp. Some examples (canebrakes) are dominated by *Arundinaria gigantea ssp. tecta*.

Dynamics: Seepage is the most important ecological factor determining where this system occurs. Seepage provides a steady source

of water, so that soils remain saturated but seldom have surface flooding. The importance of fire varies widely in this system. Fire is the most important dynamic process in many examples, but is of minor importance in others, and is probably an important driver of the different vegetation associations. Fire frequency and intensity vary among associations, from moderately frequent intense fires to infrequent low-intensity fires. This system occurs within larger upland landscapes that had frequent fire in the past, but the wetness of these headwater wetlands often limits fire spread into them. Associations dominated by *Pinus serotina* and evergreen shrubs such as *Ilex, Lyonia, Gaylussacia, Persea, Morella, Arundinaria gigantea ssp. tecta* and *Cyrilla*, or canebrakes dominated by *Arundinaria gigantea ssp. tecta* can have intense canopy fires that are the dominant influence on vegetation structure. Those dominated by *Chamaecyparis thyoides* have infrequent fire that may catastrophically kill the canopy trees, while also promoting *Chamaecyparis thyoides* regeneration. Associations with hardwood canopies, such as *Acer rubrum, Liriodendron tulipifera*, or *Nyssa biflora*, especially those with limited shrub abundance, are not very flammable and usually burn with low intensity and limited effect. Wind can be an important natural disturbance. Forests of *Chamaecyparis thyoides* are susceptible to heavy windthrow that can affect a substantial part of the canopy. Wind damage in hardwood and pine forests tends to consist mainly of small to medium-sized canopy gaps. In ravine bottom sites that have some streamflow, beavers can be an important influence. Beaver ponds convert the forested vegetation to open water. Upon abandonment, beaver pond sites go through a succession that may lead to a long-lasting mire community, or to regeneration of a swamp canopy and lower strata.

Component Associations:
- *Arundinaria gigantea ssp. tecta* Shrubland (CEGL003843, G1)
- *Chamaecyparis thyoides - (Liriodendron tulipifera) / Lyonia lucida* Forest (CEGL007563, G2)
- *Cyrilla racemiflora - Cliftonia monophylla* Scrub (CEGL003847, G4)
- *Gordonia lasianthus - Magnolia virginiana - Persea palustris / Sphagnum* spp. Forest (CEGL007044, G4)
- *Gordonia lasianthus / Woodwardia virginica - Osmunda regalis var. spectabilis* Forest (CEGL004410, G2G3)
- *Ilex coriacea - Lyonia lucida - Smilax laurifolia* Shrubland (CEGL004666, G3G4)
- *Magnolia virginiana - Nyssa biflora / Carpinus caroliniana / Thelypteris noveboracensis - Athyrium filix-femina* Forest (CEGL004722, G3G4)
- *Nyssa biflora - (Acer rubrum) / Ilex opaca / Leucothoe axillaris / Carex atlantica ssp. capillacea* Forest (CEGL004427, G2G3)
- *Nyssa biflora - Acer rubrum var. trilobum - Liriodendron tulipifera / Ilex coriacea - Lyonia lucida* Forest (CEGL004645, G3)
- *Pinus serotina - (Liriodendron tulipifera) / Lyonia lucida - Clethra alnifolia - Ilex glabra* Woodland (CEGL004435, G4)
- *Pinus serotina / Gordonia lasianthus - Persea palustris* Saturated Woodland (CEGL007996, G3?Q)

SPATIAL CHARACTERISTICS

Spatial Summary: Occurs as large patches or as long narrow bodies following ravines, often in dendritic networks interfingered with upland systems.
Size: Most occurrences are in narrow bodies that may be very local or may be long and connected in dendritic networks. Networks may contain hundreds of contiguous acres but with few areas very far from an edge.
Adjacent Ecological Systems:
- Atlantic Coastal Plain Blackwater Stream Floodplain Forest (CES203.247)
- Atlantic Coastal Plain Fall-line Sandhills Longleaf Pine Woodland (CES203.254)
- Atlantic Coastal Plain Sandhill Seep (CES203.253)

Adjacent Ecological System Comments: Most frequently associated with Atlantic Coastal Plain Fall-line Sandhills Longleaf Pine Woodland (CES203.254) in the northern part of the range. Potentially associated with a variety of upland systems in the southern part of the range. Many examples will grade downstream to small or large floodplain systems.

DISTRIBUTION

Range: This ecological system is found in the Atlantic Coastal Plain, from southeastern Virginia south through South Carolina and into the Inner Coastal Plain of Georgia, primarily in the Fall-line Sandhills region; rarely in dissected terrain in the Outer Coastal Plain.
Divisions: 203:C
Nations: US
Subnations: GA, NC, SC, VA

BOREAL BLACK SPRUCE SWAMP (CES103.335)

CLASSIFIERS

Classification Status: Standard

Primary Division: Boreal (103)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Swamp; Boreal
National Mapping Codes: ESLF 9394

CONCEPT

Summary: This ecological system encompasses lower-slope, level and depressional wetlands on morainal, lacustrine sites, often on organic soils. It also occurs on the edges of small lakes and ponds. Typically these sites are transitional from peatland to upland. Soils are saturated to subhydric, medium to very rich, and nutrient levels are poor. Swamps are distinguished from other wetland types in that they are wooded (treed or shrub) wetlands that are in contact with minerotrophic water in either mineral or peatland soils. An abundance of woody material in swamps provides another important distinction in that the peat is primarily composed of decomposing wooded material (shrub and tree) rather than the *Sphagnum* or sedge-dominated peat types that comprise the organic layer in poor fens and bogs. Further, peat soils in swamps are fairly well decomposed compared to peat in peatlands, which is caused by fluctuating water tables that allow for oxygen and decomposition. Tree cover is low, approximately 30-50%, predominantly *Picea mariana* with some *Picea glauca X engelmannii* (hybrid white spruce) or sometimes *Larix laricina* Shrub cover is also low, about 35% cover, with *Betula glandulosa, Betula neoalaskana, Betula pumila, Salix barclayi, Ledum groenlandicum, Rosa acicularis, Alnus incana ssp. tenuifolia (= Alnus tenuifolia),* and regenerating canopy trees. Herbaceous cover is high, 40-75%, with *Carex disperma, Caltha palustris, Equisetum arvense, Equisetum fluviatile, Cornus canadensis, Vaccinium vitis-idaea, Rubus chamaemorus, Orthilia secunda, Petasites frigidus var. palmatus (= Petasites palmatus),* and *Comarum palustre (= Potentilla palustris)*. Moss cover is also high at 75-90%; typical species include *Tomentypnum nitens, Pleurozium schreberi, Sphagnum* spp., and *Hylocomium splendens*, among others.

Classification Comments: We are splitting black spruce swamps from black spruce bogs. Black spruce bogs in Alaska are placed into Western North American Boreal Black Spruce Dwarf-tree Peatland (CES105.139) or Western Canadian Boreal Black Spruce Bog and Dwarf-tree Peatland (CES103.799). This system is probably not mappable, except at very fine, local scales. This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

BOREAL BLANKET BOG (CES103.870)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Boreal (103)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Boreal [Boreal Continental]; Seepage-Fed Sloping; Depressional; Sphagnum spp.
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated)
National Mapping Codes: ESLF 9174

CONCEPT

Summary: This ecological system extends across the western boreal regions of North America with occurrences in inland British Columbia. These are peatlands that occur on expansive, flat landscapes in areas of high rainfall and low temperatures. They are thought to have developed under cool, moist climatic regimes of the past 2500 to 3000 years, where the paludification process results in previously forested landscapes being blanketed by expanding peat from adjacent low-lying areas, hence the term "blanket" bog. Trees are generally quite stunted. Dominant tree species include *Picea mariana, Picea glauca, Picea sitchensis*, and *Larix laricina*. Low ericaceous shrubs, including *Kalmia* spp., *Ledum groenlandicum*, *Chamaedaphne calyculata*, and *Betula glandulosa*, occur with patches of graminoids and bryophyte lawns. *Sphagnum* species, including *Sphagnum magellanicum*, *Sphagnum fuscum*, and *Sphagnum cuspidatum*, may be characteristic.
Classification Comments: It's unclear where this system occurs, but for now it is assumed to not occur in Alaska. More information is needed to solidify its concept and distribution.
Related Concepts:
- Sitka Spruce: 223 (Eyre 1980) Intersecting

DISTRIBUTION

Range: This system occurs in the western boreal regions of North America with occurrences in inland British Columbia.
Divisions: 103:C; 105:P; 204:P; 306:C
Nations: CA, US
Subnations: AB, AK, BC, NT, YT?
TNC Ecoregions: 7:C, 69:?

BOREAL DEPRESSIONAL SHRUB BOG (CES103.871)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Boreal (103)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Depressional [Lakeshore]; Depressional [Sinkhole]; Organic Peat (>40 cm); Sphagnum spp.
Non-Diagnostic Classifiers: Boreal Fen; Boreal [Boreal Continental]; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9175

CONCEPT

Summary: These wetlands are found at higher temperate and boreal latitudes of Canada, extending south into the Pacific Maritime and Rocky Mountain divisions. They form where the rate of sphagnum peat accumulation exceeds its decomposition, resulting in ombrotrophic and acidic peatlands in which the bog surface is raised above the water table. These peatlands are typically formed as lake-filled basins or depressions. The surface morphology of the peatland may be more-or-less level, domed, or eccentric. Secondary bog pools may be present. While the raised portion defines these bogs, boreal fen systems may occupy some portion of the same basin, due to localized groundwater input. Soils are saturated throughout the growing season from groundwater upwelling. The vegetation is dominated by low ericaceous shrubs (including *Kalmia polifolia*, *Andromeda polifolia*, *Ledum groenlandicum*, *Rubus chamaemorus*, *Vaccinium oxycoccos*, *Betula glandulosa*, *Empetrum nigrum*, and *Chamaedaphne calyculata*), and with patches of graminoids and bryophyte lawns. *Sphagnum* species are characteristic, including *Sphagnum capillifolium*, *Sphagnum magellanicum*, *Sphagnum fuscum*, *Sphagnum papillosum*, and *Sphagnum cuspidatum*. Conifers sometimes occur (*Picea mariana* or *Larix laricina*), especially late in succession.
Classification Comments: It's somewhat unclear where this system occurs, but for now it is assumed to not occur in Alaska. More information is needed to solidify its concept and distribution differences from the several peatland systems defined for Alaska. Where this system occurs in Idaho, Montana and eastern Oregon, it is very uncommon, and is disjunct from the true boreal distribution of the system. Bogs and fens in the maritime climate regions of Oregon, Washington and British Columbia are placed into North Pacific Bog and Fen (CES204.063).

BOREAL WHITE SPRUCE SWAMP AND BOG (CES105.340)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Boreal; Bog
National Mapping Codes: ESLF 9399

CONCEPT

Summary: This ecological system encompasses moist lower and toeslope seepage sites, often near stream channels, with subhydric soils with medium to very rich nutrients. Some sites are not near the groundwater; at others, the groundwater table is within 50 cm of the surface. Soils are loamy sands, silt, or organics with up to 40 cm Hemimor or Humimor humus. Occurrences are small in size and widely distributed. Forest canopy ranges from very open to moderately closed and dominated by *Picea galuca X engelmannii* (hybrid white spruce) with *Picea mariana*, other species often include *Pinus contorta, Populus tremuloides*, and scattered *Abies lasiocarpa* in colder sites or *Pseudotsuga menziesii* in warmer pockets. The shrub layer can be absent to abundant with *Lonicera involucrata, Rosa acicularis*, and *Vaccinium membranaceum*. The undergrowth has abundant *Equisetum scirpoides, Equisetum arvense, Calamagrostis rubescens, Petasites frigidus var. palmatus (= Petasites palmatus)*, and *Maianthemum stellatum (= Smilacina stellata)*. Moss cover is abundant and generally dominated by leafy mosses.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

BOREAL WILLOW-ALDER SWAMP THICKET (CES103.524)

CLASSIFIERS

Classification Status: Standard

Primary Division: Boreal (103)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Shrubland (Shrub-dominated); Muck; Broad-Leaved Deciduous Shrub
National Mapping Codes: ESLF 9397

CONCEPT

Summary: These are deciduous tall-shrub swamps found throughout boreal Canada. They include medium-tall to short shrublands of slow-moving streams and rivers, around beaver ponds in the peripheral zones of wetlands and lakeshores, where there is early-season flooding, continuous seepage near the surface and poor drainage. These shrub swamps are related to both mineral and peatland wetland types, and can occur in widely different landscape settings from mineral-soil floodplains to peatland soil. For this reason swamps have traditionally been harder to identify than other wetland types and are often confused or grouped with other wetland classes. Swamps are distinguished from other wetland types in that they are wooded (treed or shrub) wetlands that are in contact with minerotrophic water in either mineral or peatland soils. An important distinction is that the woody vegetation dominates swamp areas (often in percentages greater than 30% and up to 100% of the canopy) as a result of greater contact with nutrients, aerated soils, and high water availability. The majority of swamps have closed canopies (greater than 50%). This abundance of woody material in swamps provides another important distinction in that the peat is primarily composed of decomposing wooded material (shrub and tree) rather than the *Sphagnum* or sedge-dominated peat types that comprise the organic layer in poor fens and bogs. Further, peat soils in swamps are fairly well-decomposed as a result of fluctuating water tables that allow for oxygen and decomposition. Shrubs, generally >2 m in height, dominate the cover of these swamps. These are deciduous shrubs, predominantly willows (*Salix* spp.) and alders (*Alnus incana ssp. tenuifolia, Alnus incana ssp. rugosa*). They are typically dense thickets, or patches of shrubs intermingled with patches of wet meadows. Common shrub species include *Alnus incana ssp. tenuifolia, Alnus incana ssp. rugosa (= Alnus rugosa), Alnus viridis, Cornus sericea (= Cornus sericea*), and a number of species of *Salix*. A shorter shrub layer can be present, including *Betula glandulosa, Betula nana, Betula pumila, Rosa* spp., *Vaccinium* spp., as well as a number of forbs, ferns, sedges, and mosses.
Classification Comments: This system is similar to Western North American Boreal Deciduous Shrub Swamp (CES105.122) of Alaska, and exactly where one transitions to the other is not yet determined. They could possibly be merged into one boreal willow-alder swamp system, but this needs review. Certainly there is a lot of similar composition in these swamps across boreal North America, with some shifts in the willows found in Alaska versus those found in eastern Canada. This system is also similar to North Pacific Interior Shrub Swamp (CES207.397) of interior British Columbia. That system should probably be merged into this one.
Similar Ecological Systems:
- North Pacific Interior Shrub Swamp (CES207.397)--of interior British Columbia.
- Western North American Boreal Deciduous Shrub Swamp (CES105.122)--of Alaska.

DESCRIPTION

Environment: *Hydrology/Moisture Regime*: Water regime (fluctuating water table) and availability play a significant role in swamps. The water table in swamps fluctuates seasonally, or in some systems bi-yearly, but pools of water are often visible in the hummocky ground surface. Thus, for most of the growing season, the majority of the soil layer is aerated, but water availability is still high in the continually saturated lower portions of the rooting zone. Treed swamps (such as hardwood or mixedwood swamps) in mineral soils are often drier, while swamps that grade into treed fens (tamarack swamps) are wetter. Shrub swamps are almost always wetter than most of the treed swamps, except in some riparian floodplain-associated areas on mineral soils. Moisture regimes for swamps range from hygric to hydric. Flow through swamps is fairly dynamic with good lateral flow through the ground water layer, and fluctuations of this water table allow for aeration of the rooting zone during the growing season. *Soils*: Swamps exist in both peat and mineral soils. Swamps are sometimes termed peatlands but the substrate is from woody (silvic) peat and is well-decomposed. Decomposition is driven by the fluctuating water levels which are absent in *Sphagnum*-derived peatlands. Swamp soils are typically composed of gleysols with mottling in the upper horizons and gleying in the lower horizons. Mottling occurs in a soil that has been inundated with water intermittently (the mottles are iron and manganese oxides). Gleization occurs during the chemical reduction of iron, thus changing the soil colors. Soils with low chromas are indicative of hydric conditions. *Nutrient Regime*: The nutrient regime in swamp wetlands ranges from poor to rich, depending on the amount of contact with dissolved mineral water. Most shrub swamps range from medium to rich.

DISTRIBUTION

Range: This system is found throughout boreal Canada, from Yukon Territory east and south into Alberta, Saskatchewan and further east.
Divisions: 103:C; 105:C
Nations: CA
Subnations: AB, MB, ON?, QC?, SK, YT

BOREAL-LAURENTIAN BOG (CES103.581)

CLASSIFIERS

Classification Status: Standard

Primary Division: Boreal (103)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Oligotrophic Water; Organic Peat (>40 cm); Dwarf-Shrub; Graminoid
Non-Diagnostic Classifiers: Saturated Soil; >180-day hydroperiod; Moderate (100-500 yrs) Persistence; Shrubland (Shrub-dominated); Depressional; Isolated Wetland [Partially Isolated]; Bryophyte; Picea mariana - Larix laricina
National Mapping Codes: ESLF 9354

CONCEPT

Summary: These raised peatlands are found at the higher temperate and near-boreal latitudes of the northeastern and north-central United States and adjacent Canada, where climate allows the rate of peat accumulation to exceed its decomposition, resulting in acidic peatlands. Most are ombrotrophic, at least over part of their area, though some examples may be weakly minerotrophic (poor fen), especially around the margins. The surface morphology of the bog may be more-or-less level, domed, or eccentric, but typically is over the water table. The vegetation is either semi-treed and dominated by low ericaceous shrubs (including *Kalmia angustifolia, Kalmia polifolia, Ledum groenlandicum*, and *Chamaedaphne calyculata*), with patches of conifers, graminoids and bryophyte lawns, or more open forest, where trees form a partial to moderate cover over parts of the peatland. In the latter situation, stunted *Picea mariana* and *Larix laricina* are the dominant trees, and dwarf-shrubs (*Chamaedaphne calyculata, Ledum groenlandicum*) and sedges are common in the understory.

Secondary bog pools (schlenke) may be present. While the raised portion defines these bogs, fen vegetation is often present along the perimeter.

This broadly defined peatland system can be subdivided based on the geomorphology of the peatland. A variety of approaches have been taken: in Maine, see Davis and Anderson (2001); in Canada, see National Wetlands Working Group (1988); and in Minnesota, see Glaser (1992). In Canada, bog and fen peatlands each have their own set of forms. In Minnesota, Glaser treats bogs and fens together as part of larger patterned peatland complexes (mire complexes).
Classification Comments: This system corresponds to Glaser and Janssens' (1986) forested and "semi-forested continental bogs," but this system is somewhat broader in scope as it includes both the domed bogs and the flat bogs in the system type. Thus it extends further southward, into the central Great Lakes and northeasternmost United States. Eastward, it extends roughly to the Acadian region, where it is replaced by Acadian Maritime Bog (CES201.580). Northwestward in northern Ontario, continental non-forested bogs are common (Glaser and Janssens 1986, fig. 2).

These bogs may overlap in common terminology with that of "muskeg," a flat bog peatland with scattered trees and a fairly dense shrub layer on hummocky peat. But muskeg could include poor fens and acidic swamps as well as bogs.

Similar Ecological Systems:
- Acadian Maritime Bog (CES201.580)
- Boreal-Laurentian Conifer Acidic Swamp and Treed Poor Fen (CES103.724)
- North-Central Interior and Appalachian Acidic Peatland (CES202.606)

BOREAL-LAURENTIAN CONIFER ACIDIC SWAMP AND TREED POOR FEN (CES103.724)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Boreal (103)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Depressional; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9177

CONCEPT

Summary: This ecological system extends across the boreal regions of central and western Canada, and east and south into northern New England and the Great Lakes region. The system is primarily weakly to moderately minerotrophic (poor fen), though some stands may approach ombrotrophic (bog) conditions. Decomposition is so slow that fibrous or woody peat accumulates, and the water is slightly to very acidic and nutrient-poor (also called mesotrophic). Acidic (also called poor or transitional) fens have organic soils and are dominated by aquatics, emergents, and dwarf-shrubs, or raised peat dominated by shrubs and trees. Groundwater, the primary water source, is nutrient-rich due to its contact with mineral soils, however, acidic fens have less contact with nutrient-rich waters, as the amount of peat has accumulated to raise the level of the fen, but it remains in contact with groundwater (hence "transitional" on its way to becoming a bog). The water is acidic, with a pH generally between 4.0 and 5.8. This is a forested peatland where the trees form partial to full cover over most or all of the peatland. Stunted to well-developed *Picea mariana* and *Larix laricina* are the dominant trees. Heaths and sedges are common in the understory, but the dwarf-shrub layer is less well-developed than in open acidic peatlands, though it may be prominent in more open parts of the system. *Chamaedaphne calyculata, Kalmia polifolia, Ledum groenlandicum, Vaccinium macrocarpon (= Oxycoccus macrocarpus), Vaccinium vitis-idaea*, and *Salix* spp. are the dominant dwarf-shrubs. Other fen indicators also occur, such as *Betula glandulosa* or *Betula pumila*. Other poor fens are graminoid-dominated with herbaceous indicators such as *Drosera* spp., *Equisetum fluviatile, Maianthemum trifolium, Sarracenia purpurea*, and sedges (*Carex* spp.)
Classification Comments: This forested system is most common in poorly drained basins, with some minerotrophic influence. It is sometimes referred to as "muskeg," a flat bog peatland with scattered trees and a fairly dense shrub layer on mounded or hummocky peat, though this system is not, technically, an ombrotrophic bog [see Boreal-Laurentian Bog (CES103.581)]. Muskeg is probably a complex of bogs and acidic swamps. Black spruce swamps in northeastern Vermont, northern New Hampshire, Adirondack region of New York, and Maine are included here. There appears to be no need for a true Boreal alkaline swamp system, but further review is needed. In Acadia and the Northern Appalachian regions, this system is mostly replaced by the sub-boreal Northern Appalachian-Acadian Conifer-Hardwood Acidic Swamp (CES201.574). Small kettlehole bogs in the northeastern U.S. are attributed to North-Central Interior and Appalachian Acidic Peatland (CES202.606). In western Canada, this system is uncommon because the substrates are mostly calcareous, resulting in a preponderance of rich, alkaline fens either dominated by *Larix laricina* with some *Picea mariana*, or else shrub-sedge fens lacking trees.
Similar Ecological Systems:
- Boreal-Laurentian Bog (CES103.581)--only partly wooded, if at all.
- Boreal-Laurentian-Acadian Acidic Basin Fen (CES201.583)
- North-Central Interior and Appalachian Acidic Peatland (CES202.606)
- Northern Appalachian-Acadian Conifer-Hardwood Acidic Swamp (CES201.574)--characterized by *Picea rubens* rather than *Picea mariana*.

BOREAL-LAURENTIAN-ACADIAN ACIDIC BASIN FEN (CES201.583)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Acidic Water; Depressional; Organic Peat (>40 cm); Broad-Leaved Shrub; Dwarf-Shrub; Graminoid; Picea mariana - Larix laricina
Non-Diagnostic Classifiers: Oligotrophic Water; Shallow (<15 cm) Water; Moderate (100-500 yrs) Persistence; Shrubland (Shrub-dominated); Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9353

CONCEPT

Summary: This peatland system ranges over a broad geographic area across the glaciated Northeast to the Great Lakes and upper Midwest. The fens have developed in open or closed, relatively shallow basins with nutrient-poor and acidic conditions. Many occur in association with larger lakes or streams. Some occur as kettlehole fens (usually called kettlehole "bogs") associated with eskers or other glacial deposits. The substrate is *Sphagnum*, and vegetation typically includes areas of graminoid dominance and dwarf-shrub dominance. *Chamaedaphne calyculata* is usually present and often dominant. Scattered stunted trees may be present. These fens often develop adjacent to open water and may form a floating mat over water.

Particularly distinctive are the ribbed bogs or fens in which a pattern of narrow (2- to 3-m wide), low (less than 1 m deep) ridges are oriented at right angles to the direction of the drainage (National Wetlands Working Group 1988). Wet pools or depressions occur between the ridges. These patterned peatlands may include string bog, Atlantic ribbed fen, or northern ribbed fen (National Wetlands Working Group 1988). They develop almost entirely north of 46 degrees N latitude in east-central Canada and the adjacent U.S. They are minerotrophic peatlands in which the vegetation has developed into a pattern of strings (raised, usually linear features) and flarks (wet depressions separating the strings). The substrate chemistry is entirely acidic in some peatlands; in others, where bedrock or other substrate influence creates circumneutral to calcareous conditions, peatland chemistry may be entirely calcareous or vary from acidic to calcareous within the same peatland. In acidic portions, typical bog heaths predominate mixed with sedges. *Dasiphora fruticosa ssp. floribunda* is diagnostic of circumneutral to calcareous conditions. These peatlands usually develop in open basins and flat plains, and the patterned portion may occupy only a fraction of the entire peatland. The edge of the basin may be shallow to deep peat over a sloping substrate, where seepage waters provide nutrients.

Classification Comments: Need to clarify the conceptual boundaries between this and the boreal fens in central and eastern Canada. This system is also similar to acidic peatlands in the southern edge of the glaciated region, which are treated under North-central Interior and Appalachian Acidic Peatland (CES202.606); those often tend to be smaller-patch landscape elements. USFS sections are used to differentiate the ranges.

CALIFORNIA CENTRAL VALLEY ALKALI SINK (CES206.954)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Playa Mosaic; Lowland [Lowland]; Mediterranean [Mediterranean Xeric-Oceanic]; Depressional
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); Herbaceous; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9181

CONCEPT

Summary: These strongly saline/alkaline playa-like depressions are limited to the San Joaquin Valley and typically occur in a matrix of mixed salt desert scrub. These areas are seasonally to intermittently flooded. They are not flooded every year and respond to localized thunderstorms. Soils typically are fine-textured with an impermeable caliche layer or clay pan. Salt encrustations are often deposited on the surface as the playa dries. Species are salt-tolerant and halophytic species such as *Allenrolfea occidentalis, Suaeda moquinii, Distichlis spicata, Cressa truxillensis, Frankenia salina, Arthrocnemum*, and *Hemizonia pungens (= Centromadia pungens)*. During exceptionally wet years, an increase in precipitation can dilute the salt concentration in the soils of some of examples of this system which may allow for less salt-tolerant species to occur.
Related Concepts:
- Wetlands (217) (Shiflet 1994) Broader. Many wetland systems are related to this very broad SRM type.

CENTRAL ATLANTIC COASTAL PLAIN WET LONGLEAF PINE SAVANNA AND FLATWOODS (CES203.265)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Short Disturbance Interval; Needle-Leaved Tree
Non-Diagnostic Classifiers: Extensive Wet Flat
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2449; ESLF 9118; ESP 1449

CONCEPT

Summary: This ecological system of wet *Pinus palustris*-dominated savannas and flatwoods ranges from southern Virginia to central South Carolina. It was once one of the most extensive systems in the coastward part of its range. Examples and associations share the common features of wet, seasonally saturated, mineral soils and exposure to frequent fire. They occur on a wide range of soil textures, which is an important factor in distinguishing different associations. The vegetation is naturally dominated by *Pinus palustris* or, less frequently, *Pinus serotina*. There is a dense ground cover of herbs and low shrubs; grasses dominate but there is often a large diversity of other herbs. Frequent, low-intensity fire is the dominant natural ecological force.
Classification Comments: This system is distinguished from Southern Atlantic Coastal Plain Wet Pine Savanna and Flatwoods (CES203.536) because of substantial biogeographic differences. The break is placed at the Santee River, which approximates the transition between the ranges of *Aristida stricta* and *Aristida beyrichiana*, which are keystone species in the communities where they occur. This corresponds roughly with the geographic break in the upland longleaf pine systems as well. This system is distinguished from Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281) because of that system's more upland character. However, the two systems have much in common, including frequent fire, the same primary dominant canopy tree, and many herbaceous species. They can also occur in the same landscapes. However, floristic differences are well marked, and no associations are shared. This system occurs primarily in the Outer Coastal Plain, but small patches may occur in atypical landforms in the Fall-line Sandhills. Sandhills examples are not treated as a separate system, as the upland longleaf pine systems are, because they are confined to sites that more resemble the Outer Coastal Plain. They are distinguished in the Sandhills from Atlantic Coastal Plain Sandhill Seep (CES203.253) by landform and apparent hydrology that is driven by seasonal high water table rather than seepage.
Similar Ecological Systems:
- Atlantic Coastal Plain Fall-line Sandhills Longleaf Pine Woodland (CES203.254)
- Atlantic Coastal Plain Sandhill Seep (CES203.253)
- Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281)
- Southern Atlantic Coastal Plain Wet Pine Savanna and Flatwoods (CES203.536)

Related Concepts:
- Longleaf Pine - Slash Pine: 83 (Eyre 1980) Finer
- Longleaf Pine: 70 (Eyre 1980) Finer
- Pond Pine: 98 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on wet mineral soil sites, primarily in the Middle and Outer Coastal Plain but occasionally in the Fall-line Sandhills. Landforms include low areas in relict beach ridge systems and eolian sand deposits, and poorly drained clayey, loamy, or sandy flats. They occasionally occur on river terraces above current flood levels. Soils range from clayey to sandy, with no accumulated organic surface layer. Soils are seasonally saturated, due to high water table or poor soil drainage. The unifying feature of this system is wet mineral soils associated with a high frequency of fire. Variation in soil texture appears to be a primary driver of differences between associations within the system, with biogeography also important.
Vegetation: Vegetation is a set of associations that are naturally woodlands or savannas dominated by *Pinus palustris* or, less frequently, by *Pinus serotina*, *Pinus elliottii*, or some combination. Hardwoods are present in any abundance only in examples altered by fire suppression. The ground cover is a dense combination of herbs and low shrubs. A variety of ericaceous shrubs and hollies is common, with density determined by fire history. Grasses naturally dominate the ground cover. *Aristida stricta* often dominates within its range, but *Ctenium aromaticum, Sporobolus pinetorum, Sporobolus teretifolius*, or other grasses may dominate. A great diversity of other herbs is often present, including composites, sedges, insectivorous plants, and variety of showy forbs. Communities in this system are often very high in species richness, with some of the highest values measured anywhere at the 1/10-hectare, 1/100-hectare, and 1-square-meter levels. However, some associations are naturally low to moderate in species richness.
Dynamics: Frequent fire is the predominant natural disturbance in this system. Communities naturally burned every few years, many averaging as often as every 3 years. Fires are naturally low to moderate in intensity. They burn above-ground parts of herbs and shrubs but have little effect on the fire-tolerant trees. Vegetation recovers very quickly from fire, with live herbaceous biomass often restored in just a few weeks. Many plants have their flowering triggered by burning, the effects on subsequent establishment are not well-documented. In the absence of fire, the shrubs increase and hardwoods may invade the system. Herb layer density and diversity

decline after a number of years without fire. In time, unburned examples will become nearly indistinguishable from the drier associations of Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267).

Canopies are believed to naturally be multi-aged, consisting of a mosaic of even-aged patches driven by gap-phase regeneration. *Pinus palustris* is shade-intolerant and slow to reach reproductive age but is very long-lived.

Component Associations:
- *Hypericum reductum / Aristida stricta* Dwarf-shrubland (CEGL003954, G1G2Q)
- *Pinus palustris - (Pinus serotina) / Ilex glabra - Gaylussacia frondosa - (Kalmia carolina)* Woodland (CEGL003647, G2)

- *Pinus palustris / Arundinaria gigantea ssp. tecta - Liquidambar styraciflua / Andropogon glomeratus - Sarracenia minor* Woodland (CEGL004495, G1)
- *Pinus palustris / Ilex glabra / Aristida stricta* Woodland (CEGL003648, G3)
- *Pinus palustris / Leiophyllum buxifolium / Aristida stricta* Woodland (CEGL003649, G1)
- *Pinus palustris / Serenoa repens - Ilex glabra* Woodland (CEGL003653, G2G3)

Spatial Characteristics

Spatial Summary: This system naturally occurs as large to small patches, sometimes part of extensive matrix mosaics with other systems. It was naturally one of the most abundant systems on the lower terraces of the Outer Coastal Plain.
Size: Ranges from large to small patch, which may form a matrix mosaic with other systems. Many remaining examples are naturally bounded islands.
Adjacent Ecological Systems:
- Atlantic Coastal Plain Clay-Based Carolina Bay Wetland (CES203.245)
- Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267)
- Atlantic Coastal Plain Small Blackwater River Floodplain Forest (CES203.249)
- Atlantic Coastal Plain Small Brownwater River Floodplain Forest (CES203.250)
- Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281)
- Southern Atlantic Coastal Plain Depression Pond (CES203.262)
- Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242)

Adjacent Ecological System Comments: Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281) and Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267) are the most frequently associated systems. Southern Atlantic Coastal Plain Depression Pondshore (CES203.262) patches may be embedded, and Atlantic Coastal Plain Small Blackwater River Floodplain Forest (CES203.249), Atlantic Coastal Plain Small Brownwater River Floodplain Forest (CES203.250), and Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242) may adjoin.

Distribution

Range: This system ranges from southern Virginia to central South Carolina. To the south, the equivalent system is Southern Atlantic Coastal Plain Wet Pine Savanna and Flatwoods (CES203.536), the range of which includes Georgia and northern Florida.
Divisions: 203:C

CENTRAL INTERIOR HIGHLANDS AND APPALACHIAN SINKHOLE AND DEPRESSION POND (CES202.018)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland [Lowland]; Depressional [Pond]; Depressional [Sinkhole]; Muck; Mineral: W/ A-Horizon >10 cm
Non-Diagnostic Classifiers: Alkaline Water; Circumneutral Water; Forest and Woodland (Treed); Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9160

CONCEPT

Summary: This system of ponds and wetlands is found in the Interior Highlands of the Ozark, Ouachita, and Interior Low Plateau regions, and ranges north from the Southern and Central Appalachians to the northern Piedmont regions. Stands occur in basins of sinkholes or other isolated depressions on uplands. Soils are very poorly drained, and surface water may be present for extended periods of time, rarely becoming dry. Water depth may vary greatly on a seasonal basis and may be a meter deep or more in the winter. Some examples become dry in the summer. Soils may be deep (100 cm or more), consisting of peat or muck, with parent material of peat, muck or alluvium. Ponds vary from open water to herb-, shrub-, or tree-dominated. Tree-dominated examples typically contain *Quercus* species, *Platanus occidentalis*, *Fraxinus pennsylvanica*, *Acer saccharinum*, or *Nyssa* species, or a combination of these. In addition, *Liquidambar styraciflua* may be present in southern examples. *Cephalanthus occidentalis* is a typical shrub component. The herbaceous layer is widely variable depending on geography.
Classification Comments: Many of these ponds have their geologic origin as a more-or-less complete karst collapse feature. Some of them may display this geologic origin in a more explicit manner, with definite walls and exposed limestone or dolomite at the surface ("sinkholes"). Others are more subtle, and exist as more gentle depressions, with no exposed surface geology ("depression ponds"). This includes the "sagponds" of northwestern Georgia and adjacent Alabama. Rare examples in the Ridge and Valley of Georgia (Coosa Valley) are included here. These occur on limestones or dolomites of the Chickamauga Group. Matt Elliott (pers. comm.): "I would put Ridge and Valley sagponds in with Interior Highlands ponds rather than Piedmont, as they are essentially karst features. R&V sagponds are generally pretty rare but are common in parts of Bartow County, Georgia, and a few other places. The shallower ones are dominated by willow oak, the deeper ones *Nyssa biflora*. On the Cumberland Plateau, the ones I have seen usually have sweetgum and *Nyssa sylvatica*, but I think willow oak and possibly *Nyssa biflora* might occur in some of the deeper ones. A lot of the plateau ponds seem more like swales than deep ponds, but they still may be related to underlying karst features. The Ridge and Valley sagponds may be somewhat different from those on the plateau - often deeper and with even more Coastal Plain elements; it also includes sinkhole ponds of northern New Jersey (K. Strakosch-Walz pers. comm.) and possibly ponds of the Ridge and Valley in Pennsylvania. These are very similar to Shenandoah sinkhole ponds of Virginia and are in Maryland as well (L. Sneddon pers. comm.). The only documented occurrence in Pennsylvania is the Maple Hills sinkhole in Lycoming County; "there are plenty of other sinkholes in Pennsylvania, but they have not been associated with any specific plant community" (G. Podniesinski pers. comm. 2010).

DESCRIPTION

Environment: Examples of this system occur in basins of sinkholes or other isolated depressions on uplands. Soils are very poorly drained, and surface water may be present for extended periods of time, rarely becoming dry. The watershed of these sites is typically small so water depth may vary greatly on a seasonal basis, and may be a meter deep or more in the winter (Homoya and Hedge 1985). Some examples become dry in the summer. The rate of water level rise and fall may also be related to whether these sites have internal drainage within the karst features or are essentially closed depressions (Wolfe 1996). Soils may be deep (100 cm or more), consisting of peat or muck, with parent material of peat, muck or alluvium. Many of these ponds have their geologic origin as a more-or-less complete karst collapse feature. Some of them may display this geologic origin in a more explicit manner, with definite

walls and exposed limestone or dolomite at the surface ("sinkholes"). Others are more subtle and exist as more gentle depressions, with no exposed surface geology ("depression ponds").
Vegetation: Ponds vary from open water to herb-, shrub-, or tree-dominated types. Tree-dominated examples typically contain *Quercus* species, *Platanus occidentalis, Fraxinus pennsylvanica, Acer saccharinum,* or *Nyssa* species, or a combination of these. In addition, *Liquidambar styraciflua* may be present in southern examples. *Cephalanthus occidentalis* is a typical shrub component. The herbaceous layer is widely variable depending on geography.
Dynamics: Water depth may vary greatly on a seasonal basis, and may be a meter deep or more in the winter. Some examples become dry in the summer.

Component Associations:
- *(Quercus palustris) / Panicum rigidulum var. rigidulum - Panicum verrucosum - Eleocharis acicularis* Herbaceous Vegetation (CEGL007858, G1)
- *Acer (rubrum, saccharinum) - Fraxinus pennsylvanica / Ilex verticillata / Osmunda regalis* Forest (CEGL006630, GNR)
- *Boltonia asteroides var. asteroides - Symphyotrichum racemosum - Mentha arvensis* Herbaceous Vegetation (CEGL006900, G1G2)
- *Brasenia schreberi* Eastern Herbaceous Vegetation (CEGL004527, G4?)
- *Carex aquatilis - Dulichium arundinaceum* Herbaceous Vegetation (CEGL008542, G1?)
- *Carex barrattii* Herbaceous Vegetation (CEGL007857, G1)
- *Carex comosa - Carex decomposita - Dulichium arundinaceum - Lycopus rubellus* Herbaceous Vegetation (CEGL002413, G3G4)
- *Carex joorii - Eleocharis tenuis var. verrucosa - Juncus* spp. *- Panicum rigidulum* Interior Highlands Channel Scar Depression Wooded Herbaceous Vegetation (CEGL007116, G2?)
- *Cephalanthus occidentalis - (Salix nigra, Quercus lyrata)* Karst Depression Shrubland (CEGL008439, G1Q)
- *Cephalanthus occidentalis / Hibiscus moscheutos ssp. moscheutos* Depression Pond Shrubland (CEGL004742, G3?)
- *Ceratophyllum demersum - Stuckenia pectinata* Herbaceous Vegetation (CEGL004528, G4G5)
- *Dasiphora fruticosa ssp. floribunda / Rhynchospora capillacea - Scleria verticillata* Shrub Herbaceous Vegetation (CEGL006356, G1)
- *Eleocharis microcarpa - Juncus repens - Rhynchospora corniculata - (Mecardonia acuminata, Proserpinaca* spp.) Herbaceous Vegetation (CEGL004748, G2G3)
- *Fraxinus pennsylvanica - Acer saccharinum - Quercus bicolor / Boehmeria cylindrica* Forest (CEGL006634, GNR)
- *Liquidambar styraciflua - Acer rubrum / Carex* spp. *- Sphagnum* spp. Forest (CEGL007388, G2G3Q)
- *Ludwigia peploides* Herbaceous Vegetation (CEGL007835, G4G5)
- *Nelumbo lutea* Herbaceous Vegetation (CEGL004323, G4?)
- *Nuphar advena - Nymphaea odorata* Herbaceous Vegetation (CEGL002386, G4G5)
- *Nyssa aquatica / Cephalanthus occidentalis* Pond Forest (CEGL004712, G1?)
- *Nyssa biflora / Cephalanthus occidentalis - Lyonia lucida* Sagpond Forest (CEGL004116, G1G2)
- *Orontium aquaticum - Schoenoplectus subterminalis - Eriocaulon aquaticum* Herbaceous Vegetation (CEGL007859, G1)
- *Panicum hemitomon - Dulichium arundinaceum* Herbaceous Vegetation (CEGL004126, G1)
- *Platanus occidentalis - Fraxinus pennsylvanica - Ulmus americana / Cornus sericea* Forest (CEGL006901, G2G3)
- *Pontederia cordata - Sagittaria graminea - Sagittaria latifolia* Semipermanently Flooded Herbaceous Vegetation (CEGL004986, G1G2Q)
- *Quercus alba - Nyssa sylvatica* Sandstone Ridgetop Depression Forest (CEGL008440, G2Q)
- *Quercus bicolor - Fraxinus pennsylvanica / Carex* spp. Forest (CEGL004422, G1G2)
- *Quercus lyrata - Quercus (palustris, phellos) - Liquidambar styraciflua - (Populus heterophylla)* Forest (CEGL004421, G2G3)
- *Quercus lyrata / Betula nigra / Pleopeltis polypodioides ssp. michauxiana* Forest (CEGL004975, G1)
- *Quercus lyrata* Pond Forest (CEGL004642, G1G3)
- *Quercus palustris - (Quercus bicolor) / Carex crinita / Sphagnum* spp. Forest (CEGL002406, G3?)
- *Quercus palustris - Quercus bicolor - (Liquidambar styraciflua)* Mixed Hardwood Forest (CEGL002432, G3G4)
- *Quercus palustris* Pond Forest (CEGL007809, G2)
- *Quercus phellos - Liquidambar styraciflua / Chasmanthium laxum* Cumberland / Southern Ridge and Valley Forest (CEGL008441, G3)
- *Saccharum baldwinii - Calamagrostis coarctata - Panicum rigidulum - Rhynchospora capitellata* Herbaceous Vegetation (CEGL004750, G2G3)
- *Salix nigra - Acer (rubrum, saccharinum) / Alnus serrulata - Cephalanthus occidentalis* Forest (CEGL007703, G5)
- *Scirpus cyperinus - Dulichium arundinaceum / Sphagnum* spp. Herbaceous Vegetation (CEGL004134, G1Q)
- *Scirpus cyperinus - Panicum rigidulum - Rhynchospora corniculata - (Dulichium arundinaceum)* Herbaceous Vegetation (CEGL004719, G2G3)
- *Sparganium americanum - (Sparganium erectum ssp. stoloniferum) - Epilobium leptophyllum* Herbaceous Vegetation (CEGL004510, G3?)
- *Typha latifolia* Southern Herbaceous Vegetation (CEGL004150, G5)
- *Vaccinium oxycoccos - (Vaccinium macrocarpon) / Rhynchospora alba - Drosera rotundifolia / Sphagnum* spp. Dwarf-shrubland (CEGL007856, G2)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Eastern Highland Rim Prairie and Barrens (CES202.354)
- Interior Highlands Unglaciated Flatwoods (CES202.454)

DISTRIBUTION

Range: This system is found from the Ozark and Ouachita mountains east to the southern and central Appalachians and the northern Piedmont regions (?), including the unglaciated Interior Low Plateau and Ridge and Valley. It ranges from Missouri, West Virginia, Pennsylvania, and Delaware south to Arkansas, Alabama and Georgia.
Divisions: 202:C

COLUMBIA BASIN FOOTHILL RIPARIAN WOODLAND AND SHRUBLAND (CES304.768)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval; Short (50-100 yrs) Persistence; Montane [Lower Montane]; Lowland [Foothill]; Riverine / Alluvial
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Shrubland (Shrub-dominated); Temperate [Temperate Continental]; Unconsolidated; Needle-Leaved Tree; Broad-Leaved Deciduous Tree; Broad-Leaved Deciduous Shrub
National Mapping Codes: ESLF 9170

CONCEPT

Summary: This is a low-elevation riparian system found on the periphery of the mountains surrounding the Columbia River Basin, along major tributaries and the main stem of the Columbia at relatively low elevations. This is the riparian system associated with all streams at and below lower treeline, including permanent, intermittent and ephemeral streams with woody riparian vegetation. These forests and woodlands require flooding and some gravels for reestablishment. They are found in low-elevation canyons and draws, on floodplains, or in steep-sided canyons, or narrow V-shaped valleys with rocky substrates. Sites are subject to temporary flooding during spring runoff. Underlying gravels may keep the water table just below the ground surface and are favored substrates for cottonwood. Large bottomlands may have large occurrences, but most have been cut over or cleared for agriculture. Rafted ice and logs in freshets may cause considerable damage to tree boles. Beavers crop younger cottonwood and willows and frequently dam side channels occurring in these stands. In steep-sided canyons, streams typically have perennial flow on mid to high gradients. Important and diagnostic trees include *Populus balsamifera ssp. trichocarpa, Alnus rhombifolia, Populus tremuloides, Celtis laevigata var. reticulata, Betula occidentalis*, or *Pinus ponderosa*. Important shrubs include *Crataegus douglasii, Philadelphus lewisii, Cornus sericea, Salix lucida ssp. lasiandra, Salix eriocephala, Rosa nutkana, Rosa woodsii, Amelanchier alnifolia, Prunus virginiana*, and *Symphoricarpos albus*. Grazing is a major influence in altering structure, composition, and function of the system.

DESCRIPTION

Environment: This is a low-elevation riparian system found on the periphery of the mountains surrounding the Columbia River Basin, along major tributaries and the main stem of the Columbia at relatively low elevations. This is the riparian system associated with all streams at and below lower treeline, including permanent, intermittent and ephemeral streams with woody riparian vegetation. These forests and woodlands require flooding and some fresh exposed gravel for reestablishment. They are found in low-elevation canyons and draws, on floodplains, or in steep-sided canyons, or narrow V-shaped valleys with rocky substrates. Sites are subject to temporary flooding during spring runoff. Underlying gravels may keep the water table just below the ground surface and are favored substrates for cottonwood. Large bottomlands may have large occurrences, but most have been cut over or cleared for agriculture. Rafted ice and logs in freshets may cause considerable damage to tree boles. Beavers crop younger cottonwood and willows and frequently dam side channels occurring in these stands. In steep-sided canyons, streams typically have perennial flow on mid to high gradients.
Vegetation: Important and diagnostic trees include *Populus balsamifera ssp. trichocarpa, Alnus rhombifolia, Populus tremuloides, Celtis laevigata var. reticulata, Betula occidentalis*, or *Pinus ponderosa*. Important shrubs include *Crataegus douglasii, Philadelphus lewisii, Cornus sericea, Salix lucida ssp. lasiandra, Salix eriocephala, Rosa nutkana, Rosa woodsii, Amelanchier alnifolia, Prunus virginiana*, and *Symphoricarpos albus*.
Dynamics: The majority of these forests and woodlands require flooding and freshly deposited gravel/sand for seedling establishment. The natural hydrologic cycle in these reaches includes high spring and early summer flow pulses from snowmelt run off and a natural drawdown into late-summer and fall months. Spring and early summer months also see a rise of the underlying alluvial groundwater table as well as natural lowering of the groundwater in late summer into fall months. High flows and flooding scour (removal) and deposit sediments that stimulate growth of cottonwoods and willows, replenish nutrients, move seeds and aquatic organisms (Merritt and Wohl 2002). These processes stimulate and revive riparian ecosystems. Some reaches are supported by groundwater discharge where flood disturbances are less vital to long-term viability.

COLUMBIA PLATEAU SILVER SAGEBRUSH SEASONALLY FLOODED SHRUB-STEPPE (CES304.084)

CLASSIFIERS

Classification Status: Standard

Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Impermeable Layer; Intermittent Flooding; Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Lowland [Lowland]; Playa; Temperate [Temperate Xeric]; Depressional
National Mapping Codes: ESLF 9321

CONCEPT

Summary: This ecological system includes sagebrush communities occurring at lowland and montane elevations in the Columbia Plateau-northern Great Basin region, east almost to the Great Plains. These are generally depressional wetlands or non-alkaline playas, occurring as small- or occasionally large-patch communities, in a sagebrush or montane forest matrix. Climate is generally semi-arid, although it can be cool in montane areas. This system occurs in poorly drained depressional wetlands, the largest characterized as playas, the smaller as vernal pools, or along seasonal stream channels in valley bottoms or mountain meadows. *Artemisia cana ssp. bolanderi* or *Artemisia cana ssp. viscidula* are dominant, with *Artemisia tridentata ssp. tridentata, Artemisia tridentata ssp. wyomingensis*, or *Artemisia tridentata ssp. vaseyana* occasionally codominant; *Dasiphora fruticosa ssp. floribunda* can also be codominant. Understory graminoids and forbs are characteristic, with *Poa secunda (= Poa nevadensis), Poa cusickii, Festuca idahoensis, Muhlenbergia filiformis, Muhlenbergia richardsonis*, and *Leymus cinereus* dominant at the drier sites; *Eleocharis palustris, Deschampsia caespitosa*, and *Carex* species dominate at wetter or higher-elevation sites.
Related Concepts:
- Other Sagebrush Types (408) (Shiflet 1994) Intersecting. *Artemisia cana ssp. viscidula* shrublands are included in this ecological system.

CUMBERLAND RIVERSCOUR (CES202.036)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval; Riparian Mosaic; Riverine / Alluvial; Graminoid
Non-Diagnostic Classifiers: Lowland [Foothill]; Woody-Herbaceous; Broad-Leaved Deciduous Tree; Broad-Leaved Deciduous Shrub
National Mapping Codes: ESLF 9164

CONCEPT

Summary: Examples of this riverscour-influenced system may occur on high-gradient and very high-gradient streams in the gorges of the Cumberland Plateau, the Cumberland Mountains, and the more rugged parts of the Ridge and Valley in Kentucky, Tennessee, and Alabama, and possibly in Georgia. The succession of woody plants (particularly trees) is retarded by the force of "flashy," high-velocity water traveling down the stream channels. This system may occur on flood-scoured acidic or calcareous bedrock, cobble, pebble, or sandbar substrates of sandstone, limestone, dolomite, and possibly other sedimentary and weakly metamorphosed geologies. The most distinctive parts of the system are dominated by shrubs, perennial grasses, and forbs. In some areas, a riparian woodland composed of *Betula nigra* and *Platanus occidentalis* may be a component association. Some common shrubs include *Alnus serrulata, Betula nigra, Cephalanthus occidentalis, Cornus amomum, Fothergilla major, Itea virginica, Salix caroliniana, Rhododendron arborescens, Toxicodendron radicans*, and *Juniperus virginiana var. virginiana*. Some grasses (typical of prairies) include *Andropogon gerardii, Sorghastrum nutans, Schizachyrium scoparium, Chasmanthium latifolium, Tripsacum dactyloides*, and/or *Panicum virgatum*. Forbs are diverse and variable from occurrence to occurrence. This system is affected by flood-scouring in some areas and deposition in others. There is typically a gradient from dry, nutrient-poor conditions upslope to moist and relatively enriched conditions downslope. A variety of these conditions may exist at any one site. Some areas are prone to severe drought periods that may stress or kill some (particularly woody) vegetation. Flood-scouring is a powerful and ecologically important abrasive force along the riverbanks where this system is found.
Classification Comments: Examples of the system are sometimes called "scoured riverbank prairies," "riverside prairies," "linear prairies," "rivershore grasslands," or "scoured riverine bluff prairie." River systems where it is found include the Cumberland and its tributaries, the Obed, the Obey, Chickasaw Creek (Tennessee), the Cahaba (Alabama), the Red River Gorge (Kentucky), Rockcastle River (Kentucky), the Big South Fork of the Cumberland (Kentucky/Tennessee) and its tributaries, and others.
Similar Ecological Systems:
- Central Appalachian Stream and Riparian (CES202.609)--occurs to the north and east.
- South-Central Interior Small Stream and Riparian (CES202.706)

Related Concepts:
- River Birch - Sycamore: 61 (Eyre 1980) Finer

DESCRIPTION

Environment: Examples may occur on high-gradient and very high-gradient streams in the gorges of the Cumberland Plateau, the Cumberland Mountains, and rugged parts of the Ridge and Valley, in Kentucky, Tennessee, and Alabama, and possibly in Georgia. The succession of woody plants (particularly trees) is retarded by the force of "flashy," high-velocity water traveling down the stream channels. This system may occur on flood-scoured acidic or calcareous bedrock, cobble, pebble, or sandbar substrates of sandstone, limestone, dolomite, and possibly other sedimentary and weakly metamorphosed geologies. It is presumably more extensive and better developed in materials derived from sandstone, where the erodibility creates more material circulating in the stream to create the sandbar/gravelbar areas where the system may occur in extensive patches, and where the extremely well-drained qualities of the coarse sediments further help to retard woody plant succession.
Vegetation: Examples of this system are typically dominated by shrubs, perennial grasses, and forbs. In some areas, a riparian woodland composed of *Betula nigra* and *Platanus occidentalis* may be a component association. Some common shrub component species include *Alnus serrulata, Betula nigra, Cephalanthus occidentalis, Cornus amomum, Fothergilla major, Itea virginica, Salix caroliniana, Rhododendron arborescens, Toxicodendron radicans*, and *Juniperus virginiana var. virginiana*. More southern examples may contain *Hydrangea quercifolia*, *Hypericum densiflorum*, and *Morella cerifera (= Myrica cerifera var. cerifera)*. Some grasses and forbs include *Andropogon gerardii, Sorghastrum nutans, Schizachyrium scoparium, Chasmanthium latifolium, Tripsacum dactyloides, Panicum virgatum, Baptisia australis, Conoclinium coelestinum (= Eupatorium coelestinum), Coreopsis pubescens, Coreopsis tripteris, Elephantopus carolinianus, Helenium autumnale, Hydrocotyle* sp., *Ludwigia leptocarpa, Lycopus* spp., *Orontium aquaticum, Osmunda regalis var. spectabilis, Oxypolis rigidior, Phlox carolina, Pityopsis graminifolia var. latifolia, Rhynchospora colorata (= Dichromena colorata), Rudbeckia laciniata*, and *Vernonia gigantea*. Patches of *Carex torta* may be present in some examples. Distinctive shoals with *Hymenocallis coronaria* and *Justicia americana* may be present as well. Some of these species are typical of prairies, and thrive in the well-lit environment.
Dynamics: This system is prone to flooding in the upper regions and deposition in the topographically lower areas. There is typically

a gradient from dry acidic conditions higher on the bank to moist, fairly enriched conditions lower down may exist at any one site. It is prone to severe drought periods that may stress or kill some vegetation. Flood scouring is a powerful and ecologically important abrasive force along the riverbanks where this system is found. Soils in sandstone areas are rapidly drained Psamments, and may be restricted to the narrow interstices of tightly packed boulders, or to small crevices in bedrock exposures. Within the system the various species are distributed patchily probably due to microsite conditions.

Component Associations:
- *(Salix caroliniana, Rhododendron arborescens) - Andropogon gerardii - Baptisia australis - (Solidago simplex ssp. randii)* Herbaceous Vegetation (CEGL008471, G2?)
- *Alnus serrulata - Xanthorhiza simplicissima* Shrubland (CEGL003895, G3G4)
- *Betula nigra - Platanus occidentalis / Alnus serrulata / Boehmeria cylindrica* Forest (CEGL007312, G4G5)
- *Carex torta* Herbaceous Vegetation (CEGL004103, G3G4)
- *Hymenocallis coronaria - Justicia americana* Herbaceous Vegetation (CEGL004285, G1)
- *Hypericum densiflorum - Alnus serrulata / Jamesianthus alabamensis - Xyris tennesseensis* Shrubland (CEGL008494, G1G2)
- *Hypericum densiflorum - Alnus serrulata / Tripsacum dactyloides* Shrubland (CEGL008495, G1G2)
- *Justicia americana* Herbaceous Vegetation (CEGL004286, G4G5)
- *Osmunda regalis var. spectabilis* Seepage Scour Herbaceous Vegetation (CEGL008404, G3?)
- *Podostemum ceratophyllum* Herbaceous Vegetation (CEGL004331, G3G5)
- *Vallisneria americana - (Heteranthera dubia)* Riverine Herbaceous Vegetation (CEGL004333, G3G4)

DISTRIBUTION

Range: This system is found in the Cumberland Plateau, the Cumberland Mountains, and the more rugged parts of the Ridge and Valley, in Kentucky, Tennessee, and Alabama, and possibly in Georgia.
Divisions: 202:C
Nations: US
Subnations: AL, GA?, KY, TN, WV

CUMBERLAND SEEPAGE FOREST (CES202.361)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Seepage-Fed Sloping [Mineral]; Broad-Leaved Tree
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9316

CONCEPT

Summary: This system of seepage-influenced, primarily forested wetlands is found in the Cumberland Plateau and Ridge and Valley regions of Alabama, Tennessee, West Virginia, and Kentucky. It is also found on the flat metasedimentary upland surfaces of Chilhowee Mountain, Tennessee. This area is part of the Southern Blue Ridge (TNC Ecoregion 51), but its ecological communities are similar to those of the Cumberlands. Examples most often occur in streamhead swales or on broad sandstone ridges where soils are sandy and saturated due to a combination of perched water table and seepage flow. Examples range in condition from open woodlands to forests, and some may lack a canopy and then will be dominated by shrubs or herbs. Typical woody species, when present, include *Acer rubrum, Nyssa sylvatica, Liriodendron tulipifera, Liquidambar styraciflua, Ilex opaca var. opaca, Oxydendrum arboreum*, and *Kalmia latifolia*.
Classification Comments: Examples range in condition from open woodlands to forests, and some may lack a canopy and then will be dominated by shrubs or herbs.
Similar Ecological Systems:
- East Gulf Coastal Plain Northern Seepage Swamp (CES203.554)

Related Concepts:
- Red Maple: 108 (Eyre 1980) Finer

DESCRIPTION

Environment: Examples occur in streamhead swales or on broad sandstone ridges. Soils are sandy and saturated due to a combination of perched water table and seepage flow.
Vegetation: Typical woody species, when present, include *Acer rubrum, Nyssa sylvatica, Liriodendron tulipifera, Liquidambar styraciflua, Ilex opaca var. opaca, Oxydendrum arboreum*, and *Kalmia latifolia*. Some extreme southerly examples may contain *Nyssa biflora*. Some stands are more open due to fire frequency, windthrow, or other disturbance. These are more likely to contain noteworthy herbaceous plant species (e.g., *Platanthera* spp.). Typical shrubs include *Ilex verticillata, Alnus serrulata, Rhododendron maximum, Photinia melanocarpa (= Aronia melanocarpa), Vaccinium simulatum, Viburnum nudum var. nudum* (or *Viburnum nudum var. cassinoides* in the Southern Blue Ridge), and *Cornus foemina*. Woody vines can be common and include *Toxicodendron radicans* and (especially towards the south), *Decumaria barbara*, and *Bignonia capreolata*. Typical herbaceous species include *Osmunda cinnamomea, Osmunda regalis var. spectabilis, Chasmanthium laxum, Thelypteris noveboracensis, Woodwardia areolata, Oxypolis rigidior, Carex intumescens, Carex debilis, Carex crinita, Medeola virginiana, Lobelia cardinalis, Juncus effusus var. pylaei, Scirpus polyphyllus, Rubus hispidus, Solidago patula var. patula, Athyrium filix-femina ssp. asplenioides*, and *Viola X primulifolia*. *Platanthera integrilabia* and *Platanthera clavellata* are also known from these forested seeps but are more typical in more open examples. Patches of *Sphagnum* spp. are common and *Sphagnum lescurii* is typical.

Component Associations:
- *Acer rubrum var. trilobum - Nyssa sylvatica / Osmunda cinnamomea - Chasmanthium laxum - Carex intumescens / Sphagnum lescurii* Forest (CEGL007443, G3?)
- *Acer rubrum var. trilobum / Alnus serrulata / Calamagrostis coarctata* Saturated Woodland (CEGL003737, G2G3)

DISTRIBUTION

Range: This systems is found in the Cumberland Plateau and Ridge and Valley regions of Alabama, Tennessee, West Virginia, and Kentucky. Related stands in the Interior Low Plateau of Kentucky ("Shawnee Hills") need to be provided for here or in a separate system.

EAST GULF COASTAL PLAIN FRESHWATER TIDAL WOODED SWAMP (CES203.299)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Riverine / Alluvial; Tidal / Estuarine
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: ESLF 9132

CONCEPT

Summary: This ecological system encompasses the tidally flooded portions of river floodplains which flow into the northern Gulf of Mexico east of the Mississippi River. Large outflows of freshwater keep salinity levels at a minimum, and flooding is of short enough duration to allow survival of tree canopies. Stands are dominated by a combination of *Nyssa aquatica, Nyssa biflora, Taxodium distichum*, and *Fraxinus pennsylvanica*. Other plants that are typically present include *Magnolia virginiana, Sabal palmetto, Juniperus virginiana var. silicicola, Cyrilla racemiflora, Quercus laurifolia, Sabal minor, Taxodium ascendens, Cliftonia monophylla, Pinus elliottii var. elliottii, Chamaecyparis thyoides, Hypericum nitidum, Cladium mariscus ssp. jamaicense*, and *Persea palustris*. These swamps may be regularly flooded at least twice daily.

Similar Ecological Systems:
- East Gulf Coastal Plain Small Stream and River Floodplain Forest (CES203.559)
- Southern Atlantic Coastal Plain Tidal Wooded Swamp (CES203.240)

Related Concepts:
- Baldcypress - Tupelo: 102 (Eyre 1980) Finer

- Water Tupelo - Swamp Tupelo: 103 (Eyre 1980) Finer
- Willow Oak - Water Oak - Diamondleaf (Laurel) Oak: 88 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in lower reaches of river floodplains and along estuary shorelines, in places regularly or irregularly flooded by lunar or wind tides. The water has little salt content, due to distance from the ocean and/or strong freshwater input. Soils may be mineral or organic. Soils are generally permanently saturated even when the tide is low. The transition of the hydrology to flood dominance rather than tidal dominance may be very gradual.

Vegetation: Stands are dominated by a combination of *Nyssa aquatica, Nyssa biflora, Taxodium distichum*, and *Fraxinus pennsylvanica*. Other plants that are typically present include *Magnolia virginiana, Sabal palmetto, Juniperus virginiana var. silicicola, Cyrilla racemiflora, Quercus laurifolia, Sabal minor, Taxodium ascendens, Cliftonia monophylla, Pinus elliottii var. elliottii, Chamaecyparis thyoides, Hypericum nitidum, Cladium mariscus ssp. jamaicense*, and *Persea palustris*.

Dynamics: Regular or irregular tidal flooding with freshwater is the ecological factor that makes this system distinct. These swamps may be regularly flooded at least twice a day for several hours and remain inundated for days during flood or storm events (Wharton et al. 1982, FNAI 1990). River floods may also seasonally affect this system. Wind and flooding are the dominant disturbance agents in this type and this includes wind damage from hurricanes and tornadoes as well as inundation of young stands. Canopy gaps can be created by high winds, such as from nor'easters, tropical storms and hurricanes (Nordman 2013). Infrequent intrusion of saltier water, which is stressful or fatal to many of the plant species, is an important periodic disturbance created by storms. Insect outbreaks would occur infrequently in these closed-canopy forests (Landfire 2007a). This system generally appears to be in a shifting relationship with tidal freshwater marshes of the same region. Most marshes have standing dead trees in them, suggesting they recently were swamps. But, conversely, some marshes are being invaded with trees and may be turning into swamps. Freshwater tidal marshes generally occur at the shallow edge of tidal rivers and streams, where river and tidal flow is high, and the vegetation is affected by the changing meanders of the tidal channel. Rising sea level is driving shifts in the communities of this system, causing upstream non-tidal swamps to develop into this system (as they become subject to tides) and causing parts of this system to turn into brackish marshes. In areas not too strongly affected by saltwater intrusion or drowning by rising sea level, these communities can be expected to exist as old-growth, multi-aged forests.

Component Associations:
- *Nyssa aquatica* Tidal Forest (CEGL008561, G3?)
- *Nyssa biflora - (Taxodium distichum, Nyssa aquatica) / Morella cerifera - Rosa palustris* Tidal Forest (CEGL004484, G3G4)
- *Nyssa biflora - Magnolia virginiana - Sabal palmetto - Juniperus virginiana var. silicicola* Forest (CEGL004684, G2)
- *Nyssa biflora - Magnolia virginiana / Cyrilla racemiflora* Forest (CEGL004683, G2)
- *Quercus laurifolia - Fraxinus pennsylvanica - Nyssa aquatica / Sabal minor* Tidal Forest (CEGL007884, G3?)

- *Taxodium ascendens - Cliftonia monophylla - Pinus elliottii var. elliottii - Chamaecyparis thyoides / Hypericum nitidum - Cladium mariscus ssp. jamaicense* Forest (CEGL004981, G2?)
- *Taxodium distichum - Nyssa aquatica - Persea palustris* Forest (CEGL004681, G2)
- *Taxodium distichum - Nyssa biflora - Magnolia virginiana - Fraxinus profunda* Forest (CEGL004682, G2)

EAST GULF COASTAL PLAIN INTERIOR SHRUB BOG (CES203.385)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Seepage-Fed Sloping
National Mapping Codes: ESLF 9341

CONCEPT

Summary: This ecological system includes wet, shrub-dominated seepage communities in the Upper East Gulf Coastal Plain of Alabama, adjacent Georgia, and possibly Mississippi. These wetlands generally occur in small patches on slopes within a matrix of longleaf pine-dominated vegetation. Wetland conditions are maintained by seepage flow from adjacent uplands. Examples of this system can vary between densely shrubby and fairly open and herbaceous, depending on frequency of fire and amount of elapsed time since the previous fires. However, this system tends to be much shrubbier due to topographic isolation than related seepage bog system of the Outer Coastal Plain such as Southern Coastal Plain Herbaceous Seep and Bog (CES203.078). The globally rare pitcher plant *Sarracenia rubra ssp. alabamensis* may be present in some examples of this system.

Similar Ecological Systems:
- Atlantic Coastal Plain Sandhill Seep (CES203.253)
- Southern Coastal Plain Herbaceous Seep and Bog (CES203.078)

DESCRIPTION

Environment: Examples may be found along steep to gentle slopes in the historically longleaf pine-dominated landscape of the Upper East Gulf Coastal Plain.

Vegetation: The physiognomy is variable, depending on fire history, and can vary from densely shrubby to herbaceous. In current condition, most examples are shrubby. Dominant species include *Morella cerifera (= Myrica cerifera var. cerifera), Kalmia latifolia, Symplocos tinctoria, Ilex coriacea, Ilex glabra, Arundinaria gigantea ssp. tecta,* and *Cyrilla racemiflora*. A number of other shrubs may also be present. Some stands, or portions of them, are strongly dominated by *Arundinaria gigantea ssp. tecta*. A fairly rich herb layer is present that may include *Osmunda cinnamomea* (dominant), *Eupatorium album, Xyris caroliniana, Aletris farinosa, Aristida purpurascens, Dichanthelium dichotomum var. ensifolium, Epigaea repens, Eupatorium pilosum, Eupatorium rotundifolium, Helianthus angustifolius, Lachnocaulon anceps, Polygala nana, Pteridium aquilinum var. pseudocaudatum, Rhexia alifanus, Rhexia petiolata, Rhynchospora plumosa, Sarracenia rubra ssp. alabamensis, Schizachyrium scoparium, Solidago odora var. odora,* and *Xyris ambigua*.

Component Associations:
- *Arundinaria gigantea ssp. tecta* Shrubland (CEGL003843, G1)
- *Ilex (coriacea, glabra) / Osmunda cinnamomea - Rhexia petiolata* Herbaceous Vegetation (CEGL008550, G2?)
- *Ilex coriacea - Lyonia lucida - Smilax laurifolia* Shrubland (CEGL004666, G3G4)
- *Morella cerifera - Kalmia latifolia - Symplocos tinctoria / Osmunda cinnamomea* Herbaceous Vegetation (CEGL008548, G2?)
- *Pinus serotina / Lyonia lucida - Ilex glabra - (Cyrilla racemiflora)* Shrubland (CEGL003846, G3)

DISTRIBUTION

Range: This system is found in the Upper East Gulf Coastal Plain of Alabama, adjacent Georgia, and possibly Mississippi.

EAST GULF COASTAL PLAIN LARGE RIVER FLOODPLAIN FOREST (CES203.489)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Riverine / Alluvial [Brownwater]
National Mapping Codes: ESLF 9199

CONCEPT

Summary: This system represents a geographic subset of Southern Floodplain Forest. Examples may be found along large rivers of the East and Upper East Gulf Coastal Plain, especially the Apalachicola, Alabama/Cahaba, Tombigbee, Pascagoula, and Pearl rivers, all of which ultimately drain into the Gulf of Mexico. Several distinct plant communities can be recognized within this system that may be related to the array of different geomorphologic features present within the floodplain. Some of the major geomorphic features associated with different community types include natural levees, point bars, meander scrolls, oxbows, and sloughs. Vegetation generally includes forests dominated by bottomland hardwood species and other trees tolerant of flooding. However, herbaceous and shrub vegetation may be present in certain areas as well.
Classification Comments: In the Upper East Gulf Plain of Kentucky, this system is represented in the Ecoregions of Kentucky map (Woods et al. 2002) by the lower part of the Wabash-Ohio bottomlands (72a). In the lower Gulf Coastal Plain, this includes at least EPA (Omernik) Level IV ecoregions 65p and 75i (EPA 2004).

DESCRIPTION

Environment: This system represents a geographic subset of Kuchler's (1964) Southern Floodplain Forest. Examples of this system are generally forested with stands of bottomland hardwood species and other trees tolerant of flooding. Local composition varies depending upon actual position within the floodplain, disturbance history, and underlying soils and geology. Although most examples of this system may be thought of as acidic, some examples of this system flow through regions with sufficient calcareous influence to effect vegetation composition. Some of the major geomorphic features associated with different community types include natural levees, point bars, meander scrolls, oxbows, and sloughs (Sharitz and Mitsch 1993).
Dynamics: In pre-European settlement forests, community diversity in these bottomland systems was much more complex than in the modified landscapes of today. Fire, beaver activity, and flooding of varied intensity and frequency created a mosaic whose elements included canebrake, grass and young *Betula-Platanus* beds on reworked gravel or sand bars, beaver ponds, and grass-sedge meadows

in abandoned beaver clearings, as well as the streamside zones and mixed hardwood and/or pine forests that make up more than 95% of the land cover that exists today.

The dominant ecological processes in bottomland hardwood forests are windfall gaps and periodic flooding. Windfall gaps occur on the local scale (the fall of a single mature canopy tree) as well as the landscape scale (storms, hurricanes). When canopy trees fall, seedlings in the understory are released and compete for a spot in the canopy. This leads to dense areas of herbaceous and woody vegetation in windfall gaps of all sizes. This is a major process in forest regeneration in bottomland hardwood forests. Canopy decline and reproductive failure can create late-seral open stands.

Flooding is more frequent on the lower terraces but frequently impacts higher terraces as well (Wharton et al. (1982) zones IV & V). Catastrophic floods can cause the loss of canopy over large areas, and large coastal areas are also impacted by storm surges from hurricanes and tropical storms as well as by salt deposition in the immediate coastal area. The duration of flooding varies with the placement of a particular site in the landscape and is a dominant process affecting vegetation on a given site. Flooding can deposit alluvium or scour the ground, depending on the landscape position of a site and the severity of the flood event.

Fire is infrequent and of limited importance in lower, wetter areas, but was historically important in the older and higher terraces, especially areas adjacent to upland pine or pine flatwoods, and also crept into the floodplains. Putnam (1951 as cited in Wharton et al. 1982) states that a serious fire season occurs on an average of about every 5 to 8 years in the bottomland hardwood forests of the Mississippi Alluvial Plain. It is conjectured that Native Americans maintained canebrakes by deliberate fall burning. Infrequent, mild surface fires would occur in the system and would cause changes in composition and structure due to low fire tolerance.

Changes in hydrology due to the activities of beaver are also an important ecological process in bottomland hardwood forests. Beaver impoundments kill trees (sometimes over large areas) and may create open water habitat, cypress-tupelo stands, or cause stand replacement. Meandering streams are dynamic and frequently change course, eroding into the floodplain and depositing new point bars, thus creating new habitat for early-seral plant communities. In addition, insect outbreaks would occur infrequently in closed-canopy states, opening up the canopy at least temporarily.

Component Associations:

EAST GULF COASTAL PLAIN NORTHERN SEEPAGE SWAMP (CES203.554)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Seepage-Fed Sloping
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 9351

CONCEPT

Summary: This wetland system of the Upper East Gulf Coastal Plain consists of forested wetlands in acidic, seepage-influenced habitats. These are mostly deciduous forests (and less commonly herbaceous communities) generally found at the base of slopes or other habitats where seepage flow is concentrated. Resulting moisture conditions are saturated or even inundated. The vegetation is characterized by *Nyssa sylvatica, Nyssa biflora,* and *Acer rubrum*. Examples occur in portions of the Coastal Plain north of the range of *Persea palustris* and *Magnolia grandiflora*. *Magnolia virginiana* is of less value as a differential species. To the south this system grades into Southern Coastal Plain Seepage Swamp and Baygall (CES203.505), where evergreen species are of much greater importance in the canopy and understory. Due to excessive wetness, these habitats are normally protected from fire except those which occur during extreme droughty periods. These environments are prone to long-duration standing water and tend to occur on highly acidic, nutrient-poor soils.
Classification Comments: Some authors have treated *Persea palustris* (of wetlands) and *Persea borbonia* (of uplands) as one taxon under a broadly conceived *Persea borbonia*. We recognize two distinct taxa, following Kartesz (1999) and Weakley (2005).
Similar Ecological Systems:

DESCRIPTION

Vegetation: The vegetation is characterized by *Nyssa sylvatica, Nyssa biflora,* and *Acer rubrum*. The canopies of stands are primarily deciduous-dominated. Stands in the southern part of the system's range may contain *Magnolia virginiana,* particularly in the understory. This system occurs north of the range of *Persea palustris* and *Magnolia grandiflora,* and these species will be lacking from stands.
Dynamics: Due to excessive wetness, these habitats are normally protected from fire except those which occur during extreme droughty periods. These environments are prone to long-duration standing water and tend to occur on highly acidic, nutrient-poor soils.

Component Associations:
- *Acer rubrum var. trilobum - Nyssa sylvatica / Rhododendron canescens - Viburnum nudum var. nudum / Woodwardia areolata* Forest (CEGL004425, G2G3)
- *Carex crinita - Osmunda* spp. / *Sphagnum* spp. Herbaceous Vegetation (CEGL002263, G2G3)
- *Magnolia virginiana - Nyssa biflora / Oxydendrum arboreum / Viburnum nudum var. nudum* Forest (CEGL008552, G3?)
- *Nyssa biflora - Liquidambar styraciflua / Magnolia virginiana / Hamamelis virginiana - Viburnum nudum* Forest (CEGL008477, G2G3)

DISTRIBUTION

Range: This system is found in the East Gulf Coastal Plain portions of western Kentucky (Funk 1975) and Tennessee, northern Mississippi, northwestern and central Alabama, and southern Illinois.

EAST GULF COASTAL PLAIN SMALL STREAM AND RIVER FLOODPLAIN FOREST (CES203.559)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Intermittent Flooding; Forest and Woodland (Treed); Riverine / Alluvial [Brownwater]
National Mapping Codes: ESLF 9339

CONCEPT

Summary: This is a predominantly forested system of the East Gulf Coastal Plain associated with small brownwater rivers and creeks. In contrast to East Gulf Coastal Plain Large River Floodplain Forest (CES203.489), it has fewer major geomorphic floodplain features typically associated with large river floodplains. Those features that are present tend to be smaller and more closely intermixed with one another, resulting in less obvious vegetational zonation. Bottomland hardwood tree species are typically important and diagnostic, although mesic hardwood species are also present in areas with less inundation, such as upper terraces and possibly second bottoms. As a whole, flooding occurs annually, but the water table usually is well below the soil surface throughout most of the growing season. Areas impacted by beaver impoundments are also included in this system.
Classification Comments: This is primarily a linear system, with some variability as to the size type of the associations included within it. Most are temporarily flooded, with the possible addition of smaller-scale seasonally flooded features such as beaver-created herbaceous wetlands and shrub-dominated features. It is confined to floodplains or terraces of streams and creeks. This system is dependent on a natural hydrologic regime, especially annual to episodic flooding. These landscapes usually encompass a variety of habitats resulting from natural hydrological spatial patterns (i.e., meander scars, sloughs, old depressions, and/or oxbows are present).

DESCRIPTION

Environment: This system is associated with small brownwater rivers and creeks of the East Gulf Coastal Plain. It is confined to floodplains or terraces of streams and creeks. This system is dependent on a natural hydrologic regime, especially annual to episodic flooding. These landscapes usually encompass a variety of habitats resulting from natural hydrological spatial patterns (i.e., meander scars, sloughs, gravel bars, old depressions, and/or oxbows are present). Most component associations are temporarily flooded, with the possible addition of smaller-scale seasonally flooded features such as beaver-created herbaceous wetlands and shrub-dominated features. Some larger examples of this system include the Escambia, the Yellow (Alabama, Florida), the Choctawhatchee, the

Chattahoochee, and the Flint rivers.

Vegetation: Examples of this system may include a number of different plant communities, each with distinctive floristic compositions. Drew et al. (1998) described vegetation attributable to this systems as including the following species: *Carya glabra, Magnolia grandiflora, Quercus virginiana, Liquidambar styraciflua, Acer barbatum, Fraxinus americana, Fraxinus caroliniana, Celtis laevigata, Sabal minor, Sebastiania fruticosa, Serenoa repens*, and *Itea virginica*. Smaller-scale features may be dominated by shrubs (*Cephalanthus occidentalis, Decodon verticillatus*) and/or perennial and annual herbs.

Dynamics: In pre-European settlement forests, community diversity in these bottomland systems was much more complex than in the modified landscapes of today. Fire, beaver activity, and flooding of varied intensity and frequency created a mosaic whose elements included canebrake, grass and young *Betula-Platanus* beds on reworked gravel or sand bars, beaver ponds, and grass-sedge meadows in abandoned beaver clearings, as well as the streamside zones and mixed hardwood and/or pine forests that make up more than 95% of the land cover that exists today.

Flooding is the principal disturbance in this system. When flooded, these systems may have a substantial aquatic faunal component, with high densities of invertebrates, and may play an important role in the life cycle of fish in the associated river. Unusually long or deep floods may stress vegetation or act as a disturbance for some species. Flood waters have significant energy. Larger floods cause local disturbance by scouring and depositing sediment along channels and occasionally causing channel shifts. There are two general types of floods: occasional catastrophic, prolonged floods (due to beaver activity or other severe event); and more frequent repeated minor flooding (i.e., several minor floods within a 10 year period). Flooding is more frequent on the lower terraces but frequently floods higher terraces (Wharton et al. (1982) zones IV and V). Catastrophic floods can cause the loss of canopy over large areas. Canopy decline and reproductive failure can create late-seral open stands. Duration of flooding varies with the placement of a site in the landscape and is a dominant process affecting vegetation on a given site. Flooding can deposit alluvium or scour the ground, depending on the landscape position of a site and the severity of the flood event. The sorting of plant communities by depositional landforms of different height suggest that wetness or depth of flood waters helps drive this process. Scouring and reworking of sediment make up an important factor in bar and bank communities. In addition to disturbance, floods bring nutrient input, deposit sediment, and disperse plant seeds (Landfire 2007a).

In addition to periodic flooding, the dominant ecological process in bottomland hardwood forests is the formation of windfall gaps, which can occur on the local scale (a single mature canopy tree) as well as the landscape scale (effects of tornadoes or hurricanes). Except for primary successional communities such as bars, most forests exist naturally as multi-aged old-growth forests driven by gap-phase regeneration. Windthrow is probably the most important cause of gaps, and is the primary cause of mortality in bottomlands. Major storms or hurricanes occurring at approximately 20-year intervals would have impacted whole stands. When canopy trees fall, seedlings in the understory are released and compete for a spot in the canopy. This leads to dense areas of herbaceous and woody vegetation in windfall gaps of all sizes. This is a major process in forest regeneration in bottomland hardwood forests.

Component Associations:

- *Acer rubrum var. trilobum - Nyssa sylvatica / Rhododendron canescens - Viburnum nudum var. nudum / Woodwardia areolata* Forest (CEGL004425, G2G3)

EAST GULF COASTAL PLAIN SOUTHERN LOBLOLLY-HARDWOOD FLATWOODS (CES203.557)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Extensive Wet Flat
Non-Diagnostic Classifiers: Pimple mounds; Isolated Wetland [Partially Isolated]; Needle-Leaved Tree; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2455; ESLF 9124; ESP 1455

CONCEPT

Summary: This forested system occurs on broad upland flats in the East Gulf Coastal Plain of Alabama and Mississippi, as well as western parts of the lower terraces of the East Gulf Coastal Plain ("Florida Parishes"; EPA Ecoregion 74d) of Louisiana, and likely occurs in other parts of the region as well. Its status and extent in this intervening terrain is unknown. Known examples in the Alabama/Mississippi parts of the range include a mosaic of open forests dominated by *Pinus taeda* interspersed with patches of *Quercus phellos* and sometimes other tree species. The ground surface displays an evident microtopography of alternating mounds and swales occurring in a tight local mosaic. These mounds are most likely "gilgai" resulting from vertic or shrink-swell properties of the Luinn soil series. Known examples display a range of moisture conditions from dry to wet. The wettest examples trap significant moisture from local rainfall events. These areas have ponded water for a minimum of several days at an interval and potentially for long periods of the year, especially when evapotranspiration is lowest. The vegetation of this system supports relatively low vascular plant diversity and thus may appear floristically similar to other pine-hardwood vegetation of the region. The dry portion of this vegetational mosaic is dominated by grassy ground cover (*Chasmanthium sessiliflorum*) with scattered emergent greenbriars (*Smilax* spp.) underneath a nearly pure *Pinus taeda* overstory. The historical composition of this type is unknown, but it seems likely that *Pinus taeda* was a natural and even dominant component of this system, as it is in related systems in the West Gulf Coastal Plain. Wetter areas are dominated by an overstory of *Quercus phellos* with an abundance of *Sabal minor* in the understory. Although the specific role of fire in this system is unknown, low-intensity surface fires may have been ecologically important. Such fires could have originated in the surrounding East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506).

In the western parts of the lower terraces of the East Gulf Coastal Plain ("Florida Parishes") of Louisiana (EPA Ecoregion 74d and adjacent 75a), the flatwoods vegetation tends to be dominated primarily by hardwoods in the most western portion, and a mixture of *Pinus glabra* and *Pinus taeda* in the intermediate portion to the east of this (Smith 1996b). In this "Louisiana Florida Parishes Spruce Pine Flatwoods Forest" some characteristic species include *Pinus glabra, Quercus laurifolia, Quercus michauxii, Quercus nigra, Quercus pagoda, Quercus virginiana, Pinus taeda*, and *Magnolia grandiflora*. Some important understory trees and shrubs include *Crataegus opaca, Sabal minor* (which may often be very abundant or dominant), and *Arundinaria gigantea ssp. tecta*.
Classification Comments: The description of associations in the NVC for this system is undoubtedly incomplete. Classification work is in progress, but more information is needed.

DESCRIPTION

Environment: In the Alabama/Mississippi parts of this system's range, the ground surface displays an evident microtopography of alternating mounds and swales occurring in a tight local mosaic. In Louisiana, the soils are described as Hydric, acidic silt loams (including the Encrow, Gilbert, and Springfield series). The setting is broad, low flats, in small to large depressions, and along small, ill-defined drainages locally known as "slashes" (Smith 1996b).
Vegetation: Known examples of this system in the Alabama/Mississippi parts of its range include a mosaic of open forests dominated by *Pinus taeda* interspersed with patches of *Quercus phellos* and sometimes other tree species. The vegetation of this system supports a relatively low vascular plant diversity and thus may appear floristically similar to other pine-hardwood vegetation of the region. The dry portion of this vegetational mosaic is dominated by grassy ground cover (e.g., *Chasmanthium sessiliflorum*) with scattered emergent greenbriars (*Smilax* spp.) underneath a nearly pure *Pinus taeda* overstory. The historical composition of this type is unknown, but it seems likely that *Pinus taeda* was a natural and even dominant component of this system, as it is in related systems in the West Gulf Coastal Plain (R. Evans pers. obs., T. Foti pers. comm.). Wetter areas are dominated by an overstory of *Quercus phellos* with an abundance of *Sabal minor* in the understory.

In the western parts of the lower terraces of the East Gulf Coastal Plain ("Florida Parishes") of Louisiana, the flatwoods vegetation tends to be dominated primarily by hardwoods in the most western portion, and a mixture of *Pinus glabra* and *Pinus taeda* in the intermediate portion to the east of this. In this "Louisiana Florida Parishes Spruce Pine Flatwoods Forest" stands contain *Pinus glabra, Quercus laurifolia, Quercus phellos, Quercus michauxii, Quercus nigra, Quercus pagoda, Quercus virginiana, Pinus taeda, Nyssa*

biflora, Nyssa sylvatica, Magnolia grandiflora, Salix nigra, Liquidambar styraciflua, Carya glabra, Acer rubrum, and *Fraxinus pennsylvanica*. Understory trees and shrubs include *Crataegus opaca* and *Sabal minor* (which may often be very abundant or dominant), as well as *Arundinaria gigantea ssp. tecta, Cephalanthus occidentalis, Diospyros virginiana, Cornus foemina, Crataegus viridis, Ilex opaca var. opaca, Ilex decidua, Itea virginica, Morella cerifera (= Myrica cerifera), Sambucus canadensis, Styrax americanus*, and *Viburnum dentatum* (Smith 1996b).

Component Associations:
- *(Quercus laurifolia) / Crataegus opaca - Crataegus viridis* Forest (CEGL007386, G1)
- *Fagus grandifolia - Magnolia grandiflora - Quercus nigra - Pinus glabra / Viburnum dentatum* Forest (CEGL004964, G3)
- *Pinus glabra - Quercus laurifolia / Crataegus opaca / Sabal minor* Forest (CEGL004534, G1G2)
- *Quercus michauxii - Quercus (nigra, pagoda) - Liquidambar styraciflua - Pinus taeda* Forest (CEGL007715, G2G3)

SPATIAL CHARACTERISTICS

Spatial Summary: Apparently occurs in a variable patch size (large to small) across its range.
Adjacent Ecological Systems:
- East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506)

DISTRIBUTION

Range: This forested system occurs on broad upland flats in the East Gulf Coastal Plain of Alabama and Mississippi, as well as western parts of the lower terraces of the East Gulf Coastal Plain ("Florida Parishes") in Louisiana. The complete and detailed range of this system is being developed and is not completely understood. It is not thought to extend into the Mississippi River Alluvial Plain of Louisiana (P. Faulkner pers. comm.).

EDWARDS PLATEAU FLOODPLAIN TERRACE (CES303.651)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Floodplain; Lowland; Forest and Woodland (Treed); Depositional stream terrace
National Mapping Codes: ESLF 4154

CONCEPT

Summary: This forest/woodland system occurs on floodplain terraces along perennial rivers and streams in central Texas. Canopy dominants may include *Ulmus crassifolia, Juniperus ashei, Celtis laevigata, Quercus fusiformis, Fraxinus texensis, Platanus occidentalis, Acer negundo, Juglans major, Quercus macrocarpa,* or *Carya illinoinensis*. *Carya illinoinensis* may be more likely to occur in deeper and better-developed alluvial soils. Occurrences typically have a multi-layered physiognomy with a woody understory and patchy ground flora. Alluvial sedimentation processes dominate the formation and maintenance of this system. However, overgrazing and/or overbrowsing may influence recruitment of overstory species and composition of the understory and herbaceous layers.

Classification Comments: Further field investigation is needed to better develop the association-level information for this system. It occurs along larger, lower gradient rivers and streams in contrast with Edwards Plateau Riparian (CES303.652) which occurs along smaller, higher gradient streams. Any particular reach of a river would be classified and mapped as one or the other system.

Similar Ecological Systems:
- Edwards Plateau Riparian (CES303.652)--occurs along smaller, higher gradient streams.
- Southeastern Great Plains Floodplain Forest (CES205.710)

- Sugarberry - American Elm - Green Ash: 93 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is found in central Texas and usually occupies Quaternary alluvial deposits often within drainages underlain by Cretaceous limestones, or drainages that receive outwash from landscapes dominated by these limestones (Elliott 2011). Landforms include valley floors of large rivers and perennial streams. This system tends to occupy broad valley bottoms with alluvial deposits on the Edwards Plateau, and rivers and large creeks where outwash from the Edwards Plateau influences the substrate (Elliott 2011). Soils include bottomland soils of various types (loamy, clayey, and sandy).

Vegetation: These are forests and woodlands with a canopy dominated or codominated by *Carya illinoinensis, Ulmus crassifolia, Ulmus americana, Celtis laevigata, Celtis laevigata var. reticulata,* and/or *Quercus fusiformis*. *Carya illinoinensis* may be more likely to occur in deeper and better-developed alluvial soils (Elliott 2011). Apparent dominance of *Carya illinoinensis* may also be an artifact of preferential harvesting of other species, leaving this species in greater abundance. Other species present may include *Fraxinus texensis, Fraxinus pennsylvanica, Juglans major, Quercus macrocarpa, Quercus buckleyi, Acer negundo, Sapindus saponaria var. drummondii, Juniperus ashei, Prosopis glandulosa,* and *Platanus occidentalis*. *Quercus stellata* may be dominant on sandy soils within the floodplain at some sites. *Melia azedarach* is a common non-native tree encountered on floodplains. Woody species in the subcanopy may include *Sideroxylon lanuginosum, Ptelea trifoliata, Cornus drummondii, Morus rubra, Diospyros texana, Parthenocissus quinquefolia, Vitis* spp., *Smilax bona-nox, Baccharis neglecta, Malvaviscus arboreus var. drummondii, Juniperus ashei,* and *Ilex decidua*. The herbaceous layer may be continuous, though relatively sparse or patchy with species such as *Elymus virginicus, Chasmanthium latifolium, Nassella leucotricha, Verbesina virginica,* and *Carex* spp. Some sites lack, or have very sparse, overstory canopies and represent shrublands or grasslands. Shrublands may be dominated by species in the shrub layer of the surrounding woodlands. Other components or dominants may include species such as *Prosopis glandulosa, Acacia farnesiana, Sapindus saponaria var. drummondii, Juglans microcarpa, Mahonia trifoliolata,* and *Cephalanthus occidentalis*. Native species that may also be present in (and sometimes dominate) these sites include *Panicum virgatum, Andropogon glomeratus, Elymus virginicus, Nassella leucotricha, Hordeum pusillum, Tripsacum dactyloides, Muhlenbergia lindheimeri, Carex* spp., and *Eleocharis* spp. (Elliott 2011). Some grassland sites are frequently dominated by the non-native species *Cynodon dactylon* and/or *Bothriochloa ischaemum var. songarica*. Floodplain occurrences often include portions that resemble Edwards Plateau Riparian (CES303.652), especially along

stream margins, where *Platanus occidentalis, Taxodium distichum, Juglans microcarpa, Brickellia* spp., *Cladium mariscus ssp. jamaicense,* and *Panicum virgatum* are frequently encountered (Elliott 2011).
Dynamics: Alluvial sedimentation processes dominate the formation and maintenance of this system. However, overgrazing and/or overbrowsing may influence recruitment of overstory species and composition of the understory and herbaceous layers.

Component Associations:
- *Carya illinoinensis - Celtis laevigata* Forest (CEGL002087, G4?)
- *Carya illinoinensis - Ulmus crassifolia / Elymus virginicus* Floodplain Forest (CEGL004200, GNR)
- *Justicia americana - Bacopa monnieri* Edwards Plateau Herbaceous Vegetation (CEGL004926, G3)
- *Muhlenbergia reverchonii - Bouteloua curtipendula - Desmanthus velutinus* Herbaceous Vegetation (CEGL004219, GNR)
- *Panicum virgatum - Andropogon glomeratus - Cladium mariscus ssp. jamaicense* Herbaceous Vegetation (CEGL004928, G2G3)
- *Platanus occidentalis - Salix nigra* Woodland (CEGL002093, G5?)
- *Quercus fusiformis - (Celtis laevigata var. reticulata, Ulmus crassifolia)* Woodland (CEGL002153, G4?)
- *Quercus macrocarpa - Carya illinoinensis / Cornus drummondii - Frangula caroliniana* Forest (CEGL004196, GNR)
- *Salix nigra* Forest (CEGL002103, G4)
- *Ulmus americana - Celtis (laevigata, occidentalis) - Fraxinus pennsylvanica* Forest (CEGL002090, G3?)
- *Ulmus crassifolia - Celtis laevigata / Ilex decidua / Elymus virginicus* Forest (CEGL008468, G3?)
- *Zizania texana - Potamogeton illinoensis* Herbaceous Vegetation (CEGL004512, G1)

SPATIAL CHARACTERISTICS

Spatial Summary: This system is characteristically linear in spatial configuration.
Adjacent Ecological Systems:
- Edwards Plateau Carbonate Glade and Barrens (CES303.655)
- Edwards Plateau Cliff (CES303.653)
- Edwards Plateau Dry-Mesic Slope Forest and Woodland (CES303.656)
- Edwards Plateau Limestone Savanna and Woodland (CES303.660)
- Edwards Plateau Limestone Shrubland (CES303.041)
- Edwards Plateau Mesic Canyon (CES303.038)
- Edwards Plateau Riparian (CES303.652)
- Edwards Plateau Upland Depression (CES303.654)
- Llano Uplift Acidic Forest, Woodland and Glade (CES303.657)

DISTRIBUTION

Range: This system occurs along larger permanent rivers and streams throughout the Edwards Plateau of Texas and possibly adjacent ecoregions. It occurs from the Leon watershed in the Limestone Cutplain (EPA 29e) south to the edge of the Bacones Canyonlands (EPA 30c), west through the Edwards Plateau and north to the Pecan Bayou and Concho River watersheds in the lower Limestone Plains (EPA 27j) and lower Crosstimbers (EPA 29c) (EPA 2001).

EDWARDS PLATEAU RIPARIAN (CES303.652)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Shrubland (Shrub-dominated); Woody-Herbaceous; Herbaceous; Streambed; Flood Scouring
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2525; ESLF 9165; ESP 1525

CONCEPT

Summary: This system occurs in various situations along small and intermittent streams of the Edwards Plateau, with drier representatives occurring in the western plateau and the Stockton Plateau, and moister representatives (such as communities dominated by *Juglans microcarpa* and *Brickellia laciniata*) in the eastern plateau. Representatives of this system typically occur in stream-scoured situations and vary in the openness of the habitat and physiognomy. Woodland examples may have *Quercus fusiformis, Platanus occidentalis, Taxodium distichum, Fraxinus texensis, Fraxinus pennsylvanica, Ulmus crassifolia, Celtis laevigata* (including *var. reticulata*), *Acer negundo, Prosopis glandulosa, Quercus buckleyi, Juniperus ashei, Salix nigra,* and/or *Sapindus saponaria*. Shrub species that may be encountered in the understory of these woodlands include *Juglans microcarpa, Chilopsis linearis, Baccharis* spp., *Salix nigra, Juniperus ashei, Sapindus saponaria, Cornus drummondii, Sophora secundiflora, Sideroxylon lanuginosum, Diospyros texana, Ungnadia speciosa, Prosopis glandulosa, Cephalanthus occidentalis*, and/or *Aloysia gratissima*. Substantial patches of herbaceous cover may be present and often include species such as *Andropogon glomeratus, Panicum virgatum, Cladium mariscus ssp. jamaicense, Tripsacum dactyloides, Setaria scheelei, Nassella leucotricha, Eleocharis* spp., *Brickellia* spp., *Justicia americana, Hydrocotyle* spp., and/or *Muhlenbergia lindheimeri*.
Classification Comments: Further field investigation is needed to better develop the association-level information for this system. Edwards Plateau Floodplain (CES303.651) occurs along larger, lower gradient rivers and streams in contrast with Edwards Plateau Riparian (CES303.652) which occurs along smaller, higher gradient streams. Any particular reach of a river would be classified and mapped as one or the other system.

DESCRIPTION

Environment: This system occurs on minor intermittent streams and tributaries throughout the Edwards Plateau of Texas. Its geology is usually Quaternary deposits along headwater streams. These may be alluvial or gravel deposits and are often within drainages dominated by limestone or other calcareous substrates on the Edwards Plateau or where substrate is influenced by outwash from the Edwards Plateau. This riparian system occupies small streams, either intermittent or perennial. These sites tend to be in erosional situations, as opposed to broad alluvial depositional sites. This system was mapped by TPWD in areas upstream of significant development of bottomland soils on soil types of the surrounding uplands. It includes vegetation along very small streams, reaching upstream to spring heads and runs (Elliott 2011).
Vegetation: Riparian vegetation may be characterized as woodlands, shrublands, or herbaceous vegetation. These erosional sites may be gravelly, cobbly or rocky and generally occupy the upper reaches of streams. Woodland examples may have *Quercus fusiformis, Platanus occidentalis, Taxodium distichum, Fraxinus texensis, Fraxinus pennsylvanica, Ulmus crassifolia, Celtis laevigata* (including *var. reticulata*), *Acer negundo, Prosopis glandulosa, Quercus buckleyi, Juniperus ashei, Salix nigra*, and/or *Sapindus saponaria*

(Elliott 2011). Shrub species that may be encountered in the understory of these woodlands include *Juglans microcarpa, Chilopsis linearis, Baccharis* spp., *Salix nigra, Juniperus ashei, Sapindus saponaria, Cornus drummondii, Sophora secundiflora, Sideroxylon lanuginosum, Diospyros texana, Ungnadia speciosa, Prosopis glandulosa, Cephalanthus occidentalis,* and/or *Aloysia gratissima*. In some cases, these species may form shrublands lacking a significant overstory tree canopy (Elliott 2011). Substantial patches of herbaceous cover may be present and often include species such as *Andropogon glomeratus, Panicum virgatum, Cladium mariscus ssp. jamaicense, Tripsacum dactyloides, Setaria scheelei, Nassella leucotricha, Eleocharis* spp., *Brickellia* spp., *Justicia americana, Hydrocotyle* spp., and/or *Muhlenbergia lindheimeri*. Frequently, *Cynodon dactylon* and/or *Bothriochloa ischaemum var. songarica* dominate these grassland sites. *Sorghum halepense* is also a commonly encountered non-native grass.

Component Associations:
- *Adiantum capillus-veneris - (Thelypteris ovata var. lindheimeri, Thelypteris kunthii)* Herbaceous Vegetation (CEGL004514, G2)
- *Celtis laevigata var. reticulata - Juglans microcarpa / Leptochloa dubia* Woodland (CEGL002166, GNR)
- *Chilopsis linearis / Brickellia laciniata* Scrub Woodland (CEGL004933, G3G4)
- *Juglans microcarpa - Brickellia laciniata / Indigofera lindheimeriana* Edwards Plateau Scrub Woodland (CEGL004932, G2?)
- *Justicia americana - Bacopa monnieri* Edwards Plateau Herbaceous Vegetation (CEGL004926, G3)
- *Muhlenbergia reverchonii - Bouteloua curtipendula - Desmanthus velutinus* Herbaceous Vegetation (CEGL004219, GNR)
- *Panicum virgatum - Andropogon glomeratus - Cladium mariscus ssp. jamaicense* Herbaceous Vegetation (CEGL004928, G2G3)
- *Platanus occidentalis - (Salix nigra) / Juglans microcarpa - Baccharis salicifolia* Woodland (CEGL004930, G5)
- *Platanus occidentalis - Juglans major* Woodland (CEGL004929, G5)
- *Platanus occidentalis - Salix nigra* Woodland (CEGL002093, G5?)
- *Quercus fusiformis - (Celtis laevigata var. reticulata, Ulmus crassifolia)* Woodland (CEGL002153, G4?)
- *Quercus muehlenbergii - Juglans major - (Ulmus rubra) / Verbesina virginica* Forest (CEGL004927, G2G3)
- *Salix nigra* Forest (CEGL002103, G4)
- *Taxodium distichum - Platanus occidentalis* Edwards Plateau Forest (CEGL002104, G2)
- *Ulmus americana - Celtis (laevigata, occidentalis) - Fraxinus pennsylvanica* Forest (CEGL002090, G3?)
- *Ulmus crassifolia - (Carya illinoinensis)* Small Stream Forest (CEGL004207, GNR)

SPATIAL CHARACTERISTICS

GREAT BASIN FOOTHILL AND LOWER MONTANE RIPARIAN WOODLAND AND SHRUBLAND (CES304.045)

CLASSIFIERS

Classification Status: Standard

Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval; Riparian Mosaic; Forest and Woodland (Treed); Riverine / Alluvial
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Temperate [Temperate Continental]
National Mapping Codes: ESLF 9168

CONCEPT

Summary: This system occurs in mountain ranges of the Great Basin and along the eastern slope of the Sierra Nevada within a broad elevation range from about 1220 m (4000 feet) to over 2135 m (7000 feet). This system often occurs as a mosaic of multiple communities that are tree-dominated with a diverse shrub component. The variety of plant associations connected to this system reflects elevation, stream gradient, floodplain width, and flooding events. Dominant trees may include *Abies concolor, Alnus incana, Betula occidentalis, Populus angustifolia, Populus balsamifera ssp. trichocarpa, Populus fremontii, Salix laevigata, Salix gooddingii*, and *Pseudotsuga menziesii*. Dominant shrubs include *Artemisia cana, Cornus sericea, Salix exigua, Salix lasiolepis, Salix lemmonii*, or *Salix lutea*. Herbaceous layers are often dominated by species of *Carex* and *Juncus*, and perennial grasses and mesic forbs such *Deschampsia caespitosa, Elymus trachycaulus, Glyceria striata, Iris missouriensis, Maianthemum stellatum*, or *Thalictrum fendleri*. Introduced forage species such as *Agrostis stolonifera, Poa pratensis, Phleum pratense*, and the weedy annual *Bromus tectorum* are often present in disturbed stands. These are disturbance-driven systems that require flooding, scour and deposition for germination and maintenance. Livestock grazing is a major influence in altering structure, composition, and function of the system.

Related Concepts:
- Cottonwood - Willow: 235 (Eyre 1980) Broader
- Riparian (422) (Shiflet 1994) Broader
- Riparian Woodland (203) (Shiflet 1994) Broader. System and SRM type overlap along eastern Sierran foothills region of California.

DESCRIPTION

Environment: This system is found in low-elevation canyons and draws, on floodplains, steep-sided canyons, or narrow V-shaped valleys with rocky substrates. This includes both perennial and intermittent streams. Sites are typically subject to temporary flooding during spring or late winter runoff. Overbank flooding and some gravel areas are required for regeneration of these riparian forests and woodlands, especially for cottonwoods.

Dynamics: The hydrologic regime is naturally highly variable temporally and spatially among the streams and rivers of this system. Where present, spring discharges from bedrock aquifers provide flows unaffected by rainfall and snowmelt. Otherwise, stream and river flows - where they occur, at what magnitudes, and when and how often - are subject to wide fluctuations as a result of the wide variation in where and when precipitation takes place, what form the precipitation takes (rain versus snow), and where and when snowmelt takes place (e.g., Abell et al. 2000, Levick et al. 2008, Miller et al. 2010a). Intense runoff associated with intense rainfall events is highly erosive, resulting in rapid reconfiguration of aquatic and riparian macrohabitats particularly along reaches with sand and gravel substrates. Fire disturbances occur in riparian zones, but are generally less severe and less often than in neighboring uplands (Reeves et al. 2005).

Component Associations:
- *Alnus incana / Cornus sericea* Shrubland (CEGL001145, G3G4)
- *Artemisia cana (ssp. bolanderi, ssp. viscidula) / Leymus cinereus* Shrubland (CEGL001460, G1)
- *Artemisia cana ssp. viscidula / Deschampsia caespitosa* Shrubland (CEGL001074, G2G3)
- *Artemisia nova - Ericameria nana* Shrubland (CEGL002773, G3)
- *Betula occidentalis / Cornus sericea* Shrubland (CEGL001161, G3)
- *Betula occidentalis / Maianthemum stellatum* Shrubland (CEGL001162, G4?)
- *Betula occidentalis* / Mesic Graminoids Shrubland (CEGL002654, G3)
- *Cornus sericea* Rocky Mountain Shrubland (CEGL001165, G4Q)
- *Pinus ponderosa - Populus tremuloides / Carex* spp. - (*Poa* spp.) Forest (CEGL000191, G2G3)
- *Populus angustifolia / Betula occidentalis* Woodland (CEGL000648, G3)
- *Populus angustifolia / Rhus trilobata* Woodland (CEGL000652, G3)
- *Populus balsamifera ssp. trichocarpa / Alnus incana* Forest (CEGL000667, G3)
- *Populus balsamifera ssp. trichocarpa* / Mixed Herbs Forest (CEGL000675, G3?)
- *Populus fremontii / Acer negundo* Forest (CEGL000662, G2Q)
- *Populus fremontii / Leymus triticoides* Woodland (CEGL002756, GNR)
- *Populus fremontii* / Mesic Forbs Woodland (CEGL002470, GNR)
- *Populus fremontii* / Mesic Graminoids Woodland (CEGL002473, GNR)

- *Populus fremontii / Salix exigua* Forest (CEGL000666, GNR)
- *Populus fremontii / Salix geyeriana* Woodland (CEGL000943, G3?)
- *Salix lasiolepis / Rosa woodsii* / Mixed Herbs Shrubland (CEGL001217, G3Q)
- *Salix lemmonii* / Mesic-Tall Forbs Shrubland (CEGL002771, G3?)
- *Salix lemmonii / Rosa woodsii* Shrubland (CEGL002772, G3)
- *Salix lutea / Carex utriculata* Shrubland (CEGL001220, G4)
- *Salix lutea* / Mesic Forbs Shrubland (CEGL002774, G3?)

HAWAI'I FLOODPLAIN FOREST (CES412.221)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval; Riparian Mosaic; Floodplain; Forest and Woodland (Treed); Riverine / Alluvial; Broad-Leaved Evergreen Tree
Non-Diagnostic Classifiers: Lowland; Toeslope/Valley Bottom; Tropical/Subtropical; Broad-Leaved Evergreen Shrub
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2800; ESLF 9388; ESP 1800

CONCEPT

Summary: The discerning features of this ecological system are low-elevation (up to 122 m [400 feet])] valley floors containing perennial streams that flood every 1 to 5 years. Valley floors typically widen towards the ocean (up to 1 mile), forming broad floodplains that allow periodic shifting of the stream channel. Soils are alluvial deposits and clay that remain moist due to influence from stream channel flooding, a shallow subsurface water table, and nutrient-rich alluvium deposited during flood events. Vegetation of floodplain forests is typically dominated by a patchy matrix of native and Polynesian-introduced lowland wet trees tolerant of occasional flooding. *Aleurites moluccana* and *Metrosideros polymorpha* can form a patch mosaic with *Hibiscus tiliaceus* that extends onto adjacent steeper gulches and coastal areas. *Aleurites moluccana* mixes in patches and extends up steep gulches well into the lowland zone. Plant species indicative of Polynesian agriculture dominate the majority of the floodplain forest, including *Cordyline fruticosa, Colocasia esculenta* and *Syzygium malaccense*.

DESCRIPTION

Environment: This low-elevation ecological system occurs on valley floors up to about 125 m (400 feet) elevation containing perennial streams that flood every 1 to 5 years. Valley floors typically widen towards the ocean (up to 1 mile), forming broad floodplains that allow periodic shifting of the stream channel. Climate is variable depending on which coast a stand occurs and ranges from arid to very wet (Zones 1-7), but is generally moderately dry to moderately wet (Zones 3-6) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). Annual precipitation may vary from less than 500 mm to over 4500 mm.
Dynamics: Typical disturbances during the pre-European era included flood, landslide, and storms. A major threat now is Hawaiian wet valley irrigated agriculture that has nearly completely converted natural vegetation into *Colocasia esculenta* (kalo) and other planted vegetation. This ecological system is threatened by invasion of numerous alien fishes, mollusks, crustaceans and plants, which interfere with ecological functions and interrupt ecological processes.

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Hawai'i Freshwater Aquatic Bed (CES412.225)

Adjacent Ecological System Comments: The origins of Hawaiian freshwater stream biota is unique with fish, shrimp and mollusks descended from marine forms; and native damselflies and dragonflies descended from continental freshwater habitats. Damselfly (*Megalagrion*) and dragonfly (*Anax, Pantala*) naids utilize stream sediments as habitats, while adults utilize emergent vegetation. Shore bugs (*Saldula* spp.), freshwater snails (*Nertera* spp.), freshwater shrimp (*Halocaridina, Atyoida, Machrobrachium, Metabetaeus, Caligus, Hyalella, Penaeus,* and *Calappa*), and five endemic amphidromous freshwater fishes (*Awaous, Lentipes, Sicyopterus, Stenogobius,* and *Eleotris*) are part of the aquatic stream system in the stream. These lowland reaches of Hawaiian streams and rivers serve as important habitat to waterbirds such as the widely distributed black-crowned night heron (*Nycticorax nycticorax hoactli*).

DISTRIBUTION

Range: This system occurs from sea level to 122 m (400 feet) elevation on Kaua'i, O'ahu, Moloka'i, LÃ¢na'i, Maui, and Hawai'i.

HIGH ALLEGHENY WETLAND (CES202.069)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: >180-day hydroperiod; Bog and Fen Mosaic; Fen; Montane; Marsh; Swamp; Peat and mud; Temperate; Extensive Wet Flat; Depressional; Unglaciated; Palustrine; Bog; Depression
National Mapping Codes: ESLF 9356

CONCEPT

Summary: This system occurs along the high plateau of the Allegheny Mountains, immediately west of the Allegheny Front at elevations between 730 and 1430 m. Wetlands in this system are drained by low-gradient, meandering, intermittent to small headwater streams. Drainage is impounded in high, flat-lying basins by natural dams or "knickpoints" of resistant sandstone. In addition to poor moisture drainage, cold air drains from the surrounding uplands to pool in the flat basins, which function as frost pockets. Rainfall is plentiful, averaging about 1300 mm/year. Communities in this system may have substrates of shallow to deep peat or, less commonly, mineral soil. Soils are acidic to circumneutral. These high Allegheny wetlands form complex mosaics ranging in size from a few hectares to 6000 hectares. Forested swamps occupy the less disturbed margins or slightly higher "islands." This system has a distinctly northern character in its resemblance to bogs and swamps of New England. However, the striking absence of *Chamaedaphne calyculata* and *Picea mariana*, two abundant and common species of northern bogs and swamps, as well as the presence of species characteristic of the Southern Appalachians, such as *Hypericum densiflorum, Vaccinium erythrocarpum*, and *Rhododendron maximum*, distinguishes this system from its northern counterpart. Ombrotrophic bogs are rare but occur in undisturbed portions of a few of the larger wetlands. The more central, flood- or beaver-influenced portions contain shrub swamps, sedge fens, wet meadows, and open marshes. Forested swamps are dominated by *Picea rubens*, with varying cover by *Acer rubrum, Tsuga canadensis*, and *Betula alleghaniensis var. alleghaniensis*. It is likely that the role of *Pinus strobus* played a greater role in the structure and function of this system historically than it does today (Maryland Geological Survey and Curran 1902). Residual white pines in remote areas of this system in Cranesville Swamp in Maryland also suggest this possibility. Where limestone or calcareous shale influences seepage water, *Abies balsamea* and *Fraxinus nigra* are typical canopy dominants. Common shrub species are *Viburnum nudum var. cassinoides, Rhododendron maximum, Vaccinium myrtilloides, Alnus incana ssp. rugosa, Hypericum densiflorum, Ilex verticillata*, and *Photinia melanocarpa*. Herbaceous species frequently include *Rubus hispidus, Solidago uliginosa, Juncus effusus, Eriophorum virginicum, Osmunda cinnamomea var. cinnamomea, Polygonum sagittatum, Carex folliculata, Carex gynandra, Leersia oryzoides, Galium tinctorium, Solidago rugosa, Symplocarpus foetidus, Lycopus uniflorus var. uniflorus, Scirpus cyperinus, Carex scoparia var. scoparia*, and *Carex trisperma var. trisperma*. *Sphagnum* spp. and *Polytrichum* spp. dominate the bryophyte layer. This system is maintained by a spatially complex mix of seepage, low-energy flooding, beaver activity, and rainfall. Undisturbed examples exist (e.g., Cranberry Glades), where old-growth swamp buffers the central peatlands, which have been dated to 10,000 years. In presettlement time, some wetland mosaics in this system had significant forested components (e.g., Canaan Valley, Cranesville Swamp in West Virginia; Finzel Swamp, Hammel Glades in Maryland), while others (e.g., Cranberry Glades, Big Run Bog) were largely open peatlands with forested swamp only on the margins.

Similar Ecological Systems:
- North-Central Appalachian Acidic Swamp (CES202.604)
- Southern and Central Appalachian Bog and Fen (CES202.300)
- Southern Appalachian Seepage Wetland (CES202.317)

DESCRIPTION

Environment: This system occurs along the high plateau of the Allegheny Mountains, immediately west of the Allegheny Front at elevations between 610 and 1430 m. Wetlands in this system are drained by low-gradient, meandering, intermittent to small streams that form the headwaters of larger (often high-gradient) mountain rivers. The system is underlain by gently folded sedimentary rocks of Carboniferous and Devonian age. Drainage is impounded in high, flat-lying basins by natural dams or "knickpoints" of resistant sandstone (Pottsville and Price formations). These sandstone layers come to the surface along the gently dipping axes of breached anticlines or synclines, or occasionally on the gently dipping limb of a fold. Cold air drains from the surrounding uplands to pool in the flat basins, which function as frost pockets. Rainfall is plentiful, averaging about 1300 mm/year. Communities in this system may have substrates of shallow to deep peat (a few centimeters to up to 3 m depth) or, less commonly, mineral soil. Soils are acidic to circumneutral, with pH ranging from 3.1 to 6.5. High values for soil organic matter, total exchange capacity, exchangeable nitrogen,

soluble sulphur, and phosphorus are typical. Most soils are low in boron, copper, potassium, and manganese.
Vegetation: These High Allegheny wetlands form complex mosaics of small-patch communities. Forested swamps occupy the less disturbed margins or slightly higher "islands" in the wetland mosaic. Ombrotrophic bogs are rare but occur in undisturbed portions of a few of the larger wetlands. The more central, flood- or beaver-influenced sections contain shrub swamps, sedge fens, wet meadows, and open marshes. A number of species have northern affiliations, including some that are disjunct (e.g., *Abies balsamea, Larix laricina,* and *Andromeda polifolia var. glaucophylla*). The shrub strata include characteristic central Appalachian species (e.g., *Rhododendron maximum*), Appalachian endemic species (e.g., *Ilex collina*), and species with a more southern affiliation (e.g., *Vaccinium erythrocarpum*). Forested swamps are dominated by *Picea rubens*, with varying cover by *Acer rubrum, Tsuga canadensis*, and *Betula alleghaniensis var. alleghaniensis*. Where limestone or calcareous shale influences seepage water, *Abies balsamea* and *Fraxinus nigra* are typical canopy dominants. Common shrub species are *Viburnum nudum var. cassinoides, Rhododendron maximum, Vaccinium myrtilloides, Alnus incana ssp. rugosa, Hypericum densiflorum, Ilex verticillata, Photinia melanocarpa, Viburnum recognitum,* and *Kalmia latifolia*. Herbaceous species frequently include *Rubus hispidus, Solidago uliginosa, Juncus effusus, Eriophorum virginicum, Osmunda cinnamomea var. cinnamomea, Polygonum sagittatum, Carex folliculata, Carex gynandra, Leersia oryzoides, Galium tinctorium, Solidago rugosa, Symplocarpus foetidus, Lycopus uniflorus var. uniflorus, Scirpus cyperinus, Carex scoparia var. scoparia, Carex trisperma var. trisperma, Carex stipata,* and *Calamagrostis canadensis var. canadensis*. *Sphagnum* spp. and *Polytrichum* spp. dominate the bryophyte layer.
Dynamics: This system is maintained by a spatially complex mix of seepage, low-energy flooding, beaver activity, and rainfall. Drainage in the flat headwater basins is partly impounded by resistant sandstone at the basin outlet. Low-gradient, meandering headwater streams provide regular low-energy inundation. Seepage from surrounding forests provides nutrients at the margins of the wetland mosaic, and where limestone or calcareous shale is present, circumneutral wetlands are maintained. Beaver activity encourages the cycling of early- to mid-successional types. In the rare ombrotrophic bogs, rainfall is the only source of moisture. Many of the forested swamps in this system were logged during 1880-1920, and some were subsequently burned and/or heavily grazed. Flat headwater basins function as frost pockets, catchment areas for cold air draining from surrounding uplands. Cool temperatures (mean annual temperature 6.7-9.4 degrees C) and high rainfall (1220-1680 mm/year) are characteristic. Floristic diversity is controlled by underlying sedimentary rocks that weather to form high diversity of nutrient, acidity, and drainage conditions (Byers et al. 2007).

Component Associations:

- *Scirpus cyperinus* Seasonally Flooded Herbaceous Vegetation (CEGL006349, GNR)
- *Solidago rugosa - Euthamia graminifolia* Herbaceous Vegetation (CEGL006568, GNR)
- *Sparganium americanum - (Sparganium erectum ssp. stoloniferum) - Epilobium leptophyllum* Herbaceous Vegetation

(CEGL004510, G3?)
- *Spiraea alba* Shrubland (CEGL006595, GNR)
- *Vaccinium myrtilloides / Pteridium aquilinum / Polytrichum* spp. Shrubland (CEGL006596, GNR)
- *Vaccinium oxycoccos - (Vaccinium macrocarpon) / Rhynchospora alba - Drosera rotundifolia / Sphagnum* spp. Dwarf-shrubland (CEGL007856, G2)

SPATIAL CHARACTERISTICS

Spatial Summary: Large-patch system of wetland mosaics ranging in size from 5 to 6000 ha. Individual associations comprising the mosaic occur in small patches from 0.05 to 10 ha in size.

Adjacent Ecological Systems:
- Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593)
- Central and Southern Appalachian Spruce-Fir Forest (CES202.028)
- Southern Appalachian Northern Hardwood Forest (CES202.029)

Adjacent Ecological System Comments: Occurrences are embedded in Central and Southern Appalachian Spruce-Fir Forest (CES202.028), Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593), or Southern Appalachian Northern Hardwood Forest (CES202.029).

DISTRIBUTION

Range: The system occurs in a southwest/northeast-trending band about 40 km wide and 200 km long along the high, flat plateau of the Allegheny Mountains. The eastern boundary is the Allegheny Front, and the western boundary is the heavily dissected, lower elevation Allegheny Plateau. Minimum elevations range from 730 m in the north to 940 m in the south (Droop Mountain, West Virginia). The maximum elevation is 1422 m on Mount Porte Crayon, West Virginia.

INTERIOR HIGHLANDS FORESTED ACIDIC SEEP (CES202.321)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Ozark/Ouachita; Seepage-Fed Sloping
Non-Diagnostic Classifiers: Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 9311

CONCEPT

Summary: This system of forested seeps occurs mainly in the Ouachita Mountains of central Arkansas, as well as on Mount Magazine and in the Ozarks. Examples may be found along the bottom slopes of smaller valleys where rock fractures allow water to seep out of the mountainsides and in the riparian zones of larger creeks, sometimes extending upslope along small ephemeral drainages. The soil remains saturated to very moist throughout the year. The vegetation is typically forested with highly variable canopy composition. *Acer rubrum var. trilobum, Nyssa sylvatica, Liquidambar styraciflua,* and *Quercus alba* are common and typical. Other canopy species may include *Fagus grandifolia* and *Magnolia tripetala*. Canopy coverage can be moderately dense to quite open. The subcanopy is often well-developed and characteristically includes *Ilex opaca var. opaca, Magnolia tripetala, Carpinus caroliniana,* and *Ostrya virginiana*.
Classification Comments: There are physiognomically and compositionally similar forested seep systems in the Appalachian Plateau that lack abundant evergreen ericads and are apparently less sphagnous. Examples from the Ozarks (on sandstone) are apparently less species-rich and may be associated with more acidic substrates; these are also included here.
Related Concepts:
- Black Ash - American Elm - Red Maple: 39 (Eyre 1980) Finer

DESCRIPTION

Environment: Examples of this system of forested seeps may be found along the bottom slopes of smaller valleys of the Ouachita Mountains of central Arkansas (where rock fractures allow water to seep out of the mountainsides), and in the riparian zones of larger creeks, sometimes extending upslope along small ephemeral drainages. The soil remains saturated to very moist throughout the year. More information is needed on the environmental details of Ozarkian examples.
Vegetation: Stands are typically forested with highly variable canopy composition. Some common and typical components are *Acer rubrum var. trilobum, Nyssa sylvatica, Liquidambar styraciflua,* and *Quercus alba*. Other canopy species may include *Fagus grandifolia* and *Magnolia tripetala*. The subcanopy is often well-developed and characteristically includes *Ilex opaca var. opaca, Magnolia tripetala, Carpinus caroliniana,* and *Ostrya virginiana*.

Component Associations:
- *Acer rubrum - Fraxinus pennsylvanica / Carex* spp. / *Climacium americanum* Forest (CEGL002407, GU)
- *Acer rubrum var. trilobum - Liquidambar styraciflua - Magnolia tripetala / Osmunda regalis - (Cypripedium kentuckiense)* Forest (CEGL007444, G3?)
- *Acer rubrum var. trilobum - Nyssa sylvatica / Rhexia mariana var. interior* Forest (CEGL007822, G2?)

SPATIAL CHARACTERISTICS

Spatial Summary: Many are less than one hectare in area, but riparian seeps are often much larger.

DISTRIBUTION

Range: This system is found in the Ozark and Ouachita mountains of Arkansas, possibly extending into adjacent Oklahoma and Missouri.

LAURENTIAN-ACADIAN ALKALINE CONIFER-HARDWOOD SWAMP (CES201.575)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Mesotrophic Water; Circumneutral Water; Depressional; Thuja occidentalis - Fraxinus nigra
Non-Diagnostic Classifiers: Saturated Soil; Moderate (100-500 yrs) Persistence; Forest and Woodland (Treed); Mineral: W/ A-Horizon >10 cm; Mineral: W/ A-Horizon <10 cm; Needle-Leaved Tree; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2481; ESLF 9345; ESP 1481

CONCEPT

Summary: These forested wetlands are found across northern New England and the upper Midwest and eastern to south-central Canada in basins or floodplains where higher pH and/or nutrient levels are associated with a rich flora. The substrate is typically mineral soil, but there may be some peat; often, there is an organic epipedon over mineral soil. *Thuja occidentalis* is a diagnostic canopy species and may dominate the canopy or be mixed with other conifers or with deciduous trees, most commonly *Acer rubrum* or *Fraxinus nigra* but also *Tsuga canadensis*, *Larix laricina*, and *Betula alleghaniensis*. Some examples can be almost entirely deciduous and dominated by *Fraxinus nigra*. *Cornus sericea* is a common shrub. The herb layer tends to be more diverse than in acidic swamps. Small open fenny areas may occur within the wetland. Seepage may influence parts of the wetland, but the hydrology is dominated by the basin setting.
Classification Comments: This system encompasses both wet forests (on saturated mineral soils) and forest rich peatlands. Areas dominated by *Fraxinus nigra* and found throughout the Laurentian area in Minnesota and north of Green Bay in Wisconsin are included in this system.
Similar Ecological Systems:
- Laurentian-Acadian Alkaline Fen (CES201.585)
- North-Central Interior and Appalachian Rich Swamp (CES202.605)
- Northern Appalachian-Acadian Conifer-Hardwood Acidic Swamp (CES201.574)

Related Concepts:

- Black Ash Swamp (Gawler and Cutko 2010) Finer
- Northern White Cedar Swamp (Gawler and Cutko 2010) Finer
- Northern White-Cedar: 37 (Eyre 1980) Finer
- Tamarack: 38 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is typically found in basins or in floodplains with higher pH and/or nutrient levels. Groundwater typically keeps these sites saturated or nearly so through most of the growing season. Surface water, either overland flow or from nearby lakes and streams, often contributes to the hydrologic regime, especially through flooding in the spring or after heavy rains. Some movement of groundwater is important in maintaining the dominant trees in this system (Schwintzer 1981, Johnson and Booker 1983). Soils are mineral or muck (well-decomposed peat) with sometimes a thin layer of peat over mineral soil. There is often pronounced microtopographic relief between hummock/mounds created by tree boles and roots and rotting fallen logs and small depressions. These provide different microhabitats and contribute to the diversity of the system.
Dynamics: Cold, nutrient-rich and alkaline groundwater is important in maintaining this system. While water chemistry is similar to alkaline fens (Laurentian-Acadian Alkaline Fen (CES201.585)), this is a treed conifer, conifer-hardwood, or hardwood swamp versus a shrub- or graminoid-dominated fen, implying other factors beyond just water chemistry are important in creating differing vegetation (Schwintzer and Tomberlin 1982). Other factors are likely hydrologic regime (length and degree of soil saturation), site history, and degree of water movement. Patchy windthrow creates small-scale canopy gaps. These swamps often occur on structurally weak organic soils where trees root shallowly due to anaerobic conditions and are thus particularly susceptible to windthrow (Slaughter et al. 2007). Fire was very infrequent in this system but could occur in very dry periods. If other factors remain the same, this system could regenerate after fire since *Thuja occidentalis* and many other dominants grow well on exposed mineral soil (Johnson and Booker 1983). Beaver (*Castor canadensis*) flooding can also shape conifer-hardwood swamp structure, species composition, and direct successional pathways.

Component Associations:
- *Acer rubrum - Fraxinus* spp. - *Betula papyrifera / Cornus canadensis* Forest (CEGL002071, G4)
- *Fraxinus nigra* - Mixed Hardwoods - Conifers / *Cornus sericea / Carex* spp. Forest (CEGL002105, G4)
- *Larix laricina - Thuja occidentalis* Swamp Forest (CEGL002455, G3G4)
- *Larix laricina / Alnus incana* Forest (CEGL002471, G4)
- *Populus tremuloides - Populus balsamifera* - Mixed Hardwoods Lowland Forest (CEGL005036, G5)

- *Thuja occidentalis - (Picea mariana, Abies balsamea) / Alnus incana* Forest (CEGL002456, G4)

LAURENTIAN-ACADIAN ALKALINE FEN (CES201.585)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Mesotrophic Water; Alkaline Water; Circumneutral Water; Organic Peat (>40 cm)
Non-Diagnostic Classifiers: Shallow (<15 cm) Water; Saturated Soil; Moderate (100-500 yrs) Persistence; Shrubland (Shrub-dominated); Extensive Wet Flat; Depressional; Broad-Leaved Shrub; Dwarf-Shrub; Graminoid
National Mapping Codes: ESLF 9198

CONCEPT

Summary: These fens, distributed across glaciated eastern and central North America, develop in open basins where bedrock or other substrate influence creates circumneutral to calcareous conditions. They are most abundant in areas of limestone bedrock, and widely scattered in areas where calcareous substrates are scarce. Shore fens, which are peatlands that are occasionally flooded along stream and lakeshores, are also included here because flooding tends to create moderately alkaline conditions. The vegetation may be graminoid-dominated, shrub-dominated, or a patchwork of the two; *Dasiphora fruticosa ssp. floribunda* is a common diagnostic shrub. The herbaceous flora is usually species-rich and includes calciphilic graminoids and forbs. *Sphagnum* dominates the substrate in many sites though in Michigan a patchy to continuous carpet of brown mosses is more typical; *Campylium stellatum* is an indicator bryophyte. The edge of the basin may be shallow to deep peat over a sloping substrate, where seepage waters provide nutrients.
Classification Comments: Need to clarify the conceptual boundaries between this and the boreal fens in central and eastern Canada. Alkaline wooded swamps, some of which have fen-like characteristics, are treated under Laurentian-Acadian Alkaline Conifer-Hardwood Swamp (CES201.575).
Similar Ecological Systems:
- Laurentian-Acadian Alkaline Conifer-Hardwood Swamp (CES201.575)
- North-Central Interior Shrub-Graminoid Alkaline Fen (CES202.702)
- Western Canadian Boreal Shrub-Sedge Rich and Alkaline Fen (CES103.872)

Related Concepts:
- Low Sedge - Buckbean Fen Lawn (Gawler and Cutko 2010) Finer
- Northern White Cedar Woodland Fen (Gawler and Cutko 2010) Finer
- Northern White-Cedar: 37 (Eyre 1980) Undetermined
- Shrubby Cinquefoil - Sedge Circumneutral Fen (Gawler and Cutko 2010) Finer

DESCRIPTION

Environment: This system usually occurs where there is flat, highly calcareous bedrock near the surface. Water slowly moves along this bedrock and, where it comes to the surface, fens can form in the cold, mineral-rich, anoxic water. Soils are organic and saturated most or all of the growing season. Waterflow through this system is slow but greater than in bogs (Schwintzer and Tomberlin 1982). Some fens in this system occur on the shore of lakes or ponds where wave action is low.
Dynamics: The presence of cold, mineral-rich, alkaline groundwater which promotes the formation of peat and marl is key to the formation and maintenance of this system. Where cold, mineral-rich groundwater emerges as diffuse seeps, decomposition of plant matter is slowed and peat can accumulate. Marl forms under sustained flow of calcium- and magnesium-rich water. Peat can form hummocks which have microenvironments that are drier and more acidic than the bulk of the fen. The hummock-and-hollow microtopography, which generates small-scale gradients in soil moisture and chemistry, contributes to fen floristic diversity. The high pH of the bulk of the fens strongly shapes the floristic composition.

LOWER MISSISSIPPI RIVER FLATWOODS (CES203.193)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2513; ESLF 9191; ESP 1513

CONCEPT

Summary: This system encompasses forests, prairies and woodlands on Pleistocene terraces in the Mississippi Alluvial Plain of Arkansas, Missouri and Louisiana. It occurs primarily west of Crowley's Ridge on Pleistocene glacial outwash deposits in Arkansas and Missouri, and on Macon Ridge in Louisiana and adjacent Arkansas. The sites are above modern floodplains, but have poor internal drainage and are flat with poor runoff, leading to very wet conditions in winter and spring. They also often have a claypan that restricts both internal drainage and, later in the year, water availability. Therefore, they are very wet in the winter/spring and very dry in the summer, a moisture regime termed hydroxeric. Because of this moisture regime, the communities are variable, ranging from willow oak flats to post oak flats to prairies. In the 1940s, the Arkansas Game and Fish Commission produced a wildlife habitat map of Arkansas in which these sites were classified as "terrace hardwood forests." These communities have a large variety of upland and lowland tree species, ranging from post oak to overcup oak in a small area. Such species diversity may be explained by regeneration of species with dramatically different moisture tolerances on the same site in dry and wet years on these hydroxeric sites. Because the sites are above current floodplains and susceptible to being drained, they have been cleared at an even greater rate than nearby floodplain forests.
Classification Comments: T. Foti (pers. comm. 2007): "I think it does encompass the Louisiana Mesic Hardwood Flatwoods, and the species listed in that description look good for the whole system. Do we want to leave the potential for prairies in this system or include them in the Grand Prairie system? I am inclined to think that small prairie inclusions should remain in this system and larger, individually definable prairies, such as those formerly across the White River from the Grand Prairie proper, could be included in that system. That distinction might be mentioned in the description. The Grand Prairie should be listed as a similar ecological system."
Similar Ecological Systems:
- Interior Highlands Unglaciated Flatwoods (CES202.454)
- Lower Mississippi Alluvial Plain Grand Prairie (CES203.549)
- Mississippi River High Floodplain (Bottomland) Forest (CES203.196)
- West Gulf Coastal Plain Nonriverine Wet Hardwood Flatwoods (CES203.548)

Related Concepts:
- Mesic Hardwood Flatwood (LNHP 2004) Finer
- Wet Hardwood Flatwood (LNHP 2004) Finer

DESCRIPTION

Environment: The sites where this system is found are above modern floodplains, but have poor internal drainage and are flat with poor runoff, leading to very wet conditions in winter and spring. They also often have a claypan that restricts both internal drainage and, later in the year, water availability. Therefore, they are very wet in the winter/spring and very dry in the summer, a moisture regime termed hydroxeric. In Louisiana, distinct mesic and wet community variants are recognized (LNHP 2004, 2009).
Vegetation: The communities of this system are variable, ranging from willow oak flats to post oak flats to prairies. In examples on Macon Ridge (Louisiana), overstory dominants include *Carya alba, Nyssa sylvatica, Quercus alba, Quercus pagoda, Quercus nigra, Quercus michauxii*, and *Liquidambar styraciflua*. In addition, *Quercus shumardii* and *Quercus falcata* are fairly frequent but not usually abundant. Common midstory trees include *Cornus florida, Ostrya virginiana, Aralia spinosa, Ulmus alata, Sassafras albidum*, and *Acer rubrum*. Important shrubs/small trees are *Vaccinium arboreum, Vaccinium virgatum, Viburnum rufidulum, Crataegus marshallii, Aesculus pavia, Frangula caroliniana, Asimina triloba, Hypericum hypericoides*, and *Euonymus americanus*. Although infrequent, *Hamamelis virginiana* can be locally abundant. Important woody vines include *Toxicodendron radicans, Parthenocissus quinquefolia, Vitis rotundifolia, Vitis aestivalis*, and *Smilax smallii*. *Toxicodendron radicans* and *Parthenocissus quinquefolia* are usually thick on the ground, as well as being represented by high climbing individuals. Common and characteristic herbaceous plants include *Chasmanthium sessiliflorum, Dichanthelium boscii, Podophyllum peltatum, Carex cherokeensis, Elephantopus carolinianus, Elephantopus tomentosus, Scleria oligantha, Aristolochia serpentaria, Botrychium virginianum, Passiflora lutea, Dioscorea villosa, Clitoria mariana, Sanicula canadensis, Geum canadense, Galium circaezans, Agrimonia rostellata, Spigelia marilandica, Clematis virginiana, Phryma leptostachya, Ruellia caroliniensis*, and *Smallanthus uvedalius* (LNHP 2004).

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Mississippi River High Floodplain (Bottomland) Forest (CES203.196)

Adjacent Ecological System Comments: These flatwoods are above existing floodplains and they are ecologically controlled by

edaphic factors and precipitation.

DISTRIBUTION

Range: This system is found in the Mississippi Alluvial Plain from the Missouri "bootheel" south to Louisiana. It occurs primarily west of Crowley's Ridge on Pleistocene glacial outwash deposits in Arkansas and Missouri. In southeastern Arkansas and northeastern Louisiana it is found on Macon Ridge (Ecoregion 73j (EPA 2004, LNHP 2009)). It is not reported from Kentucky, Tennessee, or Mississippi.
Divisions: 203:C
Nations: US
Subnations: AR, LA, MO

MEDITERRANEAN CALIFORNIA ALKALI MARSH (CES206.947)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Alkaline Water; Saline Water Chemistry; Shallow (<15 cm) Water; Caliche Layer; Mediterranean [Mediterranean Xeric-Oceanic]; Depressional
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Lowland [Lowland]; Woody-Herbaceous; Herbaceous; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9188

CONCEPT

Summary: These highly variable systems occur in scattered locations throughout the California Central Valley and along California's south coast extending into Baja Norte, all at elevations below 300 m (1000 feet). They are found in old lake beds or in floodplains of major river systems where seasonal water inputs are limited, and often include some groundwater seepage. High rates of evaporation lead to alkaline water and soil conditions, with layers of salt encrusted soils often accumulating near seeps. These are highly variable in plant composition, but often include *Schoenoplectus americanus (= Scirpus americanus), Atriplex* spp., *Triglochin maritima*, and *Cirsium* spp. Endemic plant species include *Puccinellia howellii*.
Related Concepts:
- Wetlands (217) (Shiflet 1994) Broader

DESCRIPTION

Environment: This system occurs at elevations below 300 m (1000 feet). Examples are found in old lakebeds or in floodplains of major river systems where seasonal water inputs are limited, and often include some groundwater seepage. High rates of evaporation lead to alkaline water and soil conditions, with layers of salt-encrusted soils often accumulating near seeps. Soils are alkaline to saline clays with hardpans. It is often associated with faults and seepage from salty or alkaline country rock, such as marine sediments, uplifted lake bed deposits, etc.) (T. Keeler-Wolf pers. comm. 2013).
Dynamics: Alkali marshes develop where freshwater inputs are ponded in shallow to deep pools that are exposed to strong evaporative forces, accumulating salts and creating the alkali chemistry (Mitsch and Gosselink 2000). The key process is a an internal drainage (playa) with a water source (seep, with fresh or saline waters) in inland areas with strong evapotranspiration rates, such as the southern Central Valley, and southern coastal regions (Sawyer et al. 2009).

DISTRIBUTION

Range: Scattered locations throughout the California Central Valley and along California's south coast extending into Baja Norte, all at elevations below 300 m (1000 feet).

MISSISSIPPI RIVER BOTTOMLAND DEPRESSION (CES203.490)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Riverine / Alluvial [Brownwater]; Needle-Leaved Tree; Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 9352

CONCEPT

Summary: This system represents semipermanently flooded to saturated depressional areas of the lower Mississippi River Alluvial Valley, from southern Illinois south to Mississippi and Louisiana. These areas have a distinctly longer hydroperiod than other parts of the landscape. Typical and characteristic trees in examples of this system include *Acer rubrum var. drummondii, Carya aquatica, Fraxinus profunda, Gleditsia aquatica, Nyssa aquatica, Nyssa biflora, Planera aquatica, Quercus lyrata, Quercus palustris, Salix nigra*, and *Taxodium distichum*. Some characteristic shrubs include *Cephalanthus occidentalis, Cornus foemina, Decodon verticillatus, Forestiera acuminata, Itea virginica*, and *Planera aquatica*. Herbs are uncommon, but *Ludwigia peploides, Sagittaria lancifolia, Ceratophyllum* spp., *Elodea* spp., *Potamogeton* spp., and *Lemna minor* may be found.

DESCRIPTION

Environment: Examples of this system are found in depressions and backswamps of the lower Mississippi River Alluvial Valley, from southern Illinois south to Mississippi and Louisiana. These areas have a distinctly longer hydroperiod than other parts of the landscape.

Vegetation: Typical and characteristic trees in examples of this system include *Acer rubrum var. drummondii, Carya aquatica, Fraxinus profunda, Gleditsia aquatica, Nyssa aquatica, Nyssa biflora, Planera aquatica, Quercus lyrata, Quercus palustris, Salix nigra*, and *Taxodium distichum*. Some characteristic shrubs include *Cephalanthus occidentalis, Cornus foemina, Decodon verticillatus, Forestiera acuminata, Itea virginica*, and *Planera aquatica*. Herbs are uncommon, but *Ludwigia peploides, Sagittaria lancifolia, Ceratophyllum* spp., *Elodea* spp., *Potamogeton* spp., and *Lemna minor* may be found.

Dynamics: Flooding is more frequent and of longer duration in these depressions and on the lower terraces than the upper ones. Catastrophic floods of long duration as well as wind events can cause the loss of canopy over large areas, and large coastal areas are also impacted by storm surges from hurricanes. The duration of flooding varies with the placement of a particular site in the landscape and is a dominant process affecting vegetation on a given site. Flooding can deposit alluvium or scour the ground, depending on the landscape position of a site and the severity of the flood event. Fire is infrequent and of limited importance in these lower, wetter areas, but could affect them during periods of prolonged drought. Changes in hydrology due to the activities of beaver are also an important ecological process in bottomland hardwood forests. Beaver activity can add to the dynamics of the system, altering habitat over large areas. Beaver impoundments kill trees (sometimes over large areas) but may also create open water habitat, cypress-tupelo stands, or cause stand replacement.

Component Associations:

- *Acer rubrum - Gleditsia aquatica - Planera aquatica - Fraxinus profunda* Forest (CEGL002422, G3G5)

MISSISSIPPI RIVER HIGH FLOODPLAIN (BOTTOMLAND) FOREST (CES203.196)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial [Brownwater]
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9180

CONCEPT

Summary: "High bottomlands" are often temporarily flooded on older Holocene point bars and natural levees, with flooding less frequent than every five years. Wetland functions are primarily driven by precipitation and are classed as floodplain flats in a hydrogeomorphic classification (Klimas et al. 2004). They are flooded less frequently than adjacent riparian floodplains or low floodplains. These floodplains are of particular conservation interest because they have been cleared to a greater extent than riparian or low floodplains because of the reduced flooding of these sites. Also, flood control levees protect many of these sites, and with protection from levees, almost all sites are cleared. Thus, most wetlands remaining in large bottomland areas are riparian or low bottomlands, and the species, communities and other characteristics of high bottomlands have been essentially lost. Wildlife agency partners support the recognition of this distinction. Because many of these sites are adjacent to uplands or non-flooded hydroxeric flatwoods, both of which have a relatively high fire frequency, and high floodplains are relatively dry, they have a much higher typical fire frequency than lower bottomlands. Therefore, under pre-development conditions, they would have been more open and would have had a greater ground layer diversity than other floodplain systems.

DESCRIPTION

Environment: These "high bottomlands" are often temporarily flooded on older Holocene point bars and natural levees, with flooding less frequent than every five years. Wetland functions are primarily driven by precipitation and are classed as floodplain flats in a hydrogeomorphic classification (Klimas et al. 2004). They are flooded less frequently than adjacent riparian floodplains or low floodplains.

Vegetation: Typical dominant trees in stands of this system include *Liquidambar styraciflua, Quercus laurifolia, Quercus michauxii, Quercus nigra, Quercus pagoda, Quercus phellos, Quercus shumardii, Quercus texana,* and *Carya* spp. Southern examples may contain *Quercus virginiana* and/or *Magnolia grandiflora,* northern ones may contain *Quercus palustris*. Wetter inclusions may contain *Quercus lyrata*. Some stands which lack these species may exhibit dominance by *Fraxinus pennsylvanica, Ulmus americana*, and *Celtis laevigata*. *Gleditsia triacanthos* may also be a component. *Ulmus crassifolia* may be more commonly found west of the Mississippi River. Some small trees and shrubs include *Cornus florida, Ilex decidua, Ilex opaca* var. *opaca, Viburnum dentatum,* and *Carpinus caroliniana*. Southern stands may contain *Sabal minor*. The perennial graminoid bamboo *Arundinaria gigantea* ssp. *gigantea* may dominate the shrub stratum of some forests, or it may form non-forested stands called "canebrakes." *Vitis rotundifolia, Ampelopsis arborea,* and *Campsis radicans* are common vines.

Dynamics: Flooding is the principal disturbance in this system. Flooding frequently floods higher terraces (Wharton et al. (1982) zones IV and V), but not as frequently as the lower ones. Unusually long or deep floods may stress vegetation or act to regenerate some species. Occasional, long duration flooding can cause the loss of canopy over large areas. This canopy decline and reproductive

failure can create late-seral open stands. Duration of flooding varies with the placement of a site in the landscape and is a dominant process affecting vegetation on a given site. Flooding can deposit alluvium or scour the ground, depending on the landscape position of a site and the severity of the flood event.

In addition to periodic flooding, the dominant ecological process in bottomland hardwood forests is the formation of windfall gaps, which can occur on the local scale (a single mature canopy tree) as well as the landscape scale (tornadoes or hurricanes). When canopy trees fall, seedlings in the understory are released and compete for a spot in the canopy. This leads to dense areas of herbaceous and woody vegetation in windfall gaps of all sizes. This is a major process in forest regeneration in bottomland hardwood forests.

The fire history of this type is poorly understood, in part because there has been the widespread assumption that fire was not a factor in its ecological dynamics. However, the presence of extensive cane understories and canebrakes indicates that fire was much more common than is generally believed. These canebrakes exist as a patch community maintained by wind and fire. Fire played a greater role in this system than in the related "low bottomlands." Infrequent, mild surface fires would occur in the system; however, they would not alter species composition or structure. Fire was frequent historically on older terraces outside the floodplain, and also crept into the floodplains; it is infrequent and of limited importance in the lower, wetter terraces. Putnam (1951 as cited in Wharton et al. 1982) states that a serious fire season occurs on an average of about every 5 to 8 years in the bottomland hardwood forests of the Mississippi Alluvial Plain. This system is also bordered by a number of upland communities from which fire would have occasionally burned down into the bottoms, especially in drought years. It is conjectured that Native Americans maintained canebrakes by deliberate fall burning.

Currently, the regeneration of remaining examples occurs through small gap regeneration or large patch regeneration in blowdowns from tornados or large storms. Originally, fire may have functioned to open larger patches in which regeneration occurred.

Beaver activity causes changes in hydrology, and this is an important ecological process in bottomland hardwood forests; the effects are poorly understood at the landscape level, especially in the presettlement context. Beaver impoundments can kill trees (sometimes over large areas) and may create open water habitat or cypress-tupelo stands, or cause stand replacement. Meandering streams are dynamic and frequently change course, eroding into the floodplain and depositing new point bars, thus creating new habitat for early-seral plant communities. In addition, insect outbreaks would occur infrequently in closed-canopy states.

Component Associations:
- *Arundinaria gigantea ssp. gigantea* Shrubland (CEGL003836, G2?)

MISSISSIPPI RIVER LOW FLOODPLAIN (BOTTOMLAND) FOREST (CES203.195)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial [Brownwater]
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9183

CONCEPT

Summary: These "low bottomlands" are usually seasonally flooded in backswamps, with flooding more frequent than every five years, usually more frequently than every two years, generally by still water that may be impounded behind natural levees, and are classed as Low Gradient Riverine Backwater wetlands in hydrogeomorphic classifications. Low bottomlands occur along the Mississippi River and its tributaries in the Mississippi River Alluvial Plain ecoregion. Prolonged flooding dominates this system, and its duration is greater than in the adjacent Mississippi River Riparian Forest. Overcup oak is the characteristic dominant species. Soils are clayey with poor internal drainage.

Similar Ecological Systems:
- Mississippi River High Floodplain (Bottomland) Forest (CES203.196)
- Mississippi River Riparian Forest (CES203.190)--Flooding is of lower duration.

DESCRIPTION

Environment: These "low bottomlands" are usually seasonally flooded in backswamps, with flooding more frequent than every five years, usually more frequently than every two years, generally by still water that may be impounded behind natural levees, and are classed as Low Gradient Riverine Backwater wetlands in hydrogeomorphic classifications (Klimas et al. 1981).

Dynamics: Changes in soils and vegetation of this system are much slower than in the adjacent Mississippi River riparian forest. Flooding is the principal disturbance in this system. Unusually long or deep floods may stress vegetation or act to regenerate some species. Larger floods cause local disturbance by scouring and depositing sediment along channels and occasionally causing channel shifts. Duration of flooding varies with the placement of a site in the landscape and is a dominant process affecting vegetation on a given site. Flooding can deposit alluvium or scour the ground, depending on the landscape position of a site and the severity of the flood event. Flooding occurs in lower terraces more frequently than in the higher ones. Occasional, long-duration flooding can cause the loss of canopy over large areas. This canopy decline and reproductive failure can create late-seral open stands. Duration of flooding varies with the placement of a site in the landscape and is a dominant process affecting vegetation on a given site. Flooding can deposit alluvium or scour the ground, depending on the landscape position of a site and the severity of the flood event.

In addition to periodic flooding, the dominant ecological process in bottomland hardwood forests is the formation of windfall gaps, which can occur on the local scale (a single mature canopy tree) as well as the landscape scale (effects of tornadoes or hurricanes). When canopy trees fall, seedlings in the understory are released and compete for a spot in the canopy. This leads to dense areas of herbaceous and woody vegetation in windfall gaps of all sizes. This is a major process in forest regeneration in bottomland hardwood forests.

The fire history of this type is poorly understood, in part because there has been the widespread assumption that fire was not a factor in its ecological dynamics. However, the presence of extensive cane understories and canebrakes indicates that fire was much more common than is generally believed. These canebrakes exist as a patch community maintained by wind and fire. Fire presumably played a lesser role in this system than in the related "high bottomlands." This system is also bordered by a number of upland communities from which fire would have occasionally burned down into the bottoms, especially in drought years. Beaver activity causes changes in hydrology, and this is an important ecological process in bottomland hardwood forests; the effects are poorly understood at the landscape level, especially in the presettlement context. Beaver impoundments can kill trees (sometimes over large areas) and may create open water habitat or cypress-tupelo stands, or cause stand replacement. Meandering streams are dynamic and frequently change course, eroding into the floodplain and depositing new point bars, thus creating new habitat for early-seral plant communities. In addition, insect outbreaks would occur infrequently in closed-canopy states.

MISSISSIPPI RIVER RIPARIAN FOREST (CES203.190)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial [Brownwater]
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9161

CONCEPT

Summary: This ecological system consists of riverfront vegetation, which is generally temporarily (but rarely seasonally) flooded, on point bars and natural levees adjacent to the river that formed them. The period between floods is less than five years, and the flooding is caused by water flowing directly from the channel. Examples occur along the lower Mississippi River and its tributaries in the Mississippi River Alluvial Plain ecoregion. They are classed as Low Gradient Riverine Overbank wetlands in a hydrogeomorphic classification. The flooding is of shorter duration than on adjacent backswamps where water is impounded behind riverfront natural levees, and is of longer duration than on adjacent high bottomlands that are typically temporarily flooded. Soils are typically sandier than those of low bottomlands. Giant cane is a common understory component in these forests on natural levees and higher point bars, and may become dominant after thinning or removal of the overstory. Willow and cottonwood sandbars may have an open-canopy (woodland) structure.

Similar Ecological Systems:

DESCRIPTION

Environment: Stands of this system are generally temporarily (but rarely seasonally) flooded on point bars and natural levees adjacent to the river that formed them, with flooding more frequent than every five years, by flowing water directly from the stream. They are classed as Low Gradient Riverine Overbank wetlands in a hydrogeomorphic classification (Klimas et al. 2004). Flooding is of lower duration than on adjacent backswamps where water is impounded behind riverfront natural levees. Flooding is of longer duration than on adjacent high bottomlands that are typically temporarily flooded. Soils are typically sandier than those of low bottomlands.

Vegetation: Some of the most typical and characteristic tree species found in stands of this system include *Acer negundo*, *Acer saccharinum*, *Platanus occidentalis*, *Populus deltoides*, and *Salix nigra*. Other trees may include *Celtis laevigata*, *Carya illinoinensis*, *Fraxinus pennsylvanica*, *Gleditsia triacanthos*, *Liquidambar styraciflua*, *Quercus nigra*, *Quercus pagoda*, *Quercus texana*, *Ulmus americana*, and *Ulmus crassifolia*. In addition, *Quercus virginiana* may be present within its range. *Arundinaria gigantea ssp. gigantea* is a common understory component in these forests on natural levees and higher point bars, and may become dominant after thinning or removal of the overstory.

Dynamics: Often on sites with rapid soil deposition and, therefore, with rapid development of vegetation from low-diversity willow- and cottonwood-dominated communities to more diverse communities dominated by sycamore, pecan, sugarberry, green ash or Nuttall oak. Regeneration is through small treefall gaps or large tornado tracks.

NORTH AMERICAN WARM DESERT LOWER MONTANE RIPARIAN WOODLAND AND SHRUBLAND (CES302.748)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Shrubland (Shrub-dominated); Riverine / Alluvial
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Lowland [Lowland]; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]
National Mapping Codes: ESLF 9172

CONCEPT

Summary: This ecological system occurs in foothill and mountain canyons and valleys of the warm desert regions of the southwestern U.S. and adjacent Mexico, and consists of mid-to low-elevation (1100-1800 m) riparian corridors along perennial and seasonally intermittent streams. Rivers include upper portions of the Gila, Santa Cruz, Salt, San Pedro, and tributaries of the lower Colorado River (below the Grand Canyon), the lower Rio Grande and Pecos (up to its confluence with Rio Hondo) that occur in the desert portions of their range. The vegetation is a mix of riparian woodlands and shrublands. Dominant trees include *Acer negundo, Populus deltoides ssp. wislizeni, Populus fremontii, Platanus wrightii, Juglans major, Fraxinus velutina*, and *Sapindus saponaria*. Occasionally *Populus angustifolia* may come in from higher elevations. Shrub dominants include *Salix exigua, Shepherdia argentea, Prunus* spp., *Alnus oblongifolia*, and *Baccharis salicifolia*. Vegetation is dependent upon annual or periodic flooding and associated sediment scour and/or annual rise in the water table for growth and reproduction.

DESCRIPTION

Environment: This ecological system occurs in foothill and mountain canyons and valleys of the warm desert regions of the southwestern U.S. and adjacent Mexico, and consists of mid- to low-elevation (1100-1800 m) riparian corridors and their associated perennial and seasonally intermittent streams. Some occurrences originate as, or receive flow from, headwater streams supported by surface runoff and shallow groundwater seepage; others originate at montane springs.

Dynamics: The hydrologic regime is naturally highly variable temporally and spatially among the streams of this ecosystem. Where present, bedrock formations that force alluvial and basin-fill groundwater to the surface and spring discharges from bedrock aquifers provide flows unaffected by rainfall and snowmelt. Otherwise, stream and river flows are subject to wide fluctuations in where they occur, at what magnitudes, and when and how often as a result of the wide variation in where and when precipitation takes place (cool versus warm season), what form the precipitation takes (rain versus snow), and where and when snowmelt takes place (e.g., Abell et al. 2000, Izbicki and Michel 2004, Levick et al. 2008, Miller et al. 2010a). Intense runoff associated with intense rainfall events are highly erosive, resulting in rapid reconfiguration of aquatic and riparian macrohabitats particularly along reaches with sand and gravel substrates. As a result of this intense regime of fluvial disturbance, occurrences of this ecosystem contain early-, mid- and late-seral riparian plant associations.

NORTH AMERICAN WARM DESERT RIPARIAN MESQUITE BOSQUE (CES302.752)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland [Lowland]; Toeslope/Valley Bottom; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Riverine / Alluvial; Prosopis spp.-dominated
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Shrubland (Shrub-dominated)
National Mapping Codes: ESLF 9178

CONCEPT

Summary: This ecological system consists of low-elevation (<1100 m) riparian corridors along perennial and intermittent streams in valleys of the warm desert regions of the southwestern U.S. and adjacent Mexico. Rivers include the lower Colorado (within and downstream of the Grand Canyon), Gila, Santa Cruz, Salt, lower Rio Grande, Pecos (up to near its confluence with Rio Hondo), and their tributaries that occur in the desert portions of their range. Dominant trees include *Prosopis glandulosa* and *Prosopis velutina*. Shrub dominants include *Baccharis salicifolia*, *Pluchea sericea*, and *Salix exigua*. Woody vegetation is relatively dense, especially when compared to drier washes. Vegetation, especially the mesquites, tap groundwater below the streambed when surface flows stop. Vegetation is dependent upon annual rise in the water table for growth and reproduction.

Component Associations:
- *Baccharis salicifolia / Muhlenbergia rigens* Shrubland (CEGL004572, G3?)
- *Baccharis sarothroides - Baccharis salicifolia* Shrubland (CEGL001160, G4)
- *Baccharis sarothroides - Parkinsonia microphylla* Shrubland (CEGL001159, G4)
- *Pluchea sericea* Seasonally Flooded Shrubland (CEGL003080, G3?)
- *Prosopis glandulosa - Artemisia filifolia / Sporobolus giganteus* Shrubland (CEGL002192, G4)
- *Prosopis glandulosa - Atriplex* spp. Shrubland (CEGL002193, GNR)
- *Prosopis glandulosa / Atriplex canescens* Shrubland (CEGL001382, G5)
- *Prosopis glandulosa / Bouteloua curtipendula - Nassella leucotricha* Woodland (CEGL002133, G3?)
- *Prosopis glandulosa / Bouteloua curtipendula* Shrubland (CEGL002194, GNR)
- *Prosopis glandulosa / Bouteloua eriopoda* Shrub Herbaceous Vegetation (CEGL001510, G3G4)
- *Prosopis glandulosa / Bouteloua gracilis* Shrubland (CEGL001383, G5)
- *Prosopis glandulosa* / Mixed Grasses Shrubland (CEGL001384, GNRQ)
- *Prosopis glandulosa / Muhlenbergia porteri* Shrubland (CEGL001511, G5)
- *Prosopis glandulosa / Pleuraphis mutica* Shrub Herbaceous Vegetation (CEGL001641, G5)
- *Prosopis glandulosa / Sporobolus airoides* Shrubland (CEGL001385, G5)
- *Prosopis glandulosa / Sporobolus flexuosus* Shrubland (CEGL001386, G4)
- *Prosopis glandulosa* Temporarily Flooded Woodland (CEGL004934, GNR)
- *Prosopis glandulosa var. glandulosa / Bouteloua gracilis - Buchloe dactyloides* Shrubland (CEGL003877, GNR)
- *Prosopis glandulosa var. torreyana* Shrubland (CEGL001381, G3)
- *Prosopis pubescens* Shrubland (CEGL001387, G1?)
- *Prosopis velutina - Acacia greggii* Shrubland (CEGL001388, GUQ)
- *Prosopis velutina / Celtis laevigata var. reticulata* Shrubland (CEGL001390, GNR)
- *Prosopis velutina / Muhlenbergia porteri* Shrubland (CEGL001391, G3Q)

DISTRIBUTION

Range: This system is found along perennial and intermittent streams in valleys of southern Arizona, southern Nevada, southeastern California, New Mexico, western Texas, and adjacent Mexico. Major rivers include the lower Colorado (within and downstream of the Grand Canyon), Gila, Santa Cruz, Salt, lower Rio Grande, Pecos (up to near its confluence with Rio Hondo), and their tributaries that occur in the desert portions of their range.
Divisions: 302:C
Nations: MX, US

NORTH AMERICAN WARM DESERT RIPARIAN WOODLAND AND SHRUBLAND (CES302.753)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland [Lowland]; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Riverine / Alluvial
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Toeslope/Valley Bottom
National Mapping Codes: ESLF 9182

CONCEPT

Summary: This ecological system consists of low-elevation (<1200 m) riparian corridors along medium to large perennial streams throughout canyons and desert valleys of the southwestern United States and adjacent Mexico. Rivers include the lower Colorado (into the Grand Canyon), Gila, Santa Cruz, Salt, lower Rio Grande (below Elephant Butte Reservoir in New Mexico to the Coastal Plain of Texas), and the lower Pecos (up to near its confluence with Rio Hondo in southeastern New Mexico). These are disturbance-driven plant communities that require flooding, scour and deposition of sands and gravel, and a periodically elevated water table for germination and maintenance. The aquatic communities, in turn, vary with the frequency, intensity, duration and timing of flow, including its often extreme inter-annual variability; the relative contributions of rainfall, snowmelt, and diffuse groundwater and spring discharges to flow; water temperature and chemistry; channel substrate and form; the extent of the hyporheic zone; and drainage network connectivity. These latter conditions, in turn, vary with elevation, latitude and longitude, channel gradient, floodplain width (a function of topography and geology), and surrounding geology and land cover. The vegetation is a mix of riparian woodlands and shrublands. Dominant trees include *Fraxinus velutina, Populus fremontii, Salix gooddingii, Salix lasiolepis, Celtis laevigata var. reticulata, Platanus racemosa*, and *Juglans major*. Shrub dominants include *Salix geyeriana* and *Salix exigua*. Vegetation is dependent upon annual or periodic flooding and associated sediment scour and/or annual rise in the water table for growth and reproduction.

DESCRIPTION

Environment: These are disturbance-driven plant communities that require flooding, scour and deposition of sands and gravel, and a periodically elevated water table for germination and maintenance. The aquatic communities, in turn, vary with the frequency, intensity, duration and timing of flow, including its often extreme inter-annual variability; the relative contributions of rainfall, snowmelt, and diffuse groundwater and spring discharges to flow; water temperature and chemistry; channel substrate and form; the extent of the hyporheic zone; and drainage network connectivity. These latter conditions, in turn, vary with elevation, latitude and longitude, channel gradient, floodplain width (a function of topography and geology), and surrounding geology and land cover.
Dynamics: From MBR conceptual model (Comer et al. 2013b): The hydrologic regime is naturally highly variable temporally and spatially among the streams of this ecosystem. Where present, bedrock formations that force alluvial and basin-fill groundwater to the surface and spring discharges from bedrock aquifers provide flows unaffected by rainfall and snowmelt. Otherwise, stream and river flows are subject to wide fluctuations in where they occur, at what magnitudes, and when and how often as a result of the wide variation in where and when precipitation takes place (cool versus warm season), what form the precipitation takes (rain versus snow), and where and when snowmelt takes place (e.g., Abell et al. 2000, Izbicki and Michel 2004, Levick et al. 2008, Miller et al. 2010a). Intense runoff associated with intense rainfall events are highly erosive, resulting in rapid reconfiguration of aquatic and riparian macrohabitats particularly along reaches with sand and gravel substrates. As a result of this intense regime of fluvial disturbance, occurrences of this ecosystem contain early-, mid- and late-seral riparian plant associations. Occurrences also contains non-obligate riparian species. Cottonwood communities are early-, mid- or late-seral, depending on the age-class of the trees and the associated species of the occurrence (Kittel et al. 1999b). Cottonwoods, however, do not reach a climax stage as defined by Daubenmire (1952). Mature cottonwood occurrences do not regenerate in place, but regenerate by "moving" up and down a river reach. Over time, a healthy riparian area supports all stages of cottonwood communities (Kittel et al. 1999b).

Component Associations:
- *Acer negundo - Celtis laevigata var. reticulata* Woodland (CEGL002599, GNR)
- *Baccharis emoryi - Salix exigua* Shrubland (CEGL005947, G3)
- *Baccharis salicifolia* Riparian Shrubland (CEGL003549, G5)
- *Celtis laevigata var. reticulata - Juglans microcarpa / Leptochloa dubia* Woodland (CEGL002166, GNR)
- *Celtis laevigata var. reticulata / Celtis pallida* Shrubland (CEGL001163, G3)
- *Chilopsis linearis / Brickellia laciniata* Scrub Woodland (CEGL004933, G3G4)

- *Fallugia paradoxa* Colorado Plateau Desert Wash Shrubland (CEGL002357, GNR)
- *Juglans major - Pinus edulis / Bromus carinatus* Forest (CEGL001101, GUQ)
- *Juglans major - Prosopis velutina* Forest (CEGL005326, GNR)
- *Juglans microcarpa* Scrub (CEGL001103, GNR)
- *Platanus wrightii - Alnus oblongifolia / Baccharis salicifolia* Forest (CEGL002686, G2)

NORTH AMERICAN WARM DESERT WASH (CES302.755)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Intermittent Flooding; Lowland [Lowland]; Shrubland (Shrub-dominated); Toeslope/Valley Bottom; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Riverine / Alluvial
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Sideslope
National Mapping Codes: ESLF 9151

CONCEPT

Summary: This ecological system is restricted to intermittently flooded washes or arroyos that dissect bajadas, mesas, plains and basin floors throughout the warm deserts of North America. Although often dry, the intermittent fluvial processes define this system, which are often associated with rapid sheet and gully flow. This system occurs as linear or braided strips within desert scrub-or desert grassland-dominated landscapes. The vegetation of desert washes is quite variable, ranging from sparse and patchy to moderately dense, and typically occurs along the banks, but may occur within the channel. The woody layer is typically intermittent to open and may be dominated by shrubs and small trees such as *Acacia greggii, Brickellia laciniata, Baccharis sarothroides, Chilopsis linearis, Fallugia paradoxa, Hymenoclea salsola, Hymenoclea monogyra, Juglans microcarpa, Olneya tesota, Parkinsonia florida, Prosopis* spp., *Psorothamnus spinosus, Prunus fasciculata, Rhus microphylla, Salazaria mexicana,* or *Sarcobatus vermiculatus*. Common upland shrubs such as *Larrea tridentata* and *Ambrosia dumosa* are often present along the edges of these washes.
Related Concepts:
- Creosotebush - Bursage (506) (Shiflet 1994) Intersecting. Washes occur as linear inclusions in the SRM type.
- Palo Verde - Cactus (507) (Shiflet 1994) Intersecting. Washes occur as linear inclusions in this SRM type.

Component Associations:
- *Acacia greggii - Parkinsonia microphylla* Shrubland (CEGL001340, G4G5)
- *Acacia greggii* Wash Shrubland (CEGL005390, GNR)
- *Baccharis salicifolia / Muhlenbergia rigens* Shrubland (CEGL004572, G3?)
- *Baccharis sarothroides - Baccharis salicifolia* Shrubland (CEGL001160, G4)
- *Baccharis sarothroides - Parkinsonia microphylla* Shrubland (CEGL001159, G4)
- *Bebbia juncea* Shrubland (CEGL005391, GNR)
- *Brickellia laciniata - Hymenoclea monogyra* Shrubland (CEGL001953, G4)
- *Brickellia longifolia* Shrubland (CEGL005392, GNR)
- *Chilopsis linearis / Brickellia laciniata* Scrub Woodland (CEGL004933, G3G4)
- *Chilopsis linearis* Shrubland (CEGL001164, G3)
- *Encelia virginensis* Shrubland (CEGL001335, G4)
- *Ericameria paniculata* Wash Shrubland (CEGL002706, G4G5)
- *Fallugia paradoxa* Colorado Plateau Desert Wash Shrubland (CEGL002357, GNR)
- *Fallugia paradoxa* Grand Canyon Desert Wash Shrubland (CEGL005298, GNR)
- *Grayia spinosa - Lycium andersonii* Shrubland (CEGL001347, G5)
- *Grayia spinosa - Lycium pallidum* Shrubland (CEGL001348, G5)
- *Hymenoclea monogyra* Thicket Shrubland (CEGL001169, G3)
- *Hymenoclea salsola - (Ambrosia eriocentra)* Shrubland (CEGL002702, G5)
- *Hymenoclea salsola - Salazaria mexicana* Shrubland (CEGL002703, G3?)
- *Isocoma acradenia* Shrubland (CEGL005395, GNR)

NORTH PACIFIC BOG AND FEN (CES204.063)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland [Foothill]; Shrubland (Shrub-dominated); Temperate [Temperate Oceanic]; Depressional; Organic Peat (>40 cm); Sphagnum spp.
National Mapping Codes: ESLF 9166

CONCEPT

Summary: This wetland system occurs in peatlands along the Pacific Coast from British Columbia south to northern California, in and west of the coastal mountain summits but including the Puget Sound lowlands. Elevations are mostly under 457 m (1500 feet), and annual precipitation ranges from 890-3050 mm (35-120 inches). These wetlands are relatively abundant in British Columbia but diminish rapidly in size and number farther south. They occur in river valleys, around lakes and marshes, or on slopes. The organic soils are characterized by an abundance of sodium cations from oceanic precipitation. Poor fens and bogs are often intermixed except in a few calcareous areas in British Columbia where rich fen vegetation may dominate. *Sphagnum* characterizes poor fens and bogs (pH <5.5), and the two are lumped here, while "brown mosses" and sedges characterize rich fens (pH >5.5). Mire profiles in British Columbia may be flat, raised (domed), or sloping, but most occurrences in Washington and Oregon are flat with only localized hummock development. Vegetation is usually a mix of conifer-dominated swamp, shrub swamp, and open sphagnum or sedge mire, often with small lakes and ponds interspersed. Vegetation includes many species common to boreal continental bogs and fens, such as *Ledum groenlandicum, Vaccinium uliginosum, Myrica gale, Andromeda polifolia, Vaccinium oxycoccos, Equisetum fluviatile, Comarum palustre*, and *Drosera rotundifolia*. However, it is also distinguished from boreal continental bogs and fens by the presence of Pacific coastal species, including *Chamaecyparis nootkatensis, Pinus contorta var. contorta, Picea sitchensis, Tsuga heterophylla, Ledum glandulosum, Thuja plicata, Gaultheria shallon, Spiraea douglasii, Carex aquatilis var. dives, Carex lyngbyei, Carex obnupta, Carex pluriflora, Darlingtonia californica, Sphagnum pacificum, Sphagnum henryense*, and *Sphagnum mendocinum*.
Classification Comments: This system is distinguished and split from Boreal Depressional Shrub Bog (CES103.871) and Western Canadian Boreal Shrub-Sedge Rich and Alkaline Fen (CES103.872). The communities comprising this system are not well-described or classified. Several bog or fen ecological systems have recently (2007-2008) been classified for southeastern Alaska, hence this system no longer is considered to occur in Alaska. Where the "muskeg" of northern British Columbia should be placed is unclear and needs review from ecologists there. Discussion is that muskeg in the hypermaritime region is extensive, covering large areas of landscape, whereas this system in Oregon and Washington tends to occur in much smaller patches. How distinct is the hypermaritime muskeg of northern British Columbia from bogs and fens from central Vancouver Island south?

DESCRIPTION

Dynamics: Successional patterns of wet meadows to fens to bogs in Alaska have been documented as follows, and are likely to be similar in this ecological system. Species that dominate the early stages of succession in newly formed ponded basins include *Equisetum variegatum, Equisetum fluviatile*, and *Comarum palustre*. *Sphagnum* species invade the surface and help in forming peat. Acidic and nutrient-poor-tolerant vascular species eventually dominate the sites, such as *Myrica gale, Empetrum nigrum, Vaccinium uliginosum, Andromeda polifolia*, and *Vaccinium oxycoccos (= Oxycoccus microcarpus)*. The late-successional stage of a peatland supports various community types, depending on the pH, waterflow, and nutrient status of a site such as *Myrica gale / Empetrum nigrum* and *Picea sitchensis / Sphagnum* plant associations. Peat buildup, patterned ground, and changes in water table are recurrent aspects of peatland development rather than unidirectional successional events. It is unlikely that any of the late-seral peatland communities are stable in the sense of climax vegetation.

Component Associations:

DISTRIBUTION

Range: This system occurs along the Pacific Coast from British Columbia south to northern California, west of the coastal mountain summits but including the Puget Sound lowlands. Occurrences diminish rapidly in size and number south of British Columbia.
Divisions: 204:C; 206:P
Nations: CA, US
Subnations: BC, OR, WA
Map Zones: 1:C, 2:C, 7:C
USFS Ecomap Regions: 242A:CC, 242B:CP, 342C:P?, 342H:PP, M242A:CC, M242B:CC, M242C:CC, M242D:CC, M332G:CC
TNC Ecoregions: 1:C, 2:C, 3:C, 69:P, 81:C

NORTH PACIFIC HARDWOOD-CONIFER SWAMP (CES204.090)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Eutrophic Water; Lowland [Lowland]; Forest and Woodland (Treed); Temperate [Temperate Oceanic]; Depressional [Lakeshore]; Needle-Leaved Tree; Broad-Leaved Deciduous Tree; Pinus contorta; Sphagnum spp.
National Mapping Codes: ESLF 9190

CONCEPT

Summary: This wetland ecological system occurs from southern coastal British Columbia south into coastal Washington and Oregon, west of the coastal mountain summits (not interior). Treed swamps are common in southeastern Alaska (but are placed into different systems than this one), less so farther south. Forested swamps are mostly small-patch size, occurring sporadically in glacial depressions, in river valleys, around the edges of lakes and marshes, or on slopes with seeps that form subirrigated soils. These are primarily on flat to gently sloping lowlands up to 457 m (1500 feet) elevation but also occur up to near the lower limits of continuous forest (below the subalpine parkland). It can occur on steeper slopes where soils are shallow over unfractured bedrock. This system is indicative of poorly drained, mucky areas, and areas are often a mosaic of moving water and stagnant water. Soils can be woody peat, muck, or mineral. It can be dominated by any one or a number of conifer and hardwood species (*Tsuga heterophylla, Picea sitchensis, Tsuga mertensiana, Chamaecyparis nootkatensis, Pinus contorta var. contorta, Alnus rubra, Fraxinus latifolia, Betula papyrifera*) that are capable of growing on saturated or seasonally flooded soils. Overstory is often less than 50% cover, but shrub understory can have high cover. In the southern end of the range of this type, e.g., the Willamette Valley, tends to have more hardwood-dominated stands (especially *Fraxinus latifolia*) and very little in the way of conifer-dominated stands. While the typical landscape context for the type is extensive upland forests, for the *Fraxinus latifolia* stands, landscapes were very often formerly dominated by prairies and now by agriculture. Many conifer-dominated stands have been converted to dominance by *Alnus rubra* due to timber harvest.
Classification Comments: Shrub swamps are usually not intermixed with the forested swamps and tend to be more wet. Deciduous and conifer forested swamps are often intermixed and more similar to each other in hydrology, and so are combined here in this system.

NORTH PACIFIC INTERIOR LODGEPOLE PINE BOG (CES207.390)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Depression
National Mapping Codes: ESLF 9501

CONCEPT

Summary: Most of the site series included in this ecosystem concept are identified as very wet, dominated by *Pinus contorta*, with *Aulacomnium palustre* or other wetland indicator mosses. These bogs are variable, differing in the depth of organic material and the richness of the water moving through the site. Most of the bogs are in shallow depressions over lacustrine material. Tree cover is very low, around 10%, with *Picea mariana* and *Pinus contorta* intermixed. Shrub cover is around 30-50% with *Ledum groenlandicum* and *Betula glandulosa*. Herb cover is abundant (30-50%) cover. The moss layer is significant with 75-95% cover, generally dominated by *Sphagnum* spp. and *Pleurozium schreberi*.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC INTERIOR SHRUB SWAMP (CES207.397)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Swamp
National Mapping Codes: ESLF 9506

CONCEPT

Summary: This ecological system encompasses medium-tall to short shrublands of slow-moving interior streams and rivers, around beaver ponds in the peripheral zones of wetlands and lakeshores, where there is early season flooding, continuous seepage near the surface and poor drainage. Stands are dominated by *Alnus incana, Salix maccalliana, Betula glandulosa, Arctostaphylos uva-ursi*, or *Salix glauca*. Soils are often fine-textured, poorly to imperfectly drained with some accumulation of organics.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC INTERIOR WET TOESLOPE/RIPARIAN HYBRID WHITE SPRUCE-WESTERN RED-CEDAR FOREST (CES207.392)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Fluvial; Toeslope
National Mapping Codes: ESLF 9503

CONCEPT

Summary: This ecological system encompasses toeslopes of colluvial and steep lacustrine sites and subirrigated sites dominated by *Thuja plicata, Tsuga heterophylla, Picea glauca X engelamannii* (hybrid white spruce), and *Abies lasiocarpa*. Shrubs include *Acer glabrum, Ribes lacustre, Amelanchier alnifolia,* and *Spiraea betulifolia*. The herb layer is variable with *Chimaphila umbellata, Gymnocarpium dryopteris, Maianthemum racemosum (= Smilacina racemosa),* and others. Moss cover is about 50% with *Pleurozium schreberi, Hylocomium splendens,* and others.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC LOWLAND RIPARIAN FOREST AND SHRUBLAND (CES204.869)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland [Lowland]; Forest and Woodland (Treed); Riverine / Alluvial
Non-Diagnostic Classifiers: Temperate [Temperate Oceanic]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2156; ESLF 9106; ESP 1156

CONCEPT

Summary: Lowland riparian systems occur throughout the Pacific Northwest. They are the low-elevation, alluvial floodplains that are confined by valleys and inlets and are more abundant in the central and southern portions of the Pacific Northwest Coast. These forests and tall shrublands are linear in character, occurring on floodplains or lower terraces of rivers and streams. Major broadleaf dominant species are *Acer macrophyllum*, *Alnus rubra*, *Populus balsamifera ssp. trichocarpa*, *Salix sitchensis*, *Salix lucida ssp. lasiandra*, *Cornus sericea*, and *Fraxinus latifolia*. Conifers tend to increase with succession in the absence of major disturbance. Conifer-dominated types are relatively uncommon and not well-described; *Abies grandis*, *Picea sitchensis*, and *Thuja plicata* are important. Riverine flooding and the succession that occurs after major flooding events are the major natural processes that drive this system. Very early-successional stages can be sparsely vegetated or dominated by herbaceous vegetation.
Classification Comments: This system is driven by snowmelt and rainfall hydrology. It differs from Alaskan Pacific Maritime Floodplain Forest and Shrubland (CES204.154) by the presence of mature black cottonwood gallery forests, and generally narrow linear deciduous riparian forests and shrublands. The Alaskan type includes glacier melt-driven hydrology, which results in very wide riverine habitats with fewer mature deciduous forests, as well as non-glacial rivers common on the island archipelago, but also on the mainland, which are narrower and are mostly dominated by Sitka spruce with and without the codominance of black cottonwood.

DESCRIPTION

Environment: Stands occur on low-elevation, alluvial floodplains on alluvial soils in valleys and inlets, on riverbanks, outer floodplains or low terraces of rivers and streams.
Dynamics: Beaver activity is an important driver of hydrological change and subsequent development of a diversity of habitat patches. The contribution of large woody debris (LWD) from riparian or adjacent upland trees is important to maintaining the hydrological and sediment regimes. LWD has a significant impact on the evolution of channel morphology and also contributes to the spatial distribution and diversity of habitat patches within this system (Naiman and Bilby 1998). Major flood events and consequent flood scour, overbank deposition of water and sediments, and stream meandering are the key fluvial processes that provide new substrates, remove old banks and stimulate renewed growth of cottonwood and willow species (Sawyer et al. 2009). Natural fire-return interval was long or moderate with low-intensity surface fires.

Component Associations:

NORTH PACIFIC MONTANE RIPARIAN WOODLAND AND SHRUBLAND (CES204.866)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Temperate [Temperate Oceanic]; Riverine / Alluvial
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Montane [Montane]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2158; ESLF 9108; ESP 1158

CONCEPT

Summary: This ecological system occurs throughout mountainous areas of the Pacific Northwest coast, both on the mainland and on larger islands. It occurs on steep streams and narrow floodplains above foothills but below the alpine environments, e.g., above 1500 m (4550 feet) elevation in the Klamath Mountains and western Cascades of Oregon, up as high as 3300 m (10,000 feet) in the southern Cascades, and above 610 m (2000 feet) in northern Washington. Surrounding habitats include subalpine parklands and montane forests. In Washington, they are defined as occurring primarily above the *Tsuga heterophylla* zone, i.e., beginning at or near the lower boundary of the *Abies amabilis* zone. Dominant species include *Pinus contorta var. murrayana, Populus balsamifera ssp. trichocarpa, Abies concolor, Abies magnifica, Populus tremuloides, Alnus incana ssp. tenuifolia (= Alnus tenuifolia), Alnus viridis ssp. crispa (= Alnus crispa), Alnus viridis ssp. sinuata (= Alnus sinuata), Alnus rubra, Rubus spectabilis, Ribes bracteosum, Oplopanax horridus, Acer circinatum,* and several *Salix* species. In western Washington, major species are *Alnus viridis ssp. sinuata, Acer circinatum, Salix, Oplopanax horridus, Alnus rubra, Petasites frigidus, Rubus spectabilis,* and *Ribes bracteosum.* This is a disturbance-driven system that requires flooding, scour and deposition for germination and maintenance. It occurs on streambanks where the vegetation is significantly different than surrounding forests, usually because of its shrubby or deciduous character.
Classification Comments: Riparian and floodplain woodlands and shrublands in Alaska have been placed into a different system. Still need to determine where the Alaskan type grades into this one, and whether British Columbian riparian systems should be placed here or in the new Alaskan system.

DISTRIBUTION

Range: This system occurs throughout mountainous areas of the Pacific Northwest Coast, both on the mainland and on larger islands, above 1500 m (4550 feet) elevation in the Klamath Mountains and western Cascades, up as high as 3300 m (10,000 feet) in the southern Cascades, and above 610 m (2000 feet) in northern Washington.

NORTH PACIFIC SHRUB SWAMP (CES204.865)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Eutrophic Water; Forest and Woodland (Treed); Depressional [Lakeshore]; Broad-Leaved Deciduous Tree; Broad-Leaved Deciduous Shrub
Non-Diagnostic Classifiers: Lowland [Lowland]; Depressional [Pond]; Depressional [Sinkhole]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2663; ESLF 9173; ESP 1663

CONCEPT

Summary: Swamps vegetated by shrublands occur throughout the Pacific Northwest Coast, from Cook Inlet and Prince William Sound, Alaska, to the southern coast of Oregon. These are deciduous broadleaf tall shrublands that are located in depressions, around lakes or ponds, or river terraces where water tables fluctuate seasonally (mostly seasonally flooded regime), in areas that receive nutrient-rich waters. These depressions are poorly drained with fine-textured organic, muck or mineral soils and standing water common throughout the growing season. *Alnus viridis ssp. sinuata* often dominates the shrub layer, but many *Salix* species may also occur. The shrub layer can have many dead stems. However, various species of *Salix, Spiraea douglasii, Malus fusca, Cornus sericea, Alnus incana ssp. tenuifolia (= Alnus tenuifolia), Alnus viridis ssp. crispa (= Alnus crispa),* and/or *Alnus viridis ssp. sinuata (= Alnus sinuata)* can be the major dominants. They may occur in mosaics with marshes or forested swamps, being on average more wet than forested swamps and more dry than marshes. However, it is also frequent for them to dominate entire wetland systems. Hardwood-dominated stands (especially *Fraxinus latifolia*) may be considered a shrub swamp when they are not surrounded by conifer forests but do not occur in Alaska. Typical landscape for the *Fraxinus latifolia* stands were very often formerly dominated by prairies and now by agriculture. Wetland species, including *Carex aquatilis var. dives (= Carex sitchensis), Carex utriculata, Equisetum fluviatile*, and *Lysichiton americanus*, dominate the understory. On some sites, *Sphagnum* spp. are common in the understory (Stikine, Yakutat Forelands, Copper River Delta).
Classification Comments: Shrub swamps are usually not intermixed with the forested swamps and tend to be more wet. Deciduous and conifer forested swamps are often intermixed and more similar to each other in hydrology, and so are combined into North Pacific Hardwood-Conifer Swamp (CES204.090). This system includes what is known by the Alaska Natural Heritage Program as Maritime Tall-Shrub Swamp. Associations found in this system in Alaska need to be identified and added to the list. Deciduous shrub swamps in the Cook Inlet Basin are better placed in Western North American Boreal Deciduous Shrub Swamp (CES105.122).
Similar Ecological Systems:

NORTH PACIFIC SUB-BOREAL RIPARIAN WOODLAND AND SHRUBLAND (CES207.394)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Fluvial
National Mapping Codes: ESLF 9505

CONCEPT

Summary: This ecological system encompasses tall willow woodlands lining streams, rivers, oxbow lakes on levees or bars of active floodplains of sluggish, low-gradient streams. Stands are dominated by *Salix lucida* or *Salix sitchensis* with *Salix drummondiana* and *Cornus sericea (= Cornus stolonifera)*. The herb layer is sparse but *Equisetum* spp. can be abundant. Soils are sandy and well-drained but remain saturated at depth for much of the growing season.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC SUB-BOREAL WET TOESLOPE/RIPARIAN HYBRID WHITE SPRUCE FOREST (CES207.391)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Fluvial; Toeslope
National Mapping Codes: ESLF 9502

CONCEPT

Summary: These are wet and well-aerated sites, with highly variable soils, slopes and aspects. What they have in common is that they occur on the toeslopes of hillsides, or on the edges of forested, more poorly drained wetlands. They are usually on or near fluvial-derived parent materials. Coarse fragments have 0-87% cover. Tree cover is generally closed to moderately closed and dominated by *Picea glauca X engelmannii* (hybrid white spruce), mixed with *Abies lasiocarpa, Pinus contorta*, or others. The shrub layer is generally abundant with *Oplopanax horridus, Ribes lacustre, Rubus parviflorus, Vaccinium membranaceum, Lonicera involucrata*, and *Vaccinium ovalifolium*. The herb layer is often varied and abundant with *Dryopteris expansa, Gymnocarpium dryopteris, Rubus pedatus, Streptopus lanceolatus var. roseus (= Streptopus roseus), Cornus canadensis, Athyrium filix-femina, Galium triflorum, Tiarella trifoliata, Veratrum viride*, and *Streptopus amplexifolius*. The moss layer is moderate, with 30-45% cover, and includes *Pleurozium schreberi, Ptilium crista-castrensis*, and *Rhytidiadelphus triquetrus*.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH-CENTRAL APPALACHIAN ACIDIC SWAMP (CES202.604)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: 30-180-day hydroperiod; Forest and Woodland (Treed); Extensive Wet Flat; Needle-Leaved Tree
Non-Diagnostic Classifiers: Acidic Water; Shallow (<15 cm) Water; Moderate (100-500 yrs) Persistence; Lowland; Temperate; Mineral: W/ A-Horizon >10 cm; Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 9307

CONCEPT

Summary: These swamps are distributed from central New England through the Central Appalachians south to Virginia and west to Ohio. They are found at low to mid elevations (generally <700 m) in basins or on gently sloping seepage lowlands. The acidic substrate is mineral soil, often with a component of organic muck; if peat is present, it usually forms an organic epipedon over the mineral soil rather than a true peat substrate (although peat layers up to 1 m deep have been found in some of these swamps). *Tsuga canadensis* is usually present and may be dominant. It is often mixed with deciduous wetland trees such as *Acer rubrum* or *Nyssa sylvatica*. *Sphagnum* is an important component of the bryoid layer. Basin swamps tend to be more nutrient-poor and less species-rich than seepage swamps; in some settings, the two occur adjacent to each other with the basin swamp vegetation surrounded by seepage swamp vegetation on its upland periphery.
Classification Comments: This system excludes swamps with *Chamaecyparis thyoides*, a tree more characteristic of the Coastal Plain but which sometimes occurs inland. See Northern Atlantic Coastal Plain Basin Peat Swamp (CES203.522). Some examples of this system may appear similar to Southern and Central Appalachian Bog and Fen (CES202.300) or North-Central Interior and Appalachian Acidic Peatland (CES202.606); those systems are distinguished by their deeper peat substrate and overall partly forested character compared to the shallower organic soil and generally forested nature of the present system. Wetlands on the Allegheny Plateau, at higher elevations, are a distinct system, High Allegheny Wetland (CES202.069). There are many species with this type, but it is distinguished by occurring as a mosaic of open wetlands and smaller forest patches with a distinctive hydrology.
Similar Ecological Systems:
- High Allegheny Wetland (CES202.069)
- Northern Appalachian-Acadian Conifer-Hardwood Acidic Swamp (CES201.574)
- Northern Atlantic Coastal Plain Basin Peat Swamp (CES203.522)
- Piedmont Seepage Wetland (CES202.298)
- Piedmont Upland Depression Swamp (CES202.336)

Related Concepts:
- Eastern Hemlock: 23 (Eyre 1980) Finer
- Hemlock - Yellow Birch: 24 (Eyre 1980) Finer
- Mountain / Piedmont Acidic Seepage Swamps (Fleming et al. 2005) Broader. can be attributed to one of two systems depending on their location. Occurrences in the central Appalachians are attributed to this system (CES202.604) while occurrences in the Piedmont are attributed to Piedmont Seepage Wetland (CES202.298).
- Red Maple: 108 (Eyre 1980) Finer

Component Associations:

NORTH-CENTRAL INTERIOR AND APPALACHIAN ACIDIC PEATLAND (CES202.606)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Acidic Water; >180-day hydroperiod; Shrubland (Shrub-dominated); Organic Peat (>40 cm)
Non-Diagnostic Classifiers: Oligotrophic Water; Long (>500 yrs) Persistence; Lowland; Temperate; Depressional; Isolated Wetland [Partially Isolated]; Unconsolidated
National Mapping Codes: ESLF 9193

CONCEPT

Summary: These *Sphagnum* and shrub peatlands occur in basins south of the Laurentian-Acadian region down to near the glacial boundary in the northeastern and north-central U.S. Unlike the true raised bogs of boreal regions, the vegetation is not raised above the groundwater level. They are found in colder regions, mostly in areas where glacial stagnation left coarse deposits and glacial depressions (many are "kettleholes"). The basins are generally closed, i.e., without inlets or outlets of surface water, and typically small in area. The nutrient-poor substrate and the reduced throughflow of water create oligotrophic conditions fostering the development of *Sphagnum* peat and the growth of peatland vegetation. In deeper basins, the vascular vegetation grows on a *Sphagnum* mat over water, with no mineral soil development. Ericaceous shrubs and dwarf-shrubs (e.g., *Chamaedaphne calyculata*) dominate, with patches of graminoid dominance. Some peatlands may have a sparse tree layer. Although these are often called bogs, in most cases they are technically fens (albeit nutrient-poor ones), as the vegetation remains in contact with the surface water.
Classification Comments: This system occurs south of the Laurentian-Acadian division in the Midwest, south of the Northern Appalachian-Boreal ecoregion in the Northeast, and inland from the Coastal Plain, and these acidic peatlands are distinctive and discrete elements of the landscape. They are related to Northern Appalachian-Acadian Conifer-Hardwood Acidic Swamp (CES201.574) and Boreal-Laurentian-Acadian Acidic Basin Fen (CES201.583), but occur in a different landscape setting and often have some more temperate floristic elements to distinguish them. They include treed, shrub, and graminoid associations, often occurring in a mosaic. In the Midwest, it may be necessary to split off the shrub/graminoid acid peatland (poor fen) types.
Similar Ecological Systems:
- Atlantic Coastal Plain Northern Bog (CES203.893)
- Boreal-Laurentian Bog (CES103.581)--raised bogs of Canada and parts of the extreme northeastern and northern midwestern U.S.
- Boreal-Laurentian Conifer Acidic Swamp and Treed Poor Fen (CES103.724)
- Boreal-Laurentian-Acadian Acidic Basin Fen (CES201.583)--similar fens but more northerly in distribution, centered in Division 201 rather than 202.
- Northern Appalachian-Acadian Conifer-Hardwood Acidic Swamp (CES201.574)--more-or-less uniform tree cover.

DESCRIPTION

Environment: These peatlands occur in kettle depressions on pitted outwash and moraines and in flat areas and shallow depressions on glacial outwash and glacial lakeplain. Groundwater and surface water feed these temperate peatlands. It is not strongly calcareous and may be acidic in some places but not as much as boreal sites. These peatlands occurred in landscapes dominated by either forest or grassland/savanna. The fire regime is not well known but periodic surface fires likely helped limit the cover by trees. The basins in which these occur tend to be small and, where open water is still present, these peatlands form where wave energy is low (Swinehart 1997). These peatlands are characterized by organic soils composed of saturated peat that contains partially decomposed sphagnum mosses and frequently fragments of sedges and wood. The peat soils are acidic, cool, and characterized by low nutrient availability and oxygen levels. The water-retaining capacity of sphagnum peat is tremendous and as a result these are saturated, anoxic systems with water tables near the surface (Kost et al. 2007).
Dynamics: The cool, nutrient-poor water which feeds into this system favors peat development. This water can come from surface runoff or groundwater. Basins in which these peatlands occur are small, which limits the amount of nutrients that can be brought in by surface water. Groundwater sources flow through nutrient-poor, neutral to somewhat acidic substrates. Once peat begins to develop, it tends to create conditions favorable for continued peat development by contributing to the acidic, anoxic character of the water.

Component Associations:
- *Acer rubrum / Alnus incana - Ilex verticillata / Osmunda regalis* Woodland (CEGL006395, GNR)

NORTH-CENTRAL INTERIOR AND APPALACHIAN RICH SWAMP (CES202.605)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Mesotrophic Water; Saturated Soil; Temperate; Depressional; Broad-Leaved Deciduous Tree
Non-Diagnostic Classifiers: Intermittent Flooding; Moderate (100-500 yrs) Persistence; Lowland; Forest and Woodland (Treed); Extensive Wet Flat; Mineral: W/ A-Horizon >10 cm
National Mapping Codes: ESLF 9306

CONCEPT

Summary: These forested wetlands are scattered throughout the north-central Midwest (south of the Laurentian region), the north-central Appalachians and southern New England at low to mid elevations. They are found in basins where higher pH and/or nutrient levels are associated with a rich flora. Species include *Acer rubrum, Fraxinus nigra*, as well as calciphilic herbs. Conifers include *Larix laricina*, but typically not *Thuja occidentalis*, which is characteristic of more northern wetland systems. There may be shrubby or herbaceous openings within the primarily wooded cover. The substrate is primarily mineral soil, but there may be some peat development.
Classification Comments: This system occurs south of the Laurentian-Acadian region, and these circumneutral or enriched swamps are often rather distinctive and discrete elements of the landscape. They are related to Laurentian-Acadian Alkaline Conifer-Hardwood Swamp (CES201.575) but have more temperate elements and generally lack *Thuja occidentalis*. More alkaline shrub/herb fens are treated as part of North-Central Interior Shrub-Graminoid Alkaline Fen (CES202.702).
Similar Ecological Systems:
- Laurentian-Acadian Alkaline Conifer-Hardwood Swamp (CES201.575)
- North-Central Interior Shrub-Graminoid Alkaline Fen (CES202.702)
- Piedmont Seepage Wetland (CES202.298)--ranges north into Virginia.

Related Concepts:
- Black Ash - American Elm - Red Maple: 39 (Eyre 1980) Finer
- Mountain / Piedmont Basic Seepage Swamp (Fleming et al. 2005) Intersecting. in Virginia.
- Tamarack: 38 (Eyre 1980) Finer

DESCRIPTION

Environment: Water can come from nutrient-rich groundwater or surface runoff. Sites are basins or low areas in floodplains, usually near the edge of the floodplain in a localized basin or at the base of a bluff where groundwater emerges. Soils are muck or fine-textured mineral. Small hummocks and depressions, created from tree tip-ups, sluggish streams, or tree root build up, create drier and wetter microsites within the system. Sites are usually flooded in the spring, and low areas may remain wet for all or most of the growing season, but if stands remain under water for multiple years, the trees die (Kost et al. 2007). The microsite differences allow a mixture of wet-mesic upland species and wetland species to exist in the herbaceous layer of this system (WNHI 2012).
Dynamics: The hydrologic regime is critical to maintenance of this system. Sites must be wet or flooded for part of the growing season but not completely saturated or under water for too long over a large portion of the site. Periodic sustained floods or droughts can kill canopy trees and allow the mostly shade-intolerant canopy trees (*Fraxinus nigra, Fraxinus pennsylvanica, Larix laricina*) to regenerate. Trees are shallowly rooted in this system so wind can blow canopy trees over relatively easily. This creates gaps in the canopy and allows smaller trees enough light to reach the canopy. Windthrow contributes to hummock-and-hollow microtopography, which generates small-scale gradients in soil moisture and chemistry, contributing to floristic diversity.

Component Associations:
- *Acer (rubrum, saccharinum) - Fraxinus* spp. - *Ulmus americana* Forest (CEGL005038, G4?)
- *Acer rubrum - Fraxinus americana - Fraxinus nigra - Betula alleghaniensis / Veratrum viride - Carex bromoides* Forest (CEGL008416, G3)
- *Acer rubrum - Fraxinus nigra - (Larix laricina) / Rhamnus alnifolia* Forest (CEGL006009, GNR)
- *Acer rubrum - Fraxinus nigra - (Tsuga canadensis) / Tiarella cordifolia* Forest (CEGL006502, GNR)
- *Fraxinus nigra - Acer rubrum / Rhamnus alnifolia / Carex leptalea* Saturated Forest (CEGL007441, GNR)
- *Larix laricina - Acer rubrum / (Rhamnus alnifolia, Vaccinium corymbosum)* Forest (CEGL005232, G2G3)

DISTRIBUTION

Range: This system is found from central New England to the southern Great Lakes and south-central Minnesota south to northern Illinois, Indiana, Ohio, and Pennsylvania. It is not known to extend south into the Southern Blue Ridge.
Divisions: 202:C
Nations: CA, US
Subnations: CT, DE?, IL, IN, MA, MD, MI, MN, NJ, NY, OH, ON, PA, RI, VT, WI

NORTH-CENTRAL INTERIOR SHRUB-GRAMINOID ALKALINE FEN (CES202.702)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Alkaline Water; Saturated Soil; Fen; Shrubland (Shrub-dominated); Woody-Herbaceous; Herbaceous; Seepage-Fed Sloping; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9184

CONCEPT

Summary: This fen system is found in the glaciated portions of the Midwest and southern Canada. Examples of this system can be located on level to sloping seepage areas, in pitted outwash or in kettle lakes associated with kettle-kame-moraine topography. Groundwater flows through marls and shallow peat soils, and groundwater is typically minerotrophic and slightly alkaline. Examples of this system contain a core fen area of graminoids surrounded by shrubs. Herbaceous and shrub cover is variable with little to no tree cover. Characteristic species include prairie grasses such as *Andropogon gerardii* and *Spartina pectinata* with prairie forbs and sedges (*Carex* spp.). Common shrub species include *Dasiphora fruticosa ssp. floribunda*, *Cornus* spp., *Salix* spp., and *Toxicodendron vernix*. Alterations in wetland hydrology and agricultural development can threaten examples of this system.

Similar Ecological Systems:
- Laurentian-Acadian Alkaline Fen (CES201.585)
- North-Central Interior and Appalachian Rich Swamp (CES202.605)
- Western Canadian Boreal Shrub-Sedge Rich and Alkaline Fen (CES103.872)

DESCRIPTION

Environment: Examples of this system can be located on level to sloping seepage areas, in pitted outwash or in kettle lakes associated with kettle-kame-moraine topography. Prairie fens can occur along the margins of small lakes or on slopes or level areas among upland vegetation. This system can form where mineral-rich groundwater emerges as springs or seeps. Soils are saturated peat or marl, and these fens typically show strong zonal patterns in soil chemistry, physiognomy, and floristic composition, between areas with peat versus marly areas where groundwater springs run (Van der Valk 1976, Moran 1981b, Bowles et al. 2005).
Vegetation: Examples of this system contain a core fen area of graminoids surrounded by shrubs with a fairly continuous sphagnum moss layer. Herbaceous and shrub cover is variable with little to no tree cover. Characteristic species include prairie grasses such as *Andropogon gerardii* and *Spartina pectinata* with prairie forbs and sedges (*Carex* spp.). Common shrub species include *Dasiphora fruticosa ssp. floribunda*, *Cornus* spp., and *Salix* spp.
Dynamics: The presence of cold, mineral-rich groundwater which promotes the formation of peat and marl is key to the formation and maintenance of this system. Where cold, mineral-rich groundwater emerges as seeps and diffuse springs, decomposition of plant matter is slowed and peat can accumulate. Marl forms under sustained flow of calcium- and magnesium-rich water. The marl occurs where the groundwater emerges and in "spring runs" where water has cut a channel through the peat. Peat accumulation tends to be thickest in the center of the fens and can form raised mounds over time (Stuckey and Denny 1981). Periodic fire is an important factor in limiting the growth of trees and shrubs.

Component Associations:
- *Betula pumila - Salix candida / Carex lasiocarpa - Symphyotrichum boreale* Prairie Fen Shrubland (CEGL002189, G3)
- *Carex lasiocarpa - Calamagrostis* spp. - (*Eleocharis rostellata*) Herbaceous Vegetation (CEGL002383, G3G4)
- *Carex lasiocarpa - Carex oligosperma / Sphagnum* spp. Herbaceous Vegetation (CEGL002265, G3G4)
- *Cladium mariscoides - (Carex lasiocarpa, Hypericum kalmianum, Oligoneuron riddellii, Eleocharis elliptica)* Herbaceous Vegetation (CEGL005104, G2?)
- *Cornus amomum - Salix* spp. - *Toxicodendron vernix - Rhamnus lanceolata* Fen Shrubland (CEGL005087, G2G3)
- *Cornus racemosa / Carex (sterilis, aquatilis, lacustris)* Shrub Herbaceous Vegetation (CEGL006123, G2G3)
- *Cornus* spp. - *Salix* spp. - *Vaccinium corymbosum - Rhamnus alnifolia - Toxicodendron vernix* Shrubland (CEGL005083, G4?)
- *Dasiphora fruticosa ssp. floribunda / Carex interior - Carex flava - Sarracenia purpurea* Shrub Herbaceous Vegetation (CEGL005140, G3)
- *Dasiphora fruticosa ssp. floribunda / Carex sterilis - Andropogon gerardii - Arnoglossum plantagineum* Shrub Herbaceous Vegetation (CEGL005139, G3G4)
- *Symplocarpus foetidus* - Mixed Forbs Wet Meadow (CEGL002385, G4?)
- *Vaccinium corymbosum - Gaylussacia baccata - Photinia melanocarpa / Calla palustris* Shrubland (CEGL005085, G2G3)

DISTRIBUTION

Range: This system is found in the glaciated, prairie landscape of the northern Midwest and southern Canada from the eastern Dakotas and northwestern Iowa through southern Wisconsin and Michigan, northern Illinois and Indiana, to western and northeastern Ohio and western Pennsylvania.

NORTH-CENTRAL INTERIOR WET FLATWOODS (CES202.700)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Saturated Soil; Flat; Forest and Woodland (Treed); Extensive Wet Flat; Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2518; ESLF 9186; ESP 1518

CONCEPT

Summary: This small-patch system is found throughout the northern glaciated Midwest ranging east into Lower New England and the Champlain Valley. It usually occurs on somewhat poorly drained uplands or in depressions associated with glacial features such as tillplains, lakeplains or outwash plains. Soils often have an impermeable or nearly impermeable clay layer that can create a shallow, perched water table. Saturation can vary, with ponding common during wetter seasons, and drought possible during the summer and autumn months. Microtopography and fluctuating moisture levels can lead to complexes of forest upland and wetland species occurring within this system. *Quercus palustris* and/ or *Quercus bicolor* typically dominate the wetter portions and are often associated with *Acer rubrum*. *Quercus alba*, *Quercus rubra*, and *Fagus grandifolia* are common in the better-drained areas. *Carya ovata* is a characteristic tree in the Champlain Valley. *Liquidambar styraciflua, Nyssa sylvatica, Acer saccharinum, Fraxinus americana*, and *Fraxinus pennsylvanica* are also common associates, though their occurrence varies somewhat by region. Understory herbaceous and shrub species present in examples of this system can vary. Stands with more dense tree cover have less shrub and herbaceous cover, while those with moderate tree canopy cover tend to have a dense understory. Some common species in the wetter portions include *Carex* spp., *Osmunda cinnamomea, Cephalanthus occidentalis, Alnus* spp., and *Ilex* spp. Flooding, windthrow, drought, and fire can influence this system.
Classification Comments: These are mostly north of the glacial line, but one association is in the Interior Low Plateau and that placement may need to be reviewed. Some examples in Michigan, Indiana, Ohio, Vermont, and southern Ontario are dominated by *Fagus grandifolia*, oak (primarily *Quercus alba* and *Quercus rubra*) and maple species (*Acer* spp.). Vermont's Valley Clayplain Forest is placed here tenuously as it has more of an upland component and occurs at a local matrix scale, not as a small-patch element.
Related Concepts:
- Pin Oak - Sweetgum: 65 (Eyre 1980) Finer

DESCRIPTION

Environment: This system usually occurs on poorly drained uplands or in depressions associated with glacial features such as tillplains, lakeplains, or outwash plains. Soils often have an impermeable or nearly impermeable clay layer that impedes waterflow. This favors flooding or ponding in the spring or after heavy rains. It also restricts subsurface water movement into the system and slows the growth of roots through it. Both of these factors lead to water deficits for the vegetation in the late summer and fall. These fluctuating moisture levels can lead to complexes of forest upland and wetland species occurring within this system. Overall topographic relief is very flat in this system though small tip-up mounds and depressions can occur from windthrow and often create small pockets with vegetation more typical of upland or swamp forest, respectively.
Vegetation: *Quercus palustris* and/or *Quercus bicolor* typically dominate the wetter portions and are often associated with *Acer rubrum*. *Quercus alba, Quercus rubra, Fagus grandifolia*, and *Acer saccharum* are common in the better-drained areas, seen in some examples around the southern Great Lakes and Lake Champlain. *Carya ovata* is a characteristic tree in the Champlain Valley. *Liquidambar styraciflua, Nyssa sylvatica, Fraxinus americana*, and *Fraxinus pennsylvanica* are also common associates, though their occurrence varies somewhat by region. Understory herbaceous and shrub species present in examples of this system can vary. Stands with more dense tree cover have less shrub and herbaceous cover, while those with moderate tree canopy cover tend to have a dense understory. Some common species include *Carex* spp., *Osmunda cinnamomea, Cephalanthus occidentalis, Alnus* spp., and *Ilex* spp. In the clayplain forests of Vermont, characteristic herbs include *Waldsteinia fragarioides* and *Moehringia lateriflora (= Arenaria lateriflora)*.
Dynamics: The large seasonal change in local available moisture is key to the development and maintenance of this system. Plants must be able to tolerate the excessive available moisture (surface flooding or saturation) and drought conditions that occur in most growing seasons. Fire can occur after the system dries, typically late in the growing season. Fires rarely start in this system but under favorable conditions can spread from nearby fire-prone systems (typically prairies, oak savannas, or oak woodlands). Under proper hydrologic conditions, this system can be self-maintaining (Tecic and McCain 2001). With the often shallowly-rooted trees, strong winds can create canopy openings. Small-scale windthrow is a characteristic disturbance in flatwoods that influences composition and structure by creating canopy gaps that are suitable for the colonization and growth of light-dependent tree seedlings and saplings, shrubs, and herbs. Windthrow also tips and uproots trees, creating pit-and-mound topography that provides suitable microhabitats for a diversity of plant species (Slaughter et al. 2010).

Component Associations:

NORTH-CENTRAL INTERIOR WET MEADOW-SHRUB SWAMP (CES202.701)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Depressional [Lakeshore]; Broad-Leaved Shrub; Graminoid
Non-Diagnostic Classifiers: Circumneutral Water; Acidic Water; Shallow (<15 cm) Water; Moderate (100-500 yrs) Persistence; Herbaceous; Depressional [Pond]; Isolated Wetland [Partially Isolated]; Muck
National Mapping Codes: ESLF 9185

CONCEPT

Summary: This system is found throughout the northern Midwest ranging into southern Canada. It is typically found on glacial potholes, river valleys, ponds, channels in glacial outwash, and on lakeplains. This system contains a deep to shallow area of freshwater marsh dominated by emergent species surrounded by a zone of wet meadow. The emergent marsh zone within this system contains hydric soils flooded by water ranging from several centimeters to over 1 meter for most of the growing season. Emergent marsh species such as *Typha* spp. and *Schoenoplectus* spp. dominate the core of this system. Wet meadows can surround the emergent marsh core along wet mineral soils or shallow peat with the water table typically just below the surface for most of the growing season. The vegetation in this zone of the system is dominated by sedges (*Carex* spp.) and grasses such as *Calamagrostis canadensis*. This system also can contain a zone of wet prairie species such as *Spartina pectinata*. Shrub swamps can also be associated with the wet meadows within this system. Typical shrub species include *Cornus* spp., *Salix* spp., and/or *Cephalanthus occidentalis*. Trees are generally absent and, if present, are scattered. Fire originating in adjacent uplands, as well as hydrology, can influence this system. In the absence of fire, drought and/or ditching can increase the proportion of shrubs compared to the wet meadow or prairie species.
Classification Comments: If examples of these associations are found within a medium to large floodplain, they should be considered part of North-Central Interior Floodplain (CES202.694). The freshwater marsh component was removed from this system to create a new system, North-Central Interior Freshwater Marsh (CES202.899).
Similar Ecological Systems:
- Cumberland Wet-Mesic Meadow and Savanna (CES202.053)
- Laurentian-Acadian Shrub-Herbaceous Wetland Systems (CES201.642)
- Laurentian-Acadian Wet Meadow-Shrub Swamp (CES201.582)

DESCRIPTION

NORTHERN APPALACHIAN-ACADIAN CONIFER-HARDWOOD ACIDIC SWAMP (CES201.574)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Acidic Water; Extensive Wet Flat; Picea (rubens, mariana) - Acer rubrum
Non-Diagnostic Classifiers: Mesotrophic Water; Oligotrophic Water; Saturated Soil; Intermittent Flooding [Intermittent interval, Irregular Flooding]; Intermittent Flooding [Intermittent interval, Spring Flooding]; Moderate (100-500 yrs) Persistence; Forest and Woodland (Treed); Isolated Wetland [Partially Isolated]; Mineral: W/ A-Horizon <10 cm; Needle-Leaved Tree; Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 9346

CONCEPT

Summary: These forested wetlands are found in temperate northeastern and north-central U.S., primarily in glaciated regions in the eastern Laurentian-Acadian region. They occur on mineral soils that are nutrient-poor; there may be an organic epipedon, but the substrate is generally not deep peat. These basin wetlands remain saturated for all or nearly all of the growing season, and may have standing water seasonally. There may be some seepage influence, especially near the periphery. *Acer rubrum*, *Fraxinus* spp., *Picea rubens* (rarely *Picea mariana*), and *Abies balsamea* are the most typical trees. The herbaceous and shrub layers tend to be fairly species-poor. *Nemopanthus mucronatus* and *Osmunda* spp. are typical shrub and herb species.
Classification Comments: Acadian Sub-boreal Spruce Flat (CES201.562) is related but is more northern and occurs on imperfectly drained but not persistently saturated soils. *Picea rubens* in the East versus *Picea mariana* in the West and North may be helpful in distinguishing between this type and the more boreal acidic swamp, Boreal-Laurentian Conifer Acidic Swamp and Treed Poor Fen (CES103.724). This type is distributed in the Acadian and Northern Appalachian region of the U.S. and Canada, whereas Boreal-Laurentian Conifer Acidic Swamp and Treed Poor Fen (CES103.724) is found in the Upper Great Lakes region and into Canada. The attribution of CEGL006380 to this system is questionable given that it is a seepage wetland, not a basin swamp association, but is included because portions of these wetlands may have seepage influence.
Similar Ecological Systems:
- Acadian Sub-boreal Spruce Flat (CES201.562)
- Boreal-Laurentian Conifer Acidic Swamp and Treed Poor Fen (CES103.724)--is similar but occurs in the upper Great Lakes region and adjacent Canada.
- Laurentian-Acadian Alkaline Conifer-Hardwood Swamp (CES201.575)
- North-Central Appalachian Acidic Swamp (CES202.604)
- North-Central Interior and Appalachian Acidic Peatland (CES202.606)

NORTHERN ATLANTIC COASTAL PLAIN BASIN PEAT SWAMP (CES203.522)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Depressional [Peaty]; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9343

CONCEPT

Summary: This system is comprised of acidic peat swamps formed in basins of various sizes, predominantly Atlantic white-cedar swamps, occurring on the northern portion of the Atlantic Coastal Plain from Massachusetts south to Virginia. The hydrology is saturated, as evidenced by *Sphagnum*-dominated hummock-and-hollow microtopography. *Chamaecyparis thyoides* is characteristic and often dominant. *Acer rubrum* may also be an important species, especially after logging.
Classification Comments: Atlantic white-cedar swamps do occur inland of the coastal plain and are considered inland disjuncts of this type. Where *Chamaecyparis* is present but not dominant inland, and other coastal plain indicators are absent, North-Central Appalachian Acidic Swamp (CES202.604) is the more appropriate system.
Similar Ecological Systems:
- North-Central Appalachian Acidic Swamp (CES202.604)
- Southern Atlantic Coastal Plain Nonriverine Swamp and Wet Hardwood Forest (CES203.304)--has a *Chamaecyparis thyoides* component which is similar to this system in certain respects.

- Atlantic White Cedar Swamp (Gawler and Cutko 2010) Finer
- Atlantic White-Cedar: 97 (Eyre 1980) Finer
- Red Maple: 108 (Eyre 1980) Finer

DESCRIPTION

Environment: Topographic depression.
Dynamics: Seasonal to saturated hydrology.

Component Associations:
- *Acer rubrum - Nyssa sylvatica - Magnolia virginiana / Viburnum nudum var. nudum / Osmunda cinnamomea - Woodwardia areolata* Forest (CEGL006238, G3?)
- *Acer rubrum / Rhododendron maximum* Forest (CEGL006396, GNR)
- *Acer rubrum / Rhododendron viscosum - Clethra alnifolia* Forest (CEGL006156, GNR)
- *Chamaecyparis thyoides - (Tsuga canadensis, Betula alleghaniensis) / Clethra alnifolia* Forest (CEGL006189, G3)
- *Chamaecyparis thyoides - Acer rubrum - Magnolia virginiana* Forest (CEGL006078, GNR)
- *Chamaecyparis thyoides - Acer rubrum / Lycopus* spp. Forest (CEGL006364, GNR)
- *Chamaecyparis thyoides - Picea rubens / Gaylussacia baccata / Gaultheria hispidula* Forest (CEGL006363, G3?)
- *Chamaecyparis thyoides / Ilex glabra - Rhododendron viscosum* Forest (CEGL006188, G3)
- *Chamaecyparis thyoides / Rhododendron maximum* Forest (CEGL006355, G2G3)
- *Vaccinium corymbosum - Rhododendron viscosum - Clethra alnifolia* Shrubland (CEGL006371, G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Northern Atlantic Coastal Plain Pitch Pine Barrens (CES203.269)

DISTRIBUTION

Range: This system occurs on the northern portion of the Atlantic Coastal Plain from Massachusetts south to Virginia, with sporadic occurrences north to mid-coast Maine, and occasional disjunct occurrences inland; it is historic in eastern Pennsylvania.
Divisions: 201:C; 202:C; 203:C
Nations: US
Subnations: CT, DE, MA, MD, ME, NH, NJ, NY, VA
Map Zones: 60:C, 65:C, 66:C
USFS Ecomap Regions: 211Da:CCC, 221Ah:CCC, 221Ai:CCC, 221Ak:CCC, 221Al:CCC, M211Bc:CCC
TNC Ecoregions: 58:C, 60:P, 61:C, 62:C, 63:C

NORTHERN ATLANTIC COASTAL PLAIN BASIN SWAMP AND WET HARDWOOD FOREST (CES203.520)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); North Atlantic Coastal Plain; Seepage-Fed Sloping
Non-Diagnostic Classifiers: Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9342

CONCEPT

Summary: This system is comprised of nonriverine hardwood swamps of seasonally flooded habitats, including relatively shallow groundwater-influenced depressions and Coastal Plain terraces. It ranges from the southern glaciated Atlantic Plain of Long Island, New York, south along the northern Coastal Plain to Virginia. Although supporting some seepage indicators, it is also affected by overland flow. The substrate is mineral soil overlain by a variable organic but non-peaty layer. Characteristic tree species include *Acer rubrum*, *Liquidambar styraciflua*, *Nyssa sylvatica*, *Quercus michauxii*, *Quercus pagoda*, *Quercus palustris*, and *Quercus phellos*. *Pinus taeda* is not uncommon south of Delaware Bay.
Classification Comments: Vegetation along streams is accommodated in a new system, Northern Atlantic Coastal Plain Stream and River (CES203.070).
Similar Ecological Systems:
- Southern Coastal Plain Nonriverine Basin Swamp (CES203.384)

Related Concepts:
- Pin Oak - Sweetgum: 65 (Eyre 1980) Finer
- Pond Pine: 98 (Eyre 1980) Finer
- Red Maple: 108 (Eyre 1980) Finer
- Swamp Chestnut Oak - Cherrybark Oak: 91 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in low-lying areas, such as stream headwaters or depressions, or along water courses.
Vegetation: Characteristic tree species include *Acer rubrum*, *Liquidambar styraciflua*, *Nyssa sylvatica*, *Quercus phellos*, and *Fraxinus pennsylvanica*. *Pinus taeda* is not uncommon south of Delaware Bay.
Dynamics: This system occurs on extensive, flat terraces and very wide, ancient floodplains that are no longer subject to alluvial processes. Its hydrology is seasonally to nearly permanently saturated, with occasional ponding or groundwater sheetflows, and is maintained by a high water table rather than riverine or estuarine flooding.

Component Associations:
- *Acer rubrum - Fraxinus pennsylvanica / Saururus cernuus* Forest (CEGL006606, G3G4)
- *Acer rubrum - Nyssa sylvatica - Liquidambar styraciflua - Populus heterophylla* Forest (CEGL006013, G1)
- *Liquidambar styraciflua - Acer rubrum - Nyssa biflora / Carex joorii* Forest (CEGL006223, G1G2)
- *Liquidambar styraciflua - Acer rubrum - Quercus phellos / Leucothoe racemosa* Forest (CEGL006110, G3)
- *Quercus (phellos, pagoda, michauxii) / Ilex opaca var. opaca / Clethra alnifolia / Woodwardia areolata* Forest (CEGL004644, G2?)
- *Quercus falcata - Quercus phellos / Ilex opaca* Forest (CEGL006390, GNR)
- *Quercus palustris - (Quercus bicolor) - Acer rubrum / Vaccinium corymbosum / Osmunda cinnamomea* Forest (CEGL006240, GNR)

DISTRIBUTION

Range: It ranges from Long Island, New York, south to Virginia.
Divisions: 203:C
Nations: US
Subnations: DE, MD, NJ, NY, PA, VA
Map Zones: 60:C, 65:C
TNC Ecoregions: 58:C, 62:C

NORTHERN ATLANTIC COASTAL PLAIN PITCH PINE LOWLAND (CES203.374)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Woody-Herbaceous; Extensive Wet Flat
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2456; ESLF 9125; ESP 1456

CONCEPT

Summary: This system is comprised of wetland Pine Barrens vegetation and Coastal Plain peatlands from the New Jersey Pine Barrens south into the Delmarva Peninsula and upper Chesapeake Bay. Although this system can be extensive, components often co-occur as a mosaic with upland pine barrens vegetation as well. The vegetation is characterized by associations having variable hydroperiods, occurring on a range of substrates from saturated deep peats to seasonally saturated mineral soils. Physiognomy of the component associations is similarly widely variable, ranging from wet grasslands dominated by *Calamovilfa brevipilis*, to boggy shrublands characterized by *Gaylussacia dumosa, Chamaedaphne calyculata, Leucothoe racemosa*, and others, to seasonally saturated pine forests characterized by mesic species such as *Clethra alnifolia*. Fire frequency, as well as hydrology, has a profound influence on the vegetation. Where fire frequency is high, woody vegetation is impeded, favoring the development of large wet grasslands.
Classification Comments: Ponded wetlands with standing water (which may drop over the course of the season) and mineral soils are treated as Northern Atlantic Coastal Plain Pond (CES203.518).
Similar Ecological Systems:
- Atlantic Coastal Plain Northern Bog (CES203.893)--occurs to the north.
- Northern Atlantic Coastal Plain Pond (CES203.518)--pitch pine wetlands set in low areas of the pine barrens and similar areas.

Related Concepts:
- Pitch Pine: 45 (Eyre 1980) Undetermined

DESCRIPTION

Environment: This system occurs within the larger matrix of pitch pine - scrub oak barrens of the New Jersey Pinelands. Hydrology is primarily groundwater-controlled; vegetation composition is a reflection of depth to water table.
Dynamics: This system and the composition and structure of its mosaic of patch types are influenced by depth to water table (Ehrenfeld 1986). Pitch pines are also structured by fires, but fire regime differs from uplands in that in the wet environment, fire frequency is lower, but the high shrub density often leads to crown fires. In high-intensity fires, pitch pines are killed, and even the organic layer may be consumed during periods of drought. Successional pathways following fire depend on depth of remaining organic layer and proximity of seed source (Little 1979c).

Component Associations:
- *Acer rubrum - Nyssa sylvatica - Magnolia virginiana / Viburnum nudum var. nudum / Osmunda cinnamomea - Woodwardia areolata* Forest (CEGL006238, G3?)
- *Chamaedaphne calyculata / Carex striata* Dwarf-shrubland (CEGL006208, GNR)
- *Gaylussacia dumosa / Calamovilfa brevipilis* Shrub Herbaceous Vegetation (CEGL006397, G1)
- *Nyssa sylvatica - Magnolia virginiana - (Pinus rigida) / Rhododendron viscosum - Toxicodendron vernix / Smilax pseudochina* Woodland (CEGL006219, G1)
- *Panicum virgatum* Seasonally Flooded Herbaceous Vegetation (CEGL004128, GNR)
- *Pinus rigida - Nyssa sylvatica / Clethra alnifolia - Leucothoe racemosa* Forest (CEGL006926, G2G3)
- *Pinus rigida / Chamaedaphne calyculata / Sphagnum* spp. Woodland (CEGL006194, G3G5)
- *Pinus rigida / Gaylussacia baccata - Kalmia angustifolia* Woodland (CEGL006387, GNR)
- *Pinus rigida / Gaylussacia dumosa / Calamovilfa brevipilis* Woodland (CEGL006388, G1)
- *Pinus rigida / Vaccinium corymbosum - Leucothoe racemosa / Sphagnum* spp. Woodland (CEGL006195, G3)
- *Vaccinium corymbosum / Sphagnum* spp. Shrubland (CEGL006190, G4)

DISTRIBUTION

Range: This system is best developed in the New Jersey Pine Barrens, but occurrences are present south to the inner Coastal Plain of Maryland.
Divisions: 203:C
Nations: US
Subnations: DE?, MD, NJ
Map Zones: 60:C
USFS Ecomap Regions: 232A:CC, 232H:CC
TNC Ecoregions: 58:C, 62:C

NORTHERN ATLANTIC COASTAL PLAIN TIDAL SWAMP (CES203.282)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Tidal / Estuarine
National Mapping Codes: ESLF 9303

CONCEPT

Summary: This system encompasses freshwater to oligohaline tidally-flooded deciduous forests and shrublands in lower river floodplains and edges of estuaries of the North Atlantic Coastal Plain. This system is restricted to narrow zones along upper tidal reaches of Inner Coastal Plain rivers and tributaries which have sufficient volumes of freshwater and short flooding to support tree canopies. These areas are influenced by lunar tides up to 1 m (3 feet), but diluting freshwater flows from upstream, keeping salinity levels below 0.5 ppt. Deciduous hardwood species predominate, especially *Nyssa biflora* and/or *Fraxinus profunda* or *Fraxinus pennsylvanica*. In Maryland and Virginia, *Taxodium distichum* may be locally dominant.
Classification Comments: The range of this system is generally conceived as Chesapeake Bay and northward (e.g., in the Coastal Plain from the James River, Virginia, northward to New Jersey). Examples of tidal swamp forests south of this region are treated under Southern Atlantic Coastal Plain Tidal Wooded Swamp (CES203.240); the boundaries may overlap somewhere in Virginia.
Similar Ecological Systems:
- Southern Atlantic Coastal Plain Tidal Wooded Swamp (CES203.240)

Related Concepts:
- Baldcypress: 101 (Eyre 1980) Finer

DESCRIPTION

Environment: This association occurs along fresh reaches of tidal rivers, usually receiving diurnal or irregular tidal flooding. There is distinct hummock-and-hollow microtopography with hollows flooded during higher tides. Soil is generally organic-rich and contains a frequently deep organic horizon over silty alluvial deposits. Pronounced hummock-and-hollow microtopography is characteristic. Hollows are inundated by diurnal tides; hummocks may be only irregularly flooded, and the tops of hummocks are only rarely (< annually) submerged (Rheinhardt and Hershner 1992).
Dynamics: Development and persistence of this association appears to be limited downstream by halinity and upstream by the availability of sufficient sediment. Hence, tidal hardwood swamps are associated primarily with the upper (higher halinity) end of the freshwater portion of the halinity gradient and typically occur on higher landscape positions adjacent to tidal freshwater marshes (Rheinhardt and Hershner 1992). These swamps are maintained by regular biomass input deposited by regular tidal flow.

Component Associations:
- *Acer rubrum - Fraxinus pennsylvanica / Polygonum* spp. Forest (CEGL006165, G2)
- *Alnus (incana ssp. rugosa, serrulata) - Cornus amomum* Shrubland (CEGL006337, GNR)
- *Fraxinus profunda - Nyssa biflora - (Fraxinus pennsylvanica) / Ilex verticillata / Polygonum arifolium* Forest (CEGL006287, G3)
- *Pinus taeda - Nyssa biflora - Taxodium distichum / Morella cerifera / Osmunda regalis var. spectabilis* Forest (CEGL004651, G2?)
- *Taxodium distichum - Nyssa biflora - Fraxinus profunda / Peltandra virginica - (Bignonia capreolata)* Tidal Forest (CEGL006850, G3)
- *Taxodium distichum / Carex hyalinolepis* Woodland (CEGL004654, G2?)

DISTRIBUTION

Range: This system ranges from the James River, Virginia, northward to the New Jersey Coastal Plain. Possible occurrence of this system in Pennsylvania requires additional study. Examples are probably most common in the Chesapeake Bay region.
Divisions: 203:C
Nations: US

NORTHERN ROCKY MOUNTAIN CONIFER SWAMP (CES306.803)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Forest and Woodland (Treed); Seepage-Fed Sloping [Mineral]; Depressional; Mineral: W/ A-Horizon <10 cm
Non-Diagnostic Classifiers: Montane; Toeslope; Valley bottom; Temperate [Temperate Continental]; Bench; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2161; ESLF 9111; ESP 1161

CONCEPT

Summary: This ecological system occurs in the northern Rocky Mountains from northwestern Wyoming north into the Canadian Rockies and west into eastern Oregon and Washington. It is dominated by conifers on poorly drained soils that are saturated year-round or may have seasonal flooding in the spring. These are primarily on flat to gently sloping lowlands, but also occur up to near the lower limits of continuous forest (below the subalpine parkland). It can occur on steeper slopes where soils are shallow over unfractured bedrock. This system is indicative of poorly drained, mucky areas, and areas are often a mosaic of moving water and stagnant water. Soils can be woody peat, muck or mineral but tend toward mineral. Stands generally occupy sites on benches, toeslopes or valley bottoms along mountain streams. Associations present include wetland phases of *Thuja plicata, Tsuga heterophylla,* and *Picea engelmannii* forests. The wetland types are generally distinguishable from other upland forests and woodlands by shallow water tables and mesic or hydric undergrowth vegetation; some of the most typical species include *Athyrium filix-femina, Dryopteris* spp., *Lysichiton americanus, Equisetum arvense, Senecio triangularis, Mitella breweri, Mitella pentandra, Streptopus amplexifolius, Calamagrostis canadensis*, or *Carex disperma*.
Classification Comments: May need to split out calcareous cedar (*Thuja plicata*) swamps from the other conifer swamps- needs more review.

NORTHERN ROCKY MOUNTAIN LOWER MONTANE RIPARIAN WOODLAND AND SHRUBLAND (CES306.804)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval [Short interval, Spring Flooding]; Montane [Lower Montane]; Riverine / Alluvial
Non-Diagnostic Classifiers: Circumneutral Water; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Temperate [Temperate Continental]; Unconsolidated
National Mapping Codes: ESLF 9155

CONCEPT

Summary: This ecological system of the northern Rocky Mountains and the east slopes of the Cascades consists of deciduous, coniferous, and mixed conifer-deciduous forests that occur on streambanks and river floodplains of the lower montane and foothill zones. Riparian forest stands are maintained by annual flooding and hydric soils throughout the growing season. Riparian forests are often accompanied by riparian shrublands or open areas dominated by wet meadows. *Populus balsamifera* is the key indicator species. Several other tree species can be mixed in the canopy, including *Populus tremuloides*, *Betula papyrifera*, *Betula occidentalis*, *Picea mariana*, and *Picea glauca*. *Abies grandis*, *Thuja plicata*, and *Tsuga heterophylla* are commonly dominant canopy species in British Columbia, western Montana and northern Idaho occurrences, in lower montane riparian zones. Shrub understory components include *Cornus sericea*, *Acer glabrum*, *Alnus incana*, *Betula papyrifera*, *Oplopanax horridus*, and *Symphoricarpos albus*. Ferns and forbs of mesic sites are commonly present in many occurrences, including such species as *Athyrium filix-femina*, *Gymnocarpium dryopteris*, and *Senecio triangularis*.
Classification Comments: This system is from the Canadian Rockies ecoregion project and represents lower montane riparian in Montana north into Canada. In the Okanagan, this is defined as all the cottonwood-dominated or -codominated riparian systems below subalpine and above the Ponderosa pine zone. This system occurs in fire-dominated landscapes, which distinguishes it from North Pacific and subalpine/alpine landscapes that have significantly different fire regimes. This system is distinguished from the similar Rocky Mountain Subalpine-Montane Riparian Woodland (CES306.833) by the floristic component of northern Rocky Mountain species, both in the woody layers and in the herbaceous taxa. This system may occur in northwestern Wyoming where *Populus balsamifera* dominates or codominates some woodlands, but those woodlands may be better placed into Rocky Mountain Lower Montane-Foothill Riparian Woodland and Shrubland (CES306.821), which lists *Populus balsamifera* as a possible dominant.
Similar Ecological Systems:
- Columbia Basin Foothill Riparian Woodland and Shrubland (CES304.768)
- Rocky Mountain Subalpine-Montane Riparian Woodland (CES306.833)

DESCRIPTION

Environment: Alluvial soils along perennial and intermittent streams. Valley type is an important variable, as riparian woodlands are mostly found in V-shaped, steep valleys with many large boulders and coarse soils or U-shaped gullies formed by glacial processes. These systems can also be found in broad unconfined reaches with deeper soils and more complex geomorphic surfaces. Narrow and steep (i.e., confined) occurrences have minimal to no floodplain development, whereas less steep and wider valley bottoms (i.e., unconfined) occurrences are often associated with substantial floodplain development (Gregory et al. 1991).

Dynamics: Natural disturbance regimes are the primary influence on riparian system characteristics. Maintained by the complex interaction of hydrological and geomorphological processes which influence periodic flooding and hydric soils, riparian systems are the most dynamic of all forested, woodland and shrub systems. Hydrogeomorphology determines the form, composition and function of riparian woodland and shrub systems. Typically occurring in watersheds with snow-dominated hydrological processes, sometimes mixed rain and snow, these riparian systems are further influenced by the variability of inter-annual and seasonal weather patterns. Typical flow regimes of British Columbia's central interior plateau and mountains are snow- (nival) dominated. Precipitation falls as snow and is stored for long periods of time, resulting in low winter flows, and peak flows following snowmelt in May to July (depending on annual temperature variations and snow depth). Glacial snow regimes are similar to nival, except that high flows may continue until August or September (Eaton and Moore 2010). Periods of peak flow have greatest influence on channel morphology and vegetation dynamics. Large woody debris is important for affecting channel morphology.

Beaver can be important hydrogeomorphic driver of montane riparian systems, especially along unconfined reaches. The direct, local

presence of beaver creates a heterogeneous complex of wet meadows, marshes and riparian shrublands and increases species richness on the landscape. Naiman et al. (1988) note that beaver-influenced streams are very different from those not impacted by beaver activity by having numerous zones of open water and vegetation, large accumulations of detritus and nutrients, more wetland areas, having more anaerobic biogeochemical cycles, and in general are more resistance to disturbance.

NORTHERN ROCKY MOUNTAIN WOODED VERNAL POOL (CES304.060)

CLASSIFIERS

Classification Status: Standard

Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Depressional; Isolated Wetland [Strictly Isolated]
National Mapping Codes: ESLF 9162

CONCEPT

Summary: These wooded vernal pools are small shallow circumneutral freshwater wetlands of glacial origin that partially or totally dry up as the growing season progresses. They are documented to occur in northern Idaho and western Montana. These vernal ponds and wetlands usually fill with water over the fall, winter and early spring, but then at least partially dry up towards the end of the growing season. Depending on annual patterns of temperature and precipitation, the drying of the pond may be complete or partial by the fall. These sites are usually shallow and less than 1 m in depth, but can be as much as 2 m deep. The pool substrate is a poorly drained, often clayey layer with shallow organic sediments. The freshwater ponds have pH ranges from 6.2 to 7.8 with most measurements between 6.5 and 7.5, i.e., relatively neutral. The ponds in Montana were thought to be isolated, but it has been shown that in high water years the ponds spill over, and there is an exchange of surface water between ponds. The pools have a ring of trees surrounding the ponds that provide shade and influence their hydrology. A variety of tree species dominant the upper canopy, including *Abies grandis*, *Abies lasiocarpa*, *Larix occidentalis*, *Picea engelmannii*, *Pinus contorta*, *Pseudotsuga menziesii*, and the broadleaf trees *Populus balsamifera ssp. trichocarpa (= Populus trichocarpa)* (black cottonwood), *Fraxinus latifolia*, and, to a lesser extent, *Populus tremuloides* (quaking aspen) and *Betula papyrifera* (paper birch). Common shrubs include *Alnus incana*, *Cornus sericea (= Cornus stolonifera)*, *Rhamnus alnifolia*, and *Salix* spp. *Alopecurus aequalis*, *Callitriche heterophylla*, *Carex vesicaria* (inflated sedge), *Eleocharis palustris*, and *Phalaris arundinacea* (reed canarygrass) are common herbaceous plant associates.

NORTHWESTERN GREAT PLAINS FLOODPLAIN (CES303.676)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Long (>25 yrs) Flooding Interval; Floodplain; Forest and Woodland (Treed); Riverine / Alluvial
National Mapping Codes: ESLF 9159

CONCEPT

Summary: This ecological system is found in the floodplains of medium and large rivers of the northwestern Great Plains, ranging from the Dakotas Mixedgrass Prairie west through the Northern Great Plains Steppe and north into Canada. This system occurs in the upper Missouri River Basin and includes parts of the Niobrara, White, Cheyenne, Little Missouri, Yellowstone, Powder, Bighorn, Milk, and Musselshell rivers. Alluvial soils and periodic, intermediate flooding (every 5-25 years) typify this system. These are the perennial big rivers of the region with hydrologic dynamics largely driven by snowmelt in the mountains, rather than local precipitation events. Dominant communities within this system range from floodplain forests to wet meadows to gravel/sand flats, however, they are linked by underlying soils and flooding regime. Dominant species are *Populus balsamifera ssp. trichocarpa* or *Populus deltoides* and *Salix* spp. *Fraxinus pennsylvanica, Salix amygdaloides*, and *Ulmus americana* are common in some stands. If present, common shrub species include *Amorpha fruticosa, Cornus drummondii, Cornus sericea, Symphoricarpos occidentalis, Salix exigua, Salix interior*, and *Salix planifolia*. Grass cover underneath the trees is an important part of this system and is a mix of cool-season graminoid species, including *Carex pellita (= Carex lanuginosa), Elymus lanceolatus, Pascopyrum smithii*, and *Schoenoplectus* spp., with warm-season species such as *Panicum virgatum, Schizachyrium scoparium*, and *Spartina pectinata*. This system is often subjected to heavy grazing and/or agriculture and can be heavily degraded. In Montana, most occurrences are now degraded to the point where the cottonwood overstory is the only remaining natural component; undergrowth is dominated by *Bromus inermis*, or a complex of pasture grasses. Another factor is that groundwater depletion and lack of fire have created additional species changes. In most cases, the majority of the wet meadow and prairie communities may be extremely degraded or extirpated from the system.

Classification Comments: This system needs to be more clearly delineated from Northwestern Great Plains Riparian (CES303.677). The component plant association list is incomplete. All the riparian/floodplain/alluvial systems of the Great Plains region need to be revisited for naming conventions, along with better definitions of conceptual boundaries. There is much apparent overlap in their concepts and distribution, and the names add to the confusion. In particular, the difference between "riparian" and "floodplain" usage in the names needs revisiting and possible changing. These systems include Northwestern Great Plains Floodplain (CES303.676), Northwestern Great Plains Riparian (CES303.677), Western Great Plains Floodplain (CES303.678), and Western Great Plains Riparian (CES303.956).

PIEDMONT SEEPAGE WETLAND (CES202.298)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Seepage-Fed Sloping
National Mapping Codes: ESLF 9308

CONCEPT

Summary: This Piedmont system consists of seepage-fed wetlands on gentle slopes, with substantial seepage flow. Vegetation is variable, both within and among examples. Included are hillside seepage bogs with substantial boggy flora and with strong influence by fire, and lower slope and floodplain edge seeps with forb-dominated vegetation.
Classification Comments: This system is fairly heterogeneous, covering a broad range of environments and vegetation. Two distinct subtypes can be recognized, which may warrant separating into different systems. Seepage bogs have a very distinctive flora, appear to be naturally influenced by fire, and usually occur in more upland settings, often with upland systems completely surrounding them. Some are related to the Atlantic Coastal Plain Sandhill Seep (CES203.253). Non-boggy seeps have a non-fire-tolerant flora and occur in lower topographic settings. Between these two extremes are seepage bogs with less Coastal Plain character, though they still have *Sarracenia* spp. There are also streamhead seeps, which have some bog flora and have Coastal Plain species, but which occur along drainages. They are transitional to Southern Piedmont Small Floodplain and Riparian Forest (CES202.323), but are also related to the Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252). These different Piedmont wetland communities are put into one system, rather than separated as in the Coastal Plain, because the differences are not as sharp and the range of variation smaller within each. This system is readily distinguished from adjacent upland systems by the presence of wetland flora and soils, as well as seepage. They are somewhat less clearly distinguished from adjacent floodplain systems, but are distinctly wetter most of the time. They are saturated without having standing water as floodplain pools do. These differences are reflected in the vegetation.

Piedmont seepage wetlands are separated from Southern Appalachian Seepage Wetland (CES202.317) by floristic differences. A few examples in the upper Piedmont may be better placed with the southern Appalachian system, but most are geographically separated.
Similar Ecological Systems:
- Atlantic Coastal Plain Sandhill Seep (CES203.253)
- Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252)
- East Gulf Coastal Plain Northern Seepage Swamp (CES203.554)
- North-Central Appalachian Acidic Swamp (CES202.604)--ranges south to northern Virginia.
- North-Central Interior and Appalachian Rich Swamp (CES202.605)--ranges south to northern Virginia.
- Southern Appalachian Seepage Wetland (CES202.317)
- Southern Piedmont Small Floodplain and Riparian Forest (CES202.323)

Related Concepts:
- Red Maple: 108 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in small patches where seepage water creates wetland conditions. Seepage commonly occurs at the base of slopes. In Georgia, this occurs where water percolates through quartzite or where shallow soils overlie bedrock (Edwards et al. 2013) on the edge of bottomlands or in headwaters of small streams. Others occur on gently sloping hillsides where impermeable soils and slope force shallow groundwater to the surface. The soil is saturated seasonally to permanently, but has no substantial amount of standing water.
Vegetation: Vegetation generally is patchy and heterogeneous in structure. Most examples do not have closed tree canopies, and well-developed shrub or herb layers are almost always present. The trees are often not very distinctive, consisting of widespread wetland species, such as *Acer rubrum*, or of non-wetland species shared with adjacent communities. Often tree cover comes primarily from trees rooted in adjacent communities. The shrub layer normally consists of wetland species. *Alnus serrulata, Viburnum nudum, Vaccinium* spp., and other ericaceous species are most common. The herb layer is quite variable. Large wetland ferns such as *Osmunda cinnamomea* are often prominent. Various wetland grasses, sedges, and rushes may be abundant, and forbs such as *Impatiens capensis, Saururus cernuus, Boehmeria cylindrica,* and *Rudbeckia laciniata* are also often prominent. A distinct subtype is boggy in character, with substantial amounts of *Sphagnum*. The boggy seeps often have a number of species characteristic of Coastal Plain wetlands and otherwise absent in the Piedmont, such as *Sarracenia purpurea*, *Sarracenia flava, Smilax laurifolia,* and *Cyrilla racemiflora*. Examples from the southwestern end of this system's range (e.g., in Alabama's Talladega Ridge Subsection [231Dd] or level IV ecoregion 45d), contain *Magnolia virginiana*, which is more typical of the Coastal Plain.
Dynamics: The presence of seepage is the primary determinant of this system. Long-term droughts that affect seepage flow presumably have an effect. Canopy dynamics are not well known and potentially may vary substantially over short distances in response to wetness. Wetness clearly limits recruitment of most tree and shrub seedlings to drier microsites in the wettest examples.

Smaller examples are often shaded by trees rooted in adjacent forest communities. As in the surrounding forests, trees likely regenerate primarily in small gaps created by wind. Fire is an important influence in some examples. Many of the boggy seeps are associated with Southeastern Interior Longleaf Pine Woodland (CES202.319) and have a substantial fire-tolerant flora. At the other end of the spectrum, floodplain edge seeps may seldom if ever have burned. Long-term geomorphic processes may be important in these systems. Headward erosion by small streams, or meandering by larger stream channels, sometimes drains seeps and eliminates the wetland vegetation. Piedmont Seepage Wetland (CES202.298) are often left undisturbed when surrounding forests are logged. Effects of logging on water infiltration or surface flow may have significant indirect effects.

Component Associations:
- *Acer rubrum - Fraxinus (pennsylvanica, americana) / Lindera benzoin / Symplocarpus foetidus* Forest (CEGL006406, G4G5)
- *Acer rubrum - Nyssa sylvatica - Magnolia virginiana / Viburnum nudum var. nudum / Osmunda cinnamomea - Woodwardia areolata* Forest (CEGL006238, G3?)
- *Acer rubrum / Alnus serrulata - Lindera benzoin / Glyceria striata - Impatiens capensis* Seep Forest (CEGL007031, G4)
- *Acer rubrum / Viburnum nudum - Photinia pyrifolia / Smilax laurifolia / Carex debilis var. pubera* Seepage Forest (CEGL007041, G2)
- *Acer rubrum var. trilobum - Liriodendron tulipifera / Ilex opaca var. opaca / Osmunda cinnamomea* Forest (CEGL004551, G2G3)
- *Acer rubrum var. trilobum / Morella caroliniensis - Gaylussacia frondosa / Andropogon glomeratus - (Sarracenia flava)* Woodland (CEGL004781, G2)
- *Acer rubrum var. trilobum / Viburnum nudum var. nudum / Osmunda cinnamomea - Saururus cernuus - Impatiens capensis* Forest (CEGL004426, G3?)
- *Alnus serrulata - Magnolia virginiana / Andropogon glomeratus - Eupatorium pilosum - Rhynchospora gracilenta - Xyris torta* Shrubland (CEGL006499, GNR)

SPATIAL CHARACTERISTICS

Spatial Summary: Small-patch system, usually less than one acre.
Size: Occurs as small patches, most less than one acre in size. A few stream seepage wetlands may cover a couple of acres in branching linear bodies. Occasionally two or three patches will occur close enough together to be treated as a single occurrence, but most examples are isolated.
Adjacent Ecological Systems:
- Southeastern Interior Longleaf Pine Woodland (CES202.319)
- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)
- Southern Piedmont Large Floodplain Forest (CES202.324)
- Southern Piedmont Small Floodplain and Riparian Forest (CES202.323)

Adjacent Ecological System Comments: This system may be embedded in a variety of other systems. Most common are Southern Piedmont Dry Oak-(Pine) Forest (CES202.339), Southeastern Interior Longleaf Pine Woodland (CES202.319), Southern Piedmont Small Floodplain and Riparian Forest (CES202.323), and Southern Piedmont Large Floodplain Forest (CES202.324).

DISTRIBUTION

Range: This system ranges throughout the Piedmont, from Alabama to North Carolina and possibly southern Virginia.

PIEDMONT UPLAND DEPRESSION SWAMP (CES202.336)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Depressional
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); Isolated Wetland [Strictly Isolated]
National Mapping Codes: ESLF 9302

CONCEPT

Summary: This system represents isolated wetlands primarily of the Piedmont in small, shallow basins in upland settings where water pools due to limited soil drainage. Most known examples occur over mafic bedrock. The typical hydrology is seasonally flooded. Most examples consist of forests of wetland oaks, but a few are treeless or open-canopied ponds. Vegetation in open ponds is typically zoned with an outer ring of trees, a more interior ring of shrubs, herbs and vines, and a central area with or without standing water year round depending on precipitation. This system also includes the wet hardwood forests ("Iredell Flatwoods" or "Gabbro Glades") which occur on gently sloping terrain or shallowly depressed upland flats over gabbro-derived clays in the Piedmont of Georgia and South Carolina. A few examples of this system occur in the adjacent Southern Blue Ridge; these are extremely rare and small-patch examples.

Classification Comments: This system is distinct from all other Piedmont systems in its ponded wetland hydrology in upland settings. The vegetation is generally also distinct from all other Piedmont systems. Though apparently quite different, Piedmont Hardpan Woodland and Forest (CES202.268) is closely related by the importance of an impermeable clay hardpan, and some intermediate gradations occur. A few examples of this system (CES202.336) appear to be closely related to Coastal Plain depressional wetlands, sharing some flora, but most are more distinct. The system has significant variation in vegetation and environment. The forested swamps and open pools represent well-marked subtypes. There is a more subtle distinction between the basic and acidic soil swamps. There is substantial variation among the pools, related to substrate, basin morphology, and geographic location. This system includes the depression swamps of the Triassic Basins of Virginia and Maryland. A few disjunct examples may occur in the Southern Blue Ridge because of similarity in topographic setting and general structure. They do, however, occur on different substrates (quartzite and sandstone) than any examples in the Piedmont. Their vegetation is different from other examples but not in having more montane flora. Their vegetation is no more different than most other pools are from each other.

DESCRIPTION

Environment: This system occurs in small, shallow basins or gentle swales on flat to rolling upland sites, and occasionally in depressions on narrow, steeper ridgetops. Soils have a dense clay hardpan or occasionally bedrock which limits internal drainage. Rainwater accumulates in the basins and persists through the wet season, occasionally persisting all year. Only a few kinds of rock are known to form these depressions. Most examples occur on soils derived from mafic rocks such as gabbro or diabase, but a few occur over slates or mafic to felsic tuffs where a dense clay hardpan has formed, and a few occur over unfractured bedrock. Some sites in Georgia have soils with shrink-swell tendencies which allow for both wetness and extreme dryness and inhibit the survival of trees, promoting an open woodland structure (Edwards et al. 2013). Examples in North Carolina may lack trees in the deepest water parts of basins. A few occur over bedrock of other kinds. Rock chemistry affects soil chemistry and influences variation in vegetation, but hydroperiod is a more important influence.

Vegetation: Vegetation consists either of swamps dominated by wetland oaks, or of more open-canopy pools with sparse trees and with substantial shrub or herbaceous vegetation. Swamps are most often dominated by *Quercus phellos*, with a substantial minority dominated by *Quercus lyrata* and a few having *Quercus bicolor*, *Quercus michauxii*, or other species. Examples that have been logged or cleared may be dominated by *Acer rubrum* or *Liquidambar styraciflua*. Lower strata are generally sparse in the swamps, often just a few shrubs such as *Vaccinium* spp., patches of *Smilax*, and a few wetland herbs. Open ponds may have the same canopy species on the edges, but a few have *Nyssa sylvatica* or other wetland species. The lower strata are better developed in the open pools, with *Cephalanthus occidentalis*, *Leucothoe racemosa*, *Vaccinium* spp., or other wetland species occurring as thickets along the edge or scattered in the interior. Large *Smilax* tangles sometimes occur. Herbs are usually still sparse or patchy, but may include dense beds of

various graminoids or ferns, as well as scattered clumps. *Sphagnum* is sometimes extensive in parts of the pools. These isolated seasonal wetlands are often important breeding sites for amphibians.
Dynamics: The dynamics of water levels are the most important factor in these systems, differentiating them from the surrounding uplands and differentiating the various communities within the system. These wetlands typically have very small watersheds, and input of water comes largely from rainfall. Variation in rainfall patterns will drive variation in duration of flooding, though most upland depression swamps have an outlet that limits water depth. Fire may be naturally rare in some examples of these systems, such as in North Carolina. Though they could naturally be exposed to fires occurring in the surrounding uplands, standing water and lack of continuous fuel would limit fires to the edges, expect perhaps very rarely in early fall. Other examples in South Carolina and Georgia are naturally prone drying out and to fire, and have an open woodland structure with a grassy understory, typical of wet flatwoods which naturally burned (Edwards et al. 2013). Presumably important as a dynamic process is the migration of amphibians, which concentrate in these systems for breeding. Ecosystem dynamics may be strongly affected by the suitability of surrounding uplands for amphibian adult habitat.

Component Associations:
- *Cephalanthus occidentalis - (Leucothoe racemosa) / Carex joorii* Shrubland (CEGL004075, G1)
- *Leucothoe racemosa - Vaccinium fuscatum - Smilax walteri* Shrubland (CEGL004533, G1?)

- *Quercus phellos - Quercus (michauxii, shumardii) - Fraxinus americana / (Quercus oglethorpensis) / Zephyranthes atamasca* Gabbro Upland Depression Forest (CEGL008484, G2?)
- *Quercus phellos / Carex (albolutescens, intumescens, joorii) / Climacium americanum* Forest (CEGL007403, G2G3)
- *Scirpus cyperinus - Dulichium arundinaceum / Sphagnum* spp. Herbaceous Vegetation (CEGL004134, G1Q)

SPATIAL CHARACTERISTICS

Spatial Summary: Small-patch system, occurring as isolated bodies surrounded by upland systems. Open pools are usually less than one acre, while swamps may be up to several acres in size.
Size: Occurs as small patches. Pools are usually less than one acre, and may be substantially smaller. Swamps range up to several acres, a few to ten or more acres. Most examples occur as isolated patches, but a few occur as small groups. Extensive mafic rock areas may support a number of swamps, but most are probably not close enough together to be treated as single occurrences. Most remaining examples are of natural size.
Adjacent Ecological Systems:
- Piedmont Hardpan Woodland and Forest (CES202.268)
- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)

Adjacent Ecological System Comments: Most examples are surrounded by Southern Piedmont Dry Oak-(Pine) Forest (CES202.339) or Piedmont Hardpan Woodland and Forest (CES202.268).

DISTRIBUTION

Range: This system ranges throughout the Piedmont, from Virginia to Alabama. A few examples attributable to this system are found in the adjacent Southern Blue Ridge.

RED RIVER LARGE FLOODPLAIN FOREST (CES203.065)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed)
Non-Diagnostic Classifiers: Riverine / Alluvial [Brownwater]
National Mapping Codes: ESLF 9319

CONCEPT

Summary: This floodplain forest system is specifically restricted to the main stem of the Red River in the West Gulf Coastal Plain and Upper West Gulf Coastal Plain of southwestern Arkansas, adjacent Texas, and Louisiana. Several distinct plant communities can be recognized within this system that may be related to the array of different geomorphic features present within the floodplain. Some of the major geomorphic features associated with different community types within the system include natural levees, point bars, meander scrolls, oxbows, and sloughs. The vegetation generally includes forests dominated by bottomland hardwood species and other trees tolerant of flooding, including bald-cypress and water tupelo. Herbaceous and shrub vegetation may also be present in certain areas. Some canopy trees that may occur in examples of this system include *Betula nigra, Platanus occidentalis, Fraxinus pennsylvanica, Celtis laevigata, Liquidambar styraciflua, Ulmus americana, Nyssa biflora, Populus deltoides, Salix nigra*, and *Quercus texana*. Components with longer hydroperiods may contain *Quercus lyrata, Gleditsia aquatica, Carya aquatica, Nyssa aquatica*, and *Taxodium distichum*. Smaller trees include *Quercus similis, Quercus sinuata var. sinuata, Ulmus crassifolia*, and *Carpinus caroliniana*. Shrubs include *Alnus serrulata, Forestiera acuminata, Planera aquatica, Cephalanthus occidentalis, Ilex decidua, Crataegus viridis, Sabal minor*, and *Itea virginica*. Herbs are limited due to the length of flooding, but some examples are *Boehmeria cylindrica, Mikania scandens*, and *Lysimachia radicans*. Typical floating aquatic plants include *Nelumbo lutea, Nuphar advena, Nymphaea odorata*, and *Lemna minor*.
Classification Comments: This system is generally similar in concept to West Gulf Coastal Plain Large River Floodplain Forest (CES203.488) but is distinct both from it and from the floodplain forests of the Mississippi River Alluvial Plain primarily because of the difference in magnitude between the typical large rivers (such as the Trinity, Neches, and Sabine), on the one hand, and the Mississippi River on the other. In Arkansas (at least), this system is most closely affiliated with the "Billyhaw-Perry-Portland" Soil Association (MUID=AR033 in STATSGO).

DESCRIPTION

Environment: Some of the major geomorphic features associated with different community types within the system include natural levees, point bars, meander scrolls, oxbows, and sloughs (Sharitz and Mitsch 1993). The "flatwoods" of the upper terraces within the floodplain are a different system. The geology is Quaternary alluvial deposits. Landforms include the floodplains of the Red River and its major tributaries. Some local topographic variation exists and includes terraces and oxbows. The soils include loams and other

bottomland soils (Elliott 2011).

Vegetation: The vegetation generally includes forests dominated by bottomland hardwood species and other trees tolerant of flooding, including *Taxodium distichum* and *Nyssa aquatica*. Herbaceous and shrub vegetation may also be present in certain areas. Riverfront sites, and newly exposed or disturbed sites, are occupied by *Platanus occidentalis, Populus deltoides, Salix nigra, Betula nigra, Acer negundo,* and *Fraxinus pennsylvanica*. Some portions of the system are seasonally flooded, and these may contain species such as *Quercus lyrata, Carya aquatica, Taxodium distichum, Nyssa aquatica, Nyssa biflora, Quercus phellos, Gleditsia aquatica*, and *Planera aquatica*. Less frequently flooded areas may be dominated by numerous hardwood species, including *Liquidambar styraciflua, Quercus nigra, Quercus phellos, Quercus shumardii, Quercus macrocarpa, Quercus michauxii, Quercus falcata, Carya illinoinensis, Celtis laevigata, Ulmus alata, Ulmus americana, Ulmus crassifolia, Ulmus rubra, Gleditsia triacanthos, Nyssa sylvatica,* and *Fraxinus pennsylvanica*. In addition, *Juniperus virginiana, Pinus taeda,* and, to a lesser extent, *Pinus echinata* may also be found in the canopy. A midstory component may include young individuals of the overstory, as well as *Quercus similis, Quercus sinuata var. sinuata, Carpinus caroliniana, Ostrya virginiana, Acer rubrum, Sassafras albidum, Maclura pomifera,* and *Morus rubra*. The wetland shrub *Cephalanthus occidentalis* may dominate some open sites within the floodplain. In addition to these species, shrubs such as *Alnus serrulata, Forestiera acuminata, Crataegus viridis, Crataegus marshallii, Callicarpa americana, Ilex decidua, Sabal minor, Itea virginica,* and *Arundinaria gigantea* may be found in the understory of forests, as well as the exotic shrub *Ligustrum sinense*. Numerous woody vines may be encountered, including *Smilax rotundifolia, Brunnichia ovata, Berchemia scandens, Lonicera japonica, Ampelopsis arborea,* and *Toxicodendron radicans*. Herbaceous species may be present in the understory of forest, occur as marshy areas, or occupy herbaceous-dominated sites on areas less frequently flooded. *Saururus cernuus, Nymphaea odorata, Rhynchospora* spp., *Carex* spp., *Dichanthelium* spp., *Chasmanthium* spp., *Juncus* spp., *Leersia* sp., *Geum canadense, Sanicula canadensis, Woodwardia areolata, Boehmeria cylindrica, Mikania scandens*, and *Polygonum* spp. are among the herbaceous species that may be commonly encountered in this system. Typical floating aquatic plants include *Nelumbo lutea, Nuphar advena, Nymphaea odorata,* and *Lemna minor* (Elliott 2011). The forests of the Red River are thought to differ from those of other systems because of the greater presence of "riverfront" species (P. Faulkner pers. comm.). More information is needed, including a review of the affiliations of associations to this system versus West Gulf Coastal Plain Large River Floodplain Forest (CES203.488).

Dynamics: This system is maintained by natural large river hydrological processes (e.g., meanders, flooding, backswamps, natural levees). Occasional, long duration flooding can cause the loss of canopy over large areas. This canopy decline and reproductive failure can create late-seral open stands. Duration of flooding varies with the placement of a site in the landscape and is a dominant process affecting vegetation on a given site. Meandering rivers are dynamic and change course, eroding into the floodplain and depositing new point bars, thus creating new habitat for early-seral plant communities. Changes in hydrology due to the activities of beaver are also an important ecological process in bottomland hardwood forests. Beaver activity causes changes in hydrology, and this is an important ecological process in bottomland hardwood forests; the effects are poorly understood at the landscape level, especially in the presettlement context. Beaver impoundments kill trees (sometimes over large areas) but may also create open water habitat, cypress-tupelo stands, or cause stand replacement. In addition to periodic flooding, the dominant ecological process in bottomland hardwood forests is the formation of windfall gaps, which can occur on the local scale (a single mature canopy tree) as well as the landscape scale (tornadoes or hurricanes). When canopy trees fall, seedlings in the understory are released and compete for a spot in the canopy. This leads to dense areas of herbaceous and woody vegetation in windfall gaps of all sizes. This is a major process in forest regeneration in bottomland hardwood forests. This system is also bordered by a number of upland communities from which fire would have occasionally burned down into the bottoms, especially in drought years.

Component Associations:

- *Betula nigra - Platanus occidentalis / Alnus serrulata / Boehmeria cylindrica* Forest (CEGL007312, G4G5)
- *Forestiera acuminata - (Planera aquatica, Cephalanthus occidentalis)* Shrubland (CEGL003911, G3?)

- *Quercus sinuata var. sinuata - Ulmus crassifolia / Sabal minor* Red River Bottomland Forest (CEGL004130, G1G2)
- *Salix nigra* Large River Floodplain Forest (CEGL007410, G3G5)
- *Taxodium distichum - (Nyssa aquatica) / Forestiera acuminata - Planera aquatica* Forest (CEGL002421, G3G5)
- *Taxodium distichum - Nyssa aquatica - Acer rubrum / Itea virginica* Forest (CEGL007422, G4?)
- *Taxodium distichum / Lemna minor* Forest (CEGL002420, G4G5)
- *Taxodium distichum* West Gulf Coastal Plain Lakeshore Woodland (CEGL008497, G2G3)

Spatial Characteristics

Adjacent Ecological Systems:
- West Gulf Coastal Plain Nonriverine Wet Hardwood Flatwoods (CES203.548)
- West Gulf Coastal Plain Pine-Hardwood Flatwoods (CES203.278)

Adjacent Ecological System Comments: What are the flatwoods in the Red River area really?

Distribution

Range: This system is restricted to the main stem of the Red River in the West Gulf Coastal Plain and Upper West Gulf Coastal Plain of southwestern Arkansas, adjacent Texas, and Louisiana. Its range is conceptually coincident with the vast majority of Subsection 234Ai of Keys et al. (1995), excluding the portion of 234Ai within TNC Ecoregion 42 (Mississippi River Alluvial Plain). Its range is also coincident with EPA Ecoregion 35g (Red River Bottomlands) (EPA 2004). The portion of the Red River to the west (231Em of Keys et al. 1995) is treated as part of West Gulf Coastal Plain Large River Floodplain Forest (CES203.488).

ROCKY MOUNTAIN LOWER MONTANE-FOOTHILL RIPARIAN WOODLAND AND SHRUBLAND (CES306.821)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval; Short (50-100 yrs) Persistence; Montane [Lower Montane]; Riverine / Alluvial; Mineral: W/ A-Horizon <10 cm; Unconsolidated
Non-Diagnostic Classifiers: Circumneutral Water; Floodplain; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Stream terrace (undifferentiated); Valley bottom; Temperate [Temperate Continental]; Braided channel or stream; Drainage bottom (undifferentiated)
National Mapping Codes: ESLF 9156

CONCEPT

Summary: This ecological system is found throughout the Rocky Mountain and Colorado Plateau regions within a broad elevational range from approximately 900 to 2800 m. This system often occurs as a mosaic of multiple communities that are tree-dominated with a diverse shrub component. It is dependent on a natural hydrologic regime, especially annual to episodic flooding. Occurrences are found within the flood zone of rivers, on islands, sand or cobble bars, and immediate streambanks. It can form large, wide occurrences on mid-channel islands in larger rivers or narrow bands on small, rocky canyon tributaries and well-drained benches. It is also typically found in backwater channels and other perennially wet but less scoured sites, such as floodplains swales and irrigation ditches. In some locations, occurrences extend into moderately high intermountain basins where the adjacent vegetation is sage steppe. Dominant trees may include *Acer negundo, Populus angustifolia, Populus deltoides, Populus fremontii, Pseudotsuga menziesii, Picea pungens, Salix amygdaloides*, or *Juniperus scopulorum*. Dominant shrubs include *Acer glabrum, Alnus incana, Betula occidentalis, Cornus sericea, Crataegus rivularis, Forestiera pubescens, Prunus virginiana, Rhus trilobata, Salix monticola, Salix drummondiana, Salix exigua, Salix irrorata, Salix lucida, Shepherdia argentea*, or *Symphoricarpos* spp. Exotic trees of *Elaeagnus angustifolia* and *Tamarix* spp. are common in some stands. Generally, the upland vegetation surrounding this riparian system is different and ranges from grasslands to forests. In the Wyoming Basins, the high-elevation *Populus angustifolia*-dominated rivers are included here, including along the North Platte, Sweetwater, and Laramie rivers. In these situations, *Populus angustifolia* is extending down into the sage steppe zone of the basins.
Classification Comments: This system is physiognomically diverse; because of relatively rapid spatial and temporal shifts in structure and composition, it was too complex to split into different, structurally defined systems (e.g., a shrubland system and a woodland system). This riparian system has been applied to the Green, Yampa, and Colorado rivers (upstream of the Grand Canyon) on the Colorado Plateau. Within and below the Grand Canyon is classified as North American Warm Desert Riparian Woodland and Shrubland (CES302.753). More research is needed to determine if creating a Colorado Plateau riparian woodland and shrubland system is ecologically justified.

- Riparian (422) (Shiflet 1994) Broader

DESCRIPTION

Environment: This system is dependent on a natural hydrologic regime, especially annual to episodic flooding. It is found within the flood zone of rivers, on islands, sand or cobble bars, and immediate streambanks. It can form large, wide occurrences on mid-channel islands in larger rivers or narrow bands on small, rocky canyon tributaries and well-drained benches. It is also typically found in backwater channels and other perennially wet but less scoured sites, such as floodplains swales and irrigation ditches. It may also occur in upland areas of mesic swales and hillslopes below seeps and springs. The climate of this system is continental with typically cold winters and hot summers. Surface water is generally high for variable periods. Soils are typically alluvial deposits of sand, clays, silts and cobbles that are highly stratified with depth due to flood scour and deposition. Highly stratified profiles consist of alternating layers of clay loam and organic material with coarser sand or thin layers of sandy loam over very coarse alluvium. Soils are fine-textured with organic material over coarser alluvium. Some soils are more developed due to a slightly more stable environment and greater input of organic matter.
Vegetation: Dominant trees may include *Acer negundo, Populus angustifolia, Populus deltoides, Populus fremontii, Pseudotsuga menziesii, Picea pungens, Salix amygdaloides*, or *Juniperus scopulorum*. Dominant shrubs include *Acer glabrum, Alnus incana, Betula occidentalis, Cornus sericea, Crataegus rivularis, Forestiera pubescens, Prunus virginiana, Rhus trilobata, Salix monticola, Salix drummondiana, Salix exigua, Salix irrorata, Salix lucida, Shepherdia argentea*, or *Symphoricarpos* spp. Exotic trees of *Elaeagnus angustifolia* and *Tamarix* spp. are common in some stands. Generally, the upland vegetation surrounding this riparian system is different and ranges from grasslands to forests.
Dynamics: This ecological system contains early-, mid- and late-seral riparian plant associations. It also contains non-obligate

riparian species. Cottonwood communities are early-, mid- or late-seral, depending on the age class of the trees and the associated species of the occurrence (Kittel et al. 1999b). Cottonwoods, however, do not reach a climax stage as defined by Daubenmire (1952). Mature cottonwood occurrences do not regenerate in place, but regenerate by "moving" up and down a river reach and regeneration is often associated with flooding events. Over time a healthy riparian area supports all stages of cottonwood communities (Kittel et al. 1999b).

- *Populus deltoides - (Salix amygdaloides) / Salix (exigua, interior)* Woodland (CEGL000659, G3G4)
- *Populus deltoides / Symphoricarpos occidentalis* Woodland (CEGL000660, G2G3)
- *Populus deltoides ssp. wislizeni / Acer negundo* Woodland (CEGL002336, GNR)
- *Populus deltoides ssp. wislizeni* / Disturbed Understory Woodland (CEGL003810, GNR)
- *Populus deltoides ssp. wislizeni / Rhus trilobata* Woodland (CEGL000940, G2)
- *Populus fremontii - Salix gooddingii* Woodland (CEGL000944, G2)
- *Populus fremontii / Acer negundo* Forest (CEGL000662, G2Q)
- *Populus fremontii / Artemisia tridentata* Woodland (CEGL005365, GNR)
- *Populus fremontii / Betula occidentalis* Wooded Shrubland (CEGL002981, GNR)
- *Populus fremontii / Ericameria nauseosa* Woodland (CEGL002465, GNR)
- *Populus fremontii / Leymus triticoides* Woodland (CEGL002756, GNR)
- *Populus fremontii* / Mesic Forbs Woodland (CEGL002470, GNR)
- *Populus fremontii* / Mesic Graminoids Woodland (CEGL002473, GNR)
- *Populus fremontii / Salix exigua* Forest (CEGL000666, GNR)
- *Populus fremontii / Salix geyeriana* Woodland (CEGL000943, G3?)
- *Pseudotsuga menziesii / Betula occidentalis* Woodland (CEGL002639, G3?)
- *Pseudotsuga menziesii / Cornus sericea* Woodland (CEGL000899, G4)
- *Rhus trilobata* Intermittently Flooded Shrubland (CEGL001121, G3)
- *Salix amygdaloides* Woodland (CEGL000947, G3)
- *Salix eastwoodiae / Carex aquatilis* Shrubland (CEGL001195, G2)
- *Salix eastwoodiae / Carex utriculata* Shrubland (CEGL001196, G2?)
- *Salix eastwoodiae* Shrubland (CEGL001194, G2Q)
- *Salix exigua - Salix ligulifolia* Shrubland (CEGL002655, G2G3)
- *Salix exigua - Salix lucida ssp. caudata* Shrubland (CEGL001204, G2)
- *Salix exigua* / Barren Shrubland (CEGL001200, G5)
- *Salix exigua / Elymus X pseudorepens* Shrubland (CEGL001198, G3)
- *Salix exigua / Equisetum arvense* Shrubland (CEGL001201, G3?)
- *Salix exigua* / Mesic Forbs Shrubland (CEGL001202, G2)
- *Salix exigua* / Mesic Graminoids Shrubland (CEGL001203, G5)
- *Salix gooddingii / Salix exigua* Woodland (CEGL003778, GNR)
- *Salix irrorata* Shrubland (CEGL001214, GNR)
- *Salix lasiolepis - Cornus sericea / Rosa woodsii* Shrubland (CEGL003453, G2G3)
- *Salix lasiolepis* / Barren Ground Shrubland (CEGL001216, G3?)
- *Salix lasiolepis / Rosa woodsii* / Mixed Herbs Shrubland (CEGL001217, G3Q)
- *Salix ligulifolia* Shrubland (CEGL001218, G2G3)
- *Salix lutea / Leymus cinereus* Shrubland (CEGL005322, GNR)
- *Salix lutea* Shrubland (CEGL003780, GNR)
- *Shepherdia argentea* Shrubland (CEGL001128, G3G4)
- *Spartina gracilis* Herbaceous Vegetation (CEGL001588, GU)
- *Spartina pectinata* Western Herbaceous Vegetation (CEGL001476, G3?)

DISTRIBUTION

Range: This system is found throughout the lower montane Rocky Mountain and Colorado Plateau regions within a broad elevation range from approximately 900 to 2800 m. It is also found in the island mountain ranges of central and eastern Montana.
Divisions: 304:C; 306:C
Nations: US
Subnations: AZ, CO, ID, MT, NM, NV, OR, SD, UT, WY
Map Zones: 8:?, 9:C, 13:C, 15:C, 16:C, 17:P, 18:C, 20:C, 21:C, 22:C, 23:C, 24:C, 25:C, 26:C, 27:C, 28:C, 29:C, 33:C

ROCKY MOUNTAIN SUBALPINE-MONTANE RIPARIAN SHRUBLAND (CES306.832)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval; RM Subalpine/Montane Riparian Woodland; Short (50-100 yrs) Persistence; Montane [Upper Montane]; Montane [Montane]; Shrubland (Shrub-dominated); Riverine / Alluvial; Broad-Leaved Deciduous Shrub
Non-Diagnostic Classifiers: Circumneutral Water; Erosional stream terrace; Floodplain; Montane [Lower Montane]; Stream terrace (undifferentiated); Valley bottom; Alluvial terrace; Temperate [Temperate Continental]; Mineral: W/ A-Horizon <10 cm; Drainage bottom (undifferentiated)
National Mapping Codes: ESLF 9187

CONCEPT

Summary: This system is found throughout the Rocky Mountain cordillera from New Mexico north into Montana and northwestern Alberta, and also occurs in mountainous areas of the Intermountain West region and Colorado Plateau. These are montane to subalpine riparian shrublands occurring as narrow bands of shrubs lining streambanks and alluvial terraces in narrow to wide, low-gradient valley bottoms and floodplains with sinuous stream channels. Generally, the system is found at higher elevations, but can be found anywhere from 1500-3475 m, and may occur at even lower elevations in the Canadian Rockies. Occurrences can also be found around seeps, fens, and isolated springs on hillslopes away from valley bottoms. Many of the plant associations found within this system are associated with beaver activity. This system often occurs as a mosaic of multiple communities that are shrub- and herb-dominated and includes above-treeline, willow-dominated, snowmelt-fed basins that feed into streams. The dominant shrubs reflect the large elevational gradient and include *Alnus incana, Betula glandulosa, Betula occidentalis, Cornus sericea, Salix bebbiana, Salix boothii, Salix brachycarpa, Salix drummondiana, Salix eriocephala, Salix geyeriana, Salix monticola, Salix planifolia*, and *Salix wolfii*. Generally the upland vegetation surrounding these riparian systems are of either conifer or aspen forests.
Related Concepts:
- Barclay's willow - Arrow-leaved groundsel (ESSFdc2/Sc03) (Steen and Coupe 1997) Intersecting
- Riparian (422) (Shiflet 1994) Broader
- Willow - Sedge (ESSFxc/10) (Steen and Coupe 1997) Intersecting

Component Associations:
- *Acer glabrum* Drainage Bottom Shrubland (CEGL001062, G4?)
- *Alnus incana - Betula occidentalis* Shrubland (CEGL001142, G2G3)
- *Alnus incana - Salix (monticola, lucida, ligulifolia)* Shrubland (CEGL002651, G3)
- *Alnus incana - Salix drummondiana* Shrubland (CEGL002652, G3)
- *Alnus incana / Athyrium filix-femina* Shrubland (CEGL002628, G3)
- *Alnus incana / Calamagrostis canadensis* Shrubland (CEGL001143, G3Q)
- *Alnus incana / Carex (aquatilis, deweyana, lenticularis, luzulina, pellita)* Shrubland (CEGL001144, G3)
- *Alnus incana / Carex scopulorum var. prionophylla* Shrubland (CEGL000122, G1)
- *Alnus incana / Cornus sericea* Shrubland (CEGL001145, G3G4)
- *Alnus incana / Equisetum arvense* Shrubland (CEGL001146, G3)
- *Alnus incana / Glyceria striata* Shrubland (CEGL000228, G3)
- *Alnus incana / Lysichiton americanus* Shrubland (CEGL002629, G3)
- *Alnus incana* / Mesic Forbs Shrubland (CEGL001147, G3)
- *Alnus incana* / Mesic Graminoids Shrubland (CEGL001148, G3)
- *Alnus incana / Ribes (inerme, hudsonianum, lacustre)* Shrubland (CEGL001151, G3)
- *Alnus incana / Scirpus microcarpus* Shrubland (CEGL000481, G2G3)
- *Alnus incana / Spiraea douglasii* Shrubland (CEGL001152, G3)
- *Alnus incana / Symphoricarpos albus* Shrubland (CEGL001153, G3G4)
- *Alnus incana* Shrubland (CEGL001141, GNRQ)
- *Alnus incana ssp. tenuifolia - Salix irrorata* Shrubland (CEGL002687, G3)
- *Alnus oblongifolia / Symphoricarpos oreophilus* Forest (CEGL001063, GU)
- *Alnus viridis ssp. sinuata / Athyrium filix-femina - Cinna latifolia* Shrubland (CEGL001156, G4)
- *Betula glandulosa* / Mesic Forbs - Mesic Graminoids Shrubland (CEGL002653, G3G4)
- *Betula occidentalis - Dasiphora fruticosa ssp. floribunda* Shrubland (CEGL001083, G2Q)
- *Betula occidentalis / Cornus sericea* Shrubland (CEGL001161, G3)
- *Betula occidentalis / Maianthemum stellatum* Shrubland (CEGL001162, G4?)
- *Betula occidentalis* / Mesic Graminoids Shrubland (CEGL002654, G3)

- *Betula occidentalis* Shrubland (CEGL001080, G3G4)
- *Cornus sericea / Galium triflorum* Shrubland (CEGL001166, G3?)
- *Cornus sericea / Heracleum maximum* Shrubland (CEGL001167, G3)
- *Cornus sericea* Rocky Mountain Shrubland (CEGL001165, G4Q)
- *Corylus cornuta* Shrubland (CEGL002903, G3)
- *Dasiphora fruticosa ssp. floribunda / Deschampsia caespitosa* Shrubland (CEGL001107, G4)
- *Fraxinus anomala* Woodland (CEGL002752, GUQ)
- *Ribes lacustre - Ribes hudsonianum / Cinna latifolia* Shrubland (CEGL003445, G2)
- *Ribes lacustre - Ribes hudsonianum / Glyceria striata* Shrubland (CEGL003446, G2G3)
- *Ribes lacustre / Mertensia ciliata* Shrubland (CEGL001172, G1G2Q)
- *Salix (boothii, geyeriana) / Carex aquatilis* Shrubland (CEGL001176, G3)
- *Salix bebbiana* / Mesic Graminoids Shrubland (CEGL001174, G3)
- *Salix bebbiana* Shrubland (CEGL001173, G3?)
- *Salix boothii - Salix eastwoodiae / Carex nigricans* Shrubland (CEGL002607, G3)
- *Salix boothii - Salix geyeriana / Carex angustata* Shrubland (CEGL001185, G2)
- *Salix boothii - Salix geyeriana* Shrubland (CEGL001184, GU)
- *Salix boothii - Salix lemmonii* Shrubland (CEGL001186, G3)
- *Salix boothii / Calamagrostis canadensis* Shrubland (CEGL001175, G3G4Q)
- *Salix boothii / Carex nebrascensis* Shrubland (CEGL001177, G4G5)
- *Salix boothii / Carex utriculata* Shrubland (CEGL001178, G4)
- *Salix boothii / Deschampsia caespitosa - Geum rossii* Shrubland (CEGL002904, G4)
- *Salix boothii / Equisetum arvense* Shrubland (CEGL002671, G3)
- *Salix boothii / Maianthemum stellatum* Shrubland (CEGL001187, G3Q)
- *Salix boothii* / Mesic Forbs Shrubland (CEGL001180, G3)
- *Salix boothii* / Mesic Graminoids Shrubland (CEGL001181, G3?)
- *Salix brachycarpa / Carex aquatilis* Shrubland (CEGL001244, G2G3)
- *Salix brachycarpa* / Mesic Forbs Shrubland (CEGL001135, G4)
- *Salix candida / Carex utriculata* Shrubland (CEGL001188, G2)
- *Salix commutata / Carex scopulorum* Shrubland (CEGL001189, G3)
- *Salix commutata* / Mesic Graminoid Shrubland (CEGL003497, GNR)
- *Salix drummondiana / Calamagrostis canadensis* Shrubland (CEGL002667, G3)
- *Salix drummondiana / Carex scopulorum var. prionophylla* Shrubland (CEGL001584, G2G3)
- *Salix drummondiana / Carex utriculata* Shrubland (CEGL002631, G4)
- *Salix drummondiana* / Mesic Forbs Shrubland (CEGL001192, G4)
- *Salix eriocephala / Ribes aureum - Rosa woodsii* Shrubland (CEGL001233, G3)
- *Salix geyeriana - Salix eriocephala* Shrubland (CEGL001213, GU)
- *Salix geyeriana - Salix lemmonii / Carex aquatilis var. dives* Shrubland (CEGL001212, G3)
- *Salix geyeriana - Salix monticola / Calamagrostis canadensis* Shrubland (CEGL001247, G3)
- *Salix geyeriana - Salix monticola* / Mesic Forbs Shrubland (CEGL001223, G3)
- *Salix geyeriana / Calamagrostis canadensis* Shrubland (CEGL001205, G5)
- *Salix geyeriana / Carex aquatilis* Shrubland (CEGL001206, G3)
- *Salix geyeriana / Carex utriculata* Shrubland (CEGL001207, G5)
- *Salix geyeriana / Deschampsia caespitosa* Shrubland (CEGL001208, G4)
- *Salix geyeriana* / Mesic Forbs Shrubland (CEGL002666, G3)
- *Salix geyeriana* / Mesic Graminoids Shrubland (CEGL001210, G3?)
- *Salix glauca / Deschampsia caespitosa* Shrubland (CEGL001137, G4)
- *Salix lemmonii* / Mesic-Tall Forbs Shrubland (CEGL002771, G3?)
- *Salix lemmonii / Rosa woodsii* Shrubland (CEGL002772, G3)
- *Salix ligulifolia* Shrubland (CEGL001218, G2G3)
- *Salix lucida ssp. caudata / Rosa woodsii* Shrubland (CEGL002621, G3)
- *Salix lucida ssp. caudata* Shrubland (CEGL001215, G3Q)
- *Salix lutea / Calamagrostis canadensis* Shrubland (CEGL001219, G3?)
- *Salix lutea / Carex utriculata* Shrubland (CEGL001220, G4)
- *Salix lutea* / Mesic Forbs Shrubland (CEGL002774, G3?)
- *Salix lutea / Rosa woodsii* Shrubland (CEGL002624, G3)
- *Salix monticola / Angelica ampla* Shrubland (CEGL001221, GNR)
- *Salix monticola / Calamagrostis canadensis* Shrubland (CEGL001222, G3)
- *Salix monticola / Carex aquatilis* Shrubland (CEGL002656, G3)
- *Salix monticola / Carex utriculata* Shrubland (CEGL002657, G3)
- *Salix monticola* / Mesic Forbs Shrubland (CEGL002658, G4)
- *Salix monticola* / Mesic Graminoids Shrubland (CEGL002659, G3)
- *Salix monticola* Thicket Shrubland (CEGL001139, G2Q)

- *Salix planifolia / Calamagrostis canadensis* Shrubland (CEGL001225, G4)
- *Salix planifolia / Caltha leptosepala* Shrubland (CEGL002665, G4)
- *Salix planifolia / Carex aquatilis* Shrubland (CEGL001227, G5)
- *Salix planifolia / Carex scopulorum* Shrubland (CEGL001229, G4)
- *Salix planifolia / Deschampsia caespitosa* Shrubland (CEGL001230, G2G3)
- *Salix planifolia* / Mesic Forbs Shrubland (CEGL002893, G4)
- *Salix planifolia* Shrubland (CEGL001224, G4)
- *Salix wolfii / Carex aquatilis* Shrubland (CEGL001234, G4)
- *Salix wolfii / Carex microptera* Shrubland (CEGL001235, G3Q)
- *Salix wolfii / Carex nebrascensis* Shrubland (CEGL001236, G3Q)
- *Salix wolfii / Carex utriculata* Shrubland (CEGL001237, G4)
- *Salix wolfii / Deschampsia caespitosa* Shrubland (CEGL001238, G3)
- *Salix wolfii / Fragaria virginiana* Shrubland (CEGL001239, G4?)
- *Salix wolfii* / Mesic Forbs Shrubland (CEGL001240, G3)
- *Salix wolfii / Swertia perennis - Pedicularis groenlandica* Shrubland (CEGL001242, G2)
- *Vaccinium caespitosum - (Salix farriae) / Danthonia intermedia* Dwarf-shrubland (CEGL000484, G1G2)

DISTRIBUTION

Range: This system is found throughout the Rocky Mountain cordillera from New Mexico north into Montana and the Canadian Rockies of Alberta and British Columbia (including the isolated "island" mountain ranges of central and eastern Montana), and also occurs in mountainous areas of the Intermountain West and Colorado Plateau.

ROCKY MOUNTAIN SUBALPINE-MONTANE RIPARIAN WOODLAND (CES306.833)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval; RM Subalpine/Montane Riparian Shrubland; Montane [Upper Montane]; Montane [Montane]; Forest and Woodland (Treed); Riverine / Alluvial
Non-Diagnostic Classifiers: Circumneutral Water; Floodplain; Montane [Lower Montane]; Stream terrace (undifferentiated); Valley bottom; Temperate [Temperate Continental]; Needle-Leaved Tree; Broad-Leaved Deciduous Tree; Drainage bottom (undifferentiated)
National Mapping Codes: ESLF 9171

CONCEPT

Summary: This riparian woodland system is comprised of seasonally flooded forests and woodlands found at montane to subalpine elevations of the Rocky Mountain cordillera, from southern New Mexico north into Montana, and west into the Intermountain region and the Colorado Plateau. It occurs throughout the interior of British Columbia and the eastern slopes of the Cascade Mountains. This system contains the conifer and aspen woodlands that line montane streams. These are communities tolerant of periodic flooding and high water tables. Snowmelt moisture in this system may create shallow water tables or seeps for a portion of the growing season. Stands typically occur at elevations between 1500 and 3300 m (4920-10,830 feet), farther north elevation ranges between 900 and 2000 m. This is confined to specific riparian environments occurring on floodplains or terraces of rivers and streams, in V-shaped, narrow valleys and canyons (where there is cold-air drainage). Less frequently, occurrences are found in moderate-wide valley bottoms on large floodplains along broad, meandering rivers, and on pond or lake margins. Dominant tree species vary across the latitudinal range, although it usually includes *Abies lasiocarpa* and/or *Picea engelmannii*; other important species include *Pseudotsuga menziesii*, *Picea pungens*, *Picea engelmannii X glauca*, *Populus tremuloides*, and *Juniperus scopulorum*. Other trees possibly present but not usually dominant include *Alnus incana*, *Abies concolor*, *Abies grandis*, *Pinus contorta*, *Populus angustifolia*, *Populus balsamifera ssp. trichocarpa*, and *Juniperus osteosperma*.

Similar Ecological Systems:
- Northern Rocky Mountain Lower Montane Riparian Woodland and Shrubland (CES306.804)

Related Concepts:
- Blue Spruce: 216 (Eyre 1980) Intersecting. Blue spruce commonly occurs in riparian zones
- Engelmann Spruce - Subalpine Fir: 206 (Eyre 1980) Intersecting. Engelmann spruce occurs as as a dominant in riparian zones.

SOUTH FLORIDA BAYHEAD SWAMP (CES411.366)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Depressional; Broad-Leaved Evergreen Tree
National Mapping Codes: ESLF 9317

CONCEPT

Summary: This ecological system consists of stands of predominately broad-leaved hardwoods which are emergent amidst marshes of the south Florida Everglades region. These areas are often called "tree islands" as they occur on slightly elevated sites above the low-relief marshes. Loveless, writing in 1959, considered them to be "perhaps the most striking botanical feature in the Everglades." Individual islands often have a characteristic shape depending upon the size; large islands are often teardrop-shaped, smaller islands are circular. Patches range in size from one-quarter acre to 300 acres or more. These islands often form an abrupt ecotone with adjacent fire-prone marshes. Fires enter bayhead swamps only under extreme drought conditions and may kill much of the bayhead vegetation and heavily reduce peat accumulation. If left long unburned, bayheads may succeed to hardwood hammocks.

Related Concepts:

- Baygall (FNAI 1990) Undetermined
- Cabbage Palmetto: 74 (Eyre 1980) Finer
- Hydric Hammock (FNAI 1990) Undetermined
- Sweetbay - Swamp Tupelo - Redbay: 104 (Eyre 1980) Finer
- Tropical Hardwoods: 105 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on sites elevated above surrounding marshes; they are inundated 2-6 months during the year, and often found on Gandy Peat soils (Gunderson and Loftus 1993). Tree islands in the northern Everglades occur on acidic, deep peat sites, while southern examples are higher in pH, and shallower peat. Individual islands often have a characteristic shape depending upon the size; large islands are often teardrop-shaped, smaller islands are circular (Loveless 1959, Gunderson and Loftus 1993). Patches range in size from one-quarter acre to 300 acres or more.
Vegetation: Although plant communities in this system have quite similar floristic composition across the Everglades region, there are suggestions that pH and peat depth vary between northern and southern examples, factors which may influence species composition (Loveless 1959). Stands often support a luxuriant ground layer of ferns.
Dynamics: These islands often form an abrupt ecotone with adjacent marshes. Although fires often burn through the marshes, they enter bayhead swamps only under extreme drought conditions. Under these conditions, fires may kill much of the bayhead vegetation and heavily reduce peat accumulation. If left long unburned, bayheads may succeed to hardwood hammocks. Bayheads in some areas are inundated 2-6 months during the year (Gunderson and Loftus 1993), but hydroperiods may vary from 1-4 months in the northern to middle part of Taylor Slough; small, higher areas within a bayhead may never be under water (Olmstead et al. 1980b).

Component Associations:
- *Conocarpus erectus - Metopium toxiferum - Acoelorraphe wrightii / Chrysobalanus icaco* Forest (CEGL007057, G1?)
- *Magnolia virginiana - Persea palustris - Chrysobalanus icaco / Acrostichum danaeifolium - Nephrolepis exaltata* Forest (CEGL007015, G1)
- *Magnolia virginiana - Persea palustris - Chrysobalanus icaco / Cladium mariscus ssp. jamaicense* Woodland (CEGL007016, G1)
- *Quercus laurifolia - Sabal palmetto / Myrsine floridana - Psychotria nervosa* Forest (CEGL007060, G1?)
- *Rhizophora mangle - Taxodium distichum - Metopium toxiferum / Chrysobalanus icaco / Apteria aphylla* Forest (CEGL007454, G1)
- *Roystonea elata - Taxodium distichum - Quercus laurifolia / Psychotria nervosa / Nephrolepis* spp. Forest (CEGL007455, G1)
- *Taxodium distichum / Persea palustris - Fraxinus caroliniana - Chrysobalanus icaco / Blechnum serrulatum* Forest (CEGL007440, G2?)

SOUTH FLORIDA CYPRESS DOME (CES411.365)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Depressional
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2447; ESLF 9116; ESP 1447

CONCEPT

Summary: This system is found primarily in the Everglades and Big Cypress regions. This system consists of small forested wetlands in poorly drained depressions which are underlain by an impervious layer that impedes drainage and traps precipitation. *Taxodium ascendens* is the dominant tree, with the oldest and largest individuals characteristically occupying the center, and smaller and younger individuals around the margins. Pools of stagnant, highly acidic water may stand in the center of these depressions ranging from 1-4 feet in depth, but becoming increasingly shallow along the margins. The understory flora is typified by species with tropical affinities. These ponds are important for many wildlife species.

Related Concepts:

- Dome Swamp (FNAI 1990) Broader
- Pondcypress: 100 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in areas of low relief, occupying poorly drained to permanently wet depressions. Pools of stagnant, highly acidic water may stand in the center of these depressions ranging from 1-4 feet in depth, but becoming increasingly shallow along the margins.

Vegetation: In addition to *Taxodium ascendens*, other taxa that may be present include *Annona glabra, Chrysobalanus icaco, Ficus aurea, Persea palustris*, and *Bacopa caroliniana*.

Dynamics: Cypress domes get their common name from the unique dome-shaped appearance in which trees in the center are higher than those around the sides (Monk and Brown 1965). The water draws down more frequently along the edges than in the deeper center. This allows for more frequent recruitment of *Taxodium ascendens* seedlings along the edges, which are also exposed to more frequent wildland fire than the center of the ponds which remain flooded for longer durations. These two factors are reflected in the presence of large trees in the center and smaller trees closer to the edges of the ponds.

Component Associations:

- *Taxodium ascendens / Annona glabra - Cephalanthus occidentalis - Morella cerifera - Salix caroliniana* Forest (CEGL007415, G2?)
- *Taxodium ascendens / Annona glabra / Bacopa caroliniana* Forest (CEGL007414, G2?)
- *Taxodium ascendens / Chrysobalanus icaco - Ficus aurea - Persea palustris* Forest (CEGL007416, G2?)

SOUTH FLORIDA DWARF CYPRESS SAVANNA (CES411.290)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Woody-Herbaceous; Extensive Wet Flat
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2445; ESLF 9114; ESP 1445

CONCEPT

Summary: The scrub or dwarf cypress system covers extensive areas of south Florida, especially in the Big Cypress Swamp region of southwest Florida. These stunted stands of *Taxodium ascendens* grow on shallow sands or marl soils above limestone bedrock. Individual trees are usually quite small and widely scattered, with canopy coverage ranging from 30-45% (Flohrschutz 1978). The understory shares much overlap with wet prairies of the region (Drew and Schomer 1984) and is dominated by the following genera: *Rhynchospora*, *Cyperus*, *Muhlenbergia*, and *Cladium*. The open, stunted aspect is maintained in part by stresses imposed by extreme seasonal water level changes and low-nutrient soils (Anonymous 1978). Ewel (1990b) suggests a hydroperiod of approximately 6 months for this type.
Classification Comments: Related vegetation occurs in north Florida on clay soils of Tates Hell Swamp.
Related Concepts:
- Marl Prairie (FNAI 1990) Broader
- Pondcypress: 100 (Eyre 1980) Finer

Component Associations:

SOUTH FLORIDA HYDRIC HAMMOCK (CES411.273)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
National Mapping Codes: ESLF 4330

CONCEPT

Summary: This system includes wet hardwood-dominated hammocks occupying flat lowlands in extreme southern Florida. Examples are underlain by limestone substrate. They are wetlands with high water tables and/or ponded surface water, and often mucky soils. Although often found within or adjacent to floodplains, examples of this system are only infrequently subject to overbank flooding. Like other hydric hammocks of Florida, the vegetation is characterized by mixed hardwood species. *Quercus virginiana, Sabal palmetto*, and *Acer rubrum* may be diagnostic, but the flora tends to include some tropical elements that are absent from more northern examples.
Classification Comments: This concept apparently includes low hammocks of Taylor Alexander (A. Johnson pers. comm.).
Related Concepts:
- Cabbage Palmetto: 74 (Eyre 1980) Finer
- Hydric Hammock (FNAI 1990) Broader
- Prairie Hammock (FNAI 1990) Finer

DESCRIPTION

Environment: Examples of this system are associated with limestone-rich sites in southern Florida, often adjacent to floodplains.
Vegetation: Like other hydric hammocks of Florida, the vegetation is characterized by mixed hardwood species (FNAI 1997), although examples of this type have somewhat depauperate canopies when compared with more northern examples (A. Johnson pers. comm.). *Quercus virginiana, Sabal palmetto*, and *Acer rubrum* may be diagnostic; but the flora tends to include some tropical elements that are absent from more northern examples.
Dynamics: The major natural disturbances in hydric hammocks are flooding, fire, grazing or browsing by white tailed deer (*Odocoileus virginianus*) and feral hogs (*Sus scrofa*), and wind damage (Vince et al. 1989). While fires are infrequent in hydric hammocks, fire scars are apparent at many sites, preserved on the trunks of *Sabal palmetto*, which can survive even severe fires (Vince et al. 1989).

Component Associations:
- *Quercus laurifolia - Sabal palmetto / Myrsine floridana - Psychotria nervosa* Forest (CEGL007060, G1?)
- *Sabal palmetto - Quercus laurifolia - Quercus virginiana - Magnolia virginiana - Ulmus americana* Forest (CEGL004674, G2G3)
- *Sabal palmetto - Quercus virginiana - Ulmus americana - Ficus aurea / Acrostichum danaeifolium - Nephrolepis exaltata* Forest (CEGL004409, G2?)

DISTRIBUTION

Range: Endemic to south Florida.
Divisions: 411:C
Nations: US
Subnations: FL

SOUTH FLORIDA MANGROVE SWAMP (CES411.289)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Tidal / Estuarine
National Mapping Codes: ESLF 9304

CONCEPT

Summary: This swamp ecological system of southern Florida occurs along intertidal and supratidal shorelines. The primary species comprising this system are *Rhizophora mangle*, *Avicennia germinans*, *Laguncularia racemosa*, and *Conocarpus erectus*, each with essentially tropical affinities and poor survival in cold temperatures. This system attains best development in low wave-energy, depositional environments. Examples occur on soils generally saturated with brackish water at all times and which become inundated during high tides. The brackish environment tends to limit competition from other species. At least three broad variants of this system can be recognized: riverine mangrove forests, fringe mangrove forests, and basin mangrove forests; all are included here.
Classification Comments: Although at least three broad variants of this system can be recognized, i.e., riverine mangrove forests, fringe mangrove forests, and basin mangrove forests (Lugo et al. 1988), all are included here for now.
Related Concepts:
- Mangrove: 106 (Eyre 1980) Finer
- Tidal Swamp (FNAI 1990) Equivalent

DESCRIPTION

Environment: Mangroves are essentially tropical species that occur only infrequently in areas where the average annual temperature is below 19 degrees Celsius; fluctuations greater than 10 degrees Celsius and short-duration freezes are detrimental to all species. Low-temperature stress leads to decreased height, leaf area, and increased tree density (Odum and McIvor 1990). *Avicennia* is apparently the most cold hardy species, extending as far north as the Gulf Coast (Sherrod and McMillan 1985) and on the Atlantic Coast nearly to the Florida stateline (30 degrees N latitude) (Savage 1972, Odum et al. 1982). *Rhizophora* and *Laguncularia* reach approximately 29 degrees N latitude on both coasts of Florida (Rehm 1976, Teas 1977, Odum et al. 1982). However, the northern limits of all species fluctuate due to short-term climatic swings making exact delineations impossible. Mangroves are also affected by substrate type and wave energy, with best development in low wave-energy, depositional environments; high wave energy prevents establishment and may destroy their shallow root systems (Odum and McIvor 1990). Examples occur on soils generally saturated with brackish water at all times, and which become inundated during high tides (FNAI 1990). The species sometimes sort along salinity gradients, with *Rhizophora* limited to salinities below 60-65 ppt, while *Avicennia* and *Laguncularia* tolerate levels above 80-95 ppt [see references in Odum and McIvor (1990)]. The species employ different strategies to cope with fluctuations and extremes in salinity. Red mangroves exclude salt by a reverse osmosis process, while black and white mangroves use salt glands to excrete excess salts. However, most species may use combined strategies of salt exclusion and excretion (Albert 1975).
Vegetation: The primary species comprising this system are the true mangroves, *Rhizophora mangle*, *Avicennia germinans*, and *Laguncularia racemosa*, as well as the close associate *Conocarpus erectus*. The combined stresses of flooding and salinity tend to result in limited competition (FNAI 1990), lack of plant species richness, and relatively simple stand structure (Mendelssohn and McKee 1988). However, other salt-tolerant species may also be present. Broad classifications of mangroves have included six types (Lugo and Snedaker 1974) and more recently three broad variants (Lugo et al. 1988), i.e., riverine mangrove forests, fringe mangrove forests, and basin mangrove forests [see also Mendelssohn and McKee (1988)].

Component Associations:
- *Acrostichum aureum - (Acrostichum danaeifolium)* Tidal Herbaceous Vegetation (CEGL004899, G3?)
- *Avicennia germinans - (Rhizophora mangle) / Batis maritima* Basin Forest (CEGL007061, G4?)
- *Avicennia germinans / Sarcocornia pacifica* Shrubland (CEGL003802, G3?)
- *Avicennia germinans / Spartina alterniflora* Shrubland (CEGL003801, G2?)
- *Avicennia germinans* Forest (CEGL004827, G5)
- *Conocarpus erectus - (Avicennia germinans) / Borrichia arborescens - Borrichia frutescens / Sporobolus virginicus - Monanthochloe littoralis* Scrub (CEGL003805, G3?)
- *Conocarpus erectus - (Laguncularia racemosa) / Batis maritima - Borrichia frutescens / Sesuvium portulacastrum - Suaeda linearis* Scrub (CEGL003806, G2?)
- *Conocarpus erectus - (Laguncularia racemosa) / Cladium mariscus ssp. jamaicense* Scrub (CEGL003798, G2?)
- *Conocarpus erectus - Metopium toxiferum - Acoelorraphe wrightii / Chrysobalanus icaco* Forest (CEGL007057, G1?)
- *Conocarpus erectus - Rhizophora mangle - Laguncularia racemosa - Metopium toxiferum / Tillandsia* spp. Woodland (CEGL003505, G2)
- *Conocarpus erectus / Sporobolus virginicus - Spartina spartinae* Woodland (CEGL003506, G1?)
- *Conocarpus erectus* Forest (CEGL007600, G3G5)

- *Laguncularia racemosa* Basin Forest (CEGL007063, G3?)
- *Rhizophora mangle - (Avicennia germinans, Laguncularia racemosa) / Acrostichum* spp. Forest (CEGL007067, G2G3)
- *Rhizophora mangle - (Avicennia germinans, Laguncularia racemosa)* Riverine Forest (CEGL007066, G4)
- *Rhizophora mangle - Laguncularia racemosa - Avicennia germinans - Conocarpus erectus / Jacquinia keyensis* Forest (CEGL007053, G2?)
- *Rhizophora mangle / Eleocharis cellulosa* Shrubland (CEGL003800, G3?)
- *Rhizophora mangle* Fringe Forest (CEGL004764, G3G5)
- *Rhizophora mangle* Medium Island Forest (CEGL007603, G5)
- *Rhizophora mangle* Overwash Island Forest (CEGL004765, G3G5)
- *Rhizophora mangle* Scrub (CEGL003803, G5)
- *Sporobolus virginicus - Distichlis spicata* Herbaceous Vegetation (CEGL007663, G5)

DISTRIBUTION

Range: This system is best developed in southern Florida, extending north to approximately 29 degrees N latitude on both coasts.
Divisions: 203:C; 411:C
Nations: US
Subnations: FL
Map Zones: 56:C
TNC Ecoregions: 54:C, 55:C

SOUTH FLORIDA POND-APPLE/POPASH SLOUGH (CES411.486)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: >180-day hydroperiod; Forest and Woodland (Treed); Depressional [Peaty]
National Mapping Codes: ESLF 9195

CONCEPT

Summary: This wetland system of south Florida occupies deep muck soils with long hydroperiods. Examples are dominated by *Fraxinus caroliniana* and/or *Annona glabra*. Aquatic herb species that are also found in other wetland systems of south Florida, such as *Crinum americanum*, *Bacopa caroliniana*, and *Sagittaria graminea*, may also be present (Hilsenbeck et al. 1979, Gunderson and Loope 1982). Examples of this system are important nesting, feeding, and roosting habitats for Everglades wading birds (Hilsenbeck et al. 1979). Large areas of this system that formerly occurred around Lake Okeechobee were cleared for farming around 1900 (Craighead 1971); only small examples still persist in Big Cypress National Preserve and portions of Everglades National Park.
Classification Comments: This system is related to South Florida Slough, Gator Hole and Willow Head (CES411.485) but occupies lower elevations with longer hydroperiods and has different vegetation. As currently conceived, this system includes the pond-apple - willow forests of Hilsenbeck et al. (1979).
Similar Ecological Systems:
- South Florida Slough, Gator Hole and Willow Head (CES411.485)

Related Concepts:
- Slough (FNAI 1990) Broader
- Strand Swamp (FNAI 1990) Undetermined

DESCRIPTION

Environment: Examples occupy some of the deepest muck soils and relatively lowest soil elevations in the Big Cypress National Preserve (Gunderson and Loope 1982).
Dynamics: The successional dynamics of this system are not clearly understood.

Component Associations:
- *Annona glabra - Conocarpus erectus / Acrostichum aureum* Forest (CEGL007617, G2G3)
- *Annona glabra / Crinum americanum - Bacopa caroliniana* Forest (CEGL007055, G1G2)
- *Fraxinus caroliniana / Crinum americanum - Bacopa caroliniana* Forest (CEGL004478, G2G3)

DISTRIBUTION

Range: Endemic to south Florida.
Divisions: 411:C
Nations: US
Subnations: FL
Map Zones: 56:C
TNC Ecoregions: 54:C

SOUTH-CENTRAL INTERIOR / UPPER COASTAL PLAIN WET FLATWOODS (CES203.480)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Extensive Wet Flat; Broad-Leaved Deciduous Tree
Non-Diagnostic Classifiers: Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2457; ESLF 9126; ESP 1457

CONCEPT

Summary: This system represents predominantly wet flatwoods of limited areas of the most inland portions of the East Gulf Coastal Plain in western Kentucky, as well as related broad, flat areas of the western Interior Low Plateau. This part of the Coastal Plain is referred to as the Jackson Purchase or "Jackson Plain." They tend to be confined to relatively small areas near the eastern flank of the region where loess deposits thin out. Unlike South-Central Interior / Upper Coastal Plain Flatwoods (CES203.479) of the same general region (which is typified by complex microtopography), this system occupies broad flats underlain by fragipans. These fragipans impede the downward migration of water, resulting in wet conditions for portions of the year. Fire was important, probably maintaining relatively open-canopied stands. Stands are dominated by hardwood trees, including *Acer rubrum, Fagus grandifolia, Liquidambar styraciflua, Quercus falcata, Quercus pagoda*, and *Quercus palustris*.
Classification Comments: The primary range of this system is limited areas of the "Jackson Purchase" or "Jackson Plain" of Kentucky and possibly related areas in adjacent western Tennessee, as well as related broad, flat areas of the western Interior Low Plateau. According to Bryant and Martin (1988) the "Flatwoods" portion of the Jackson Purchase (which is primarily where the "Wet Flatwoods" are located in that area) occupies less than 2% of the total area, but localized occurrences could have been present in other parts of the region. These apparently related wet flatwoods in the western end of the Moulton Valley of Alabama are found in northeastern Franklin and extreme western Lawrence counties, from 10 to 20 km east of Russellville. More information is needed. In Alabama, this system is apparently found in the Moulton Valley region (A. Schotz pers. comm. 2006), which is technically part of TNC Ecoregion 50 but ambiguously placed there.
Similar Ecological Systems:
- Interior Highlands Unglaciated Flatwoods (CES202.454)
- South-Central Interior / Upper Coastal Plain Flatwoods (CES203.479)

Related Concepts:
- Flatwoods (Evans 1991) Intersecting
- Pin Oak - Sweetgum: 65 (Eyre 1980) Finer
- Sweetgum - Willow Oak: 92 (Eyre 1980) Finer

DESCRIPTION

Environment: These flatwoods have long been recognized as the primary vegetation type of a distinctive subdivision within the Upper East Gulf Coastal Plain region (Davis 1923, Bryant and Martin 1988), as well as related areas of the western Interior Low Plateau. Within the "Jackson Plain" portion of the Upper East Gulf Coastal Plain, these flatwoods tend to be confined to relatively small areas near the eastern flank of the "Jackson Plain" region where the loess deposits thin out. Like drier *Quercus stellata* flatwoods of these areas (which are typified by microtopographic variation), this system occupies broad flats underlain by fragipans. These fragipans impede the downward migration of water resulting in wet conditions for longer portions of the year. In the Jackson Plain area the soils include Henry silt loam, Routon silt loam (Bryant and Held 2001) and Calloway silt loam (Karathanasis et al. 2003). Fire is probably relatively infrequent in this system (M. Evans pers. comm.). In the Pennyroyal Plain, this system occurs on upland flats and depressions with poor drainage, underlain by limestone; soils include Robertsville silt loam (Chester et al. 1995) and Henry silt loam (M. Evans pers. comm.).
Vegetation: Stands are typically dominated by various combinations of oaks and other hardwoods, including *Quercus pagoda, Quercus stellata, Carya ovata, Prunus serotina, Diospyros virginiana, Ulmus alata, Ulmus americana, Quercus palustris* (Bryant 1999), *Quercus michauxii, Liquidambar styraciflua, Carya* spp., *Nyssa sylvatica*, and *Acer rubrum* (Chester et al. 1995). Most stands of this system have been severely altered or destroyed, and the characteristic herbs are poorly known. *Campsis radicans* may be found, along with *Carex* spp., including *Carex leptalea* and *Carex cherokeensis*. Other herbs may include *Leersia* spp. and *Cardamine bulbosa*. *Quercus phellos* and/or *Quercus lyrata* may also be present in stands of this system in Kentucky (M. Evans pers. comm. 2006). Some stands placed here are dominated by *Quercus falcata* (e.g., at Shiloh National Military Park), others (e.g., in the Moulton Valley of Alabama) by a combination of *Quercus phellos* and *Quercus nigra* (A. Schotz pers. comm. 2006).
Dynamics: Fire was an important but relatively infrequent natural process in this system, probably maintaining relatively open-canopied stands (M. Evans pers. comm.). Under such conditions *Andropogon gerardii* and *Chasmanthium* spp. may have dominated the herbaceous ground cover. Flooding and saturation are part of the natural dynamics. Due to the fragipan, deep rooting of trees is limited and the trees are particularly prone to windthrow during storms. This has helped maintain open woodland conditions.

Component Associations:
- *Quercus falcata* Flatwoods Forest (CEGL004412, G2?)
- *Quercus palustris - (Quercus stellata) - Quercus pagoda / Isoetes* spp. Forest (CEGL002101, G2G3)
- *Quercus phellos - (Quercus lyrata) / Carex* spp. - *Leersia* spp. Forest (CEGL002102, G3G4Q)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- East Gulf Coastal Plain Northern Loess Plain Oak-Hickory Upland (CES203.482)

DISTRIBUTION

Range: The primary range of this system is limited areas of the "Jackson Purchase" or "Jackson Plain" of Kentucky and possibly related areas in adjacent western Tennessee, as well as related broad, flat areas of the western Interior Low Plateau. Examples in the Pennyroyal Plain (of the western Interior Low Plateau) have been known for many years and referred to as "pondywoods" or "crawfishy land" (Chester et al. 1995). They are also known from the Shawnee Hills of Kentucky, on periglacial lakebeds (M. Evans pers. comm. 2006), and related wet flatwoods have been discerned from wetland modeling and confirmed in the Moulton Valley of Alabama (A. Schotz pers. comm. 2006) and are included here. It is assumed to cross the Ohio River into adjacent Indiana.

SOUTHEASTERN COASTAL PLAIN NATURAL LAKESHORE (CES203.044)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Woody-Herbaceous; Depressional [Pond]; Coastal plain
National Mapping Codes: ESLF 9167

CONCEPT

Summary: This system consists of wetland vegetation along large natural lakeshores in the Outer Coastal Plain of the southeastern United States. Natural lakes are generally rare features throughout most of this region. However, examples range northward to the Atlantic Coastal Plain in southeastern Virginia and North Carolina, but no examples are known from South Carolina and Georgia. However examples are present in Florida, where they are apparently found on smaller lakes than those to the north. Hydroperiod remains relatively constant from year to year, especially when compared to smaller limesink depressions of the region. Vegetation may appear to be zonal in relationship to distance from the lakeshore and may range from open water or floating-leaved aquatics in the deeper waters of the lakes, to emergent marsh zones along the edges. In some cases there are wet hardwood swamps present.
Classification Comments: This system is related to Southern Atlantic Coastal Plain Depression Pondshore (CES203.262) which is found primarily on limesink depressions that are smaller in scale and have greater hydrologic fluctuation. This system is also related to Atlantic Coastal Plain Clay-Based Carolina Bay Wetland (CES203.245) in that some of the natural lake basins it occurs on are thought to be Carolina bays (Bennett and Nelson 1991).
Similar Ecological Systems:
- Atlantic Coastal Plain Clay-Based Carolina Bay Wetland (CES203.245)
- Southern Atlantic Coastal Plain Depression Pond (CES203.262)

- Lacustrine (FNAI 2010a) Intersecting
- Open Water Lake (Bennett and Nelson 1991) Finer
- Sinkhole Lake (FNAI 1990) Intersecting

DESCRIPTION

Environment: Occurs along the edges of lakes, where the water is flooded for long durations, but may dry out during dry summer months, or during drought.
Dynamics: Long hydroperiod flooding is characteristic of these wetlands which occur along the shore of coastal plain natural lakes. Most of these habitats are naturally nutrient-poor.

Component Associations:
- *Adiantum capillus-veneris / Concocephalum salebrosum* Herbaceous Vegetation (CEGL004515, G1Q)
- *Cyrilla racemiflora - Lyonia lucida* Shrubland (CEGL003844, G3?)
- *Liquidambar styraciflua / Persea palustris* Forest (CEGL004481, G1)
- *Nuphar sagittifolia - Eriocaulon aquaticum* Lakeshore Herbaceous Vegetation (CEGL004297, G1)
- *Nymphaea odorata - Nuphar advena - (Nymphoides aquatica, Xyris smalliana)* Herbaceous Vegetation (CEGL004326, G3?)
- *Panicum hemitomon - Eleocharis equisetoides - Rhynchospora inundata* Herbaceous Vegetation (CEGL004127, G3)
- *Panicum hemitomon - Juncus* spp. Coastal Plain Lakeshore Herbaceous Vegetation (CEGL004307, G1)
- *Panicum hemitomon - Pluchea (camphorata, rosea) - Ludwigia* spp. Herbaceous Vegetation (CEGL007792, G3)
- *Taxodium distichum - Liquidambar styraciflua - Platanus occidentalis / Asimina triloba* Forest (CEGL004424, G1?)
- *Taxodium distichum - Taxodium ascendens / Panicum hemitomon - Sclerolepis uniflora* Woodland (CEGL004465, G1)
- *Taxodium distichum - Taxodium ascendens / Panicum hemitomon* Woodland (CEGL004466, G3?)
- *Taxodium distichum / Cephalanthus occidentalis / Juncus repens* Woodland (CEGL004653, G1?)

DISTRIBUTION

Range: This system is found in the Outer Coastal Plain of Virginia (apparently from a single site, Lake Drummond) and North Carolina, apparently absent from South Carolina and Georgia, but examples are present in Florida (i.e., Ocean Pond on Osceola National Forest).

SOUTHEASTERN GREAT PLAINS FLOODPLAIN FOREST (CES205.710)

CLASSIFIERS

Classification Status: Standard

Primary Division: Eastern Great Plains (205)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Deep (>15 cm) Water; Intermediate (5-25 yrs) Flooding Interval; Forest and Woodland (Treed); Herbaceous; Riverine / Alluvial
National Mapping Codes: ESLF 4160

CONCEPT

Summary: This ecological system is found in the floodplains of medium and larger rivers of the East Central Texas Plains, Texas Blackland Prairie Regions, Crosstimbers, and the southeastern edge of the Central Great Plains (Level 3 Ecoregions 33, 32, 29 and 27 respectively). Alluvial soils and sedimentation processes typify this system. Periodic, intermediate flooding and deposition (every 5-25 years) dominates the formation and maintenance of this system. Dominant communities within this system range from floodplain forests to wet meadows to gravel/sand flats; however, they are linked by underlying soils and the flooding regime. Canopy dominants may include *Carya illinoinensis, Ulmus crassifolia, Ulmus americana, Celtis laevigata, Quercus nigra, Platanus occidentalis, Acer negundo, Quercus macrocarpa, Morus rubra, Fraxinus pennsylvanica, Salix nigra*, and Sapindus *saponaria var. drummondii (= Sapindus drummondii)*. Overgrazing and/or overbrowsing may influence recruitment of overstory species and composition of the understory and herbaceous layers. Shrub species may include *Callicarpa americana, Ilex decidua, Sideroxylon lanuginosum, Diospyros virginiana, Juniperus virginiana, Cornus drummondii*, and *Viburnum rufidulum*, which may occur as dense patches following disturbance, but are otherwise generally fairly sparse. Vines such as *Berchemia scandens, Campsis radicans, Vitis* spp., *Parthenocissus quinquefolia*, and *Ampelopsis arborea* may be conspicuous. Herbaceous cover includes *Elymus virginicus, Verbesina virginica, Chasmanthium latifolium, Chasmanthium sessiliflorum, Tripsacum dactyloides, Symphyotrichum drummondii var. texanum, Geum canadense, Sanicula canadensis, Panicum virgatum, Galium* spp., and *Carex* sp. Herbaceous cover may be quite high, especially in situations where shrub cover is low. The environment and vegetation of this system become generally and correspondingly drier from east to west with moister representatives (such as communities containing *Quercus phellos, Quercus pagoda, Quercus alba*, and *Quercus lyrata*) occurring along the eastern and northeastern margins of the range. Representatives of this system may vary in the openness of the habitat and physiognomy.
Classification Comments: More data are needed to determine if this system should be split and a new system developed for the southern parts of Ecoregion 32 and 33 (*sensu* EPA; Griffith et al. 2004), south of the Brazos or Colorado rivers. Further field investigation is needed to better develop the association-level information for this system. This system grades into Edwards Plateau Floodplain (CES303.651) but can be distinguished by the absence or low cover of western species such as *Juglans major, Juglans microcarpa, Juniperus ashei, Mahonia trifoliolata (= Berberis trifoliolata), Sapindus saponaria var. drummondii*, and the presence or higher cover of more eastern species such as *Maclura pomifera, Ilex decidua, Ilex vomitoria, Quercus nigra, Ulmus americana*, and *Juniperus virginiana*. Species common in both systems include *Ulmus crassifolia, Carya illinoinensis, Platanus occidentalis*, and *Celtis laevigata*. More information is need to better differentiate these systems.

Along the Red River and a few of its tributaries, thin bands of riparian vegetation occurring on sandy floodplain terraces, bluffs and sandbars are significantly different in species composition from riparian communities elsewhere in the region. The floodplains of the Red River have been recognized as a separate system (Red River Large Floodplain Forest (CES203.065)). Occurrences may include *Salix* spp. (especially *Salix exigua*), *Acer saccharinum* (which probably does not occur in any other basin in Texas), *Juniperus virginiana*, and *Populus deltoides*. Adjacent slopes and higher floodplain terraces support woodlands of *Juniperus virginiana, Quercus macrocarpa, Quercus shumardii, Quercus muehlenbergii, Fraxinus texensis, Cornus drummondii*, and *Viburnum rufidulum*.
Similar Ecological Systems:
- Edwards Plateau Floodplain Terrace (CES303.651)
- Western Great Plains Floodplain (CES303.678)

- Silver Maple - American Elm: 62 (Eyre 1980) Finer
- Sugarberry - American Elm - Green Ash: 93 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occupies relatively broad flats at low topographic positions, along large streams where alluvial deposition dominates. Rivers such as the Sulphur (and tributaries such as White Oak and Cuthand creeks), Sabine (and Lake Fork), Trinity (and its major tributaries), Navasota, and portions of the Lower and Middle Brazos (and its major tributaries), Colorado, Guadalupe, Lavaca, Navidad, and San Antonio rivers may support this system. The geological setting is Quaternary Alluvium (Elliott 2011). It is found in the floodplains of medium and larger rivers of the East Central Texas Plains, Texas Blackland Prairie Regions, Cross Timbers, and the southeastern edge of the Central Great Plains (Level 3 Ecoregions 33, 32, 29 and 27, respectively, *sensu* Griffith et al. (2004)). Bottomland Ecological Sites (including Loamy, Sandy, and Clayey) characterize this system. Soils are primarily alluvial and range from sandy to dense clays.

Vegetation: Dominant communities within this system range from floodplain forests to wet meadows to gravel/sand flats; however, they are linked by underlying soils and the flooding regime. Canopy dominants may include *Carya illinoinensis, Fraxinus americana, Quercus nigra, Ulmus crassifolia, Celtis laevigata, Ulmus americana, Quercus fusiformis* or *Quercus virginiana, Platanus occidentalis, Acer negundo, Gleditsia triacanthos, Quercus macrocarpa, Morus rubra, Fraxinus pennsylvanica*, and *Sapindus saponaria var. drummondii*. Especially along river margins, species such as *Platanus occidentalis, Populus deltoides*, and *Salix nigra* may dominate. In this eastern part of the range of the system, *Liquidambar styraciflua, Quercus phellos*, and *Betula nigra* may also be commonly encountered. Seasonally flooded sites, especially within the Trinity River basin, may have *Quercus lyrata* as an overstory component. Overgrazing and/or overbrowsing may influence recruitment of overstory species and composition of the understory and herbaceous layers. Shrub species may include *Callicarpa americana, Cephalanthus occidentalis, Ilex decidua, Ilex vomitoria, Sideroxylon lanuginosum, Diospyros virginiana, Vaccinium arboreum, Juniperus virginiana, Cornus drummondii*, and *Viburnum rufidulum* which may occur as dense patches following disturbance, but are otherwise generally fairly sparse. In the southern expressions of the system, other shrubs such as *Prosopis glandulosa, Acacia farnesiana, Diospyros texana*, and *Condalia hookeri* may be commonly encountered. Vines such as *Berchemia scandens, Campsis radicans, Vitis* spp., *Parthenocissus quinquefolia, Toxicodendron radicans, Smilax bona-nox*, and *Ampelopsis arborea* may be conspicuous. Herbaceous cover includes *Elymus virginicus, Verbesina virginica, Chasmanthium latifolium, Chasmanthium sessiliflorum, Carex cherokeensis, Tripsacum dactyloides, Symphyotrichum drummondii var. texanum, Calyptocarpus vialis, Geum canadense, Sanicula canadensis, Ambrosia trifida, Panicum virgatum, Galium* spp., *Teucrium canadense*, and *Carex* spp. Wetter sites may contain species such as *Zizaniopsis miliacea, Rhynchospora* spp., *Eleocharis* spp., *Nymphaea odorata*, and *Peltandra virginica*. In early-successional states, growth rates among species are variable with species such as *Acer negundo* having rapid growth rate and species such as *Quercus macrocarpa* growing more slowly. There may be an open canopy resulting from flood events and rare fire events. The environment and vegetation of this system become generally and correspondingly drier from east to west with moister representatives (such as communities containing *Quercus phellos, Quercus pagoda, Quercus alba*, and *Quercus lyrata*) occurring along the eastern and northeastern margins of the range. Non-native grasses that may dominate these sites include *Cynodon dactylon, Bothriochloa ischaemum var. songarica*, and *Sorghum halepense*. Herbaceous cover may be quite high, especially in situations where shrub cover is low. The non-native trees *Triadica sebifera* and *Melia azedarach* may be present.

Dynamics: Periodic and intermediate flooding is the most significant process controlling this system and is expected every 5 to 25 years. Grazing and conversion to agriculture can significantly impact this system and can lead to the degradation or extirpation of the majority of prairie and wet meadow communities from this system. Fire occurs infrequently relative to surrounding systems. Fuels tend to stay moister due to shady conditions and low topographic position. Other disturbances include ice storm/blowdowns, which are capable of setting back small to large patches; as well as beaver pond flooding, which even though a small-patch event, is expected to cycle throughout the forest over the long term, perhaps at a scale of hundreds or thousands of years.

Component Associations:

- *Fraxinus pennsylvanica - Ulmus crassifolia - Celtis laevigata* Forest (CEGL004618, GNR)
- *Quercus macrocarpa - Carya illinoinensis / Cornus drummondii - Frangula caroliniana* Forest (CEGL004196, GNR)
- *Ulmus americana - Celtis (laevigata, occidentalis) - Fraxinus pennsylvanica* Forest (CEGL002090, G3?)
- *Ulmus crassifolia - Carya illinoinensis - Celtis laevigata / Chasmanthium sessiliflorum - Carex cherokeensis* Forest (CEGL002388, G2G3)

SPATIAL CHARACTERISTICS

Spatial Summary: The scale of occurrences is wider and longer than the equivalent riparian system and can be hundreds to the low tens of thousands of acres.

Adjacent Ecological Systems:

- Central Texas Coastal Prairie River Floodplain (CES203.713)
- Southeastern Great Plains Riparian Forest (CES205.709)

Adjacent Ecological System Comments: The equivalent riparian woodland/forest system occurs along upper reaches of streams where streamflows become intermittent and alluvial deposits are thinner. Like other wooded wetland systems, this tends to blend into riparian systems as streams become smaller upstream.

DISTRIBUTION

Range: This system is found along major river floodplains in the East Central Texas Plains, Texas Blackland Prairie Regions, Crosstimbers, and the southeastern edge of the Central Great Plains (Level 3 Ecoregions 33, 32, 29 and 27, respectively, *sensu* Griffith et al. (2004)). Rivers such as the Sulphur (and tributaries such as White Oak and Cuthand creeks), Sabine (and Lake Fork), Trinity (and its major tributaries), Navasota, portions of the Lower and Middle Brazos rivers (and major tributaries), portions of the middle

and upper Red River, and portions of the Guadalupe, Colorado, and San Antonio rivers downstream of the Edwards Plateau ecoregion may support this system.

SOUTHEASTERN GREAT PLAINS RIPARIAN FOREST (CES205.709)

CLASSIFIERS

Classification Status: Standard

Primary Division: Eastern Great Plains (205)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Shrubland (Shrub-dominated); Woody-Herbaceous; Herbaceous; Streambed; Flood Scouring
National Mapping Codes: ESLF 4159

CONCEPT

Summary: This ecological system occurs in various situations along small and intermittent streams in the East Central Texas Plains, Texas Blackland Prairie Regions, Crosstimbers, and the southeastern edge of the Central Great Plains (Level 3 Ecoregions 33, 32, 29 and 27, respectively, *sensu* Griffith et al. (2004)). Some trees that may be present in stands of this system include *Celtis laevigata var. laevigata, Celtis laevigata var. reticulata, Platanus occidentalis, Quercus nigra, Quercus phellos, Amorpha fruticosa, Forestiera acuminata, Acer saccharinum, Sapindus saponaria, Salix nigra, Fraxinus pennsylvanica, Gleditsia triacanthos, Carya illinoinensis*, and *Ulmus crassifolia*. The environment and vegetation of this system become generally and correspondingly drier from east to west with moister representatives (such as communities containing *Quercus nigra*) occurring in the eastern parts of the range. Representatives of this system typically occur in stream-scoured situations and vary in the openness of the habitat and physiognomy.
Classification Comments: More data are needed to determine if this system should be split and a new system developed for the southern parts of Ecoregion 32 and 33 (sensu EPA; Griffith et al. 2004), south of the Brazos or Colorado rivers. Further field investigation is needed to better develop the association-level information for this system.

DESCRIPTION

Environment: This system occurs on minor intermittent streams and tributaries throughout the East Central Texas Plains, Texas Blackland Prairies, Cross Timbers, and the southeastern edge of the Central Great Plains (Level 3 Ecoregions 33, 32, 29 and 27 respectively, sensu Griffith et al. (2004)). As defined, this system occupies buffer zones of headwater streams, and soils develop in place over a variety of geologic surfaces (Elliott 2011). It is found along medium to very small, intermittent to ephemeral drainages. These include the valleys and drainages along headwater streams of the Sulphur, Sabine, Navasota, Brazos, upper Trinity rivers, and middle portions of the Guadalupe and San Antonio river basins, typically in areas with erosional processes dominating over alluvial deposition. In the Trinity River basin, occurrences were mapped upstream of approximately the Leon/Madison countyline, near the confluence with Cobb Creek. This type is ubiquitous throughout, but species composition and flood regimes are variable and are thought to be dependent on soil and geologic substrates. Generally, these are less thick alluvium than in floodplain terraces. By definition, this system is mapped along drainages upstream of the Bottomland Ecoclasses, so they will be mapped on soils of the surrounding uplands.
Vegetation: Trees that may be present in stands of this system include *Celtis laevigata, Ulmus crassifolia, Platanus occidentalis, Populus deltoides, Quercus fusiformis, Quercus nigra, Quercus phellos, Sapindus saponaria var. drummondii, Salix nigra, Fraxinus americana, Fraxinus pennsylvanica, Gleditsia triacanthos, Prosopis glandulosa*, and *Carya illinoinensis*. Height of vegetation is variable on an east-to-west moisture gradient. To the east, *Quercus falcata* and *Liquidambar styraciflua* may become important components of the overstory. To the east, evergreen-dominated occurrences may contain *Pinus taeda* or *Pinus echinata*, as well as *Juniperus virginiana*. The shrub layer development is variable, sometimes with species such as *Amorpha fruticosa, Forestiera acuminata, Ilex decidua, Ilex vomitoria, Sideroxylon lanuginosum, Juniperus virginiana, Diospyros virginiana, Cornus drummondii, Condalia hookeri, Acacia farnesiana*, and/or *Viburnum rufidulum*. A few sites may be shrub-dominated without an overstory canopy, containing species such as *Forestiera acuminata, Cephalanthus occidentalis, Acacia farnesiana*, or *Sesbania drummondii*. Herbaceous cover is also variable, depending on overstory and shrub canopies and recent flooding history. Herbaceous species may include

Andropogon glomeratus, Panicum virgatum, Elymus virginicus, Verbesina virginica, Chasmanthium latifolium, Chasmanthium sessiliflorum, Tripsacum dactyloides, Symphyotrichum drummondii var. texanum, Clematis pitcheri, Amphiachyris dracunculoides, Ambrosia psilostachya, Geum canadense, Sanicula canadensis, Justicia americana Galium spp., and *Carex* spp. Upland species such as *Schizachyrium scoparium, Nassella leucotricha,* and *Sorghastrum nutans* may be common. Herbaceous species may occur as clumps or as a continuous herbaceous layer, this being controlled by soil development. Some early-successional stands may have *Amorpha fruticosa* as a dominant woody species, comprising up to 50% of the canopy cover. Woody vines such as *Smilax bona-nox, Toxicodendron radicans, Ampelopsis arborea*, and *Vitis* spp. may be common.

The environment and characteristics of the vegetation of this system become drier from east to west, with moister representatives (such as communities containing *Quercus nigra*) occurring in the eastern parts of the range. There are many plant communities which make up this system; *Amorpha* is typical in some locales. It is likely that other communities have a shrubby successional stage which may include *Forestiera acuminata, Prunus rivularis,* and tree seedlings and saplings of later-successional communities (J. Eidson pers. comm. 2007). Non-native grass species that may be common to dominant on these sites include *Arundo donax, Cynodon dactylon,* and *Sorghum halepense*. The non-native species such as *Ligustrum* spp. and *Triadica sebifera* may be commonly encountered (Elliott 2011).

Dynamics: These are flashy streams, and flooding rather than fire will be the dominant process in this system. Fuels in this system are variable, and fire-return interval is partially determined by that of the adjacent and surrounding matrix upland system, where fuels are present.

Spatial Characteristics

Adjacent Ecological Systems:

- Southeastern Great Plains Floodplain Forest (CES205.710)
- Western Great Plains Riparian (CES303.956)

Distribution

Range: This system is found along major river floodplains in the East Central Texas Plains, Texas Blackland Prairie Regions, Crosstimbers, and the southeastern edge of the Central Great Plains (Level 3 Ecoregions 33, 32, 29 and 27, respectively, *sensu* Griffith et al. (2004)). Occurrences of this system occupy drainages of the Sulphur (and tributaries such as White Oak and Cuthand creeks), Sabine (and Lake Fork), Trinity (and its major tributaries), Navasota, and portions of the Lower and Middle Brazos rivers (and major tributaries).

SOUTHERN AND CENTRAL APPALACHIAN BOG AND FEN (CES202.300)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Fen; Shrubland (Shrub-dominated); Depressional; Bog
Non-Diagnostic Classifiers: Graminoid
National Mapping Codes: ESLF 9309

CONCEPT

Summary: This system consists of wetlands associated with flat sites in the Southern Blue Ridge, Central Appalachians, Cumberland Mountains, and possibly upper Piedmont and adjacent Ridge and Valley. These sites occur at elevations below 1220 m (4000 feet) in poorly drained bottomlands on soils which are often saturated and mucky. Wetness results from a combination of groundwater input, seepage from adjacent slopes, rainfall and impeded drainage. The amount of seepage water input is variable among examples, and these wetlands are typically primarily depressional. Vegetation is at least partially open, with herbaceous-dominated areas as well as shrub thickets and often forested zones. Vegetation is a complex of zones or patches with a mix of physiognomies. The wettest areas have herbaceous vegetation dominated by *Carex* spp., usually with abundant *Sphagnum*. Scattered trees and shrubs may be present in the herbaceous zones. Most examples also have a dense shrub zone around the edges. Some examples have forested zones as well, around the edges or as a matrix in which numerous small herbaceous openings are embedded. Characteristic tree species are *Tsuga canadensis, Acer rubrum, Nyssa sylvatica,* and *Pinus rigida*. Characteristic tree species are *Tsuga canadensis, Acer rubrum, Nyssa sylvatica,* and *Pinus rigida*. Characteristic shrubs include *Rhododendron maximum, Alnus serrulata, Viburnum nudum var. cassinoides,* and *Toxicodendron vernix*.
Classification Comments: This system includes communities known locally as either "bogs" or "fens," but it is uncertain as to how their hydrology and soils relate to the definitions of these terms as used in other regions. Bogs are typically defined as rainwater-fed peatlands, and fens as groundwater-fed peatlands, ranging from poor to rich, with from weakly minerotrophic to strongly minerotrophic groundwater, respectively. In the Southern Appalachians, there are a few examples with obvious calcareous groundwater input, but more often the vegetation and flora are more characteristic of northern poor fens than either "bogs" or northern "rich fens," although mossy peat layers may be relatively thin. All of these wetland associations are placed in the same system despite the variation in vegetation dominance and uncertainly about the hydrology and soils.

This system is distinguished from Southern Appalachian Seepage Wetland (CES202.317) by patterns of flora and vegetation. Though both systems have heterogeneous and variable vegetation, they share few or no associations. The setting also differs, with Southern and Central Appalachian Bog and Fen (CES202.300) occurring on flat sites such as valley bottoms, where impeded drainage is important, while the seeps occur on sloping sites where water flow is freer and more groundwater flow is needed to create a wetland. High-elevation wetlands in West Virginia are placed in High Allegheny Wetland (CES202.069).

Similar Ecological Systems:
- High Allegheny Wetland (CES202.069)
- Southern Appalachian Seepage Wetland (CES202.317)

- Southern Appalachian Bog (Schafale and Weakley 1990) Intersecting

DESCRIPTION

Environment: This system occurs in patches in flat valley bottoms, usually on the outer edges of stream floodplains at elevations below 1220 m (4000 feet). The soil is saturated most or all of the year, at least in the wettest parts, and may be very mucky. Although sites rarely flood, wetness results from a combination of groundwater input, rainfall, seepage from adjacent slopes, and impeded drainage. The groundwater is usually highly acidic and low in dissolved bases, but one or a few examples have somewhat calcareous water input because groundwater flows through mafic rock substrates. Overland flow and stream flooding are presumably only rare events. The geologic substrate is usually alluvium. Often, but not always, there is an adjacent slope with a seep at its base or some visible microtopographic feature, such as a stream levee or ridge, that impedes water drainage out of the area. Some occurrences have substantial microtopography of abandoned stream channels or ridge-and-swale systems that pond water in low areas.
Vegetation: Vegetation is a complex of zones or patches with a mix of physiognomies. The wettest areas have herbaceous vegetation dominated by *Carex* spp., usually with abundant *Sphagnum*. Scattered trees and shrubs may be present in the herbaceous zones. Most examples also have a dense shrub zone around the edges. Some examples have forest zones as well, around the edges or as a matrix in which numerous small herbaceous openings are embedded. Characteristic tree species are *Tsuga canadensis, Acer rubrum, Nyssa sylvatica,* and *Pinus rigida*. Characteristic shrubs include *Rhododendron maximum, Alnus serrulata, Viburnum nudum var. cassinoides,* and *Toxicodendron vernix*. A number of plant species are shared with northern bogs, including some that are disjunct

long distances and occur in the south only in bogs. Other species are narrow endemics, such as *Sarracenia rubra ssp. jonesii*. In the more southern examples, some species are shared with bog communities in the Coastal Plain. The very rare richer fen examples have very distinctive vegetation, sharing a number of species with northern rich fens.

Dynamics: The natural dynamics of this system are not well known and are subject to debate. The factors that created and naturally maintain this system are unclear. Most examples show a strong tendency at present for shrubs and trees to increase in density in the open areas, threatening to eliminate the characteristic herb species. This suggests that an important process has been altered or lost. One hypothesis is that bogs are an ephemeral feature developing from abandoned beaver ponds. Another hypothesis is that they result from a narrow combination of moisture and nutrient conditions, which have been widely altered in an obscure way that has changed ecosystem stability. The cattle grazing that was nearly universal in examples of this system in the past appears to have delayed woody succession but may also have altered the natural characteristics. Fire is sometimes considered as a factor, but most examples do not appear flammable enough to burn. Besides woody encroachment, bogs may be altered by changes in adjacent drainage, such as entrenchment by streams.

- *Spiraea alba var. latifolia - Cornus racemosa / Calamagrostis canadensis - Sanguisorba canadensis - Carex scoparia* Shrub Herbaceous Vegetation (CEGL006249, G1)
- *Tsuga canadensis - Acer rubrum - (Liriodendron tulipifera, Nyssa sylvatica) / Rhododendron maximum / Sphagnum* spp. Forest (CEGL007565, G2)

SPATIAL CHARACTERISTICS

Spatial Summary: Small-patch system, from one to several acres in size.

Size: Occurs as small patches, from about one acre to several acres. The largest examples are swamp forest-bog complexes that may cover 10 or more acres. Except for the small openings in the swamp forest-bog complexes, bog and fen patches tend to occur singly or in small clusters only.

Adjacent Ecological Systems:

- Southern and Central Appalachian Cove Forest (CES202.373)
- Southern Appalachian Northern Hardwood Forest (CES202.029)

Adjacent Ecological System Comments: Usually associated with Southern and Central Appalachian Cove Forest (CES202.373).

DISTRIBUTION

Range: This system ranges from the southern Appalachians of northern Georgia and South Carolina north to Virginia. It is also found in the Cumberland Mountains of Kentucky.
Divisions: 202:C

SOUTHERN ATLANTIC COASTAL PLAIN LARGE RIVER FLOODPLAIN FOREST (CES203.066)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Riverine / Alluvial [Brownwater]
National Mapping Codes: ESLF 9313

CONCEPT

Summary: This system represents a geographic subset of Southern Floodplain Forest. Examples may be found along large rivers of the Atlantic Coastal Plain, especially the Roanoke, Great Pee Dee, Congaree/Santee, Savannah, and Altamaha rivers. Several distinct plant communities can be recognized within this system that may be related to the array of different geomorphologic features present within the floodplain. Some of the major geomorphic features associated with different community types include natural levees, point bars, meander scrolls, oxbows, and sloughs. Vegetation generally includes forests dominated by bottomland hardwood species and other trees tolerant of flooding. However, herbaceous and shrub vegetation may be present in certain areas as well.
Classification Comments: This system has some overlap in associations with CES203.489, but many more are not in common. In addition "...most, if not all, associations in the system are shared with Atlantic Coastal Plain Small Brownwater River Floodplain Forest (CES203.250). The main difference is in the scale of landscape pattern, but the extent and relief of fluvial landforms like natural levees and backswamps and the general flooding dynamics also differ" (M. Schafale pers. comm.).

DESCRIPTION

Environment: This system represents a geographic subset of Kuchler's (1964) Southern Floodplain Forest. Examples of this system are generally forested with stands of bottomland hardwood species and other trees tolerant of flooding. Local composition varies depending upon actual position within the floodplain, disturbance history, and underlying soils and geology. Some of the major geomorphic features associated with different community types include natural levees, point bars, meander scrolls, oxbows, and sloughs (Sharitz and Mitsch 1993). Although most examples of this system may be thought of as acidic, some examples of this system flow through regions with sufficient calcareous influence to effect vegetation composition.
Vegetation: Trees dominating stands of this system can include *Acer negundo, Acer rubrum var. rubrum, Acer rubrum var. drummondii, Acer saccharinum, Betula nigra, Carya aquatica, Celtis laevigata, Fraxinus caroliniana, Fraxinus pennsylvanica, Liquidambar styraciflua, Liriodendron tulipifera, Nyssa aquatica, Nyssa biflora, Nyssa ogeche, Platanus occidentalis, Populus deltoides, Quercus laurifolia, Quercus michauxii, Salix nigra,* and *Ulmus americana*. Some disturbed stands may contain *Pinus taeda*. Shrubs and small trees can include *Alnus serrulata, Asimina triloba, Carpinus caroliniana, Cephalanthus occidentalis, Cornus foemina, Decodon verticillatus, Hypericum prolificum, Ilex decidua, Itea virginica, Lindera benzoin, Lyonia lucida, Planera aquatica, Sabal minor, Salix caroliniana, Sebastiania fruticosa,* and *Arundinaria gigantea ssp. gigantea*. Vines can include *Ampelopsis arborea,*

Vitis spp., and others. Herbs can include *Boehmeria cylindrica, Carex abscondita, Carex albolutescens, Carex bromoides, Carex grayi, Carex intumescens, Carex joorii, Carex lupulina, Carex retroflexa, Chasmanthium laxum, Commelina virginica, Glyceria septentrionalis, Hydrocotyle ranunculoides, Leersia lenticularis, Lemna minor, Onoclea sensibilis, Saururus cernuus, Typha latifolia*, and *Zizaniopsis miliacea*, as well as the epiphytes *Tillandsia bartramii* and *Tillandsia usneoides*, and the aquatic exotic *Alternanthera philoxeroides*.

Dynamics: In pre-European settlement forests, community diversity in these bottomland systems was much more complex than in the modified landscapes of today. Fire, beaver activity, and flooding of varied intensity and frequency created a mosaic whose elements included canebrake, grass and young *Betula-Platanus* beds on reworked gravel or sand bars, beaver ponds, and grass-sedge meadows in abandoned beaver clearings, as well as the streamside zones and mixed hardwood and/or pine forests that make up more than 95% of the land cover that exists today.

When flooded, these systems may have a substantial aquatic faunal component, with high densities of invertebrates, and may play an important role in the life cycle of fish in the associated river. Unusually long or deep floods may stress vegetation or act as a disturbance for some species. Larger floods cause local disturbance by scouring and depositing sediment along channels and occasionally causing channel shifts. There are two general types of floods: occasional catastrophic, prolonged floods (due to beaver activity or other severe event); and more frequent repeated minor flooding (i.e., several minor floods within a 10-year period).

Except for primary successional communities such as bars, most forests exist naturally as multi-aged old-growth forests driven by gap-phase regeneration. Windthrow is probably the most important cause of gaps, and is the primary cause of mortality in bottomlands. Major storms or hurricanes occurring at approximately 20-year intervals would have impacted whole stands. Fire is of limited importance in lower, wetter areas, but was historically important in the higher terraces.

The dominant ecological processes in bottomland hardwood forests are windfall gaps and periodic flooding. Windfall gaps occur on the local scale (a single mature canopy tree) as well as the landscape scale (tornadoes or hurricanes). When canopy trees fall, seedlings in the understory are released and compete for a spot in the canopy. This leads to dense areas of herbaceous and woody vegetation in windfall gaps of all sizes. This is a major process in forest regeneration in bottomland hardwood forests.

Flooding is more frequent on the lower terraces but frequently floods higher terraces (Wharton et al. (1982) zones IV and V). Catastrophic floods can cause the loss of canopy over large areas. Canopy decline and reproductive failure can create late-seral open stands. Duration of flooding varies with the placement of a site in the landscape and is a dominant process affecting vegetation on a given site. Flooding can deposit alluvium or scour the ground, depending on the landscape position of a site and the severity of the flood event.

Fire is infrequent on the lower terraces, but was frequent historically on older terraces outside the floodplain, and also crept into the floodplains. Putnam (1951 as cited in Wharton et al. 1982) states that a serious fire season occurs on an average of about every 5 to 8 years in the bottomland hardwood forests of the Mississippi Alluvial Plain. It is conjectured that Native Americans maintained canebrakes by deliberate fall burning. Infrequent, mild surface fires would occur in the system; however, they would not alter species composition or structure.

Changes in hydrology due to the activities of beaver are also an important ecological process in bottomland hardwood forests. Beaver impoundments kill trees (sometimes over large areas) and may create open water habitat, cypress-tupelo stands, or cause stand replacement. Meandering streams are dynamic and frequently change course, eroding into the floodplain and depositing new point bars, thus creating new habitat for early-seral plant communities. In addition, insect outbreaks would occur infrequently in closed canopy states.

Component Associations:

- *Acer negundo* Forest (CEGL005033, G4G5)
- *Acer saccharinum / Leersia lenticularis - Commelina virginica* Forest (CEGL007727, G3?)
- *Arundinaria gigantea ssp. gigantea* Shrubland (CEGL003836, G2?)
- *Betula nigra - Platanus occidentalis / Alnus serrulata / Boehmeria cylindrica* Forest (CEGL007312, G4G5)
- *Betula nigra / Salix nigra / Hypericum prolificum - Ampelopsis arborea* Forest (CEGL007794, G3?)
- *Celtis laevigata - Fraxinus pennsylvanica - Acer negundo - (Juglans nigra) / Asimina triloba / Carex grayi* Forest (CEGL004740, G3G5)
- *Cephalanthus occidentalis / Carex* spp. - *Lemna* spp. Southern Shrubland (CEGL002191, G4)
- *Decodon verticillatus* Seasonally Flooded Shrubland (CEGL003905, G4)
- *Fraxinus pennsylvanica - Quercus laurifolia - Quercus lyrata - Carya aquatica* Forest (CEGL004695, G3G4)
- *Fraxinus pennsylvanica - Ulmus americana / Carpinus caroliniana / Boehmeria cylindrica* Forest (CEGL007806, G4?)
- *Fraxinus pennsylvanica / Leersia lenticularis - Carex lupulina* Forest (CEGL007728, G2G3)
- *Liquidambar styraciflua - Liriodendron tulipifera / Onoclea sensibilis* Forest (CEGL007329, G4)
- *Liquidambar styraciflua - Quercus (laurifolia, nigra) - (Pinus taeda) / Arundinaria gigantea / Carex abscondita* Forest (CEGL007732, G3G4)
- *Nelumbo lutea* Herbaceous Vegetation (CEGL004323, G4?)
- *Nyssa aquatica - Nyssa biflora* Forest (CEGL007429, G4G5)
- *Nyssa aquatica* Forest (CEGL002419, G4G5)
- *Nyssa biflora - Acer rubrum var. rubrum / Lyonia lucida* Forest (CEGL007864, G3G4)
- *Nyssa ogeche - (Nyssa biflora, Taxodium ascendens)* Forest (CEGL007392, G4)
- *Nyssa ogeche - Nyssa aquatica* Forest (CEGL007393, G3)

- *Pinus taeda - Liquidambar styraciflua - Nyssa biflora* Temporarily Flooded Forest (CEGL004606, G4)
- *Pinus taeda* Temporarily Flooded Forest (CEGL007142, G4?)
- *Planera aquatica* Forest (CEGL007394, G4?)
- *Platanus occidentalis - Celtis laevigata - Fraxinus pennsylvanica / Lindera benzoin - Ilex decidua / Carex retroflexa* Forest (CEGL007730, G4?)
- *Polygonum* spp. - *Phanopyrum gymnocarpon* Seasonally Flooded Herbaceous Vegetation (CEGL008555, G4)
- *Populus deltoides - Salix caroliniana* Forest (CEGL007343, G4G5)
- *Populus deltoides - Salix nigra / Mikania scandens* Forest (CEGL007346, G4G5)
- *Populus deltoides / Acer negundo / Boehmeria cylindrica* Forest (CEGL007731, G3G5)
- *Quercus laurifolia - Quercus lyrata / Carpinus caroliniana - Persea palustris / Vaccinium elliottii* Forest (CEGL004737, G4?)
- *Quercus laurifolia - Quercus michauxii - Liquidambar styraciflua / Carpinus caroliniana* Forest (CEGL004678, G3G4)
- *Quercus lyrata - Carya aquatica* Forest (CEGL007397, G4G5)
- *Quercus lyrata - Liquidambar styraciflua* Forest (CEGL008583, G3G4)
- *Quercus lyrata - Quercus laurifolia - Taxodium distichum / Saururus cernuus* Forest (CEGL004735, G3G5)
- *Quercus michauxii / Carpinus caroliniana - Ilex opaca / Leucothoe racemosa* Forest (CEGL007737, G2G3)
- *Quercus virginiana - (Pinus taeda) / (Sabal minor, Serenoa repens)* Forest (CEGL007039, G3G4)
- *Salix caroliniana* Temporarily Flooded Coastal Plain Shrubland (CEGL007052, G4?)
- *Salix nigra - Fraxinus pennsylvanica* Forest (CEGL007734, G3G4)
- *Salix nigra* Large River Floodplain Forest (CEGL007410, G3G5)
- *Salix nigra* Temporarily Flooded Shrubland (CEGL003901, G4?)
- *Scirpus cyperinus* Seasonally Flooded Southern Herbaceous Vegetation (CEGL003866, G4)
- *Taxodium distichum - Betula nigra / Cyrilla racemiflora - Sebastiania fruticosa* Forest (CEGL004505, G3?)
- *Taxodium distichum - Fraxinus pennsylvanica - Quercus laurifolia / Acer rubrum / Saururus cernuus* Forest (CEGL007719, G3G4)
- *Taxodium distichum - Nyssa aquatica - Acer rubrum / Itea virginica* Forest (CEGL007422, G4?)
- *Taxodium distichum - Nyssa aquatica - Nyssa biflora / Fraxinus caroliniana / Itea virginica* Forest (CEGL007432, G3G4)
- *Taxodium distichum - Nyssa aquatica / Fraxinus caroliniana* Forest (CEGL007431, G5?)
- *Taxodium distichum - Nyssa biflora / Fraxinus caroliniana / Lyonia lucida* Forest (CEGL004733, G3G4)
- *Taxodium distichum - Nyssa biflora / Sabal palmetto / Tillandsia (bartramii, usneoides)* Forest (CEGL003850, G3G4)
- *Taxodium distichum - Nyssa ogeche* Forest (CEGL003841, G3G4)
- *Taxodium distichum / Lemna minor* Forest (CEGL002420, G4G5)
- *Typha latifolia* Southern Herbaceous Vegetation (CEGL004150, G5)
- *Zizaniopsis miliacea* Coastal Plain Slough Herbaceous Vegetation (CEGL004139, G4?)

DISTRIBUTION

Range: This system is found on the Atlantic Coastal Plain, from North Carolina south to Georgia, especially (from north to south) the Roanoke, Great Pee Dee, Congaree/Santee, and Savannah rivers. This includes Omernik Level 4 Ecoregions 63n, 65p, 75i (in part) (EPA 2004).
Divisions: 203:C
Nations: US
Subnations: GA, NC, SC
Map Zones: 55:C, 58:C
USFS Ecomap Regions: 232C:CC, 232H:CC, 232I:CC, 232J:CC
TNC Ecoregions: 56:C, 57:C

SOUTHERN ATLANTIC COASTAL PLAIN NONRIVERINE SWAMP AND WET HARDWOOD FOREST (CES203.304)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Extensive Wet Flat; Needle-Leaved Tree; Broad-Leaved Tree
Non-Diagnostic Classifiers: Organic Peat (>40 cm); Mineral: W/ A-Horizon >10 cm
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2501; ESLF 9310; ESP 1501

CONCEPT

Summary: This system consists of poorly drained, organic or mineral soil flats of the outer Atlantic Coastal Plain. These areas are saturated by rainfall and seasonal high water tables without influence of river or tidal flooding. Fire is generally infrequent but may be important for some associations. Vegetation consists of hardwood or mixed forests of *Taxodium distichum, Nyssa* spp., bottomland oaks, *Acer rubrum*, or other wetland trees of similar tolerance. The lower strata have affinities with pocosin or baygall systems rather than the river floodplain systems that have affinities with the canopy. The combination of hardwood/deciduous canopy dominants and nonriverine, non-seepage hydrology distinguishes this system from other Coastal Plain systems. Stands with a high cover of *Chamaecyparis thyoides* formerly occupied much of the acreage of this system. This phase is presently only present in high-quality examples, and it helps distinguish this system from other Coastal Plain systems. Disturbed and fire-disrupted examples (those dominated by *Nyssa* spp., bottomland oaks, *Acer rubrum*) may be hard to distinguish from other wetland forests based purely on canopy composition.
Classification Comments: This system contains two to three distinctive subgroups within it. A wetter group has communities containing significant amounts of *Taxodium* or *Nyssa*. A drier group has communities with *Quercus* as a significant component. Within this group the calcareous association (CEGL007316) is very distinctive floristically.

The combination of canopy species with nonriverine hydrology distinguishes this system from all others. This system is distinguished from the various floodplain systems, with which the canopy shares affinities, by the distinctive hydrology and the differences in nutrient dynamics and other ecosystem process that follow from it. The overall flora is usually distinct and reflects these differences in nutrient status. The invertebrate fauna is likely very distinct. This system is distinguished from Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267), which can share organic soils and a number of shrub and herb species, by the canopy dominants and the lack of *Pinus serotina* and evergreen hardwoods as major canopy components. Fire frequency is an important difference. It is unclear if fire frequency determines the difference in vegetation or if the different flammability of the vegetation determines the fire regime.

The boundary between this system and Southern Coastal Plain Hydric Hammock (CES203.501) of Florida and Georgia may need clarification. Similarly, the boundary between this and Northern Atlantic Coastal Plain Basin Peat Swamp (CES203.522) has not been precisely delineated. Great Dismal Swamp is included with this system (CES203.304).

Similar Ecological Systems:
- Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267)
- Northern Atlantic Coastal Plain Basin Peat Swamp (CES203.522)--replaces this system to the north (both are found in Virginia and in mapzone 60).
- Southern Atlantic White-cedar Peatland Forest (CES203.068)
- Southern Coastal Plain Nonriverine Basin Swamp (CES203.384)

DESCRIPTION

Environment: This system occurs on flat areas of the outer Atlantic Coastal Plain from southeastern Virginia to Georgia, where soils are seasonally to nearly semipermanently saturated because of low relief, poor soil drainage, and seasonal high water table. The largest

areas are on broad interfluvial flats, but substantial areas occur on organic deposits in drowned river valleys in the Embayed Region of North Carolina and Virginia, beyond the reach of the influence of wind tides. Hydrology is dominated by rainfall and sheetflow, and overbank flooding, tidal flooding, and seepage are a secondary influence, if at all. Soils may be loamy to clayey, or may be shallow to deep organic. A distinctive small subset has soils with limestone near the surface, influencing soil chemistry. Natural fire is infrequent in this system, and varies from a minor to a significant influence on vegetational composition and structure. Infrequency of fire may be an important factor in differentiating this system from Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267) and the various wet longleaf pine forest systems. In a phase or component of this system on mucky peat soils (Terric or Typic Medisaprists) up to 3 m deep and occasionally on mucky sand or wet mineral soils with an organic epipedon, *Chamaecyparis thyoides* was the most common dominant species; it occurred in a fire-generated patch mosaic in which the various patch dominants are a variable combination of *Acer rubrum, Chamaecyparis thyoides, Nyssa biflora, Pinus serotina*, and *Taxodium*, most frequently *Taxodium ascendens*. While this is fire-dominated, it is only found in substantially fire-sheltered portions of the landscape where scarps or water bodies prevent easy access by fire, resulting in a long fire-return interval. The original vegetation constituted a true shifting mosaic. The original extent was up to 1 million acres of which at least 400,000 acres were Atlantic white-cedar in Mapzones 58 and 60. This is a long-interval, fire-dependent, forested peatland with its greatest extent found on the Pamlico Terrace of Virginia and North Carolina. The largest sites lie at less than 9 m (30 feet) above sea level (C. Frost pers. comm.).

Vegetation: Vegetation is a closed-canopy forest of wetland trees. The wetter sites are dominated by combinations of *Taxodium distichum, Nyssa biflora*, and occasionally *Nyssa aquatica, Pinus taeda, Chamaecyparis thyoides, Liquidambar styraciflua*, and *Liriodendron tulipifera*. Less wet sites have canopies of wetland oaks such as *Quercus laurifolia, Quercus michauxii*, and *Quercus pagoda*. Most communities have a well-developed shrub layer that has more floristic affinities with pocosins or baygalls than with river floodplain communities that have similar canopies. The shrub layer is usually dominated by *Clethra alnifolia, Leucothoe axillaris*, or species shared with pocosins. The herb layer is not usually well-developed but may be dense where shrubs are atypically sparse. Wetland ferns, such as *Osmunda regalis* and *Woodwardia areolata*, and *Carex* spp. usually dominate. In the Atlantic white-cedar-related phase of this system, stands that regenerated from crown fire often have nearly pure cover of *Chamaecyparis thyoides*. The most common subcanopy species are *Acer rubrum, Persea palustris*, and *Magnolia virginiana*. Typical shrubs include *Ilex glabra, Ilex coriacea, Leucothoe racemosa, Itea virginica*, and *Lyonia lucida*. Herbs, chiefly ferns and sedges, are typically sparse, but mosses may be common (C. Frost pers. comm.).

Dynamics: Fire is an important influence in a subset of this system. Communities dominated by *Chamaecyparis thyoides* depend on fire for regeneration of the canopy trees. The occurrence of fires on the time scale of several decades to a century or more may determine the mosaic of *Chamaecyparis thyoides* forests and other associations. Some areas may once have been canebrakes, with dominance of *Arundinaria* determined by more frequent fire. In the oak-dominated communities and in wetter *Taxodium* and *Nyssa* communities, fire is probably of little ecological significance because the vegetation is not flammable. Without fire as a major factor, most communities probably occur naturally as old-growth multi-aged forests dominated by gap-phase regeneration. Hurricanes may create larger canopy gaps, and sometimes cause more extensive damage. Examples in drowned river valleys are subject to influence by rising sea level and can be expected to evolve into tidal swamp systems, sometimes fairly quickly.

In specific relation to the *Chamaecyparis thyoides*-dominated phase of this system, succession pathways depend on water table depth at time of replacement fire. Having the water table at the surface results in regeneration of *Chamaecyparis thyoides* from the seedbank. If the water table is slightly to moderately below the surface, the seedbank is destroyed and succession is dominated by some combination of *Acer rubrum, Nyssa biflora, Pinus taeda*, and related taxa. If the water table is well below the surface, the seedbank is destroyed and a deeper hole is created in the peat. In this case, succession is dominated by *Taxodium distichum* and a deeper water area is created with *Chamaecyparis thyoides* only on the edge.

Component Associations:

- *Arundinaria gigantea ssp. gigantea* Shrubland (CEGL003836, G2?)
- *Arundinaria gigantea ssp. tecta* Shrubland (CEGL003843, G1)
- *Carya cordiformis - Quercus pagoda - Quercus shumardii - Carya myristiciformis / Sabal minor - Cornus asperifolia* Forest (CEGL007316, G1)
- *Chamaecyparis thyoides / Persea palustris / Lyonia lucida - Ilex coriacea* Forest (CEGL006146, G2)
- *Liquidambar styraciflua - Acer rubrum - (Nyssa biflora) / Woodwardia virginica* Forest (CEGL007848, G2G3)

- *Quercus virginiana - Quercus nigra - Quercus pagoda - Liquidambar styraciflua / Sabal minor - Ilex vomitoria* Forest (CEGL007851, G1G2Q)
- *Taxodium distichum - Nyssa biflora / Berchemia scandens - Toxicodendron radicans / Woodwardia areolata* Forest

(CEGL004429, G2G3)

Spatial Characteristics

Spatial Summary: Occurs as large patches in the Embayed Region of North Carolina and Virginia, as small patches most other places.

Size: Size distribution may vary across the range. In the Embayed Region of North Carolina and Virginia, this system can cover thousands of contiguous acres. Elsewhere in the region, occurrences tend to be much smaller, usually tens of acres. The drier, oak-dominated associations are now known only from remnants with artificial boundaries. Historical stands ranged in size from the Great Dismal Swamp of Virginia and North Carolina, which included the largest Atlantic white-cedar stand of 112,000 acres, associated with a considerable acreage of swamp blackgum and bald-cypress, as well as smaller peatlands of only a 50-100 acres. The scale of disturbances included fires, ranging in size from 50 to >10,000 acres, and winds, especially those associated with hurricanes, in which effects were more limited, typically consisting of locally intense small blowdowns of a few acres each.

Adjacent Ecological Systems:

- Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267)
- Atlantic Coastal Plain Small Blackwater River Floodplain Forest (CES203.249)
- Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242)
- Southern Atlantic Coastal Plain Tidal Wooded Swamp (CES203.240)

Adjacent Ecological System Comments: May be bordered by tidal swamps, Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267), upland hardwoods, or less frequently by longleaf pine systems.

Distribution

Range: This system ranges from southeastern Virginia to Georgia. This system is most abundant in the Embayed Region of northeastern North Carolina and southeastern Virginia (south of the James River), where it covers large expanses.

SOUTHERN ATLANTIC COASTAL PLAIN TIDAL WOODED SWAMP (CES203.240)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Tidal / Estuarine
National Mapping Codes: ESLF 9194

CONCEPT

Summary: This system encompasses the tidally flooded areas in lower river floodplains and edges of estuaries of the Atlantic Coastal Plain from southeastern Virginia southward to northern Florida that have sufficiently freshwater and short enough flooding to be able to support tree canopies. *Taxodium*, *Nyssa*, or *Fraxinus* generally dominate. Swamps may be either regularly flooded by lunar tides or irregularly flooded by wind tides.
Classification Comments: This system is distinguished from all adjacent systems by the combination of tidal flooding and tree-dominated vegetation. It is related to East Gulf Coastal Plain Freshwater Tidal Wooded Swamp (CES203.299) but is distinguished because of differences in the tidal flooding regime between the Gulf and Atlantic and because of biogeographic differences.
Similar Ecological Systems:
- East Gulf Coastal Plain Freshwater Tidal Wooded Swamp (CES203.299)
- Northern Atlantic Coastal Plain Tidal Swamp (CES203.282)

Related Concepts:
- Baldcypress - Tupelo: 102 (Eyre 1980) Finer
- Baldcypress: 101 (Eyre 1980) Finer
- Southern Redcedar: 73 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in lower reaches of river floodplains and along estuary shorelines, in places regularly or irregularly flooded by lunar or wind tides. The water has little salt content, due to distance from the ocean and/or strong freshwater input. Soils may be mineral or organic. Soils are generally permanently saturated even when the tide is low. The transition of the hydrology to flood dominance rather than tidal dominance may be very gradual.
Vegetation: Vegetation is forest or woodland with canopies of the most water-tolerant tree species, generally *Taxodium distichum*, *Nyssa* spp., or *Fraxinus* spp. Lower strata generally are denser and more species-rich than those of river or nonriverine swamps, containing species from those systems as well as a variety of shrubs and herbs shared with freshwater marshes. *Morella cerifera* and *Rosa palustris* are often characteristic.
Dynamics: Regular or irregular tidal flooding with freshwater is the ecological factor that makes this system distinct. These swamps may be regularly flooded at least twice a day for several hours and remain inundated for days during flood or storm events (Wharton et al. 1982, FNAI 1990). River floods may also seasonally affect this system. Wind and flooding are the dominant disturbance agents in this type and this includes wind damage from hurricanes and tornadoes as well as inundation of young stands. Canopy gaps can be created by high winds, such as from nor'easters, tropical storms and hurricanes (Nordman 2013). Infrequent intrusion of saltier water, which is stressful or fatal to many of the plant species, is an important periodic disturbance created by storms. Insect outbreaks would occur infrequently in these closed-canopy forests (Landfire 2007a). This system generally appears to be in a shifting relationship with tidal freshwater marshes of the same region. Most marshes have standing dead trees in them, suggesting they recently were swamps. But, conversely, some marshes are being invaded with trees and may be turning into swamps. Freshwater tidal marshes generally occur at the shallow edge of tidal rivers and streams, where river and tidal flow is high, and the vegetation is affected by the changing meanders of the tidal channel. Rising sea level is driving shifts in the communities of this system, causing upstream non-tidal swamps to develop into this system (as they become subject to tides) and causing parts of this system to turn into brackish marshes. In areas not too strongly affected by saltwater intrusion or drowning by rising sea level, these communities can be expected to exist as old-growth, multi-aged forests.

SPATIAL CHARACTERISTICS

Spatial Summary: Occurrences are generally large patches, ranging to small patches.
Size: Occurrences tend to be wide to narrow bands along rivers, streams, or shorelines. The largest patches, on large rivers, are thousands of acres, broken only by stream channels. Small occurrences are also common, with a zone of this system occurring in most streams that reach the ocean or estuaries.
Adjacent Ecological Systems:
- Atlantic Coastal Plain Blackwater Stream Floodplain Forest (CES203.247)
- Atlantic Coastal Plain Embayed Region Tidal Freshwater Marsh (CES203.259)
- Southern Atlantic Coastal Plain Nonriverine Swamp and Wet Hardwood Forest (CES203.304)
- Southern Atlantic White-cedar Peatland Forest (CES203.068)

Adjacent Ecological System Comments: In most rivers, this system grades upstream to floodplain systems and downstream to fresh or salt marsh systems. In the Embayed Region of North Carolina and Virginia, it often grades to Southern Atlantic Coastal Plain Nonriverine Swamp and Wet Hardwood Forest (CES203.304) inland within peat-filled drowned river valleys.

DISTRIBUTION

Range: This system is found from southeastern Virginia southward to northern Florida along the Atlantic Coast.
Divisions: 203:C
Nations: US

SOUTHERN ATLANTIC COASTAL PLAIN WET PINE SAVANNA AND FLATWOODS (CES203.536)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Woody-Herbaceous; Extensive Wet Flat
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2450; ESLF 9119; ESP 1450

CONCEPT

Summary: This ecological system of pine-dominated savannas and/or flatwoods is restricted to the Coastal Plain from central South Carolina to northeastern Florida. It was the former matrix system in this region. This general area has been referred to as the Longleaf Pine Wiregrass Savannas region and the Sea Island Flatwoods (EPA Ecoregion 75f). Examples of this system and component community associations share the common features of wet, seasonally saturated, mineral soils and historic exposure to frequent low-intensity fire. They occur on a wide range of soil textures, which is an important factor in distinguishing different associations. The vegetation is naturally dominated by *Pinus palustris* or, on wetter sites, *Pinus elliottii* or less commonly *Pinus serotina*. Understory conditions may be dramatically altered by fire frequency and seasonality. In natural condition (with frequent fires, including some growing-season fire) there tends to be a dense ground cover of herbs and low shrubs; grasses can dominate, but there is often a large diversity of other herbs and shrubs.
Classification Comments: This system is distinguished from Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265) because of substantial biogeographic differences. The break is placed at the Santee River, which approximates the transition between the ranges of *Aristida stricta* and *Aristida beyrichiana*, which are keystone species in the communities where they occur. This corresponds roughly with the geographic break in the upland longleaf pine systems as well. This system is distinguished from Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281) because of that system's more upland character. However, the two systems have much in common, including frequent fire, the same primary dominant canopy tree, and many herbaceous species. They can also occur in the same landscapes. However, floristic differences are well marked, and no associations are shared.
Similar Ecological Systems:
- Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265)
- East Gulf Coastal Plain Near-Coast Pine Flatwoods (CES203.375)

DESCRIPTION

Environment: This system occurs on wet mineral soil sites, in the middle and outer Coastal Plain. Landforms include low areas in relict beach ridge systems and eolian sand deposits, and poorly drained clayey, loamy, or sandy flats.
Vegetation: The best examples are typically open woodlands naturally dominated by *Pinus palustris* or *Pinus elliottii* and/or *Pinus serotina* on wetter sites. In many areas past logging and subsequent lack of frequent growing-season fire have led to much greater dominance by *Pinus elliottii*. In natural condition, there is typically a dense ground cover of herbs and low shrubs; grasses can dominate, but there is often a large diversity of other herbs and shrubs. The shrubs are mainly *Serenoa repens, Ilex glabra*, and *Ilex coriacea* along with various ericaceous species. These shrub species become especially prominent on sites not frequently burned.
Dynamics: Frequent low-intensity fire is important. Lightning has been an important source of ignition for these fires, especially historically. Disturbances are an important part of the natural functions of wet pine savanna and flatwoods. In order for these habitats to burn frequently (every 2-3 years), there needs to be enough fine fuel, such as needles from *Pinus palustris* trees, healthy populations of native warm-season grasses, and evergreen shrubs with volatile oils in their leaves, such as *Gaylussacia frondosa, Ilex coriacea, Ilex glabra, Lyonia* spp., *Serenoa repens*, and *Vaccinium* spp. The frequent fires promote flowering, seed production, and seed germination of many plants and provide open areas in patches (Van Lear et al. 2005).

SOUTHERN COASTAL PLAIN BLACKWATER RIVER FLOODPLAIN FOREST (CES203.493)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial [Blackwater]
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9340

CONCEPT

Summary: This ecological system occurs along certain river and stream drainages of the southern Coastal Plain of Florida, Alabama, Mississippi, and southwestern Georgia that are characterized by dark waters high in particulate and dissolved organic materials, and that generally lack floodplain development. In most cases these are streams that have their headwaters in sandy portions of the Outer Coastal Plain. Consequently, they carry little mineral sediment or suspended clay particles and are not turbid except after the heaviest rain events. The water is classically dark in color due to concentrations of tannins, particulates, and other materials derived from drainage through swamps or marshes. In comparison with spring-fed rivers and brownwater rivers of the region, this system tends to be much more acidic in nature and generally lacks extensive and continuous floodplains and levees. Steep banks alternating with floodplain swamps are more characteristic. This system includes mixed rivers, with a mixture of blackwater and spring-fed tributaries such as the Suwannee River. Canopy trees typical of this system are obligate to facultative wetland species such as *Taxodium distichum*, *Nyssa aquatica*, and *Chamaecyparis thyoides*.

Classification Comments: A new ecological system is needed for Florida spring-fed streams/rivers, such as the Wakulla River, Ichetucknee River, etc.

DESCRIPTION

Environment: The rivers in which this system occurs are characterized by dark waters high in particulate and dissolved organic materials, and that generally lack floodplain development. In most cases these are streams that have their headwaters in sandy portions of the Outer Coastal Plain (Smock and Gilinsky 1992). Consequently, they carry little mineral sediment or suspended clay particles and are not turbid except after the heaviest rain events. The water is classically dark in color due to concentrations of tannins, particulates, and other materials derived from drainage through swamps or marshes (FNAI 1990). In comparison with spring-fed rivers and brownwater rivers of the region, this system tends to be much more acidic in nature and generally lacks extensive and continuous floodplain and levees; steep banks alternating with floodplain swamps are more characteristic (FNAI 1990). This system includes mixed rivers, with a mixture of blackwater and spring-fed tributaries such as the Suwannee River.

This is a linear to large-patch ecological system; stands may be contiguous over thousands of acres. The largest examples could be called matrix examples of this ecological system. Examples are by nature linear and tend to be narrow. The Satilla River in Georgia is about 375 km in length and may be the largest example. The lower floodplain is about 2 km across, an approximate size of 750 square km could be used as a working upper bound. There may be limited areas with trees greater than 150 years. Probably there are many stands aged 70-100 years, and many that are younger than 70 years. Stands that have not had extensive timber removal will probably have more woody debris and constitute better habitat for component animal and plant species. Areas that have been logged may become dominated by *Pinus taeda*, *Liquidambar styraciflua*, and *Acer rubrum* with a common shrub being *Morella cerifera*.

Dynamics: Flooding is the most important ecological factor in this system. Frequency and duration of flooding determine the occurrences of different associations and separate the system from other kinds of wetlands. Flooding brings nutrients and excludes non-flood-tolerant species. When flooded, the system may have a substantial aquatic faunal component, with high densities of invertebrates, and may play an important role in the life cycle of fish in the associated river. Unusually long or deep floods may stress vegetation or act as a disturbance for some species. Larger floods cause local disturbance by scouring and depositing sediment along channels, and occasionally causing channel shifts. However, the low gradient and binding of sediment by vegetation generally makes these processes much slower and less frequent than in river systems of most other regions. The areas flooded for the longest durations tend to have high amounts of total organic carbon in the soil and sediments which deplete levels of aquatic dissolved oxygen (Todd et

al. 2010).

Except for primary successional communities such as bars, most forests exist naturally as multi-aged old-growth forests driven by gap-phase regeneration. Windthrow is probably the most important cause of gaps. In addition to periodic flooding, the formation of windfall gaps is a dominant ecological processes in bottomland hardwood forests. Windfall gaps occur from the local scale (a single mature canopy tree) to the landscape scale (effects of tornadoes and hurricanes). When canopy trees fall, seedlings in the understory are released and compete for a spot in the canopy. This leads to dense areas of herbaceous and woody vegetation in windfall gaps of all sizes. This is a major process in forest regeneration in bottomland hardwood forests.

Flooding is more frequent on the lower terraces but frequently floods higher terraces (Wharton et al. (1982) zones IV and V). Catastrophic floods can cause the loss of canopy over large areas. Canopy decline and reproductive failure can create late-seral open stands. Duration of flooding varies with the placement of a site in the landscape and is a dominant process affecting vegetation on a given site. Flooding can deposit alluvium or scour the ground, depending on the landscape position of a site and the severity of the flood event.

Fire is not believed to be important, due to low flammability of much of the vegetation, wetness, and abundance of natural firebreaks. Fire is infrequent on the lower terraces, but was frequent historically on older terraces outside the floodplain and crept into the floodplains. Putnam (1951 as cited in Wharton et al. 1982) states that a serious fire season occurs on an average of about every 5 to 8 years in the bottomland hardwood forests of the Mississippi Alluvial Plain. Some areas of bottomlands apparently were once occupied by canebrakes, which presumably were maintained through deliberate fall burning by Native Americans. Infrequent, mild surface fires would occur in the system; however, they would not alter species composition or structure.

Changes in hydrology due to the activities of beaver are also an important ecological process in bottomland hardwood forests. Beaver impoundments kill trees (sometimes over large areas) and may create open water habitat, cypress-tupelo stands, or cause stand replacement. Meandering streams are dynamic and frequently change course, eroding into the floodplain and depositing new point bars, thus creating new habitat for early-seral plant communities. Insect outbreaks would occur infrequently in closed canopy states.

SOUTHERN COASTAL PLAIN HYDRIC HAMMOCK (CES203.501)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Seepage-Fed Sloping
National Mapping Codes: ESLF 9192

CONCEPT

Summary: This ecological system occupies flat lowlands along the southern and outermost portions of the Coastal Plain of the southeastern United States, usually over limestone substrates. The vegetation of this system is characterized by mixed hardwood species, often with hydric oak species common. In Florida, examples of this system are often found adjacent to the floodplain of spring-fed rivers with relatively constant flows. In some areas, such as the Big Bend region of Florida, they occupy large areas of broad, shallow, mucky or seepy wetlands but generally do not receive overbank flooding. In Alabama, this system is apparently confined to floodplains of the Mobile-Tensaw, where examples are topographically higher than the surrounding floodplains.
Classification Comments: The original name of this system was too geographically restrictive and was broadened to Southern Coastal Plain to better reflect the range of this system. Confirmed in South Atlantic Coastal Plain portion of Florida by Ann Johnson (pers. comm.).
Similar Ecological Systems:
- Southern Coastal Plain Nonriverine Basin Swamp (CES203.384)
- Southern Coastal Plain Spring-run Stream Aquatic Vegetation (CES203.275)

Related Concepts:
- Atlantic White-Cedar: 97 (Eyre 1980) Finer
- Cabbage Palmetto: 74 (Eyre 1980) Finer
- Hydric Hammock (FNAI 1990) Broader

DESCRIPTION

Environment: Examples of this system are associated with limestone-rich sites. Soils may range from sand to clay to organic (FNAI 1990). In Florida, examples of this system are often found adjacent to the floodplain of spring-fed rivers with relatively constant flows. In some areas, such as the Big Bend region of Florida, they occupy large areas of broad, shallow, mucky or seepy wetlands but generally do not receive overbank flooding (A. Johnson pers. comm.). In Alabama, this system is apparently confined to floodplains of the Mobile-Tensaw, where examples are topographically higher than the surrounding floodplains (A. Schotz pers. comm.).
Vegetation: The vegetation of this system is characterized by mixed hardwood species, often with hydric oak species common (FNAI 1997, A. Johnson pers. comm.). Stands may be dominated by a variety of wetland and upland tree species, including *Chamaecyparis thyoides*, *Sabal palmetto*, and *Quercus laurifolia*, as well as *Quercus virginiana*, *Magnolia virginiana*, and *Ulmus americana*. Some shrubs and understory trees include *Ilex cassine* and *Morella cerifera*.
Dynamics: Saturation, but usually not inundation, is characteristic of the hydrology of some hydric hammocks; lower areas generally are prone to more flooding. The distributions of trees within hydric hammocks are influenced by the timing and depth of flooding (Vince et al. 1989). These are sites are only occasionally subject to wildland fire (FNAI 2010a) and are dominated by mixed evergreen and deciduous forest, often with *Sabal palmetto* which is fire-tolerant.

Component Associations:
- *Chamaecyparis thyoides - Sabal palmetto* Forest (CEGL008598, G2)
- *Fagus grandifolia - Pinus glabra - Magnolia grandiflora / Serenoa repens* Forest (CEGL004977, G2G3)
- *Fraxinus caroliniana - Sabal palmetto - Ulmus americana / Cephalanthus occidentalis* Forest (CEGL008592, G3?)
- *Sabal palmetto - Quercus laurifolia - Quercus virginiana - Magnolia virginiana - Ulmus americana* Forest (CEGL004674, G2G3)
- *Sabal palmetto - Quercus virginiana* Saturated Forest (CEGL007040, G3?)
- *Sabal palmetto / Ilex cassine - Morella cerifera* Saturated Woodland (CEGL003527, G3?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Central Florida Pine Flatwoods (CES203.382)
- Southern Coastal Plain Nonriverine Basin Swamp (CES203.384)

DISTRIBUTION

Range: As currently documented, this system occurs in Florida, Georgia and rarely in southern Alabama. In Alabama, this system is apparently confined to floodplains of the Mobile-Tensaw (A. Schotz pers. comm.).

SOUTHERN COASTAL PLAIN NONRIVERINE BASIN SWAMP (CES203.384)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Herbaceous; Depressional
Non-Diagnostic Classifiers: Isolated Wetland [Partially Isolated]; Organic Peat (>40 cm)
National Mapping Codes: ESLF 9323

CONCEPT

Summary: This ecological system occupies large, seasonally inundated basins with peaty substrates in the southern and outermost portions of the Coastal Plain of the southeastern United States. These basins are nonriverine and do not receive overbank flooding. The southern limit of this system extends into central Florida, especially along the Atlantic Coast in Volusia and Brevard counties. Examples are generally forested; the vegetation is characterized by *Taxodium distichum, Nyssa biflora*, evergreen "bay" shrubs, and/or mixed hardwoods. Emergent *Pinus elliottii* may also be present. Some characteristic shrubs include *Cliftonia monophylla, Cyrilla racemiflora, Lyonia lucida*, and *Smilax laurifolia*.
Classification Comments: Manifestations of this in the Atlantic and Gulf coastal plains are not differentiated at this time. There may be some minor floristic differences, particularly between the northernmost and southernmost examples, but these are not thought to warrant any subdivision of the type. Examples of this system differ from Southern Coastal Plain Hydric Hammock (CES203.501) by the absence of oaks (especially swamp laurel oak and live oak) and other less flood-tolerant species such as sweetgum (A. Johnson pers. comm.). In addition, this type is found in basins with peaty substrates as opposed to limestone-influenced substrates.
Similar Ecological Systems:
- Northern Atlantic Coastal Plain Basin Swamp and Wet Hardwood Forest (CES203.520)--has a similar name but only comes south to Virginia.
- Southern Atlantic Coastal Plain Nonriverine Swamp and Wet Hardwood Forest (CES203.304)
- Southern Atlantic White-cedar Peatland Forest (CES203.068)
- Southern Coastal Plain Hydric Hammock (CES203.501)

DESCRIPTION

Environment: This system occupies large, seasonally inundated basins with peaty substrates. These basins are nonriverine and do not receive overbank flooding. Even though the ecological system tends to occur in large basins, the basin may become full of water, and then there will be some flowout. This is due to high rainfall, and probably is more common in winter, when evapotranspiration is lower than summer. During periods of drought, the amount of water flowing out of a basin swamp may be quite low or none at all, and parts of the basin may become dry. The water tends to be nutrient-poor and acidic, and often it appears tea-colored from tannins in the water (called blackwater).
Vegetation: Examples are generally forested; the vegetation is characterized by *Taxodium distichum, Nyssa biflora*, evergreen "bay" shrubs, and/or mixed hardwoods (FNAI 1997). Emergent *Pinus elliottii* may also be present. Some characteristic shrubs include *Cliftonia monophylla, Cyrilla racemiflora, Lyonia lucida*, and *Smilax laurifolia*. Some examples (e.g., Okefenokee Swamp) have extensive open herbaceous areas dominated by various combinations of *Panicum hemitomon, Sagittaria* spp., *Dulichium arundinaceum, Sarracenia* spp., *Carex glaucescens, Carex striata, Orontium aquaticum, Woodwardia virginica, Eriophorum virginicum, Eriocaulon compressum*, and *Peltandra virginica*. In addition, other floating and emergent aquatic plants are present including *Nuphar orbiculata (= Nuphar lutea ssp. orbiculata), Nymphaea odorata ssp. odorata, Nymphoides aquatica, Habenaria repens*, and *Utricularia* spp.(Wharton 1978). These herbaceous zones are called "prairies" or "sphagnum bogs" depending on their composition.
Dynamics: The primary source of water in basin swamps is local rainfall, with additional input from runoff and seepage from the surrounding uplands (FNAI 2010a). Flooding is a regular dynamic process. These basins are prone to long periods of inundation with limited waterflow. The deep parts of basin swamps may go without fire for decades or even centuries, while the drier outer edges can be more susceptible to frequent fire. Basin swamps within mesic flatwoods will burn more frequently than basin swamps within a matrix of mesic or hydric hammock. Without fire, bay shrubs and hardwoods increase in density and peat accumulates more rapidly. *Taxodium* and *Pinus* trees are tolerant of light surface fires, but muck fires burning into the peat can kill the trees, lower the ground surface, and transform a swamp into a pond, lake, marsh, or shrub bog (FNAI 2010).

Component Associations:

SOUTHERN COASTAL PLAIN NONRIVERINE CYPRESS DOME (CES203.251)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Depressional; Needle-Leaved Tree
Non-Diagnostic Classifiers: Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2460; ESLF 9129; ESP 1460

CONCEPT

Summary: This system consists of small forested wetlands, typically dominated by *Taxodium ascendens*, often with a dome-shaped appearance in which trees in the center of the depression are taller than those around the exterior. Examples are known from the Southern Coastal Plain (Omernik Ecoregion 75 and adjacent 65) of Florida and Georgia, extending into Alabama, Mississippi and Louisiana. Examples occupy poorly drained depressions which are most often embedded in a matrix of pine flatwoods or mesic to dry pine woodlands. The oldest and largest individual trees typically occupy the center of these domed wetlands, with smaller and younger individuals around the margins. Pools of stagnant, highly acidic water may stand in the center of these depressions ranging from 30-120 cm (1-4 feet) in depth, but becoming increasingly shallow along the margins. These sites are underlain by an impervious clay pan which impedes drainage and perches precipitation. Depending on fire regime and hydroperiod, some examples may have thick (50-100 cm) organic layers. In addition to *Taxodium ascendens*, other woody species may include *Cephalanthus occidentalis, Clethra alnifolia, Hypericum chapmanii, Hypericum myrtifolium, Ilex myrtifolia, Leucothoe racemosa, Liquidambar styraciflua, Lyonia lucida, Morella cerifera, Nyssa biflora*, and *Styrax americanus*.
Classification Comments: The original range of this system was thought to include only the East Gulf Coastal Plain (TNC Ecoregion 53) and was named accordingly. Examples were later confirmed in central Florida (TNC Ecoregion 55) and the South Atlantic Coastal Plain portion of Florida (A. Johnson pers. comm.) (TNC Ecoregion 56), whereupon the name was broadened to Southern Coastal Plain Nonriverine Cypress Dome. Cypress "stringers" are included here as well; these are more-or-less linear features that are parts of disconnected drainageways that arise in a pine flatwoods landscape (e.g., CEGL007419). The vegetation of the "stringers" is somewhat analogous to that of the edges of the true "dome swamps."
Related Concepts:
- Dome Swamp (FNAI 1990) Undetermined
- Pondcypress: 100 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in areas of low relief, occupying poorly drained to permanently wet depressions in uplands such as pine flatwoods or mesic to dry pine woodlands. Pools of stagnant, highly acidic water may stand in the center of these depressions ranging from 30-120 cm (1-4 feet) in depth, but becoming increasingly shallow along the margins (Monk and Brown 1965). Some examples may have thick (50-100 cm) organic layers (Drew et al. 1998). Some of the depressions are fed by groundwater, while others are dependent on local precipitation.
Vegetation: According to Drew et al. (1998), dominant plant taxa include *Taxodium ascendens, Nyssa biflora, Cephalanthus occidentalis, Liquidambar styraciflua, Clethra alnifolia, Lyonia lucida*, and *Styrax americanus*. A few less typical upland depression ponds in Florida dominated by *Nyssa sylvatica* are also accommodated in this system for now (A. Johnson pers. comm.). Other species found in this system can include *Nyssa ursina, Hypericum chapmanii, Hypericum myrtifolium, Ilex myrtifolia, Leucothoe racemosa, Morella cerifera, Lobelia floridana, Polygala cymosa, Carex striata*, and *Carex turgescens*.
Dynamics: Cypress domes get their common name from the dome-shaped appearance in which trees in the center are taller than those around the sides (Monk and Brown 1965). The water draws down more frequently along the shallow margins than in the deeper center. This allows for more frequent recruitment of *Taxodium ascendens* seedlings along the edges, which are also exposed to more frequent wildland fire than the center of the ponds which remain flooded for longer durations. These two factors are reflected in the presence of large trees in the center and smaller trees closer to the edges of the ponds (FNAI 2010a), and greater amounts of herbaceous graminoid plants along the margins of the depression. Where fires are more frequent, open herbaceous vegetation is favored. Without periodic fires *Taxodium ascendens* may become less dominant as hardwood or bay canopy species increase and peat accumulates. *Taxodium ascendens* has fairly thick, fire-resistant bark and is tolerant of light surface fires; however, the seedlings and small *Taxodium ascendens* trees are vulnerable to fire (FNAI 2010a). When the forest canopy is harvested, the disturbed vegetation can transition to an herbaceous graminoid-dominated wetland, such as represented by the ecological systems East Gulf Coastal Plain Depression Pond (CES203.558) or Southern Atlantic Coastal Plain Depression Pond (CES203.262). Transitions like this can also occur in response to the natural disturbance dynamics of Coastal Plain depressions, in which the influences of flooding, hurricanes and occasional wildland fire (or lack of fire) can lead to vegetation transition from wooded to herbaceous, or without canopy disturbance, succession from herbaceous to wooded or wetland forest vegetation.

Component Associations:

- *Carex striata var. striata - Xyris fimbriata - Lachnanthes caroliana* Herbaceous Vegetation (CEGL007718, G2G3)
- *Crataegus aestivalis* Forest (CEGL004639, G2G3)

SOUTHERN COASTAL PLAIN SEEPAGE SWAMP AND BAYGALL (CES203.505)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); East Gulf Coastal Plain; Seepage-Fed Sloping; Broad-Leaved Evergreen Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2461; ESLF 9130; ESP 1461

CONCEPT

Summary: This wetland system consists of forested wetlands in acidic, seepage-influenced habitats of the East Gulf and Atlantic coastal plains, extending from Mississippi and the Florida Parishes of Louisiana east into southern Georgia and central Florida. These are mostly evergreen forests generally found at the base of slopes or other habitats where seepage flow is concentrated. Resulting moisture conditions are saturated or even inundated. The vegetation is characterized by *Magnolia virginiana* and *Nyssa biflora*. Examples occur in the outer portions of the Coastal Plain within the range of *Persea palustris*, and where *Magnolia virginiana* is an important or even dominant species. To the north this system grades into East Gulf Coastal Plain Northern Seepage Swamp (CES203.554), where evergreen species are largely replaced by deciduous species in the canopy. Due to excessive wetness, these habitats are normally protected from fire except those which occur during extreme droughty periods. These environments are prone to long-duration standing water, and tend to occur on highly acidic, nutrient-poor soils.
Classification Comments: Some authors have treated *Persea palustris* (of wetlands) and *Persea borbonia* (of uplands) as one taxon under a broadly conceived *Persea borbonia*. We recognize the two distinct taxa, following Godfrey (1988), Kartesz (1999) and Weakley (2005).
Similar Ecological Systems:
- Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252)
- East Gulf Coastal Plain Northern Seepage Swamp (CES203.554)

Related Concepts:
- Atlantic White-Cedar: 97 (Eyre 1980) Finer
- Baygall (FNAI 1990) Undetermined
- Bayhead Swamp (Smith 1996a) Intersecting
- Pond Pine: 98 (Eyre 1980) Finer
- Sweetbay - Swamp Tupelo - Redbay: 104 (Eyre 1980) Finer

DESCRIPTION

Environment: These wetlands may occur in poorly developed upland drainages, narrow ravine bottoms, bases of steepheads, and small headwaters stream bottoms. In most cases, these wetlands are embedded in uplands with deep sandy soils. When this system is associated with streams, they tend to be low-gradient, with narrow, often braided channels and diffuse drainage patterns. Habitat also includes baygall vegetation in oval depressions (Carolina bays) in southern Georgia (e.g., in Liberty and Long counties, Georgia).
Vegetation: The vegetation is characterized by *Magnolia virginiana* and *Nyssa biflora*. Examples occur in the outer portions of the Coastal Plain within the range of *Persea palustris*, and where *Magnolia virginiana* is an important or even dominant species. Dominant trees in some stands may include *Quercus laurifolia, Liquidambar styraciflua*, and *Liriodendron tulipifera*. In addition, some stands may be dominated by *Cyrilla racemiflora* and/or *Cliftonia monophylla*. Other shrubs include *Ilex coriacea, Leucothoe axillaris, Lyonia lucida, Morella caroliniensis, Morella inodora*, and *Viburnum nudum var. nudum*. Herbs include *Carex atlantica ssp. capillacea, Carex glaucescens, Carex lonchocarpa, Chasmanthium ornithorhynchum, Polygala cymosa, Solidago patula var. strictula*, and *Sphagnum* spp.
Dynamics: Due to excessive wetness, these habitats are normally protected from fire except those which occur during extreme droughty periods. These environments are prone to long-duration standing water and tend to occur on highly acidic, nutrient-poor soils and saturated peat (FNAI 2010a). This system occurs in landscapes that had frequent fire in the past, but the wetness usually limited fire spread, creating an infrequent fire-return interval. While infrequent, fire intensity varies among associations; those dominated by evergreen shrubs such as *Ilex, Lyonia, Illicium, Cliftonia, Gaylussacia, Persea, Morella, Arundinaria*, and *Cyrilla* and with *Pinus serotina* or *Chamaecyparis thyoides* can produce intense canopy fire when they burn (especially when ladder fuels are present), while others probably experience only low-intensity surface fires because of low flammability. When severe drought has allowed the peat to dry, wildfire can burn out the peat. If shrubs survive, they will resprout, but if the roots of shrubs are killed, the site may respond to the intense fire and transition to herbaceous marsh or eventually *Taxodium - Nyssa* swamp vegetation (FNAI 2010a).

Component Associations:
- *(Pinus elliottii) / Cyrilla racemiflora - Persea palustris - Magnolia virginiana - Smilax laurifolia* Shrubland (CEGL004974, G2?)

SOUTHERN PIEDMONT LARGE FLOODPLAIN FOREST (CES202.324)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9324

CONCEPT

Summary: This ecological system consists of vegetated communities along Piedmont rivers, south of the James River in Virginia, where flooding and flood-related environmental factors affect vegetational composition and dynamics. Well-developed examples of this system occur in the Triassic basins. The vegetation includes both non-forested bar and scour communities and the more extensive forested floodplain communities. Forests are generally differentiated by depositional landforms such as levees, sloughs, ridges, terraces, and abandoned channel segments. The system is affected by flooding through wetness, scouring, deposition of material, and input of nutrients. Piedmont floodplain systems are generally quite distinct from Coastal Plain ones, with steeper river gradients, harder rocks and more limited floodplain development. The near absence of *Taxodium distichum, Nyssa* spp., and other species of the Coastal Plain corresponds well to the geologic boundary in most places.
Classification Comments: This system is distinguished from Southern Piedmont Small Floodplain and Riparian Forest (CES202.323) by having well-developed fluvial landforms which differentiate vegetation. The smaller rivers are less differentiated both because the fluvial landforms are smaller and because the flooding regime is more variable. This system is distinguished from upland systems by the significant presence of plants indicative of alluvial or bottomland settings. This suite of species is absent or occurs incidentally in upland sites.

Piedmont floodplain systems are generally quite distinct from those of the Coastal Plain, with more limited development of floodplains and depositional features, because of the steeper river gradients and harder rocks. The near absence of *Taxodium distichum, Nyssa* spp., and other species largely confined to the Coastal Plain corresponds well to the geologic boundary in most places. The floodplains on Triassic sediments have some similarity to those in the Coastal Plain because of their more extensive floodplain development. The break with South-Central Interior Large Floodplain (CES202.705) is less sharp. The presence of Appalachian mesophytic species is often the best indicator.

Distinctive subgroups within this system, which could potentially be the basis for further subdivision, include the Triassic Basin floodplains and the distinction between forests and non-forested communities. The non-forested communities, maintained by periodic severe disturbance, have very different dynamics as well as vegetation structure, but are always associated with the forests and share the flooding regime. Triassic Basin floodplains have large floodplains with small streams. They likely have differences in flooding regime, including longer duration of flooding. Swamp forests, where periods of standing water are an important environmental influence, occupy larger portions of Triassic Basin floodplains than of other floodplains.
Similar Ecological Systems:
- South-Central Interior Large Floodplain (CES202.705)
- Southern Piedmont Mesic Forest (CES202.342)
- Southern Piedmont Small Floodplain and Riparian Forest (CES202.323)

- Swamp Chestnut Oak - Cherrybark Oak: 91 (Eyre 1980) Finer

DESCRIPTION

Environment: Examples of this ecological system occur near rivers, on floodplains and terraces affected by river flooding and on emergent bars and banks within channels. The site usually includes distinct depositional landforms, including levees, sloughs, ridges, terraces, and abandoned channel segments. The relative extent of these features varies among the stretches of different rivers depending on factors such as channel morphology (Edwards et al. 2013). The substrate is primarily alluvium. Soils are usually sandy to loamy, but include local clayey and gravelly areas. Soils are generally fertile, among the most nutrient-rich in the Piedmont region. Emergent and vegetated bars of gravel to cobbles are included here as well, as are scoured bedrock areas. Floods are generally of short duration, and wetness is a major influence only within channels and where water is ponded in local depressions. The geologic substrate may be of any kind, but geological substrates in the Piedmont are primarily acidic. A special case is the soft Triassic sedimentary rocks of the Piedmont, where even small streams develop large floodplains with well-developed fluvial landforms and therefore fall into this category.
Vegetation: Most of the extent of the system is forest vegetation. The forest canopy is usually dominated by a mix of characteristic

alluvial and bottomland species such as *Platanus occidentalis, Betula nigra, Acer negundo, Celtis laevigata, Fraxinus pennsylvanica, Liquidambar styraciflua, Quercus michauxii*, and *Quercus pagoda*. Some more widespread species such as *Liriodendron tulipifera* and *Acer rubrum* are also abundant. Mesophytic species such as *Fagus grandifolia* are a component on the driest areas. Successional areas are often dominated by *Pinus taeda, Pinus virginiana, Liquidambar styraciflua*, or *Liriodendron tulipifera*. Lower strata in the forests are similarly dominated by bottomland species, but may contain more mesophytic species. *Lindera benzoin, Xanthorhiza simplicissima, Elymus hystrix, Elymus canadensis, Chasmanthium latifolium*, and *Boehmeria cylindrica* are among the characteristic species. Non-forested vegetation is generally limited to small patches or bands along the channel, and is quite variable in structure and composition. Partly submerged bars may be dominated by *Justicia americana*. Frequently reworked gravel bars may be dominated by young *Salix nigra, Platanus occidentalis*, or *Betula nigra*, or they may have sparse vegetation of a wide variety of annual and perennial herbs of weedy habits. The few extensive bedrock-scour areas in gorges have distinctive vegetation dominated by perennial herbs rooted in pockets and crevices.

Dynamics: The distinctive dynamics of river flooding are presumably the primary reason for the distinctive vegetation of this system, though not all of the factors are well known. The large rivers have the largest watersheds in the region, but the gradients of most of these rivers limit floods to fairly short duration. Flooding is most common in the winter, but may occur in other seasons. The sorting of plant communities by depositional landforms of different height suggest that wetness or depth of flood waters may be of significance, though it has much less influence than in the Coastal Plain. Flood waters have significant energy, and scouring and reworking of sediment are an important factor in bar and bank communities. However, in the forested floodplains, flood disturbances that kill established woody plants are rare, and canopy population dynamics are dominated by windthrow. In addition to disturbance, floods bring nutrient input, deposit sediment, and disperse plant seeds.

Wind disturbance is at least as important in this system as other Piedmont forests, perhaps more important than in uplands because of frequently wet and less dense soils and more shallowly-rooted trees. Fire does not appear to be a dominant factor, and most floodplain vegetation is not very flammable. However, historical references to canebrakes dominated by *Arundinaria gigantea* suggest that fire may have once been more possible and more important in at least some portions.

These systems are commonly subject to a variety of indirect modern human influences beyond those that affect most forests. A large fraction of the large Piedmont rivers have been dammed, and power generation and regulation of waterflow create unnatural flood regimes. Extensive erosion of uplands, caused by poor agricultural practices dating back to colonial times, transported large amounts of sediment into floodplains (Edwards et al. 2013). As in uplands, large floodplains often have substantial areas in cultivation. River bottoms were the focus of agriculture among Native Americans, so some of these systems have a long history of human clearing. A number of exotic plant species have invaded floodplains, more than in any other Piedmont system. These include *Ligustrum sinense*, which can form extensive and continuous stands in the understories of floodplain forests (Edwards et al. 2013).

Component Associations:
- *Acer rubrum - Fraxinus pennsylvanica / Saururus cernuus* Forest (CEGL006606, G3G4)
- *Acer saccharinum - Acer negundo / Ageratina altissima - Laportea canadensis - (Elymus virginicus)* Forest (CEGL006217, G4)
- *Alnus serrulata* Southeastern Seasonally Flooded Shrubland (CEGL008474, G4)
- *Carpinus caroliniana - Ilex decidua* Shrubland (CEGL006484, G1?)
- *Eragrostis hypnoides - Ludwigia palustris - Lindernia dubia - Cyperus squarrosus* Herbaceous Vegetation (CEGL006483, G3)
- *Eupatorium serotinum - Polygonum (lapathifolium, punctatum, pensylvanicum)* Herbaceous Vegetation (CEGL006481, GNR)
- *Fagus grandifolia - Acer barbatum / Asimina triloba / Toxicodendron radicans / Carex blanda* Forest (CEGL007321, G3?)
- *Fraxinus pennsylvanica - Platanus occidentalis - Celtis laevigata / Chasmanthium latifolium* Piedmont River Levee Forest (CEGL007013, G3G4)
- *Justicia americana* Herbaceous Vegetation (CEGL004286, G4G5)
- *Liquidambar styraciflua - Quercus (phellos, nigra, alba) / Carpinus caroliniana* Forest (CEGL007006, G3G4)
- *Pinus taeda - Quercus (phellos, nigra, laurifolia)* Temporarily Flooded Forest (CEGL007551, GNR)
- *Platanus occidentalis - Acer negundo - Juglans nigra / Asimina triloba / Mertensia virginica* Forest (CEGL004073, G4)
- *Platanus occidentalis - Betula nigra - Salix (caroliniana, nigra)* Woodland (CEGL003896, G4G5)
- *Quercus pagoda - Quercus phellos - Quercus lyrata - Quercus michauxii / Chasmanthium latifolium* Forest (CEGL007356, G2?)
- *Quercus phellos - Quercus (palustris, lyrata) / Ilex decidua / Carex typhina - (Carex grayi)* Forest (CEGL006498, G3?)
- *Quercus shumardii - Quercus michauxii - Quercus nigra / Acer barbatum - Tilia americana var. heterophylla* Forest (CEGL008487, G3)

SPATIAL CHARACTERISTICS

Spatial Summary: Naturally a large patch system, occurring in narrow to broad linear patches along rivers. Widespread heavy human alteration has left mostly small patch remnants, with only a few large patches.

Size: Examples probably originally extended for miles along rivers, forming patches of hundreds to thousands of acres. Intense modern human alteration has made this a rare system, with examples now mostly limited to small patches. Some examples of hundreds to over 1000 acres remain.

Adjacent Ecological Systems:
- Piedmont Seepage Wetland (CES202.298)
- Southern Piedmont Cliff (CES202.386)
- Southern Piedmont Mesic Forest (CES202.342)

Adjacent Ecological System Comments: Always associated with a riverine aquatic system. Usually bordered by Southern Piedmont

Mesic Forest (CES202.342). Some adjacent uplands may have drier systems, and locally may have rock outcrop systems.

DISTRIBUTION

Range: This system is widespread in the Piedmont, from Alabama to southern Virginia. The northern boundary in Virginia is not well-determined, but roughly corresponds with the James River.

SOUTHERN PIEDMONT SMALL FLOODPLAIN AND RIPARIAN FOREST (CES202.323)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9312

CONCEPT

Summary: This ecological system consists of vegetated communities along streams and small rivers in the Piedmont of the southeastern United States where flooding and flood-related environmental factors affect vegetation composition and dynamics. The vegetation includes both non-forested bar and scour communities, as well as more extensive forested floodplain communities. The forests of these smaller floodplains and bottomlands are not differentiated by depositional landforms such as levees, sloughs, ridges, terraces, and abandoned channel segments, because these features are small and flooding regimes are variable. The system is affected by flooding through wetness, scouring, deposition of material, and input of nutrients. Piedmont floodplain systems are generally quite distinct from Coastal Plain ones, with steeper river gradients, harder rocks and more limited floodplain development. The near absence of *Taxodium distichum, Nyssa* spp., and other species of the Coastal Plain corresponds well to the geologic boundary in most places.
Classification Comments: This system is distinguished from Southern Piedmont Large Floodplain Forest (CES202.324) by lacking well-developed fluvial landforms which differentiate vegetation. The smaller rivers are less differentiated both because the fluvial landforms are smaller and because the flooding regime is more variable. The large floodplains created by small streams in Triassic sediments are included with Southern Piedmont Large Floodplain Forest (CES202.324). Both of the Piedmont floodplain systems are distinguished from upland systems by the significant presence of plants indicative of alluvial or bottomland settings. This suite of species is absent or occurs incidentally in upland sites.

Piedmont floodplain systems are generally quite distinct from those of the Coastal Plain, with more limited development of floodplains and depositional features, because of the steeper river gradients and harder rocks. The near absence of *Taxodium distichum, Nyssa* spp., and other species largely confined to the Coastal Plain corresponds well to the geologic boundary in most places. The break with South-Central Interior Large Floodplain (CES202.705) is less sharp. The presence of Appalachian mesophytic species is often the best indicator. The floodplains of the westernmost Piedmont generally belong to South-Central Interior Large Floodplain (CES202.705).

Similar Ecological Systems:

DESCRIPTION

Environment: Examples occur on moderately to very high-gradient streams over a wide range of elevations, near streams and small rivers, on floodplains and terraces affected by river flooding and includes emergent bars and banks within channels. Depositional landforms, including levees, sloughs, ridges, terraces, and abandoned channel segments may be present, but occur less frequently and are smaller than the scale of the communities of the floodplain. Fine-scale alluvial floodplain features are abundant. The substrate is primarily alluvium. Soils are usually sandy to loamy, but include local clayey and gravelly areas. Soils are generally fertile, among the most nutrient-rich in the Piedmont region. Alluvial soils may be as important a factor as ongoing flooding in differentiating these systems from adjacent uplands. Emergent and vegetated bars of gravel to cobbles occur occasionally but are generally not extensive or as distinctive as they are on larger rivers. Floods are generally of short duration, and wetness is a major influence only within channels and where water is ponded in local depressions. The geologic substrate may be of any kind, but areas on Triassic sediments tend to have large floodplain systems even on fairly small streams.
Vegetation: Almost all of the extent of the system is naturally forested. The forest canopy is usually a mix of mesophytic and widespread species such as *Liriodendron tulipifera, Liquidambar styraciflua*, and *Acer rubrum*, along with characteristic alluvial and bottomland species such as *Platanus occidentalis, Betula nigra, Acer negundo, Celtis laevigata, Fraxinus pennsylvanica, Liquidambar styraciflua, Quercus michauxii*, and *Quercus pagoda*. *Fagus grandifolia* may be present in drier portions, mixed with the other

species. Successional areas are often strongly dominated by *Pinus taeda, Pinus virginiana, Liquidambar styraciflua*, or *Liriodendron tulipifera*. Lower strata in the forests may be either primarily of mesophytic species shared with moist uplands systems, or a mix of mesophytic and bottomland species. Non-forested vegetation is generally limited to very small patches or bands along the channel, and seldom forms distinct communities.

Dynamics: The distinctive dynamics of stream flooding are presumably the primary reason for the distinctive vegetation of this system, though not all of the factors are well known. Small rivers and streams with small watersheds have more variable flooding regimes that larger rivers. Floods tend to be of short duration and unpredictably variable as to season and depth. Flood waters may have significant energy in higher gradient systems, but scouring and reworking of sediment rarely affect more than small patches. They are important in maintaining the small non-forested patches. In the forested floodplains, flood disturbances that kill established woody plants are rare, and canopy population dynamics are dominated by windthrow. In addition to disturbance, floods bring nutrient input, deposit sediment, and disperse plant seeds.

In pre-European settlement forests, community diversity in these streamside systems was much more complex than in the modified landscapes of today. Fire, beaver activity, and flooding of varied intensity and frequency created a mosaic whose elements included canebrake, grass and young *Betula-Platanus* beds on reworked gravel or sand bars, beaver ponds, and grass-sedge meadows in abandoned beaver clearings, as well as the streamside zones and mixed hardwood and/or pine forests that make up more than 95% of the land cover that exists today.

Flooding is the major process affecting the vegetation, with the substrate more rapidly drained than in flat floodplain areas. The higher gradients of most of these streams and rivers limit floods to fairly short duration. Flooding is most common in the winter, but may occur in other seasons particularly in association with hurricanes, tornados, or microbursts from thunderstorms. Flood waters may have significant energy in higher gradient systems, but scouring and reworking of sediment are important in maintaining the small non-forested patches of the bar and bank communities. Flooding can act as a replacement disturbance in areas where beavers impounded a channel or in rare years with severe prolonged flood events. There are two general types of floods: occasional catastrophic, prolonged floods (due to beaver activity or other severe event); and more frequent repeated minor flooding (i.e., several minor floods within a 10-year period).

The wind disturbance associated with flooding is very significant along small streams because of wet and less dense soils and shallow-rooted trees. Canopy tree mortality from more common windstorms would have resulted in tree-by-tree or small group replacement. Windthrow is the primary cause of mortality in bottomlands. Major storms or hurricanes occurring at approximately 20-year intervals would have impacted whole stands. Tornado tracks can be found passing across uplands and bottomlands [see one such indicated on a map of Umstead State Park, Raleigh, NC], leaving narrow swaths of felled trees (Landfire 2007a). The majority of windthrow in the Piedmont seems to have been the result of hurricanes and tornadoes spawned by them. Even though the Piedmont is removed from the coast by 25 to over 100 miles, extensive windthrow occurred in middle-aged and old-growth trees in Piedmont bottomlands following Hurricane Fran in 1996 (Xi et al. 2008). Bottomland *Quercus* species, even though seemingly in more sheltered positions, were much more heavily affected than hardwoods on adjacent uplands. Gaps as large as one hectare were seen intermixed in areas with extensive single-tree windthrow. Windthrow may also occur because of thunderstorm microbursts or tornados. In addition, ice damage is an infrequent but potentially catastrophic disturbance.

Component Associations:

- *Acer rubrum - Fraxinus pennsylvanica / Saururus cernuus* Forest (CEGL006606, G3G4)

- *Platanus occidentalis - Acer negundo - Juglans nigra / Asimina triloba / Mertensia virginica* Forest (CEGL004073, G4)
- *Platanus occidentalis - Celtis laevigata - Fraxinus pennsylvanica / Lindera benzoin - Ilex decidua / Carex retroflexa* Forest (CEGL007730, G4?)
- *Podostemum ceratophyllum* Herbaceous Vegetation (CEGL004331, G3G5)
- *Quercus phellos - Quercus (palustris, lyrata) / Ilex decidua / Carex typhina - (Carex grayi)* Forest (CEGL006498, G3?)
- *Quercus phellos - Quercus alba - (Quercus michauxii) - Carya carolinae-septentrionalis* Small Stream Forest (CEGL004042, G2)
- *Quercus shumardii - Quercus michauxii - Quercus nigra / Acer barbatum - Tilia americana var. heterophylla* Forest (CEGL008487, G3)
- *Salix nigra* Temporarily Flooded Shrubland (CEGL003901, G4?)
- *Schizachyrium scoparium - Solidago plumosa* Herbaceous Vegetation (CEGL004459, G1)

Spatial Characteristics

Spatial Summary: Naturally a small- to medium-patch or narrow linear system, following streams.
Size: Examples probably originally extended for miles in branching networks of smaller stream systems, and might extend for miles along the larger streams. Patches might be hundreds and potentially even thousands of contiguous acres, but most intact remnants are 100 acres or less.
Adjacent Ecological Systems:

- Piedmont Seepage Wetland (CES202.298)
- Southern Piedmont Cliff (CES202.386)
- Southern Piedmont Mesic Forest (CES202.342)

Adjacent Ecological System Comments: Always associated with an intermittent stream, perennial stream, or small river aquatic system. Usually bordered by Southern Piedmont Mesic Forest (CES202.342). Some adjacent uplands may have drier systems, and locally may have rock outcrop systems.

Distribution

Range: This system is widespread in the Piedmont, from Alabama to southern Virginia. The northern boundary in Virginia is roughly the watershed of the James River.
Divisions: 202:C
Nations: US
Subnations: AL, GA, NC, SC, VA
Map Zones: 49:P, 54:C, 59:C, 61:C

SOUTHWEST FLORIDA PERCHED BARRIERS TIDAL SWAMP AND LAGOON (CES203.540)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Tidal / Estuarine [Haline]
National Mapping Codes: ESLF 9347

CONCEPT

Summary: This system includes tidal wetlands along the western coast of Florida from approximately Tampa Bay south to Charlotte Harbor. In this region, instead of the tidal marshes found to the north, these are mangrove forests with canopies up to 10 m tall (Montague and Wiegert 1990). Odum and McIvor (1990) show a diagram displaying the community zonation present in this system at Tampa Bay. A narrow high marsh zone of *Batis* and *Juncus* grades into low swamps with *Laguncularia racemosa, Avicennia germinans*, and *Rhizophora mangle*. Interpretation of the vegetation is difficult due to extensive human alteration. For example, Lewis et al. (1979) estimated that 44% loss of intertidal vegetation in the Tampa Bay region had taken place.
Classification Comments: The use of the term "perched" in the name refers to the elevated nature of the barrier islands, which are built on remnant limestone reefs.
Related Concepts:
- Mangrove: 106 (Eyre 1980) Finer

Component Associations:
- *Avicennia germinans / Spartina alterniflora* Shrubland (CEGL003801, G2?)
- *Conocarpus erectus - (Laguncularia racemosa) / Batis maritima - Borrichia frutescens / Sesuvium portulacastrum - Suaeda linearis* Scrub (CEGL003806, G2?)

DISTRIBUTION

Range: Endemic to south Florida.

TAMAULIPAN CLOSED DEPRESSION WETLAND (CES301.197)

CLASSIFIERS

Classification Status: Standard

Primary Division: Madrean Semidesert (301)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Intermittent Flooding; Lowland [Lowland]; Woody-Herbaceous; Depression
National Mapping Codes: ESLF 9392

CONCEPT

Summary: This ecological system occupies small, internally drained basins or depressions occurring over various substrates. It occurs over various geologic formations, but is primarily concentrated over the Lissie and Goliad formations and the South Texas Sandsheet south of the Nueces River, as well as other eolian sands. The sites may be locally referred to as potholes, lagunas, lagunitas, ponds, or copitas. Occurrences are local and appear to be unrelated to underlying strata, though in some cases they may result from solution of underlying caliche bedrock. The soils are a matrix of sandy substrates; the depressions that characterize the system are typically lined by clays or clay loams. Lakebed Ecological Sites typify the occurrences. These basins are typically lined by clay or clay loam soils which tend to hinder drainage, resulting in moist conditions over extended periods. Characteristic woody species surrounding these basins include *Acacia farnesiana, Parkinsonia aculeata*, and *Prosopis glandulosa*, which make up a relatively sparse woodland canopy at a height of about 6 m. *Celtis laevigata, Celtis pallida (= Celtis ehrenbergiana)*, and *Ulmus crassifolia* may sometimes be present. Shrubs of these species, and other species such as *Condalia hookeri, Lycium carolinianum, Heimia salicifolia*, and *Sideroxylon celastrinum*, may be present but typically do not occur as a dense shrub layer. *Sesbania drummondii* is often encountered, particularly in areas with reduced woodland canopy where water may stand for extended periods. The herbaceous layer within the woodland may commonly contain species such as *Urochloa maxima, Chloracantha spinosa, Clematis drummondii*, and *Teucrium cubense*. Toward the center of the basin, woody cover is reduced, or often absent, and the herbaceous layer is often dominated by *Cynodon dactylon*, but may also be characterized by a number of sedge species of the genera *Eleocharis* (including *Eleocharis quadrangulata* and *Eleocharis palustris*) and *Cyperus* (including *Cyperus articulatus, Cyperus acuminatus*, and *Cyperus squarrosus*), as well as *Schoenoplectus saximontanus*. Numerous other species may be present, including *Paspalum distichum, Setaria parviflora, Eragrostis spicata, Calyptocarpus vialis, Eryngium nasturtiifolium, Eclipta prostrata, Phyla nodiflora, Soliva mutisii, Rorippa teres, Lindernia dubia, Rotala ramosior, Bacopa rotundifolia, Heteranthera limosa, Echinodorus berteroi, Echinodorus tenellus, Sagittaria longiloba, Nymphaea elegans, Marsilea macropoda, Lemna* sp., and *Wolffia* sp.
Classification Comments: This system is called a closed depression wetland (a wooded herbaceous wetland) because calling it a woodland/shrubland may be misleading.
Similar Ecological Systems:
- Tamaulipan Ramadero (CES301.992)
- Western Great Plains Closed Depression Wetland (CES303.666)

DESCRIPTION

Environment: This ecological system is found in local internally draining basins or depressions. It occurs over various geologic formations, from eolian sands, to the Lissie Formation, to the Goliad Formation. Occurrences are local and appear to be unrelated to underlying strata, though in some cases they may result from solution of underlying caliche bedrock. The sites may be locally referred to as potholes, lagunas, lagunitas, ponds, or copitas. Occurrences are local and appear to be unrelated to underlying strata, though in some cases they may result from solution of underlying caliche bedrock. The soils are a matrix of sandy substrates; the depressions that characterize the system are typically lined by clays or clay loams. Lakebed Ecological Sites typify the occurrences. These basins are typically lined by clay or clay loam soils which tend to hinder drainage, resulting in moist conditions over extended periods.
Vegetation: Characteristic woody species surrounding these basins include *Acacia farnesiana, Parkinsonia aculeata*, and *Prosopis glandulosa*, which make up a relatively sparse woodland canopy at a height of about 6 m. *Celtis laevigata, Celtis pallida (= Celtis ehrenbergiana)*, and *Ulmus crassifolia* may sometimes be present. Shrubs of these species, and other species such as *Condalia hookeri, Lycium carolinianum*, and *Sideroxylon celastrinum*, may be present but typically do not occur as a dense shrub layer. *Sesbania drummondii* is often encountered, particularly in areas with reduced woodland canopy where water may stand for extended periods. The herbaceous layer within the woodland may commonly contain species such as *Urochloa maxima, Chloracantha spinosa, Clematis drummondii*, and *Teucrium cubense*. Toward the center of the basin, woody cover is reduced, or often absent, and the herbaceous layer is often dominated by *Cynodon dactylon*, but may also be characterized by a number of sedge species of the genera *Eleocharis* (including *Eleocharis quadrangulata* and *Eleocharis palustris*) and *Cyperus* (including *Cyperus articulatus, Cyperus acuminatus*, and *Cyperus squarrosus*), as well as *Schoenoplectus saximontanus*. Numerous other species may be present, including *Paspalum distichum, Setaria parviflora, Calyptocarpus vialis, Eryngium nasturtiifolium, Eclipta prostrata, Phyla nodiflora, Soliva mutisii, Rorippa teres, Lindernia dubia, Rotala ramosior, Bacopa rotundifolia, Heteranthera limosa, Echinodorus berteroi, Echinodorus tenellus, Sagittaria longiloba, Nymphaea elegans, Marsilea macropoda, Lemna* sp., and *Wolffia* sp.
Dynamics: This ecological system is primarily driven by hydrological processes. It occurs on sites that are seasonally to semipermanently flooded, usually retaining water into the growing season, drying completely only in drought years. Increases in

precipitation and/or runoff can dilute the salt concentration and allow for less salt-tolerant species to occur.

Component Associations:
- *Acacia farnesiana - (Prosopis glandulosa)* Woodland (CEGL002131, G5)
- *Acacia farnesiana - Parkinsonia aculeata* Temporarily Flooded Forest (CEGL007755, G4)

TAMAULIPAN FLOODPLAIN (CES301.990)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Intermediate (5-25 yrs) Flooding Interval; Lowland [Lowland]; Forest and Woodland (Treed); Tropical/Subtropical [Tropical Xeric]; Riverine / Alluvial
Non-Diagnostic Classifiers: Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2467; ESLF 9136; ESP 1467

CONCEPT

Summary: This ecological system is limited to riparian areas of the lower Rio Grande Valley and Rio Corona in southern Texas and northeastern Mexico. Stands occur on riverbanks, floodplains and deltas. Stands are generally deciduous woodlands or forests with tree height reaching to 15 m. Canopy cover is variable, but sometimes reaches near 100%. The canopy may have a conspicuous (sometimes dominant to codominant) evergreen component of species such as *Ebenopsis ebano* and *Ehretia anacua*. Dominant species of the overstory canopy often include one or more of the following: *Celtis laevigata, Ulmus crassifolia, Fraxinus berlandieriana, Prosopis glandulosa, Acacia farnesiana, Diospyros texana, Leucaena pulverulenta, Celtis pallida (= Celtis ehrenbergiana), Sapindus saponaria var. drummondii, Ebenopsis ebano, Ehretia anacua,* and *Parkinsonia aculeata*. These woodlands are a unique mix of species from southeastern North America and subtropical Central America and are often dominated by *Acacia farnesiana, Diospyros texana, Ebenopsis ebano, Ehretia anacua, Fraxinus berlandieriana,* or *Ulmus crassifolia*, and many other tree species present to locally dominant. The highly variable understory is dependent on canopy density and may include dense shrub or herbaceous layers.

DESCRIPTION

Environment: Stands of this ecological system occur on riverbanks, floodplains, deltas and other riparian areas of the lower Rio Grande Valley and Rio Corona in southern Texas and northeastern Mexico. The geology is Quaternary alluvium. Landforms are floodplains of rivers and large creeks where sediment is deposited. The topography is relatively level with some relief associated with levees and depressions developed from meanders of the waterway, or historical meanders of the Rio Grande (Resaca). It is typically found on alluvial soils of the Bottomland Ecological Sites, including loamy, clayey, and sandy. The Lowland Ecological Site type also supports this system. This ecological system occurs along rivers and major drainages in south Texas from the central portion of the Nueces River south to northeastern Mexico and west to the vicinity of Del Rio, Texas.

Vegetation: Stands of this system are generally deciduous woodlands or forests with tree heights reaching to 15 m. Canopy cover is variable but sometimes reaches near 100%. The canopy may have a conspicuous (sometimes dominant to codominant) evergreen component of species such as *Ebenopsis ebano* and *Ehretia anacua*. Dominant species of the overstory canopy often include one or more of the following: *Celtis laevigata, Ulmus crassifolia, Fraxinus berlandieriana, Prosopis glandulosa, Acacia farnesiana, Diospyros texana, Leucaena pulverulenta, Celtis pallida (= Celtis ehrenbergiana), Sapindus saponaria var. drummondii, Ebenopsis ebano, Ehretia anacua,* and *Parkinsonia aculeata* (Elliott 2011). In northern portions of the range of this system, particularly within the Nueces River drainage, *Carya illinoinensis* and *Quercus fusiformis* may be conspicuous components of the overstory. Forests and woodlands may have significant shrub cover, including saplings of the overstory species in addition to species such as *Zanthoxylum fagara, Condalia hookeri, Forestiera angustifolia, Sideroxylon* spp., *Aloysia gratissima, Acacia greggii var. wrightii, Malpighia glabra, Guajacum angustifolium, Ziziphus obtusifolia,* and *Amyris texana*. Other shrub species, such as *Buddleja sessiliflora, Phaulothamnus spinescens, Lippia alba,* and *Amyris madrensis* may be encountered in southern expressions of the system. *Salix nigra*

may dominate sites, especially at river's edge and wet sites. Riverbanks and other sites with a reduced overstory canopy (either from disturbance or prolonged inundation) may also be shrub-dominated, often with one or few species such as *Baccharis neglecta, Baccharis salicifolia, Arundo donax, Sesbania drummondii*, or *Cephalanthus occidentalis*, and *Salix exigua, Mimosa asperata*, or *Cephalanthus salicifolius* in the lower Rio Grande Valley (Elliott 2011). The herbaceous layer is typically not well-developed, but may include species such as *Chloris pluriflora (= Trichloris pluriflora), Setaria scheelei, Panicum virgatum, Paspalum langei, Paspalum lividum (= Paspalum denticulatum), Carex crus-corvi, Cyperus articulatus, Rivina humilis, Calyptocarpus vialis, Chromolaena odorata, Teucrium cubense, Urtica chamaedryoides, Parietaria pensylvanica, Verbesina microptera, Chloracantha spinosa, Parthenium confertum*, and *Malvaviscus arboreus var. drummondii*. Vines such as *Serjania brachycarpa, Cocculus diversifolius, Clematis drummondii*, and *Cissus trifoliata* are frequently encountered, and *Tillandsia usneoides* often drapes the branches of overstory species. Non-native grasses such as *Cynodon dactylon, Urochloa maxima, Pennisetum ciliare, Bothriochloa ischaemum var. songarica*, and *Bromus catharticus* are often present to dominant, and sometimes to the exclusion of most other herbaceous species (Elliott 2011).

Dynamics: Stands occur as linear patches along much of the lower Rio Grande and occupy large patches on the delta (Landfire 2007a). Key ecological processes are succession and disturbance. Disturbance was primarily flooding and, to a lesser extent, fire may have occurred within these woodlands and forests. Occurrence of patches of *Phragmites* spp. may have provided adequate fuel to carry fire to the canopy. Floods may have been annual and were primarily depositional floods rather than scouring floods (Landfire 2007a). Long-term succession would occur due to deposition and development of this system into more upland characteristics of another system (Landfire 2007a). Extreme floods may have occurred in association with hurricanes. Freezes would have had significant impacts on the largely tropical/subtropical species, though these impacts more directly affect riparian woodlands where tropical species are more common. Drought would also affect this system, and may provide the unusual opportunity for fire to carry in the system (Landfire 2007a).

This system was modeled as part of the Tamaulipan Riparian Systems group by Landfire (2007a) using three classes: early-, mid- and late-seral. Fire frequency may be over-emphasized in this model for this system, as other ecologists suggest fire less frequent historically.

The early-seral class (0-12 years): Herbaceous cover following 1000-year scouring flood and replacement fire in mid-seral class. Herbaceous cover of sedges and rushes develops as sedimentation produces an adequate substrate not continually flooded to allow development of cover. Areas of *Phragmites* spp. may occur in areas where fires would have occurred. Replacement fire-return interval is approximately 10 years in this class due to the fine fuel (Landfire 2007a).

Mid-seral class (13-20 years): Low canopy cover of trees. Shrub layer well-developed, but composition is similar to the understory of late-seral class. Scouring floods associated with river channel migration on the delta is modeled as encountering a site every 1000 years, taking the class back to early-seral. Replacement fire is modeled as occurring at a similar MFRI to surface fires in mid-seral class (30 years). *Celtis laevigata* is developing as a canopy but still occurs with low cover (Landfire 2007a).

The late-seral class (21+ years): Dominated by *Celtis laevigata* with 60-100% canopy, with *Ulmus crassifolia, Celtis pallida, Mimosa pigra*, and *Condalia hookeri* in the midstory, and other shrubs in the understory. Scouring floods modeled as occurring every 1000 years take class back to early-seral. Hurricane of sufficient strength to take out the canopy is modeled as occurring every 50 years, takes class back to mid-seral. Maintenance surface fires occur every 30 years (Landfire 2007a).

TAMAULIPAN PALM GROVE RIPARIAN FOREST (CES301.991)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland [Lowland]; Forest and Woodland (Treed); Tropical/Subtropical [Tropical Xeric]; Riverine / Alluvial; Palm Tree; Sabal mexicana
National Mapping Codes: ESLF 9152

CONCEPT

Summary: This ecological system is limited to riparian areas along the lower Rio Grande and Rio Corona in southern Texas and northeastern Mexico. Stands occur on riverbanks and floodplains. The characteristic species are the neotropical *Sabal mexicana* with *Ebenopsis ebano, Ehretia anacua, Leucaena pulverulenta*, and many other riparian species such as *Acacia farnesiana, Diospyros texana, Fraxinus berlandieriana*, or *Ulmus crassifolia*. The understory is dominated by neotropical species.

- South Texas: Palm Grove (7502) [CES301.991] (Elliott 2011) Equivalent

DESCRIPTION

Environment: Stands of this ecological system occur on riverbanks and floodplains in riparian areas along the lower Rio Grande and Rio Corona in southern Texas and northeastern Mexico. The geologic substrate is Quaternary alluvium. It is currently found on levees and resaca margins and adjacent lower sites near the current Rio Grande channel (Elliott 2011). It was historically more widespread within the Rio Grande delta. Soils are Loamy or Clayey Bottomland Ecological Sites. This system is currently limited to relatively small groves (typically less than 20 hectares) of Sabal mexicana (sometimes referred to as Sabal texana) located on loamy or clayey bottomland soils, such as those of the Rio Grande, Zalla, and Matamoros series, on the Rio Grande Delta and near the Rio Grande itself in Cameron County, Texas, and similar sites in adjacent Mexico. These often occupy slight elevations along the margins of resacas or old river terraces, but may also occur on level sites. The system may have once occurred along the Rio Grande more than 120 km from its mouth, but is now limited to a few sites near the Gulf of Mexico, with a few small stands identified in extreme southern Hidalgo County, Texas (Elliott 2011).
Vegetation: This system is currently limited to relatively small groves (typically less than 20 hectares) of *Sabal mexicana* (sometimes referred to as *Sabal texana*). These forests and woodlands often have a canopy dominated by *Sabal mexicana*, or may share dominance with other floodplain species such as *Ebenopsis ebano, Celtis laevigata, Leucaena pulverulenta, Ulmus crassifolia, Ehretia anacua*, and *Fraxinus berlandieriana*. *Prosopis glandulosa, Sapindus saponaria var. drummondii*, and *Diospyros texana* are often present in the subcanopy (Elliott 2011). The canopy of these forests may reach a height of 15 m, and the subcanopy (to 10 m) may be composed of some of the species mentioned above. The shrub layer can be patchy with some areas extremely dense and containing species such as *Zanthoxylum fagara, Malpighia glabra, Celtis pallida (= Celtis ehrenbergiana), Erythrina herbacea, Ziziphus obtusifolia, Randia rhagocarpa, Parkinsonia aculeata, Havardia pallens, Chiococca alba, Iresine palmeri*, and members of the canopy and subcanopy, and other areas relatively open. In some situations the ground may be covered with a layer of dead palm fronds, restricting the development of an herbaceous layer. In other areas, species including, but not limited to, *Leersia monandra, Salvia coccinea, Petiveria alliacea, Rivina humilis, Plumbago scandens, Tamaulipa azurea, Cocculus diversifolius*, and *Malvaviscus arboreus* may be present in the herbaceous layer (Elliott 2011).
Dynamics: Fire may have been an important process in these forests as the sites may become extremely dry and a significant, if patchy, layer of palm thatch may be present. These forests appear to differ from other forests dominated by *Sabal mexicana* further to the south. Martinez-Ojeda and GonzÃ¡lez-Medrano (1977) describe a site of limited distribution in the northern part of the Sierra de San JosÃ© de las Rusias in the Municipio of Soto La Marina in Tamaulipas, Mexico. It occurs at higher altitudes and on Oligocene geologic formations. Their brief description suggests that this is likely different in composition and process from the presently described system. Lopez and Dirzo (2007) describe a site further south in Vera Cruz that also seems to differ relative to composition. Palm groves were once common in the lower Rio Grande Valley 80 miles from the Gulf of Mexico, but have since largely been converted to agriculture.

The major process in this system was flooding. Freezes can have significant impacts on canopy species such as *Ebenopsis, Sabal* and *Leucaena pulverulenta* in the delta. Hurricanes may not significantly affect dense ebony/anacua forest, except through flood effects. Lengthy droughts (lasting 10 years) can influence this system, but most species are drought-tolerant. Infrequent fires may also occur (Landfire 2007a).

Component Associations:
- *Sabal mexicana - Ebenopsis ebano* Forest (CEGL002056, G2)

TAMAULIPAN RAMADERO (CES301.992)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Intermittent Flooding; Lowland [Lowland]; Shrubland (Shrub-dominated); Arroyo; Tropical/Subtropical [Tropical Xeric]; Riverine / Alluvial
National Mapping Codes: ESLF 9158

CONCEPT

Summary: This Tamaulipan riparian shrubland system is restricted to drainages in upland areas or ramaderos of southern Texas and adjacent Mexico that are intermittently flooded. Typical stands have a closed canopy (relative to the surrounding landscape) from 5 to 10 m in height. The overstory canopy is typically dominated by species such as *Prosopis glandulosa, Acacia farnesiana, Celtis pallida (= Celtis ehrenbergiana)*, and/or *Parkinsonia aculeata*. In addition, *Celtis laevigata* and/or *Ebenopsis ebano* may also be present in the canopy. Some sites have a relatively open subcanopy, but more commonly the shrub layer is thick, sometimes impenetrable, and varies in height from 1 to 5 m. Species commonly encountered in the shrub layer include *Aloysia gratissima, Phaulothamnus spinescens, Celtis pallida, Condalia hookeri, Forestiera angustifolia, Diospyros texana, Ziziphus obtusifolia, Koeberlinia spinosa, Malpighia glabra, Zanthoxylum fagara, Opuntia engelmannii var. lindheimeri, Guajacum angustifolium, Colubrina texensis,* and *Amyris texana*. Ground cover can be sparse or, in more open stands, may have a fairly continuous grassy cover.
Classification Comments: The Ramadero of Jahrsdoerfer and Leslie (1988) is equivalent to this system concept, but could be considered narrower if more information on how it occurs elsewhere in Mexico can be obtained. Not much more information is likely to be found because this system is not sampled very often. Intermittent drainages (arroyos and ramaderos) are not sampled that often because of scale and variability issues. More information is needed to fully characterize this system.
Similar Ecological Systems:
- Edwards Plateau Limestone Shrubland (CES303.041)
- Tamaulipan Closed Depression Wetland (CES301.197)

Related Concepts:

- South Texas: Ramadero Woodland (7604) [CES301.992.4] (Elliott 2011) Finer

DESCRIPTION

Environment: This Tamaulipan riparian shrubland system is restricted to drainages in upland areas or ramaderos (isolated strips of dense brush associated with arroyos) that are intermittently flooded. This is a widespread system on various geologic strata. It is typically found in upland drainages in various landscapes. Drainages are extremely flashy from runoff from surrounding landscape. These sites are infrequently flooded during local rainfall events, but because they accumulate runoff, they tend to be slightly more mesic in this otherwise xeric landscape. Soils are various upland soils (but not Bottomland ecological site types). These are sometimes mapped specifically as Ramadero Ecological Site. These woodlands are found along drainages (locally known as ramaderos) that are extremely flashy and are infrequently and briefly flooded during local rain events. The soils are typically clay loams or sandy clay loams
Vegetation: Moisture accumulation due to the topographic position of these woodlands promotes the development of a closed canopy (relative to the surrounding landscape) from 5 to 10 m in height. The overstory canopy is typically dominated by species such as *Prosopis glandulosa, Acacia farnesiana, Celtis pallida (= Celtis ehrenbergiana)*, and/or *Parkinsonia aculeata*. In addition, *Celtis laevigata* and/or *Ebenopsis ebano* may also be present in the canopy. Some sites have a relatively open subcanopy, but more commonly the shrub layer is thick, sometimes impenetrable, and varies in height from 1 to 5 m (Elliott 2011). Species commonly encountered in the shrub layer include *Aloysia gratissima, Phaulothamnus spinescens, Celtis pallida, Condalia hookeri, Forestiera angustifolia, Diospyros texana, Ziziphus obtusifolia, Koeberlinia spinosa, Malpighia glabra, Zanthoxylum fagara, Opuntia engelmannii var. lindheimeri, Guajacum angustifolium, Colubrina texensis*, and *Amyris texana*. Ground cover can be sparse or, in more open stands, may have a fairly continuous grassy cover. Species encountered in the herbaceous layer include *Clematis drummondii, Parietaria pensylvanica, Salvia coccinea, Calyptocarpus vialis, Rivina humilis, Malvastrum americanum, Ruellia* sp., and *Verbesina microptera*. Grasses include *Chloris pluriflora (= Trichloris pluriflora), Bothriochloa barbinodis, Bouteloua curtipendula, Setaria scheelei, Setaria vulpiseta (= Setaria macrostachya), Setaria leucopila, Chloris cucullata, Digitaria californica, Pappophorum bicolor, Bouteloua trifida, Buchloe dactyloides (= Bouteloua dactyloides),* and *Hilaria belangeri*. The introduced grasses *Pennisetum ciliare, Urochloa maxima,* and *Cynodon dactylon* often dominate these sites, sometimes to the near exclusion of other herbaceous cover (Elliott 2011). This system may merge downstream with Tamaulipan Floodplain (CES301.990).
Dynamics: Intermittent fluvial processes define this system, which are often associated with rapid sheet and gully flow that scours

the channel bottoms.

Component Associations:
- *Acacia farnesiana - (Prosopis glandulosa)* Woodland (CEGL002131, G5)

WEST GULF COASTAL PLAIN LARGE RIVER FLOODPLAIN FOREST (CES203.488)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); West Gulf Coastal Plain; Riverine / Alluvial [Brownwater]; Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 9197

CONCEPT

Summary: This system represents a geographic subset of Kuchler's (1964) Southern Floodplain Forest found west of the Mississippi River. Examples may be found along large rivers of the West Gulf Coastal Plain and Upper West Gulf Coastal Plain, especially the Trinity, Neches, Sabine, and others. Several distinct plant communities can be recognized within this system that may be related to the array of different geomorphic features present within the floodplain. Some of the major geomorphic features associated with different community types include natural levees, point bars, meander scrolls, oxbows, and sloughs. Vegetation generally includes forests dominated by bottomland hardwood species and other trees tolerant of flooding, including bald-cypress and water tupelo. Some other trees which may be associated with examples of this system include *Acer rubrum var. drummondii, Betula nigra, Carya aquatica, Celtis laevigata, Fraxinus pennsylvanica, Liquidambar styraciflua, Platanus occidentalis, Gleditsia aquatica, Nyssa aquatica, Nyssa biflora, Pinus taeda, Populus deltoides, Quercus laurifolia, Quercus lyrata, Quercus michauxii, Quercus nigra, Quercus pagoda, Quercus phellos, Quercus similis, Quercus texana, Salix nigra, Ulmus americana*, and *Ulmus crassifolia*. Smaller areas of herbaceous- and shrub-dominated vegetation may also be present in certain areas. Shrubs and small trees include *Alnus serrulata, Arundinaria gigantea, Carpinus caroliniana, Cephalanthus occidentalis, Clethra alnifolia, Cornus foemina, Crataegus viridis, Forestiera acuminata, Ilex decidua, Itea virginica, Morella cerifera, Planera aquatica, Sabal minor*, and *Sebastiania fruticosa*. Vines may include *Berchemia scandens* and *Smilax bona-nox*. Herbaceous species may include *Boehmeria cylindrica, Carex complanata, Carex debilis, Carex intumescens, Carex joorii, Leersia virginica, Lycopus virginicus, Mikania scandens, Saccharum baldwinii*, and *Typha latifolia*. Aquatic and floating herbs include *Lemna minor, Nelumbo lutea, Nuphar advena (= Nuphar lutea ssp. advena)*, and *Nymphaea odorata*.

Classification Comments: It is unclear to what system the Brazos and Colorado rivers belong. A new system is apparently required to accommodate these and other rivers in the Coastal Plain south and west of Galveston Bay. Or would they go into West Gulf Coastal Plain Near-Coast Large River Swamp (CES203.459)?

DESCRIPTION

Environment: Some of the major geomorphic features associated with different community types within this system include natural levees, point bars, meander scrolls, oxbows, and sloughs (Sharitz and Mitsch 1993). This system typically occupies Quaternary Alluvial geology along major rivers including the Trinity (downstream of Cobb Creek), Neches, Angelina, Sabine, Sulphur, and San Jacinto, and a few of their major tributaries. Landforms include broad floodplains with significant development of bottomland soils. These areas include an array of local geomorphic features such as natural levees, point bars, meander scrolls, oxbows, terraces, and sloughs. This system occupies soils of various textures derived from alluvial processes of the associated rivers. The hydrology of these soils is variable, including temporary, seasonal, and semipermanent flooding regimes.

Vegetation: This system is typically represented by forests that vary relative to the flooding regime, which is often controlled by local topographic variation and proximity to a river. Swamps are typically represented by forests of *Taxodium distichum*, with other species such as *Nyssa aquatica*, *Gleditsia aquatica*, and *Carya aquatica* also present. Some semipermanently flooded sites may also be dominated by *Planera aquatica*. Floating aquatics, such as *Lemna minor*, *Potamogeton* spp., *Ceratophyllum demersum*, and *Nymphaea odorata*, may also be present at those sites. *Quercus lyrata* is characteristic of seasonally flooded bottomlands, but numerous other species are also important components of the canopy, including *Taxodium distichum, Quercus phellos, Fraxinus pennsylvanica, Liquidambar styraciflua, Nyssa biflora, Fraxinus caroliniana*, and *Quercus similis*. Commonly encountered, and sometimes dominant, species of temporarily flooded sites include *Liquidambar styraciflua, Quercus nigra*, and *Fraxinus pennsylvanica*. Numerous other species, such as *Quercus laurifolia, Quercus michauxii, Quercus pagoda, Quercus phellos, Quercus texana, Celtis laevigata, Acer rubrum var. drummondii, Ulmus crassifolia, Ulmus americana*, and *Carya illinoinensis*, may also be important components of the canopy. *Platanus occidentalis, Populus deltoides, Betula nigra*, and *Salix nigra* are more conspicuous as early-successional species along the riverfront. Understory and shrub cover is variable but is typically relatively low, particularly in more frequently flooded sites and sites with significant overstory canopy. The understory may have small individuals of the overstory, as well as species such as *Alnus serrulata, Arundinaria gigantea, Carpinus caroliniana, Ilex decidua, Ilex opaca, Callicarpa americana, Crataegus viridis, Crataegus marshallii, Crataegus opaca, Styrax americanus, Sebastiania fruticosa (= Ditrysinia fruticosa), Sambucus canadensis (= Sambucus nigra ssp. canadensis), Clethra alnifolia, Cornus foemina, Forestiera acuminata, Ilex decidua, Itea virginica, Morella cerifera*, and/or *Sabal minor*. Where the overstory canopy is open, *Planera aquatica, Cephalanthus occidentalis*, or *Forestiera acuminata* may form dense stands. Woody vines that may be encountered include *Berchemia scandens, Smilax bona-nox, Vitis rotundifolia, Toxicodendron radicans*, and *Campsis radicans*. Herbaceous species may include *Boehmeria cylindrica, Saururus cernuus, Saccharum baldwinii, Elymus virginicus, Onoclea sensibilis, Carex cherokeensis, Carex complanata, Carex intumescens, Carex joorii, Carex debilis*, other *Carex* species, *Chasmanthium latifolium, Chasmanthium sessiliflorum, Justicia ovata, Bidens aristosa, Panicum hemitomon, Leersia virginica, Lycopus virginicus, Mikania scandens, Saccharum baldwinii, Typha latifolia*, and numerous others. *Pinus taeda* may be found, particularly on some better-drained sites and where it has been planted. *Triadica sebifera* sometimes invades this system. Aquatic and floating herbs include *Lemna minor, Nelumbo lutea, Nuphar advena (= Nuphar lutea ssp. advena)*, and *Nymphaea odorata*.

- *Typha latifolia* Southern Herbaceous Vegetation (CEGL004150, G5)

DISTRIBUTION

Range: This system occurs along large rivers of the West and Upper West Gulf coastal plains, especially the Trinity, Neches, Sabine, and others, as well as the portion of the Red River represented by Keys et al. (1995) (231Em) at the Oklahoma-Texas border.
Divisions: 203:C
Nations: US
Subnations: AR, LA, OK, TX
Map Zones: 37:C, 44:C, 98:C
TNC Ecoregions: 31:C, 40:C, 41:C

WEST GULF COASTAL PLAIN NEAR-COAST LARGE RIVER SWAMP (CES203.459)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: West Gulf Coastal Plain; Riverine / Alluvial; Tidal / Estuarine
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9314

CONCEPT

Summary: These swamp forests are found along rivers flowing through the Gulf Coast Prairies and Marshes region of the Outer Coastal Plain of western Louisiana and adjacent Texas. Included are areas where the rivers enter bays and estuaries along the northern Gulf of Mexico that are somewhat tidally influenced. This is restricted to Vermillion Bay in Louisiana west to and including Galveston Bay and Trinity Bay in Texas. Stands of vegetation included in this system are typically dominated by *Taxodium distichum, Nyssa aquatica*, or perhaps a combination of these species. These are forested areas in an area primarily dominated by marshes. Other species are usually more minor components of the canopy, including *Fraxinus pennsylvanica, Acer negundo*, and the exotic tree *Triadica sebifera*. These swamps are typically interspersed with marshes of the coastal region.

Related Concepts:
- Baldcypress: 101 (Eyre 1980) Finer
- Gulf Coast: Near-Coast Baldcypress Swamp (5004) [CES203.459] (Elliott 2011) Equivalent
- Water Tupelo - Swamp Tupelo: 103 (Eyre 1980) Finer

DESCRIPTION

Environment: The environment of this system consists of rivers flowing through the Gulf Coast Prairies and Marshes ecoregion of the Outer Coastal Plain of western Louisiana and adjacent Texas. This includes somewhat tidally-influenced areas where the rivers enter bays and estuaries along the northern Gulf of Mexico. The geological substrate consists of Quaternary alluvium deposited within the Beaumont/Deweyville surfaces. Landforms include the large river floodplains of the Sabine, Neches, and Trinity rivers near the coast, often with some tidal influence. Typical soils include bottomland soils of the near-coast region. Stands are generally distributed downstream of Interstate Highway 10 (a coincidental landmark for the distribution of this system). On the Neches River, this is nearly coincident with the area downstream of the confluence with Pine Island Bayou (Elliott 2011).

Vegetation: Stands of vegetation included in this system are typically dominated by *Taxodium distichum, Nyssa aquatica*, or perhaps a combination of these species. These are forested areas in an area primarily dominated by marshes. Other species are usually more minor components of the canopy, including *Fraxinus pennsylvanica, Acer negundo*, and the exotic tree *Triadica sebifera*. These swamps are typically interspersed with marshes of the coastal region (Elliott 2011).

Component Associations:
- *Taxodium distichum / Lemna minor* Forest (CEGL002420, G4G5)

DISTRIBUTION

Range: This system is found along rivers flowing through the Gulf Coast Prairies and Marshes (TNC Ecoregion 31) of the Outer Coastal Plain of western Louisiana and adjacent Texas. This is restricted to EPA 34g (Texas-Louisiana Coastal Marshes) from Vermillion Bay in Louisiana west to, and including Galveston Bay and Trinity Bay in Texas (EPA 2004).

WEST GULF COASTAL PLAIN NONRIVERINE WET HARDWOOD FLATWOODS (CES203.548)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); West Gulf Coastal Plain; Hardpan; Depressional; Silt Soil Texture
Non-Diagnostic Classifiers: Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2506; ESLF 9350; ESP 1506

CONCEPT

Summary: This ecological system represents predominantly wet hardwood flatwoods of the West Gulf Coastal Plain of southern Arkansas, eastern Texas, and western Louisiana. Examples may be somewhat more common in the inland portions of the region but are also found in the Outer Coastal Plain as well. These areas are usually found on Pleistocene high terraces (EPA Ecoregion 35c) primarily associated with the Red and Mississippi rivers that are located above the current floodplain. The hydrology is controlled by local rainfall events and not by overbank flooding. Soils are fine-textured, and hardpans may be present in the subsurface. The limited permeability of these soils contributes to perched water tables during fairly substantial portions of the year (when precipitation is greatest and evapotranspiration is lowest). Saturation occurs not from overbank flooding but typically whenever precipitation events occur. The local landscape is often a complex of ridges and swales, usually occurring in close proximity. There is vegetation variability related to soil texture and moisture and disturbance history. Most examples support hardwood forests or swamps, which are often heavily oak-dominated. Important species are tolerant of inundation. They include *Quercus michauxii, Quercus phellos, Quercus laurifolia*, and *Liquidambar styraciflua*, with sparse coverage of wetland herbs such as *Carex glaucescens*. Some swales support unusual pockets of *Fraxinus caroliniana* and *Crataegus* spp. Some examples can contain *Pinus taeda*.
Classification Comments: This system may grade upslope into West Gulf Coastal Plain Pine-Hardwood Flatwoods (CES203.278) and down into West Gulf Coastal Plain Flatwoods Pond (CES203.547). Apparently, this system occurs within the historic range of longleaf pine [see USFS ecomap attributions]. Within this range, more information is needed to identify the toposequence between longleaf pine-dominated flatwoods/savannas/uplands and hardwood/loblolly-dominated flatwoods. The distribution of this system in the South Central Plains Flatwoods and Southern Tertiary Uplands (EPA 35e and f) needs to be better defined.
Similar Ecological Systems:
- Interior Highlands Unglaciated Flatwoods (CES202.454)
- Lower Mississippi River Flatwoods (CES203.193)
- West Gulf Coastal Plain Flatwoods Pond (CES203.547)
- West Gulf Coastal Plain Pine-Hardwood Flatwoods (CES203.278)

DESCRIPTION

Environment: This system is found on the wettest inclusions of Pleistocene terraces in the West Gulf Coastal Plain of southern Arkansas, eastern Texas, and western Louisiana. The geology of this system is similar to that of West Gulf Coastal Plain Pine-Hardwood Flatwoods (CES203.278), being associated with high Pleistocene terraces of the Lissie and upper Beaumont formations, as well as the Quaternary Fluviatile Terrace Deposits to the north. In terms of landforms, this system represents the lowest topographic position within the level to very gently undulating terraces occupied by flatwoods. Hydrology is controlled by local rainfall, not overbank flooding of nearby streams. Soils are fine-textured, with an impermeable subsurface horizon, which leads to a perched water table. Because of the lower topographic position of these flatwoods, saturated soil conditions tend to occur over extended periods of the year (Elliott 2011).
Vegetation: This system represents the wetter end of the wooded toposequence of the flatwoods and occurs within low positions of swales and other wet circumstances. Stands are closed-canopy forests, typically dominated by deciduous hardwoods, including *Quercus michauxii*. Important species are tolerant of inundation. The canopy is often dominated by *Quercus phellos, Quercus laurifolia, Quercus lyrata, Quercus nigra, Quercus michauxii, Ulmus alata*, and *Liquidambar styraciflua*. *Pinus taeda* may be present in the canopy. *Triadica sebifera* is a commonly encountered non-native species invading this system. The understory and herbaceous layers of this system are not well-developed, as the canopy tends to be closed (Elliott 2011). There is sparse coverage of wetland herbs such as *Carex glaucescens*. Some swales support unusual pockets of *Fraxinus caroliniana* and *Crataegus* spp. Some examples can contain *Pinus taeda*.

Dynamics: The predominant ecological processes affecting this system are related to soil texture and moisture and disturbance history. These are wetlands that hold standing water for variable periods during the year after rainfall events. The wettest examples were likely not affected to a large degree by fires; however, they are often embedded in pyrogenic landscapes which did burn frequently (R. Evans pers. obs., T. Foti pers. comm.). The difference in the dynamics between this system and the "non-wet" (dry-mesic, xero-hydric) flatwoods of the region (CES203.278) is their different structure: the wetter type occurs as a closed forest, the dry/mesic one as a more open forest or woodland (with an open canopy, a full herbaceous expression, and few shrubs). The fire regime is different as well: the xero-hydric type is short-interval, low-intensity, low-severity versus medium- to long-interval, low-intensity, high-severity for the wet one (D. Zollner pers. comm. 2006).

Component Associations:
- *(Quercus laurifolia) / Crataegus opaca - Crataegus viridis* Forest (CEGL007386, G1)
- *Fraxinus caroliniana* Seasonally Flooded Forest (CEGL004753, G2G3)
- *Nyssa biflora - Quercus laurifolia / Sphagnum* spp. Depression Forest (CEGL007390, G3?)
- *Quercus laurifolia - Liquidambar styraciflua - Nyssa biflora - Acer rubrum / Sabal minor* Forest (CEGL007804, G3?)
- *Quercus laurifolia - Quercus phellos - Quercus nigra / Viburnum dentatum - (Sebastiania fruticosa) / Carex glaucescens* Upper West Gulf Flatwoods Forest (CEGL007961, G2G3)
- *Quercus lyrata - Quercus phellos - Ulmus americana / Rhynchospora* spp. Forest (CEGL007549, G2G3)
- *Quercus phellos - Quercus similis / Crataegus marshallii - Crataegus spathulata / Chasmanthium laxum* Forest (CEGL007363, G3?)
- *Quercus phellos / Chasmanthium laxum - Carex (flaccosperma, intumescens) - Hymenocallis liriosme* Flatwoods Forest (CEGL007371, G3G4)
- *Quercus phellos / Chasmanthium laxum* Forest (CEGL008576, G3?)
- *Taxodium distichum - Nyssa biflora - Magnolia virginiana - Acer rubrum* Forest (CEGL007902, G2?)

WEST GULF COASTAL PLAIN SEEPAGE SWAMP AND BAYGALL (CES203.372)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: West Gulf Coastal Plain; Seepage-Fed Sloping; Broad-Leaved Tree
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated)
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2462; ESLF 9131; ESP 1462

CONCEPT

Summary: This West Gulf Coastal Plain ecological system consists of forested wetlands (often densely wooded) in acidic, seepage influenced wetland habitats. These wetlands may occur in poorly developed upland drainages, toeslopes, and small headwaters stream bottoms. These environments are prone to long duration standing water, and tend to have highly acidic, nutrient-poor soils. The vegetation is characterized by an overstory of *Magnolia virginiana, Nyssa sylvatica, Nyssa biflora,* and *Acer rubrum,* although there is some variation according to latitude. Understory vegetation throughout the region consistently supports the vines *Smilax laurifolia* and *Smilax walteri*, and a dense abundance of ferns, such as *Osmunda cinnamomea, Osmunda regalis var. spectabilis*, and *Woodwardia areolata*. In most cases, these wetlands are embedded in uplands with deep sandy soils, recharge areas for this wetland system. When these communities are associated with streams, they tend to be low gradient, with narrow, often braided channels and diffuse drainage patterns. Due to excessive wetness, these habitats are normally protected from fire except those which occur during extreme droughty periods. The limited examples in Oklahoma are somewhat depauperate and lack some of the more southern and eastern taxa (e.g., *Magnolia virginiana, Nyssa biflora*).

DESCRIPTION

Environment: This system occurs on saturated soils associated with springs and seepage flow in a variety of landscape positions. In the Outer Coastal Plain, these settings tend to be low landscape positions typically along low-gradient creeks, headwaters of drainages, or local depressions (Elliott 2011). The low-gradient creek channels tend to be highly meandering, often with multiple channels and extremely shallow banks. Nixon et al. (1983a) measured stream depths of 0.3-0.6 m and widths of less than 1 m in a study of this system. Inner Coastal Plain examples tend to be embedded within deep sandy slopes and uplands, and may also occur in association with flatwoods drainages (Martin et al. 1990, Martin and Smith 1991, Smith 1996a, Singhurst pers. comm. 2013). It may occur on a range of geological formations, including intermediate to high Pleistocene terraces, Eocene sands, the Catahoula Formation, and the Wilcox Formation. Soils are typically sandy to loamy soils, often with an impermeable subsurface layer that restricts water percolation. These sites are typically semipermanently saturated. These are typically soils of medium to strong acidity, with low available nutrients and significant organic accumulation (Elliott 2011). The deep, poorly drained, strongly acidic, loamy fine sand soils have high organic matter content (Brooks et al. 1993). Van Kley (1999a) indicates that these habitats, sometimes mapped as the Betis soil series and Guyton soil complex, are notably low in calcium and magnesium. Soils of other examples may be mapped as Lovelady (Arenic Glossudalf), Rentzel (Arenic Plinthaquic Paleudult), Corrigan (Typic Albaqualf), Melhomes (Humaqueptic Psammaquent), and Osier (Typic Psammaquent). This system is known from the Pleistocene Terraces and Tertiary uplands in Louisiana, Texas, Arkansas and to a limited extent in Oklahoma. Geologic formations where this system occurs include: Bentley (Intermediate Pleistocene Terraces), Willis (High Pleistocene Terraces), Fleming (Miocene), Catahoula (Oligocene), Cockfield (Eocene), Sparta (Eocene), Carrizo (Eocene), Wilcox (Eocene), Queen City (Eocene) and possibly the Vicksburg (Oligocene) and other formations.

Vegetation: Examples of this system are characterized by overstory species such as *Magnolia virginiana, Nyssa biflora*, and *Acer rubrum*. Other species in the overstory may include *Fraxinus pennsylvanica, Quercus nigra, Liquidambar styraciflua,* and *Quercus laurifolia*. A well-developed woody understory is often present and includes species such as *Morella caroliniensis, Itea virginica, Persea palustris, Rhododendron prinophyllum, Rhododendron canescens, Ilex decidua, Vaccinium fuscatum, Ilex opaca, Toxicodendron vernix, Viburnum nudum, Morella cerifera, Alnus serrulata, Smilax laurifolia*, and *Vitis rotundifolia*. There is some variation with latitude. Southerly examples generally consist of broad-leaved evergreen forests, while more northerly examples support more mixed evergreen-deciduous forests. In addition, evergreen species are especially pronounced in the shrub layer of southern examples. Southern expressions of the type are more likely to have *Ilex coriacea* and/or *Cyrilla racemiflora*. The herbaceous

layer is often dominated by ferns such as *Woodwardia areolata, Osmunda regalis, Osmunda cinnamomea,* and *Athyrium filix-femina*. *Carex* spp., *Rhynchospora* spp., and *Eleocharis* spp. are also frequently encountered. *Sphagnum* occurs in patches throughout, and other bryophytes are common. The rare species *Bartonia texana* may be encountered in this system, along with other interesting forbs such as *Burmannia biflora* and *Apteria aphylla* (Elliott 2011).
Dynamics: This system is maintained by groundwater seepage. Soils have high available water capacity and surface runoff is very slow to ponded. This ecological system is embedded within fire-maintained systems. The role of fire in this system was probably minimal except during droughts or in narrow occurrences where fire may have maintained an example of this system dominated by *Arundinaria gigantea*.

Component Associations:
- *(Magnolia virginiana) / Ilex coriacea - Morella caroliniensis* Shrubland (CEGL003530, G3?)
- *Acer rubrum (var. drummondii) - Nyssa* spp. - *Liquidambar styraciflua - Quercus nigra / Osmunda* spp. Saturated Forest (CEGL007982, G3?)
- *Dichanthelium scoparium - Boehmeria cylindrica / Sphagnum* spp. - *Polytrichum commune* Herbaceous Vegetation (CEGL004916, G2Q)
- *Magnolia virginiana - Nyssa (biflora, sylvatica) - Acer rubrum / Morella caroliniensis / Woodwardia areolata* Forest (CEGL007904, G3?)
- *Nyssa (biflora, sylvatica) - Magnolia virginiana - Quercus laurifolia / Cyrilla racemiflora - Ilex coriacea - Rhododendron oblongifolium* Forest (CEGL007474, G3?)
- *Quercus laurifolia - (Quercus nigra, Nyssa biflora) / Diospyros virginiana* Forest (CEGL007871, G3?)
- *Viburnum nudum var. nudum - Morella cerifera - Smilax laurifolia* Shrubland (CEGL007874, G1?)

DISTRIBUTION

Range: This system is restricted to eastern Texas, western Louisiana, southern Arkansas, and extreme southeastern Oklahoma.
Divisions: 203:C
Nations: US

WEST GULF COASTAL PLAIN SMALL STREAM AND RIVER FOREST (CES203.487)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Intermittent Flooding; Forest and Woodland (Treed); West Gulf Coastal Plain; Riverine / Alluvial
National Mapping Codes: ESLF 9196

CONCEPT

Summary: This is a predominantly forested system of the West Gulf Coastal Plain associated with small rivers and creeks. In contrast to West Gulf Coastal Plain Large River Floodplain Forest (CES203.488), examples of this system have fewer major geomorphic floodplain features. Those features that are present tend to be smaller and more closely intermixed with one another, resulting in less obvious vegetational zonation. Bottomland hardwood tree species are typically important and diagnostic, although mesic hardwood species are also present in areas with less inundation, such as upper terraces and possibly second bottoms. As a whole, flooding occurs annually, but the water table usually is well below the soil surface throughout most of the growing season. Areas impacted by beaver impoundments are also included in this system. Stands of this system are typically dominated by hardwood tree species such as *Liquidambar styraciflua, Quercus nigra, Celtis laevigata, Fraxinus pennsylvanica, Betula nigra, Quercus laurifolia, Ulmus americana, Ulmus crassifolia, Ulmus alata, Ulmus rubra, Quercus michauxii, Quercus texana, Quercus pagoda, Quercus falcata, Platanus occidentalis, Diospyros virginiana, Gleditsia triacanthos,* and *Acer rubrum*. Wetter sites tend to be dominated by more flood-tolerant species such as *Taxodium distichum, Nyssa aquatica, Gleditsia aquatica, Carya aquatica, Quercus lyrata, Quercus similis, Planera aquatica,* and *Quercus phellos*.

DESCRIPTION

Environment: This system is associated with small rivers and creeks in the West Gulf Coastal Plain. It largely occurs on Quaternary alluvium, but may also be found on other mapped geologic surfaces on drainages lacking significant alluvial development. This system occupies small rivers, streams, creeks, and upland drainages. These sites tend to be higher in the watershed where less depositional activity occurs. The local geomorphological variation tends to be less than in West Gulf Coastal Plain Large River Floodplain Forest (CES203.488). Soils are bottomland soils on small streams. A minority of sites are seasonally or semipermanently flooded (Elliott 2011).

Vegetation: Stands of this system are typically dominated by hardwood tree species such as *Liquidambar styraciflua, Quercus nigra, Celtis laevigata, Fraxinus pennsylvanica, Betula nigra, Quercus laurifolia, Ulmus americana, Ulmus crassifolia, Ulmus alata, Ulmus rubra, Quercus michauxii, Quercus texana, Quercus pagoda, Quercus falcata, Platanus occidentalis, Diospyros virginiana, Gleditsia triacanthos,* and *Acer rubrum*. Wetter sites tend to be dominated by more flood-tolerant species such as *Taxodium distichum, Nyssa aquatica, Gleditsia aquatica, Carya aquatica, Quercus lyrata, Quercus similis, Planera aquatica*, and *Quercus phellos*. In addition,

Pinus taeda, *Pinus elliottii*, and/or *Juniperus virginiana* may be present in the canopy, or occur as a subcanopy stratum. Rarely, *Fagus grandifolia*, *Magnolia virginiana*, *Quercus alba*, *Quercus muehlenbergii*, and/or *Pinus palustris* may appear with *Chasmanthium sessiliflorum* in mesic, upper terrace examples. Shrubs may form dense patches with species such as *Cephalanthus occidentalis* or *Planera aquatica* being typical. Other shrubs and understory trees may include (depending on length of hydroperiod) *Carpinus caroliniana*, *Ostrya virginiana*, *Cornus obliqua*, *Crataegus marshallii*, *Ilex opaca*, *Ilex decidua*, *Ilex vomitoria*, *Salix nigra*, *Morus rubra*, *Sabal minor*, *Morella cerifera*, *Callicarpa americana*, *Itea virginica*, *Alnus serrulata*, *Maclura pomifera*, and *Vaccinium fuscatum*. In addition, *Arundinaria gigantea* may be present. Woody vines may be conspicuous and may include *Berchemia scandens*, *Brunnichia ovata*, *Ampelopsis arborea*, *Smilax bona-nox*, and *Toxicodendron radicans*. Some herbs may include *Ambrosia trifida*, *Bidens aristosa*, *Boehmeria cylindrica*, *Carex cherokeensis*, *Carex debilis*, *Carex digitalis*, *Carex joorii*, *Chasmanthium latifolium*, *Chasmanthium laxum*, *Dichanthelium* spp., *Elymus virginicus*, *Geum canadense*, *Glyceria striata*, *Leersia virginica*, *Panicum virgatum*, *Paspalum floridanum*, *Polygonum hydropiperoides*, *Tripsacum dactyloides*, and *Xanthium strumarium*. Early-successional woodlands may be mapped as shrublands, due to reduced woody cover. These sites may be dominated by early-successional species such as *Salix nigra*, *Gleditsia triacanthos*, *Platanus occidentalis*, or *Ulmus alata*. Non-native woody species that may be present include *Triadica sebifera*, *Lonicera japonica*, and *Ligustrum* spp. Non-native herbs such as *Cynodon dactylon*, *Lolium perenne*, *Paspalum notatum*, and *Sorghum halepense* may be dominant in disturbed examples (Elliott 2011).

Component Associations:
- *Betula nigra - Liquidambar styraciflua - Platanus occidentalis - Quercus nigra* Forest (CEGL007898, G4Q)

WEST GULF COASTAL PLAIN WET LONGLEAF PINE SAVANNA AND FLATWOODS (CES203.191)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); West Gulf Coastal Plain; Extensive Wet Flat; Very Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2451; ESLF 9120; ESP 1451

CONCEPT

Summary: This system was the historical matrix vegetation of the outer (seaward) portions of the West Gulf Coastal Plain between the coastal prairies and the inner coastal plain in Louisiana and eastern Texas within the range of longleaf pine. These areas are characterized by poorly drained upland soils with high and highly fluctuating water tables. In natural condition, monospecific stands of *Pinus palustris* and species-rich herbaceous layers characterize this system. Other species in the canopy include *Quercus stellata, Quercus marilandica, Nyssa sylvatica, Quercus laurifolia, Quercus falcata*, and *Liquidambar styraciflua*. Shrubs are typically limited in distribution within the system to local topographic highs and include species such as *Morella cerifera, Ilex vomitoria, Symplocos tinctoria, Cyrilla racemiflora*, and others. Widespread alterations following European settlement, including changes to natural fire regimes, have produced drastic changes to this system, and few large examples are extant. Examples appear to be somewhat more common in western Louisiana than in eastern Texas.
Classification Comments: In Louisiana, two Natural Heritage communities (variants) of this system are recognized (Smith 1996b). These two variants are the longleaf pine flatwoods (which are mesic to dry-mesic [non-wetland] stands) and the true pine savannas which occupy poorly drained and seasonally saturated/flooded depressional areas and low flats. These two types form an interdigitated mosaic (Smith 1996b), which constitutes this system as here described and defined.
Similar Ecological Systems:

DESCRIPTION

Environment: This system represents the presumed matrix vegetation on relatively recent (Pleistocene) geologic formations within the range of longleaf pine in the outer (seaward) portions of the West Gulf Coastal Plain between the coastal prairies and the inner coastal plain in Louisiana and eastern Texas. In Louisiana, these are mapped as the Intermediate Terrace and the upper Prairie Terrace (Snead and McCulloh 1984), and in Texas as the Lissie Formation and the upper Beaumont Formation (Sellards et al. 1932). The Intermediate Terrace of Snead and McCulloh (1984) includes terraces formerly designated as the Montgomery, Irene, and most of the Bentley. These areas are characterized by poorly drained upland soils with high water tables (Bridges and Orzell 1989a). Landforms include mesic to seasonally saturated low areas and flats, on level to gently rolling uplands. Microtopographic variation is provided by the presence of swales and pimple mounds. Soils are sandy to silty loams that are strongly acidic, nutrient poor, and low in organic constituents. Typically these soils are hydric, with seasonal fluctuations between saturation and droughtiness (Elliott 2011). Within the range of longleaf pine, this system is bounded on the landward side by West Gulf Coastal Plain Upland Longleaf Pine Forest and Woodland (CES203.293).
Vegetation: This system may be characterized as having a sparse canopy (under natural fire cycles) dominated by *Pinus palustris*. Other species in the canopy include *Quercus stellata, Quercus marilandica, Nyssa sylvatica, Quercus laurifolia, Quercus falcata*, and *Liquidambar styraciflua*. Shrubs are typically limited in distribution within the system to local topographic highs and include species such as *Morella cerifera, Ilex vomitoria, Symplocos tinctoria, Cyrilla racemiflora*, and others. The herbaceous layer may be highly diverse. Drier sites may be dominated by *Schizachyrium scoparium, Schizachyrium tenerum, Eupatorium rotundifolium*, and others. Wetter sites may not have species showing a clear dominance. Species such as *Liatris* spp., *Xyris* spp., *Rhexia* spp., *Rhynchospora* spp., *Fuirena* spp., *Marshallia graminifolia, Aletris aurea*, and many other species may share dominance in this system. Suppression of fire has lead to increased woody dominance. *Pinus taeda, Pinus elliottii, Liquidambar styraciflua, Nyssa sylvatica*, and *Acer rubrum* may now dominate the canopy of these sites, with a thick understory dominated by *Ilex vomitoria* and *Morella cerifera* (Elliott 2011).
Dynamics: Frequent fires (every 1-4 years), seasonal wetness and low nutrient availability of this ecological system inhibit the

establishment of woody understory species and maintain a sparse canopy of longleaf pine (Stambaugh et al. 2011a and others). This frequent fire regime is necessary to maintain the open savanna condition and provides bare ground for *Pinus palustris* regeneration. Current examples must be managed with prescribed fire. Fires are usually low in intensity overall, consuming only shrubs and herbs, but will occasionally kill patches of young pine regeneration and rarely kill individual older trees. Historically, individual fires covered extensive areas. This high fire frequency is dependent on the presence of fine fuels in the form of grasses and other graminoids. Prescribed fire has been used as an attempt to reverse the effects of decades of fire suppression. However, the results of these attempts have been mixed. Uncertainty remains over the frequency of burning necessary to restore fire-dependent ecosystems; however, a return frequency of every 2-5 years appears best. Application of burns is often too infrequent, allowing woody understory species to crowd out longleaf or, in hardwood forests, oaks, beeches and other dominant trees. Similarly, burns are ineffective if applied at the wrong life stage of plants or at the wrong point in the growing season. An example: late-spring to early-summer burns favor longleaf and associated herbaceous plants, whereas late-season or winter burns favor woody shrubs. However, prescribed burns, properly applied, are a crucial restoration and management tool in the pyrogenic longleaf pine ecosystems. Canopy gaps are created by fire mortality, lightning, and windthrow from hurricanes and tornados.

Component Associations:
- *Pinus palustris / Eryngium integrifolium - Rhynchospora* spp. - (*Ctenium aromaticum*) Woodland (CEGL003646, G2G3)
- *Pinus palustris / Rhynchospora elliottii - Lobelia flaccidifolia - Platanthera nivea - (Helenium drummondii)* Woodland (CEGL007802, G2G3)
- *Pinus palustris / Schizachyrium scoparium - Schizachyrium tenerum - Silphium gracile* Woodland (CEGL003581, G2)
- *Pinus palustris / Sporobolus silveanus - Muhlenbergia capillaris - Chaetopappa asteroides* Woodland (CEGL003654, G1)

SPATIAL CHARACTERISTICS

WESTERN CANADIAN BOREAL BLACK SPRUCE BOG AND DWARF-TREE PEATLAND (CES103.799)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Boreal (103)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Forest and Woodland (Treed); Boreal [Boreal Continental]; Depressional; Organic Peat (>40 cm)
Non-Diagnostic Classifiers: Acidic Water
National Mapping Codes: ESLF 9169

CONCEPT

Summary: These wetlands are found at higher temperate and boreal latitudes of western and central Canada, extending into the Rocky Mountain Division. They form where the rate of peat accumulation exceeds its decomposition, resulting in ombrotrophic and acidic peatlands in which the bog surface is raised above the water table. The surface morphology of the peatland may be more-or-less level, domed, or eccentric. These are primarily depressional wetlands, and secondary bog pools may also be present. While the raised portion defines these bogs, poor-fen vegetation may be present along the perimeter, due to localized groundwater input. Soils are saturated throughout the growing season from groundwater upwelling. The vegetation is dominated by dense to scattered trees with *Picea mariana* and occasionally *Larix laricina*, low ericaceous shrubs, including *Andromeda polifolia, Kalmia polifolia, Ledum groenlandicum, Chamaedaphne calyculata, Empetrum nigrum, Rubus chamaemorus, Vaccinium oxycoccos, Vaccinium vitis-idaea, Vaccinium uliginosum*,, and with patches of graminoids and bryophyte lawns. Common graminoids include *Carex pluriflora, Rhynchospora alba, Eriophorum angustifolium*, and *Calamagrostis canadensis*. *Sphagnum* species are characteristic, including *Sphagnum capillifolium, Sphagnum magellanicum, Sphagnum fuscum, Sphagnum papillosum*, and *Sphagnum cuspidatum*.
Classification Comments: Black spruce bogs and peatlands in Alaska are placed into Western North American Boreal Black Spruce Dwarf-Tree Peatland (CES105.139). It's very likely that these two systems will be combined into one North American boreal black spruce bog and peatland system.

WESTERN CANADIAN BOREAL MIXED HARDWOOD-CONIFER SWAMP AND FLOODPLAIN (CES103.523)

CLASSIFIERS

Classification Status: Standard

Primary Division: Boreal (103)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval [Short interval, Spring Flooding]; Forest and Woodland (Treed); Riverine / Alluvial; Flood Scouring
National Mapping Codes: ESLF 9396

CONCEPT

Summary: This ecological system is found throughout western boreal Canada and into central Canada. It is related to both mineral and peatland wetland types, and can occur in widely different landscape settings from mineral-soil floodplains to peatland soil. For this reason swamps have traditionally been harder to identify than other wetland types and are often confused or grouped with other wetland classes. Swamps are distinguished from other wetland types in that they are wooded (treed or shrub) wetlands that are in contact with minerotrophic water in either mineral or peatland soils. An important distinction is that the woody vegetation dominates swamp areas (often in percentages greater than 30% and up to 100% of the canopy) as a result of greater contact with nutrients, aerated soils, and high water availability. The majority of swamps have closed canopies (greater than 50%). This abundance of woody material in swamps provides another important distinction in that the peat is primarily composed of decomposing wooded material (shrub and tree) rather than the *Sphagnum*- or sedge-dominated peat types that comprise the organic layer in poor fens and bogs. Further, peat soils in swamps are fairly well-decomposed as a result of fluctuating water tables that allow for oxygen and decomposition. Important deciduous trees in these swamps and floodplains include *Betula papyrifera, Betula neoalaskana, Populus balsamifera*, and occasionally *Populus tremuloides*. In the eastern region of this type, *Acer negundo, Fraxinus pennsylvanica*, and *Ulmus americana* can occur, but are not typical. The predominant conifer is *Picea glauca*, but other conifers do occur, including *Larix laricina* and sometimes *Picea mariana*. There is often a thicket of short and tall shrubs along with the trees, or sometimes with no trees, including *Alnus incana ssp. tenuifolia, Alnus incana ssp. rugosa (= Alnus rugosa), Cornus sericea, Betula glandulosa, Betula nana, Betula pumila*, several species of *Salix*, and ericaceous shrubs such as *Empetrum nigrum, Vaccinium vitis-idaea, Vaccinium uliginosum*, and others. Sedges, forbs, ferns and mosses are all common to abundant.
Classification Comments: Boreal Canadian floodplain forests and shrublands can be expected to be diverse from west to east, but could be considered as one ecological system? Smith et al. (2007) places *Populus balsamifera*-dominated mineral wetlands along rivers into Deciduous Swamp category. So by their definition, riparian is a type of swamp. Need more information on species composition to write more specific description.

DESCRIPTION

Environment: *Hydrology/Moisture Regime*: Water regime (fluctuating water table) and availability play a significant role in swamps. The water table in swamps fluctuates seasonally, or in some systems bi-yearly, but pools of water are often visible in the hummocky ground surface. Thus, for most of the growing season, the majority of the soil layer is aerated, but water availability is still high in the continually saturated lower portions of the rooting zone. Treed swamps (such as hardwood or mixedwood swamps) in mineral soils are often drier, while swamps that grade into treed fens (tamarack swamps) are wetter. Shrub swamps are almost always wetter than most of the treed swamps, except in some riparian floodplain-associated areas on mineral soils. Moisture regimes for swamps range from hygric to hydric. Flow through swamps is fairly dynamic with good lateral flow through the ground water layer, and fluctuations of this water table allow for aeration of the rooting zone during the growing season. *Soils*: Swamps exist in both peat and mineral soils. Swamps are sometimes termed peatlands but the substrate is from woody (silvic) peat and is well-decomposed. Decomposition is driven by the fluctuating water levels which are absent in *Sphagnum*-derived peatlands. Swamp soils are typically composed of gleysols with mottling in the upper horizons and gleying in the lower horizons. Mottling occurs in a soil that has been inundated with water intermittently (the mottles are iron and manganese oxides). Gleization occurs during the chemical reduction of iron, thus changing the soil colors. Soils with low chromas are indicative of hydric conditions. *Nutrient Regime*: The nutrient regime in swamp wetlands ranges from poor to rich, depending on the amount of contact with dissolved mineral water. Most shrub swamps range from medium to rich.

DISTRIBUTION

WESTERN CANADIAN BOREAL SHRUB-SEDGE RICH AND ALKALINE FEN (CES103.872)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Boreal (103)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Eutrophic Water; Depressional [Sinkhole]
Non-Diagnostic Classifiers: Montane; Lowland; Shrubland (Shrub-dominated); Boreal [Boreal Continental]
National Mapping Codes: ESLF 9176

CONCEPT

Summary: This ecological system extends across the western boreal regions of North America, with occurrences in inland British Columbia, east into western Alberta, and north into Yukon Territory. These fens, distributed across glaciated western and central Canada, develop in open basins where bedrock or other substrate influence creates circumneutral to calcareous conditions. They are most abundant in areas of limestone bedrock, and widely scattered in areas where calcareous substrates are scarce. Shore fens, which are peatlands that are occasionally flooded along streams and lakeshores, are also included here because flooding tends to create moderately alkaline conditions. Fens are nutrient-rich and have a thick peat layer that may be floating or submerged. Standing water is usually present. The edge of the basin may be shallow to deep peat over a sloping substrate, where seepage waters provide nutrients. The vegetation may be graminoid-dominated, shrub-dominated, or a patchwork of the two. *Dasiphora fruticosa ssp. floribunda* is a common diagnostic shrub, along with *Betula pumila, Betula glandulosa, Betula nana, Myrica gale, Salix barclayi, Salix candida, Salix maccalliana, Vaccinium macrocarpon*, and *Larix laricina*. The herbaceous flora is usually species-rich and includes calciphilic graminoids and forbs. Dominant species may include *Carex lasiocarpa, Carex diandra, Menyanthes trifoliata, Equisetum fluviatile, Comarum palustre, Calla palustris, Eriophorum angustifolium, Trichophorum caespitosum*, and *Carex aquatilis*. Other common but non-dominant species include *Caltha palustris, Cicuta virosa (= Cicuta mackenzieana), Galium trifidum, Rumex arcticus*, and *Utricularia* spp. Aquatic plants such as *Myriophyllum spicatum, Hippuris vulgaris, Potamogeton* spp., and *Sparganium* spp. may be present *Sphagnum* can dominate the substrate, along with other calciphilic mosses; common indicator bryophytes include *Calliergon trifarium, Limprichtia revolvens, Scorpidium scorpioides, Sphagnum girgensohnii, Sphagnum squarrosum, Sphagnum warnstorfii, Tomentypnum nitens*, and *Campylium stellatum*.
Classification Comments: Fens in Alaska are placed into several other systems. Also fens occurring in the Pacific Northwest coastal regions are placed into North Pacific Bog and Fen (CES204.063). This system is similar to North-Central Interior Shrub-Graminoid Alkaline Fen (CES202.702) and Laurentian-Acadian Alkaline Fen (CES201.585).
Similar Ecological Systems:
- Laurentian-Acadian Alkaline Fen (CES201.585)

WESTERN GREAT PLAINS FLOODPLAIN (CES303.678)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Deep (>15 cm) Water; Long (>25 yrs) Flooding Interval; Floodplain; Forest and Woodland (Treed); Herbaceous; Riverine / Alluvial
National Mapping Codes: ESLF 9153

CONCEPT

Summary: This ecological system is found in the floodplains of medium and large rivers of the western Great Plains. It occurs on the lower reaches of the North and South Platte, Platte, Arkansas, and Canadian rivers, among others. Alluvial soils and periodic, intermediate flooding (every 5-25 years) typify this system. These are the perennial big rivers of the region with hydrologic dynamics largely driven by snowmelt in the mountains, instead of local precipitation events. Dominant communities within this system range from floodplain forests to wet meadows to gravel/sand flats; however, they are linked by underlying soils and the flooding regime. Dominant species include *Populus deltoides* and *Salix* spp. Grass cover underneath the trees is an important part of this system and is a mix of tallgrass species, including *Panicum virgatum* and *Andropogon gerardii*. Sometimes, *Tamarix* spp. and less desirable or exotic grasses and forbs can invade degraded areas within the floodplains, especially in the western portion of the province. These areas are often subjected to heavy grazing and/or agriculture and can be heavily degraded. Groundwater depletion and lack of fire have created additional alterations in species composition. In most cases, the majority of the wet meadow and prairie communities may be extremely degraded or extirpated from examples of this system.
Classification Comments: All the riparian/floodplain/alluvial systems of the Great Plains region need to be revisited for naming conventions, along with better definitions of conceptual boundaries. There is much apparent overlap in their concepts and distribution, and the names add to the confusion. In particular, the difference between "riparian" and "floodplain" usage in the names needs revisiting and possible changing. These systems include Northwestern Great Plains Floodplain (CES303.676), Northwestern Great Plains Riparian (CES303.677), Western Great Plains Floodplain (CES303.678), and Western Great Plains Riparian (CES303.956). Need to review if there needs to be another split of this system into a Central Great Plains floodplain system and a Southern Great Plains floodplain system. Will need to review in conjunction with Northwestern Great Plains Floodplain (CES303.676).
Similar Ecological Systems:
- Northwestern Great Plains Floodplain (CES303.676)
- South-Central Interior Large Floodplain (CES202.705)
- Southeastern Great Plains Floodplain Forest (CES205.710)

DESCRIPTION

Environment: This system is found primarily in Quaternary alluvium along floodplains of medium and large rivers. Soils are primarily alluvial and range from sandy to dense clays. This system occurs on valley floors of large rivers and perennial streams where significant alluvial deposition occurs, and tends to occupy broad valley bottoms with deep alluvial deposits. In Texas, this system is found within the Clear Fork of the Middle Brazos watersheds and occurs on Loamy Bottomland, Clayey Bottomland, and Draw ecoclasses. Broad alluvial deposits commonly occur and are generally mapped as bottomland soils (Elliott 2011). Water velocity and volume change greatly during the year as rains and snowmelt deliver pulses of water and seasonal droughts (typically including winter in the northern portion of this system's range when most precipitation is frozen) result in low water. Within a short distance on a river floodplain, different soil textures can be found. Within the space of a few years, floods of differing magnitude can deposit sand over silt or vice versa, resulting in complex soil topology.
Vegetation: This system is variable in its expression and can occur as various cover types, including forest, woodland, shrubland, as

well as herbaceous vegetation. Herbaceous variants include marshes, which may develop in the floodplain soils, or mesic prairie dominated by *Andropogon gerardii* and *Panicum virgatum* which also may be conspicuous (Elliott 2011). *Populus deltoides, Sapindus saponaria var. drummondii, Prosopis glandulosa, Salix nigra, Ulmus americana,* and/or *Celtis laevigata* may be important components of forests or woodlands of this system. In parts of Texas, *Juniperus ashei, Juniperus pinchotii*, and/or *Quercus fusiformis* may be present to dominant (Elliott 2011). Species such as *Quercus fusiformis* and *Ulmus americana* occur in the system at the western edge of their range, and may not be represented further west within the range of the system. Shrubland examples may also have *Prosopis glandulosa* and *Salix nigra* as important components. Some shrublands may be dominated by non-native *Tamarix* spp. Herbaceous vegetation may include marshes occupying floodplain sites, with species such as *Schoenoplectus* spp. and/or *Typha* spp. Some sites may be dominated by tallgrass species such as *Andropogon gerardii* and *Panicum virgatum*. Sparsely vegetated areas, such as gravel and sand flats, are also included within this system.

Dynamics: Periodic and intermediate flooding (i.e., every 5-25 years) constitutes the major process influencing this system. Flood frequency depends on precipitation patterns within the watershed and proximity to the main channel. Areas adjacent to the main channel or low islands within the channel are flooded most often, while areas further from the channel or on terraces may only be flooded once every several years. Free-flowing rivers migrate across their floodplain, cutting new channels or eroding the bank on one side while building up the bank on the other, so the flooding regime of any one point in the floodplain will change over time. Flooding redeposits alluvium, eroding some areas and aggrading others, can bury or wash away small plants, and redistributes nutrients, especially in less frequently flooded zones where silt and clay tend to be deposited. These processes open up new areas for colonization. In the newly exposed or reworked areas, there is a common succession sequence of annual herbaceous species followed by shrub *Salix* spp., followed by *Populus deltoides* and *Salix amygdaloides*, followed by a number of trees, including *Acer negundo, Carya illinoinensis, Celtis laevigata, Celtis occidentalis, Fraxinus pennsylvanica,* and *Ulmus americana* (Bellah and Hulbert 1974). This sequence can be reset by major floods and erosion/deposition.

Fire could impact parts of this system. Most of the forests in this system were not fire-prone due to the lack of litter, frequent flooding, and relatively protected landscape position in the river valley with wetlands often near, but forests on higher, coarser soils or wet-mesic prairies on the margins of the floodplain could become dry in late summer and burn, if an ignition source was present.

Component Associations:

- *Carex nebrascensis* Herbaceous Vegetation (CEGL001813, G4)
- *Ericameria nauseosa / Pseudoroegneria spicata* Shrubland (CEGL001330, G3Q)

- Riverine Sand Flats - Bars Sparse Vegetation (CEGL002049, G4G5)
- *Salix exigua* / Mesic Graminoids Shrubland (CEGL001203, G5)
- *Schoenoplectus acutus - Typha latifolia - (Schoenoplectus tabernaemontani)* Sandhills Herbaceous Vegetation (CEGL002030, G4)
- *Schoenoplectus pungens - Suaeda calceoliformis* Alkaline Herbaceous Vegetation (CEGL002040, G3G4)
- *Schoenoplectus tabernaemontani - Typha* spp. - (*Sparganium* spp., *Juncus* spp.) Herbaceous Vegetation (CEGL002026, G4G5)
- *Spartina pectinata - Eleocharis* spp. - *Carex* spp. Herbaceous Vegetation (CEGL002223, G2G4)
- *Sporobolus airoides* Southern Plains Herbaceous Vegetation (CEGL001685, G3Q)
- *Symphoricarpos occidentalis* Shrubland (CEGL001131, G4G5)
- *Typha (angustifolia, domingensis, latifolia) - Schoenoplectus americanus* Herbaceous Vegetation (CEGL002032, G3G4)
- *Typha (latifolia, angustifolia)* Western Herbaceous Vegetation (CEGL002010, G5)
- *Ulmus (americana, rubra) - Quercus muehlenbergii* Forest (CEGL002091, GNR)
- *Ulmus americana - Celtis (laevigata, occidentalis) - Fraxinus pennsylvanica* Forest (CEGL002090, G3?)

DISTRIBUTION

Range: This system is found along major river floodplains in the southern and central portions of the Western Great Plains Division. This system occurs on the middle to lower reaches of the North and South Platte, Platte, Arkansas, and Canadian rivers, among others. Major river floodplains of eastern Wyoming and Montana are included in Northwestern Great Plains Floodplain (CES303.676) and not this system.

WESTERN NORTH AMERICAN BOREAL BLACK SPRUCE DWARF-TREE PEATLAND (CES105.139)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Permafrost; Saturated Soil; Toeslope/Valley Bottom; Boreal [Boreal Subcontinental]; Acidic Soil; Organic Peat (>40 cm); Picea mariana
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2621; ESLF 9376; ESP 1621

CONCEPT

Summary: This system occurs in the boreal and boreal transition regions of Alaska in valley bottoms and on abandoned floodplains and includes treed bogs (and poor fens) and other organic-rich lowland black spruce forests. Sites are generally flat to gently sloping terrain, on slopes up to 8 degrees. Soils are poorly drained and acidic, often with a well-developed peat layer. Permafrost is generally present and may form permafrost plateaus supporting the system in boreal Alaska but is generally absent in the boreal transition region. The forest canopy is typically open to woodland and trees are generally stunted. Common species include *Picea mariana, Ledum palustre ssp. decumbens, Ledum groenlandicum, Andromeda polifolia, Betula nana, Empetrum nigrum, Vaccinium vitis-idaea, Vaccinium uliginosum, Chamaedaphne calyculata, Carex pluriflora, Carex* spp., *Eriophorum angustifolium, Calamagrostis canadensis*, and *Sphagnum* spp. The major disturbances in this type are fire and thermokarst collapse.
Classification Comments: This system combines those known as Boreal Transition Lowland Wet Black Spruce and Boreal Lowland Wet Black Spruce by the Alaska Natural Heritage Program.

DESCRIPTION

Environment: This system occurs in the boreal and boreal transition regions of Alaska in valley bottoms and on abandoned floodplains and includes treed bogs (and poor fens) and other organic-rich lowland black spruce forests. Sites are generally flat to gently sloping terrain, on slopes up to 8 degrees. Soils are poorly drained and acidic, often with a well-developed peat layer. Permafrost is generally present and may form permafrost plateaus supporting the system in boreal Alaska but is generally absent in the boreal transition region.
Vegetation: The forest canopy is typically open to woodland and trees are generally stunted. Common species include *Picea mariana, Ledum palustre ssp. decumbens, Ledum groenlandicum, Andromeda polifolia, Betula nana, Empetrum nigrum, Vaccinium vitis-idaea, Vaccinium uliginosum, Chamaedaphne calyculata, Carex pluriflora, Carex* spp., *Eriophorum angustifolium, Calamagrostis canadensis*, and *Sphagnum* spp. (DeVelice et al. 1999).
Dynamics: In boreal wetlands the general successional trend is from marsh to fen to treed bog; however, succession is not necessarily directional, and environmental conditions, such as nutrient content and abundance of groundwater, may prevent fens from developing into bogs (Zoltai et al. 1988). Succession begins in shallow ponds or low-lying wetlands formed by processes such as glacial recession and floodplain dynamics (oxbows) or thermokarst. An organic root mat typically develops and is either anchored to the mineral soil or floating on water such as a pond's edge. Over time, peat-forming mosses and sedges may fill in the basin. As the peat layer develops, low and/or dwarf-shrubs become established. Dwarf-trees may establish on the well-developed peat and also around the margin of the peatland.

Many peatlands on the Kenai Lowland formed in kettles after remnant glacial ice melted. In this region there is a trend toward peatlands drying and ponds shrinking and filling in (Klein et al. 2005).

Permafrost degradation leading to collapse scars and thaw ponds is common in boreal Alaska, and studies from the Tanana Flats show areas of widespread degradation (Racine et al. 1998, Jorgenson et al. 2001a, 2001b, 2003). Thaw ponds form when ice-rich permafrost degrades and collapses forming a basin. Aquatic plants rapidly colonize the pond. Over time, marsh plants and sphagnum moss invade creating peatland conditions. This trend is leading to widespread ecosystem conversion in the Tanana Flats (Jorgenson et al. 2001b). If a collapse scar is isolated, succession follows a bog development model, whereas in an open hydrologic setting, succession follows a fen development model. Pond systems may become connected as adjacent permafrost thaws.

Succession to peatlands can also occur through paludification of previously forested landscapes. Restricted drainage from permafrost development (on inactive alluvial terraces, for example) can lead to the establishment of *Sphagnum* spp. or other peat-forming mosses or sedges, and overtime, peatland plants dominate the site.

DISTRIBUTION

Range: This system occurs in lowlands of the boreal and boreal transition regions of Alaska.

WESTERN NORTH AMERICAN BOREAL BLACK SPRUCE WET-MESIC SLOPE WOODLAND (CES105.120)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Permafrost; Forest and Woodland (Treed); Boreal [Boreal Subcontinental]; Acidic Soil; Sphagnum spp.; Picea mariana
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Organic Peat (>40 cm)
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2622; ESLF 9377; ESP 1622

CONCEPT

Summary: This system occurs on north-facing slopes underlain by permafrost with low productivity *Picea mariana*. Soils are poorly drained and acidic with a well-developed peat layer. Sites on lower concave slopes and toeslopes are wet, while sites on upper slopes, convex slopes and ridges may be mesic. Common species include *Ledum groenlandicum, Ledum palustre ssp. decumbens, Betula nana, Empetrum nigrum, Vaccinium vitis-idaea, Vaccinium uliginosum, Carex* spp., and *Sphagnum* spp. This system has less *Sphagnum* than Western North American Boreal Black Spruce Dwarf-Tree Peatland (CES105.139). The slope angle is generally greater than 8 degrees.
Classification Comments: This system is known as Boreal North-Facing Black Spruce by the Alaska Natural Heritage Program. Wet black spruce on slopes with slope angle between 0-8 degrees are classified with Western North American Boreal Black Spruce Dwarf-Tree Peatland (CES105.139).
Related Concepts:

WESTERN NORTH AMERICAN BOREAL BLACK SPRUCE-TAMARACK FEN (CES105.121)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Eutrophic Water; Saturated Soil; Lowland [Lowland]; Forest and Woodland (Treed); Toeslope/Valley Bottom; Seepage-Fed Sloping [Peaty]; Depressional [Sinkhole]; Acidic Soil; Organic Peat (>40 cm); Picea mariana - Larix laricina
Non-Diagnostic Classifiers: Montane; Alluvial flat; Boreal [Boreal Continental]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2623; ESLF 9378; ESP 1623

CONCEPT

Summary: This ecological system occurs in lowlands across boreal Alaska and includes treed fens and other organic-rich lowland black spruce-tamarack forests. Soils are poorly drained and often have a well-developed peat layer. Sites are less acidic than Western North American Boreal Black Spruce Dwarf-Tree Peatland (CES105.139). Sites with at least 40 cm of peat are classified as fens. The forest canopy is typically open to woodland and trees may be stunted. Common species include *Picea mariana, Larix laricina, Betula nana, Ledum groenlandicum, Ledum palustre ssp. decumbens, Empetrum nigrum, Vaccinium vitis-idaea, Vaccinium uliginosum, Chamaedaphne calyculata, Carex* spp., *Eriophorum angustifolium*, and *Sphagnum* spp.
Classification Comments: This system is known as Boreal Wet Black Spruce Tamarack by the Alaska Natural Heritage Program.
Related Concepts:
- I.A.2.h - Black spruce-tamarack (Viereck et al. 1992) Equivalent

DESCRIPTION

Environment: *Larix laricina* is considered a fen indicator in some regions.
Dynamics: There has been a major impact from larch sawfly (*Pristiphora erichsonii*) in Alaska (but not in Canadian populations). There are two models: fire (without thermokarst collapse) and thermokarst collapse. Model is similar to boreal wet black spruce, but with *Larix* as endpoint.

DISTRIBUTION

Range: This system is found in the lowlands of the boreal region of Alaska. The range of *Larix laricina* in Alaska is disjunct from the Canadian population.
Divisions: 105:C
Nations: US
Subnations: AK
Map Zones: 70:C, 71:C, 72:C, 73:C, 74:C, 76:?

WESTERN NORTH AMERICAN BOREAL DECIDUOUS SHRUB SWAMP (CES105.122)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Shrubland (Shrub-dominated); Muck; Broad-Leaved Deciduous Shrub
Non-Diagnostic Classifiers: Silt Soil Texture
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2624; ESLF 9379; ESP 1624

CONCEPT

Summary: Shrub swamps occur throughout the boreal and boreal transition regions of Alaska on poorly drained, fine-textured soil. Depressions with standing water are common throughout the growing season. Soils range from muck to mineral and are relatively nutrient-rich. Some sites have a thin peat layer. The shrub layer is typically dominated by *Alnus incana ssp. tenuifolia*, but *Alnus viridis ssp. sinuata, Salix pulchra*, or *Salix richardsonii (= Salix lanata ssp. richardsonii)* may be dominant or codominant. Common understory species include *Calamagrostis canadensis, Equisetum* spp., *Comarum palustre (= Potentilla palustris)*, and hydrophytic mosses.
Classification Comments: This system is known as Boreal Tall Shrub Swamp by the Alaska Natural Heritage Program.
Similar Ecological Systems:
- Boreal Willow-Alder Swamp Thicket (CES103.524)

DESCRIPTION

Environment: Shrub swamps occur throughout the boreal and boreal transition regions of Alaska on poorly drained, fine-textured soil. Depressions with standing water are common throughout the growing season. Soils range from muck to mineral and are relatively nutrient-rich. Some sites have a thin peat layer.
Vegetation: The shrub layer is typically dominated by *Alnus incana ssp. tenuifolia*, but *Alnus viridis ssp. sinuata, Salix pulchra*, or *Salix richardsonii (= Salix lanata ssp. richardsonii)* may be dominant or codominant. Common understory species include *Calamagrostis canadensis, Equisetum* spp., *Comarum palustre (= Potentilla palustris)*, and hydrophytic mosses (Viereck et al. 1992).

DISTRIBUTION

Range: This system occurs in lowlands of the boreal and boreal transition regions of Alaska.
Divisions: 105:C
Nations: US
Subnations: AK

WESTERN NORTH AMERICAN BOREAL LOW SHRUB PEATLAND (CES105.140)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland; Boreal [Boreal Subcontinental]; Muck; Dwarf-Shrub
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated)
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2620; ESLF 9380; ESP 1620

CONCEPT

Summary: This ecological system occurs in lowlands of the boreal and boreal transition regions of Alaska and includes low shrub-dominated wetlands. Sites may be bogs, fens, or wetlands. Soils are saturated for at least a portion of the growing season, and permafrost is absent. An organic peat layer is usually present, but peat depth is variable but often less than 40 cm deep. Common species include *Ledum palustre ssp. decumbens, Ledum groenlandicum, Betula nana, Rubus chamaemorus, Vaccinium oxycoccos (= Oxycoccus microcarpos), Myrica gale, Calamagrostis canadensis, Carex aquatilis, Comarum palustre, Salix fuscescens, Salix pulchra, Empetrum nigrum, Chamaedaphne calyculata*, and *Sphagnum* spp. *Myrica gale* and *Chamaedaphne calyculata* indicate fen conditions. This system often occurs in association with other peatland systems.
Classification Comments: This system combines those known as Boreal Transition Wet Low Shrub and Boreal Wet Low Shrub by the Alaska Natural Heritage Program.
Related Concepts:

DESCRIPTION

Environment: This ecological system occurs in lowlands of the boreal and boreal transition regions of Alaska and includes low shrub-dominated wetlands. Sites may be bogs, fens, or wetlands. Soils are saturated for at least a portion of the growing season, and permafrost is absent. An organic peat layer is usually present, but peat depth is variable but often less than 40 cm deep.
Vegetation: Common species include *Ledum palustre ssp. decumbens, Ledum groenlandicum, Betula nana, Rubus chamaemorus, Vaccinium oxycoccos (= Oxycoccus microcarpos), Myrica gale, Calamagrostis canadensis, Carex aquatilis, Comarum palustre, Salix fuscescens, Salix pulchra, Empetrum nigrum, Chamaedaphne calyculata*, and *Sphagnum* spp. (DeVelice et al. 1999, Jorgenson et al. 2003). *Myrica gale* and *Chamaedaphne calyculata* indicate fen conditions.
Dynamics: In boreal wetlands the general successional trend is from marsh to fen to treed bog; however, succession is not necessarily directional, and environmental conditions, such as nutrient content and abundance of groundwater, may prevent fens from developing into bogs (Zoltai et al. 1988). Succession begins in shallow ponds or low-lying wetlands formed by processes such as glacial recession and floodplain dynamics (oxbows) or thermokarst. An organic root mat typically develops and is either anchored to the mineral soil or floating on water such as a pond's edge. Over time, peat-forming mosses and sedges may fill in the basin. As the peat layer develops, low and/or dwarf-shrubs become established. Dwarf-trees may establish on the well-developed peat and also around the margin of the peatland.

Many peatlands on the Kenai Lowland formed in kettles after remnant glacial ice melted. In this region there is a trend toward peatlands drying and ponds shrinking and filling in (Klein et al. 2005).

Permafrost degradation leading to collapse scars and thaw ponds is common in boreal Alaska, and studies from the Tanana Flats show areas of widespread degradation (Racine et al. 1998, Jorgenson et al. 2001a, 2001b, 2003). Thaw ponds form when ice-rich permafrost degrades and collapses forming a basin. Aquatic plants rapidly colonize the pond. Over time, marsh plants and sphagnum moss invade creating peatland conditions. This trend is leading to widespread ecosystem conversion in the Tanana Flats (Jorgenson et al. 2001b). If a collapse scar is isolated, succession follows a bog development model, whereas in an open hydrologic setting, succession follows a fen development model. Pond systems may become connected as adjacent permafrost thaws.

Succession to peatlands can also occur through paludification of previously forested landscapes. Restricted drainage from permafrost development (on inactive alluvial terraces, for example) can lead to the establishment of *Sphagnum* spp. or other peat-forming mosses or sedges, and overtime, peatland plants dominate the site.

DISTRIBUTION

Range: This system occurs in lowlands of the boreal transition region of Alaska, and lowlands through subalpine in boreal Alaska.
Divisions: 105:C
Nations: US

Subnations: AK

WESTERN NORTH AMERICAN BOREAL LOW SHRUB-TUSSOCK TUNDRA (CES105.126)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland; Herbaceous; Tussock-forming grasses; Eriophorum vaginatum
Non-Diagnostic Classifiers: Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2628; ESLF 9381; ESP 1628

CONCEPT

Summary: This is a common lowland system dominated by tussock sedges and low shrubs. *Eriophorum vaginatum* is the primary tussock-former in most stands, but *Carex bigelowii* may be the dominant tussock sedge on some sites. Other indicator species include *Betula nana, Salix pulchra, Ledum palustre ssp. decumbens, Ledum groenlandicum, Vaccinium vitis-idaea, Vaccinium uliginosum, Empetrum nigrum,* and *Carex* spp. Grasses, including *Calamagrostis canadensis* and *Arctagrostis* spp., may also be present. Lichens are scarce (with the possible exception of *Peltigera canina*). Sites are often underlain by permafrost. This ecological system is similar to Alaska Arctic Shrub-Tussock Tundra (CES102.180) (and the Tussock Tundra 2 PNV) that occurs in Alaska's arctic and has a longer mean fire-return interval. Geographic location is the best determinant between these two systems.
Classification Comments: This system is known as Boreal Tussock Low Shrub Tundra by the Alaska Natural Heritage Program. It includes two categories of tussock tundra: (1) tussock low shrub (shrub birch and/or willow) and (2) tussock dwarf-shrub lichen; for now we are calling this a drier variant of the low shrub tussock tundra (this may be more common in western and arctic Alaska, and we may split out in arctic and western Alaska discussion). From Witten (2004): "On the drier tussock tundra sites on the Seward Peninsula and western Alaska, *Sphagnum* may be absent or a minor constituent. Conversely, lichens are scarce (with the possible exception of *Peltigera canina*) in boreal and boreal transition Alaska, and may be abundant on the Seward Peninsula and western Alaska sites. Here, lichens may include *Cetraria cucullata, Cetraria islandica, Cladonia* spp., *Cladina rangiferina,* and *Thamnolia subuliformis*."
Similar Ecological Systems:
- Alaska Arctic Shrub-Tussock Tundra (CES102.180)

Related Concepts:
- II.C.2.a - Mixed shrub-sedge tussock tundra (Viereck et al. 1992) Intersecting
- II.C.2.b - Mixed shrub-sedge tussock bog (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: Permafrost is usually present at depths of 30-50 cm. Soils are generally acidic, poorly drained, gleyed, and often with a poorly decomposed organic horizon at the surface, which may constitute most of the active layer. Frost scars are common. Tussock communities occur on gentle slopes, terraces, and old alluvial deposits. Sites are often underlain by silty mineral soils with a surface peat layer 10 to 40 cm thick surrounding the tussocks (Viereck et al. 1992).
Dynamics: The fuel layer in sedge-shrub tussock tundra is dense and continuous and leads to large, fast-spreading fires (Racine et al. 1987, Duchesne and Hawkes 2000). Differences in topography, moisture, vegetation composition, and organic matter depth cause variation in burn severity and lead to a patchy burn pattern (Racine 1979). Fire severity in *Eriophorum* tussock tundra types tends to be light because of the wet soil profile (Wein 1976). Burns in this type usually consume all aerial woody and herbaceous plant material and litter; regeneration is vigorous via rhizomes and root sprouts. In most areas of tussock-shrub tundra on the Seward Peninsula, less than one half of accumulated organic soil layer was removed by fire (Racine 1979). Thaw depths increased to reach into the mineral soil, but were not greatly increased except where organics were removed. Subsidence and thermal erosion following fire are usually minimal in tundra ecosystems (Walker 1996).

Estimates of the mean fire-return interval for tussock tundra ecosystems range from 50-600 years (Racine et al. 1983, Payette et al. 1989). The fire regime of tundra systems are likely variable from one region to another making generalizations difficult (Viereck and Schandelmeier 1980).

On interior and south-central Alaska tussock tundra sites, the thaw pond cycle and paludification are important disturbances. On the Seward Peninsula and western Alaska, frost action creates polygonal ground and other periglacial features and is a widespread, small-scale and continuous disturbance. Change in the arctic and subarctic climate is another source of disturbance that is currently affecting tundra ecosystems.

DISTRIBUTION

Range: This system occurs in lowland through subalpine zones of the boreal and boreal transition (northern portion and higher elevation) regions of Alaska.
Divisions: 105:C
Nations: CA, US

Subnations: AK

WESTERN NORTH AMERICAN BOREAL LOWLAND LARGE RIVER FLOODPLAIN FOREST AND SHRUBLAND (CES105.117)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Very Short Flooding Interval [Short interval, Spring Flooding]; Riparian Mosaic [Trees, shrublands, meadows]; Floodplain; Lowland [Lowland]; Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2615; ESLF 9382; ESP 1615

CONCEPT

Summary: This system includes large floodplains associated with high-volume interior rivers (such as the Yukon, Kuskokwim, Koyukuk, and Tanana rivers). Flooding regime is characterized by large spring floods at ice break-up. Young successional stages are dominated by willow and alder followed by balsam poplar and/or white spruce. Wetland development in abandoned channels is intermixed with succession on more mesic sites [see description for Western North American Boreal Shrub and Herbaceous Floodplain Wetland (CES105.118)]. The active flooding zone is often several km wide. Permafrost is usually absent.
Classification Comments: This system is known as Boreal Large River Floodplain by the Alaska Natural Heritage Program.

DESCRIPTION

Environment: This system includes large floodplains associated with high-volume interior rivers (such as the Yukon, Kuskokwim, Koyukuk, and Tanana rivers). Flooding regime is characterized by large spring floods at ice break-up. Wetland development in abandoned channels is intermixed with succession on more mesic sites. The active flooding zone is often several km wide. Permafrost is usually absent. Ice-scour and ice dams are important dynamics that may cause regeneration of willow carrs where scoured by ice.
Vegetation: Primary succession on floodplains begins when new alluvial surfaces are colonized by tree, shrub, and herbaceous species. Common woody species include *Populus balsamifera, Picea glauca, Alnus viridis ssp. sinuata, Alnus incana ssp. tenuifolia, Salix barclayi*, and *Salix alaxensis* (Viereck 1966, Scott 1974, Thilenius 1990, Shephard 1995, Boggs 2000). Common early-seral herbaceous species may include *Lupinus* spp., *Hedysarum* spp., and *Equisetum* spp. The next seral stage includes communities dominated by *Populus balsamifera* and/or *Picea glauca* with an understory of *Alnus viridis ssp. sinuata, Salix* spp., and bryophytes. The tall-shrub component of the early-successional stages diminishes rapidly, probably because of decreased light from the dense tree overstory. *Populus balsamifera* does not regenerate in the understory, and consequently, *Picea glauca* gains dominance in the overstory within 150 years. On older surfaces common shrubs include *Rosa acicularis, Viburnum edule,* and *Linnaea borealis*, and common herbs include *Pyrola* ssp. and *Cornus canadensis*. Feathermosses and lichens such as *Peltigera* spp occur on older surfaces.
Dynamics: Flooding can be caused by snowmelt, precipitation, ice jams and glacial runoff. Different rivers or portions of rivers may be more prone to certain types of flooding. Frequent flooding and channel migration create a pattern of gravel bars and early-successional stages across the valley bottom. Sediment deposition raises the surface of the floodplain over time. As the terrace becomes farther removed from the channel, flooding becomes less frequent. Water availability on terraces plays a major role in community structure and composition. Water inputs are from overbank flow (flooding), groundwater, and precipitation. Fine sediments are trapped when the floodwaters recede; this ongoing sediment input maintains high productivity.

Fire frequency in floodplain systems is less than that of the surrounding terrain because channels can act as firebreaks and early-seral vegetation is less flammable than mature boreal forest.

DISTRIBUTION

Range: This system is found in the boreal region of Alaska.
Divisions: 105:C
Nations: US
Subnations: AK

WESTERN NORTH AMERICAN BOREAL MONTANE FLOODPLAIN FOREST AND SHRUBLAND (CES105.141)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Very Short Flooding Interval [Short interval, Spring Flooding]; Riparian Mosaic [Trees, shrublands, meadows]; Floodplain; Montane; Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2614; ESLF 9383; ESP 1614

CONCEPT

Summary: This system includes glacially-fed and non-glacially-fed rivers and streams throughout the boreal and boreal transition regions of Alaska. It includes the active and inactive portions of the floodplain, but not abandoned floodplains. Soils are alluvial, well-drained and poorly developed. Frequent river channel migration and associated flooding and fluvial processes constitute the major disturbances in this type. On glacially-fed rivers, braided outwash plains occur near the glacier terminus. This portion of the river is characterized by high sediment input and very frequent flooding. Substrates are excessively well-drained and frequently scoured. A high proportion of barren and early-seral landscape classes characterize the outwash plain. Farther downstream (distal outwash), vegetation dominance on the floodplain depends on seral stage and frequency of flooding: later seral stages and wetlands become more common. On rivers and streams without major glacial inputs, flooding and sediment deposition still drive the disturbance cycle; however, the timing and severity of flooding may differ from that on glacial rivers. Both glacially-fed and non-glacially-fed rivers are characterized by young successional stages dominated by willow and alder followed by extensive stands of balsam poplar and/or white spruce. Floodplains range in width from less than 50 m to over 1 km. Large floodplains (several km wide, such as the Yukon) are classified as separate systems. Oxbows and other wet depressions commonly form on the floodplains. Wetland succession and species composition are variable due to diverse environmental conditions such as water depth, substrate, and nutrient input. Wetland classes and succession are described in the floodplain wetlands ecological system.
Classification Comments: This system combines those known as Boreal Transition Floodplain Forest and Shrub and Boreal Floodplain Forest and Shrub by the Alaska Natural Heritage Program.

DESCRIPTION

Environment: Floodplains range in width from less then 50 m to over 1 km (Viereck et al. 1986, Witten 2004). The substrate is typically well-drained sand, gravel, or cobble, although finer silts and clays can be found on higher terraces, in ponds, on distal floodplains, and in lower energy systems. Permafrost is usually absent. Oxbows and other wet depressions commonly form on the floodplains, and these sites commonly develop into wetlands.
Vegetation: Primary succession on floodplains begins when new alluvial surfaces are colonized by tree, shrub, and herbaceous species. Common woody species include *Populus balsamifera, Picea glauca, Alnus viridis ssp. sinuata, Alnus incana ssp. tenuifolia, Salix barclayi*, and *Salix alaxensis* (Viereck 1966, Scott 1974, Thilenius 1990, Shephard 1995, Boggs 2000). Common early-seral herbaceous species may include *Lupinus* spp., *Hedysarum* spp., *Equisetum* spp., *Calamagrostis canadensis*, and *Chamerion latifolium* (Viereck 1966, Scott 1974, Thilenius 1990, Shephard 1995, Boggs 2000). The next seral stage includes communities dominated by *Populus balsamifera* and/or *Picea glauca* with an understory of *Alnus viridis ssp. sinuata, Salix* spp., and bryophytes. On dry sites the shrub layer may be dominated by *Shepherdia canadensis, Dryas octopetala, Dryas integrifolia*, and fruticose lichens (*Stereocaulon*

spp.). The tall-shrub component of the early-successional stages diminishes rapidly, probably because of decreased light from the dense tree overstory. *Populus balsamifera* does not regenerate in the understory, and consequently, *Picea glauca* gains dominance in the overstory within 150 years. *Rosa acicularis* and *Viburnum edule* are common understory shrubs on older surfaces.
Dynamics: Frequent river channel migration and associated flooding and fluvial processes constitute the major disturbances in this type (Viereck et al. 1986, Walker et al. 1987). Flooding can be caused by snowmelt, precipitation, ice jams, and glacial runoff. Different rivers or portions of rivers may be more prone to certain types of flooding. Frequent flooding and channel migration create a pattern of gravel bars and early-successional stages across the valley bottom. Sediment deposition raises the surface of the floodplain over time. As the terrace becomes farther removed from the channel, flooding becomes less frequent. Water availability on terraces plays a major role in community structure and composition. Water inputs are from overbank flow (flooding), groundwater, and precipitation. Deposits with high permeability become progressively drier as they are vertically and horizontally removed from the active channels.

Vegetation succession on gravel bars can be represented by the following seral stages: barren or herbaceous, willow or willow-alder, alder, poplar or spruce poplar, spruce. Oxbows and other wet depressions commonly form on the floodplains. Wetland succession and species composition are variable due to diverse environmental conditions such as water depth, substrate and nutrient input. Aquatic bed, marsh, and fen communities are common.

Fire frequency in floodplain systems is less than that of the surrounding terrain because channels can act as firebreaks and early-seral vegetation is less flammable than mature boreal forest. The boreal floodplain system burns more frequently than the boreal transition floodplain system, but we don't have specific information on fire frequency.

DISTRIBUTION

WESTERN NORTH AMERICAN BOREAL RIPARIAN STRINGER FOREST AND SHRUBLAND (CES105.144)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riparian Mosaic; Floodplain; Boreal [Boreal Subcontinental]
Non-Diagnostic Classifiers: Alluvial terrace
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2616; ESLF 9384; ESP 1616

CONCEPT

Summary: This system occurs throughout the boreal and boreal transition regions of Alaska and is characterized by low-energy riparian communities. These riparian zones are typically narrow bands of forest or shrubs along streams in low-gradient and low-volume drainages. Seasonal overbank flooding may occur, but generally it does not result in shifting channels or gravel bar formation. Common species include *Picea glauca*, *Betula papyrifera*, *Populus balsamifera*, *Alnus* spp., *Salix* spp., *Carex* spp., and *Calamagrostis canadensis*.
Classification Comments: This system combines those known as Boreal Transition Riparian Forest and Shrub Stringer and Boreal Riparian Forest and Shrub Stringer by the Alaska Natural Heritage Program.

DESCRIPTION

Dynamics: Fire may set the system back to an earlier successional stage, though fire frequency is lower in riparian zones than in adjacent sites. Wetter sites may be stable (with shrubs such as *Salix* and *Alnus* and wet herbaceous). Succession on better drained sites is similar to Western North American Boreal White Spruce-Hardwood Forest (CES105.106). Use a fire type model for this system since it does not necessarily have a floodplain succession. Narrow spruce-hardwood stringers often act as firebreaks, but many burned during 2004 and 2005 fire seasons.

DISTRIBUTION

Range: This system occurs throughout the boreal and boreal transition regions of Alaska.
Divisions: 105:C; 204:C

WESTERN NORTH AMERICAN BOREAL SEDGE-DWARF-SHRUB BOG (CES105.138)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Boreal [Boreal Subcontinental]; Depressional; Eutrophic Soil; Acidic Soil; Organic Peat (>40 cm); Dwarf-Shrub; Graminoid
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2619; ESLF 9385; ESP 1619

CONCEPT

Summary: This ecological system occurs in the boreal and boreal transition regions of Alaska and is not associated with permafrost processes. It includes bogs and poor fens (systems with little or no groundwater inputs) with thick (>40 cm) peat deposits. Organic soils are acidic and nutrient-poor. Common species include *Vaccinium oxycoccos (= Oxycoccus microcarpos), Andromeda polifolia, Vaccinium uliginosum, Ledum palustre ssp. decumbens, Ledum groenlandicum, Betula nana, Empetrum nigrum, Carex microglochin, Carex rotundata, Carex rariflora, Carex lasiocarpa, Carex limosa, Carex chordorrhiza, Carex livida, Carex pluriflora, Carex pauciflora, Carex stylosa, Carex membranacea, Eriophorum brachyantherum, Eriophorum angustifolium, Rubus chamaemorus*, and *Drosera* spp. *Sphagnum* spp. are usually abundant in the ground layer.
Classification Comments: This system combines those known as Boreal Transition Sedge-Dwarf-Shrub Bog and Boreal Sedge-Dwarf-Shrub Bog by the Alaska Natural Heritage Program. String bogs and ribbed fens are included in this system.
Related Concepts:

- III.A.3.k - Subarctic lowland sedge-moss bog meadow (Viereck et al. 1992) Intersecting
- III.C.1.a - Wet bryophyte (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: This system includes hydrologically closed bogs and poor fens (systems with little or no groundwater inputs) with thick (>40 cm) peat deposits. Organic soils are acidic and nutrient-poor. It includes basin or blanket bogs. Permafrost is usually absent.
Vegetation: Common species include *Vaccinium oxycoccos (= Oxycoccus microcarpos), Andromeda polifolia, Vaccinium uliginosum, Ledum palustre ssp. decumbens, Ledum groenlandicum, Betula nana, Empetrum nigrum, Carex microglochin, Carex rotundata, Carex rariflora, Carex lasiocarpa, Carex limosa, Carex chordorrhiza, Carex livida, Carex pluriflora, Carex pauciflora, Carex stylosa, Carex membranacea, Eriophorum brachyantherum, Eriophorum angustifolium, Rubus chamaemorus*, and *Drosera* spp. (Gracz et al. 2005). *Sphagnum* spp. are usually abundant in the ground layer.
Dynamics: In boreal wetlands the general successional trend is from marsh to fen to treed bog; however, succession is not necessarily directional, and environmental conditions, such as nutrient content and abundance of groundwater, may prevent fens from developing into bogs (Zoltai et al. 1988). Succession begins in shallow ponds or low-lying wetlands formed by processes such as glacial recession and floodplain dynamics (oxbows) or thermokarst. An organic root mat typically develops and is either anchored to the mineral soil or floating on water such as a pond's edge. Over time, peat-forming mosses and sedges may fill in the basin. As the peat layer develops, low and/or dwarf-shrubs become established. Dwarf-trees may establish on the well-developed peat and also around the margin of the peatland.

Many peatlands on the Kenai Lowland formed in kettles after remnant glacial ice melted. In this region there is a trend toward peatlands drying and ponds shrinking and filling in (Klein et al. 2005).

Permafrost degradation leading to collapse scars and thaw ponds is common in boreal Alaska, and studies from the Tanana Flats show areas of widespread degradation (Racine et al. 1998, Jorgenson et al. 2001a, 2001b, 2003). Thaw ponds form when ice-rich permafrost degrades and collapses forming a basin. Aquatic plants rapidly colonize the pond. Over time, marsh plants and sphagnum moss invade creating peatland conditions. This trend is leading to widespread ecosystem conversion in the Tanana Flats (Jorgenson et al. 2001b). If a collapse scar is isolated, succession follows a bog development model, whereas in an open hydrologic setting, succession follows a fen development model. Pond systems may become connected as adjacent permafrost thaws.

Succession to peatlands can also occur through paludification of previously forested landscapes. Restricted drainage from permafrost development (on inactive alluvial terraces, for example) can lead to the establishment of *Sphagnum* spp. or other peat-forming mosses or sedges, and overtime, peatland plants dominate the site.

DISTRIBUTION

WESTERN NORTH AMERICAN BOREAL SHRUB AND HERBACEOUS FLOODPLAIN WETLAND (CES105.118)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Bog and Fen Mosaic; Floodplain; Lowland [Lowland]; Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2617; ESLF 9386; ESP 1617

CONCEPT

Summary: This system occurs within the active and inactive portions of floodplains. Wetlands develop on poorly drained deposits, oxbows, and abandoned channels and are often mosaiced with well-drained floodplain vegetation. Frequent river channel migration and associated flooding and fluvial processes constitute the major disturbances. Wetland succession and species composition are variable due to diverse environmental conditions such as water depth, substrate, and nutrient input. Floodplain wetland vegetation includes the following classes: aquatic bed, freshwater marsh, fen, and wet low shrub. These have been described as unique systems in this classification, but because floodplain wetland dynamics differ from wetland dynamics outside the floodplain, we will consider floodplain wetlands a distinct system and model succession accordingly. Wetland succession beginning in open water can proceed through the following wetland classes: aquatic bed, marsh, wet meadow or fen. Over time, fens can succeed to shrub bogs or wet low shrub. At any stage in succession, flooding can set back the vegetation to open water. Less dramatic changes in hydrology (such as an increase in water table from beaver activity) can reverse the direction of succession. Wetlands can also develop through paludification on poorly drained, fine-textured deposits.
Classification Comments: This system is known as Boreal Floodplain Wetland by the Alaska Natural Heritage Program.

WESTERN NORTH AMERICAN BOREAL WET BLACK SPRUCE-TUSSOCK WOODLAND (CES105.128)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Woody Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Permafrost; Saturated Soil; Forest and Woodland (Treed); Boreal [Boreal Subcontinental]; Aquic; Tussock-forming grasses; Picea mariana; Eriophorum vaginatum
Non-Diagnostic Classifiers: Lowland [Lowland]; Carex bigelowii
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2630; ESLF 9387; ESP 1630

CONCEPT

Summary: This ecological system is common throughout boreal Alaska on north-facing slopes, gentle hills, and inactive alluvial surfaces underlain by permafrost. Soils are poorly drained and consist of tussocks over peat or mineral soil. *Picea mariana* is the dominant overstory species in an open to woodland canopy. Tussock-forming sedges contribute at least 25% of the vegetation cover. Common understory shrubs include *Betula nana, Ledum palustre ssp. decumbens, Ledum groenlandicum, Vaccinium uliginosum*, and *Vaccinium vitis-idaea*. Herbaceous species include *Eriophorum vaginatum, Carex bigelowii*, and *Rubus chamaemorus*. Mosses may be abundant and include *Sphagnum* spp. and *Hylocomium splendens*.
Classification Comments: This system is known as Boreal Black Spruce Tussock by the Alaska Natural Heritage Program.
Related Concepts:
- I.A.3.d - Black spruce (woodland) (Viereck et al. 1992) Intersecting
- II.A.3.a - Black spruce scrub (woodland) (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: This ecological system is common throughout boreal Alaska on north-facing slopes, gentle hills, and inactive alluvial surfaces underlain by permafrost. Soils are poorly drained and consist of tussocks over peat or mineral soil (Jorgenson et al. 2001a, Boggs and Sturdy 2005).
Vegetation: *Picea mariana* is the dominant overstory species in an open to woodland canopy. Tussock-forming sedges contribute at least 25% of the vegetation cover. Common understory shrubs include *Betula nana, Ledum palustre ssp. decumbens, Ledum groenlandicum, Vaccinium uliginosum,* and *Vaccinium vitis-idaea*. Herbaceous species include *Eriophorum vaginatum, Carex bigelowii,* and *Rubus chamaemorus*. Mosses may be abundant and include *Sphagnum* spp. and *Hylocomium splendens* (Jorgenson et al. 2001a, Boggs and Sturdy 2005).
Dynamics: Two possible disturbance cycles are thermokarst or burn model (grass-tussock sedge, tussock low shrub, black spruce tussock low shrub).

DISTRIBUTION

Range: This system is common throughout lowlands of boreal Alaska.

HERBACEOUS WETLAND

ACADIAN COASTAL SALT MARSH (CES201.578)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saltwater (Polyhaline); Tidal / Estuarine; Graminoid; Spartina (patens, alterniflora)
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Long (>500 yrs) Persistence; Herbaceous; Organic Peat (>40 cm); Mineral: W/ A-Horizon >10 cm
National Mapping Codes: ESLF 9278

CONCEPT

Summary: This system ranges from northern Massachusetts on the Gulf of Maine north to Newfoundland, along the immediate ocean shore and near estuary mouths, where salinity regime is polyhaline. Sometimes called "salt meadows," these marshes display strong graminoid dominance, with patchy forbs. *Spartina patens* and *Spartina alterniflora* are the major dominants. Characteristic associates include *Puccinellia maritima, Juncus balticus, Plantago maritima var. juncoides (= Plantago juncoides)*, and *Juncus gerardii*. These marshes may be extensive where the local topography allows their development; they are generally not associated with sand beach and dune systems, being more characteristic of the primarily rocky portions of the Gulf of Maine coast. Where the coastal topography becomes more dissected, they are more commonly seen as a fairly narrow fringe along tidal shorelines. These marshes are typically less extensive and with some different floristic elements than the marshes southward along the Atlantic Coast from Cape Cod to Chesapeake Bay.

Similar Ecological Systems:
- Northern Atlantic Coastal Plain Tidal Salt Marsh (CES203.519)

Related Concepts:
- Mixed Graminoid - Forb Saltmarsh (Gawler and Cutko 2010) Finer
- Spartina Saltmarsh (Gawler and Cutko 2010) Finer

DESCRIPTION

Environment: Forms behind barrier beaches or at the outer mouths of tidal rivers where freshwater input is minimal and where vegetation is protected from high-energy wave action. Substrate is organic peat, which can reach 1-2 m in depth in low marsh.
Dynamics: Tidal flooding is regulated by elevation; flooding is diurnal in low marshes, decreasing to more irregular flooding in high marsh and fringing salt shrublands. Ponded water remains in depressions, causing hypersaline conditions and panne formation. In the northern portion of the range, ice-rafting of large boulders creates a barrier, behind which salt marshes form. Ice-scour causes substantial impacts on the structure of salt marshes, causing patches of marsh to be removed. Furrows and ridges are physical features formed by ice movement. Strong onshore wind causes berm development in winter, with a transition to offshore winds in summer that level the berms. Such processes result in a substantial amount of sediment transport. Large amounts of wrack are deposited annually. Geese also impact the marshes (Roberts and Robertson 1986).

Component Associations:
- *Ascophyllum nodosum - Fucus vesiculosus* Tidal Algal Nonvascular Vegetation (CEGL006341, GNR)
- *Ruppia maritima* Acadian/Virginian Zone Temperate Herbaceous Vegetation (CEGL006167, GNR)
- *Salicornia (virginica, bigelovii, maritima) - Spartina alterniflora* Herbaceous Vegetation (CEGL004308, G5)
- *Spartina alterniflora / (Ascophyllum nodosum)* Acadian/Virginian Zone Herbaceous Vegetation (CEGL004192, G5)
- *Spartina patens - Distichlis spicata - (Juncus gerardii)* Herbaceous Vegetation (CEGL006006, G5)

DISTRIBUTION

Range: This system occurs along the coastline of the Gulf of Maine, from northern Massachusetts north and east to Newfoundland, with the northern border at the Strait of Belle Isle between Labrador and Newfoundland.
Divisions: 201:C; 202:C
Nations: CA, US
Subnations: LB, MA, ME, NB, NF, NH, NS
Map Zones: 65:C, 66:C

ACADIAN ESTUARY MARSH (CES201.579)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Brackish (Mesohaline); Tidal / Estuarine; Graminoid; Spartina (patens, alterniflora)
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Herbaceous; Organic Peat (>40 cm); Mineral: W/ A-Horizon >10 cm
National Mapping Codes: ESLF 9292

CONCEPT

Summary: This brackish marsh system is found along mesohaline reaches of estuaries of the Gulf of Maine north to southern Newfoundland. Emergent and submergent vegetation characterizes this system. Dominance ranges from extensive grasslands to sparsely vegetated mudflats, all tidally influenced. Characteristic species include *Carex paleacea, Crassula aquatica, Juncus arcticus, Lilaeopsis chinensis, Limosella australis, Samolus valerandi ssp. parviflorus (= Samolus parviflorus), Schoenoplectus robustus, Schoenoplectus tabernaemontani, Spartina pectinata*, and *Triglochin maritima*. These marshes grade into the salt marsh system at the mouth of estuaries. They are typically less extensive and more floristically depauperate than the marshes southward along the Atlantic Coast to Chesapeake Bay.
Classification Comments: Differences between marshes in Division 202 and Division 201 may be sufficient to distinguish them as separate systems; however, data on estuarine marshes in Division 201 (Laurentian-Acadian) is very sketchy and should be better documented before such a split is made.
Similar Ecological Systems:
- Northern Atlantic Coastal Plain Brackish Tidal Marsh (CES203.894)--occurs to the south.
- Northern Atlantic Coastal Plain Fresh and Oligohaline Tidal Marsh (CES203.516)--occurs upriver to the limit of tidal influence.

Related Concepts:
- Brackish Tidal Marsh (Gawler and Cutko 2010) Finer

DESCRIPTION

Environment: This vegetation develops on tidal reaches of large rivers where freshwater from inland alluvial inputs mixes with marine saltwater incursion. Salinity levels are variable but generally range from 0.5 to 18 ppt. These marshes most commonly form on freely drained river levees. The substrate is moderately consolidated peat (Barrett 1989).
Dynamics: Tidal flooding by mesohaline waters; alluvial deposition of sediments forms levees where this vegetation develops.

Component Associations:
- *Alnus (incana ssp. rugosa, serrulata) - Cornus amomum* Shrubland (CEGL006337, GNR)
- *Amaranthus cannabinus* Tidal Herbaceous Vegetation (CEGL006080, G3G5)
- *Sagittaria subulata - Limosella australis* Tidal Herbaceous Vegetation (CEGL004473, G2G4)
- *Schoenoplectus pungens* Tidal Herbaceous Vegetation (CEGL004188, GNR)
- *Stuckenia pectinata - Potamogeton perfoliatus - (Zannichellia palustris)* Tidal Herbaceous Vegetation (CEGL006027, G3G5)
- *Typha angustifolia - Hibiscus moscheutos* Herbaceous Vegetation (CEGL004201, G4G5)

DISTRIBUTION

Range: This system is found along the coastline of the Gulf of Maine, from Cape Cod north and east to southern Newfoundland, extending upstream in estuaries to the brackish water limit.
Divisions: 201:C; 202:C
Nations: CA, US
Subnations: MA, ME, NB, NF, NH, NS
Map Zones: 65:C, 66:C

ALASKA ARCTIC COASTAL BRACKISH MEADOW (CES102.210)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Estuary; Polar [Polar Hyperoceanic]; Salt Spray; Graminoid; Delta
Non-Diagnostic Classifiers: Marsh; Herbaceous; Mineral: W/ A-Horizon <10 cm
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2712; ESLF 9414; ESP 1712

CONCEPT

Summary: This coastal brackish meadow system typically occurs immediately above tidal marshes in arctic Alaska. It has >25% herbaceous cover and <25% shrub cover. These sites are tidally inundated during storm tides and extreme high tides and, consequently, are brackish. The soils typically lack organics, and permafrost is uncommon. The main indicators on the Yukon-Kuskokwim Delta and the Kotzebue Sound lowlands ecoregions are *Carex rariflora* (>10%), *Calamagrostis deschampsioides*, and *Dendranthema arcticum (= Chrysanthemum arcticum)*. Other common species include *Eriophorum russeolum, Carex ramenskii* (usually present but not dominant), and *Salix ovalifolia*. Additional dominants on the Beaufort Coastal Plain are *Eriophorum angustifolium, Carex aquatilis*, and *Dupontia fisheri*.
Classification Comments: This system is known as Coastal Brackish Meadow by the Alaska Natural Heritage Program.
Related Concepts:
- III.A.3.i - Halophytic sedge wet meadow (Viereck et al. 1992) Broader

DESCRIPTION

Dynamics: This system's disturbance processes and succession have not been described.

DISTRIBUTION

Range: This system occurs along Alaska's arctic coastline, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: US
Subnations: AK

ALASKA ARCTIC FRESHWATER AQUATIC BED (CES102.182)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lake; Pond; Herbaceous; Polar [Polar Oceanic]; Aquatic Herb
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Hydromorphic-rooted grassland
National Mapping Codes: EVT 2696; ESLF 9415; ESP 1696

CONCEPT

Summary: This system is found throughout arctic Alaska as small patches confined to lakes and ponds. In large bodies of water, it is usually restricted to the littoral region where penetration of light is the limiting factor for growth. Large to small floodplains support the various wetlands that form in oxbows, wet depressions, low-lying areas, and abandoned channels, including freshwater aquatic beds. This system has standing water (typically more than 30 cm deep) with >25% cover of submerged or floating aquatic species, including *Potamogeton* spp., *Sparganium* spp., aquatic *Ranunculus* spp., *Myriophyllum* spp., and *Callitriche* spp.
Classification Comments: This system includes the systems known as Freshwater Aquatic Bed and Floodplain Freshwater Aquatic Bed by the Alaska Natural Heritage Program. The proposed floodplain aquatic bed ecological system will not be mappable from non-floodplain aquatic beds, and will be better treated as a component of this system. For now, aquatic beds found in arctic Alaska floodplains are included in this non-floodplain aquatic bed system.

DESCRIPTION

Dynamics: Freshwater aquatic beds are early-successional wetlands and will likely be replaced by marshes, wet meadows, fens, or permafrost plateaus. The rate of succession is unclear. In floodplains, primary succession on the Yukon-Kuskokwim Delta may move rapidly from aquatic bed to marsh to wet sedge and, possibly, wet low-tall shrub. An alternate wetland pathway is mesic sites supporting low or tall willows moving to wet low-tall shrub to wet sedge to tussocks, but this last stage is no longer part of floodplain dynamics. Primary succession on the Beaufort Coastal Plain progresses slowly from gravel bars to tall willow (possibly persisting for 300 years) or alder-willow, then to wet low willow (possibly persisting for 500 years). Paludification may lead to wet sedge (possibly persisting for 1000-2000 years), and permafrost formation may lead to tussock tundra, but this last stage is no longer part of the floodplain dynamics.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C

ALASKA ARCTIC PENDANTGRASS FRESHWATER MARSH (CES102.183)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland; Herbaceous; Polar [Polar Oceanic]; Aquic; Arctophila fulva
Non-Diagnostic Classifiers: Lake; Pond; Depressional; Riverine / Alluvial
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2697; ESLF 9416; ESP 1697

CONCEPT

Summary: Freshwater marshes dominated by *Arctophila fulva* occur as small patches throughout arctic Alaska, typically on the margins of ponds and lakes. They are semipermanently flooded, but some have seasonal flooding, and the water depth typically exceeds 10 cm. It is also found on large to small floodplains where various wetlands form in oxbows, wet depressions, low-lying areas, and abandoned channels, including freshwater marshes. Soils are muck or mineral, and water is nutrient-rich. In floodplains, permafrost is absent. This system has standing water with >10% cover of emergent herbaceous vegetation, primarily *Arctophila fulva*. Species diversity is low.
Classification Comments: This system includes those types known as Freshwater Marsh- *Arctophila fulva* and Floodplain Freshwater Marsh by the Alaska Natural Heritage Program. It is proposed to classify a separate floodplain freshwater marsh, but mapping and modeling of that as its own system is difficult. For now, marshes found in arctic Alaska floodplains are included in either this non-floodplain marsh system or in Alaska Arctic Sedge Freshwater Marsh (CES102.184).
Similar Ecological Systems:
- Alaska Arctic Sedge Freshwater Marsh (CES102.184)
- Aleutian Freshwater Marsh (CES105.235)

Related Concepts:
- III.A.3.e - Fresh grass marsh (Viereck et al. 1992) Broader

DESCRIPTION

Dynamics: This system occurs within a variety of successional processes, including thaw lakes, ice-wedge polygons, and oriented lakes. Seral stages and the rate of succession are unclear. In floodplains, primary succession on the Yukon-Kuskokwim Delta may move rapidly from aquatic bed to marsh to wet sedge and, possibly, wet low-tall shrub. An alternate wetland pathway is mesic sites supporting low or tall willows moving to wet low-tall shrub to wet sedge to tussocks, but this last stage is no longer part of floodplain dynamics. Primary succession on the Beaufort Coastal Plain progresses slowly from gravel bars to tall willow (possibly persisting for 300 years) or alder-willow, then to wet low willow (possibly persisting for 500 years). Paludification may lead to wet sedge (possibly persisting for 1000-2000 years), and permafrost formation may lead to tussock tundra, but this last stage is no longer part of the floodplain dynamics.

ALASKA ARCTIC POLYGONAL GROUND TUSSOCK TUNDRA (CES102.204)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Ice-Wedge Polygons; Polar [Polar Oceanic]; Shallow Soil; Silt Soil Texture; Graminoid; Tussock-forming grasses
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2707; ESLF 9417; ESP 1707

CONCEPT

Summary: Ice-wedge polygons and the thaw-lake cycle dominate the Beaufort Coastal Plain ecoregion. The ice-wedge polygons generally occur on level surfaces (0- to 2-degree slopes), and the ice wedges may be 2 m wide at the top. Polygon diameter ranges from several to more than 30 m. In addition to the Beaufort Coastal Plain, ice-wedge polygons are a common feature on level ground within foothills and mountains, on glacial drift, lacustrine and floodplain terrace surficial deposits. These sites are cold, poorly drained, and underlain by mesic, silty mineral soils with a shallow surface organic layer surrounding the tussocks. Permafrost is present. Patch size is small to large. This ecological system occurs primarily on high-center polygons. Their centers are commonly mesic, dominated by tussocks, and their perimeters are typically wet, supporting wet sedges. *Eriophorum vaginatum* is the primary tussock-former in most sites, but *Carex bigelowii* may dominate some sites. *Calamagrostis canadensis, Arctagrostis latifolia*, and *Chamerion latifolium* may be common. Shrubs include *Betula nana, Ledum palustre ssp. decumbens*, and *Vaccinium* spp. Common mosses include *Sphagnum* spp., *Polytrichum strictum*, and *Hylocomium splendens*. The wet perimeters typically support *Carex aquatilis* and *Eriophorum angustifolium*.
Related Concepts:

DESCRIPTION

Environment: Ice-wedge polygons and the thaw-lake cycle dominate the Beaufort Coastal Plain ecoregion. The ice-wedge polygons generally occur on level surfaces (0- to 2-degree slopes), and the ice wedges may be 2 m wide at the top. Polygon diameter ranges from several to more than 30 m. In addition to the Beaufort Coastal Plain, ice-wedge polygons are a common feature on level ground within foothills and mountains, on glacial drift, lacustrine and floodplain terrace surficial deposits. These sites are cold, poorly drained, and underlain by mesic, silty mineral soils with a shallow surface organic layer surrounding the tussocks (Viereck et al. 1992). Permafrost is present. Patch size is small to large.
Vegetation: This ecological system occurs primarily on high-center polygons. Their centers are commonly mesic, dominated by tussocks, and their perimeters are typically wet, supporting wet sedges. *Eriophorum vaginatum* is the primary tussock-former in most sites, but *Carex bigelowii* may dominate some sites. *Calamagrostis canadensis, Arctagrostis latifolia*, and *Chamerion latifolium* may be common. Shrubs include *Betula nana, Ledum palustre ssp. decumbens*, and *Vaccinium* spp. Common mosses include *Sphagnum* spp., *Polytrichum strictum*, and *Hylocomium splendens*. The wet perimeters typically support *Carex aquatilis* and *Eriophorum angustifolium*.
Dynamics: Ice-wedge polygons are formed by large ice wedges which grow in thermal contraction cracks in permafrost. High-center polygons indicate that erosion, deposition, or thawing are more prevalent than the up-pushing of the sediments along the sides of the wedge. Ice-wedge polygons are typically part of a spatially coarser thaw-lake cycle.

Most of the land on the Beaufort Coastal Plain (Nowacki et al. (2001) ecoregion 1) is polygonal ground and pond complexes. To be able to model and map polygonal ground systems in this region, first mask out lakes, ponds, floodplains and tidal marshes. Then, use only land with less than a 2-degree slope as being polygonal ground.

DISTRIBUTION

Range: This system is typically found in the lowland regions of arctic Alaska, particularly on the Beaufort Coastal Plain in northern Alaska, and the Kotzebue Sound lowlands of west-central Alaska, but it also occurs in other scattered locations of arctic Alaska where there ice-wedge processes occur.
Divisions: 102:C; 104:C

DESCRIPTION

Dynamics: Ice-wedge polygons are formed by large ice wedges which grow in thermal contraction cracks in permafrost. Low-center polygons indicate that ice wedges are actually growing and that sediments are being actively upturned. High-center polygons indicate that erosion, deposition, or thawing are more prevalent than the up-pushing of the sediments along the sides of the wedge. Ice-wedge polygons are typically part of a spatially coarser thaw-lake cycle.

Most of the land on the Beaufort Coastal Plain (Nowacki et al. (2001) ecoregion 1) is polygonal ground and pond complexes. To be able to model and map polygonal ground systems in this region, first mask out lakes, ponds, floodplains and tidal marshes. Then, use only land with less than a 2-degree slope as being polygonal ground.

ALASKA ARCTIC TIDAL MARSH (CES102.209)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saline Water Chemistry; Estuary; Herbaceous; Tidal / Estuarine; Graminoid
Non-Diagnostic Classifiers: Brackish (Mesohaline); Lagoon; Marsh
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2711; ESLF 9420; ESP 1711

CONCEPT

Summary: This system consists of herbaceous marshes with >10% vascular species cover that are subject to regular tidal inundation. The marshes are salt or brackish. Some are primarily freshwater that are infrequently flooded during storm surges or extreme high tides. Tidal marshes are primarily associated with estuaries or coastal lagoons or other locations protected from wave action. Two different types of tidal marshes are included in this system: tidal sedge marshes and tidal herbaceous (non-sedge) marshes. *Carex ramenskii* or *Carex subspathacea* dominate the tidal sedge marshes. *Carex subspathacea* is more common along the Beaufort Sea. *Carex lyngbyei* may dominate on portions of the Yukon-Kuskokwim Delta and is often found more inland or adjacent to tidal creeks. *Dupontia fisheri* and *Puccinellia* spp. dominate the tidal herbaceous marshes. *Argentina egedii (= Potentilla egedii)* may dominate on Alaska's west coast but not on the Beaufort Coastal Plain.

Tidal marshes often form an ecotone with freshwater non-tidal wetlands, especially on the Yukon-Kuskokwim Delta. On this delta, the first system moving inland is tidal marsh (*Puccinellia* spp. then *Carex ramenskii* or *Carex subspathacea*), then Alaska Arctic Coastal Brackish Meadow (CES102.210) (*Carex rariflora, Calamagrostis deschampsioides*, and *Dendranthema arcticum (= Chrysanthemum arcticum)*), then Alaska Arctic Coastal Sedge-Dwarf-Shrubland (CES102.211) (*Empetrum nigrum, Salix fuscescens, Salix ovalifolia, Carex rariflora, Calamagrostis deschampsioides, Deschampsia caespitosa*), and then raised bogs or permafrost plateaus supporting Alaska Arctic Dwarf-Shrub-Sphagnum Peatland (CES102.201) or Alaska Arctic Permafrost Plateau Dwarf-Shrub Lichen Tundra (CES102.202).

Classification Comments: This system is known as Tidal Marsh by the Alaska Natural Heritage Program. This system is very similar in composition and processes to the Aleutian tidal marsh system; for now they are maintained as two distinct systems, but may be merged in the future.

Similar Ecological Systems:
- Aleutian Tidal Marsh (CES105.279)

ALASKA ARCTIC TUSSOCK TUNDRA (CES102.179)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Polar [Polar Oceanic]; Graminoid; Tussock-forming grasses; Eriophorum vaginatum
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2694; ESLF 9421; ESP 1694

CONCEPT

Summary: Tussock tundra is common in valleys and slopes throughout arctic Alaska. These sites are cold, poorly drained, and underlain by mesic, silty mineral soils with a shallow surface organic layer surrounding the tussocks. Permafrost is present. Patch size is small to large. Tussock tundra has >35% cover of sedges in a tussock growth form; the combined cover of dwarf- and low shrubs is <25%, and lichen cover is <25%. *Eriophorum vaginatum* is the primary tussock-former in most stands, but *Carex bigelowii* may dominate some sites. *Calamagrostis canadensis, Arctagrostis latifolia,* and *Chamerion latifolium (= Epilobium latifolium)* may be common. Shrubs include *Betula nana, Ledum palustre ssp. decumbens,* and *Vaccinium* spp. Mosses (*Sphagnum* spp., *Polytrichum strictum*, and *Hylocomium splendens*) may form a nearly continuous mat between tussocks. There are also distinctions between acidic and non-acidic tussock tundra. Acidic sites have more ericaceous shrubs and *Sphagnum* and less *Eriophorum* spp., *Betula nana*, and *Carex bigelowii*. Acidic sites also have more organic matter buildup and the tussocks tend to be larger.
Classification Comments: This system is known as Tussock Tundra by the Alaska Natural Heritage Program.
Related Concepts:
- III.A.2.d - Tussock tundra (Viereck et al. 1992) Broader

DESCRIPTION

Environment: Tussock tundra is common in valleys and slopes throughout arctic Alaska. These sites are cold, poorly drained, and underlain by mesic, silty mineral soils with a shallow surface organic layer surrounding the tussocks (Viereck et al. 1992). Permafrost is present. Patch size is small to large.
Vegetation: Tussock tundra has >35% cover of sedges in a tussock growth form; the combined cover of dwarf- and low shrubs is <25%, and lichen cover is <25%. *Eriophorum vaginatum* is the primary tussock-former in most stands, but *Carex bigelowii* may dominate some sites. *Calamagrostis canadensis, Arctagrostis latifolia,* and *Chamerion latifolium (= Epilobium latifolium)* may be common. Shrubs include *Betula nana, Ledum palustre ssp. decumbens,* and *Vaccinium* spp. Mosses (*Sphagnum* spp., *Polytrichum strictum*, and *Hylocomium splendens*) may form a nearly continuous mat between tussocks. There are also distinctions between acidic and non-acidic tussock tundra. Acidic sites have more ericaceous shrubs and *Sphagnum* and less *Eriophorum* spp., *Betula nana*, and *Carex bigelowii*. Acidic sites also have more organic matter buildup and the tussocks tend to be larger.
Dynamics: According to lake-core records, the fire-return interval is approximately 240 years on the Seward Peninsula and 1000+ years on the Beaufort Coastal Plain (J. Allen pers. comm.). These figures may apply to acidic more than non-acidic tussock tundra. This system is sometimes an early-seral stage following fire in the tussock shrub tundra system. The shrubs often recover to pre-fire cover within 15 years.

ALASKA ARCTIC TUSSOCK-LICHEN TUNDRA (CES102.181)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Polar [Polar Oceanic]; Shallow Soil; Silt Soil Texture; Graminoid; Lichen; Tussock-forming grasses; Eriophorum vaginatum
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2695; ESLF 9422; ESP 1695

CONCEPT

Summary: The tussock lichen tundra system is common in valleys and slopes throughout arctic Alaska. These sites are cold, poorly drained, and underlain by mesic, silty mineral soils with a shallow surface organic layer surrounding the tussocks. Permafrost is present. Lichens are more common on the drier tussock tundra sites in western Alaska. Patch size is small to large. Tussock lichen tundra has >35% cover of sedges in a tussock growth form, shrub cover is <25%, and lichen cover is >25%. Dwarf-shrubs may be common. *Eriophorum vaginatum* is the primary tussock-former in most stands, but *Carex bigelowii* may dominate some sites. Lichens may include *Flavocetraria cucullata (= Cetraria cucullata), Cetraria islandica, Cladonia* spp., *Cladina rangiferina*, and *Thamnolia subuliformis*. There are also distinctions between acidic and non-acidic tussock tundra. Acidic sites have more ericaceous shrubs and *Sphagnum* and less *Eriophorum* spp., *Betula nana*, and *Carex bigelowii*. Acidic sites also have more organic matter buildup and the tussocks tend to be larger.
Classification Comments: This system is known as Tussock Lichen Tundra by the Alaska Natural Heritage Program.
Related Concepts:
- III.A.2.d - Tussock tundra (Viereck et al. 1992) Broader

DESCRIPTION

Environment: The tussock lichen tundra system is common in valleys and slopes throughout arctic Alaska. These sites are cold, poorly drained, and underlain by mesic, silty mineral soils with a shallow surface organic layer surrounding the tussocks (Viereck et al. 1992). Permafrost is present. Lichens are more common on the drier tussock tundra sites in western Alaska. Patch size is small to large.
Vegetation: Tussock lichen tundra has >35% cover of sedges in a tussock growth form, shrub cover is <25%, and lichen cover is >25%. Dwarf-shrubs may be common. *Eriophorum vaginatum* is the primary tussock-former in most stands, but *Carex bigelowii* may dominate some sites. Lichens may include *Flavocetraria cucullata (= Cetraria cucullata), Cetraria islandica, Cladonia* spp., *Cladina rangiferina*, and *Thamnolia subuliformis*. There are also distinctions between acidic and non-acidic tussock tundra. Acidic sites have more ericaceous shrubs and *Sphagnum* and less *Eriophorum* spp., *Betula nana*, and *Carex bigelowii*. Acidic sites also have more organic matter buildup and the tussocks tend to be larger.
Dynamics: This system's successional status is unclear. According to lake-core records, the fire-return interval is approximately 240 years on the Seward Peninsula and 1000+ years on the Beaufort Coastal Plain (J. Allen pers. comm.). These figures may apply to acidic more than non-acidic tussock tundra.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK

ALASKA ARCTIC WET SEDGE MEADOW (CES102.185)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Herbaceous; Polar [Polar Oceanic]; Eriophorum angustifolium
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2698; ESLF 9423; ESP 1698

CONCEPT

Summary: This ecological system occurs on wet sites (typically with 0-10% visible surface water) with >25% cover of sedge species. Sites are flat to sloping in valley bottoms, basins, low-center polygons, water tracks and adjacent to streams. It also includes patterned wetlands such as ribbed fens. These wet sedge meadows are also found on large to small floodplains, which support the various wetlands that form in oxbows, wet depressions, low-lying areas, and abandoned channels, including wet sedge meadows. Soils range from acidic to non-acidic, are saturated during the summer, and have an organic horizon over silt with permafrost, although on floodplains, permafrost is absent. Patch size is small to moderate and may be linear. Species diversity is much higher than in the freshwater marsh systems. Sites are typically dominated by *Carex aquatilis* and *Eriophorum angustifolium* but may also be dominated or codominated by *Carex glareosa, Carex rotundata, Carex rariflora, Carex chordorrhiza, Carex rostrata, Carex saxatilis, Carex utriculata, Eriophorum russeolum,* and *Eriophorum scheuchzeri*. *Dupontia fisheri* may also occur. Dwarf-shrubs such as *Salix fuscescens, Salix pulchra, Andromeda polifolia, Betula nana, Empetrum nigrum, Ledum palustre ssp. decumbens*, and *Vaccinium uliginosum* may be common but make up <25% cover. Moss species include *Drepanocladus* spp. and *Sphagnum* spp.
Classification Comments: This system include those types known as Wet Sedge and Floodplain Wet Sedge by the Alaska Natural Heritage Program. It is proposed to classify a separate floodplain wet sedge meadow, but mapping and modeling of that as its own system is difficult. For now, wet sedge meadows found in arctic Alaska floodplains are included in this sedge meadow system.
Related Concepts:

- III.A.3.f - Subarctic lowland sedge wet meadow (Viereck et al. 1992) Intersecting
- III.A.3.g - Subarctic lowland sedge-shrub wet meadow (Viereck et al. 1992) Intersecting
- III.A.3.j - Subarctic lowland sedge bog meadow (Viereck et al. 1992) Intersecting
- III.B.3.b - Subarctic lowland herb wet meadow (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: This system occurs within a variety of successional processes, including thaw lakes, polygonal ground, ice-wedge polygons, oriented lakes, water tracks and adjacent to streams. Seral stages and the rate of succession in this system are unclear. In floodplains, primary succession on the Yukon-Kuskokwim Delta may move rapidly from aquatic bed to marsh to wet sedge and, possibly, wet low-tall shrub. An alternate wetland pathway is mesic sites supporting low or tall willows moving to wet low-tall shrub to wet sedge to tussocks, but this last stage is no longer part of floodplain dynamics. Primary succession on the Beaufort Coastal Plain progresses slowly from gravel bars to tall willow (possibly persisting for 300 years) or alder-willow, then to wet low willow (possibly persisting for 500 years). Paludification may lead to wet sedge (possibly persisting for 1000-2000 years), and permafrost formation may lead to tussock tundra, but this last stage is no longer part of the floodplain dynamics.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US

ALASKA ARCTIC WET SEDGE-SPHAGNUM PEATLAND (CES102.200)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Herbaceous; Polar [Polar Oceanic]; Acidic Soil; Organic Peat (>40 cm); Sphagnum spp.; Eriophorum angustifolium; Eriophorum vaginatum
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2702; ESLF 9424; ESP 1702

CONCEPT

Summary: This system occurs on the Yukon-Kuskokwim Delta and the Kotzebue Sound lowlands ecoregions. It is common in wet depressions and old lake basins. Soils are poorly drained and acidic, typically with a well-developed peat layer. Permafrost may be present. Patch size is small to large. *Sphagnum* cover is >25% (usually continuous), and herbaceous species (primarily sedges) cover is >25%. The dominant sedges are *Eriophorum* spp. and *Carex utriculata*. Other common species include *Betula nana, Comarum palustre (= Potentilla palustris)*, and *Equisetum fluviatile*.
Classification Comments: This system is known as Lowland Wet Sedge Sphagnum by the Alaska Natural Heritage Program.
Related Concepts:
- III.A.3.a - Wet sedge meadow tundra (Viereck et al. 1992) Intersecting
- III.A.3.k - Subarctic lowland sedge-moss bog meadow (Viereck et al. 1992) Intersecting
- III.B.3.c - Subarctic lowland herb bog meadow (Viereck et al. 1992) Intersecting
- III.C.1.a - Wet bryophyte (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: This is an early-seral stage in the thaw-pond cycle. It starts with the collapse of a permafrost plateau resulting in a wet depression often with open water. This is colonized by marsh species or *Sphagnum* spp. or a combination of both. Sedges eventually invade, and this wet sedge-*Sphagnum* system develops. If organic matter buildup or permafrost uplift the surface, then this system may be seral to Alaska Arctic Dwarf-Shrub-Sphagnum Peatland (CES102.201). This system, in turn, may be seral to Alaska Arctic Permafrost Plateau Dwarf-Shrub Lichen Tundra (CES102.202). The seral sequence may not be unidirectional, and the timeframe is unclear, possibly taking hundreds of years.

DISTRIBUTION

Range: This system occurs on the Yukon-Kuskokwim Delta and the Kotzebue Sound lowlands ecoregions of Alaska.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK
Map Zones: 67:C, 68:C, 72:C, 76:C

ALASKAN PACIFIC MARITIME ALPINE WET MEADOW (CES204.160)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Alpine/AltiAndino; Riparian Mosaic; Toeslope/Valley Bottom; Temperate [Temperate Oceanic]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2673; ESLF 9425; ESP 1673

CONCEPT

Summary: This small-patch ecological system often occurs as a mosaic of alpine wetlands including headwater fens, marshes, and riparian zones. Common species include *Salix reticulata, Salix stolonifera, Viola* spp., *Lupinus nootkatensis, Mimulus guttatus, Mimulus lewisii, Petasites frigidus var. frigidus, Sanguisorba canadensis,* and *Leptarrhena pyrolifolia*; *Valeriana sitchensis, Castilleja parviflora, Ranunculus* spp., *Caltha* spp., and *Saxifraga* spp. often occur along streambanks. Peatlands and associated wet meadows and marshes often feature *Trichophorum caespitosum, Carex anthoxanthea*, and *Juncus mertensianus*.
Classification Comments: This system is known as Alpine Wet Meadow by the Alaska Natural Heritage Program.
Related Concepts:
- III.A.3.c - Wet sedge-herb meadow tundra (Viereck et al. 1992) Intersecting

DISTRIBUTION

Range: This system occurs from Kodiak Island through southeastern Alaska.
Divisions: 204:C
Nations: US

ALASKAN PACIFIC MARITIME COASTAL MEADOW AND SLOUGH-LEVEE (CES204.159)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland; Herbaceous; Temperate [Temperate Hyperoceanic]; Tidal / Estuarine
Non-Diagnostic Classifiers: Levee; Raised beach; Raised estuary; Slough; Forb; Graminoid; Delta
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2665; ESLF 9426; ESP 1665

CONCEPT

Summary: This ecological system includes moist and wet meadows associated with delta deposits, uplifted marshes, or beach deposits. These meadows occur inland of tidal marshes and are also common along sloughs and levees. Meadows are dominated by a wide variety of graminoids and forbs, including *Deschampsia beringensis, Festuca rubra, Argentina egedii (= Potentilla egedii), Lathyrus japonicus var. maritimus, Castilleja* spp., *Heracleum maximum, Parnassia palustris, Lupinus nootkatensis, Achillea millefolium var. borealis (= Achillea borealis), Angelica lucida*, and *Carex mackenziei*. *Leymus mollis* and *Lupinus nootkatensis* are common on levees, and *Carex lyngbyei* often dominates in sloughs and wet depressions.
Classification Comments: This system is known as Coastal Meadow and Slough-Levee by the Alaska Natural Heritage Program.
Related Concepts:

ALASKAN PACIFIC MARITIME FEN AND WET MEADOW (CES204.158)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Herbaceous; Temperate [Temperate Oceanic]; Carex aquatilis var. dives
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2661; ESLF 9427; ESP 1661

CONCEPT

Summary: This ecological system includes herbaceous wetlands in fens (not including bogs) and non-peatlands. The fen/wet meadow system may be dominated either by sedges, sedges with a variety of forbs, or forbs. The organic layer ranges from thick to thin, and may be composed of sphagnum, sedge, or other organic material and can occur over mineral soil, or may be floating or submerged. Rich fens consistently feature *Carex aquatilis var. dives (= Carex sitchensis)*, although a variety of other sedges and forbs may be present, including *Dodecatheon pulchellum, Parnassia fimbriata, Eriophorum russeolum, Menyanthes trifoliata*, and *Comarum palustre*. Ericaceous shrubs are absent. Bryophytes (when present) include *Calliergon giganteum, Sphagnum squarrosum*, and *Sphagnum riparium*. Mixed sedge and forb meadows include *Carex saxatilis, Carex lyngbyei, Sanguisorba canadensis, Swertia perennis*, and *Platanthera dilatata*. Forb-dominated sites include *Equisetum fluviatile, Comarum palustre (= Potentilla palustris)*, and *Menyanthes trifoliata*.

Classification Comments: This system is known as Fen and Wet Meadow by the Alaska Natural Heritage Program. This type does not include poor fens; these are included with bog types. Species composition in the *Menyanthes* fen type is similar in composition through south-central, southwestern, and interior Alaska (Drury 1956, Tande 1983, Racine and Walters 1991), but processes driving succession vary.

Similar Ecological Systems:
- North Pacific Bog and Fen (CES204.063)
- Temperate Pacific Subalpine-Montane Wet Meadow (CES200.998)

DESCRIPTION

Environment: This ecological system includes herbaceous wetlands in fens (not including bogs) and non-peatlands. The fen/wet meadow system may be dominated either by sedges, sedges with a variety of forbs, or forbs. The organic layer ranges from thick to thin, and may be composed of sphagnum, sedge, or other organic material and can occur over mineral soil, or may be floating or submerged.

Vegetation: Rich fens consistently feature *Carex aquatilis var. dives (= Carex sitchensis)* (McClellan et al. 2003), although a variety of other sedges and forbs may be present, including *Dodecatheon pulchellum, Parnassia fimbriata, Eriophorum russeolum, Menyanthes trifoliata*, and *Comarum palustre*. Ericaceous shrubs are absent. Bryophytes (when present) include *Calliergon giganteum, Sphagnum squarrosum*, and *Sphagnum riparium* (Shephard 1995, Boggs 2000). Mixed sedge and forb meadows include *Carex saxatilis, Carex lyngbyei, Sanguisorba canadensis, Swertia perennis*, and *Platanthera dilatata*. Forb-dominated sites include *Equisetum fluviatile, Comarum palustre (= Potentilla palustris)*, and *Menyanthes trifoliata*.

Component Associations:

- *Carex aquatilis var. dives - Comarum palustre* Herbaceous Vegetation (CEGL003433, G2)
- *Carex aquatilis var. dives* Herbaceous Vegetation (CEGL001826, G4)
- *Menyanthes trifoliata* Herbaceous Vegetation (CEGL003410, G5)

DISTRIBUTION

Range: This system occurs from Kodiak Island through southeastern Alaska.

ALEUTIAN FRESHWATER AQUATIC BED (CES105.234)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lake; Pond; Herbaceous; Boreal [Boreal Oceanic]; Aquatic Herb
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Hydromorphic-rooted grassland
National Mapping Codes: EVT 2721; ESLF 9428; ESP 1721

CONCEPT

Summary: Freshwater aquatic beds occur in permanently flooded depressions, shallow ponds, and the littoral zone of lakes where penetration of light is the limiting factor for growth. They are small patch in size. Soils are mineral or muck. This system has standing water with >25% cover of submerged or floating aquatic species. Genera and species include *Subularia, Callitriche, Limosella, Isoetes maritima, Isoetes occidentalis, Potamogeton alpinus, Ranunculus aquatilis, Ranunculus trichophyllus var. trichophyllus, Sparganium hyperboreum*, and *Nuphar polysepala (= Nuphar lutea ssp. polysepala)*.
Classification Comments: This system is known as Freshwater Aquatic Bed by the Alaska Natural Heritage Program. This system should probably be merged with other aquatic bed systems in Alaska; it's unlikely that aquatic beds in the Aleutians are significantly different from those in the boreal or maritime regions.
Similar Ecological Systems:
- Alaska Arctic Freshwater Aquatic Bed (CES102.182)
- North American Boreal Freshwater Aquatic Bed (CES103.125)
- Temperate Pacific Freshwater Aquatic Bed (CES200.876)

Related Concepts:

ALEUTIAN FRESHWATER MARSH (CES105.235)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Boreal [Boreal Oceanic]; Graminoid
Non-Diagnostic Classifiers: Lake; Marsh; Pond
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2722; ESLF 9429; ESP 1722

CONCEPT

Summary: Freshwater marshes typically occur with other wetland systems on the margins of ponds and lakes. They are mostly small patch, semipermanently flooded, but some have seasonal flooding. Water is at or above the surface for most of the growing season. Soils are muck or mineral. Freshwater marshes have >10% cover of emergent herbaceous vegetation. Species include *Carex aquatilis*, *Carex utriculata*, *Menyanthes trifoliata*, *Comarum palustre*, *Equisetum fluviatile*, *Equisetum palustre*, and *Hippuris* spp. Species of *Eriophorum* do not commonly occur in this system. Species diversity is often low.
Classification Comments: This system is known as Freshwater Marsh by the Alaska Natural Heritage Program. This system should probably be merged with other freshwater marsh systems in Alaska; it's unlikely that freshwater marshes in the Aleutians are significantly different from those in the boreal or maritime regions.
Similar Ecological Systems:

ALEUTIAN NONVASCULAR PEATLAND (CES105.237)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Moss/Lichen (Nonvascular); Boreal [Boreal Oceanic]; Organic Peat (>40 cm)
Non-Diagnostic Classifiers: Seepage-Fed Sloping [Peaty]; Depressional [Lakeshore]; Depressional [Pond]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Nonvascular, Bryophyte
National Mapping Codes: EVT 2724; ESLF 9430; ESP 1724

CONCEPT

Summary: This ecological system occurs in shallow depressions, seepage channels on gentle slopes, and pond margins. Peat depth is >40 cm and may be over mineral soil, floating or submerged. The sites are wet, and patch size is small. Dominance ranges from mosses and forbs (*Sphagnum* spp. or *Philonotis fontana var. americana* and *Parnassia kotzebuei*) to liverworts (*Scapania* spp., *Nardia* spp., *Marsupella* spp., *Siphula* spp.)
Classification Comments: This system is known as Nonvascular Peatland by the Alaska Natural Heritage Program.
Related Concepts:
- III.C.1.a - Wet bryophyte (Viereck et al. 1992) Intersecting

DESCRIPTION

ALEUTIAN TIDAL MARSH (CES105.279)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saline Water Chemistry; Marsh; Herbaceous; Boreal [Boreal Oceanic]; Tidal / Estuarine; Graminoid
Non-Diagnostic Classifiers: Brackish (Mesohaline); Estuary; Lagoon
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2726; ESLF 9431; ESP 1726

CONCEPT

Summary: This system consists of herbaceous marshes with >10% vascular species cover that are subject to regular tidal inundation. The marshes are typically salt or brackish. Some, however, are primarily freshwater that are infrequently flooded by storm surges or extreme high tides. Tidal marshes are primarily associated with estuaries or coastal lagoons or other locations protected from wave action. Lagoons with outer spits and beaches are well developed and common in the Aleutians. Tidal marshes, however, are not extensive within these lagoons because of constant winds and waves, plus winter sea ice may be extensive and blown to shore, battering the vegetation. It appears that tectonic/isostatic uplift is common, lifting the marshes above the tide. Two existing vegetation types dominate the system: tidal sedge and tidal herbaceous. *Carex lyngbyei, Carex glareosa,* and *Carex mackenziei* dominate the tidal sedge class. Other species include *Hippuris tetraphylla, Hippuris vulgaris, Ruppia cirrhosa, Stellaria humifusa,* and *Zannichellia palustris*. *Puccinellia* spp. or *Plantago maritima* dominate the tidal herbaceous type, often with <25% cover.
Classification Comments: This system is known as Tidal Marsh by the Alaska Natural Heritage Program. This system should probably be merged with other tidal marsh systems in Alaska; it's unlikely that tidal marshes in the Aleutians are significantly different from those in the maritime or southern arctic regions.
Similar Ecological Systems:
- Alaska Arctic Tidal Marsh (CES102.209)

ATLANTIC COASTAL PLAIN EMBAYED REGION SEAGRASS BED (CES203.243)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Aquatic Herb
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9295

CONCEPT

Summary: This system of seagrass beds occurs primarily in the embayed regions of North Carolina and southeastern Virginia. The vast series of barriers provides ample area for colonization of hydromorphic herbaceous vegetation in protected sounds and lagoons which are subject to wind tides only. Local habitats range from small guts, shallow tributary creeks, and large marsh pools along freshwater and oligohaline sections of tidal rivers to shallow estuarine bays, tidal creeks, and salt marsh pools. This system lies outside the climatic range for most tropical species, especially *Thalassia testudinum* and *Cymodocea filiformis*. These species are largely replaced by *Zostera marina*. This region is the northern terminus for *Halodule wrightii (= Halodule beaudettei)*, and most typical beds of the region can be characterized as *Zostera - Halodule*.
Classification Comments: Northern Atlantic Coastal Plain Seagrass Bed (CES203.246) is a related system with a range to the north of this type that is generally characterized as *Zostera - Ruppia* (Thayer et al. 1984).
Similar Ecological Systems:
- Atlantic Coastal Plain Embayed Region Tidal Salt and Brackish Marsh (CES203.260)
- Northern Atlantic Coastal Plain Seagrass Bed (CES203.246)

DESCRIPTION

Environment: Water salinity ranges from oligohaline at the mouths of tidal rivers to brackish waters.
Vegetation: According to Fleming et al. (2001), *Ceratophyllum demersum* is the most important and abundant species found along the freshwater margins of this system, where associates include *Utricularia* spp., *Elodea nuttallii*, *Spirodela polyrrhiza*, and *Wolffiella gladiata*. Shallow waters may support sparse to dense surface cover of *Nymphaea odorata* or, rarely, *Nelumbo lutea*. More saline areas support *Ruppia maritima*, *Zostera marina*, *Zannichellia palustris*, and *Stuckenia pectinata*. Aquatic algae are frequent to abundant associates. In portions of the area where *Zostera* and *Halodule* co-occur, each attains maximum biomass at different times of the year (Thayer et al. 1984).
Dynamics: The dynamics of tidal, aquatic communities dominated by vascular plants are complex and poorly understood. The distribution and abundance of vascular plants in these habitats are probably controlled by responses to water chemistry, water clarity and light penetration, the impact of currents and boat wakes, and herbivory by aquatic animals (Fleming et al. 2001).

Component Associations:
- *Halodule wrightii* Herbaceous Vegetation (CEGL004318, G4?)
- *Ruppia maritima* Carolinian Zone Herbaceous Vegetation (CEGL004335, G4G5)
- *Zostera marina* Herbaceous Vegetation (CEGL004336, G4G5)

DISTRIBUTION

Range: This system is found in the embayed regions of North Carolina and southeastern Virginia southward to Cape Fear. South of Cape Fear seagrasses are largely absent until the St. Johns region of Florida (Kenworthy pers. comm.).

ATLANTIC COASTAL PLAIN EMBAYED REGION TIDAL FRESHWATER MARSH (CES203.259)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Freshwater]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9276

CONCEPT

Summary: Embayed region tidal freshwater marshes are characterized by fresh to oligohaline waters which are driven by irregular wind tides, with minimal lunar tidal influence. They are the predominant marsh system in the drowned creeks and inland estuary shores of the embayed region of northeastern North Carolina and adjacent Virginia. This system typically occurs as complexes of several associations dominated by large graminoids such as *Spartina cynosuroides, Cladium mariscus ssp. jamaicense, Schoenoplectus pungens, Typha angustifolia, Typha latifolia*, and *Juncus roemerianus*, sometimes with species-rich associations of shorter graminoids, forbs, and floating or submerged aquatics. While some association dominants are tolerant of brackish water, they are associated with plants restricted to oligohaline or freshwater. Irregular flooding and fire are both important forces in this system, and rising sea level is a particularly important driver of long-term trends.
Classification Comments: The distinction between this system and other tidal freshwater marsh systems is based on the distinctive dynamics of the irregular wind tidal flooding.

DESCRIPTION

Environment: The embayed region of the Mid-Atlantic Coastal Plain stretches along northeastern North Carolina and adjacent areas of Virginia. Estuaries in drowned river valleys are unusually extensive here. The barrier islands along the coast are unusually continuous and the ocean's tidal range modest. This produces estuaries where irregular wind tides are the dominant hydrological process. The water is oligohaline to fresh over most of the tidal areas, with brackish water near the coast and saltwater only on or near the barrier island inlets. Rainfall may be an important influence in marsh interiors for significant periods of time between high wind tides. Soils appear to be essentially always saturated, with shallow flooding for periods of several days at all times of year. Due to limited sediment transport, marsh soils are primarily organic. Marshes occur in small to large patches or bands along the drowned creeks and rivers. Most give way to tidal swamps inland and upstream, but some occur on islands. Those near the transition to brackish water may grade to wind tide-influenced brackish marshes downstream.
Vegetation: This system consists largely of wetland vegetation dominated by large graminoid herbs that are tolerant of constant saturation but intolerant of too much salt. *Spartina patens, Cladium mariscus ssp. jamaicense, Schoenoplectus pungens, Typha angustifolia*, and *Typha latifolia* dominate large areas. *Juncus roemerianus* is sometimes a dominant, especially in areas that have become fresh in the last 100 years as a result of coastal inlet changes. All of these dominants are accompanied by at least a few other plants intolerant of saltwater. Vegetation dominated by smaller graminoids, wetland forbs, submerged or floating aquatics, shrubs, or open stands of trees may also be present. Individual marshes usually are mosaics or zoned complexes of patches of the component associations.
Dynamics: Hydrology is the most important driving process, with the constant saturation determining the potential vegetation, and the variable flooding and variations in salinity in the fresh to brackish range a primary disturbance. Wind tides flood or expose the marshes at irregular intervals and transport nutrients and organic matter. Storm surges and unusually high tides associated with storms may bring saltier water into these systems, disturbing the less salt-tolerant plants. These disturbances may be an important factor determining the boundary between this system and adjacent tidal swamps, but this is not well documented. Rising sea level is an important driver of longer term vegetation trends, including expansion into adjacent swamp areas. Fire is also an important natural process in all but the smallest and most isolated patches. Frost (pers. comm.) estimates that many marshes burned as often as every three years in presettlement times and were an important source of ignition for adjacent communities. Marshes that have not burned recently have lower species richness, are more strongly dominated by the large graminoids, and are believed to be poorer habitat for waterfowl. Marshes often show evidence of transition to or from tree-dominated communities, in the form of young invading trees and shrubs or standing dead older trees. Lack of fire appears to be allowing sufficient tree invasion to eventually produce a swamp forest in some upstream examples, but the trend in most places is toward development of marshes in former swamp areas.

Component Associations:

- *Schoenoplectus pungens - (Osmunda regalis var. spectabilis)* Herbaceous Vegetation (CEGL004189, G2G3)
- *Spartina alterniflora - Lilaeopsis chinensis* Herbaceous Vegetation (CEGL004193, G3G4)
- *Spartina cynosuroides - Panicum virgatum - Phyla lanceolata* Herbaceous Vegetation (CEGL007741, G2G3)
- *Spartina cynosuroides* Herbaceous Vegetation (CEGL004195, G4)
- *Typha angustifolia - Hibiscus moscheutos* Herbaceous Vegetation (CEGL004201, G4G5)
- *Typha latifolia* Southern Herbaceous Vegetation (CEGL004150, G5)
- *Zizania aquatica* Tidal Herbaceous Vegetation (CEGL004202, G4?)
- *Zizaniopsis miliacea* Tidal Herbaceous Vegetation (CEGL004705, G3G5)

SPATIAL CHARACTERISTICS

Size: Patches range from a few square meters to 1000-2000 acres.

Adjacent Ecological Systems:

- Atlantic Coastal Plain Embayed Region Tidal Salt and Brackish Marsh (CES203.260)
- Southern Atlantic Coastal Plain Tidal Wooded Swamp (CES203.240)

Adjacent Ecological System Comments: Generally grades to Southern Atlantic Coastal Plain Tidal Wooded Swamp (CES203.240) inland and upstream. May grade to Atlantic Coastal Plain Embayed Region Tidal Salt and Brackish Marsh (CES203.260) downstream or seaward. Occasionally borders uplands or other wetlands.

DISTRIBUTION

Range: This system is restricted to the embayed region of North Carolina and Virginia, with the best development in coastal areas along the North Carolina-Virginia border. The transition to areas with more lunar tidal influence is fairly gradual to the south over a space of 50 miles.

ATLANTIC COASTAL PLAIN EMBAYED REGION TIDAL SALT AND BRACKISH MARSH (CES203.260)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Haline]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9261

CONCEPT

Summary: This ecological system encompasses the brackish to salt intertidal marshes of the Embayed Region of southeastern Virginia and adjacent North Carolina. It is distinguished by the extensive brackish water and tidal flooding driven by winds which are characteristic of that region. Low in plant diversity, these marshes are found on intertidal flats generally cut off from direct oceanic influence by a series of protective barrier islands. Embedded within the matrix of marshes are smaller hypersaline areas or salt pannes. Vegetation is primarily herbaceous marsh, most of it dominated by *Juncus roemerianus*. Areas near tidal inlets have salt marsh dominated by *Spartina alterniflora*. The marshes are low in plant species richness and are strongly dominated by a single plant species. Also part of the system are more limited communities such as hypersaline flats dominated by *Distichlis spicata* and *Sarcocornia*, as well as salt-tolerant shrublands and a few tree-dominated hammocks that occur on small elevated areas closely associated with the marshes.

Classification Comments: This system is distinguished from the salt marsh systems to the north and south because of the characteristic hydrology of the embayed region and its implications to ecosystem dynamics. However, the species-poor vegetation is not notably different. There is some question whether the few salt marshes on near inlets on the barrier islands in this region should be considered part of this system. They have regular lunar tidal flooding and full strength saltwater, both not characteristic of most of the region. However, lunar tidal flooding is muted compared to other regions. Submerged aquatic vegetation (*Ruppia*, etc.) is covered under Atlantic Coastal Plain Embayed Region Seagrass Bed (CES203.243).

Similar Ecological Systems:
- Atlantic Coastal Plain Embayed Region Seagrass Bed (CES203.243)
- Atlantic Coastal Plain Indian River Lagoon Tidal Marsh (CES203.257)
- Southern Atlantic Coastal Plain Salt and Brackish Tidal Marsh (CES203.270)

Related Concepts:

- Southern Redcedar: 73 (Eyre 1980) Finer

DESCRIPTION

Environment: Occurs on intertidal flats that are tidally flooded with salt to brackish water in the Embayed Region of the Mid-Atlantic Coastal Plain in North Carolina and Virginia. The Embayed Region is characterized by very extensive sounds cut off from the ocean by long barrier islands with few tidal inlets. A low tidal range in the ocean in this region limits tidal exchange at the inlets. Saltwater is present only in limited areas near the inlets. Brackish water prevails in most of the southern part of the region and some of the seaward side of the northern part of the region, grading to oligohaline and freshwater inland and northward, as well as upstream in tidal creeks. Lunar tidal fluctuation is negligible in most of the Embayed Region, and the irregular flooding of wind tides dominates. Soils are generally organic, but mineral soils are present in the more regularly flooded areas.

Vegetation: Vegetation is primarily herbaceous marsh, most of it dominated by *Juncus roemerianus*. Areas near tidal inlets have salt marsh dominated by *Spartina alterniflora*. The marshes are low in species richness and are strongly dominated by a single species. Also part of the system are more limited communities such as hypersaline flats dominated by *Distichlis spicata* and *Sarcocornia*, salt-tolerant shrublands, and a few hammocks that occur on small elevated areas closely associated with the marshes.

Dynamics: Tidal flooding is an ecological factor that distinguishes this system from others. Because tides are irregular and shifts not as frequent or as strong as in lunar tide-dominated areas, sediment transport and probably productivity are lower in the marshes. Storms may drive increased amounts of salt into the sounds, stressing or killing plants in the brackish marshes. For marshes on the back of barrier islands, overwash in storms may deposit sand in the marsh. Marshes usually recover from this, but if sufficient sand is deposited, a different system may develop on the site. Fire is a natural force in the larger and less isolated patches of marsh, removing dead material, stimulating growth, and increasing species richness slightly but not altering overall composition. Rising sea level will affect this system strongly, drowning some marsh areas, promoting shoreline erosion, and causing salt or brackish marshes to spread into freshwater marsh areas. However, elevated atmospheric CO2 increases the productivity of marsh grasses, which can lead to marsh elevation gain (Langley et al. 2009). The marsh snail (*Littoraria irrorata*) is a native and characteristic part of the marsh ecosystem, and is eaten by blue crabs. The disruption of marsh snail predation by blue crabs can lead to a trophic cascade (Silliman and Bertness 2002, Bertness et al. 2004).

ATLANTIC COASTAL PLAIN INDIAN RIVER LAGOON SEAGRASS BED (CES203.256)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Aquatic Herb
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9254

CONCEPT

Summary: Seagrass beds comprising this ecological system are found on the Atlantic Coast of Florida from approximately the St. Johns River (near the Florida-Georgia border) south to Sebastian Inlet (approximately from 30 degrees 30 minutes N latitude to 28 degrees N latitude). This region is the northernmost range of *Thalassia testudinum* and *Cymodocea filiformis* along the Atlantic Coast (W. Kenworthy pers. comm.). Seagrasses in this region are found in a narrow longitudinal complex of lagoonal embayments, including Mosquito Lagoon, Indian River, and Banana River, where they occupy approximately 2% of the available bottom area (Moore 1992). All of the typical seagrass species are present, including *Cymodocea filiformis, Halodule wrightii (= Halodule beaudettei), Halophila engelmannii, Ruppia maritima*, and *Thalassia testudinum*. Little specific information is available on the extent of each type, but it is believed that several of the individual seagrass species may be found in mixed-species beds. More commonly, they are likely to exhibit the general pattern of individual species zonation typical of other systems where zones are largely related to water depth. Beds along the northern boundary of the system are somewhat less diverse than those associated with the Indian River Lagoon, due largely to the absence of *Halophila engelmannii* (which does not extend northward of the lagoon) (W. Kenworthy pers. comm.).

Similar Ecological Systems:
- East Gulf Coastal Plain Florida Big Bend Seagrass Bed (CES203.244)
- Florida Keys Seagrass Bed (CES411.285)
- Southwest Florida Seagrass Bed (CES203.274)

Related Concepts:
- Seagrass Bed (FNAI 1990) Broader

DESCRIPTION

Environment: This system is largely protected from storm surges by a nearly continuous series of protective barriers which are perched on limestone and consequently wind tides predominate. This region is connected to the Atlantic by 4 small inlets. However, since freshwater inputs are so localized and minimal, water salinity is close to sea strength.
Vegetation: All of the typical seagrass species are present, including *Cymodocea filiformis, Halodule beaudettei, Halophila engelmannii, Ruppia maritima*, and *Thalassia testudinum*. Little specific information is available on the extent of each type, but it is believed that several of the individual seagrass species may be found in mixed-species beds.
Dynamics: Very high levels of light are required by seagrasses. Because of this, increased water turbidity leads to seagrass decline. Eutrophication can lead to algal blooms which increase turbidity; also increased sediment in the water from dredging or erosion can cause increased turbidity. When seagrasses decline, the substrate can erode, which further increases turbidity and slows or prevents recovery of the seagrasses. Seagrasses are a critical part of estuarine and near-shore marine food webs. Seagrass beds provide habitat for many commercially valuable and sensitive fish and other marine species.

Component Associations:
- *Cymodocea filiformis - (Thalassia testudinum)* Herbaceous Vegetation (CEGL004317, G4?)
- *Halodule wrightii* Herbaceous Vegetation (CEGL004318, G4?)
- *Halophila engelmannii* Herbaceous Vegetation (CEGL004688, G3?)
- *Ruppia maritima* Carolinian Zone Herbaceous Vegetation (CEGL004335, G4G5)
- *Thalassia testudinum* Herbaceous Vegetation (CEGL004319, G4?)

DISTRIBUTION

ATLANTIC COASTAL PLAIN INDIAN RIVER LAGOON TIDAL MARSH (CES203.257)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9253

CONCEPT

Summary: This tidally influenced marsh system of the Indian River Lagoon along Florida's Atlantic Coast supports approximately 10% of the salt marshes in Florida. It is endemic to the Atlantic Coast of Florida where it ranges from central Volusia County, southward through Brevard, Indian River, St. Lucie, and northern Martin counties, beginning in the vicinity of Daytona Beach and extending south from there. The bulk of these are "high marshes" wholly above mean high water levels. They are protected from direct exposure to the Atlantic Ocean by perched barrier islands, and consequently receive natural inundation only from wind tides and seasonal sea level changes. A berm or levee generally separates these high marshes from lower fringing marshes of *Spartina alterniflora* (to the north) and *Rhizophora mangle* (to the south). Landward of this berm, salt flats or hypersaline zones often develop with *Salicornia, Distichlis spicata, Borrichia frutescens, Batis maritima,* and *Paspalum vaginatum*. In some areas these species occur in monospecific zones, while in others they co-occur, grading into occasional *Avicennia germinans*. These zones are followed by a typical *Juncus roemerianus* zone, and the most inland fringes may be dominated by *Spartina bakeri*. Marshes of this region have been heavily altered by mosquito control impoundments of the 1950s and 1960s.

Similar Ecological Systems:
- Atlantic Coastal Plain Embayed Region Tidal Salt and Brackish Marsh (CES203.260)
- Southern Atlantic Coastal Plain Salt and Brackish Tidal Marsh (CES203.270)

Related Concepts:
- Tidal Marsh (FNAI 1990) Broader

DESCRIPTION

Environment: Tidal amplitudes in this region range from 0.6-1.5 m. Tides have a minute range in the north contributing to a very narrow intertidal zone, which is sometimes occupied by *Spartina alterniflora*. In the south where tidal range is greater, mangroves occupy the intertidal zone, replacing *Spartina alterniflora*.
Vegetation: *Spartina alterniflora* zone is dominant, with lesser area of *Juncus roemerianus* and *Spartina patens*.
Dynamics: Tidal flooding is the ecological factor that distinguishes this system, but tidal amplitudes along the east coast of Florida are low. Due to evaporation in the Indian River Lagoon, salt flats with *Batis maritima, Salicornia virginica,* and *Salicornia bigelovii* were a common feature (Rey and Connelly 2012). Some of these salt flats were lost to mosquito-control impoundments (Rey and Connelly 2012). Tides bring nutrients, making the regularly flooded marshes fertile. Storms may push saltwater into brackish areas and higher zones, acting as a disturbance to vegetation. For marshes on the back of barrier islands, storm overwash may deposit sand in the marsh. Marshes usually recover from this, but if sufficient sand is deposited, a different system may develop on the site. Fire may be a natural force in some patches that are connected to the mainland. Prescribed fire has been used to manage tidal marshes for wildlife. Rising sea level will affect this system, drowning some marsh areas, promoting shoreline erosion, and causing salt or brackish marshes to spread inland into freshwater marsh areas. However, elevated atmospheric CO2 increases the productivity of marsh grasses, which can lead to marsh elevation gain (Langley et al. 2009). The marsh snail (*Littoraria irrorata*) is a native and characteristic part of the marsh ecosystem, and is eaten by blue crabs. The disruption of marsh snail predation by blue crabs can lead to a trophic cascade (Silliman and Bertness 2002, Bertness et al. 2004).

Component Associations:
- *Cladium mariscus ssp. jamaicense* Tidal Herbaceous Vegetation (CEGL004178, G4?)

ATLANTIC COASTAL PLAIN NORTHERN SALT POND MARSH (CES203.892)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9274

CONCEPT

Summary: This system occurs from New Hampshire to New York on ponds behind sandy or cobbly barrier beaches that are breached periodically by storm surges, causing seawater incursion into the pond. Salinity levels, and thus effects on vegetation, are highly variable as a result. A mixture of salt marsh, brackish marsh, and shrublands occur on the periphery of the pond. *Spartina patens, Typha angustifolia, Eleocharis parvula, Eleocharis halophila, Schoenoplectus maritimus (= Scirpus maritimus), Schoenoplectus pungens (= Scirpus pungens),* and *Hibiscus moscheutos* are typical species; *Spartina pectinata* is a major component in marshes of Massachusetts and New York. Salt shrub vegetation characterized by *Iva frutescens* may occur at the upper reaches of flooding, and *Ruppia maritima* or *Zannichellia palustris* may occur in the pond.

DESCRIPTION

Environment: This vegetation occurs on the shores of coastal ponds behind barrier beaches or narrow spits that impede tidal flow. Salinity is extremely variable, influenced by freshwater input from the surrounding uplands, as well as by the periodicity of breaching of the barrier beach by coastal storms.
Dynamics: Coastal salt ponds are generally sheltered from tidal flow for at least part of the year despite their close proximity to the ocean. Their location behind barrier beaches and narrow spits exposes them to seasonal changes in the amount of inflow, intermittent breaching by coastal storms, and highly variable salinity levels ranging from nearly fresh to mesohaline.

Component Associations:
- *Baccharis halimifolia - Iva frutescens / Panicum virgatum* Shrubland (CEGL003921, G5)
- *Cornus amomum - Alnus serrulata* Shrubland (CEGL006414, GNR)
- *Panicum virgatum - Spartina patens - Carex silicea* Herbaceous Vegetation (CEGL006150, GNR)
- *Ruppia maritima* Acadian/Virginian Zone Temperate Herbaceous Vegetation (CEGL006167, GNR)
- *Schoenoplectus pungens - Eleocharis parvula* Herbaceous Vegetation (CEGL006398, GNR)
- *Spartina patens - Agrostis stolonifera* Herbaceous Vegetation (CEGL006365, GNR)
- *Spartina patens - Distichlis spicata - (Juncus gerardii)* Herbaceous Vegetation (CEGL006006, G5)
- *Spartina patens - Schoenoplectus pungens - Solidago sempervirens* Herbaceous Vegetation (CEGL004097, G2G3)
- *Typha angustifolia - Hibiscus moscheutos* Herbaceous Vegetation (CEGL004201, G4G5)

DISTRIBUTION

Range: This system occurs in New Hampshire, Massachusetts, Rhode Island and New York.

ATLANTIC COASTAL PLAIN SANDHILL SEEP (CES203.253)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Seepage-Fed Sloping
Non-Diagnostic Classifiers: Herbaceous; Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2516; ESLF 3187; ESP 1516

CONCEPT

Summary: This sandhill seep system occurs in small patches on slopes in dissected terrain, where a clay lens or other impermeable layer forces groundwater to the surface as seepage. This type occurs largely in the Fall-line Sandhills region of the Carolinas and Georgia but also rarely in other parts of the Atlantic Coastal Plain. Soils are seasonally to permanently saturated by seepage and range from sandy or clayey to mucky. Vegetation is variable and complex in composition and structure, consisting of a mixture of plants of pine savannas and streamhead pocosins, but contrasting with both in structure and proportions. The tree canopy of *Pinus serotina* and *Pinus palustris* may be open or rarely absent, and patches of dense shrubs, grasses, ferns, and various herbaceous plants may be present. Where burned every one to three years, *Arundinaria gigantea ssp. tecta* may be patch-dominant. Fire is a crucial determinant of structure and composition; it tends to occur in a variable and patchy pattern that is driven by both the fire regime of the surrounding system and the wetness of the seep vegetation.
Classification Comments: This system is distinguished from Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265) by having wetland hydrology driven by seepage rather than seasonal high water table, and by vegetational and landscape differences. Occurs rarely in southeastern Georgia in escarpment areas which have greater topography than is locally typical, and perched water tables which flow to the surface in sloping areas.
Similar Ecological Systems:
- Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252)
- Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265)
- East Gulf Coastal Plain Interior Shrub Bog (CES203.385)
- Piedmont Seepage Wetland (CES202.298)

Related Concepts:
- Longleaf Pine - Slash Pine: 83 (Eyre 1980) Finer
- Longleaf Pine: 70 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on gentle to steep slopes of dissected areas in interbedded sand and clay, largely in the Fall-line Sandhills region but rarely in other parts of the Atlantic Coastal Plain. Sites are seasonally to permanently saturated with seeping groundwater, forced to the surface by an impermeable layer such as a clay bed. Soils may be sandy, clayey, or in the wettest sites, mucky. The hydrological connection to adjacent Atlantic Coastal Plain Fall-line Sandhills Longleaf Pine Woodland (CES203.254), whose well-drained sandy soils are the source of seepage water, is crucial. Fire is a crucial natural force, and is also dependent on the adjacent systems. At Fort Benning, Georgia, examples of this system occur in wet mineral soils in zones between drier, sandhills longleaf pine communities and saturated streamside forests dominated by *Nyssa biflora*. In the Sandhills region of North Carolina, they may occur in a similar position between sandy uplands and streamhead pocosins, or they may occur as isolated wetlands on slopes surrounded by dry longleaf pine communities.
Vegetation: Vegetation is a potentially diverse mixture of plants of wet savannas and pocosins. Vegetation structure may vary widely, with dense shrubs, dense herbs, or mixtures of shrubs and herbs, and with an open tree canopy or absent tree canopy occurring in complexes or in different patches. *Pinus palustris, Pinus serotina*, or several hardwood species may dominate the canopy. Characteristic Streamhead Pocosin shrubs, such as *Ilex glabra, Lyonia lucida, Clethra alnifolia, Toxicodendron vernix, Ilex coriacea*, and *Zenobia pulverulenta*, may mix with flatwoods shrubs, such as *Gaylussacia frondosa* and *Kalmia carolina*. The herbs are primarily species shared with wet savannas, such as *Aristida stricta, Calamovilfa brevipilis, Ctenium aromaticum, Andropogon glomeratus*, and a variety of showy forbs and insectivorous plants, but often occur in very different proportions. Large wetland ferns, such as *Osmunda cinnamomea, Osmunda regalis*, and *Pteridium aquilinum*, also often dominate.
Dynamics: The ecological dynamics of the Sandhill seep are influenced by the amount and duration of saturation and the frequency and intensity of wildland fire. Fires can burn completely through Sandhill seeps, keeping shrub cover low and promoting graminoids and herbs (Nordman 2012). Fire is the predominant natural dynamic force in this system and is critical in determining its structure and even its identity. Fire regime is dominated by the fire regime of the surrounding system, which naturally burned every few years, but is modified by the wetness and flammability of the seep vegetation. Some fires do not penetrate parts of the seeps, creating variable age and vegetation structure. Areas that seldom burn have dense and tall shrubs, while areas that burn frequently are dominated by herbs, usually with patches of *Arundinaria gigantea ssp. tecta*. With long absence of fire, many seeps become indistinguishable from

Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252). Canopy dynamics are probably driven mainly by fire, with hot fires killing the less fire-tolerant trees and creating a fine mosaic or zoned complex of older trees, younger regeneration, and treeless areas. Shrubs and herbs readily sprout after fires, but relative proportions are controlled by the frequency of fire.

Component Associations:
- *(Pinus palustris, Pinus serotina) / Ctenium aromaticum - Muhlenbergia expansa - Calamovilfa brevipilis* Woodland (CEGL003659, G2)
- *Arundinaria gigantea ssp. tecta* Shrubland (CEGL003843, G1)
- *Clethra alnifolia - Toxicodendron vernix / Aristida stricta - Osmunda cinnamomea - Sarracenia* spp. Shrub Herbaceous Vegetation (CEGL004467, G2?)
- *Gaylussacia frondosa - Clethra alnifolia - Arundinaria gigantea ssp. tecta / Aristida stricta - Pteridium aquilinum var. pseudocaudatum* Herbaceous Vegetation (CEGL004468, G3?)
- *Ilex coriacea - Lyonia lucida - Smilax laurifolia* Shrubland (CEGL004666, G3G4)
- *Pinus palustris - Pinus serotina / Ilex glabra - Lyonia lucida / Ctenium aromaticum* Woodland (CEGL003860, G3)

Spatial Characteristics

Spatial Summary: Small patch, with occurrences ranging from a fraction of an acre to several acres. Patches sometimes occur in complexes in close proximity, but as often are isolated. Some seeps are linear bodies stretching across slopes, some are linear running downslope, and some are small oval bodies.

Adjacent Ecological Systems:
- Atlantic Coastal Plain Fall-line Sandhills Longleaf Pine Woodland (CES203.254)
- Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252)

Adjacent Ecological System Comments: Generally, this system is surrounded by Atlantic Coastal Plain Fall-line Sandhills Longleaf Pine Woodland (CES203.254). It is sometimes interspersed or found grading to Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252) on one side.

Distribution

Range: This system occurs from east-central North Carolina to central Georgia, primarily in the Fall-line Sandhills region but occasionally occurring in the Outer Coastal Plain. For example, this system occurs in limited parts of southeastern Georgia associated with the topography of old escarpments. It occurs primarily in the Atlantic drainage but is rarely represented in the Gulf drainage (such as at Fort Benning, Georgia).

BOREAL FRESHWATER EMERGENT MARSH (CES103.525)

CLASSIFIERS

Classification Status: Standard

Primary Division: Boreal (103)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lake; Pond; Herbaceous; Alluvial flat; Boreal [Boreal Subcontinental]; Mineral: W/ A-Horizon >10 cm; Graminoid
National Mapping Codes: ESLF 9445

CONCEPT

Summary: Freshwater marshes are found throughout boreal transition and boreal regions of central Canada, east into Ontario and Quebec. They are characterized by emergent herbaceous vegetation. Freshwater marshes typically occur with other wetland systems, occurring on the margins of ponds, lakes, and riparian systems and on inland deltas where rivers drain into large lakes. They also occur on glacial potholes, along small streams, in channels in glacial outwash and on lakeplains. Inland marshes are mostly small patch, confined to limited areas in suitable floodplain or basin topography. Often the marsh contains a deep to shallow area of freshwater dominated by emergent and submergent species. Stands may be open ponds with floating or rooted aquatics, or deep marsh with bulrush or cattails, and range from fairly small to several acres. They are typically semipermanently flooded, but some marshes have seasonal flooding. Water is at or above the surface for most of the growing season (typically 10 cm above the surface). Soils are muck or mineral, and water is nutrient-rich. These systems are highly productive and have high rates of decomposition. Freshwater marsh vegetation is dominated by emergent vegetation in the genera of *Typha, Schoenoplectus (= Scirpus), Juncus*, and *Eleocharis* with an occasional scattering of tall *Carex* spp. and forbs that can vary from dense to open cover. Trees are generally absent and, if present, are scattered. Floating aquatic herbs may also occur in areas of open water within or adjacent to the marsh. Some of the common species include *Sparganium eurycarpum, Acorus calamus, Carex utriculata, Schoenoplectus acutus, Schoenoplectus tabernaemontani (= Scirpus validus), Typha latifolia, Sagittaria cuneata, Calla palustris, Alisma plantago-aquatica, Menyanthes trifoliata, Comarum palustre (= Potentilla palustris),* and *Scheuchzeria palustris*.
Classification Comments: Exactly where this system transitions to Western North American Boreal Freshwater Emergent Marsh (CES105.123) in Alaska is uncertain, but is likely to be somewhere in Yukon Territory. It is also similar to North-Central Interior Freshwater Marsh (CES202.899) which is found the northern Midwest of the U.S., and ranges into southern Canada.
Similar Ecological Systems:
- North-Central Interior Freshwater Marsh (CES202.899)--of the northern Midwest of the U.S. and southern Canada.

DESCRIPTION

Environment: Freshwater marshes are found throughout boreal transition and boreal regions of central Canada. They are characterized by emergent herbaceous vegetation. Freshwater marshes typically occur with other wetland systems. They occur on the margins of ponds, lakes, and riparian systems and on inland deltas where rivers drain into large lakes. Inland marshes are mostly small patch, confined to limited areas in suitable floodplain or basin topography. They are typically semipermanently flooded, but some marshes have seasonal flooding. Water is at or above the surface for most of the growing season (typically 10 cm above the surface). Soils are muck or mineral, and water is nutrient-rich and may experience periodic drawdowns. These systems are highly productive and have high rates of decomposition (National Wetlands Working Group 1997).
Vegetation: Freshwater marsh vegetation is dominated by emergent vegetation such as *Sparganium eurycarpum, Acorus calamus, Carex utriculata, Schoenoplectus acutus, Schoenoplectus tabernaemontani (= Scirpus validus), Typha latifolia, Sagittaria cuneata, Calla palustris, Alisma plantago-aquatica, Menyanthes trifoliata, Comarum palustre (= Potentilla palustris),* and *Scheuchzeria palustris*.
Dynamics: This system requires a source of freshwater. Seasonal flooding is characteristic of inland deltas. Marsh zonation is related to water depth and duration of flooding. A typical sequence progresses from open water to emergent deep marsh to shallow marsh to wet meadow or fen. Floating marsh mats may be seral to fens.

Component Associations:
- *Eleocharis palustris* Herbaceous Vegetation (CEGL001833, G5)
- *Equisetum fluviatile* Boreal Herbaceous Vegetation (CEGL005292, GNR)
- *Schoenoplectus pungens* Herbaceous Vegetation (CEGL001587, G3G4)
- *Schoenoplectus tabernaemontani* Temperate Herbaceous Vegetation (CEGL002623, G5)
- *Typha (latifolia, angustifolia)* Western Herbaceous Vegetation (CEGL002010, G5)

DISTRIBUTION

Range: This system is found from lowlands through valley bottoms in the boreal and boreal transition regions of central Canada.
Divisions: 103:C

CENTRAL FLORIDA HERBACEOUS PONDSHORE (CES203.890)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Depressional; Graminoid
Non-Diagnostic Classifiers: Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2514; ESLF 9275; ESP 1514

CONCEPT

Summary: This system includes a variety of seasonal depression ponds in central Florida, especially along the Lake Wales Ridge. Examples are rounded or irregularly shaped, shallow depressions from tens to hundreds of meters in diameter. Extensive variation is present based on the variety of soils and hydroperiods. Most examples have vegetation in zones, and nearly all are ringed by *Serenoa repens*. Characteristic or dominant species associated with the interior of the ponds include *Panicum hemitomon, Panicum abscissum, Hypericum edisonianum*, and *Andropogon brachystachyus*.
Classification Comments: Compare to East Gulf Coastal Plain Depression Pondshore (CES203.558), found to the north.
Similar Ecological Systems:
- East Gulf Coastal Plain Depression Pond (CES203.558)

DESCRIPTION

Environment: Most examples are known from the Lake Wales Ridge area of central Florida. These are shallow depressions from tens to hundreds of meters in diameter, found on a variety of different soils with different hydroperiods (Abrahamson et al. 1984).
Vegetation: Most depression ponds accommodated in this system display distinct vegetational zonation. At least four vegetational zones can be readily distinguished (Abrahamson et al. 1984); the community types need to be further reconciled into associations.
Dynamics: Variation in the duration and depth of flooding is part of the natural dynamics of the ponds in central Florida. The herbaceous pondshore or rim can burn with fires that burn the surrounding uplands or flatwoods. These fires help maintain the diversity of plants which can occur along the herbaceous pondshore or rim which circles the pond.

Component Associations:
- *Amphicarpum muehlenbergianum - (Panicum hemitomon)* Herbaceous Vegetation (CEGL008588, G2G3)
- *Andropogon (capillipes, glaucopsis) - Rhynchospora fascicularis var. fascicularis - Rhexia mariana* Herbaceous Vegetation (CEGL004460, G2?)
- *Dichanthelium wrightianum - Dichanthelium erectifolium* Herbaceous Vegetation (CEGL004105, G2G3)
- *Hypericum brachyphyllum* Dwarf-shrubland (CEGL003955, G3?)
- *Panicum hemitomon - Pluchea (camphorata, rosea) - Ludwigia* spp. Herbaceous Vegetation (CEGL007792, G3)
- *Panicum hemitomon - Pontederia cordata* Herbaceous Vegetation (CEGL004461, G3G4)
- *Rhynchospora (careyana, inundata)* Seasonally Flooded Herbaceous Vegetation (CEGL004132, G3?)
- *Woodwardia virginica / Sphagnum cuspidatum* Herbaceous Vegetation (CEGL004475, G2?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Central Florida Pine Flatwoods (CES203.382)
- Central Florida Wet Prairie and Herbaceous Seep (CES203.491)
- Florida Dry Prairie (CES203.380)

Adjacent Ecological System Comments: May grade into Central Florida Wet Prairie and Herbaceous Seep (CES203.491). Surrounding matrix vegetation can include Central Florida Pine Flatwoods (CES203.382) and Florida Dry Prairie (CES203.380).

DISTRIBUTION

Range: Endemic to central Florida.

CENTRAL FLORIDA WET PRAIRIE AND HERBACEOUS SEEP (CES203.491)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Seepage-Fed Sloping; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9279

CONCEPT

Summary: This system includes herbaceous seepage wetlands and nearly treeless plains over poorly drained soils in central Florida. Although examples of this system are similar to other wetland ecological systems, these are characterized by the presence of subtropical plant species not occurring in herbaceous-dominated wetlands farther north, especially *Panicum abscissum*. At least some examples have dense cover of grasses and low shrubs, with fairly high species diversity. Examples may be most common along the southern part of the Lake Wales Ridge area.
Classification Comments: East Gulf Coastal Plain Savanna and Wet Prairie (CES203.192) is a closely related system found farther north.
Similar Ecological Systems:
- East Gulf Coastal Plain Savanna and Wet Prairie (CES203.192)

Related Concepts:
- Wet Prairie (FNAI 1990) Intersecting

DESCRIPTION

Environment: Associated with saturated soils caused by seepage or high water tables; some examples may be saturated for 50-100 days/year. Seepage-influenced examples tend to occur in areas of greater topographic relief than wet prairies.
Vegetation: Usually dominated by *Panicum abscissum*.
Dynamics: Frequent fires were an important natural process in this system, with an estimated frequency of 1-4 years (FNAI 1990, FNAI 2010a).

Component Associations:
- *Andropogon (capillipes, glaucopsis) - Rhynchospora fascicularis var. fascicularis - Rhexia mariana* Herbaceous Vegetation (CEGL004460, G2?)
- *Panicum abscissum* Herbaceous Vegetation (CEGL004113, G2G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Central Florida Herbaceous Pondshore (CES203.890)
- Central Florida Pine Flatwoods (CES203.382)
- Florida Dry Prairie (CES203.380)
- Florida Longleaf Pine Sandhill (CES203.284)

Adjacent Ecological System Comments: May grade downslope into Central Florida Herbaceous Pondshore (CES203.890). Surrounding matrix vegetation can include Central Florida Pine Flatwoods (CES203.382) and Florida Dry Prairie (CES203.380).

DISTRIBUTION

Range: Endemic to central Florida, mainly found in the southern Lake Wales Ridge.
Divisions: 203:C
Nations: US

CENTRAL TEXAS COAST RIVER TERRACE SANDYLAND GRASSLAND (CES203.712)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Herbaceous; Terrace; West Gulf Coastal Plain; Deep Soil; Sand Soil Texture; Graminoid
National Mapping Codes: ESLF 9441

CONCEPT

Summary: This grassland system occurs on deep sands of alluvial origin in the Coastal Prairie region of Texas from Austin to Refugio counties. Formed by stream deposition, these areas occur on fluvial terraces adjacent to rivers and streams. Vegetative composition is typically dominated by graminoids, including *Schizachyrium scoparium, Sorghastrum nutans, Paspalum plicatulum*, and *Andropogon gerardii*. Other grass species that may be present to dominant include *Paspalum setaceum, Trachypogon spicatus, Paspalum monostachyum, Elionurus tripsacoides, Cenchrus spinifex, Eragrostis secundiflora, Aristida* spp., and *Triplasis purpurea*.
Similar Ecological Systems:
- Central Texas Coastal Prairie Riparian (CES203.714)
- Central Texas Coastal Prairie River Floodplain (CES203.713)
- Texas-Louisiana Coastal Prairie (CES203.550)

Related Concepts:
- Central Texas Coast River Terrace Sandyland Grassland (7907) (Elliott 2011) Equivalent

DESCRIPTION

Environment: This system occurs on Quaternary alluvium comprised of deep sand terraces (typically >1 m [3 feet] in depth) along rivers and streams. These terraces and benches are higher than the adjacent level and ridge-and-swale topography of river floodplains. The ecological site type is characterized as Sand Hill on soils such as Sarita-Falfurrias fine sands, but other coarse, deep sand sites on river terraces are also occupied by this system.
Vegetation: These sites are typically dominated by graminoids, including species such as *Schizachyrium scoparium, Sorghastrum nutans, Paspalum plicatulum*, and *Andropogon gerardii*. Other grass species that may be present to dominant include *Paspalum setaceum, Trachypogon spicatus, Paspalum monostachyum, Elionurus tripsacoides, Cenchrus spinifex, Eragrostis secundiflora, Aristida* spp., and *Triplasis purpurea*. Characteristic forbs of the system include *Aphanostephus skirrhobasis, Heterotheca subaxillaris, Cnidoscolus texanus, Stillingia sylvatica, Gaillardia aestivalis, Croton argyranthemus, Acalypha radians, Croton parksii, Croton capitatus, Phyllanthus abnormis, Physalis cinerascens, Helianthus argophyllus, Verbesina encelioides, Eriogonum multiflorum, Froelichia floridana, Croptilon divaricatum, Diodia teres, Polanisia erosa*, and *Chamaecrista fasciculata*. *Prosopis glandulosa* is a common woody invader on these sites, but other woody species such as *Zanthoxylum fagara, Celtis pallida (= Celtis ehrenbergiana)*, and the uncommon *Prunus texana* may also be present.

Component Associations:
- *Schizachyrium scoparium - Triplasis purpurea - Eriogonum multiflorum - Liatris elegans var. carizzana* Herbaceous Vegetation (CEGL008483, G1)

DISTRIBUTION

Range: This system occurs on terraces of deep sand along rivers and streams of the Coastal Prairie region from Austin to Refugio counties in Texas.

COLORADO PLATEAU HANGING GARDEN (CES304.764)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil; Montane [Montane]; Montane [Lower Montane]; Cliff (Substrate); Sedimentary Rock; Temperate [Temperate Xeric]; Seepage-Fed Sloping; Forb; Fern; Graminoid; Cliff (Landform)
Non-Diagnostic Classifiers: Herbaceous; Isolated Wetland [Strictly Isolated]
National Mapping Codes: ESLF 9285

CONCEPT

Summary: Hanging gardens in the Colorado Plateau region are surrounded by arid environments and associated with canyons of the Colorado River and its tributaries. These highly localized environments occur in canyons with perennial water sources (springs) forming pocketed and often isolated wetlands and draping vegetation across wet cliff faces or associated ledges and colluvium. Four main garden types exist: alcove, terrace, windowblind and channel types. Each is determined by the nature of the geological formation and the presence or absence of joint systems. They tend to occur at all exposures of the canyon walls, but they are always shaded for much to most of each day. Temperature and humidity are relatively stable compared to the surrounding environment. Hanging gardens are dominated by herbaceous plants, and a number of these are endemic to this region. Common species include *Adiantum capillus-veneris, Carex curatorum, Mimulus eastwoodiae, Mimulus guttatus, Primula specuicola, Cirsium rydbergii*, and several species of *Aquilegia*.

DESCRIPTION

Environment: Several major sandstone and limestone aquifers exist on the Colorado Plateau, supporting thousands of springs. These springs exist in a matrix of arid and semi-arid upland plant communities, and are often strongly isolated from one another. Hanging gardens are a special type of spring associated with sedimentary rocks in strongly dissected landscapes with relatively narrow and deep bedrock canyons. These systems are defined by the presence and dominance (using canopy cover) of certain herbaceous plant species, although shrub- and tree-dominated vegetation can be associated with them. These gardens support numerous wetland plant species, including a suite of about 25 Colorado Plateau endemics. The local climate is hot and arid and supports annual precipitation from 12 to 36 cm (5-14 inches), and mean annual temperatures are high and summer temperatures greater than 100 degrees F are common.

Certain formations on the Colorado Plateau, especially eolian-derived coarse-grained sandstones, act as aquifers, with water moving through the porous matrix, often along joints. Within these aquifers there are lenses of impermeable fine-grained lake and fluvial sediments that often constrain the flow of water, and they can be underlain by older geological formations that act as major aquicludes (barriers to groundwater movement). When water reaches these impermeable layers, it flows laterally until reaching a cliff face, where it emerges as a series of seeplines, often perched well above the canyon floors. In some cases, primarily in Zion Canyon, the impermeable layers are vertically inclined (windowblind alcoves). The wet walls, ledges and associated detritus slopes are colonized by a wide variety of primarily herbaceous wetland species, and the flora is quite distinct from other spring-supported communities (Spence 2008). Some of the largest and most complex hanging gardens are found along the Virgin and Colorado rivers associated with tributary theater-headed valley networks where groundwater sapping creates large shaded alcoves at cliff bases (Laity and Malin 1985). These alcoves are best developed in the Jurassic-age Navajo Sandstone aquifer associated with the underlying Kayenta Sandstone aquiclude, but also occur in other important aquifers such as the Cedar Mesa and Entrada formations.

Although hanging gardens can occur in a variety of aspects and geological settings, the largest and most characteristic are associated with deep-shaded alcoves where climactic conditions are more stable than in the surrounding uplands. During the growing season temperatures can be as much as 10-15 degrees C cooler than in more exposed areas, with higher relative humidity and significant shading from the sun. Some of these alcoves see little if any direct solar radiation, even in June.

Water quality generally varies from neutral to mildly basic (pH 7-8), with relatively low values of specific conductance, but can be extremely high in limestone aquifers such as the Redwall and Muav formations in the Grand Canyon. However, water chemistry appears to be less important in controlling plant species presence than elevation (climate) is, as many species are found in both sandstone- and limestone-supported gardens (Spence 2008). Upper limits for hanging gardens is typically around 1800-1900 m, above which characteristic garden species are replaced by more cold-adapted montane floras.
Vegetation: The species diversity of hanging garden ranges from 1-2 species to over 50 species in the largest alcoves. Larger gardens are extremely diverse, much more so than most upland communities. The huge garden at the head of Rose Canyon, probably the largest one in the world, supports 50+ phreatophytes plus at least another 30-40 upland species in an area <1 ha in size. The diversity of vegetation is much greater in the gardens on the Colorado Plateau versus those of the Utah High Plateaus. The vegetation may overlap with the nearby riparian vegetation, but there are a series of species that are unique to hanging gardens (Welsh 1989), including boreal-temperate relicts, Colorado Plateau endemics, southwestern hot desert riparian species, and tallgrass prairie species. Several species of algae are restricted to these hanging gardens. The classic alcove type of hanging garden in the Canyonlands of

southeastern Utah and in the central Colorado Plateau around Lake Powell consists of an overhanging back wall, a vaulted face wall, a detrital slope, and a plunge basin. The back and face walls support clinging plants of *Adiantum capillus-veneris, Mimulus eastwoodiae* (*Mimulus cardinalis* in Grand Canyon and Zion), *Muhlenbergia thurberi, Petrophyton caespitosum, Primula specuicola,* and several other species. The wet, sandy to rocky detritus supports *Aquilegia formosa (= Aquilegia fosteri), Aquilegia micrantha, Calamagrostis scopulorum, Carex aurea, Cirsium rydbergii, Dichanthelium acuminatum (= Panicum acuminatum), Epipactis gigantea,* and *Zigadenus vaginatus*. A fringing margin of *Celtis laevigata var. reticulata (= Celtis reticulata), Cercis canadensis var. texensis (= Cercis occidentalis), Frangula betulifolia,* and *Quercus gambelii* often occurs outward from the footslope where the plants tend to conceal the alcove base, or on adjacent slopes. Sometimes the rare and local *Ostrya knowltonii* occurs in these woodlands. The outer and drier edges support grasses typical of the prairies and plains of the western U.S., such as *Andropogon glomeratus, Panicum virgatum,* and *Sorghastrum nutans*. In the Utah High Plateaus gardens, the dominants are usually *Sullivantia hapemanii var. purpusii* and *Aquilegia barnebyi* with *Mimulus guttatus* common. Hanging garden vegetation varies from canyon to canyon as well as among separate alcoves within a canyon. The vegetation of hanging gardens generally has some common species that are found at most of them, e.g., *Maianthemum stellatum, Adiantum capillus-veneris, Adiantum pedatum,* and *Mimulus* spp., but numerous endemics occur of which some may be represented by just one or two sites. The following species are endemic to hanging gardens of the Colorado Plateau region: *Aquilegia micrantha, Carex curatorum, Cirsium rydbergii, Erigeron kachinensis* (one occurrence outside of hanging gardens in the Abajo Mountains), *Erigeron sionis, Erigeron zothecinus, Platanthera zothecina (= Habenaria zothecina), Mimulus eastwoodiae, Perityle specuicola,* and *Primula specuicola*.

Dynamics: The most critical controlling feature of most hanging gardens is that they generally do not experience riparian-like flooding, unlike other spring types, such as rheocrenes (springs that discharge into a defined channel). The lack of flooding scour allows the development of highly unusual flood-sensitive herbaceous communities. Common disturbances in gardens include rock spalling, slumps, ungulate grazing, seasonal drought, and ice shear on wet backwalls and ledges in winter.

Key processes determining the species composition and vegetation cover include geomorphic disturbances, drought and ice shear. Groundwater sapping cause rock spalling (flaking, splitting, breakage) which can form and enlarge alcoves, and can creates gaps in the garden vegetation, as do occasional slumps on colluvial slopes. In cold winters ice sheets form on terraces and backwalls, which often collapse and shear off vegetation. Seasonal drought can also reduce canopy cover and species performance. In some channel gardens flooding can also be important, but where regular flooding occurs garden vegetation is very limited and species poor. Some gardens are visited by native ungulates, but disturbance by grazing and trampling are generally relatively minimal.

Component Associations:
- *Aquilegia micrantha - Calamagrostis scopulorum* Herbaceous Vegetation (CEGL002592, GNR)
- *Aquilegia micrantha - Mimulus eastwoodiae* Herbaceous Vegetation (CEGL002729, G2G3)
- *Aquilegia micrantha* Herbaceous Vegetation (CEGL002762, GNR)
- *Calamagrostis scopulorum* Hanging Garden Herbaceous Vegetation (CEGL002751, GNR)

COLUMBIA PLATEAU VERNAL POOL (CES304.057)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Impermeable Layer; 1-29-day hydroperiod; Vernal Pool Mosaic; Depressional [Vernal Pool]
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Herbaceous; Mediterranean [Mediterranean Xeric-Oceanic]; Temperate [Temperate Oceanic]; Isolated Wetland [Strictly Isolated]; Consolidated
National Mapping Codes: ESLF 9231

CONCEPT

Summary: This system includes shallow ephemeral waterbodies found in very small (3 m2 to 1 acre) to large depressions (1500 m2 to a square mile, average size of vernal pools is 1600 m2, while average size on non-alkaline playa lakes is 5-10 acres) throughout the exposed volcanic scablands of the Columbia Plateau in Washington, Oregon, and northern Nevada. Most of these pools and lakes are located on massive basalt flows exposed by Pleistocene floods; southward they also occur on andesite or rhyodacite caprock. Inundation is highly irregular, sometimes not occurring for several years. Depressions usually (but not always) fill with water during winter and spring. They are generally dry again within 9 months, though in exceptional times they can remain inundated for two years in a row. Water is from rainfall and snowmelt in relatively small closed basins, on average probably no more than 5-15 times the area of the ponds themselves. Because these pools and playas are perched above the general surrounding landscape, they are not generally subject to runoff from major stream systems. They typically have silty clay soils, sometimes with sandy margins. Pools are often found within a mounded or biscuit-swale topography with *Artemisia* shrub-steppe or rarely *Pinus ponderosa* savanna. In the northern Columbia Plateau, characteristic species are predominantly annual and diverse. Floristically akin to California vernal pool flora (one-third), however, many of the most abundant species are not reported in Californian pools. The Columbia Plateau vernal pools have many floristic similarities to their California counterparts. In one study. Crowe et al. (2004) found that thirty-four percent of the native taxa and 65% of the genera also occurred in a comprehensive listing of California vernal pool (Keeler-Wolf et al. 1998).Characteristic species of these vernal pools include *Callitriche marginata, Camissonia tanacetifolia, Cuscuta californica var. breviflora (= Cuscuta occidentalis), Elatine californica, Elatine chilensis, Elatine rubella, Juncus uncialis, Myosurus minimus (= Myosurus clavicaulis), Plagiobothrys* spp., *Polygonum polygaloides ssp. confertiflorum, Polygonum polygaloides ssp. polygaloides, Psilocarphus brevissimus, Psilocarphus elatior, Psilocarphus oregonus,* and *Trifolium cyathiferum*. *Artemisia ludoviciana ssp. ludoviciana* can occur on better developed soils. In northern Nevada, most of the species by biomass are perennials and include *Polygonum, Rumex, Juncus balticus, Eleocharis, Carex douglasii, Muhlenbergia richardsonis,* and *Polyctenium* species, in addition to *Camissonia tanacetifolia* and *Psilocarphus brevissimus*. Endemic plant species *Navarretia leucocephala ssp. diffusa* and *Polyctenium williamsiae* may occur.
Classification Comments: This includes Bjork (1997) vernal pool annual-dominated, vernal pool perennial-dominated and rain pools.

DESCRIPTION

Environment: This system includes shallow ephemeral waterbodies found in very small (3 m2 to 1 acre) to large depressions (1500 m2 to a square mile, average size of vernal pools is 1600 m2, while average size on non-alkaline playa lakes is 5-10 acres) throughout the exposed volcanic scablands of the Columbia Plateau in Washington, Oregon, and northern Nevada. Most of these pools and lakes are located on massive basalt flows exposed by Pleistocene floods; southward they also occur on andesite or rhyodacite caprock. Inundation is highly irregular, sometimes not occurring for several years. Depressions usually (but not always) fill with water during winter and spring. They are generally dry again within 9 months, though in exceptional times they can remain inundated for two years in a row. Water is from rainfall and snowmelt in relatively small closed basins, on average probably no more than 5-15 times the area of the ponds themselves. Because these pools and playas are perched above the general surrounding landscape, they are not generally subject to runoff from major stream systems. They typically have silty clay soils, sometimes with sandy margins. Pools are often found within a mounded or biscuit-swale topography with Artemisia shrub-steppe or rarely Pinus ponderosa savanna. Winters are colder (coldest average median temperature month in the high 20 degrees F) than California vernal pools and are climatically defined by wet winters (November through January, sporadically so southward) and severe summer drought (July-September), although May or June can be wet. The northernmost vernal pools are adapted to cold spring and long summer days (18 hours).
Vegetation: In the northern Columbia Plateau, characteristic species are predominantly annual and diverse. Floristically akin to California vernal pool flora (one-third), however, many of the most abundant species are not reported in Californian pools. Characteristic species include *Callitriche marginata, Camissonia tanacetifolia, Elatine* spp., *Epilobium densiflorum (= Boisduvalia densiflora), Eryngium vaseyi, Juncus uncialis, Myosurus X clavicaulis, Plagiobothrys* spp., *Polygonum polygaloides ssp. confertiflorum, Polygonum polygaloides ssp. polygaloides, Psilocarphus brevissimus, Psilocarphus elatior, Psilocarphus oregonus,* and *Trifolium cyathiferum*. *Artemisia ludoviciana ssp. ludoviciana* can occur on better developed soils. In northern Nevada, most of the species by biomass are perennials and include *Polygonum, Rumex, Juncus balticus, Eleocharis, Carex douglasii, Muhlenbergia richardsonis,* and *Polyctenium* species, in addition to *Camissonia tanacetifolia* and *Psilocarphus brevissimus*. Endemic plant species

Navarretia leucocephala ssp. diffusa (Bjork 2002) and *Polyctenium williamsiae* may occur.
Dynamics: Vernal pools are precipitation-filled seasonal wetlands inundated during the growing season, allowing for plant growth, followed by a brief water-logged terrestrial stage and culminating in complete drying of surface and subsurface soils. Inundation during the growing season eliminates establishment of upland species in the pool basins, and the dry period prevents the establishment of many typical wetland taxa (Keeley and Zedler 1998). Pool filling is a combination of direct precipitation and lateral flow among pools within a complex of pools and subsurface flow from uplands which buffers pool volume, keeping them filled into the dry season (Hanes and Stromberg 1998). Soils are relatively shallow (10-30 cm) underlain by basalt bedrock that prevents drainage (Crowe et al. 1994, Bjork and Dunwiddie 2004). What is unique about vernal pools is the seasonality of the wetting period followed by the desiccation period, which generally is supported by a Mediterranean climate (Crowe et al. 1994, Keeley and Zedler 1998), resulting in the development of diverse and highly endemic vegetation (Barbour et al. 2003, 2005, Solomeshch et al. 2007). Natural fire regimes for vernal pools are generally unknown, but are assumed to be similar to their surrounding upland grassland fire regimes (Wills 2006). Fire can have a positive effect on vernal pool vegetation as it can results in robust response by native grasses and can reduce non-native invasive woody and non-native herbaceous species (Pollak and Kan 1998).

SPATIAL CHARACTERISTICS

Size: Depressions (3-4608 square meters to a square mile; average 1600 sq.m to 10 acres), mean depth 0.47 to 1.5 m.
Adjacent Ecological Systems:
- Columbia Plateau Scabland Shrubland (CES304.770)
- Inter-Mountain Basins Big Sagebrush Steppe (CES304.778)

Adjacent Ecological System Comments: Primarily Columbia Plateau Scabland Shrubland (CES304.770) or Inter-Mountain Basins Big Sagebrush Steppe (CES304.778) (three-tip sagebrush) rarely into ponderosa pine savanna or pinyon-juniper.

DISTRIBUTION

Range: This system is restricted to the northern Columbia Plateau ecoregion commonly called the Columbia Basin and perhaps the Okanagan Valley in British Columbia, and to the western Great Basin.
Divisions: 304:C
Nations: CA? , US

EAST GULF COASTAL PLAIN DEPRESSION POND (CES203.558)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Herbaceous; Depressional; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9403

CONCEPT

Summary: This small-patch herbaceous or shrub dominated wetland ecological system occupies upland depressions (ponds and pondshores) in the East Gulf Coastal Plain. Included here are shallow ponds of various geomorphic origins in a variety of substrates (e.g., limesinks, Grady Ponds, Citronelle Ponds, flatwoods depression marshes) which are not separately distinguished as ecological systems. This ecological system only includes herbaceous or shrub ponds and pondshores in more-or-less isolated upland settings, not those in riparian or floodplain environments. They may serve as the origin of a stream system in a general way, releasing water gradually into the stream drainage system during periods of very wet weather. These tend to occupy basins that were formed by subsidence of surface sediments caused by solution in underlying limestone or as swales in eolian sand deposits. In some examples, a distinct zonation of vegetation is present, in others the zones are not distinct or the differing associations are present in a complex mosaic. Most seasonal depression ponds are composed of mosaics of several plant associations. The vegetation includes various zones which become exposed as water levels decline, as well as emergent (rising out of the water) or submergent/floating plants. Some typical species are *Dichanthelium wrightianum, Dichanthelium erectifolium, Eleocharis equisetoides, Eleocharis microcarpa, Juncus effusus, Juncus repens, Leersia* spp., *Ludwigia* spp., *Rhynchospora corniculata, Rhynchospora inundata, Panicum hemitomon, Panicum verrucosum, Proserpinaca* spp., *Pluchea* spp., *Saccharum* spp., *Rhexia* spp., and *Sabatia angularis*. Coastal dune lakes and related wetlands of barrier islands are covered by another system, Southeastern Coastal Plain Interdunal Wetland (CES203.258).
Classification Comments: In Mississippi, this system is apparently confined to the "Pamlico Plain" (this is meant to refer to the Outer Coastal Plain) where it is very rare and small scale in occurrence (R. Wieland pers. comm.). It is unknown how distinct these depressions are from so-called "Grady Ponds" (e.g., Cottonmouth Savanna site). This system is closely related to Southern Atlantic Coastal Plain Depression Pondshore (CES203.262) of the Atlantic Coastal Plain. This system also has karstic origins in common with Southern Coastal Plain Sinkhole (CES203.495) but occupies comparatively much shallower depressions and lacks exposed limestone. Compare to Central Florida Herbaceous Pondshore (CES203.890) to the south.
Similar Ecological Systems:

DESCRIPTION

Environment: Examples of this ecological system occur in relatively shallow depressions or basins that were formed by subsidence of surface sediments caused by solution in underlying limestone or were formed as swales in eolian sand deposits. However, sinkholes with steep, vertical, exposed limestone walls are accommodated by another ecological system, as are sandhill ponds that develop on extreme sandy sites in the East Gulf Coastal Plain of Florida and adjacent Alabama. Hydroperiod can vary substantially from year to year, and vegetation can similarly vary significantly in aspect and dominants. Highly variable hydroperiods help maintain herbaceous vegetation, and prevent the succession to forest.
Vegetation: Most seasonal depression ponds are usually composed of mosaics of several plant associations. The vegetation includes various zones which become exposed as water levels decline. These are occupied sequentially by various graminoids and/or forbs, as well as emergent (rising out of the water) and submergent/floating plants. Some typical dominant species in component associations include *Aristida palustris, Dichanthelium wrightianum, Dichanthelium erectifolium, Eleocharis elongata, Eleocharis equisetoides, Eleocharis microcarpa, Fuirena scirpoidea, Juncus repens, Rhynchospora chapmanii, Rhynchospora corniculata, Rhynchospora harperi, Rhynchospora inundata, Rhynchospora filifolia, Rhynchospora tracyi, Proserpinaca* spp., *Juncus abortivus, Juncus effusus, Panicum hemitomon, Pluchea* spp., *Ludwigia* spp., *Saccharum* spp., *Panicum verrucosum, Rhexia* spp., and *Sabatia angularis*. In

addition, associations dominated by *Polygonum* spp., *Leersia* spp., and *Typha* spp. may be present but are not characteristic. Other characteristic species include *Rhexia cubensis, Panicum rigidulum, Panicum verrucosum, Carex striata, Lachnanthes caroliana, Bartonia verna, Lachnocaulon minus*, and *Centella erecta*. Woody plants which may be present (particularly on margins) include *Cephalanthus occidentalis, Hibiscus* spp., *Hypericum chapmanii, Hypericum fasciculatum, Hypericum reductum, Ilex myrtifolia*, and *Nyssa ursina*. Some stands with trees contain *Fraxinus pennsylvanica, Populus heterophylla, Ulmus americana*, and *Quercus texana*. Vegetation may exhibit distinct zonation in response to variation in duration of flooding. Communities can range from floating aquatic types (in the centers of the deepest basins) to emergent herbaceous zones (in semipermanent water drawdown zones) to sparse, yet diverse, small graminoid and forb herbaceous vegetation to bald-cypress woodland edges. Some examples may have emergent trees throughout their extent.

Dynamics: The seasonal fluctuation in the water levels in these ponds controls both the overall vegetation composition as well as the composition of the zones of the vegetation, which may be quite distinct from one another. Hydroperiod can vary substantially from year to year, and vegetation can similarly vary significantly in aspect and dominants. Highly variable hydroperiods help maintain herbaceous vegetation and prevent the succession to forest. Fire is an important natural disturbance, and the outer, drier portions of the depressions burn most frequently. Fires may sweep through the interior of many examples during dry periods. Today, prescribed fire is important for the management of the pineland landscapes which include these herbaceous or shrub wetland ecological systems.

Component Associations:

- *Alnus serrulata* Saturated Southern Interior Shrubland (CEGL007059, G3)
- *Alnus serrulata* Southeastern Seasonally Flooded Shrubland (CEGL008474, G4)

- *Saccharum* spp. - *Panicum verrucosum* - (*Rhexia* spp., *Sabatia* spp.) Herbaceous Vegetation (CEGL004752, G2G3)
- *Salix nigra / (Cephalanthus occidentalis)* Forest (CEGL004773, G4G5)
- *Sparganium americanum - Saccharum giganteum* Herbaceous Vegetation (CEGL004769, G3)
- *Taxodium ascendens / Ilex myrtifolia* Depression Forest (CEGL007418, G3?)
- *Taxodium distichum* East Gulf Coastal Plain Pondshore Woodland (CEGL004046, G3)
- *Typha latifolia* Southern Herbaceous Vegetation (CEGL004150, G5)

SPATIAL CHARACTERISTICS

Spatial Summary: Small patch

DISTRIBUTION

Range: This ecological system is found in the East Gulf Coastal Plain, including the Gulf Coast Flatwoods (i.e., EPA Level IV Ecoregion 75a (EPA 2004)), as well as more inland portions (EPA Level III Ecoregion 65). In particular, there are clusters of large ponds in parts of the Southern Pine Plains and Hills (EPA 65f), the Dougherty Plain (EPA 65g), and Tallahassee Hills/Valdosta Limesink (EPA 65o), and the Okefenokee Plain (EPA 75e).

EAST GULF COASTAL PLAIN FLORIDA BIG BEND SEAGRASS BED (CES203.244)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Aquatic Herb
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9412

CONCEPT

Summary: This seagrass bed system overlies the drowned karst of the Florida Big Bend region extending along the west coast from approximately St. Marks National Wildlife Refuge to Tarpon Springs, Florida (Anclote Key). This area is one of the few known places in the world with a zero energy coast line (Murali 1982). This phenomenon allows for the development of seagrass beds without protective ocean barriers. Six different species of seagrasses comprise these beds which range from near-shore shoals (exposed at low tide) to relatively deep waters as far as 112 km offshore. The deepest extent of this system is constrained, at least in part, by water clarity as seagrasses require light penetration for photosynthesis. For this reason, these beds are found in deeper waters along the southern boundary of the system, deeper waters where the water is increasingly clear due apparently to reduced input of highly organic river runoff which is concentrated in the north (Zieman and Zieman 1989). Species composition and density are variable. The densest beds are found in shallow waters well removed from river mouths. Although several of the individual seagrass species may be found in mixed species beds, there is a general pattern of species zonation evident, largely related to water depth. Periodically exposed shoals tend to support monospecific stands of *Halodule*. *Thalassia* grows only in shallower subtidal areas, and *Cymodocea* is concentrated in deeper subtidal areas. Pure stands of *Halophila* are abundant in deepest areas often removed from beds of the other species, while *Ruppia* is confined to river mouths.

Similar Ecological Systems:
- Atlantic Coastal Plain Indian River Lagoon Seagrass Bed (CES203.256)
- Florida Keys Seagrass Bed (CES411.285)
- Northern Gulf of Mexico Seagrass Bed (CES203.263)
- Southwest Florida Seagrass Bed (CES203.274)

Related Concepts:
- Seagrass Bed (FNAI 1990) Broader

DESCRIPTION

Environment: This system is found along a zero energy coast line of Florida where the average wave breaker heights are 3-4 cm or less, and there is almost no significant littoral transport of sand. Factors contributing to this phenomenon are the wide gently sloping shelf, the divergence of approaching wave trains into the large expanding coastal concavity, the location of the coast in an upwind direction, small sediment supply, and wave dampening effects of submerged beaches. These are important factors which allow the development of this system without normal ocean barriers (Murali 1982).

Vegetation: Seagrasses are monocots which carry out their entire life cycle completely submerged in the marine environment. Species composition and density are variable. The densest beds are found in shallow waters well removed from river mouths. Although several of the individual seagrass species may be found in mixed-species beds, there is a general pattern of species zonation evident, largely related to water depth. Periodically exposed shoals tend to support monospecific stands of *Halodule*. *Thalassia* grows only in shallower subtidal areas, and *Cymodocea* is concentrated in deeper subtidal areas. Pure stands of *Halophila* are abundant in deepest areas often removed from beds of the other species, while *Ruppia* is confined to river mouths. Succession dynamics also helps determine composition. *Halodule beaudettei (= Halodule wrightii)* is the local pioneering species which colonizes areas from seed or vegetative reproduction. *Cymodocea* often appears next and may mix with *Halodule*. *Thalassia* occupies beds as succession advances.

Dynamics: Unlike most other seagrass systems, these beds are not protected from large storm surges. Hurricanes may cause localized disruptions and bottom scouring which may dislodge plants. The rate of recolonization depends upon the severity of the disturbance and the species involved. Colonization of seagrasses often follows a generalized successional sequence. Non-vegetated areas may first be colonized by rhizophytic macroalgae which have some sediment-binding capacity. Possibly more importantly they contribute sedimentary particles as they die and decompose (Zieman and Zieman 1989). *Halodule wrightii (= Halodule beaudettei)* is the local pioneering species which colonizes areas from seed or vegetative reproduction. *Cymodocea* often appears next and may mix with *Halodule*. *Thalassia* occupies beds as succession advances. This pattern marks a progressive increase of biomass in the system with increased leaf areas, increased sediment-trapping capacity, and increased microbial cycling. Seagrasses in this region experience large temperature fluctuations and exhibit more cold tolerance than those in more southerly areas. Cold temperatures during the winter cause leaf die-off to within several centimeters of the sediment surface.

Component Associations:
- *Cymodocea filiformis - (Thalassia testudinum)* Herbaceous Vegetation (CEGL004317, G4?)
- *Halodule wrightii* Herbaceous Vegetation (CEGL004318, G4?)

- *Halophila engelmannii* Herbaceous Vegetation (CEGL004688, G3?)
- *Ruppia maritima* Louisianian Zone Herbaceous Vegetation (CEGL004450, G4G5)
- *Thalassia testudinum* Herbaceous Vegetation (CEGL004319, G4?)
- *Vallisneria americana* Estuarine Bayou Herbaceous Vegetation (CEGL004634, G3G5)

DISTRIBUTION

Range: This system is restricted to the Florida Big Bend region extending along the west coast from approximately St. Marks to Tarpon Springs.

EAST GULF COASTAL PLAIN SANDHILL LAKESHORE DEPRESSION (CES203.292)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Depressional [Vernal Pool]; Graminoid
Non-Diagnostic Classifiers: Herbaceous; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9223

CONCEPT

Summary: This small-patch wetland system occupies upland depressions on deep sandy soils in the southern portions of the East Gulf Coastal Plain of Florida. These depressions are apparently of karstic origin but exhibit no evidence of calcareous conditions or evidence of limestone. Limestone is buried 50 or more feet below the surface under coarse sandy soils that cover the margins and, in some cases, the entire surface extent of these depressions (A. Johnson pers. comm.). The resulting appearance of these pondshores is that of large, inland white sand beach (at least in dry years). In the drier margins they even support some plant species found on coastal beaches of the region, such as *Lupinus westianus*, *Hypericum reductum*, and *Chrysoma pauciflosculosa*. The aspect of the vegetation ranges from shrublands to herbaceous-dominated with local variability. Several narrowly endemic plant species may be present such as *Hypericum lissophloeus*, *Rhexia salicifolia*, and *Xyris longisepala*. Examples may be periodically flooded to depths of as much as 1.5 m deep, but they dry down regularly. Some are fairly large, steep-sided depressions with as much as a 30-m elevation change from rim (sandhill) to center, while others form much more gradual depressions. Fire may be an important natural force in some examples.
Classification Comments: This system has karstic origins in common with Southern Coastal Plain Sinkhole (CES203.495) but lacks exposed limestone and steep vertical, limestone walls. Other upland depressions of the East Gulf Coastal Plain (that may or may not have karstic origins) on less extreme sandy soils are accommodated by East Gulf Coastal Plain Depression Pondshore (CES203.558).

This system was originally covered by the former East Gulf Coastal Plain Southern Depression Pondshore (CES203.504) but was split out and recognized as distinct in February 2004.

Similar Ecological Systems:
- East Gulf Coastal Plain Depression Pond (CES203.558)
- Southern Coastal Plain Sinkhole (CES203.495)

Related Concepts:
- Sandhill Upland Lake (FNAI 1990) Undetermined

DESCRIPTION

Environment: Examples occur in the southern Dougherty Plain of the Florida panhandle (65g of EPA 2004), only in Bay and Washington counties. This is high rolling sandhill territory (not flatwoods) with very steep-sided ponds in many cases (A. Johnson pers. comm. 2009). Some are fairly large, steep-sided depressions with as much as a 30-m elevation change from rim (sandhill) to center, while others form much more gradual depressions. The limestone beneath them is more deeply dissected than elsewhere in Florida, but it is solidly blanketed with deep sand, so it does not reach the surface at all, and the soils are all acidic. Fire may be an important natural force in some examples.
Vegetation: *Hypericum lissophloeus, Rhexia salicifolia*, and *Xyris longisepala* are some of the more unusual species associated with this system (A. Johnson pers. comm.).
Dynamics: These depressions are generally permanent waterbodies, although water levels may fluctuate substantially, sometimes becoming completely dry during extreme droughts (FNAI 2010a). They are typically lentic waterbodies without significant surface inflows or outflows. Instead, water may be largely derived from lateral groundwater seepage through the surrounding well-drained uplands and/or from artesian sources via connections with the underlying limestone aquifer (FNAI 2010a). Sandhill upland lakes are frequently extremely important breeding areas for terrestrial amphibians, including the threatened Carolina gopher frog (*Lithobates capito*), as well as many unusual or endemic insects (FNAI 2010a). They are also important watering holes for many mammals and birds inhabiting the surrounding xeric communities (FNAI 2010a). Wading birds and ducks may also use these lakes as feeding areas (FNAI 2010a).

Component Associations:
- *Hypericum lissophloeus* Shrubland (CEGL003870, G1)
- *Hypericum reductum / Syngonanthus flavidulus - Rhexia salicifolia - (Xyris longisepala)* Dwarf-shrubland (CEGL004998, G1G2)

DISTRIBUTION

Range: This system is restricted to the Florida panhandle (apparently confined to a single site) (A. Johnson pers. comm. 2009).

EAST GULF COASTAL PLAIN SAVANNA AND WET PRAIRIE (CES203.192)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Extensive Wet Flat; Very Short Disturbance Interval; Graminoid
Non-Diagnostic Classifiers: Herbaceous
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2485; ESLF 9206; ESP 1485

CONCEPT

Summary: This ecological system of western Florida and adjacent Alabama and Mississippi has been called "lush grassland," "grass-sedge savannah," wet prairie, or wet savanna. As implied by these names, this system consists of primarily herbaceous vegetation with relatively thick cover of grasses and sedge species. Examples occupy low, flat plains on poorly drained soils, often saturated for 50-100 days per year. Frequent fires, including growing-season burns, are essential for maintenance of this system. Some examples have a sparse tree component of *Pinus elliottii* or *Pinus palustris* and scattered shrubs, such as *Morella caroliniensis*.
Classification Comments: Related vegetation of central Florida is covered by another ecological system.
Similar Ecological Systems:
- Central Florida Wet Prairie and Herbaceous Seep (CES203.491)

Related Concepts:
- Pondcypress: 100 (Eyre 1980) Finer
- Wet Prairie (FNAI 2010a) Broader
- Wet Prairie (FNAI 1990) Broader

DESCRIPTION

Environment: This system occupies low, flat plains on poorly drained Ultisols. Sites are saturated for 50-100 days per year (FNAI 1990). Other soil orders may include Ultisols, Spodosols, Inceptisols, and Entisols (Collins et al. 2001); some of these soils have an argillic horizon which impedes drainage and contributes to high water tables. On Eglin Air Force Base, this system is found on the Rutledge series (Kindell et al. 1997).
Vegetation: Collins et al. (2001) documented less than 10 trees per acre (*Pinus elliottii* and *Pinus palustris*) in examples of this system on the Apalachicola National Forest. *Magnolia virginiana, Acer rubrum,* and *Morella cerifera* are often present in sometimes locally dense patches, especially when managed with infrequent fires (FNAI 1990, Collins et al. 2001). *Aristida beyrichiana, Ctenium aromaticum, Rhexia alifanus, Rhynchospora* spp., and *Eriocaulon* spp. are typical species. This ecological system may be considered a "lush grassland" (Kindell et al. 1997), "grass-sedge savannah" (Clewell 1981), wet prairie (FNAI 1990), or wet savanna (Collins et al. 2001).
Dynamics: Wet prairies are seasonally inundated or saturated for 50 to 100 days a year (FNAI 1990). Fire-return intervals have been estimated to be 2-3 years (FNAI 2010a). Wet prairies can be large areas which would have been naturally prone to frequent fire. Today prescribed fire is needed to maintain high-quality examples of wet prairies. Without frequent fire, shrubs and trees can dominate the site, and this leads to a decline in the herbaceous plant diversity.

Component Associations:
- *Aristida beyrichiana - Rhynchospora oligantha - Carphephorus pseudoliatris - Sarracenia (alata, flava, leucophylla)* Herbaceous Vegetation (CEGL004154, G2)
- *Aristida beyrichiana - Rhynchospora* spp. *- Pleea tenuifolia - Sarracenia (psittacina, flava)* Herbaceous Vegetation (CEGL004153, G2)
- *Aristida beyrichiana - Rhynchospora* spp. *- Verbesina chapmanii* Herbaceous Vegetation (CEGL004152, G2)
- *Hypericum fasciculatum / Rhynchospora (chapmanii, harperi)* Shrubland (CEGL003869, G2G3)
- *Nyssa ursina / Aristida beyrichiana - Rhynchospora (chapmanii, corniculata)* Herbaceous Vegetation (CEGL008595, G1G2)
- *Scleria baldwinii - Rhynchospora cephalantha - Polygala cymosa - Fuirena scirpoidea* Herbaceous Vegetation (CEGL007717, G2?)
- *Taxodium ascendens / Hypericum chapmanii / Rhynchospora harperi* Dwarf Woodland (CEGL007725, G1)

CONCEPT

Summary: This system is found along creeks and streams from Nebraska and Iowa to Illinois, and from Minnesota to Texas. It is also found in depressions and along lake borders, especially in the northern extension of its range into Minnesota. It is often adjacent to a floodplain system but is devoid of trees and riparian vegetation. It is also distinguished from upland prairie systems by having more hydrology, especially associated with silty, dense clay soils that are often hydric, classified as Vertic Haplaquolls. The landform is usually floodplain or poorly drained, relatively level land. The vegetation is dominated by *Spartina pectinata, Tripsacum dactyloides*, numerous large sedges, such as *Carex frankii* and *Carex hyalinolepis*, and in wetter areas, *Eleocharis* spp. Other emergent marsh species such as *Typha* spp. can be associated with this system. Forbs can include *Helianthus grosseserratus*, *Vernonia fasciculata*, and *Physostegia virginiana*. Some parts of this system may be saline and have species such as *Distichlis spicata* and *Schoenoplectus maritimus*. Fire has been the primary influence in keeping these wet areas free of trees. Other dynamic processes include grazing and flooding (often in late spring). Many areas have been converted to agricultural, but this usually requires some sort of drainage.

DESCRIPTION

Environment: This system is found primarily on silty and/or dense clay, hydric soils, usually classified as Vertic Haplaquolls. It is found within poorly drained, relatively level areas.
Vegetation: *Spartina pectinata, Tripsacum dactyloides*, and numerous large sedges, such as *Carex frankii* and *Carex hyalinolepis*, dominate this system. In wetter areas, *Eleocharis* spp. and *Typha* spp. may be significant. Forbs such as *Helianthus grosseserratus*, *Vernonia fasciculata*, and *Physostegia virginiana* also may be common. Shrub species can be present, especially in the northern range of this system; however, they are usually insignificant compared to the prairie and meadow species.
Dynamics: Fire and grazing can affect this system. Fire could spread from adjacent upland prairie, especially in the fall when water levels tended to be low and vegetation was driest. The wet prairie/wet meadow zone burned most frequently, but in the fall, dense, dry tall emergent vegetation in shallow or deep marshes could carry fire, as well. These fires could remove standing dead vegetation, allowing more light to reach the ground and returning nutrients to the soil, but they did not result in a conversion to a different system. In the eastern portion of this system's range, fire was more important in keeping woody species from invading. Native ungulates grazed the margins of potholes and used them as water sources. Muskrats live in larger, wetter potholes and, when populations get high, can have significant effects on the vegetation by eating *Typha* spp. and substantially reducing its cover. Flooding or saturation of sites for part of the growing season is required for the dominant species to survive over time. Grazing during the late summer or other dry periods can result in significant reduction in herbaceous cover but, in general, grazing is of lower importance than fire and flooding in maintaining this system.

Component Associations:
- *Calamagrostis canadensis - Carex* spp. Laurentian & Northeast Wet Meadow (CEGL005448, G4G5)
- *Calamagrostis canadensis* North-Central Wet Meadow (CEGL005449, G4G5)
- *Calamagrostis stricta - Carex sartwellii - Carex praegracilis - Plantago eriopoda* Saline Herbaceous Vegetation (CEGL002255, G2G3)
- *Carex aquatilis - Carex* spp. Herbaceous Vegetation (CEGL002262, G4?)
- *Carex atherodes* Herbaceous Vegetation (CEGL002220, G3G5)

- *Spartina pectinata - Calamagrostis stricta - Carex* spp. Herbaceous Vegetation (CEGL002027, G3?)
- *Spartina pectinata - Carex* spp. - *Calamagrostis canadensis - Lythrum alatum - (Oxypolis rigidior)* Herbaceous Vegetation (CEGL002224, G3?)
- *Spartina pectinata - Carex* spp. - *Calamagrostis canadensis* Sand Herbaceous Vegetation (CEGL005178, G3?)
- *Spartina pectinata - Eleocharis* spp. - *Carex* spp. Herbaceous Vegetation (CEGL002223, G2G4)
- *Spiraea tomentosa - Salix humilis / Andropogon gerardii - Panicum virgatum* Shrubland (CEGL005069, G1Q)
- *Typha (angustifolia, domingensis, latifolia) - Schoenoplectus americanus* Herbaceous Vegetation (CEGL002032, G3G4)
- *Typha latifolia - Thalia dealbata* Herbaceous Vegetation (CEGL004526, GNR)
- *Typha* spp. - *Schoenoplectus acutus* - Mixed Herbs Midwest Herbaceous Vegetation (CEGL002229, G4?)
- *Typha* spp. Midwest Herbaceous Vegetation (CEGL002233, G5)

DISTRIBUTION

Range: This system is found throughout the northeastern Great Plains ranging from eastern Kansas to western Illinois and north into Minnesota.
Divisions: 205:C
Nations: US
Subnations: IA, IL, KS, MN, MO, ND, NE, OK, SD, TX?
Map Zones: 31:P, 38:C, 39:C, 40:C, 41:P, 42:C, 43:C, 49:C, 50:C, 51:P, 52:P
USFS Ecomap Regions: 251A:CC, 251B:CC, 251E:CC, 251F:CC, 251G:CC, 251H:CC, 255A:PP, 332B:CP, 332C:CC, 332D:CC, 332E:CC, 332F:C?
TNC Ecoregions: 35:C, 36:C, 45:P, 46:P

EDWARDS PLATEAU UPLAND DEPRESSION (CES303.654)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Depressional; Depression
National Mapping Codes: ESLF 9239

CONCEPT

Summary: This system includes shallow wetlands formed over limestone on the Edwards Plateau of Texas. Variable in size and duration of inundation, these wetlands are typically found on level uplands. Dominant vegetation includes both graminoids and forbs tolerant of wet periods but not necessarily wetland-dependent. Dominant species may include *Pleuraphis mutica, Buchloe dactyloides, Sedum pulchellum, Sedum nuttallianum, Sporobolus vaginiflorus, Chaetopappa bellidifolia, Paronychia* spp., and the alga *Nostoc commune*. Some larger occurrences of this wetland system are found in Crocket, Reagan, Schleicher, Irion and Sterling counties in the northwest Edwards Plateau (the Eldorado Plateau). Formation of these occurrences is apparently from solution of the underlying limestone.
