Terrestrial Ecological Systems of the United States and Canada

12 July 2013

Descriptions by NatureServe

About this document

This document contains brief definitions of the NatureServe terrestrial ecological systems currently identified as occurring in the United States and Canada. This ecological systems classification has been developed in consultation with many individuals and agencies and incorporates information from a variety of publications and other classifications. This report download was made possible by funding from LANDFIRE. Comments and suggestions regarding the contents of this subset may be directed to Mary J. Russo, Central Ecology Data Manager, Durham, NC, <mary_russo@natureserve.org>.

TABLE OF CONTENTS

FOREST AND WOODLAND

ACADIAN LOW-ELEVATION SPRUCE-FIR-HARDWOOD FOREST (CES201.565)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Mesotrophic Soil; Oligotrophic Soil; Picea (glauca, mariana, rubens) - Abies
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Sideslope; Toeslope/Valley Bottom; Glaciated; Acidic Soil; Mineral: W/ A-Horizon >10 cm; Loam Soil Texture; Sand Soil Texture; Udic; Long Disturbance Interval; W-Patch/Medium Intensity; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2373; ESLF 4316; ESP 1373

CONCEPT

Summary: This system represents the Acadian and northern Appalachian red spruce-fir forest that extends to the southern boreal region of southeastern Canada. The low- to mid-elevation forests are dominated by *Picea rubens* and *Abies balsamea*. *Picea mariana* and *Picea glauca* may be present. *Betula alleghaniensis* is the most common codominant, and *Acer rubrum*, *Acer saccharum*, and *Fagus grandifolia* are sometimes present. The upland soils are acidic and usually rocky, mostly well- to moderately well-drained but with some somewhat poorly drained patches at the slope bottoms. This is the matrix forest type in the lower-elevation northern portions of this division. This system may include earlier successional patches in which *Populus* spp. and *Betula* spp. are dominant or mixed with *Picea* and *Abies* that will develop into spruce-fir forests. Blowdowns with subsequent gap regeneration are the most frequent form of natural disturbance, with large-scale fires important at longer return intervals.
Classification Comments: Differences between this and the seasonally flooded Acadian Sub-boreal Spruce Flat (CES201.562) are not well-defined; data from Canada may help to resolve this.
Similar Ecological Systems:
- Acadian Sub-boreal Spruce Flat (CES201.562)--more poorly drained and with a very well-developed bryoid layer, although the two systems can grade into one another.
- Laurentian-Acadian Northern Hardwood Forest (CES201.564)
- Laurentian-Acadian Sub-boreal Aspen-Birch Forest (CES103.020)

Related Concepts:
- Aspen - Birch Woodland/Forest Complex (Gawler and Cutko 2010) Finer
- Balsam Fir: 5 (Eyre 1980) Finer
- Black Spruce (eastern type): 12 (Eyre 1980) Finer
- Maritime Spruce - Fir Forest (Gawler and Cutko 2010) Finer
- Paper Birch - Red Spruce - Balsam Fir: 35 (Eyre 1980) Finer
- Red Spruce - Balsam Fir: 33 (Eyre 1980) Finer
- Red Spruce: 32 (Eyre 1980) Finer
- Spruce - Fir - Broom-Moss Forest (Gawler and Cutko 2010) Finer
- Spruce - Northern Hardwoods Forest (Gawler and Cutko 2010) Finer
- White Spruce: 107 (Eyre 1980) Finer

Component Associations:
- *Picea mariana - Picea rubens / Pleurozium schreberi* Forest (CEGL006361, GNR)
- *Picea mariana / Kalmia angustifolia* Woodland (CEGL006292, G4?)
- *Picea rubens - Abies balsamea - Betula papyrifera* Forest (CEGL006273, GNR)
- *Picea rubens - Abies balsamea - Betula* spp. - *Acer rubrum* Forest (CEGL006505, GNR)
- *Picea rubens - Picea glauca* Forest (CEGL006151, G4G5)

SPATIAL CHARACTERISTICS

Spatial Summary: More southerly occurrences of this system can be large patch (or even small patch) rather than matrix systems.
Adjacent Ecological Systems:
- Acadian-Appalachian Montane Spruce-Fir Forest (CES201.566)

DISTRIBUTION

Range: This system is found in northern New England, northern New York and adjacent Canada and is occasional southwards.
Divisions: 201:C; 202:C
Nations: CA, US

Subnations: ME, NB, NH, NY, PA, QC?, VT
Map Zones: 64:C, 65:C, 66:C

ACADIAN-APPALACHIAN MONTANE SPRUCE-FIR FOREST (CES201.566)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Forest and Woodland (Treed); Ridge/Summit/Upper Slope; Picea (glauca, mariana, rubens) - Abies
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Glaciated; Mesotrophic Soil; Oligotrophic Soil; Acidic Soil; Mineral: W/ A-Horizon >10 cm; Loam Soil Texture; Udic; Long Disturbance Interval; W-Patch/Medium Intensity; Needle-Leaved Tree; Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2374; ESLF 4317; ESP 1374

CONCEPT

Summary: This is the matrix forest system in the montane spruce-fir region of the northern Appalachian Mountains, extending east through the Canadian Maritimes. It occurs mostly upwards of 457 m (1500 feet) elevation and is restricted to progressively higher elevations southward. Northward, it is often contiguous with Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565). This system often forms a mosaic of strongly coniferous patches and mixed patches, with occasional smaller inclusions of northern hardwoods, but is overall more than 50% coniferous. *Picea rubens* and *Abies balsamea* are the dominant conifers. Gaps formed by wind, snow, ice, and harvesting are the major replacement agents; fires may be important but only over a long return interval.
Classification Comments: This system can occupy an intermediate elevation position between Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565) and Acadian-Appalachian Subalpine Woodland and Heath-Krummholz (CES201.568), and it could arguably be combined with one of those, probably the former. However, in the southern part of its range, it often occurs without either of these other systems. It is distinguished, in concept, from Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565) by the presence or greater abundance of montane species such as *Sorbus americana* or *Sorbus decora, Dryopteris campyloptera, Oxalis montana*, etc., and by occurring at higher positions in the toposequence. It is generally above northern hardwood forests, while Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565) is generally below (or at similar elevations to) northern hardwood forests. More careful review is needed to determine if it should remain a separate system.
Similar Ecological Systems:
- Acadian-Appalachian Subalpine Woodland and Heath-Krummholz (CES201.568)
- Central and Southern Appalachian Spruce-Fir Forest (CES202.028)

Related Concepts:
- Balsam Fir: 5 (Eyre 1980) Finer
- Fir - Heart-Leaved Birch Subalpine Forest (Gawler and Cutko 2010) Finer
- Paper Birch - Red Spruce - Balsam Fir: 35 (Eyre 1980) Finer
- Paper Birch:18 (Eyre 1980) Finer
- Red Spruce - Balsam Fir: 33 (Eyre 1980) Finer
- Red Spruce - Yellow Birch: 30 (Eyre 1980) Finer
- Red Spruce: 32 (Eyre 1980) Finer
- Spruce - Fir - Wood-sorrel - Feather-moss Forest (Gawler and Cutko 2010) Finer
- Spruce - Northern Hardwoods Forest (Gawler and Cutko 2010) Finer

Component Associations:
- *Abies balsamea - (Betula papyrifera var. cordifolia)* Forest (CEGL006112, GNR)
- *Betula alleghaniensis - Picea rubens / Dryopteris campyloptera* Forest (CEGL006267, GNR)
- *Picea rubens - Abies balsamea - Betula* spp. *- Acer rubrum* Forest (CEGL006505, GNR)
- *Picea rubens - Abies balsamea / Sorbus americana* Forest (CEGL006128, G3G5)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565)
- Acadian-Appalachian Subalpine Woodland and Heath-Krummholz (CES201.568)

Adjacent Ecological System Comments: Northward, it is often contiguous with Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565). At higher elevations it can transition to Acadian-Appalachian Subalpine Woodland and Heath-Krummholz (CES201.568).

DISTRIBUTION

Range: This system is found at higher elevations of northern New England and the Adirondacks, extending north along the mountains and higher hills into Canada and occurring southward in the Catskills.
Divisions: 201:C; 202:C

Nations: US
Subnations: MA, ME, NH, NY, VT
Map Zones: 64:C, 65:C, 66:C

ALASKA SUB-BOREAL MOUNTAIN HEMLOCK-WHITE SPRUCE FOREST (CES105.103)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Montane]; Forest and Woodland (Treed); Sideslope; Boreal [Boreal Oceanic]; Picea X lutzii; Tsuga mertensiana
Non-Diagnostic Classifiers: Very Long Disturbance Interval; F-Landscape/High Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2678; ESLF 4282; ESP 1678

CONCEPT

Summary: This ecological system occurs on sideslopes and rolling terrain on the inland side of the Kenai and Chugach mountains and represents a transition from maritime forests to south-central boreal forests. Soils are mesic and derived from colluvium, glacial deposits, or residual bedrock. Permafrost is rare. *Picea X lutzii* is the dominant spruce and *Tsuga mertensiana* is codominant in the canopy and has at least 15% cover. The major disturbance processes include fungal pathogens, human disturbance, fire, blowdown, and insect infestations.
Classification Comments: This system is known as Boreal Transition Mountain Hemlock - White Spruce by the Alaska Natural Heritage Program.
Similar Ecological Systems:
- Alaska Sub-boreal White-Lutz Spruce Forest and Woodland (CES105.102)
- Alaskan Pacific Maritime Mountain Hemlock Forest (CES204.142)
- Alaskan Pacific Maritime Subalpine Mountain Hemlock Woodland (CES204.143)
- Western North American Boreal Mesic Birch-Aspen Forest (CES105.108)

Related Concepts:
- I.A.1.f - Mountain hemlock (closed) (Viereck et al. 1992) Intersecting. no white spruce-mt hemlock in AKVC
- I.A.2.c - Mountain hemlock (open) (Viereck et al. 1992) Intersecting. no white spruce-mt hemlock in AKVC

DESCRIPTION

Environment: This system occurs on sideslopes and rolling terrain on the inland side of the Kenai and Chugach mountains and represents a transition from maritime forests to south-central boreal forests. Soils are mesic and derived from colluvium, glacial deposits, or residual bedrock. Permafrost is rare.
Vegetation: *Picea X lutzii* and *Tsuga mertensiana* are the dominant conifers, and *Tsuga mertensiana* has at least 15% cover. Other tree species that may be present include *Betula papyrifera* and *Populus balsamifera*. Common shrubs include *Menziesia ferruginea*, *Alnus viridis ssp. sinuata*, *Vaccinium ovalifolium*, *Oplopanax horridus*, *Vaccinium vitis-idaea*, and *Linnaea borealis*. Common herbaceous species include *Rubus pedatus*, *Cornus canadensis*, *Dryopteris expansa*, *Gymnocarpium dryopteris*, and *Equisetum arvense*. Common mosses include *Hylocomium splendens* and *Pleurozium schreberi*. Plant communities in this system are described by DeVelice et al. (1999).
Dynamics: The major disturbance processes are fire, human disturbance, blowdown, avalanches (on steeper slopes), and insect infestations. Although lightning and natural fires have historically been infrequent, wildfire plays an important role in the disturbance regime of this system. Under the natural fire regime, fires were infrequent but large. Estimates of the mean fire-return interval range from 600-800 years (Potkin 1997, Berg and Anderson 2006).

Spruce beetle (*Dendroctonus rufipennis*) infestations are a major natural disturbance of spruce forest in south-central Alaska. Forests of the Kenai Peninsula have experienced periodic beetle infestations which occasionally rise to epidemic proportions. The most recent infestation, which began in 1987, impacted 429,000 ha on the Kenai Peninsula (USFS 2004, Rude unpubl. data) out of 772,000 ha of total forested area (van Hees and Larson 1991).

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Alaska Sub-boreal White-Lutz Spruce Forest and Woodland (CES105.102)
- Alaskan Pacific Maritime Mountain Hemlock Forest (CES204.142)

Adjacent Ecological System Comments: Within the Kenai Mountains, this system occurs above Alaska Sub-boreal White-Lutz Spruce Forest and Woodland (CES105.102) and below Alaskan Pacific Maritime Mountain Hemlock Forest (CES204.142).

DISTRIBUTION

Range: This system occurs primarily in the Kenai and Chugach mountains of Alaska.
Divisions: 105:C; 204:C
Nations: US
Subnations: AK

Map Zones: 73:C, 74:C, 75:C, 77:?
TNC Ecoregions: 70:C, 71:C

- III.A.2.b - Bluejoint-herb (Viereck et al. 1992) Intersecting. seral
- III.B.2.b - Fireweed (Viereck et al. 1992) Intersecting. seral

DESCRIPTION

Environment: This system typically occurs on well-drained upland terrain. Soils generally develop on surficial deposits including glacial till, colluvium, and loess. Permafrost is rare.
Vegetation: *Picea glauca* and *Betula papyrifera* are typically codominant in an open canopy. *Populus tremuloides* and *Populus balsamifera* are common canopy trees and *Picea mariana* may also be present. Common understory shrubs include *Alnus viridis ssp. sinuata, Viburnum edule, Rosa acicularis, Ribes triste, Vaccinium vitis-idaea,* and *Linnaea borealis*. Common herbaceous species include *Calamagrostis canadensis, Chamerion angustifolium, Gymnocarpium dryopteris,* and *Cornus canadensis*.
Dynamics: Although lightning strikes and natural fires are rare in the region, wildfires play an infrequent but important role in the disturbance regime of the Coastal Boreal Transition Forest PNV (Potkin 1997). Under the natural fire regime of this PNV, fires were infrequent but large (USFS 2002). Estimates of mean fire-return interval (MFI) include: (1) 800 years (Berg 2004); (2) 600 years (FRCC experts' workshop March 2004 pers. comm.); and (3) 600 years (570-3010 year range) (Potkin 1997) (5 locations in the Kenai Mountains).

Spruce beetle (*Dendroctonus rufipennis*) infestations are a major natural disturbance of spruce forests in the boreal transition region. Spruce beetles typically attack larger, slow-growing spruce, but infestations periodically escalate to epidemic levels when forest and climatic conditions are favorable for beetle expansion. During epidemic-level infestations, beetles are less selective and may attack and kill a wider range of spruce trees. Beetle outbreaks that thin stands and produce a growth release in surviving trees occur on average every 50 years in white and Lutz spruce forests on the Kenai Peninsula (Berg 2004). Spruce beetle outbreaks that produce a more substantial thinning occur at longer intervals, with the last two severe infestations occurring in the 1870s-1880s and 1987-present (Berg 2004). The beetle outbreak that began in 1987 on the Kenai Peninsula has killed over 1.3 million acres of spruce (USFS 2002). Berg (2004) found no association between spruce beetle mortality and fire in the past.

When the canopy of these forests is thinned by spruce beetle mortality, *Calamagrostis canadensis* may proliferate rapidly from its predisturbance-level network of rhizomatous roots and develop into a think sod that limits spruce regeneration within a few years (Berg 2004). Boucher (2003) found that rapid spread of *Calamagrostis canadensis* occurs primarily on sites with deep, loamy soils.

Other natural disturbances include wind, avalanche and landslides. Windthrow gap disturbances are important in both spruce and hemlock recruitment in these forests (Potkin 1997).

DISTRIBUTION

Range: This system occurs in the boreal transition region of Alaska.

- I.A.1.j - White spruce (closed) (Viereck et al. 1992) Intersecting
- I.A.2.e - White spruce (open) (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: This system occurs on well-drained soils on sideslopes, toeslopes, and inactive terraces. Permafrost is rare. Within the Kenai Mountains, it occurs at lower elevations than white spruce-mountain hemlock and mountain hemlock systems.
Vegetation: *Picea glauca* or *Picea X lutzii* are the dominant conifers. Other tree species include *Betula papyrifera, Populus balsamifera*, and *Populus tremuloides*. Common shrubs include *Menziesia ferruginea, Alnus viridis ssp. sinuata, Vaccinium ovalifolium, Oplopanax horridus, Vaccinium vitis-idaea*, and *Linnaea borealis*. Common herbaceous species include *Calamagrostis canadensis, Equisetum arvense, Dryopteris expansa*, and *Gymnocarpium dryopteris*. Common mosses include *Hylocomium splendens* and *Pleurozium schreberi* (DeVelice et al. 1999).
Dynamics: The major disturbance processes are fire, human disturbance, blowdown, and insect infestations. Although lightning and natural fires have historically been infrequent, wildfire plays an important role in the disturbance regime of this system. Under the natural fire regime, fires were infrequent but large. Estimates of the mean fire-return interval range from 600-800 years (Potkin 1997, Berg and Anderson 2006).

Spruce beetle (*Dendroctonus rufipennis*) infestations are a major natural disturbance of spruce forests in the boreal transition region. Spruce beetles typically attack larger, slow-growing spruce, but infestations periodically escalate to epidemic levels when forest and climatic conditions are favorable for beetle expansion. During epidemic-level infestations, beetles are less selective and may attack and kill a wider range of spruce trees. Beetle outbreaks that thin stands and produce a growth release in surviving trees occur on average every 50 years in white and Lutz spruce forests on the Kenai Peninsula (Berg 2004). Spruce beetle outbreaks that produce a more substantial thinning occur at longer intervals, with the last two severe infestations occurring in the 1870s-1880s and 1987-present (Berg 2004). The beetle outbreak that began in 1987 on the Kenai Peninsula has killed over 1.3 million acres of spruce (USFS 2004). Berg (2004) found no association between spruce beetle mortality and fire in the past.

When the canopy of these forests is thinned by spruce beetle mortality, *Calamagrostis canadensis* may proliferate rapidly from its predisturbance-level network of rhizomatous roots and develop into a think sod that limits spruce regeneration within a few years (Berg 2004). Boucher (2003) found that rapid spread of *Calamagrostis canadensis* occurs primarily on sites with deep, loamy soils.

ALASKAN PACIFIC MARITIME MOUNTAIN HEMLOCK FOREST (CES204.142)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Sideslope; Temperate [Temperate Oceanic]; Tsuga mertensiana
Non-Diagnostic Classifiers: Montane; Boreal [Boreal Oceanic]; Picea sitchensis
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2648; ESLF 4277; ESP 1648

CONCEPT

Summary: This ecological system occurs along the Gulf of Alaska Coast and Pacific Coast from Kenai Fjords through southeastern Alaska. It occurs primarily in the maritime region, but also occurs in the sub-boreal transition on the inland side of the Kenai and Chugach mountains. This system occurs on relatively stable sideslopes and benches, and soils are generally well-drained. The lower and upper elevational limits of this system decrease from south to north and from east to west. The climate is generally characterized by short, cool summers, rainy autumns and long, cool, wet winters with heavy snow cover for 5-9 months. Fire is very rare in the sub-boreal portion of the distribution and absent from the rest of the range. *Tsuga mertensiana* is the dominant conifer with at least 15% cover, but associated canopy trees vary by region. In the northern portion of its range (from Kenai Fjords to Yakutat), the system occurs from sea level to upper forest elevations.. *Picea sitchensis* or *Tsuga heterophylla* may be codominant. In the sub-boreal region, *Picea X lutzii* may be present in the canopy, but cover is less than 15%. In southeast Alaska, this system is the predominant forest of upper elevations. It occurs above the western hemlock, western hemlock - red-cedar, and western hemlock - yellow-cedar systems and below the subalpine mountain memlock dwarf-tree system. Elevations generally range from 300 to 1000 m. *Tsuga mertensiana* is the dominant tree species. *Picea sitchensis, Chamaecyparis nootkatensis* (northern limit is Prince William Sound), or *Tsuga heterophylla* may be present but are less abundant than *Tsuga mertensiana*. Throughout the entire range of the system, the dominant understory shrub is typically *Vaccinium ovalifolium*; other common shrubs include *Menziesia ferruginea, Elliottia pyroliflorus, Vaccinium vitis-idaea*, and *Empetrum nigrum*. Common herbaceous species include *Rubus pedatus, Cornus canadensis, Gymnocarpium dryopteris, Blechnum spicant*, and *Listera cordata*. Major disturbance processes include avalanche, fungal pathogens, and blowdown. Parklands (open woodlands or sparse trees with dwarf-shrub or herbaceous vegetation) are not part of this system but of North Pacific Maritime Mesic Subalpine Parkland (CES204.837) or Alaskan Pacific Maritime Subalpine Mountain Hemlock Woodland (CES204.143).
Classification Comments: This system combines those known as Boreal Transition Mountain Hemlock, Maritime Mountain Hemlock (North), and Maritime Mountain Hemlock (SE) by the Alaska Natural Heritage Program. It is similar to Alaska Sub-boreal Mountain Hemlock-White Spruce Forest (CES105.103) but has less than 15% cover *Picea glauca* and typically occurs in the elevational zone above it. It also includes the Maritime Mountain Hemlock-Sitka Spruce of Alaska Natural Heritage's classification.
Similar Ecological Systems:
- Alaska Sub-boreal Mountain Hemlock-White Spruce Forest (CES105.103)
- Alaskan Pacific Maritime Subalpine Mountain Hemlock Woodland (CES204.143)
- North Pacific Mountain Hemlock Forest (CES204.838)

DESCRIPTION

Environment: This system occurs on mountain sideslopes, shoulders, and benches. Soils are typically well-drained, shallow and are derived from glacial and colluvial deposits, as well as residual bedrock. Within the Kenai, Chugach, and St. Elias mountains, the elevation range is from 0 to 600 m. In southeastern Alaska, the elevation range is 300 to 1000 m. This system is common on north-facing slopes and uncommon on south-facing slopes.
Vegetation: *Tsuga mertensiana* is the dominant tree with at least 15% cover. *Picea sitchensis* or *Tsuga heterophylla* may be codominant in the maritime region. In the sub-boreal region, *Picea glauca* or *Picea X lutzii* may be present but have less than 15%

canopy cover. Common shrubs include *Alnus viridis ssp. sinuata*, *Vaccinium ovalifolium*, *Oplopanax horridus*, and *Menziesia ferruginea*. Common herbaceous species include *Cornus canadensis*, *Rubus pedatus*, *Dryopteris expansa*, and *Gymnocarpium dryopteris*. Common mosses include *Hylocomium splendens* and *Pleurozium schreberi*. *Sphagnum* spp. may be abundant on some sites. Plant communities in this system are described by DeVelice et al. (1999).

Dynamics: The major disturbance processes are soil creep, snow avalanche, and fungal pathogens such as red ring rot (*Phellinus pini*). Fire is absent in the maritime region, however, fire does occur infrequently in the sub-boreal region. The fire regime has not been defined for this type, but estimates of the mean fire-return interval for adjacent vegetation range from 600 to greater then 1500 years (Lertzman and Krebs 1991, Potkin 1997).

Component Associations:

- *Tsuga mertensiana - Tsuga heterophylla / Alnus viridis ssp. sinuata* Forest (CEGL003217, GNR)
- *Tsuga mertensiana - Tsuga heterophylla / Vaccinium ovalifolium - Menziesia ferruginea* Forest (CEGL003219, GNR)
- *Tsuga mertensiana - Tsuga heterophylla / Vaccinium ovalifolium* Forest (CEGL003218, G5)
- *Tsuga mertensiana / Alnus viridis ssp. sinuata* Forest (CEGL003243, GNR)
- *Tsuga mertensiana / Elliottia pyroliflorus* Woodland (CEGL003248, G4G5)
- *Tsuga mertensiana / Vaccinium ovalifolium / Caltha leptosepala ssp. howellii* Woodland (CEGL003247, G5)

ALASKAN PACIFIC MARITIME PERIGLACIAL WOODLAND AND SHRUBLAND (CES204.311)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Glaciated plains; Temperate [Temperate Oceanic]; Very Shallow Soil; Unconsolidated; Picea sitchensis; Populus balsamifera
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2650; ESLF 4284; ESP 1650

CONCEPT

Summary: This ecological system occurs as an early-successional sere on landscapes recently exposed through deglaciation since the end of the Little Ice Age (especially common in Glacier Bay and Kenai Fjords). This is not a riverine system, and glacial outwash systems are also not included. Soils are derived from glacial till, residuum and colluvium and are shallow, stony, and well-drained to excessively well-drained. Soil profile development is lacking or minimal. Early-seral stages of forested systems with low cover of *Picea sitchensis* and *Populus balsamifera ssp. trichocarpa* occur on older landscapes at low elevations near the maximum glacial extent. Depending on time since ice has receded, some sites may have woodlands of either *Populus balsamifera* or a mix of *Populus balsamifera* and *Picea sitchensis*. On other sites *Alnus viridis ssp. sinuata* often dominates the species composition, although *Salix sitchensis, Salix alaxensis,* or *Salix barclayi* may also be abundant. *Salix* spp. and *Alnus viridis ssp. sinuata* are commonly mixed with the trees on wooded sites as well. *Rubus spectabilis* is uncommon in this system. Common herbaceous species include *Calamagrostis canadensis, Chamerion angustifolium, Chamerion latifolium, Heracleum maximum, Lupinus nootkatensis, Equisetum arvense, Athyrium filix-femina, Dryopteris expansa, Phegopteris connectilis, Streptopus amplexifolius, Pyrola* spp., *Carex mertensii,* and *Epilobium* spp. Mosses and lichens may be abundant on some sites; common early-seral nonvascular species include *Racomitrium canescens, Pohlia nutans, Drepanocladus aduncus, Stereocaulon tomentosum, Cladonia crispata*, and *Cladina portentosa*.
Classification Comments: This system is known as Upland Cottonwood-Sitka Spruce by the Alaska Natural Heritage Program. Does this include Kodiak (spruce invading shrublands)? This system is very difficult to distinguish in the sequence table. For mapping purposes, the best will be to obtain a spatial layer from Keith Boggs showing maximum glacial extent and overlay that on areas mapped as Sitka spruce or cottonwood forest, or alder shrublands (as opposed to being mapped as current snow/ice). Any areas that were covered by glaciers that are now Sitka spruce-, alder-, or cottonwood-dominated are part of this periglacial system. This system is likely to be most of the Sitka spruce on Kodiak Island (K. Boggs pers. comm.).

- II.B.2.d - Alder-willow (open) (Viereck et al. 1992) Intersecting. seral

DESCRIPTION

Dynamics: Primary succession on recently deglaciated terrain (glacial till or bedrock shields) usually begins with colonization of bare rock and soil by lichens and mosses, followed by grasses and forbs, then by shrub species such as *Alnus viridis ssp. sinuata* and *Salix* spp. In Glacier Bay, *Shepherdia canadensis* and *Dryas drummondii* are also early colonizers. The rate and direction of succession are influenced by the type of substrate. On glacial till substrates, *Alnus viridis ssp. sinuata* and/or *Salix* spp. dominate the site within about 20 years. On bedrock substrates, mosses and herbaceous species may persist longer due to the lack of microsites for shrub establishment. Disturbance-prone sites may remain dominated by *Alnus viridis ssp. sinuata*. In mid-seral stages that are transitional to forested systems, *Populus balsamifera ssp. trichocarpa* and *Picea sitchensis* emerge through the tall-shrub canopy within 50 years. *Picea sitchensis* eventually gains dominance in the canopy through competitive exclusion. This transition to a hemlock-spruce forest is evident at Glacier Bay where bark beetles killed some of the even-aged Sitka spruce approximately 140 years after colonization, yielding a multi-aged forest favoring more western hemlock. Succession on bedrock shields will likely proceed to sloping peatlands over long time scales.

Component Associations:
- *Picea sitchensis - Populus balsamifera ssp. trichocarpa / Alnus viridis ssp. sinuata* Woodland (CEGL003277, G4)

DISTRIBUTION

ALASKAN PACIFIC MARITIME SITKA SPRUCE BEACH RIDGE (CES204.153)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Temperate [Temperate Oceanic]; Beach ridge; Picea sitchensis
Non-Diagnostic Classifiers: Raised beach; Beach (Landform)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2654; ESLF 4285; ESP 1654

CONCEPT

Summary: This ecological system includes productive forests on beach ridges and occurs along the Alaska Gulf Coast in the following areas: Copper River Delta, Cape Yakataga, Yakutat Forelands, and outer coast of Glacier Bay National Park. *Picea sitchensis* is usually dominant in the canopy, but *Tsuga heterophylla* can be codominant especially on older sites. *Oplopanax horridus* is usually the most abundant understory shrub; other common shrubs include *Vaccinium ovalifolium* and *Rubus spectabilis*. Understory species include *Circaea alpina, Rubus pedatus, Streptopus amplexifolius, Tiarella trifoliata, Athyrium filix-femina, Dryopteris expansa*, and *Gymnocarpium dryopteris*. Mature forests usually have very little downed wood or snags. Beach ridges form and become removed from direct contact with saltwater through long-shore sediment transport coupled with isostatic rebound. Coastal beach communities are often dominated by *Leymus mollis* and brackish meadows. *Picea sitchensis* seedlings establish in the brackish meadows, but often do not survive, probably due to excessive salt spray. Further inland, *Picea sitchensis* seedlings establish and survive in these meadows, and the meadow transitions to forest. *Picea sitchensis* establishes about 130 years after beach ridge formation and may succeed to *Tsuga heterophylla* forest.
Classification Comments: This system is known as Sitka Spruce Beach Ridge by the Alaska Natural Heritage Program.

ALASKAN PACIFIC MARITIME SITKA SPRUCE FOREST (CES204.151)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Temperate [Temperate Hyperoceanic]; Picea sitchensis
Non-Diagnostic Classifiers: Sideslope; Toeslope/Valley Bottom; Salt Spray
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2644; ESLF 4286; ESP 1644

CONCEPT

Summary: This productive ecological system occurs on well-drained sideslopes and footslopes along the Gulf Coast of Alaska and the North Pacific, in the perhumid and subpolar rainforest zones. Sites dominated by *Picea sitchensis* are usually tied to disturbance such as slope instability, water movement (either downhill through the soil or in open streams), exposure to salt spray, or windthrow. *Picea sitchensis* is the dominant tree species, although *Tsuga mertensiana* or *Tsuga heterophylla* may be minor canopy associates. In southeastern Alaska, *Alnus rubra* may be an associated understory tree species, especially in upland alluvial fans. Common species in the shrub layer include *Alnus viridis ssp. sinuata*, *Oplopanax horridus*, *Rubus spectabilis*, and *Vaccinium ovalifolium*. Common herbaceous species include *Maianthemum dilatatum*, *Tiarella trifoliata*, *Dryopteris expansa*, and *Gymnocarpium dryopteris*. *Calamagrostis nutkaensis* may be common on exposed sites near the coast. In the northern portion of the temperate rainforest (Kodiak Island, Kenai Fjords, and Prince William Sound), *Picea sitchensis* is frequently the dominant canopy tree from sea level to treeline on productive sites, and it is the only conifer that occurs on Afognak and Kodiak islands, where its range is actively expanding. In the southern portion of the Alaskan rainforest, *Picea sitchensis* is linked more closely with disturbance (e.g., very steep sites, recently deglaciated landscapes, outer coast headlands, upland alluvial fans, ancient landslides) and karst substrates. It also occurs commonly at upper elevations just below the mountain hemlock zone.
Classification Comments: This system is known as Sitka Spruce by the Alaska Natural Heritage Program. It is being split from North Pacific Seasonal Sitka Spruce Forest (CES204.841). Sitka spruce, western hemlock, and mountain hemlock dominate the subpolar zone (Gulf of Alaska); Sitka spruce, western red-cedar, and western hemlock characterize the perhumid zone (southeastern Alaska). Associated canopy species in southeast: red alder (south), western hemlock (to Prince William Sound), mountain hemlock (in upper elevations in south to sea level in north). Alluvial fans often support Sitka spruce forests, included in this system; DeMeo et al. (1992) classified these as Sitka spruce / red alder; Sitka spruce / salmonberry; Sitka spruce / devil's club-salmonberry; and Sitka spruce / blueberry.
Similar Ecological Systems:
- North Pacific Mountain Hemlock Forest (CES204.838)

CONCEPT

Summary: This subalpine ecological system occurs in the upper slopes of mountain ranges along the Gulf Coast of Alaska, including the Kenai, Chugach, St. Elias, Fairweather, and Coast mountains. It is dominated by mountain hemlock forests and parkland growing near elevational treeline. *Tsuga mertensiana* is the dominant tree and often grows with a stunted growth form (krummholz). Patches of forest interspersed with alpine heath or tall shrub characterize this system. Treeline forests often grow as small patches at the lower elevation of alpine tundra and forb meadow systems. Common understory species include *Phyllodoce aleutica* (or *Phyllodoce glanduliflora*), *Harrimanella stelleriana, Luetkea pectinata, Empetrum nigrum, Nephrophyllidium crista-galli,* and *Geum calthifolium.* The major disturbance processes include avalanche, fungal pathogens, and blowdown.
Classification Comments: This system combines those known as Boreal Transition Treeline Mountain Hemlock and Maritime Mountain Hemlock Treeline by the Alaska Natural Heritage Program. It is similar to Alaskan Pacific Maritime Mountain Hemlock Forest (CES204.142), but it occurs at treeline just below alpine tundra or forb meadows.
Similar Ecological Systems:
- Alaska Sub-boreal Mountain Hemlock-White Spruce Forest (CES105.103)
- Alaskan Pacific Maritime Mountain Hemlock Forest (CES204.142)
- North Pacific Mountain Hemlock Forest (CES204.838)

Related Concepts:
- *Tsuga mertensiana / Harrimanella stelleriana* (DeVelice et al. 1999) Finer
- *Tsuga mertensiana / Phyllodoce aleutica* (DeVelice et al. 1999) Finer
- *Tsuga mertensiana* / Krummholz (Boggs et al. 2008a) Finer
- I.A.2.c - Mountain hemlock (open) (Viereck et al. 1992) Intersecting
- II.A.1.a - Mountain hemlock (closed) scrub (Viereck et al. 1992) Finer
- II.A.2.b - Mountain hemlock (open) scrub (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: This system occurs on upper mountain sideslopes, shoulders, and bedrock outcrops from 500 to 800 m elevation. Soils are typically shallow and are derived from glacial and colluvial deposits as well as residual bedrock. Treeline Mountain Hemlock is common on north-facing slopes with late-lying snow, but also occurs on east and west aspects. This system is uncommon on south-facing slopes.
Vegetation: *Tsuga mertensiana* is the dominant tree species and has a stunted growth form (krummholz). Common shrubs include *Menziesia ferruginea, Alnus viridis ssp. sinuata, Vaccinium ovalifolium, Oplopanax horridus, Harrimanella stelleriana (= Cassiope stelleriana),* and *Empetrum nigrum.* Common herbaceous species include *Cornus canadensis, Rubus pedatus, Dryopteris expansa,* and *Gymnocarpium dryopteris.* Common mosses include *Hylocomium splendens* and *Pleurozium schreberi*. *Sphagnum* spp. may be abundant on sites with restricted drainage. Plant communities in this system are described by DeVelice et al. (1999).
Dynamics: The major disturbance processes are soil creep, blowdown, snow avalanche, and fungal pathogens. Fire is infrequent in this system and the fire regime has not been defined, but estimates of the mean fire-return interval for lower elevation mountain hemlock zones range from 600 to greater then 1500 years (Lertzman and Krebs 1991, Potkin 1997). Treeline appears to be advancing upward in some areas; with young stems further up the hill from older ones (P. Hennon pers. obs.).

Component Associations:
- *Tsuga mertensiana / Cassiope mertensiana / Nephrophyllidium crista-galli* Woodland (CEGL003252, G5)
- *Tsuga mertensiana / Cassiope mertensiana* Woodland (CEGL003251, G5)
- *Tsuga mertensiana / Elliottia pyroliflorus* Woodland (CEGL003248, G4G5)
- *Tsuga mertensiana / Phyllodoce aleutica / Nephrophyllidium crista-galli* Woodland (CEGL003250, GNR)
- *Tsuga mertensiana / Vaccinium ovalifolium - Harrimanella stelleriana* Woodland (CEGL003246, G5)

DISTRIBUTION

Range: This system occurs primarily at the elevational limit of tree growth in the mountain ranges along the Gulf Coast of Alaska, including the Kenai, Chugach, St. Elias, Fairweather, and Coast mountains. It occurs from the Kenai Fjords to southeastern Alaska and British Columbia.

ALASKAN PACIFIC MARITIME WESTERN HEMLOCK FOREST (CES204.840)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Temperate [Temperate Oceanic]
Non-Diagnostic Classifiers: Montane [Montane]; Montane [Lower Montane]; Very Long Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2646; ESLF 4276; ESP 1646

CONCEPT

Summary: This forested ecological system is the dominant *Tsuga heterophylla* forest system along the northern portions of the Pacific Northwest Coast. It occurs from coastal British Columbia (north of the northern limit of *Pseudotsuga menziesii*) through southeast Alaska to Prince William Sound (the northwest limit of *Tsuga heterophylla*). This system ranges from sea level to about 610 m (0-2000 feet) elevation. The climate is wet with heavy snow and rainfall, but sites occupied are typically well-drained. The dominant upper canopy species is *Tsuga heterophylla* or a mix of *Picea sitchensis* and *Tsuga heterophylla*. In the northern portion of the region (Yakutat through Prince William Sound), *Tsuga mertensiana* may also be present in the canopy. *Chamaecyparis nootkatensis* may be present in the canopy in southeastern Alaska (Glacier Bay to British Columbia?) but is rare in this system in Prince William Sound (the northwestern limit of *Chamaecyparis nootkatensis*). The shrub layer is often dominated by *Vaccinium ovalifolium*, with *Menziesia ferruginea* usually present; *Rubus spectabilis* and *Oplopanax horridus* are also common. *Lysichiton americanus* occurs in poorly drained depressions. Other common forbs include *Rubus pedatus, Streptopus amplexifolius, Cornus canadensis*, and *Tiarella trifoliata*. *Dryopteris expansa* is common in well-drained, relatively nutrient-rich sites. Other common ferns include *Gymnocarpium dryopteris, Blechnum spicant*, and *Dryopteris expansa*. Disturbed sites, such as V-notches, can have abundant *Rubus spectabilis* or *Oplopanax horridus* dominating the undergrowth. Sites may receive very infrequent catastrophic disturbance leading to large older trees and multiple canopy layers where western hemlock regeneration is favored. Diseases including dwarf mistletoe and heart rot fungi perpetuate the hemlock-dominated old-growth condition. On other sites, wind disturbance yields forests approaching an even-aged condition dominated by *Tsuga heterophylla* but with a component of *Picea sitchensis*.
Classification Comments: This includes Western Hemlock - Sitka Spruce Forest initially identified for the Alaska Maritime systems classification. Wetter sites with open canopies are classified as Alaskan Pacific Maritime Poorly Drained Conifer Woodland (CES204.315). At lower elevations, these forests occur at sea level or adjacent to hypermaritime forests dominated by *Picea sitchensis*. At higher elevations in southeastern Alaska, associations can be dominated by *Chamaecyparis nootkatensis* with some *Tsuga heterophylla* forming North Pacific Mesic Western Hemlock-Yellow-cedar Forest (CES204.843), which can be considered transitional into North Pacific Mountain Hemlock Forest (CES204.838) further south in British Columbia and Washington. In southeastern Alaska, this system occurs on slightly more productive sites than North Pacific Hypermaritime Western Red-cedar-Western Hemlock Forest (CES204.842). Throughout its northern extent (Prince William Sound), this system occurs adjacent to Alaskan Pacific Maritime Mountain Hemlock Forest (CES204.142), which occurs in lower as well as higher elevation sites.
Similar Ecological Systems:
- North Pacific Dry-Mesic Silver Fir-Western Hemlock-Douglas-fir Forest (CES204.098)
- North Pacific Mesic Western Hemlock-Silver Fir Forest (CES204.097)
- North Pacific Mesic Western Hemlock-Yellow-cedar Forest (CES204.843)

DESCRIPTION

Environment: This system ranges from sea level to about 610 m (0-2000 feet) elevation. The climate is wet with heavy snow and rainfall, but sites occupied are typically well-drained.
Vegetation: The dominant upper canopy species is *Tsuga heterophylla* or a mix of *Picea sitchensis* and *Tsuga heterophylla*. In the northern portion of the region (Yakutat through Prince William Sound), *Tsuga mertensiana* may also be present in the canopy. *Chamaecyparis nootkatensis* may be present in the canopy in southeastern Alaska (Glacier Bay to British Columbia?) but is rare in this system in Prince William Sound (the northwestern limit of *Chamaecyparis nootkatensis*). The shrub layer is often dominated by *Vaccinium ovalifolium*, with *Menziesia ferruginea* usually present; *Rubus spectabilis* and *Oplopanax horridus* are also common. *Lysichiton americanus* occurs in poorly drained depressions. Other common forbs include *Rubus pedatus, Streptopus amplexifolius,*

Cornus canadensis, and *Tiarella trifoliata*. *Dryopteris expansa* is common in well-drained, relatively nutrient-rich sites. Other common ferns include *Gymnocarpium dryopteris*, *Blechnum spicant*, and *Dryopteris expansa*. Disturbed sites, such as V-notches, can have abundant *Rubus spectabilis* or *Oplopanax horridus* dominating the undergrowth.
Dynamics: Sites may receive very infrequent catastrophic disturbance leading to large older trees and multiple canopy layers where western hemlock regeneration is favored. Diseases including dwarf mistletoe and heart rot fungi perpetuate the hemlock-dominated old-growth condition (Hennon and McClellan 2003). On other sites, wind disturbance yields forests approaching an even-aged condition dominated by *Tsuga heterophylla* but with a component of *Picea sitchensis*.

Component Associations:
- *Tsuga heterophylla* / Moss Forest (CEGL003238, G4G5)
- *Tsuga heterophylla / Oplopanax horridus - Gymnocarpium dryopteris* Forest (CEGL003234, G5)
- *Tsuga heterophylla / Oplopanax horridus - Rubus spectabilis* Forest (CEGL003233, G4Q)
- *Tsuga heterophylla / Oplopanax horridus / Lysichiton americanus* Forest (CEGL003235, G4G5)
- *Tsuga heterophylla / Vaccinium ovalifolium - Menziesia ferruginea* Forest (CEGL003236, G4)
- *Tsuga heterophylla / Vaccinium ovalifolium - Oplopanax horridus* Forest (CEGL003232, G5)
- *Tsuga heterophylla / Vaccinium ovalifolium - Rubus pedatus* Forest (CEGL003229, G5)
- *Tsuga heterophylla / Vaccinium ovalifolium / Dryopteris expansa* Forest (CEGL003230, G5)
- *Tsuga heterophylla / Vaccinium ovalifolium / Lysichiton americanus* Woodland (CEGL003231, G5)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Alaskan Pacific Maritime Sitka Spruce Forest (CES204.151)
- North Pacific Mesic Western Hemlock-Silver Fir Forest (CES204.097)
- North Pacific Mesic Western Hemlock-Yellow-cedar Forest (CES204.843)

DISTRIBUTION

Range: This system is found along the Pacific Northwest Coast, occupying much of the elevations in the Coast and Cascade mountains of British Columbia and southeastern Alaska (south of Prince William Sound, the northwestern limit of *Tsuga heterophylla*), from sea level to about 610 m (0-2000 feet) elevation.
Divisions: 204:C

ALEUTIAN KENAI BIRCH-COTTONWOOD-POPLAR FOREST (CES105.146)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Forest and Woodland (Treed); Populus balsamifera
Non-Diagnostic Classifiers: Moraine; Slope; Terrace
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2642; ESLF 4161; ESP 1642

CONCEPT

Summary: These hardwood-dominated forests are common on the eastern Alaska Peninsula and on Kodiak Island. This system occurs at low elevations and also at the upper elevational limit of broad-leaved trees. At low elevations it is found predominantly on well-drained, gentle lower hillslopes, large moraines, and old riparian terraces, although floodplain stands of cottonwood are not included in this system. Patch size is typically small to large. Total hardwood tree species cover is >25% and dominated by *Betula papyrifera var. kenaica, Betula papyrifera, Populus balsamifera ssp. trichocarpa*, or *Populus balsamifera*. Tree height ranges from 6 to 21 m. Understory shrubs include *Alnus viridis ssp. sinuata, Salix barclayi, Rubus spectabilis*, and *Sambucus racemosa*. Herbaceous species may also dominate the understory, such as *Athyrium filix-femina, Calamagrostis canadensis, Calamagrostis lapponica, Chamerion angustifolium ssp. angustifolium, Equisetum* spp., *Gymnocarpium dryopteris*, and *Heracleum maximum.*
Classification Comments: This system combines those known as Kenai Birch Forest and Black Cottonwood-Balsam Poplar Forest by the Alaska Natural Heritage Program. Floristics in plots from the Alaska Peninsula suggest two proposed systems should be merged. This concept includes both the Aleutian Kenai Birch and Aleutian Black Cottonwood-Balsam Poplar Forest types. However, it may also be appropriate to combine this with hardwood forests from the boreal transition region into a new "Alaska Sub-boreal Hardwood Forest" system, that includes Kenai birch, balsam poplar and black cottonwood, along with aspen. More review is needed to resolve this; for now, this Aleutian hardwood system remains a distinct type, and the boreal transition hardwood system stays combined with Western North American Boreal Mesic Birch-Aspen Forest (CES105.108).

ALLEGHENY-CUMBERLAND DRY OAK FOREST AND WOODLAND (CES202.359)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Acidic Soil; Broad-Leaved Tree
Non-Diagnostic Classifiers: Lowland; Forest and Woodland (Treed)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2317; ESLF 4123; ESP 1317

CONCEPT

Summary: This system encompasses dry hardwood forests on predominately acidic substrates in the Allegheny and Cumberland plateaus, and ridges in the southern Ridge and Valley. Its range is more or less consistent with the "Mixed Mesophytic Forest Region" of Braun (1950) and Greller (1988), although it is not a mesic forest type. These forests are typically dominated by *Quercus alba, Quercus falcata, Quercus prinus, Quercus coccinea*, with lesser amounts of *Acer rubrum*, *Carya glabra*, and *Carya alba*. Small inclusions of *Pinus echinata* and/or *Pinus virginiana* may occur, particularly adjacent to escarpments or following fire. In addition, *Pinus strobus* may be prominent in some stands in the absence of fire. It occurs in a variety of situations, including on nutrient-poor or acidic soils. Sprouts of *Castanea dentata* can often be found where it was formerly a common tree.
Classification Comments: Related forests on more base-rich substrates may be classified as examples of Southern Ridge and Valley / Cumberland Dry Calcareous Forest (CES202.457), where this distinction may be made. Eastward and northward, this system transitions into Central Appalachian Dry Oak-Pine Forest (CES202.591). The dividing line between them is the Allegheny Front.
Similar Ecological Systems:
- Central Appalachian Dry Oak-Pine Forest (CES202.591)--occurs to the east of this system's range.
- Northeastern Interior Dry-Mesic Oak Forest (CES202.592)
- Southern Appalachian Low-Elevation Pine Forest (CES202.332)
- Southern Appalachian Oak Forest (CES202.886)--is a related broader and overlapping concept (conceptually and geographically).
- Southern Interior Low Plateau Dry-Mesic Oak Forest (CES202.898)
- Southern Ridge and Valley / Cumberland Dry Calcareous Forest (CES202.457)--is found in some similar landscapes but on more base-rich substrates, which usually correspond to different landform positions.

Related Concepts:

DESCRIPTION

Environment: This system is most likely found on predominantly nutrient-poor or acidic substrates in the Allegheny and Cumberland plateaus, and ridges in the southern Ridge and Valley.
Vegetation: These forests are typically dominated by *Quercus alba, Quercus falcata, Quercus prinus, Quercus coccinea, Acer rubrum, Carya glabra*, and *Carya alba*. These occur in a variety of situations, most likely on nutrient-poor or acidic soils and, to a much lesser extent, on circumneutral soils. Sprouts of *Castanea dentata* can often be found where it was formerly a common tree. Small inclusions of *Pinus echinata* and/or *Pinus virginiana* may occur, particularly adjacent to escarpments or following fire. In addition, *Pinus strobus* may be prominent in some stands in the absence of fire.

Component Associations:
- *Pinus rigida - Quercus coccinea / Vaccinium angustifolium* Woodland (CEGL006557, G4Q)
- *Pinus strobus - Quercus (coccinea, prinus) / (Gaylussacia ursina, Vaccinium stamineum)* Forest (CEGL007519, G4)
- *Pinus strobus - Quercus alba - (Carya alba) / Gaylussacia ursina* Forest (CEGL007517, G3G4)
- *Pinus virginiana - Pinus (rigida, echinata) - (Quercus prinus) / Vaccinium pallidum* Forest (CEGL007119, G3)
- *Quercus alba - (Quercus prinus) / (Hydrangea quercifolia) - Viburnum acerifolium / Carex picta - Piptochaetium avenaceum* Forest (CEGL008430, G3G4)
- *Quercus alba - Carya alba - (Quercus velutina) / Desmodium nudiflorum - (Carex picta)* Forest (CEGL007795, G4)
- *Quercus alba - Quercus (coccinea, velutina, prinus) / Gaylussacia baccata* Forest (CEGL008521, G5)
- *Quercus alba - Quercus falcata / Vaccinium (arboreum, hirsutum, pallidum)* Forest (CEGL008567, G3G4)
- *Quercus alba - Quercus rubra - Carya ovata / Cercis canadensis - Juniperus virginiana var. virginiana* Forest (CEGL007240, G4)

- *Quercus alba - Quercus stellata / Ostrya virginiana - Acer barbatum / Chasmanthium sessiliflorum* Forest (CEGL008443, G3G4)
- *Quercus alba - Quercus velutina - Carya (ovata, alba, glabra) - Pinus* sp. Forest (CEGL007231, G4G5)
- *Quercus falcata - Quercus (coccinea, stellata) / Vaccinium (pallidum, stamineum)* Forest (CEGL007247, G4)
- *Quercus falcata - Quercus alba - Carya alba / Oxydendrum arboreum / Vaccinium stamineum* Forest (CEGL007244, G4G5)
- *Quercus prinus - (Quercus coccinea) / Carya pallida / Vaccinium arboreum - Vaccinium pallidum* Forest (CEGL008431, G4G5)
- *Quercus prinus - Carya (alba, glabra, ovata) / Juniperus virginiana var. virginiana* Forest (CEGL004786, G2G3)
- *Quercus prinus - Carya* spp. *- Quercus velutina / Vaccinium arboreum / Iris verna var. smalliana* Forest (CEGL007261, G3G4)
- *Quercus prinus - Quercus (alba, coccinea, velutina) / Viburnum acerifolium - (Kalmia latifolia)* Forest (CEGL005023, G4?)
- *Quercus prinus - Quercus rubra - Carya (ovata, glabra) - Pinus virginiana* Forest (CEGL007269, G4?)
- *Quercus prinus - Quercus* spp. / *Vaccinium arboreum - (Kalmia latifolia, Styrax grandifolius)* Forest (CEGL007700, G4)
- *Quercus stellata - Pinus virginiana / (Schizachyrium scoparium, Piptochaetium avenaceum)* Woodland (CEGL008406, G2?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- South-Central Interior Mesophytic Forest (CES202.887)

Adjacent Ecological System Comments: The somewhat more mesic and/or more base-rich forests of the lower slopes of the Cumberlands and the lower slopes and valleys in the Ridge and Valley are covered by South-Central Interior Mesophytic Forest (CES202.887).

DISTRIBUTION

Range: This system is centered on the Allegheny and Cumberland plateaus from northern Alabama north to Ohio, West Virginia, and possibly western Pennsylvania.
Divisions: 202:C
Nations: US

APPALACHIAN (HEMLOCK)-NORTHERN HARDWOOD FOREST (CES202.593)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Mesotrophic Soil; Needle-Leaved Tree; Broad-Leaved Deciduous Tree; Pinus spp. - Tsuga canadensis
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Lowland; Forest and Woodland (Treed); Sideslope; Toeslope/Valley Bottom; Temperate; Acidic Soil; Shallow Soil; Deep Soil; Mineral: W/ A-Horizon >10 cm; Ustic; Long Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2370; ESLF 4313; ESP 1370

CONCEPT

Summary: This forested system of the eastern U.S. ranges from central New England west to Lake Erie and south to the higher elevations of Virginia and West Virginia. It is one of the matrix forest types in the northern part of the Central Interior and Appalachian Division. Northern hardwoods such as *Acer saccharum, Betula alleghaniensis,* and *Fagus grandifolia* are characteristic, either forming a deciduous canopy or mixed with *Tsuga canadensis* (or in some cases *Pinus strobus*). Other common and sometimes dominant trees include *Quercus* spp. (most commonly *Quercus rubra*), *Liriodendron tulipifera, Prunus serotina, Acer rubrum*, and *Betula lenta*. It is of more limited extent and more ecologically constrained in the southern part of its range in northern parts of Virginia and West Virginia.
Classification Comments: Northward this system is replaced by Laurentian-Acadian Pine-Hemlock-Hardwood Forest (CES201.563) and Laurentian-Acadian Northern Hardwood Forest (CES201.564), but the systems overlap on the Allegheny Plateau and in central New England. USFS ecological province lines provide a general delimiter, with areas in Provinces 211 and M211 mostly falling into the Laurentian-Acadian systems, and areas in Provinces 221 and M221 falling into this Appalachian system. The range of *Liriodendron tulipifera* is a good approximator for the northern limit of this system's range.
Similar Ecological Systems:
- Laurentian-Acadian Northern Hardwood Forest (CES201.564)
- Laurentian-Acadian Pine-Hemlock-Hardwood Forest (CES201.563)--found to the north and northeast of this system.
- North-Central Interior Beech-Maple Forest (CES202.693)
- South-Central Interior Mesophytic Forest (CES202.887)
- Southern and Central Appalachian Cove Forest (CES202.373)
- Southern Appalachian Northern Hardwood Forest (CES202.029)

DESCRIPTION

Environment: This system occurs predominantly on mesic sites over a broad range of topographic conditions, such as protected low and midslopes and valley bottoms, at elevations from 305 to 1360 m. Soils are usually acidic and retain some moisture except during

severe droughts. They are moderately well-drained to well-drained loamy or silty soils, and are rocky and usually deep in depressions among boulders. Forests in this system are also associated with high-elevation periglacial boulderfields. In the Central Appalachian center of its range, its ecological amplitude is somewhat broader, and it becomes the matrix forest in some areas of Pennsylvania, Maryland, West Virginia. At Shenandoah National Park, this system spans a broad range of environmental settings from steep west-facing slopes to south-facing gentle slopes.

Vegetation: The canopy is characterized and often usually dominated by northern hardwoods (e.g., *Fagus grandifolia* and *Acer saccharum*), often with *Tsuga canadensis*, but may also contain large amounts of *Pinus strobus* and *Quercus* spp. *Tsuga canadensis* can dominate the canopy on cool/moist sites at higher elevations and in shaded coves, valley bottoms and riparian areas. Bottomlands and toeslopes may also contain *Fraxinus americana*, as well as *Platanus occidentalis* (Whitney 1990). Other common associates may include *Acer rubrum, Prunus serotina, Betula lenta, Tilia americana, Pinus strobus, Liriodendron tulipifera, Quercus* spp., and *Magnolia acuminata*. The subcanopy and shrub layers are usually well-developed and may include *Viburnum lantanoides (= Viburnum alnifolium), Viburnum acerifolium, Hamamelis virginiana*, and *Cornus alternifolia*. A dense, low to high shrub layer of *Rhododendron maximum* and sometimes *Kalmia latifolia* is sometimes present. Common herbaceous species include *Maianthemum canadense, Onoclea sensibilis, Huperzia lucidula (= Lycopodium lucidulum), Dryopteris carthusiana (= Dryopteris spinulosa), Oxalis montana*, and *Mitchella repens* (Lutz 1930, Braun 1950).

Dynamics: In general, this system is dominated by long-lived, mesophytic species that form multi-layered uneven-aged forests. Canopy dynamics are dominated by single and multiple disturbances encouraging gap phase regeneration (Abrams and Orwig 1996). Larger disturbances include windthrow, insect attack and ice storms. Although stand-replacing wind events are rare, small to medium blowdown events are more common and occur at greater frequency on the plateau and exposed sideslopes (Ruffner and Abrams 2003).This system is currently being devastated in large parts of its range by the hemlock woolly adelgid (*Adelges tsugae*). This sucking insect is continuing to cause close to 100% mortality in some areas as it spreads from the north into the southern United States. The insect will most likely cause canopy hemlocks to be replaced by other canopy trees. Historically, this system was probably only subject to occasional fires. Fires that did occur may have been catastrophic and may have led to even-aged stands of pine and hemlock. Fire suppression appears to have increased the extent of this system at the expense of oak-pine systems.

Fire Regime Description (from Landfire 2007a): Historically, this system was probably only subject to occasional fires. Fires that did occur may have been catastrophic and may have led to even-aged stands of pine and hemlock. Due to the predominance of cool, moist site conditions, surface and replacement fires are extremely rare, occurring at 700- to 1000-year intervals. Most protected sites are essentially fire-free. The principal cause of fuel formation leading to fire in northern hardwood ecosystems is broad-scale, storm-driven windthrow of catastrophic proportions (Hough 1936, Runkle 1982). The importance of red maple, sweet birch, northern red oak, and especially black cherry in contemporary Central Appalachian examples of this community group reflects secondary succession following catastrophic logging and fire disturbances in the early part of the twentieth century. Sugar maple and beech, both abundant in understory layers and locally codominant in the overstory, appear positioned to assume dominance as current secondary stands mature. However, beech bark disease and excessive deer browsing are serious threats to the future viability of the largest stands on Allegheny Mountain (VDNH 2007).

Component Associations:

- *Acer saccharum - (Fraxinus americana) / Arisaema triphyllum* Forest (CEGL006211, G4)
- *Acer saccharum - Betula alleghaniensis - Fagus grandifolia / Viburnum lantanoides* Forest (CEGL006252, G5)
- *Acer saccharum - Betula alleghaniensis - Prunus serotina* Forest (CEGL006045, G4)
- *Acer saccharum - Fraxinus americana - Juglans cinerea / Staphylea trifolia / Adlumia fungosa* Forest (CEGL006577, GNR)

- *Tsuga canadensis - Fagus grandifolia - Acer saccharum / (Hamamelis virginiana, Kalmia latifolia)* Forest (CEGL005043, G3?)
- *Tsuga canadensis - Fagus grandifolia - Quercus (prinus, alba)* Forest (CEGL006474, G2G3)
- *Tsuga canadensis - Fagus grandifolia - Quercus rubra* Forest (CEGL006088, G4G5)

Spatial Characteristics

Spatial Summary: Matrix in the northern portion of its range to large patch on the southern end of its range in Virginia and West Virginia.
Size: Some examples may be more than 1000 acres, but smaller in the southern part of the range.
Adjacent Ecological Systems:
- High Allegheny Wetland (CES202.069)
- Northeastern Interior Dry-Mesic Oak Forest (CES202.592)

Adjacent Ecological System Comments: The concept of this system was revised in April 2007 to remove areas south and west of Virginia and West Virginia from its range; hemlock and mixed coves in that southern range are now within Southern and Central Appalachian Cove Forest (CES202.373), and small areas of non-cove hemlock are to be considered patches within the surrounding forest matrix system. The Region 8 National Forests and other Federal lands, as well as ecoregions and mapzones related to this area were also removed.

Distribution

Range: This system is found from southern New Hampshire south to Virginia and West Virginia, and possibly in adjacent Kentucky.
Divisions: 202:C
Nations: US
Subnations: CT, KY?, MA, MD, NH, NJ, NY, OH?, PA, VA, WV
Map Zones: 53:C, 60:C, 61:C, 62:C, 63:C, 64:C, 65:C, 66:C
USFS Ecomap Regions: 211E:CC, 211Fc:CCC, 211Fd:CCC, 211G:CC, 221Aa:CCC, 221B:CC, 221D:CC, 221E:CC, 221F:CC, 222I:CC, M221A:CC, M221B:CC, M221C:CC, M221D:CC
TNC Ecoregions: 48:C, 49:C, 52:C, 59:C, 60:C, 61:C

APPALACHIAN SHALE BARRENS (CES202.598)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Sideslope; Talus (Substrate); Unglaciated; Unconsolidated
Non-Diagnostic Classifiers: Lowland; Ridge/Summit/Upper Slope; Temperate; Acidic Soil; Very Shallow Soil; Ustic; Landslide
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2340; ESLF 4147; ESP 1340

CONCEPT

Summary: This system encompasses the distinctive shale barrens of the central and southern Appalachians at low to mid elevations. The exposure and lack of soil create extreme conditions for plant growth. Vegetation is mostly classified as woodland, overall, but may include large open areas of sparse vegetation. Dominant trees are primarily *Quercus prinus* and *Pinus virginiana*, although on higher-pH substrates the common trees include *Juniperus virginiana* and *Fraxinus americana*. Shale barren endemics are diagnostic in the herb layer. The substrate includes areas of solid rock as well as unstable areas of shale scree, usually steeply sloped. The fully exposed areas are extremely dry. These barrens are high in endemic species.
Classification Comments: Examples of related barrens in the "Knobs" region of Kentucky are included in Central Interior Highlands Dry Acidic Glade and Barrens (CES202.692), not here. The southern range limit is not completely clear. "Central Appalachian Shale Barrens" (sensu VDNH) are the "core" concept. The bluestone shale barrens of West Virginia are placed in this system even though many of the endemics are not present there; the same is true at the northern periphery of this system in Pennsylvania.
Similar Ecological Systems:
- Central Appalachian Pine-Oak Rocky Woodland (CES202.600)
- Central Interior Highlands Dry Acidic Glade and Barrens (CES202.692)
- Southern and Central Appalachian Mafic Glade and Barrens (CES202.348)
- Southern Appalachian Montane Cliff and Talus (CES202.330)

Related Concepts:
- Central Appalachian Shale Barrens (Fleming et al. 2004) Finer
- Chestnut Oak: 44 (Eyre 1980) Finer
- Virginia Pine: 79 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is found at low to mid elevations in the central and southern Appalachians. Most shale barrens occur between 305 and 610 m (1000-2000 feet) elevation and have a generally southern exposure. Slopes are steep and often undercut by a stream at the base. Soils are thin, with a layer weathered rock fragments covering the surface. The exposure and lack of soil create extreme conditions for plant growth. The chemistry and pH vary somewhat from site to site, and this variability may be reflected in the vegetation. The substrate includes areas of solid rock as well as unstable areas of shale scree, usually steeply sloped.
Vegetation: Although stunted trees of several species such as *Quercus prinus, Pinus virginiana*, and *Carya glabra* are common, Central Appalachian Shale Barrens are strongly characterized by their open physiognomy and by a suite of uncommon and rare plants found almost exclusively in these habitats (Fleming et al. 2004). Endemic or near-endemic shale barren species include shale-barren rock-cress (*Arabis serotina*), white-haired leatherflower (*Clematis albicoma*), Millboro leatherflower (*Clematis viticaulis*; also endemic to Virginia), shale-barren wild buckwheat (*Eriogonum allenii*), shale-barren evening-primrose (*Oenothera argillicola*), shale-barren ragwort (*Packera antennariifolia*), and Kate's Mountain clover (*Trifolium virginicum*). Other more-or-less widespread and characteristic herbaceous species of Virginia shale barrens include Pennsylvania sedge (*Carex pensylvanica*), little bluestem (*Schizachyrium scoparium*), poverty oatgrass (*Danthonia spicata*), wavy hairgrass (*Deschampsia flexuosa var. flexuosa*), moss phlox (*Phlox subulata*), mountain nailwort (*Paronychia montana*), rock spike-moss (*Selaginella rupestris*), shale-barren pussytoes (*Antennaria virginica*), Canada cinquefoil (*Potentilla canadensis*), smooth sunflower (*Helianthus laevigatus*), false boneset (*Brickellia eupatorioides var. eupatorioides*), hairy woodmint (*Blephilia ciliata*), and western wallflower (*Erysimum capitatum var. capitatum*; Bath and Alleghany counties).

Component Associations:
- *(Pinus virginiana, Juniperus virginiana) / Schizachyrium scoparium - Eriogonum allenii* Wooded Herbaceous Vegetation (CEGL008530, G2)
- *Juniperus virginiana - Fraxinus americana / Carex pensylvanica - Cheilanthes lanosa* Wooded Herbaceous Vegetation (CEGL006037, G2)
- *Pinus virginiana - Juniperus virginiana - Quercus rubra / Solidago arguta var. harrisii - Opuntia humifusa* Woodland (CEGL006288, G3)
- *Pinus virginiana - Quercus prinus / Packera antennariifolia - Phlox subulata* Woodland (CEGL006562, G3G4)
- *Pinus virginiana - Quercus prinus / Quercus ilicifolia / (Hieracium greenii, Viola pedata)* Woodland (CEGL008525, G3)

- *Pinus virginiana / Vaccinium pallidum / Schizachyrium scoparium - Carex pensylvanica* Woodland (CEGL003624, G2)
- *Quercus prinus - Juniperus virginiana - (Pinus virginiana) / Philadelphus hirsutus - Celtis occidentalis* Woodland (CEGL007720, G2)
- *Quercus prinus / Quercus ilicifolia / Danthonia spicata* Woodland (CEGL008526, G3?)

DISTRIBUTION

Range: This system is found from southern Pennsylvania south to Virginia and extreme eastern Tennessee. Application of the concept south of Virginia is uncertain. It is not attributed to Kentucky.
Divisions: 202:C

ATLANTIC BOREAL BALSAM FIR WET FOREST (CES103.433)

CLASSIFIERS

Classification Status: Standard

Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
National Mapping Codes: ESLF 4406

CONCEPT

Summary: This ecological system represents the climatically wet boreal forests of Atlantic Canada, found in southern Newfoundland and coastal areas of Labrador. The low-elevation forests are dominated by *Abies balsamea*, with *Picea glauca, Picea mariana*, and *Betula papyrifera var. cordifolia (= Betula cordifolia)* present. Trees are relatively short-statured, rarely exceeding 15 m. With increasing age, the fir-dominated forests may develop a high diversity and biomass of lichens, along with epiphytic mosses. The ground moss layer ranges from discontinuous to continuous. Because of the wet conditions, these forests have little to no history of fire. Insects, fungal diseases, and wind are the main natural disturbance factors, leading to the formation of patchy, multi-aged stands.
Classification Comments: The separation of these Atlantic boreal forests from other eastern Canadian boreal forests has been proposed by the Canadian NVC Technical Committee (K. Baldwin pers. comm. 2012), at either the macrogroup or group level. These forests differ from Eastern Boreal Balsam Fir - White Spruce - White Birch Forest Group (G638), in that they have a wet climate, fire is essentially absent, trees are short-statured, and strongly dominated by *Abies balsamea*, and epiphytic lichen cover is high. Other distinctive aspects of their flora are under review by the Canadian NVC Technical Committee (K. Baldwin pers. comm. 2012). These forests have recently been referred to as "boreal rainforests" and, more technically, as "perhumid boreal forests" (Clayden et al. 2011). The authors provide an extended summary of the climatic characteristics of these forests. They also discuss the potential for recognition of "perhumid hemi-boreal forests" of eastern Canada, including the red spruce-northern hardwoods, and even eastern hemlock types, but they note that these perhumid stands occur in an eastern humid climate, and it is not clear whether they warrant a distinctly "perhumid sector." Those "hemi-boreal" forests are included within Northern Mesic Hardwood & Conifer Forest Macrogroup (M014), belonging to either Sub-Boreal Mesic Fir - Yellow Birch - Hardwoods Forest Group (G629), Northern Appalachian & Acadian Red Spruce - Fir - Hardwoods Forest Group (G024), or Northern Hemlock - White Pine - Hardwoods Forest Group (G163).

A separate aspen-birch system is not recognized in this region; and this system is directly comparable to the group concept (G674).
Similar Ecological Systems:
- Eastern Boreal Balsam Fir-White Spruce-Paper Birch Forest (CES103.421)--contains the more continental eastern boreal forests where balsam fir is also a dominant.
- Laurentian-Acadian Sub-boreal Mesic Balsam Fir-Spruce Forest (CES103.426)--Extension of this hemi-boreal system into Newfoundland is under review.

Related Concepts:
- Balsam Fir: 5 (Eyre 1980) Finer
- Perhumid Boreal Forests of Eastern Canada (Clayden et al. 2011) Undetermined

DESCRIPTION

Environment: The climate is wet, resulting from a combination of humid continental air masses interacting with coastal oceanic conditions and relatively low air temperatures. Clayden et al. (2011) describe the climate as "perhumid" (based on Thornthwaite (1948) categories); that is, a climate in which precipitation much exceeds evaporation and plant transpiration, resulting in year-round wetness. Perhumid areas may undergo short periods during an average year when water losses exceed water gains, but these are offset by abundant moisture in adjacent months. Thornthwaite index values in this region are greater than 100 (Clayden et al. 2011, cf. Rowe 1972, p. 155). In eastern Canada, annual precipitation is mostly in the range of 1000 to 1600 mm, though locally some areas receive between 1600 and 1800 mm annually. The wetness is a consequence of major airstreams and oceanic currents along the coast. In the coastal areas, over 85% of the precipitation falls as rain; in higher elevation areas, snow may account for half of the precipitation. Fog also contributes to the wet conditions, increasing the precipitation levels and decreasing evapotranspiration. Temperate conditions are cool, with a mean annual temperate of 1-4 degrees C. Because continental airflows dominate the region, seasonal temperature variations are higher than in western North America, but moderated by the ocean.
Vegetation: The low-elevation forests are dominated by *Abies balsamea*, with *Picea glauca, Picea mariana, Betula papyrifera, Betula papyrifera var. cordifolia (= Betula cordifolia)*, and *Populus tremuloides* present. Trees are relatively short-statured, rarely exceeding 15 m. *Abies balsamea* also typically dominates the shrub layer. Common herbs include *Coptis trifolia (= Coptis groenlandica), Epigea repens, Goodyera repens, Listera cordata*, and *Streptopus lanceolatus (= Streptopus roseus)*, especially in old-growth stands. With increasing age, the fir-dominated forests may develop a high diversity and biomass of lichens, along with epiphytic mosses. The lichen composition is reflective of wet conditions, with analogues to oceanic wet sites in other boreal regions (Clayden et al. 2011). One of the common epiphytic mosses of West Coast rainforests, *Antitrichia curtipendula*, has its only known eastern North American occurrence in the wet forests of southern Newfoundland. Ground moss layer ranges from discontinuous to continuous, and is dominated by *Pleurozium schreberi, Hylocomium splendens*, and *Sphagnum* spp. (Thompson et al. 2003). *Rhytidiadelphus loreus* (lanky moss) is a common and distinctive moss, not found in balsam fir forests of more continental areas

(Clayden et al. 2011).
Dynamics: Because of the wet conditions, these forests have little to no history of fire, with fire intervals exceeding 500 to 1000 years (Thompson et al. 2003, Bouchard et al. 2008). Insects, fungal diseases, and wind are the main natural disturbance factors. Average gap size and stand age-class structure vary, depending on the frequency of such disturbances. Small disturbances are the most common, creating patchy, multi-aged stands across the landscape. Large disturbances may be created by hurricane storms in late summer or fall. *Abies balsamea* is capable of persisting as suppressed saplings in the understory of mature stands, and they can quickly dominate recently disturbed sites. Old-growth characteristics include high volume of snags and coarse woody debris, and high lichen loads, among others. These forests are now considerably altered from the natural patch structure, with large gaps and young stands created by clear-cut logging (Thompson et al. 2003).

DISTRIBUTION

Range: This system is found in eastern Canada, on Newfoundland and Labrador.
Nations: CA
Subnations: LB, NF

ATLANTIC COASTAL PLAIN FALL-LINE SANDHILLS LONGLEAF PINE WOODLAND (CES203.254)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Very Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2346; ESLF 4249; ESP 1346

CONCEPT

Summary: This system occurs in the Fall-line Sandhills region of central North Carolina south and west into central Georgia. It is the predominant system in its range, covering most of the natural landscape of the region. It occurs on upland sites ranging from gently rolling, broad ridgetops to steeper sideslopes, as well as locally in mesic swales and terraces. Most soils are well-drained to excessively-drained. The vegetation is naturally dominated by *Pinus palustris*. Most associations have an understory of scrub oaks (*Quercus laevis*, *Quercus marilandica*, *Quercus incana*, and *Quercus margarettiae*). The herb layer is generally well-developed and dominated by grasses. Wiregrasses (*Aristida stricta* in the north, *Aristida beyrichiana* in the south) dominate in most of the range, but other grasses dominate where these are absent. Forbs, including many legumes and composites, are also abundant. Frequent, low-intensity fire is the dominant natural ecological force.
Classification Comments: This system is distinguished from Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281) based on differences in landscape patterns, prevailing associations, and some floristic differences. Dissected topography with much higher relief, predominance of interbedded sands and clays, and interspersion with seepage wetlands all characterize the Fall-line Sandhills, in contrast to the low relief, pure sands or loams, and mosaics containing other wetland types in the rest of the Coastal Plain. Some matrix associations in the Fall-line Sandhills, such as *Pinus palustris / Quercus marilandica / Gaylussacia dumosa / Aristida stricta* Woodland (CEGL003595) are nearly absent in the rest of the Coastal Plain. The abundance of legumes in most Sandhills region associations and their scarcity in most Outer Coastal Plain associations is striking, and is probably related to the differences in prevailing soil texture. This system does not have a biogeographic break in southern South Carolina, as the Outer Coastal Plain systems do. It includes areas with both *Aristida stricta* and *Aristida beyrichiana*. Gopher tortoises (*Gopherus polyphemus*), used as a break in the Outer Coastal Plain systems because of their keystone species role, are not present in the Fall-line Sandhills. This system is distinguished from Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265) because of the ecological role of saturated wetland conditions in the latter.
Similar Ecological Systems:

DESCRIPTION

Environment: This system occurs on upland sites in the Fall-line Sandhills region (Ecoregion 65c of EPA (2004); 232Bq of Keys et al. (1995)). It covers the gently rolling, ancient eolian sands and the steeper side slopes in older formations that make up most of the dissected landscape in this region. Shallow swales, drier stream terraces, and rock outcrops also may support this system. Substrates include interbedded sands and clays, deep sands, and occasional loamy sediments. Soils are generally well- to excessively drained and infertile, though local richer, mesic sites occur. All soil types are underlain by a thick clay layer that impedes drainage and creates innumerable headwater creeks; the depth from the surface to this clay layer is very variable. Non-wetland conditions and frequent fire unify this system within the Fall-line Sandhills region. Soil texture appears to be the most important driver of differences among associations within the system, with biogeography also important.
Vegetation: Vegetation is a set of associations naturally dominated by longleaf pine (*Pinus palustris*). Scrub oaks (*Quercus laevis*, *Quercus marilandica*, *Quercus incana*, and *Quercus margarettiae*) form an understory in most associations, all but the mesic ones. Low shrubs, most ericaceous, may be abundant. In most of the range, wiregrass (*Aristida stricta* or in the south *Aristida beyrichiana*) is the dominant herb. In central South Carolina both species are absent and various other grass species dominate. Most associations have abundant legumes, as well as composites and other forbs. The abundance of legumes distinguishes this system from Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281), where most associations have few legumes. Many associations have moderate to high species richness, with most of the species in the herb layer. Some mesic associations have among the highest species richness values measured at the 1/10-hectare scale. Associations on deep, coarse sands may have low species richness but have a distinct set of xerophytic herbs and dwarf-shrubs.

Dynamics: Frequent fire is the predominant natural disturbance in this system. Component communities naturally burned every few years, many averaging as often as every 3 years. Fires are naturally low to moderate in intensity. They burn above-ground parts of herbs and shrubs, but have little effect on the fire-tolerant trees. Vegetation recovers very quickly from fires, with live herbaceous biomass often restored in just a few weeks. Many plants have their flowering triggered by burning. Fire is important in creating the structure of the vegetation. In the absence of fire, less fire-tolerant species increase and others invade the system. The scrub oaks and shrubs, kept to low density and mostly reduced to shrub size, become tall and dense and can suppress tree regeneration. Herb layer density and diversity decline. Only on the most excessively drained coarse sands does the vegetation not undergo substantial structural alteration and reduction in species richness after just a few years without burning. The often patchy nature of natural fires (and controlled burns) results in part from the abundance of streamheads that lace the Sandhills region and which tend to restrict fires from sweeping across large acreages.

Canopies are believed to naturally be multi-aged, consisting of a fine mosaic of small even-aged groves driven by gap-phase regeneration. *Pinus palustris* is shade-intolerant and slow to reach reproductive age, but is very long-lived. Most plants in these systems appear to be conservative, living a long time and only rarely sexually reproducing or colonizing new sites. Similar conservatism is shown by some of the vertebrates, such as Red-cockaded woodpecker (*Picoides borealis)*. Different dynamics occur in many insect populations, whose individuals are not resilient to fire and must recolonize burned areas from nearby unburned patches.

Component Associations:
- *Pinus palustris - (Pinus taeda) / Schizachyrium scoparium - Rhynchosia reniformis* Woodland (CEGL007738, G1)
- *Pinus palustris - Pinus (echinata, taeda) - Quercus (incana, margarettiae, falcata, laevis)* Woodland (CEGL007511, G4)
- *Pinus palustris / Aristida stricta - Sorghastrum nutans - Anthaenantia villosa* Woodland (CEGL003570, G2G3)
- *Pinus palustris / Quercus incana - Quercus marilandica / Aristida beyrichiana - Nolina georgiana* Woodland (CEGL007842, G2G3)
- *Pinus palustris / Quercus incana / Aristida stricta - Sorghastrum nutans - Anthaenantia villosa* Woodland (CEGL003578, G2G3)

- *Pinus palustris / Quercus marilandica / Gaylussacia dumosa / Aristida stricta* Woodland (CEGL003595, G2G3)
- *Pinus palustris / Quercus marilandica / Vaccinium crassifolium / Aristida stricta* Woodland (CEGL003599, G2?)
- *Pinus palustris / Vaccinium elliottii - Clethra alnifolia / Aristida stricta - Panicum virgatum* Woodland (CEGL003573, G1)

SPATIAL CHARACTERISTICS

Spatial Summary: This system is naturally a matrix system, covering most of the landscape in its range. Most occurrences now are artificially bounded remnants or naturally small islands. Extensive occurrences usually have embedded wetland systems, especially Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin, and Baygall (CES203.252).
Size: Natural patches once would have been contiguous over hundreds of square miles, covering most of the landscape in the region and broken only by river systems. Most occurrences are now artificially bounded remnants of small to fairly large size. A few landscape matrix areas of thousands of acres remain.
Adjacent Ecological Systems:
- Atlantic Coastal Plain Sandhill Seep (CES203.253)
- Atlantic Coastal Plain Small Blackwater River Floodplain Forest (CES203.249)
- Atlantic Coastal Plain Streamhead Seepage Swamp, Pocosin and Baygall (CES203.252)

Adjacent Ecological System Comments: Streamhead pocosins are the most frequently associated system, with Sandhill seeps and Atlantic Coastal Plain Small Blackwater River Floodplain Forest (CES203.249) also frequent associates.

DISTRIBUTION

Range: This system ranges from central North Carolina to central Georgia, in the Fall-line Sandhills region (Ecoregion 65c of EPA (2004); 232Bq of Keys et al. (1995)).
Divisions: 203:C
Nations: US
Subnations: GA, NC, SC

ATLANTIC COASTAL PLAIN UPLAND LONGLEAF PINE WOODLAND (CES203.281)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Very Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2347; ESLF 4250; ESP 1347

CONCEPT

Summary: This system of upland *Pinus palustris*-dominated vegetation is found in the Atlantic Coastal Plain of the United States, where it ranges from southern Virginia (where it is nearly extirpated and of very limited extent) to northeastern Florida. This system does not include *Pinus palustris* stands found in the Fall-line Sandhills, which are accommodated by another ecological system. Examples and associations share the common feature of upland (non-wetland) moisture regimes and natural exposure to frequent fire. They occur on a variety of well- to excessively drained soils, and on the higher parts of upland-wetland mosaics. The vegetation is naturally dominated by *Pinus palustris*. Most associations have an understory of scrub oaks. The herb layer is generally well-developed and dominated by grasses, with legumes and composites. *Aristida stricta* primarily dominates in the northern part of its range, and *Aristida beyrichiana* in the southern part. Frequent, low-intensity fire is the dominant natural ecological force.
Classification Comments: This system is distinguished from Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265) because of the ecological role of saturated wetland conditions in the latter. The two systems have much in common, including frequent fire and the same primary dominant tree and herb species. They often occur in the same landscapes. However, floristic differences are well marked, and no associations are shared. This system is distinguished from Atlantic Coastal Plain Fall-line Sandhills Longleaf Pine Woodland (CES203.254) based on the differences in landscape patterns and prevailing associations in the two regions. Dissected topography with much higher relief, predominance of interbedded sands and clays, and interspersion with seepage wetlands all characterize the Fall-line Sandhills, in contrast to the low relief, pure sands or loams, and mosaics containing other wetland types in the rest of the Coastal Plain. Some matrix associations in the Fall-line Sandhills, such as *Pinus palustris / Quercus marilandica / Gaylussacia dumosa / Aristida stricta* Woodland (CEGL003595) are nearly absent in the rest of the Coastal Plain, and there are systematic floristic differences. If this were to be split into a northern and southern component, the distinction would be justified based on differences in climate, flora, and some differences in ecological dynamics. Gopher tortoises (*Gopherus polyphemus*) are an important keystone species in the southern portion of the range. The dominant grass also changes at this approximate point, with *Aristida beyrichiana* dominating herb layers to the south.

DESCRIPTION

Environment: This system occurs on upland sites of the Middle to Outer Atlantic Coastal Plain, on landforms that include loamy to sandy flats, relict beach system deposits, eolian sand deposits, Carolina bay rims (Bennett and Nelson 1991), and occasional low rolling hills. Soils range from mesic to xeric and from sandy to loamy or occasionally clayey. Most natural remnants are on coarse sands, but most examples probably once occurred on loamy soils but have subsequently been converted to agricultural uses since the time of European settlement. Soils are largely acidic and infertile, and the coarsest sands are excessively drained and sterile. The unifying feature of this system is non-wetland sites that naturally supported frequent fire. As such, it once covered much of the landscape of the Coastal Plain. Variations in soil texture and drainage appear to be a primary driver of differences between associations within the system, with biogeography also important as there is considerable floristic turnover along a northeast-to-southwest gradient paralleling the coast. In addition, soil texture varies dramatically along this gradient with finer-textured soils predominating north of the Neuse River (in North Carolina), and again south of the Great Pee Dee River and north of the Savanna River (in South Carolina).
Vegetation: Vegetation is a set of associations that are most naturally woodlands or savannas dominated by *Pinus palustris* and

having a well-developed grassy herb layer. A few associations have sparse herb layers due to excessively drained soils, and a few are dominated by scrub oaks. Other pine species may sometimes be present. Scrub oaks (*Quercus laevis, Quercus incana, Quercus margarettiae, Quercus hemisphaerica*, and others) form an understory in most associations, all but the mesic ones. Low shrubs, most ericaceous, are often an important component. In most of the range, *Aristida stricta* is the dominant herb. In the southern and northern parts of the range, it is absent, and various other grass species dominate. Forbs, especially composites, are usually also an important herb component, and lichens are abundant in some associations. Many associations have moderate species richness, with most of the species in the herb layer. Some mesic associations have very high species richness, among the highest values ever measured at the 1/10-hectare scale. Associations on deep, coarse sands may have low species richness but have a distinct set of xerophytic herbs and dwarf-shrubs.

Dynamics: Frequent fire is the predominant natural disturbance in this ecological system, except on the most excessively drained coarse sands, where the sparse ground cover vegetation limits low intensity fire. Component communities naturally burned every few years, many averaging as often as every 3 years. Fires are naturally low to moderate in intensity. They burn above-ground parts of herbs and shrubs but have little effect on the fire-tolerant trees. Vegetation recovers very quickly from fire, with live herbaceous biomass often restored in just a few weeks. Many plants have their flowering triggered by burning. In the absence of fire, less fire-tolerant species increase and others invade the system. The scrub oaks and shrubs, kept to low density and mostly reduced to shrub size by fire, become tall and dense and can suppress *Pinus palustris* regeneration as well as dramatically reducing the herbaceous layer. Only on the most excessively drained coarse sands does the vegetation not undergo substantial structural alteration and reduction in species richness after just a few years without burning.

Canopies are believed to naturally be multi-aged, consisting of a fine mosaic of small even-aged patches driven by gap-phase regeneration. *Pinus palustris* is shade-intolerant and slow to reach reproductive age but is very long-lived.

- *Pinus palustris / Quercus marilandica / Gaylussacia dumosa / Aristida stricta* Woodland (CEGL003595, G2G3)
- *Pinus palustris / Quercus pumila - Gaylussacia dumosa / Schizachyrium scoparium* Woodland (CEGL004084, G2?)

SPATIAL CHARACTERISTICS

Spatial Summary: This system is naturally a matrix system, probably once the most extensive system in its range. Most occurrences now are artificially bounded remnants or naturally small islands. Occurrences often form mosaics with Atlantic Coastal Plain Northern Wet Longleaf Pine Savanna and Flatwoods (CES203.265) or Atlantic Coastal Plain Peatland Pocosin (CES203.267) and may have

small-patch systems embedded in them.
Size: Once the most abundant system over large parts of the Coastal Plain, forming the matrix in which most other systems occurred, most occurrences are now naturally small islands or are artificially bounded remnants of small to fairly large size. A few landscape matrix areas of several thousand acres remain.
Adjacent Ecological Systems:
- Atlantic Coastal Plain Clay-Based Carolina Bay Wetland (CES203.245)
- Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267)
- Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265)
- Southern Atlantic Coastal Plain Depression Pond (CES203.262)

Adjacent Ecological System Comments: Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265) or Atlantic Coastal Plain Peatland Pocosin and Canebrake (CES203.267) are the most commonly associated systems, often forming mosaics. Southern Atlantic Coastal Plain Depression Pondshore (CES203.262) and small floodplain systems may be embedded in matrices of this system.

DISTRIBUTION

Range: This system is found in the Atlantic Coastal Plain (exclusive of the Fall-line Sandhills) from southern Virginia to northeastern Florida.

BASTROP LOST PINES FOREST AND WOODLAND (CES205.896)

CLASSIFIERS

Classification Status: Standard

Primary Division: Eastern Great Plains (205)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2358; ESLF 4261; ESP 1358

CONCEPT

Summary: This system, dominated by *Pinus taeda*, is endemic to central Texas. Locally this is known as the "Bastrop Pines." Examples may share similarities, in terms of the vegetation, with Coastal Plain pine-hardwood systems to the east (in TNC Ecoregions 40 and 41) but differ in the fact that this system contains only loblolly pine which is generally considered successional in the more eastern systems. The vegetation includes a range of communities (that have yet to be defined) that range from very dry to xeric uplands to dry and even mesic areas with different suites of hardwood associates. The *Pinus taeda* of this region is genetically different than strains to the east; it has much greater drought tolerance. It is possible that this area was one of the epicenters of early southern pine colonization of the Coastal Plain based on fossil pollen evidence.
Classification Comments: No associations have currently been described in the NVC for this system. More information is needed.

- Bastrop Lost Pines: Loblolly Pine Slope Forest (121) [CES205.896.11] (Elliott 2011) Finer

DESCRIPTION

Environment: Stands of this system occur on dissected uplands. Sandy soils characterize this system with typical Ecological Sites being deep sand, sandy, and sandy loam. It may also occupy gravelly sites associated with more recent geologic strata. Sandy Eocene formations such as Carrizo, Sparta, and Queen City formations are most frequently associated with this system, though it may also occur on the Reklaw (another Eocene) Formation (Elliott 2010).
Vegetation: This system is dominated by *Pinus taeda*, often with *Quercus stellata* and *Quercus marilandica* present to codominant. *Quercus incana, Quercus margarettiae, Carya texana, Ulmus crassifolia, Celtis* spp., and *Juniperus virginiana* may also be present. *Vaccinium arboreum* is a frequent shrub component. Other shrub and woody vine species that may be present include *Sideroxylon lanuginosum, Callicarpa americana, Ilex vomitoria, Toxicodendron* spp., *Rhus aromatica, Smilax bona-nox, Parthenocissus quinquefolia,* and *Vitis* spp. A grassy herbaceous layer may be present with *Schizachyrium scoparium* commonly encountered, but other species include *Andropogon gerardii, Nassella leucotricha, Sporobolus junceus, Paspalum plicatulum, Paspalum setaceum, Aristida* spp., *Sporobolus clandestinus, Digitaria cognata, Dichanthelium oligosanthes var. scribnerianum*, and *Dichanthelium oligosanthes*. Forbs are conspicuous and include *Heterotheca subaxillaris, Euphorbia corollata, Monarda citriodora, Galactia volubilis, Liatris aspera, Brazoria truncata, Diodia teres*, and many others (Elliott 2011).
Dynamics: Local accumulations of pine needles result in a patchy distribution of herbaceous cover. This system bears some resemblance to pine woodlands and forests farther to the east and may represent a western, more xeric outlier of these similar systems.

DISTRIBUTION

Range: This system is endemic to central Texas.

CALIFORNIA COASTAL CLOSED-CONE CONIFER FOREST AND WOODLAND (CES206.922)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Marine Sedimentary; Cupressus macrocarpa, C. goveniana, C. abramsiana
Non-Diagnostic Classifiers: Montane [Lower Montane]; Sideslope; Acidic Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2177; ESLF 4268; ESP 1177

CONCEPT

Summary: Small occurrences of this system may be found in scattered locations along California's entire coastline and onto the Channel Islands. They are found on marine sedimentary, non-metamorphosed features, often with podsols on sterile sandstone. These forests and woodlands are limited to coastal areas with moderate maritime climate and likely receive more annual precipitation than nearby coastal chaparral. Highly localized endemic tree species include *Cupressus macrocarpa, Cupressus goveniana*, and *Cupressus abramsiana* in scattered groves along coastal Mendocino, San Mateo, Santa Cruz, and Monterey counties. *Pinus contorta var. contorta, Pinus contorta var. bolanderi, Pinus muricata, Pinus torreyana*, and *Pinus radiata* are dominant or codominant in these and other occurrences. These occurrences can also include pygmy woodland expressions where nearly lateritic subsoil underlies acidic sands (ancient marine terraces). Stunted and twisted *Pinus contorta var. contorta* stands along the Oregon coast (often called pygmy forests) are also part of this system. Other associated plant species include *Arctostaphylos nummularia, Ledum groenlandicum, Vaccinium ovatum, Gaultheria shallon, Rhododendron macrophyllum*, and *Morella californica (= Myrica californica)*. The lichen and moss component of this system is very diverse, includes *Cladonia* spp., and can be abundant in these communities.
Related Concepts:
- Knobcone Pine: 248 (Eyre 1980) Broader. includes Santa Cruz cypress, Baker cypress, McNab cypress and Sargent cypress.
- Lodgepole Pine: 218 (Eyre 1980) Intersecting. *Pinus contorta ssp. contorta* stands are a minor component of this ecological system.

DESCRIPTION

Environment: These woodlands occur in fire-prone, seasonally dry and nutritionally poor locations, in areas with a Mediterranean climate (Barbour 2007). Found in scattered locations along California's entire coastline and onto the Channel Islands, as well as along the southern Oregon coast and on two small Islands off the coast of Baja California, Mexico. These forests and woodlands are limited to coastal areas with moderate maritime climate and likely receive more annual precipitation than nearby coastal chaparral; fog drip can be an important source of moisture in some stands. They are found on marine sedimentary, non-metamorphosed features, often with Podsols on sterile sandstone. These occurrences can also include pygmy woodland expressions where nearly lateritic subsoil underlies acidic sands (ancient marine terraces). The soils are excessively well-drained in most cases, but stands of *Pinus contorta var. bolanderi* occur on poorly drained Spodosols.
Dynamics: These woodlands typically are found in sharply demarcated localized groves with a single-aged and monospecific overstory (Barbour 2007). The dominant trees are mostly serotinous in fire response (Davis and Borchert 2006), requiring heat to open the closed cones. Degree of serotiny varies widely across these species, along a continuum of conditions, but all are serotinous to some degree (Keeley and Zedler 1998, Barbour 2007). *Pinus torreyana* is reported to shed seeds from third-year cones and continuously from those cones for several years (Lanner 1999). The seeds are wingless and large, suggesting they are animal dispersed and cached in the ground which protects them from fires. Most of the closed-cone conifers are killed in crown fires because they grow in or near highly flammable chaparral (Barbour 2007). Moreover, they self-prune poorly, typically retaining lower limbs to within a meter of the ground surface (Barbour 2007) so fire easily carries into the canopy. Because they often grow in dense thickets of small-stemmed individuals, they may burn intensely even in the absence of chaparral. Basically, the fire regime of many closed-cone conifers is the same as that of the surrounding shrublands and particularly characterizes *Cupressus sargentii, Cupressus forbesii, Cupressus arizonica ssp. stephensonii (= Cupressus stephensonii), Pinus coulteri*, and *Pinus attenuata* (Landfire 2007a). The typical fire regime for most adjacent communities is known to have a return interval of less than 50 years (Barbour 2007).

Postfire regeneration of these species is closely linked to the frequency of fire relative to cone bank accumulation. For example, *Cupressus sargentii* needs at least 20 years between fires to accumulate a cone bank sufficient to regenerate the stand. *Pinus coulteri* likely needs at least 25 years and preferably 30 years to develop an adequate cone bank. Fires that kill a stand before an adequate cone bank is in place will disappear (immaturity risk) as has been observed in *Cupressus forbesii* and *Cupressus sargentii*. Fire opens closed cones but not all stands necessarily burn in crown fires. Some may burn in ground and surface fires (Landfire 2007). Severe drought can cause mortality of the trees without triggering seed dispersal; some *Cupressus* species are susceptible to cypress canker, a fungus (*Coryneum cardinale*) (Barbour 2007).

Component Associations:
- *Cupressus goveniana ssp. pygmaea* Scrub (CEGL003042, G2?)
- *Pinus muricata - Arbutus menziesii / Vaccinium ovatum* Forest (CEGL003164, G2)

- *Pinus radiata* Forest (CEGL003076, G1)

Spatial Characteristics

Size: Some occurrences of this system are large enough to map, especially those dominated by the pines; however, *Cupressus* is always too small to map. Todd Keeler-Wolf (pers. comm. 2005) and Julie Evens (pers. comm. 2005) recommend that Landfire should attempt to map where possible.

Adjacent Ecological Systems:

- California Maritime Chaparral (CES206.929)
- North Pacific Seasonal Sitka Spruce Forest (CES204.841)

Distribution

Range: This system is found in scattered locations along California's entire coastline and onto the Channel Islands and possibly just into southern Oregon in southern Coos and Curry counties.

CALIFORNIA COASTAL REDWOOD FOREST (CES206.921)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Long (>500 yrs) Persistence; Forest and Woodland (Treed); Toeslope/Valley Bottom; Mediterranean [Mediterranean Pluviseasonal-Oceanic]; Intermediate Disturbance Interval; F-Patch/Low Intensity; Needle-Leaved Tree; Sequoia sempervirens
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Sideslope; Marine Sedimentary; Ustic
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2015; ESLF 4202; ESP 1015

CONCEPT

Summary: This system occurs from the Klamath Mountains south to Monterey Bay, California. The coastal redwood forest generally can be found in areas of within the fog belt. In the northern portion, it occurs on upland slopes and in riparian zones and on riverine terraces that are flooded approximately every 50-100 years. In the southern portion of the range, annual precipitation may be as little as 500 mm, and the system is limited to coves and ravines. It is commonly found on moderately well-drained marine sediments (non-metamorphosed siltstones, sandstones, etc.). This system forms the tallest forests in North America, with individuals reaching 100 m high (tallest being 106-110 m [350-360 feet]). Typically, mature stands of *Sequoia sempervirens* produce a deep shade, so understories can be limited, but coarse woody debris from past disturbance can be quite large. *Pseudotsuga menziesii* is the common associate among the large trees. *Tsuga heterophylla* is found in old-growth stands in northern sections, and *Lithocarpus densiflorus* occurs as a subcanopy in almost all stands (possibly as a result of fire suppression). *Sequoia sempervirens* mixes with *Arbutus menziesii, Lithocarpus densiflorus, Pseudotsuga menziesii* and *Umbellularia californica*. The moist, coastal *Chamaecyparis lawsoniana* stands from southwestern Oregon and northwestern California, often mixed with *Sequoia sempervirens, Pseudotsuga menziesii*, or *Tsuga heterophylla*, are included in this system, as ecologically they function in the same way and have a similar overall floristic composition. Shade-tolerant understory species include *Rubus parviflorus, Oxalis oregana, Aralia californica, Mahonia nervosa (= Berberis nervosa), Gaultheria shallon*, and many ferns, such as *Blechnum spicant, Polystichum* spp., and *Polypodium* spp. Historically, surface fires likely exposed mineral soil for redwood seed germination. Less frequent disturbance can result in increases in *Tsuga heterophylla* in northern occurrences, as it is sensitive to fire and is a decreaser with fire and flood. Fire suppression has tended to result in increasing abundance of *Lithocarpus densiflorus, Umbellularia californica, Alnus rubra, Arbutus menziesii*, and *Acer macrophyllum*; all respond favorably to fire, flood, wind and slides, becoming more abundant in areas of frequent disturbance.
Classification Comments: Stands dominated or codominated with *Chamaecyparis lawsoniana* that are within 25 km (15 miles) of the coast are part of either California Coastal Redwood Forest (CES206.921) (extreme southern Oregon and northern California) or North Pacific Seasonal Sitka Spruce Forest (CES204.841) (central and northern coastal Oregon). Stands in these areas may or may not have redwood or Sitka spruce present. Stands away for the coast and not on serpentine soils are considered part of North Pacific Maritime Mesic-Wet Douglas-Fir-Western Hemlock Forest (CES204.002).
Related Concepts:
- Port Orford-Cedar: 231 (Eyre 1980) Intersecting. Coastal Port Orford-cedar stands occur in this system.
- Redwood: 232 (Eyre 1980) Equivalent

DESCRIPTION

Environment: Climate is wet, mild maritime. Forests along the immediate coast experience uniformly wet and mild climate, where precipitation averages 2000-3000 mm/year (500 mm for some of the driest redwood occurrences) with frequent fog and low clouds during warmer months; additional moisture from fog-drip can be significant. The coastal redwood system generally can be found in areas of lower rainfall than other coastal rainforests in this macrogroup, but still within the fog belt. In the northern portion, it occurs on upland slopes and in riparian zones and on riverine terraces that are flooded approximately every 50-100 years. In the southern portion of the range, annual precipitation may be as little as 500 mm, and the system is limited to coves and ravines. It is commonly found on moderately well-drained marine sediments (non-metamorphosed siltstones, sandstones, etc.). Redwood forests are limited to the north by ultramafic soils of the Klamath Mountains (Sawyer 2007).
Dynamics: Historically, surface fires likely exposed mineral soil for redwood seed germination. Less frequent disturbance can result in increases in *Tsuga heterophylla* in northern occurrences, as it is sensitive to fire and is a decreaser with fire and flood. Landfire (2007a) model: Redwood forests typically burned in the summer and early fall in low- to moderate-intensity surface fires that consumed irregular patches of surface fuel and understory vegetation. The great height of the canopy and separation of surface and crown fuels resulted in a pattern where fire rarely resulted in canopy tree mortality. Fire intervals ranged from less than 10 years in interior and upland locations to 100 years or more along the coast in the fog belt. More recent research funded by Save the Redwoods League suggests that fire has been historically quite variable with much lower frequencies in the extreme north coastal portion of redwood range (as low as 1 every 500 years) and very high in the southern end where ravine redwood stands occur adjacent to

California chaparral and grasslands (T. Keeler-Wolf pers. comm. 2013). Native Americans are thought to have contributed to the ignitions (perhaps as much as every 5-8 years) since lightning is relatively infrequent in the area, especially in the fog belt. Flooding events that undermine trees may be a significant disturbance, but it's not known for certain this is the case.

Component Associations:
- *Abies concolor - Chamaecyparis lawsoniana - Pseudotsuga menziesii / (Mahonia nervosa) / Achlys triphylla* Forest (CEGL000041, G2)
- *Abies grandis - Picea sitchensis / Gaultheria shallon / Polystichum munitum* Forest (CEGL000053, G1)
- *Chamaecyparis lawsoniana - Tsuga heterophylla / Gaultheria shallon - Rhododendron macrophyllum* Forest (CEGL000045, G1)
- *Chamaecyparis lawsoniana - Tsuga heterophylla / Polystichum munitum* Forest (CEGL000046, G1)
- *Chamaecyparis lawsoniana / Vaccinium ovatum* Forest (CEGL000048, G1)
- *Pseudotsuga menziesii - Sequoia sempervirens / Rhododendron macrophyllum / Vaccinium ovatum* Forest (CEGL000082, G2)
- *Sequoia sempervirens - Pseudotsuga menziesii* Forest (CEGL003173, GNR)
- *Sequoia sempervirens / Lithocarpus densiflorus / Vaccinium ovatum* Forest (CEGL003172, G3?)

CALIFORNIA MONTANE JEFFREY PINE-(PONDEROSA PINE) WOODLAND (CES206.918)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Shrubland (Shrub-dominated); Mediterranean [Mediterranean Xeric-Oceanic]; F-Patch/Low Intensity; Needle-Leaved Tree; Broad-Leaved Evergreen Shrub; Pinus jeffreyi
Non-Diagnostic Classifiers: Montane [Montane]; Montane [Lower Montane]; Acidic Soil; F-Patch/Medium Intensity; Graminoid
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2031; ESLF 4218; ESP 1031

CONCEPT

Summary: These forests are found on relatively xeric sites in mountains and plateaus from southern Oregon (600-1830 m [1800-5000 feet] elevation) south into the Sierra Nevada, throughout the Transverse Ranges of California, and into northern Baja California (1200-2740 m [4000-8300 feet]), Mexico. While the two dominant pines tend to segregate by soil fertility and temperature regimes, they may co-occur in certain areas (e.g., Modoc Plateau). These stands are more common on the east side of the Sierra Nevada, although they do occur on the west side. Stands are pure *Pinus jeffreyi, Pinus ponderosa*, or a mix of the two. Ponderosa pine and/or Jeffrey pine on the west slope of the Sierras with other conifer species are part of Mediterranean California Dry-Mesic Mixed Conifer Forest and Woodland (CES206.916). This system includes sites where *Pinus ponderosa* and/or *Pinus jeffreyi* are the predominant conifers and other tree species do not occur in high abundance, if at all. The exception to this is in southern California on the edges of the Mojave Desert where *Pinus monophylla* or *Juniperus californica* might occur in a subcanopy under *Pinus ponderosa* or *Pinus jeffreyi*. *Pinus jeffreyi* is more tolerant of colder, drier and poorer sites and replaces *Pinus ponderosa* as the dominant at higher elevations. In the north, *Pinus jeffreyi* may be replaced by *Pinus washoensis* (Carson Range and Warner Mountains). Throughout California, pure stands of ponderosa pine are relatively uncommon. Only on the Modoc Plateau do these pines co-occur in mixed stands. *Juniperus occidentalis* (both *var. australis* [in the south] and *var. occidentalis*) can co-occur in these stands but typically is not dominant. On moister and cooler sites, *Abies concolor* can be present in some stands. There can be well-developed shrub understories with strong Great Basin affinities; species can include *Artemisia tridentata, Purshia tridentata, Symphoricarpos rotundifolius var. parishii (= Symphoricarpos parishii), Arctostaphylos patula, Ceanothus cordulatus, Ceanothus prostratus, Ceanothus integerrimus, Chrysolepis sempervirens, Eriogonum wrightii, Quercus vacciniifolia,* and *Lupinus elatus*. *Cercocarpus ledifolius* is common on steeper slopes throughout the range. Historically, frequent localized ground fires maintained these systems. Stands of ponderosa pine on the east side of the Cascades transition into East Cascades Oak-Ponderosa Pine Forest and Woodland (CES204.085), or Northern Rocky Mountain Ponderosa Pine Woodland and Savanna (CES306.030) north of the Warm Springs Reservation of central Oregon.
Classification Comments: *Pinus ponderosa* forests with *Calocedrus decurrens* found on the west side of the Sierra Nevada and in the Klamath Mountains are accommodated in Mediterranean California Dry-Mesic Mixed Conifer Forest and Woodland (CES206.916).
Related Concepts:
- Bitterbrush (210) (Shiflet 1994) Intersecting. SRM type includes stands of open *P. jeffreyi* over *Purshia tridentata*.

CENTRAL AND SOUTH TEXAS COASTAL FRINGE FOREST AND WOODLAND (CES203.464)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed)
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2338; ESLF 4144; ESP 1338

CONCEPT

Summary: This system includes oak-dominated forests woodlands, shrublands and savannas occurring on deep sands of the Pleistocene-aged Ingleside barrier-strandplain of the central Texas coast and the Holocene-aged eolian sand deposits of the South Texas Sand Sheet. Topography varies from larger dunes to smaller ridges and swales. Vegetation of this physiognomically variable and dynamic system primarily includes patches (mottes) of forests, woodlands and shrublands dominated by *Quercus fusiformis*. Associated species vary in a north/south manner across the range of this system. Some examples contain dense shrublands dominated (almost to the exclusion of other species) by running clones of *Quercus fusiformis*. Other canopy species in the vicinity of Aransas National Wildlife Refuge, at the northern end of the range, include *Quercus marilandica, Quercus hemisphaerica, Persea borbonia,* and *Celtis laevigata*. In this area, understory species include *Ilex vomitoria, Smilax bona-nox, Vitis mustangensis,* and/or *Morella cerifera*. Other canopy species on the South Texas Sand Sheet, at the southern end of the range, include *Prosopis glandulosa var. glandulosa, Zanthoxylum hirsutum, Condalia hookeri, Lantana urticoides (= Lantana horrida), Ziziphus obtusifolia var. obtusifolia,* and a very few other species. Many of the species found in the northern parts of the range of this system are absent in the southern occurrences. *Quercus fusiformis - Prosopis glandulosa var. glandulosa / Malvaviscus arboreus var. drummondii* Forest (CEGL007785) can be referred to the southern expression, while *Quercus fusiformis - Persea borbonia* Forest (CEGL002117) represents the northern expression. A characteristic component of the sparse ground cover within the mottes and forests across the entire range is *Malvaviscus arboreus var. drummondii*. Canopy openings are similar in composition to surrounding grasslands. In addition to *Schizachyrium littorale*, other herbaceous species common in canopy openings across the range of this system include *Paspalum plicatulum, Paspalum monostachyum, Andropogon gerardii, Sorghastrum nutans, Muhlenbergia capillaris, Helianthemum georgianum, Croton argyranthemus,* and *Froelichia floridana*. Minor changes in drainage can cause major differences in species composition. On the Ingleside barrier-strandplain, while *Paspalum monostachyum* may dominate slightly lower areas, deeper swales are typically dominated by *Panicum virgatum, Spartina patens, Fimbristylis* spp., *Hydrocotyle bonariensis, Rhynchospora* spp., *Fuirena* spp., *Eleocharis* spp., and *Cyperus* spp.
Classification Comments: More data are needed to better define the boundary and distinction between this system and the surrounding grassland systems. The wooded component of this landscape is considered separately here due to its apparent long-term stability (>100 years) on the landscape, but some of the factors controlling its occurrence are not known. Live oak taxonomy follows that suggested by Nixon and Muller (1997), where all live oaks of coastal Texas southwest of the Brazos are considered *Quercus fusiformis*, likely introgressed with *Quercus virginiana* and/or the Mexican species *Quercus oleoides*. Though *Quercus fusiformis* is the dominant species across the range of this system, associated species vary in a north/south manner. There are probably more associations to be developed for this system.
Similar Ecological Systems:
- Texas Coast Dune and Coastal Grassland (CES203.465)

Related Concepts:

- Coastal and Sandsheet: Deep Sand Live Oak Forest and Woodland (6402) [CES203.464.2] (Elliott 2011) Finer
- Coastal and Sandsheet: Deep Sand Live Oak Shrubland (6405) [CES203.464.5] (Elliott 2011) Finer
- Coastal and Sandsheet: Deep Sand Live Oak Swale Marsh (6407) [CES203.464.7] (Elliott 2011) Finer
- Mesquite (southern type): 68 (Eyre 1980) Intersecting

DESCRIPTION

Environment: This system occurs on deep sands of the Pleistocene-aged Ingleside barrier-strandplain and the Holocene- and Pleistocene-aged eolian sand deposits of the South Texas Sand Sheet. Ridge and swale topography characterizes these sites, with some large (up to 15 m tall) vegetated dunes present. Topography varies from larger dunes to smaller ridges and swales.
Vegetation: Vegetation of this physiognomically variable and dynamic system is dominated by *Quercus fusiformis*. Stands primarily consist of patches (mottes) of forest, woodland and shrubland in a matrix of more open savannas and grasslands. Closed canopy mottes typically occur within a grassland matrix but may become more extensive forests. In the northern range of this system, other canopy components may include *Quercus marilandica, Quercus hemisphaerica, Persea borbonia,* and *Celtis laevigata*. In this area, understory species include *Callicarpa americana, Ilex vomitoria, Smilax bona-nox, Vitis mustangensis,* and *Morella cerifera*. Characteristic components of the sparse ground cover within the mottes and forests include *Malvaviscus arboreus var. drummondii, Scleria triglomerata,* and *Erythrina herbacea*. A shrubland component of this system is also present in some areas and is sometimes

extensive, consisting of a rhizomatous expression of sprouting live oaks referred to locally as "running live oak." This shrubland often appears to be a monoculture of shrubby *Quercus fusiformis* (1.5-6 m tall), but other species of the oak motte are also found here, including larger *Quercus fusiformis* trees, *Quercus hemisphaerica, Persea borbonia, Morella cerifera* (usually in swales), *Toxicodendron pubescens, Callicarpa americana, Vitis mustangensis, Ilex vomitoria, Erythrina herbacea,* and scattered *Quercus marilandica*. Small openings with *Sorghastrum nutans* hint at what is thought to have been the historical condition of these areas. These "running-live oak" thickets are thought to be a modified community that is the result of years of fire suppression and severe grazing pressures. Once this shrubland is established, it is difficult to restore the grassland community to these areas. Canopy openings are similar in composition to surrounding grasslands. In addition to *Schizachyrium littorale* and *Paspalum monostachyum,* common components include *Heteropogon contortus, Paspalum plicatulum, Trichoneura elegans, Andropogon gerardii, Sorghastrum nutans, Bothriochloa saccharoides, Muhlenbergia capillaris, Dichanthelium* spp., *Elionurus tripsacoides, Eriogonum multiflorum, Stylosanthes viscosa, Helianthemum georgianum, Croton glandulosus, Paspalum setaceum, Tradescantia humilis, Physalis cinerascens var. spathulifolia, Palafoxia hookeriana, Scleria triglomerata, Thelesperma nuecense, Lechea mucronata, Liatris elegans var. carizzana,* and *Froelichia floridana*. The oak mottes may have expanded at the expense of the oak savanna phase and become more dense in the absence of fire. A maritime component occurs on stabilized dunes composed of deep sand that stretch along San Antonio Bay. This component is characterized by a relatively tall forest (8-12 m) dominated by *Quercus fusiformis*. Other trees that reach the canopy include *Persea borbonia* and *Quercus hemisphaerica*. The midcanopy is dominated by *Persea borbonia* and *Quercus hemisphaerica* with *Celtis laevigata* and *Quercus marilandica* occurring as occasional associates. The understory includes *Ilex vomitoria* and *Callicarpa americana*. A characteristic member of the sparse ground layer is *Scleria triglomerata*. [continued in Other Comments]

Dynamics: Fire, climate, and edaphic factors all likely played a role historically in maintaining a more open structure in this vegetation. Historically, fire likely limited the development of woody cover. Likewise, edaphic conditions limited this system to deep sandy soils. Loss of these natural processes often results in a shift toward a more closed canopy and decrease in native grass cover. Threats to this system include fire suppression, coastal development, invasive exotics, and damage by vehicles.

- *Spartina patens - Fimbristylis (caroliniana, castanea) - (Panicum virgatum)* Herbaceous Vegetation (CEGL007836, G2G3)

SPATIAL CHARACTERISTICS

Spatial Summary: This system occurs in patches (mottes) or as linear occurrences on sand ridges and dunes.

Adjacent Ecological Systems:

- Tamaulipan Closed Depression Wetland (CES301.197)
- Texas Coast Dune and Coastal Grassland (CES203.465)

DISTRIBUTION

Range: This system is endemic to Texas. It is found within 10 km of the coast on deep sands of ancient Pleistocene strandplains (the Ingleside barrier-strandplain) at its northern extent and within a much greater distance from the coast (100 km) on the Holocene-aged eolian sand deposits of the South Texas Sand Sheet (primarily Kenedy and Brooks counties but extending into adjacent Jim Hogg, Hidalgo, and Willacy counties) at its southern extent.

CENTRAL AND SOUTHERN APPALACHIAN MONTANE OAK FOREST (CES202.596)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Forest and Woodland (Treed); Ridge/Summit/Upper Slope; Unglaciated; Broad-Leaved Deciduous Tree; Quercus - Carya
Non-Diagnostic Classifiers: Temperate; Oligotrophic Soil; Acidic Soil; Shallow Soil; Mineral: W/ A-Horizon <10 cm; Ustic; Consolidated; W-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2320; ESLF 4126; ESP 1320

CONCEPT

Summary: This generally oak-dominated system is found in the central and southern Appalachian Mountains. These high-elevation deciduous forests occur on exposed sites, including ridgecrests and south- to west-facing slopes, mostly between 915 and 1372 m (3000-4500 feet) elevation, less commonly ranging up to 1680 m (5500 feet). In most associations attributed to this system, the soils are thin, weathered, nutrient-poor, low in organic matter, and acidic. The forests are dominated by *Quercus* spp. (most commonly *Quercus rubra* and *Quercus alba*), with the individuals often stunted or wind-flagged. *Castanea dentata* sprouts are also common, but the importance of chestnut in these forests has been dramatically altered by chestnut blight. *Ilex montana* and *Rhododendron prinophyllum* are characteristic shrubs.
Classification Comments: This system may be interfingered with the non-oak-dominated Southern Appalachian Northern Hardwood Forest (CES202.029), particularly between 1220 and 1525 m (4000-5000 feet) elevation. Above 1372 m (4500 feet) elevation and below spruce-fir communities, this system may be replaced on certain aspects by Southern Appalachian Northern Hardwood Forest (CES202.029).
Similar Ecological Systems:
- Southern Appalachian Low-Elevation Pine Forest (CES202.332)
- Southern Appalachian Northern Hardwood Forest (CES202.029)--generally occupies more protected and moister aspects and becomes more prominent at upper elevations.
- Southern Appalachian Oak Forest (CES202.886)--occurs at lower elevations.

- Sugar Maple - Beech - Yellow Birch: 25 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer
- White Oak: 53 (Eyre 1980) Finer

DESCRIPTION

Environment: The habitat for this system includes high ridgelines and exposed upper slopes, primarily on south- to west-facing aspects, mostly between 915 and 1372 m (3000-4500 feet) elevation, and less commonly ranging up to 1680 m (5500 feet).It generally occurs as a transition between Southern Appalachian Oak Forest (CES202.886) and more mesic Southern Appalachian Northern Hardwood Forest (CES202.029) that occurs on less-exposed ridgetops and cooler, moister upper slopes (e.g., north- and east-facing aspects). At high elevations (e.g., above 1372 m [4500 feet]), this system is generally less common than Southern Appalachian Northern Hardwood Forest (CES202.029), since the habitat on most slopes at this elevation tends to favor those species adapted to a more mesic environment. Rockslides occur periodically due to the steep slopes, and severe rockslides can cause stand replacement. Ice storms occur frequently and cause extensive damage to older dwarfed trees. Fire occurs at moderate frequency and probably needed in the long run to promote growth of fire tolerant *Quercus* and maintain their dominance. Some rare examples may be too rocky to burn, and even these have mostly closed canopies and produce a substantial leaf litter layer in most places (M. Schafale pers. comm. 2013).
Vegetation: This system is dominated by *Quercus rubra* and, more rarely, *Quercus alba*. Often the trees are stunted or at least not as tall as they would be in other systems farther downslope. Species richness is low to moderate. Tree associates include *Prunus serotina, Acer rubrum, Betula lenta,* and *Betula alleghaniensis*. Typical small trees and shrubs include *Ilex montana, Hamamelis virginiana, Acer pensylvanicum, Menziesia pilosa, Rhododendron prinophyllum, Vaccinium pallidum, Corylus cornuta var. cornuta,* and sprouts of *Castanea dentata*. The understory is usually dominated by ericaceous shrubs, but some communities are dominated by graminoid species or ferns. *Dennstaedtia punctilobula*, *Carex pensylvanica*, and *Deschampsia flexuosa* are common. Only rarely are the communities dominated by other herbs.
Dynamics: The communities of this system occur on exposed high ridges in the Appalachians, and they are subject to frequent ice and wind storms in the summer and high winds throughout the year. This system exists naturally predominantly as old-growth forest,

with trees reproducing in small to medium-sized canopy gaps created by the death of individual or small groups of trees. Wind and ice storms are the main cause of tree mortality. Breakage of trees and of branches by ice storms can additionally produce partial canopy opening over large areas (M. Schafale pers. comm.). In addition, lightning-caused fires may create surface fires that change the understory composition and inhibit some ericaceous shrub species in some areas. Fire is naturally at moderate or low frequency, but appears to be important in structuring the vegetation. In many locations, fire exclusion and competing understory vegetation are factors in poor oak regeneration, with replacement by more mesophytic species such as *Acer saccharum* (Fleming et al. 2005). Fire likely was crucial for reducing the competitive advantage of these species. Presettlement forests are likely to have experienced lightning-caused fires every 40-60 years (Fleming et al. 2005). Fires likely were more frequent than this farther south. Rockslides cause severe disturbance in occasional locations, initiating a primary succession that may last many years. Despite the high elevation, *Castanea dentata* had been a fairly substantial component of this system and can still be seen as rotting stumps in the forest.

Component Associations:
- *Betula alleghaniensis - Quercus rubra / Acer (pensylvanicum, spicatum) / Dryopteris intermedia - Oclemena acuminata* Forest (CEGL008502, G3G4)
- *Betula alleghaniensis / Sorbus americana - Acer spicatum / Polypodium appalachianum* Forest (CEGL008504, G2)
- *Quercus alba - Quercus (rubra, prinus) / Rhododendron calendulaceum - Kalmia latifolia - (Gaylussacia ursina)* Forest (CEGL007230, G4G5)
- *Quercus alba / Kalmia latifolia* Forest (CEGL007295, G2Q)
- *Quercus rubra - (Quercus alba) / Ilex montana / Dennstaedtia punctilobula - Lysimachia quadrifolia* Forest (CEGL008506, G3G4)
- *Quercus rubra - (Quercus prinus) / Vaccinium* spp. / *Deschampsia flexuosa* Woodland (CEGL006134, G4)
- *Quercus rubra - Carya (ovata, ovalis) - Fraxinus americana / Actaea racemosa - Hydrophyllum virginianum* Forest (CEGL008518, G3G4)
- *Quercus rubra - Fraxinus americana - Acer saccharum / Actaea racemosa - Caulophyllum thalictroides - Collinsonia canadensis* Forest (CEGL004256, G2)
- *Quercus rubra / (Kalmia latifolia, Rhododendron catawbiense, Rhododendron maximum) / Galax urceolata* Forest (CEGL007299, G4)
- *Quercus rubra / (Vaccinium simulatum, Rhododendron calendulaceum) / (Dennstaedtia punctilobula, Thelypteris noveboracensis)* Forest (CEGL007300, G4)
- *Quercus rubra / Carex pensylvanica - Ageratina altissima var. roanensis* Forest (CEGL007298, G2)
- *Tilia americana - Fraxinus americana / Acer pensylvanicum - Ostrya virginiana / Parthenocissus quinquefolia - Impatiens pallida* Woodland (CEGL008528, G3)

Spatial Characteristics

Spatial Summary: Large patches that may be interfingered with Southern Appalachian Northern Hardwood Forest (CES202.029). Southern Appalachian Oak Forest (CES202.886) may occur downslope.
Size: Usually smaller than 10 acres but can be larger if the slope is broadly convex on the upper exposed slopes.
Adjacent Ecological Systems:
- Southern Appalachian Northern Hardwood Forest (CES202.029)
- Southern Appalachian Oak Forest (CES202.886)

Adjacent Ecological System Comments: This system often grades into Southern Appalachian Northern Hardwood Forest (CES202.029) as one proceeds upslope or around slope to less exposed areas. Below 915-1220 m (3000-4000 feet) this system can grade into Southern Appalachian Oak Forest (CES202.886).

Distribution

Range: This system is found at higher elevations of the central and southern Appalachian Mountains, Virginia and West Virginia to Georgia. In Kentucky, this system is restricted to the Cumberland Mountains in the extreme southeastern corner of that state. In West Virginia, this system is found in the Ridge and Valley.

CENTRAL AND SOUTHERN APPALACHIAN SPRUCE-FIR FOREST (CES202.028)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Forest and Woodland (Treed); Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2350; ESLF 4253; ESP 1350

CONCEPT

Summary: This system consists of forests in the highest elevation zone of the Blue Ridge and parts of the Central Appalachians, generally dominated by *Picea rubens, Abies fraseri*, or by a mixture of spruce and fir. *Abies fraseri* is the constituent fir from Mount Rogers in Virginia southward. Examples occur above 1676 m (5500 feet) in the Southern Blue Ridge, but as low as 975 m (3200 feet) at the northern range in West Virginia, and may range up to the highest peaks. Elevation and orographic effects make the climate cool and wet, with heavy moisture input from fog as well as high rainfall. Strong winds, extreme cold, rime ice, and other extreme weather are periodically important.

Classification Comments: The border of this system with adjacent systems is often gradational. The non-forested systems that occur in the same elevational zone may have transition zones of open woody vegetation, though some have sharp borders. The transition to Southern Appalachian Northern Hardwood Forest (CES202.029) or other systems that adjoin at lower elevations is marked by a gradual shift in canopy dominance from conifers to hardwoods. In relatively undisturbed stands, the canopy composition and structure are the best way to determine the boundary of this system.

This system is similar to the spruce-fir systems of the northern Appalachians and the boreal forests but differs in having less frequent natural fire, having southern seasonal dynamics (shorter winters, less extreme cold temperatures, lack of long summer days), lacking a history of glaciation, and in a flora and fauna that has southern Appalachian endemics and lacks some characteristic northern species. High-elevation spruce-fir in West Virginia is placed in this system because its location well below the glacial boundary and presence of species of more southern affinity (e.g., *Rhododendron maximum* and *Vaccinium erythrocarpum*) differentiate it from the northern Appalachian system.

Similar Ecological Systems:
- Acadian-Appalachian Montane Spruce-Fir Forest (CES201.566)--occurs on the higher elevations of the northern Appalachians, mostly from New York northward but with a few disjunct patches in Pennsylvania.

Related Concepts:
- Red Spruce - Fraser Fir: 34 (Eyre 1980) Finer
- Red Spruce - Yellow Birch: 30 (Eyre 1980) Finer
- Red Spruce: 32 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs at elevations typically above about 1300 m (4300 feet), up to the highest peaks. Species distribution follows an elevational gradient, with *Picea rubens*-dominated stands occurring between 1370 and 1675 m, mixed stands between 1675 and 1890 m, and *Abies fraseri* stands above 1890 m (Whittaker 1956 cited in Nicholas and Zedaker 1989). Examples occur on most of the landforms that are present in this elevational range; most sites are strongly exposed and convex in shape. Elevation and orographic effects make the climate cool and wet, with heavy moisture input from fog as well as high rainfall. Strong winds, extreme cold, rime ice, and other extreme weather are periodically important factors in the structure and dynamics of this vegetation. Concentration of air pollutants has been implicated as an important anthropogenic stress in recent years. In recent decades, the balsam woolly adelgid (*Adelges piceae*), an introduced insect, has killed almost all of the mature *Abies fraseri*. The saplings are not susceptible, resulting in many dense stands of young trees. Soils are generally very rocky, with the matrix ranging from well-weathered parent material to organic deposits over boulders. Soils may be saturated for long periods from a combination of precipitation and seepage. Any kind of bedrock may be present, but most sites have erosion-resistant felsic igneous or metamorphic rocks (White et al. 1993).

Vegetation: Vegetation consists primarily of forests dominated by *Picea rubens, Abies fraseri*, or occasionally by *Sorbus americana*. *Betula alleghaniensis, Tsuga canadensis*, and *Quercus rubra* are the only other locally common canopy species. *Acer rubrum, Betula lenta, Magnolia acuminata*, and *Magnolia fraseri* may occur. Lower strata are most typically dominated by mosses, ferns or forbs, but a few associations have dense shrub layers of *Rhododendron catawbiense, Rhododendron maximum*, or *Vaccinium erythrocarpum*.

Dynamics: This system is naturally dominated by stable, uneven-aged forests, with canopy dynamics dominated by gap-phase regeneration on a fine scale, as well as larger disturbances resulting primarily from ice storms (Nicholas and Zedaker 1989). Despite the extreme climate, *Picea rubens* is long-lived (300-400 or more years) (White et al. 1993). Both *Picea* and *Abies* seedlings are shade-tolerant, and advanced regeneration is important in stand dynamics. Natural disturbances are primarily wind and ice storms, but may include debris avalanches or very rarely lightning fires (White 1984b, Nicholas and Zedaker 1989, White et al. 1993). Occasional extreme wind events disturb larger patches on the most exposed slopes. Fire is a very rare event under natural conditions, due to the

wetness and limited flammability of the undergrowth (Korstian 1937 cited in White et al. 1993), and return intervals have been estimated between 500 and 1000 years or more. If fires do occur, they are likely to be catastrophic, because few of the species are at all fire-tolerant. Anthropogenic fires fueled by logging slash were extremely destructive, turning large expanses of this system into grass-shrub-hardwood scrub (e.g., Dolly Sods, Graveyard Fields) that has not recovered to conifer dominance after 100 years.

Estimates of the loss in extent of the Southern Appalachian spruce-fir forest range from 50% (White 1984c) to 90% (Korstian 1937 cited in Nicholas and Zedaker 1989). The primary disturbances are weather-related, including ice storms and windthrow, occurring at intervals of 100 to 200 years. There have been multiple events of wind and ice damage in single- and multiple-tree patches that have cumulatively damaged a lot of the canopy in spruce forests (M. Schafale pers. comm. 2013). Rare extreme weather events are also important large-scale disturbances. In contrast to northern stands of *Picea-Abies* vegetation, insect outbreaks are not important disturbances (M. Schafale pers. comm. 2013). Windthrow produces dense *Abies* seedlings if overstory is mature (Eyre 1980). In general, fire is extremely rare in Southern Appalachian *Picea-Abies* vegetation, and fire is not a primary factor in its successional dynamics.

Component Associations:
- *Abies fraseri / (Rhododendron catawbiense, Rhododendron carolinianum)* Forest (CEGL006308, G1)
- *Abies fraseri / Viburnum lantanoides / Dryopteris campyloptera - Oxalis montana / Hylocomium splendens* Forest (CEGL006049, G1)
- *Carex scabrata - Viola cucullata / Plagiomnium ciliare* Herbaceous Vegetation (CEGL006597, G3)
- *Chrysosplenium americanum* Herbaceous Vegetation (CEGL006193, G3G5)
- *Picea rubens - (Abies fraseri) / (Rhododendron catawbiense, Rhododendron maximum)* Forest (CEGL007130, G1)
- *Picea rubens - (Abies fraseri) / Vaccinium erythrocarpum / Oxalis montana - Dryopteris campyloptera / Hylocomium splendens* Forest (CEGL007131, G2)
- *Picea rubens - (Betula alleghaniensis, Aesculus flava) / Rhododendron (maximum, catawbiense)* Forest (CEGL004983, G1?)
- *Picea rubens - (Betula alleghaniensis, Aesculus flava) / Viburnum lantanoides / Oxalis montana - Solidago glomerata* Forest (CEGL006256, G2)
- *Picea rubens - (Tsuga canadensis) / Rhododendron maximum* Forest (CEGL006152, G2G3)
- *Picea rubens - Tsuga canadensis - Fagus grandifolia / Dryopteris intermedia* Forest (CEGL006029, G3)
- *Picea rubens / Betula alleghaniensis / Bazzania trilobata* Forest (CEGL008501, G2)
- *Picea rubens / Kalmia latifolia - Menziesia pilosa* Woodland (CEGL006254, G2)
- *Picea rubens / Ribes glandulosum* Forest (CEGL007128, G1)

SPATIAL CHARACTERISTICS

Spatial Summary: Large-patch to matrix system, dominating the highest mountain areas. Small patches may occur especially due to logging of the matrix/large-patch forest. Small-patch systems may be embedded.
Size: Generally covers most of the landscape in the limited areas at the tops of the highest mountain ranges. Natural patches range from hundreds to thousands of acres. A couple remnant patches of thousands of acres remain, while other intact patches are dozens of acres embedded in landscapes of degraded spruce-fir systems.
Adjacent Ecological Systems:
- High Allegheny Wetland (CES202.069)
- Southern Appalachian Grass and Shrub Bald (CES202.294)
- Southern Appalachian Northern Hardwood Forest (CES202.029)
- Southern Appalachian Rocky Summit (CES202.327)

Adjacent Ecological System Comments: Bordered by Southern Appalachian Northern Hardwood Forest (CES202.029) or Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593) at lower elevation. It may contain embedded small patches of Southern Appalachian Rocky Summit (CES202.327) and Southern Appalachian Grass and Shrub Bald (CES202.294). In addition, high-elevation wetlands may be present.

DISTRIBUTION

Range: This system ranges from the Balsam Mountains and Great Smoky Mountains of North Carolina and Tennessee northward to the mountains of western Virginia and eastern West Virginia.

CENTRAL AND SOUTHERN CALIFORNIA MIXED EVERGREEN WOODLAND (CES206.920)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Mediterranean [Mediterranean Xeric-Oceanic]; Xeric; Broad-Leaved Evergreen Tree
Non-Diagnostic Classifiers: Montane [Montane]; Montane [Lower Montane]; Sideslope; F-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2014; ESLF 4201; ESP 1014

CONCEPT

Summary: This system occurs from Monterey, California, south across the outer Central Coast Ranges to crests of Peninsular Ranges. It can occur on metasediments and granitics. In much of this area, conifers are relatively infrequent, *Pinus coulteri* occurs in scattered stands and *Pseudotsuga macrocarpa* picks up in Transverse Ranges south to Mexico. Characteristic tree species include *Quercus chrysolepis, Quercus agrifolia, Quercus kelloggii, Umbellularia californica, Acer macrophyllum,* and *Arbutus menziesii*. Historic fire frequency was likely higher in this system than in similar systems to the north.

CENTRAL APPALACHIAN DRY OAK-PINE FOREST (CES202.591)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Ridge/Summit/Upper Slope; Acidic Soil; Pinus (strobus, rigida, echinata, virginiana) - Quercus prinus
Non-Diagnostic Classifiers: Lowland; Sideslope; Oligotrophic Soil; Mineral: W/ A-Horizon <10 cm; Loam Soil Texture; Sand Soil Texture; Ustic; F-Patch/Medium Intensity; W-Patch/Low Intensity; Needle-Leaved Tree; Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2369; ESLF 4312; ESP 1369

CONCEPT

Summary: These oak and oak-pine forests cover large areas in the low- to mid-elevation Central Appalachians and middle Piedmont. The topography and landscape position range from rolling hills to steep slopes, with occasional occurrences on more level, ancient alluvial fans. In the highly dissected fall zone of Maryland and the District of Columbia, where the Piedmont and Coastal Plain meet, it is also found on dry knolls capped with Pleistocene- and Tertiary-aged fluvial cobble and gravel terrace deposits. Soils are typically coarse and infertile; they may be deep (on glacial deposits in the northern and terrace deposits in the southern parts of the system's range), or more commonly shallow, on rocky slopes of acidic rock (shale, sandstone, other acidic igneous or metamorphic rock). The well-drained soils and exposure create dry conditions. The forest is mostly closed-canopy but can include patches of more open woodlands. It is dominated by a variable mixture of dry-site oak and pine species, most typically *Quercus prinus*, *Pinus virginiana*, and *Pinus strobus*, but sometimes *Quercus alba* and/or *Quercus coccinea*. The system may include areas of oak forest, pine forest (usually small), and mixed oak-pine forest. Heath shrubs such as *Vaccinium pallidum*, *Gaylussacia baccata*, and *Kalmia latifolia* are common in the understory and often form a dense layer. Embedded submesic ravines and concave landforms support slightly more diverse forests characterized by mixtures of oaks, several hickories, *Cornus florida*, and sometimes *Liriodendron tulipifera*. Small hillslope pockets with impeded drainage may support small isolated wetlands with *Acer rubrum* and *Nyssa sylvatica* characteristic. Disturbance agents include fire, windthrow, and ice damage. Increased site disturbance generally leads to secondary forest vegetation with a greater proportion of *Pinus virginiana* and weedy hardwoods such as *Acer rubrum*.
Classification Comments: This system occurs in drier settings than the other matrix oak forest system of the division, Northeastern Interior Dry-Mesic Oak Forest (CES202.592), except in New York and New England, which are mostly out of the range of CES202.592. In that system, *Quercus rubra*, *Quercus alba*, *Quercus velutina*, and/or *Quercus coccinea* and *Carya* spp. are the typical dominants rather than *Quercus prinus*. It includes the system formerly segregated as Southern Piedmont Dry Oak-Heath Forest (CES202.023). Its analog from central Virginia south is Southern Piedmont Dry Oak-(Pine) Forest (CES202.339), which has somewhat more southern floristics, for example, the typical presence of *Pinus taeda*.
Similar Ecological Systems:
- Allegheny-Cumberland Dry Oak Forest and Woodland (CES202.359)--occurs to the west of this system (e.g., Allegheny Plateau), with the Allegheny Front as the dividing line.
- Central Appalachian Pine-Oak Rocky Woodland (CES202.600)
- Laurentian-Acadian Northern Pine-(Oak) Forest (CES201.719)--occurs to the north.
- Northeastern Interior Dry-Mesic Oak Forest (CES202.592)--more mesic.
- Northern Atlantic Coastal Plain Hardwood Forest (CES203.475)
- Southern Appalachian Oak Forest (CES202.886)--found south of Roanoke River in central Virginia (Blue Ridge/southern Appalachians only).
- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)--occurs to the south; its northern limit overlaps slightly with the southern limit of this system but is farther out on the Coastal Plain.

DESCRIPTION

Environment: These oak and oak-pine forests cover large areas in the low- to mid-elevation central Appalachians and middle Piedmont. The topography and landscape position range from rolling hills to steep slopes, with occasional occurrences on more level, ancient alluvial fans. The soils are coarse and infertile; they may be deep (on glacial deposits in the northern part of the system's range), or more commonly shallow, on rocky slopes of acidic rock (shale, sandstone, other acidic igneous or metamorphic rock). The well-drained soils and exposure create dry conditions. In the highly dissected fall zone of Maryland and the District of Columbia, where the Piedmont and Coastal Plain meet, it is also found on dry knolls capped with Pleistocene- and Tertiary-aged fluvial cobble and gravel terrace deposits.

Vegetation: Stands of this forest system are mostly closed-canopied but can include more open woodlands. They are dominated by a variable mixture of dry-site oak and pine species, including *Quercus prinus, Pinus virginiana*, and *Pinus strobus*. The system may include areas of pine forest and mixed oak-pine forest. Heath shrubs such as *Vaccinium pallidum, Gaylussacia baccata*, and *Kalmia latifolia* are common in the understory. Within these forests, hillslope pockets with impeded drainage may support small isolated wetlands with *Acer rubrum* and *Nyssa sylvatica* characteristic.

Dynamics: Disturbance agents include fire, windthrow, and ice damage.

Component Associations:

- *Acer saccharum - Quercus muehlenbergii / Carex platyphylla* Forest (CEGL006162, GNR)
- *Fagus grandifolia - Betula lenta - Quercus (alba, rubra) / Carpinus caroliniana* Forest (CEGL006921, GNR)
- *Pinus (pungens, rigida) - Quercus prinus / (Quercus ilicifolia) / Gaylussacia baccata* Woodland (CEGL004996, G4)
- *Pinus rigida - Quercus (velutina, prinus)* Forest (CEGL006290, GNR)
- *Pinus strobus - Pinus resinosa - Pinus rigida* Forest (CEGL006259, G4G5)
- *Pinus strobus - Quercus (rubra, velutina) - Fagus grandifolia* Forest (CEGL006293, G5)
- *Pinus strobus - Quercus alba - Quercus prinus / Vaccinium stamineum* Forest (CEGL008539, G4)
- *Pinus virginiana - Pinus (rigida, echinata) - (Quercus prinus) / Vaccinium pallidum* Forest (CEGL007119, G3)
- *Quercus (alba, rubra, velutina) - Carya* spp. / *Viburnum acerifolium* Forest (CEGL006336, G4G5)
- *Quercus (rubra, velutina, alba) - Betula lenta - (Pinus strobus)* Forest (CEGL006454, G4G5)
- *Quercus (velutina, alba) / Vaccinium pallidum* High Allegheny Plateau, Western Allegheny Plateau Forest (CEGL006018, GNR)
- *Quercus alba - Quercus (coccinea, velutina, prinus) / Gaylussacia baccata* Forest (CEGL008521, G5)

- *Quercus prinus - (Quercus coccinea, Quercus rubra) / Kalmia latifolia / Vaccinium pallidum* Forest (CEGL006299, G5)
- *Quercus prinus - Quercus (rubra, velutina) / Vaccinium (angustifolium, pallidum*) Forest (CEGL006282, G5)
- *Quercus prinus - Quercus rubra / Vaccinium pallidum - (Rhododendron periclymenoides)* Forest (CEGL008523, G3G4)
- *Quercus prinus / Rhododendron catawbiense - Kalmia latifolia* Forest (CEGL008524, G4)
- *Tsuga canadensis - Quercus prinus - Betula lenta* Forest (CEGL006923, G3)

SPATIAL CHARACTERISTICS

Spatial Summary: Large-patch (at outer range) to matrix (in center of range) system that may cover extensive hillslopes and low ridges.

Adjacent Ecological Systems:

- Northeastern Interior Dry-Mesic Oak Forest (CES202.592)
- Southern and Central Appalachian Cove Forest (CES202.373)
- Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242)

DISTRIBUTION

Range: This system is found from central New England through Pennsylvania and south to the Roanoke River in southern Virginia. It is primarily Appalachian but overlaps slightly into the upper Piedmont and fall zone in Virginia, Maryland and the District of Columbia.

Divisions: 202:C

Nations: US

Subnations: CT, DC, MA, MD, ME, NH, NJ, NY, OH, PA, RI, VA, VT, WV

Map Zones: 57:P, 60:C, 61:C, 63:C, 64:C, 65:C, 66:C

USFS Ecomap Regions: 211E:CC, 211F:CC, 211G:CC, 211I:CC, 221A:CC, 221B:CC, 221D:CC, 232A:CC, M221A:CC, M221Ba:CCC, M221Bb:CCC, M221Bd:CCC, M221Bf:CCC, M221Da:CCC

CENTRAL APPALACHIAN PINE-OAK ROCKY WOODLAND (CES202.600)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Shrubland (Shrub-dominated); Woody-Herbaceous; Ridge/Summit/Upper Slope; Acidic Soil; Pinus (strobus, rigida, echinata, virginiana) - Quercus prinus
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Lowland; Temperate; Oligotrophic Soil; Shallow Soil; Ustic; Consolidated; F-Patch/Medium Intensity; Needle-Leaved Tree; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2377; ESLF 4320; ESP 1377

CONCEPT

Summary: This system encompasses open or patchily wooded hilltops and outcrops or rocky slopes in the Central Appalachians, High Allegheny Plateau, and Lower New England / Northern Piedmont. It occurs mostly at lower elevations, but occasionally up to 1220 m (4000 feet) in West Virginia. The substrate rock is generally granitic or of other acidic lithology, although near the northern limit of its range in New England, examples can also occur on intermediate, base-rich, or mafic bedrock including traprock. The vegetation is patchy, with woodland as well as open portions. *Pinus rigida* (and within its range *Pinus virginiana*) is diagnostic and often mixed with xerophytic *Quercus* spp. and sprouts of *Castanea dentata*. In New England, some examples lack pine and feature *Juniperus virginiana* or *Ostrya virginiana* as important codominants with oak. Some areas have a fairly well-developed heath shrub layer, others a graminoid layer, the latter particularly common under oaks or other deciduous trees. Conditions are dry and for the most part nutrient-poor, and at many, if not most, sites, a history of fire is evident. In the Central Appalachians ecoregion, this system is rarely found on sandy soils rather than rock.
Classification Comments: The northern extent of this system in central New England may overlap with Northern Appalachian-Acadian Rocky Heath Outcrop (CES201.571), which has *Picea* spp. prominent. The southern extent overlaps with Southern Appalachian Montane Pine Forest and Woodland (CES202.331), which is characterized by *Pinus pungens*. The present type may have some *Pinus pungens* (from southern Pennsylvania south) but generally has other pines as well. This type is differentiated from the similar Central Appalachian Dry Oak-Pine Forest (CES202.591) by its mosaic nature of wooded and open patches, as opposed to being merely a "thin forest." New England dry-rich forest/woodlands (e.g., those on traprock ridges) are also housed here, expanding the concept beyond pitch pine diagnostics. Pike Knob, West Virginia, with its disjunct red pine woodlands, is put into this system.
Similar Ecological Systems:
- Appalachian Shale Barrens (CES202.598)
- Central Appalachian Dry Oak-Pine Forest (CES202.591)
- Northern Appalachian-Acadian Rocky Heath Outcrop (CES201.571)
- Southern Appalachian Montane Pine Forest and Woodland (CES202.331)--is a restricted type characterized by the dominance (not just incidental occurrence) of *Pinus pungens*.

Related Concepts:

- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs mostly at lower elevations, but occasionally up to 1220 m (4000 feet) in West Virginia. The substrate rock is generally granitic or of other acidic lithology, although near the northern limit of its range in New England, examples can also occur on intermediate, base-rich, or mafic bedrock including traprock.

This system contains species-poor, fire-influenced, mixed woodlands of xeric, exposed montane habitats. They are typically located on convex, south to west facets of steep spur ridges, narrow rocky crests, and cliff tops. Pine - oak / heath woodlands are widespread throughout both the Ridge and Valley and Blue Ridge provinces in western Virginia. They occur at elevations from below 305 m (1000 feet) to more than 1220m (4000 feet) on various substrates, but most commonly on acidic, sedimentary and metasedimentary substrates, e.g., sandstone, quartzite, and shale. A few stands occur on Piedmont monadnocks and foothills. Soils are very infertile, shallow, and droughty (VDNH 2007).

The type is restricted to poor, dry sites which have been disturbed in the recent past by heavy cutting, fire, or both. It is found on thin, rocky soils in the mountainous areas. Soils are strongly acidic and devoid of nutrients. Precipitation is low in the shale barrens of eastern West Virginia and adjacent states (Eyre 1980).
Vegetation: Short-statured *Pinus pungens* and *Pinus rigida* are usually the dominants forming an open overstory, often with codominant *Quercus prinus (= Quercus montana)*. Less important tree associates include *Quercus coccinea, Pinus virginiana*, and *Sassafras albidum*. Except in the Piedmont, *Quercus ilicifolia* is characteristically abundant in the shrub layer, along with various ericaceous species. Colonial shrubs usually preempt available microhabitats for most herbaceous species, but *Pteridium aquilinum var. latiusculum* and *Xerophyllum asphodeloides* are often competitive enough to achieve significant cover (VDNH 2007).

The globally rare *Carex polymorpha*, the state-rare northern pine snake (*Pituophis melanoleucus melanoleucus*) and several rare moths, all bear oak feeders, are locally associated with these woodlands. More common and conspicuous animals often found in these dry, rocky, semi-open habitats include the northern fence lizard (*Sceloporus undulatus hyacinthinus*) and the five-lined skink (*Eumeces fasciatus*) (VDNH 2007).
Dynamics: Periodic fire is an important ecological process that provides opportunities for regeneration of both pines and less competitive herbaceous species, while setting back successional encroachment of potential overstory oaks (especially chestnut oak). On cliffs and other very rocky sites, the vegetation is self-perpetuating due to extreme edaphic conditions. (VDNH 2007). Fire is the most common disturbance type, but frost pockets and late-spring frosts have been also documented. If disturbances occur very frequently (every 2-3years), *Quercus ilicifolia* may be replaced by low shrubs, grasses, ferns, and other herbs. If disturbances are infrequent, canopy trees can outgrow the shade-intolerant *Quercus ilicifolia*.

Component Associations:
- *Juniperus virginiana - Fraxinus americana / Danthonia spicata - Poa compressa* Woodland (CEGL006002, G3)
- *Kalmia latifolia - Gaylussacia baccata - Vaccinium (angustifolium, pallidum) - Menziesia pilosa* Shrubland (CEGL003939, G2)
- *Penstemon hirsutus* Sparse Vegetation (CEGL006535, GNR)
- *Photinia melanocarpa - Gaylussacia baccata / Carex pensylvanica* Shrubland (CEGL008508, G1?)
- *Pinus (pungens, rigida) - Quercus prinus / (Quercus ilicifolia) / Gaylussacia baccata* Woodland (CEGL004996, G4)
- *Pinus resinosa / Menziesia pilosa / Polypodium appalachianum* Forest (CEGL006108, G1)
- *Pinus rigida - Quercus coccinea / Vaccinium angustifolium* Woodland (CEGL006557, G4Q)
- *Pinus rigida / (Quercus ilicifolia) / Photinia melanocarpa / Deschampsia flexuosa* Woodland (CEGL006116, G4)
- *Pinus rigida / Corema conradii* Woodland (CEGL006154, G2)
- *Pinus rigida / Gaylussacia baccata* Shrubland (CEGL006079, G1)
- *Pinus virginiana - Pinus (rigida, echinata) - (Quercus prinus) / Vaccinium pallidum* Forest (CEGL007119, G3)
- *Quercus ilicifolia - Prunus pumila* Shrubland (CEGL006121, G4?)
- *Quercus prinus - Pinus virginiana - (Pinus pungens) / Schizachyrium scoparium - Dichanthelium depauperatum* Woodland (CEGL008540, G3?)
- *Quercus prinus / Quercus ilicifolia / Danthonia spicata* Woodland (CEGL008526, G3?)
- *Quercus prinus / Rhus* spp. / *Deschampsia flexuosa* Woodland (CEGL006074, G3)
- *Quercus rubra - (Quercus prinus) / Vaccinium* spp. / *Deschampsia flexuosa* Woodland (CEGL006134, G4)
- *Quercus rubra - Carya (glabra, ovata) / Ostrya virginiana / Carex lucorum* Forest (CEGL006301, G4)
- *Schizachyrium scoparium - Danthonia spicata - Carex pensylvanica / Cladonia* spp. Herbaceous Vegetation (CEGL006544, G3)
- *Vaccinium (angustifolium, myrtilloides, pallidum)* Central Appalachian Dwarf-shrubland (CEGL003958, G3G4)
- *Vaccinium angustifolium - Sorbus americana / Sibbaldiopsis tridentata* Dwarf-shrubland (CEGL005094, GNR)

SPATIAL CHARACTERISTICS

Size: Patch sizes can range from a few acres to 300+ acres, but typically range from 1-50 acres. It is usually a small-patch occurrence.

DISTRIBUTION

Range: This system occurs from central New England south to Virginia and West Virginia, with peripheral occurrences in southeastern Ohio and easternmost Kentucky.
Divisions: 202:C
Nations: US
Subnations: CT, KY, MA, MD?, ME, NH, NJ, NY, OH, PA, VA, VT, WV

CENTRAL ATLANTIC COASTAL PLAIN MARITIME FOREST (CES203.261)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Coast
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2361; ESLF 4264; ESP 1361

CONCEPT

Summary: This system encompasses most woody vegetation of Atlantic Coast barrier islands and similar coastal strands, from Virginia Beach to central South Carolina (south approximately to the Cooper River where the true Sea Islands begin). It includes forests and shrublands whose structure and composition are influenced by salt spray, extreme disturbance events, and the distinctive climate of the immediate coast. Many examples of this system will include a component of *Quercus virginiana* or *Morella cerifera*. Also included are embedded freshwater depressional wetlands dominated by shrubs or small trees, such as *Cornus foemina, Persea palustris*, or *Salix caroliniana*. This system may experience less effects from fire than the equivalent Southern Atlantic Coastal Plain Maritime Forest (CES203.537).
Classification Comments: Southern Atlantic Coastal Plain Maritime Forest (CES203.537) occurs south of this system where barrier islands give way to sea islands (central South Carolina, approximately the Cooper River). Sea islands are wider and more extensive and their size may contribute to a greater ecological influence of fire resulting in a greater component of *Pinus elliottii* and *Pinus palustris* in maritime forests occurring there.

Northern Atlantic Coastal Plain Maritime Forest (CES203.302) occurs north of this system where deciduous trees come to prevail in the maritime forests [see Bellis (1992)] at approximately 37 degrees North latitude. There is a zone where both evergreen and deciduous forests occur (from approximately Nags Head, North Carolina, to Virginia Beach, Virginia), making the geographic boundary between the two systems somewhat unclear. The boundary of cold and warm offshore waters near Cape Hatteras may be an important climatic influence. This system is separated from Southern Atlantic Coastal Plain Dune and Maritime Grassland (CES203.273) by the dominance of woody vegetation, which corresponds to increased shelter from salt spray and increased stability of landforms.

Similar Ecological Systems:
- Northern Atlantic Coastal Plain Maritime Forest (CES203.302)--occurs to north.
- Southern Atlantic Coastal Plain Dune and Maritime Grassland (CES203.273)
- Southern Atlantic Coastal Plain Maritime Forest (CES203.537)--occurs to south.

DESCRIPTION

Environment: This system occurs on barrier islands and on coastal strands where barrier islands are lacking, and is seldom or never found more than 2 or 3 miles from the ocean. Chronic salt spray (sea salt aerosol), as well as intense salt spray during storms are important influences on vegetation structure and composition; however, the extent to which plant communities found in this system are shaped by salt spray varies. Examples closest to the coast are most likely to exhibit classic streamlined canopy shape due to spray sculpting and are less likely to support salt-intolerant plant species. Heavier salt spray often determines the boundary of this system with Southern Atlantic Coastal Plain Dune and Maritime Grassland (CES203.273). Maritime forest requires some shelter from the ocean, in the form of high dunes or extensive sand flats, in order to develop. This system may occur from the top of interior dunes to wet swales. Soils are sandy, except for mucks in the wettest swamps. Soils range from excessively drained to permanently saturated. They are presumably low in nutrient-holding capacity. The presence of shell fragments and the input of nutrients in salt spray probably makes this system fairly fertile. Topography and apparent moisture may vary widely with little change in vegetation. The ocean's moderation of climate may be a significant factor in the character of this system. A number of plant species extend much farther north in the maritime forests than they do even a few miles inland.
Vegetation: Vegetation includes shrublands and forests. Shrubland dominated by salt-tolerant shrubs such as *Morella cerifera* and *Ilex vomitoria* or by stunted trees often occurs on the seaward edge where salt spray is heavier. Forests are typically dominated by a small set of salt-tolerant evergreen trees, mainly *Quercus virginiana, Quercus hemisphaerica, Pinus taeda*, and in the southern portions, *Sabal palmetto*. Rare forested wetlands are dominated by a variety of wetland tree species, including *Acer rubrum, Nyssa*

biflora, and *Taxodium distichum*. A few of the most sheltered areas near the northern end of the range have forests with deciduous species such as *Fagus grandifolia* and *Quercus falcata*. Also included are embedded freshwater depressional wetlands dominated by shrubs or small trees, such as *Cornus foemina, Persea palustris*, or *Salix caroliniana*. Communities tend to be low in species richness, with all strata limited to a set of salt-tolerant species.

Dynamics: Maritime forests occur in the most stable portions of barrier islands, but the maritime environment is still extremely dynamic. Wind events and hurricanes will have significant impacts on this system. The environment for these forests may be severely altered or destroyed by geologic processes, such as the slow movement of dunes or their catastrophic destruction by storms. Sand movement may also create new sites for this system to occupy. Chronic salt spray and intense salt spray during storms are important influences on vegetation structure and composition; however, the extent to which plant communities found in this system are shaped by salt spray varies. Extreme salt spray or saltwater flooding in storms can severely disturb vegetation, though it recovers if the landforms have not been altered. Mature *Quercus virginiana* trees are fire-resistant when mature, and their litter also does not easily burn (Stalter and Odum 1993). Fire may have naturally occurred infrequently in this system, but probably was not an important factor. Extreme salt spray or saltwater flooding in storms can severely disturb vegetation, although the vegetation recovers if the landforms have not been altered.

Component Associations:
- *Acer rubrum - Nyssa biflora - (Liquidambar styraciflua, Fraxinus* sp.) Maritime Swamp Forest (CEGL004082, G2)
- *Cornus foemina / Berchemia scandens* Forest (CEGL007384, G1)
- *Juniperus virginiana var. silicicola - Zanthoxylum clava-herculis - Quercus virginiana - (Sabal palmetto) / Sageretia minutiflora - (Sideroxylon tenax)* Woodland (CEGL003525, G2?)
- *Morella cerifera - Prunus caroliniana - Zanthoxylum clava-herculis* Shrubland (CEGL004784, G2?)
- *Morella cerifera / Spartina patens* Shrubland (CEGL003839, G3G4)
- *Persea palustris / Morella cerifera* Maritime Forest (CEGL004635, G1)
- *Pinus taeda / Morella cerifera / Osmunda regalis var. spectabilis* Forest (CEGL006137, G3)
- *Quercus falcata - Pinus taeda - (Fagus grandifolia, Quercus nigra) / Persea palustris* Maritime Forest (CEGL007540, G1)
- *Quercus virginiana - (Ilex vomitoria)* Shrubland (CEGL003833, G3)
- *Quercus virginiana - (Pinus elliottii var. elliottii, Sabal palmetto) / Persea borbonia - Callicarpa americana* Forest (CEGL007032, G2)
- *Quercus virginiana - Quercus hemisphaerica - Pinus taeda - Quercus falcata / Persea palustris* Forest (CEGL007026, G2)
- *Quercus virginiana - Quercus hemisphaerica - Pinus taeda / Persea palustris - Ilex vomitoria* Forest (CEGL007027, G2)
- *Quercus virginiana - Quercus hemisphaerica / Ilex vomitoria / Aristida condensata - Panicum amarum var. amarum* Forest (CEGL004399, G1G3)
- *Quercus virginiana - Quercus incana* Woodland (CEGL003750, G1)
- *Salix caroliniana / Sacciolepis striata - Boehmeria cylindrica* Woodland (CEGL004222, G2?)
- *Taxodium distichum / Cephalanthus occidentalis / Boehmeria cylindrica - Ceratophyllum muricatum* Maritime Swamp Forest (CEGL004079, G1)

Spatial Characteristics

Size: Occurs as medium to large patches. Patch size varies naturally with the character of barrier islands. South-facing islands tend to have more extensive dunes that provide shelter for extensive, contiguous maritime forests. East-facing islands tend to naturally have discontinuous dunes and only small patches sheltered enough to support maritime forests. Presettlement vegetation had a few occurrences of several thousand acres, but only a couple as large as 1000 acres remain. Most occurrences now are artificially bounded remnants or naturally small patches of tens to hundreds of acres.

Adjacent Ecological Systems:
- Southeastern Coastal Plain Interdunal Wetland (CES203.258)
- Southern Atlantic Coastal Plain Dune and Maritime Grassland (CES203.273)
- Southern Atlantic Coastal Plain Salt and Brackish Tidal Marsh (CES203.270)

Adjacent Ecological System Comments: Always bordered by Southern Atlantic Coastal Plain Dune and Maritime Grassland (CES203.273) on the seaward side, and sometimes surrounded by them. May border tidal salt marshes on the back of barrier islands.

Distribution

Range: This system is found from southernmost Virginia to central South Carolina (south approximately to the Cooper River where the true Sea Islands begin).

National Mapping Codes: ESLF 4403

CONCEPT

Classification Comments: This system is based on a group that was drafted by Don Faber-Langendoen in March 2012 as a provisional concept for discussion with USNVC and CNVC partners. It was developed to account for the hemi-boreal patterns between boreal and temperate forests. Further review is needed before its confidence status can be confirmed.

CENTRAL INTERIOR HIGHLANDS DRY ACIDIC GLADE AND BARRENS (CES202.692)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Woody-Herbaceous; Sedimentary Rock; Igneous Rock; Acidic Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2363; ESLF 4305; ESP 1363

CONCEPT

Summary: This system is primarily found in the Interior Highlands of the Ozark, Ouachita, and Interior Low Plateau regions with small occurrences in northern Missouri. It occurs on flatrock outcrops and along moderate to steep slopes or valley walls of rivers along most aspects. Parent material includes chert, igneous and/or sandstone bedrock with well- to excessively well-drained, shallow soils interspersed with rock and boulders. These soils are typically dry during the summer and autumn, becoming saturated during the spring and winter. Grasses such as *Schizachyrium scoparium* and *Sorghastrum nutans* dominate this system with stunted oak species (*Quercus stellata, Quercus marilandica*) and shrub species such as *Vaccinium* spp. occurring on variable depth soils. *Juniperus virginiana* can be present and often increases in the absence of fire. In Kentucky, this system includes both sandstone glades found in the Shawnee Hills, as well as shale glades found in the Knobs region, both in the Kentucky Interior Low Plateau. It also includes dry *Quercus stellata*-dominated barrens on Cretaceous-aged gravel substrates on the northern fringes of the Upper East Gulf Coastal Plain Ecoregion in southern Illinois and western Kentucky. This system is influenced by drought and infrequent to occasional fires. Prescribed fires help manage this system by maintaining an open glade structure.
Classification Comments: The occurrence of this system in TNC Ecoregion 43 is apparently confined to southern Illinois and/or Kentucky but does not include any portions of states to the south. Not all examples are acidic. Sometimes a layer of limestone or neutral shale occurs in these and thus are not acidic.
Similar Ecological Systems:
- Appalachian Shale Barrens (CES202.598)
- Cumberland Sandstone Glade and Barrens (CES202.337)
- Ouachita Shale Glade and Barrens (CES202.343)

DESCRIPTION

Environment: This system occurs on flat outcrops of sandstone rock and along moderate to steep slopes or valley walls of rivers along most aspects. Parent material includes chert, shale, igneous and/or sandstone bedrock with well- to excessively well-drained, shallow soils interspersed with rock and boulders. These soils are typically dry during the summer and autumn, becoming saturated during the spring and winter.
Vegetation: Grasses such as *Schizachyrium scoparium* and *Sorghastrum nutans* dominate this system with stunted oak species (*Quercus stellata, Quercus marilandica*) and shrub species such as *Vaccinium* spp. occurring on variable depth soils. In the Shawnee Hills (EPA Ecoregions 71a, 72h of Woods et al. (2002)) of the Kentucky Interior Low Plateau, *Quercus marilandica, Quercus stellata,* and *Juniperus virginiana* are the dominant trees. *Ulmus alata* may be an understory component. Scattered shrubs, such as *Vaccinium arboreum* and *Chionanthus virginicus*, occur on the margins in patches of deeper soil. *Quercus prinus* may be present in the eastern part of the range. Some other plants that may be associated with these glades include *Andropogon ternarius, Danthonia spicata, Symphyotrichum patens var. patentissimum, Silene rotundifolia, Pityopsis graminifolia var. latifolia, Coreopsis grandiflora, Silene regia, Coreopsis lanceolata, Croton willdenowii, Sedum nuttallianum, Selaginella rupestris,* and *Portulaca pilosa*.
Dynamics: Ericaceous shrubs found here are different from calcareous glades. The thin, dry soil characteristic of this system dries out during the growing season and much of the vegetation dries, as well. This allows fires to spread easily and these fires restrict the abundance of woody species. In high-quality examples where the natural fire regime operates, small trees and shrubs are limited to the edges of stands or small "islands" of deeper soil that retain more moisture while grasses are the dominant vegetation. Sparsely vegetated areas between the dominant grassy zones contain most of the rare species found in this system (Ware 2002). In the absence of fire, from active suppression or a lack of fuel due to excessive grazing, woody species can increase greatly.

Component Associations:

- *(Quercus stellata, Ulmus alata) / Schizachyrium scoparium - Symphyotrichum patens var. patentissimum* Wooded Herbaceous Vegetation (CEGL007824, G2?)
- *Asplenium montanum - Heuchera parviflora var. parviflora - Silene rotundifolia* Sparse Vegetation (CEGL004392, G3G4)
- *Pinus virginiana - Pinus (rigida, echinata) - (Quercus prinus) / Vaccinium pallidum* Forest (CEGL007119, G3)
- *Quercus marilandica - Juniperus virginiana var. virginiana / Schizachyrium scoparium - Hypericum gentianoides* Wooded Herbaceous Vegetation (CEGL004062, G3?)
- *Quercus marilandica / Vaccinium arboreum / Danthonia spicata* Scrub Woodland (CEGL002425, G3G4)
- *Quercus prinus / Cornus florida - Amelanchier arborea / Pityopsis graminifolia var. latifolia* Woodland (CEGL003706, G2?)
- *Quercus prinus / Danthonia spicata - Silene caroliniana* Woodland (CEGL004439, G2?)
- *Quercus stellata - (Pinus echinata) / Vaccinium arboreum / Andropogon gerardii - Symphyotrichum patens var. patentissimum* Wooded Herbaceous Vegetation (CEGL007814, G2?)

COLORADO PLATEAU PINYON-JUNIPER WOODLAND (CES304.767)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Mesa; Ridge/Summit/Upper Slope; Sedimentary Rock; Temperate [Temperate Xeric]; Aridic; Pinus edulis, Juniperus osteosperma
Non-Diagnostic Classifiers: Foothill(s); Piedmont; Plateau; Forest and Woodland (Treed); Sideslope; Alkaline Soil; Long Disturbance Interval; F-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2016; ESLF 4203; ESP 1016

CONCEPT

Summary: This ecological system occurs in dry mountains and foothills of the Colorado Plateau region including the Western Slope of Colorado to the Wasatch Range, south to the Mogollon Rim, and east into the northwestern corner of New Mexico. It is typically found at lower elevations ranging from 1500-2440 m. These woodlands occur on warm, dry sites on mountain slopes, mesas, plateaus, and ridges. Severe climatic events occurring during the growing season, such as frosts and drought, are thought to limit the distribution of pinyon-juniper woodlands to relatively narrow altitudinal belts on mountainsides. Soils supporting this system vary in texture, ranging from stony, cobbly, gravelly sandy loams to clay loam or clay. *Pinus edulis* and/or *Juniperus osteosperma* dominate the tree canopy. In the southern portion of the Colorado Plateau in northern Arizona and northwestern New Mexico, *Juniperus monosperma* and hybrids of *Juniperus* spp. may dominate or codominate the tree canopy. *Juniperus scopulorum* may codominate or replace *Juniperus osteosperma* at higher elevations. Understory layers are variable and may be dominated by shrubs, graminoids, or be absent. Associated species include *Arctostaphylos patula, Artemisia tridentata, Cercocarpus intricatus, Cercocarpus montanus, Coleogyne ramosissima, Purshia stansburiana, Purshia tridentata, Quercus gambelii, Bouteloua gracilis, Pleuraphis jamesii, Pseudoroegneria spicata, Poa secunda,* or *Poa fendleriana*. This system occurs at higher elevations than Great Basin Pinyon-Juniper Woodland (CES304.773) and Colorado Plateau shrubland systems where sympatric.

Similar Ecological Systems:

COLUMBIA PLATEAU WESTERN JUNIPER WOODLAND AND SAVANNA (CES304.082)

CLASSIFIERS

Classification Status: Standard

Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Forest and Woodland (Treed); Ridge/Summit/Upper Slope; Aridic; Juniperus occidentalis
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2017; ESLF 4204; ESP 1017

CONCEPT

Summary: This woodland system is found along the northern and western margins of the Great Basin, from southwestern Idaho, along the eastern foothills of the Cascades, south to the Modoc Plateau of northeastern California. Elevations range from under 200 m along the Columbia River in central Washington to over 1500 m. Generally soils are medium-textured, with abundant coarse fragments, and derived from volcanic parent materials. In central Oregon, the center of distribution, all aspects and slope positions occur. Where this system grades into relatively mesic forest or grassland habitats, these woodlands become restricted to rock outcrops or escarpments with excessively drained soils. *Pinus monophylla* is not present in this region, so *Juniperus occidentalis* is the only tree species, although *Pinus ponderosa* or *Pinus jeffreyi* may be present in some stands. *Cercocarpus ledifolius* may occasionally codominate. *Artemisia tridentata* is the most common shrub; others are *Purshia tridentata, Ericameria nauseosa, Chrysothamnus viscidiflorus, Ribes cereum,* and *Tetradymia* spp. Graminoids include *Carex filifolia, Festuca idahoensis, Poa secunda,* and *Pseudoroegneria spicata*. These woodlands are generally restricted to rocky areas where fire frequency is low. Throughout much of its range, fire exclusion and removal of fine fuels by grazing livestock have reduced fire frequency and allowed *Juniperus occidentalis* seedlings to colonize adjacent alluvial soils and expand into the shrub-steppe and grasslands. *Juniperus occidentalis* savanna may occur on the drier edges of the woodland where trees are intermingling with or invading the surrounding grasslands and where local edaphic or climatic conditions favor grasslands over shrublands.
Classification Comments: These woodlands are composed of two very different types. There are old-growth *Juniperus occidentalis* woodlands with trees and stands often over 1000 years old, with fairly well-spaced trees with rounded crowns. There are also large areas where juniper has expanded into sagebrush steppe and bunchgrass-dominated areas, with young, pointed-crowned trees growing closely together. Currently, these two very different types are about equally distributed across the landscape, with *Juniperus occidentalis* continuing to expand, either from the combination of fire exclusion, past grazing or climate change. *Juniperus occidentalis* has also expanded into *Pinus ponderosa* and *Pinus ponderosa - Pinus contorta* stands in central Oregon.
Related Concepts:
- Western Juniper - Big Sagebrush - Bluebunch Wheatgrass (107) (Shiflet 1994) Broader. Most of this SRM type corresponds to this ecological system.
- Western Juniper: 238 (Eyre 1980) Equivalent

DESCRIPTION

Environment: This woodland system is found along the northern and western margins of the Great Basin, from southwestern Idaho, along the eastern foothills of the Cascades, south to the Modoc Plateau of northeastern California. Elevations range from under 200 m along the Columbia River in central Washington to over 1500 m. Generally soils are medium-textured, with abundant coarse fragments, and derived from volcanic parent materials. In central Oregon, the center of distribution, all aspects and slope positions occur. Where this system grades into relatively mesic forest or grassland habitats, these woodlands become restricted to rock outcrops or escarpments with excessively drained soils.
Vegetation: *Pinus monophylla* is not present in this region, so *Juniperus occidentalis* is the only tree species, although *Pinus ponderosa* or *Pinus jeffreyi* may be present in some stands. *Cercocarpus ledifolius* may occasionally codominate. *Artemisia tridentata* is the most common shrub; others are *Purshia tridentata, Ericameria nauseosa, Chrysothamnus viscidiflorus, Ribes cereum,* and *Tetradymia* spp. Graminoids include *Carex filifolia, Festuca idahoensis, Poa secunda,* and *Pseudoroegneria spicata*.
Dynamics: These woodlands are generally restricted to rocky areas where fire frequency is low. Throughout much of its range, fire exclusion and removal of fine fuels by grazing livestock have reduced fire frequency and allowed *Juniperus occidentalis* seedlings to colonize adjacent alluvial soils and expand into the shrub-steppe and grasslands. *Juniperus occidentalis* savanna may occur on the drier edges of the woodland where trees are intermingling with or invading the surrounding grasslands and where local edaphic or climatic conditions favor grasslands over shrublands.

CROSSTIMBERS OAK FOREST AND WOODLAND (CES205.682)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Eastern Great Plains (205)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Loam Soil Texture; Sand Soil Texture
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2308; ESLF 4114; ESP 1308

CONCEPT

Summary: This system is primarily found within central Texas and Oklahoma, ranging north to southeastern Kansas and east into eastern Oklahoma. It is distinct from the surrounding prairie by the higher density of tree species. The area consists of irregular plains with primarily sandy to loamy Ustalf soils that range from shallow to moderately deep. Rainfall can be moderate, but somewhat erratic, therefore moisture is often limiting during part of the growing season. Short, stunted *Quercus stellata* and *Quercus marilandica* characterize and dominate this system. Other species, such as *Carya texana, Carya cordiformis, Quercus prinoides, Ulmus crassifolia*, and other *Quercus* spp., can also be present within their respective ranges. The understory often contains species typical of the surrounding prairies, in particular *Schizachyrium scoparium*. Shrubs such as *Rhus* spp. may also be present. Drought, grazing, and fire are the primary natural processes that affect this system. Overgrazing and conversion to agriculture, along with fire suppression, have led to the invasion of some areas by problematic brush species such as *Juniperus virginiana* and *Juniperus ashei* and *Prosopis glandulosa* farther south in Texas and Oklahoma. It has also led to decreases in native grass cover allowing for annual grasses and forbs to invade.
Classification Comments: This system currently includes woodlands of the Arbuckle Mountains, as well as a disjunct occurrence in the Wichita Mountains of Oklahoma comprised of the following member: *Quercus fusiformis - (Quercus stellata) / Schizachyrium scoparium* Granite Woodland (CEGL004937) (B. Hoagland pers. comm. 2005). This vegetation could also be considered an outlier of Edwards Plateau Limestone Savanna and Woodland (CES303.660).

- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Intersecting

DESCRIPTION

Environment: This system is located on irregular plains comprised of sandy to loamy Ustalf soils. These soils range from shallow to moderately deep. Rainfall can be moderate, but sporadic, leading to periods of limiting moisture. This system also includes smaller patch woodlands dominated by *Quercus stellata* occurring over Mollisols and scattered throughout the limestone uplands of the eastern Edwards Plateau and Lampasas Cutplain of Texas, locally referred to as "Redlands" (B. Carr pers. comm. 2005). The eastern occurrences of this system are associated with sandy members of the Cretaceous Woodbine Formation, while western occurrences occupy soils derived from the sands of the Cretaceous Trinity Group (such as Paluxy, Antler, and Twin Mountain-Travis Peak sands). Further west, in the fringe of the western Crosstimbers, the system occurs on more rugged, rocky and gravelly sites derived from Pennsylvanian formations. The landforms are gently rolling, moderately dissected uplands, and irregular plains becoming more rugged in the western fringe of the distribution of this system. Soils are sands or sandy loams, some with a claypan. Ecological Sites typical of the eastern expressions include Sandy Loam, Tight Sandy Loam, Claypan Prairie, Sandstone Hill, and Sandy. Those more typical of the western expressions include Sandy Loam, Loamy Sand, Tight Sandy Loam, Sandy, and Clay Loam (Elliott 2011).
Vegetation: This system is generally described as a savanna or woodland, distinguished by its dominance by short, stunted *Quercus stellata* and/or *Quercus marilandica*. It occurs in southwest/northeast-trending bands separated by the Grand Prairie. Other species in the canopy may include *Ulmus crassifolia, Quercus fusiformis, Celtis laevigata,* and *Juniperus virginiana*. The understory may have been historically dominated by *Schizachyrium scoparium*, but current understory composition may be largely determined by land-use history and grazing pressure. *Carya texana, Carya cordiformis,* and *Quercus prinoides* are lacking from Texas examples and are mainly present in stands of this system in the northern Crosstimbers of Oklahoma (L. Elliott pers. comm. 2011). In the east, where

precipitation is greater, tallgrass species such as *Andropogon gerardii* and *Sorghastrum nutans* may be important components of the understory or occupy prairie patches. In the drier west, shortgrass species such as *Buchloe dactyloides* become more conspicuous. Other graminoid species that may be present include *Schizachyrium scoparium, Paspalum setaceum, Sporobolus compositus, Bouteloua curtipendula, Bouteloua hirsuta, Bouteloua rigidiseta, Bothriochloa laguroides ssp. torreyana, Nassella leucotricha*, and *Aristida* spp. Non-native species such as *Cynodon dactylon* and *Bothriochloa ischaemum var. songarica* frequently dominate the herbaceous layer. With the disruption of a natural fire cycle, branching of overstory species may be continuous to near ground level, reducing light penetration and leading to reduced herbaceous cover. The shrub layer may contain species such as *Smilax bona-nox, Rhus glabra, Rhus trilobata, Crataegus* spp., and *Symphoricarpos orbiculatus*. Sites dominated by *Prosopis glandulosa*, sometimes with *Ziziphus obtusifolia* as a common shrub component, are particularly common to the west. Sites dominated by junipers (including *Juniperus virginiana, Juniperus ashei*, and *Juniperus pinchotii*, depending on the site) are also frequently encountered. Prairie openings and inclusions tend to occur on tighter soils. Shrubs such as *Rhus* spp. may also be present. Other species may include *Celtis laevigata, Cercis canadensis, Cotinus obovatus, Fraxinus texensis, Gleditsia triacanthos, Juniperus ashei, Juniperus virginiana var. virginiana, Quercus fusiformis, Quercus buckleyi, Quercus velutina, Ulmus alata*, and *Ulmus americana* (Elliott 2011).
Dynamics: Drought, grazing, and fire primarily influence this system. Overgrazing and conversion to agriculture have allowed for the invasion of eastern red-cedar (*Juniperus virginiana*), Ashe's juniper (*Juniperus ashei*), and honey mesquite (*Prosopis glandulosa*) in some areas. Decreases in native grass cover associated with overgrazing can also lead to an increase in invasive annual grasses and forbs.

Component Associations:
- *Quercus buckleyi - Fraxinus texensis - Quercus muehlenbergii* Forest (CEGL004912, G2G3)
- *Quercus stellata - (Ulmus crassifolia) / Sideroxylon lanuginosum / Nassella leucotricha* Paluxy Sands Woodland (CEGL004213, GNR)

CROWLEY'S RIDGE MESIC LOESS SLOPE FOREST (CES203.079)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Unglaciated
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Loess; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2322; ESLF 4128; ESP 1322

CONCEPT

Summary: This ecological system of mesic upland forests is confined to Crowley's Ridge, which extends from Missouri south into Arkansas along the western side of the lower Mississippi River. This vegetation and the ridge itself are very distinctive from that of the adjacent alluvial plain. The ridge is a remnant loess-capped feature rising from 30 m to over 60 m (100-200 feet) above the alluvial plain surface, to about 150 m (450 feet) above sea level. The base of the ridge is comprised of Tertiary substrates overlain by Quaternary alluvial deposits and capped with up to 15 m (50 feet) of Pleistocene loess. The system is generally comprised of mesic forests that occupy ravines between narrow, "finger" ridges and slopes in a highly dissected landscape. The sites tend to be more mesic than sites elsewhere in the southeastern United States. In many cases, these slopes and ravines provide habitat for plant species that are rare or absent from other parts of the alluvial plain (e.g., *Liriodendron tulipifera, Tilia americana*). Canopies are dominated by *Fagus grandifolia, Quercus alba*, and *Liriodendron tulipifera*, with many associates.

Classification Comments: This type does not include all forests across the entire extent of southern Crowley's Ridge; excluded are dry and dry-mesic forests, typically on west-facing slopes and ridgetops. This system is best developed on southern Crowley's Ridge where loess is most pronounced, and becomes much more isolated and rare on the ridge north of approximately Jonesboro, Arkansas. Conversely, dry-mesic oak and shortleaf pine communities are rare within this system, becoming dominant on western slopes and in the northern ridge, respectively. The vegetation may share some superficial similarities with types referred to as western mesophytic forests, but it is well-separated geographically from these. A similar ecological system is East Gulf Coastal Plain Northern Loess Bluff Forest (CES203.481) which occurs farther eastward and is restricted to the loess bluffs east of the Mississippi River. The vegetation of these areas is believed to share a great detail of overlap. They are recognized as distinct for now due to geographic separation; further work may suggest that these two systems should be merged. There are a number of state parks and small natural areas on Crowley's Ridge, including Village Creek State Park, Crowley's Ridge State Park, Wittsburg Natural Area and Chalk Bluff Natural Area (which is toward the northern end of the ridge). All of these have moderate to high-quality examples of this system.

Similar Ecological Systems:
- Mississippi River Alluvial Plain Dry-Mesic Loess Slope Forest (CES203.071)

Related Concepts:
- Beech - Sugar Maple: 60 (Eyre 1980) Finer
- Mesic Loess/Glacial Till Forest (Nelson 2005) Broader
- Northern Red Oak: 55 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer
- White Oak: 53 (Eyre 1980) Finer

DESCRIPTION

Environment: These diverse-canopy forests occur in ravines in a highly dissected environment. The system is best expressed on southern Crowley's Ridge, Arkansas (Cross County south through Phillips County), with additional limited occurrences to the north, in undisturbed valleys and coves. Deep loessal soil is the most characteristic and diagnostic component of the environment of this system.

Vegetation: This system consists of forests that are typically dominated by beech, oaks and other hardwoods. Canopies are dominated by *Fagus grandifolia, Quercus alba*, and *Liriodendron tulipifera* (Clark 1977d), with many associates, including *Magnolia acuminata* and *Tilia americana* (T. Witsell pers. comm. 2013). Other oaks which may be present include *Quercus falcata, Quercus pagoda, Quercus rubra*, and *Quercus velutina*. Due to the apparent richness of the loessal soils, *Ostrya virginiana* is a particularly common species across many of the component community types. Species that may be present in the shrub layer include *Arundinaria gigantea, Asimina triloba, Bignonia capreolata, Lindera benzoin, Parthenocissus quinquefolia, Toxicodendron radicans*, and *Vitis rotundifolia*. Some possible herbs include *Cynoglossum virginianum, Dioscorea quaternata*, and *Sanicula canadensis*.

Dynamics: These are stable, generally fire-sheltered forests, with relatively low fire frequency and intensity. There is some natural disturbance from the effects of windstorms and collapse of the fragile loess. This mesic loess forest type typically experiences surface fires with return intervals of from 30 to greater than 100 years. Mixed-severity fires will occur approximately every 100 years, opening the canopy with increased mortality. This effect may also be achieved by recurrent, severe insect defoliations or droughts. Straight-line winds or microbursts may cause blowdowns on a scale of 1 to 100 acres. Stand-replacement fires happen very infrequently (Landfire 2007a).

Component Associations:
- *Fagus grandifolia - Quercus (alba, rubra) / Acer barbatum / Asimina triloba* Forest (CEGL004072, G2G3)
- *Quercus (rubra, alba, velutina) / Acer barbatum / Asimina triloba* Forest (CEGL004069, G1G2)
- *Quercus alba - Quercus falcata - Quercus velutina / Ostrya virginiana* Forest (CEGL004068, G1G2)
- *Quercus alba - Quercus rubra - Acer saccharum - Carya cordiformis / Lindera benzoin* Forest (CEGL002058, G3?)

SPATIAL CHARACTERISTICS

Spatial Summary: Small patch to large patch.

DISTRIBUTION

Range: This system is endemic to Crowley's Ridge (Arkansas, Missouri), which is a distinctive landscape feature in the Mississippi River Alluvial Plain.

CROWLEY'S RIDGE SAND FOREST (CES203.072)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Sand; Unglaciated
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Needle-Leaved Tree; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2510; ESLF 4332; ESP 1510

CONCEPT

Summary: This system of upland shortleaf pine - hardwood forests is confined to Crowley's Ridge on the western side of the Mississippi River. This vegetation is very distinctive from that of the adjacent alluvial plain, and the ridge itself also contrasts sharply with the adjacent alluvial plain. Crowley's Ridge is a remnant loess-capped feature rising from 30 m to over 60 m (100-200 feet) above the alluvial plain surface, to about 150 m (450 feet) above sea level. The base of the northern ridge is comprised of Tertiary substrates overlain by alluvial deposits and capped with generally thin layers of Pleistocene loess. The Pleistocene alluvial deposits are often sandy, and in a very limited area, there are outcrops of sandstone of uncertain origin. Forests on the ridgetops are dominated by *Pinus echinata* with varying amounts of *Quercus alba, Quercus rubra, Quercus falcata, Quercus stellata, Carya texana,* and *Quercus velutina*. Loess slopes and ravines are dominated by mesic or dry-mesic hardwood forests such as those of the southern ridge, but are of relatively limited extent.
Classification Comments: This system has been little studied, with the best description in Clark (1974). The presettlement and then-current distribution were mapped, and several sites were sampled. Clark classed the predominant community as Oak-Hickory-Pine, with shortleaf pine dominance ranging from 12-56% and combined white oak and post oak, the most abundant oaks, ranging from 24-60%.
Similar Ecological Systems:
- Lower Mississippi River Dune Woodland and Forest (CES203.531)
- Mississippi River Alluvial Plain Dry-Mesic Loess Slope Forest (CES203.071)

Related Concepts:
- Dry-mesic Sand Forest (Nelson 2005) Intersecting
- Shortleaf Pine - Oak: 76 (Eyre 1980) Finer
- Shortleaf Pine: 75 (Eyre 1980) Finer

DESCRIPTION

Environment: These forests occur on sandy ridges and slopes in a dissected environment. The system is best expressed on northern Crowley's Ridge, but there are limited occurrences on the southern ridge as well, on sandy, exposed sites. They generally lie to the east of hydroxeric Pleistocene terrace flatwoods (now usually converted to cropland) that burned frequently. Those fires would have continued into these dry to dry-mesic forests, thereby increasing the fire frequency.
Vegetation: This system consists of forests that are typically dominated by shortleaf pine with oaks and other hardwoods. Depending upon local soil moisture and other factors, canopy oaks can vary from *Quercus stellata* and *Quercus falcata* on the driest sites to *Quercus alba* and other oaks on more mesic sites. Associated species in the subcanopy and understory vary along this moisture gradient as well (refer to association-level descriptions for more details).
Dynamics: These are fire-adapted forests. There is presumably some natural disturbance from the effects of windstorms and collapse of the fragile loess. This vegetation is classed as Fire Regime I, with frequent surface fire (mean fire-return interval is approximately five years) and less frequent mixed fire. In addition, straight-line winds or microbursts may cause blowdowns on a scale of 1 to 100 acres. Stand-replacement fires happen very infrequently (Landfire 2007a).

Component Associations:
- *Quercus stellata - Quercus falcata / Ostrya virginiana* Forest (CEGL004064, G1)

DISTRIBUTION

Range: This system is endemic to Crowley's Ridge in the Mississippi River Alluvial Plain of Arkansas and Missouri (Nelson 2005).

CONCEPT

Summary: This ecological system occurs on the upper east slopes of the Cascades in Washington, south of Lake Chelan and south to Mount Hood in Oregon. Elevations range from 610 to 1220 m (2000-4000 feet) in a very restricted range occupying less than 5% of the forested landscape in the east Cascades. This system is associated with a submesic climate regime with annual precipitation ranging from 100 to 200 cm (40-80 inches) and maximum winter snowpacks that typically melt off in spring at lower elevations. This ecological system is composed of variable montane coniferous forests typically below Pacific silver fir forests along the crest east of the Cascades. This system also includes montane forests along rivers and slopes, and in mesic "coves" which were historically protected from wildfires. Most occurrences of this system are dominated by a mix of *Pseudotsuga menziesii* with *Abies grandis* and/or *Tsuga heterophylla*. Several other conifers can dominate or codominate, including *Thuja plicata, Pinus contorta, Pinus monticola,* and *Larix occidentalis*. *Abies grandis* and other fire-sensitive, shade-tolerant species dominate forests on many sites once dominated by *Pseudotsuga menziesii* and *Pinus ponderosa*, which were formerly maintained by wildfire. They are very productive forests in the eastern Cascades which have been priority stands for timber production. *Mahonia nervosa, Linnaea borealis, Paxistima myrsinites, Acer circinatum, Spiraea betulifolia, Symphoricarpos hesperius, Cornus nuttallii, Rubus parviflorus*, and *Vaccinium membranaceum* are common shrub species. The composition of the herbaceous layer reflects local climate and degree of canopy closure and contains species more restricted to the Cascades, for example, *Achlys triphylla, Anemone deltoidea*, and *Vancouveria hexandra*. Typically, stand-replacement fire-return intervals are 150-500 years with moderate-severity fire-return intervals of 50-100 years.
Classification Comments: Includes *Tsuga heterophylla* and *Thuja plicata* associations and moister *Abies grandis* associations in eastern Cascades.

EAST CASCADES OAK-PONDEROSA PINE FOREST AND WOODLAND (CES204.085)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Ridge/Summit/Upper Slope; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Aridic; Intermediate Disturbance Interval [Periodicity/Polycyclic Disturbance]; F-Patch/Medium Intensity
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Montane [Montane]; Montane [Lower Montane]; Forest and Woodland (Treed); Temperate [Temperate Continental]; Circumneutral Soil; F-Landscape/Low Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2060; ESLF 4301; ESP 1060

CONCEPT

Summary: This narrowly restricted ecological system appears at or near lower treeline in foothills of the eastern Cascades in Washington and Oregon within 65 km (40 miles) of the Columbia River Gorge. It also appears in the adjacent Columbia Plateau ecoregion. Elevations range from 460 to 1920 m. Most occurrences of this system are dominated by a mix of *Quercus garryana* and *Pinus ponderosa* or *Pseudotsuga menziesii*. Isolated, taller *Pinus ponderosa* or *Pseudotsuga menziesii* over *Quercus garryana* trees characterize parts of this system. Clonal *Quercus garryana* can create dense patches across a grassy landscape or can dominate open woodlands or savannas. The understory may include dense stands of shrubs or, more often, be dominated by grasses, sedges or forbs. Shrub-steppe shrubs may be prominent in some stands and create a distinct tree / shrub / sparse grassland habitat, including *Purshia tridentata, Artemisia tridentata, Artemisia nova,* and *Chrysothamnus viscidiflorus*. Understories are generally dominated by herbaceous species, especially graminoids. Mesic sites have an open to closed sodgrass understory dominated by *Calamagrostis rubescens, Carex geyeri, Carex rossii, Carex inops,* or *Elymus glaucus*. Drier savanna and woodland understories typically contain bunchgrass steppe species such as *Festuca idahoensis* or *Pseudoroegneria spicata*. Common exotic grasses that often appear in high abundance are *Bromus tectorum* and *Poa bulbosa*. These woodlands occur at the lower treeline/ecotone between *Artemisia* spp. or *Purshia tridentata* steppe or shrubland and *Pinus ponderosa* and/or *Pseudotsuga menziesii* forests or woodlands. In the Columbia River Gorge, this system appears as small to large patches in transitional areas in the Little White Salmon and White Salmon river drainages in Washington and Hood River, Rock Creek, Moiser Creek, Mill Creek, Threemile Creek, Fifteen Mile Creek, and White River drainages in Oregon. *Quercus garryana* can create dense patches often associated with grassland or shrubland balds within a closed *Pseudotsuga menziesii* forest landscape. Commonly the understory is shrubby and composed of *Ceanothus integerrimus, Holodiscus discolor, Symphoricarpos albus,* and *Toxicodendron diversilobum*. Fire plays an important role in creating vegetation structure and composition in this habitat. Decades of fire suppression have led to invasion by *Pinus ponderosa* along lower treeline and by *Pseudotsuga menziesii* in the gorge and other oak patches on xeric sites in the east Cascade foothills. In the past, most of the habitat experienced frequent low-severity fires that maintained woodland or savanna conditions. The mean fire-return interval is 20 years, although variable. Soil drought plays a role, maintaining an open tree canopy in part of this dry woodland habitat.
Classification Comments: Mapping this system presents a typical scale problem. Areas of pure ponderosa pine are found directly adjacent to oak stands. This system is a matrix type with stands of *Pinus ponderosa, Quercus garryana, Pinus ponderosa - (Pseudotsuga menziesii) - Quercus garryana*; still need to get a mapping protocol and concept to distinguish *Pseudotsuga menziesii* with *Quercus garryana* patches in the east gorge White Salmon. The Little White Salmon drainage near Augspurger Mountain is the transition area between North Pacific Oak Woodland (CES204.852) and this system (Dog Mountain is the westernmost in Washington).
Related Concepts:

EAST GULF COASTAL PLAIN INTERIOR SHORTLEAF PINE-OAK FOREST (CES203.506)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Short Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2372; ESLF 4315; ESP 1372

CONCEPT

Summary: This forested ecological system of the East Gulf Coastal Plain occurs most extensively on generally rolling uplands north of the range of *Pinus palustris*. It was the historical matrix in large areas of the region in Alabama and Mississippi, particularly between about 32 degrees 30 minutes N latitude (the approximate local northern limit of the historic range of *Pinus palustris*), and about 35 degrees N latitude (the approximate limit where relatively extensive examples of *Pinus echinata* are replaced by predominantly hardwood-dominated systems, although isolated examples of this system may occur both north and south of these boundaries in limited areas. Stands tend to occur on generally well-drained sandy or clayey soils with dry to dry-mesic moisture regimes. *Pinus echinata* is the dominant pine species of the generalized "dry and dry-mesic oak-pine" forest type in the Gulf Coastal Plain and is the most characteristic floristic component of this system. The actual amount of *Pinus echinata* present varies based on a number of factors, but intact examples of this system often include stands that are dominated by *Pinus echinata* grading into stands with a mixture of upland hardwoods. Locally, on mid to lower slopes, *Pinus taeda* may be a component, extending further upslope in the absence of fire. Fire is possibly the most important natural process affecting the floristic composition and vegetation structure of this system, although fire-return intervals are lower than those associated with the East Gulf Coastal Plain Interior Upland Longleaf Pine Woodland (CES203.496). *Pinus echinata* may have difficulty replacing itself in the absence of fire, particularly on sites other than the driest ones. Local topographic conditions affecting natural fire compartment size generally lend themselves to this fire frequency, although some examples may have more frequent fires and some less than this generalized value. Where fire is most frequent the system may develop a relatively pure canopy of *Pinus echinata* typified by a very open woodland structure with scattered overstory trees and an herbaceous-dominated understory; such examples are rare on the modern landscape. More typical are areas in which *Quercus* spp., *Carya* spp., *Liquidambar styraciflua, Liriodendron tulipifera, Acer* spp., and *Nyssa sylvatica* have become prominent in the midstory and even overstory and in which herbaceous patches are rare. Although the general distributional boundaries described above indicate where this system formed an historical landscape matrix, smaller patches of the system may also be present in limited areas both north and south of these boundaries. Although some sources map the native range of shortleaf pine throughout a relatively large area of western Tennessee, the actual distribution of the species appears to be much more confined and almost absent from the Coastal Plain; when present, it occurs in only small stands on dry southwestern aspects.
Classification Comments: The range of this system overlaps with East Gulf Coastal Plain Northern Dry Upland Hardwood Forest (CES203.483) in the Fall Line Hills ecoregion (65i) of Alabama and in the Southern Hilly Gulf Coastal Plain ecoregion (65d) of Mississippi and may overlap to some degree with Southern Coastal Plain Dry Upland Hardwood Forest (CES203.560) as well. In parts of the overlapping range (including the Oakmulgee Ranger District of the Talladega National Forest), these types occur in a mosaic which is difficult to interpret environmentally and ecologically (A. Schotz pers. comm.). East Gulf Coastal Plain Northern Loess Plain Oak-Hickory Upland (CES203.482) replaces this system along the northern and northwestern boundary in Tennessee.

- Shortleaf Pine: 75 (Eyre 1980) Finer

DESCRIPTION

Environment: The core distribution of this system lies between about 32 degrees 30 minutes N latitude and about 35 degrees N latitude; more localized occurrences may be found as small patches both north and south of these boundaries embedded in other systems. The belted character of this region, in the form of inner lowlands and cuestas and other low-ridge landforms (Bowman 1911, Fenneman 1938), the associated diversity of soil types, and differences in settlement history appear to account for the importance of shortleaf pine in the Gulf Coast region when compared to the Atlantic Coastal Plain (White and Lloyd 1998). Cuestas and other hills create strong environmental gradients which, coupled with soil characteristics, promote a variety of mixed pine and pine-hardwood vegetation in this region; local differences in topography, parent material, and exposure influence site characteristics, resulting in numerous different plant communities. This system primarily occupies the dry and dry-mesic portion of regional moisture gradients.

Wide variation in vegetation composition across this gradient is also strongly related to fire frequency and intensity (White and Lloyd 1998). Generally to the south and southeast it grades into longleaf pine-dominated system(s), and to the north into hardwood-dominated ones.

Vegetation: This system is primarily composed of forest or woodland vegetation dominated by trees generally up to about 33 m (100 feet) in height. Individual patches or stands may be predominantly evergreen, predominantly deciduous, or mixed. The canopy will be primarily relatively closed (greater than 60%), but some areas may exhibit lower canopy closures, either as a result of repeated surface fires, timber removal, or other disturbances. This system includes the Shortleaf Pine-Oak Cover Type (Eyre 1980) as expressed in the Upper East Gulf Coastal Plain. In contrast to most of the Atlantic Coastal Plain, *Pinus echinata* is a much more ecologically and economically important species across much of the Gulf Coastal Plain, both presently and historically (Mohr 1901, Harper 1920, 1943). The actual vegetation composition depends greatly upon local site conditions, ongoing management, and disturbance history of an area. Locally, the species that comprise the system are strongly influenced by soil, slope, and aspect (Eyre 1980). Examples may be composed of various mixtures of pines and hardwoods. Although the actual amount of *Pinus echinata* present varies based on a number of factors, intact examples of this system often include stands that are dominated by *Pinus echinata* grading into stands with a mixture of upland hardwoods. Where fire is most frequent the system may develop a relatively pure canopy of shortleaf typified by a very open woodland structure with scattered overstory trees and an herbaceous-dominated understory; such examples are rare on the modern landscape. More typical are areas in which *Pinus echinata* trees occur in mixture with *Quercus* spp. and *Carya* spp. Many such areas also support *Liquidambar styraciflua, Liriodendron tulipifera, Acer* spp., and *Nyssa sylvatica*, and even *Pinus taeda*. When these species are prominent in the overstory and midstory it is generally though to be indicative of fire suppression. *Quercus alba* and *Quercus stellata* are common hardwood components, particularly in later-seral or higher-quality stands, typically combined with *Carya alba, Carya pallida, Carya glabra*, and other *Carya* spp. Higher-quality areas may exhibit somewhat open canopies. Other tree species indicative of recent disturbance and/or fire suppression are *Quercus nigra, Quercus hemisphaerica, Quercus falcata*, and *Quercus velutina*. Subcanopies will typically contain *Cornus florida, Oxydendrum arboreum, Nyssa sylvatica*, and *Liquidambar styraciflua*. The patchy shrub layer includes *Vaccinium arboreum, Vaccinium elliottii, Asimina parviflora, Aesculus pavia, Hamamelis virginiana, Callicarpa americana, Hypericum hypericoides, Gelsemium sempervirens, Vitis rotundifolia*, and *Arundinaria gigantea*. Herbs, which may be few and sparse, include *Cnidoscolus stimulosus, Indigofera caroliniana, Aristolochia serpentaria, Piptochaetium avenaceum, Chasmanthium sessiliflorum, Elephantopus tomentosus, Hexastylis arifolia, Iris verna, Rudbeckia fulgida, Solidago juncea, Euphorbia pubentissima, Mitchella repens*, and *Desmodium* spp. (NatureServe Ecology unpubl. data 2003). Other associates may include *Smilax* spp., *Symphyotrichum* spp., *Coreopsis* spp., *Lespedeza* spp., *Viola pedata, Mimosa microphylla, Antennaria* spp., *Clitoria mariana, Senna* spp., *Chasmanthium latifolium, Dichanthelium* spp., *Andropogon* spp., *Schizachyrium scoparium*, and *Carex* spp. (Lawson 1990).

Dynamics: The frequent presence of surface fire is important in order to support the reproduction of *Pinus echinata*, which is a critical species characteristic to the system. *Pinus echinata* is a shade-intolerant species and does not survive or grow well when fire-suppressed. Outbreaks of *Dendroctonus frontalis* (Southern Pine Beetle) also play an important role in shaping the dynamics of this system and the balance of pine versus hardwood dominance over time. Young shortleaf pines are generally slower growing and slower to dominate a site than *Pinus taeda* or many hardwood competitors, but they usually will endure competition longer than the common associate, *Pinus taeda*. *Pinus echinata* can maintain dominance on most sites after it overtops competing vegetation, but in general hardwoods cannot be eliminated from pine sites. On very good sites (i.e., with high site index), however, it may not outgrow competing species such as sweetgum and red maple (Lawson 1990).

Component Associations:
- *Pinus echinata - Pinus taeda - Quercus (alba, stellata) - Carya alba / Oxydendrum arboreum* Forest (CEGL008493, G2G3)
- *Pinus echinata - Quercus alba - Carya alba* East Gulf Coastal Plain Forest (CEGL004050, G2G3)
- *Pinus echinata - Quercus falcata* East Gulf Coastal Plain Forest (CEGL004052, G2G3)
- *Pinus echinata - Quercus stellata - (Quercus marilandica)* Forest (CEGL004053, G1)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- East Gulf Coastal Plain Northern Dry Upland Hardwood Forest (CES203.483)
- East Gulf Coastal Plain Southern Loblolly-Hardwood Flatwoods (CES203.557)
- Southern Coastal Plain Dry Upland Hardwood Forest (CES203.560)
- Southern Coastal Plain Limestone Forest (CES203.502)
- Western Highland Rim Prairie and Barrens (CES202.352)

Adjacent Ecological System Comments: Southern Coastal Plain Limestone Forest (CES203.502) occurs adjacent in parts of the region, especially the Black Belt.

DISTRIBUTION

Range: This system is restricted to the East Gulf Coastal Plain; it was the historical matrix in large areas of the region in Alabama and Mississippi, particularly between about 32 degrees 30 minutes N latitude and about 35 degrees N latitude. In southwestern Mississippi, this system is apparently dominant on the landscape west of 91 degrees W longitude to the limits of the alluvial plain and northwest of a line running approximately from the intersection of 31 degrees N latitude and 91 degrees W longitude, northeastward to the city of Jackson, Mississippi, extending at least to about 34 degrees N latitude. This is consistent with the ranges of Oak-Pine vegetation (generally equivalent to this system) versus Longleaf-Loblolly-Slash Pines in Shantz and Zon (1924).

EAST GULF COASTAL PLAIN INTERIOR UPLAND LONGLEAF PINE WOODLAND (CES203.496)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); East Gulf Coastal Plain; Very Short Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2349; ESLF 4252; ESP 1349

CONCEPT

Summary: This system represents *Pinus palustris* forests of rolling, dissected to relatively flat uplands of the East Gulf Coastal Plain. These stands occur primarily in EPA Ecoregion 65. It is found inland of the coastal flatlands (EPA Ecoregion 75a) and extends landward into the Upper East Gulf Coastal Plain Ecoregion by about 80 km (50 miles). It potentially occupies a much larger geographic area than the related *Pinus palustris* woodlands of the outer coastal area. The characteristic species is *Pinus palustris*, although many stands may support only relictual individuals following a long history of exploitation, harvest, and stand conversion, primarily to agriculture or to planted stands of *Pinus elliottii var. elliottii* or *Pinus taeda*. This system includes stands with a range of soil and moisture conditions. Mesic stands on medium- to fine-textured soils are more typical of the system, although limited xeric areas on deep sands are also present. In natural condition, fire is believed to have been frequent enough to limit development of fire-intolerant hardwood species as well as *Pinus taeda* and *Pinus echinata*. Although such species may be present or even common in the most mesic stands, they generally do not share dominance in the overstory unless fire has been absent from the stand.
Classification Comments: The dominance of *Pinus palustris* in examples of this ecological system may be lost through fire suppression, bark beetle infestations, forestry and agricultural land conversion, and mechanical disturbance. Loss of *Pinus palustris* dominance will fundamentally change the ecological function of the landscape occupied by the system, primarily by altering the fire regime. Without the appropriate fire regime, canopy closure will increase along with shrub dominance, and grasses, forbs and other finer-fuel components will decline, further altering the fire regime dynamics.

Systems dominated by *Pinus palustris* are subdivided by biogeography, from northeast to southwest across the coastal plains from Virginia to Texas. Longleaf pine-dominated stands in the rocky submontane areas of the Piedmont as well as the Ridge and Valley (from North Carolina to Alabama) are classified as a separate system, Southeastern Interior Longleaf Pine Woodland (CES202.319).
Similar Ecological Systems:
- East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506)
- East Gulf Coastal Plain Near-Coast Pine Flatwoods (CES203.375)
- Southeastern Interior Longleaf Pine Woodland (CES202.319)

- Sandhill (FNAI 1990) Broader
- Upland Pine Forest (FNAI 1990) Undetermined

DESCRIPTION

Environment: This system once occupied extensive areas of the East Gulf Coastal Plain from the northern range limits of Pinus palustris southward to the inland terminus of the Coastal Flatlands (sensu Peet and Allard (1993); Ecoregion 75a (EPA 2004)). In its natural condition, this system occupied a range of upland soils from clays and loams to deep sands, including weathered and older Ultisols. Due to locally distinctive understory, shrub and herbaceous vegetation associated with differing soil textures, "sandhills" and "loamhills" are generally recognizable as distinctive components of this system. However, they are generally interspersed to such an extent that differentiating them as separate systems is not practical. The topography of this system is generally more rolling than East Gulf Coastal Plain Near-Coast Pine Flatwoods (CES203.375) to the south. The largest and best examples occupy landscapes where prescribed fire is an active management practice. Localized soil characteristics will determine the specific composition of the lower strata. Ultisols are the dominant soil order and cover most of the range of the system. Ultisols most commonly associated with *Pinus palustris* are the Typic Paleudults and Plinthic Paleudults. More limited areas are occupied by Psamments and other coarser-textured materials. *Pinus palustris* grows in warm, wet temperate climates characterized by hot summers and mild winters. Annual mean temperatures range from 16 to 23 degrees C (60-74 degrees F), and annual precipitation ranges from 1090 to 1750 mm (43-69 inches) (Boyer 1990). Fall is the driest season of the year, although periods of drought during the growing season are not unusual (Boyer 1990).
Vegetation: Occurrences of this system are typically more-or-less open-canopy stands (woodlands) dominated by the evergreen needle-leaved tree *Pinus palustris*. In parts of the range, and on more rolling topography, other pines may be present, including *Pinus echinata* and *Pinus taeda*. These may increase or become codominant with extended fire-return times. Unless fire suppression is extreme, deciduous trees generally do not share dominance in the canopy. More mesic stands (e.g., those on finer-textured soils) may

contain oaks, such as *Quercus falcata, Quercus nigra,* or *Quercus pumila,* and occasionally species favoring more xeric conditions, such as *Quercus marilandica* or *Quercus stellata,* in combination with the more mesic oaks. Even more xeric stands (uncommon in this system) may contain "scrub oaks" such as *Quercus incana, Quercus laevis, Quercus margarettiae,* or *Quercus arkansana*. In fire-suppressed areas, *Quercus falcata, Liquidambar styraciflua, Acer rubrum, Quercus nigra, Nyssa sylvatica, Cornus florida, Callicarpa americana,* and/or *Rhus copallinum* may invade or increase. Some typical mesic to dry-mesic herbaceous species include *Andropogon ternarius, Andropogon gyrans var. gyrans, Schizachyrium scoparium, Sorghastrum nutans*, and *Panicum virgatum. Aristida stricta* or *Aristida beyrichiana* are also dominant or at least present in the herbaceous layer of many more southern and coastward examples. Variation in floristic composition of this wide-ranging system is related to site conditions, fire-return interval, and local or regional floristics. The herbaceous layer typically becomes much less diverse with increased fire-return interval. The wiregrass *Aristida beyrichiana* is not present throughout the range of this system, and even within the range of this species, it tends to be dominant or more abundant in moister sites, particularly in the western part of the system's range (and also in examples of East Gulf Coastal Plain Near-Coast Pine Flatwoods (CES203.375)).

Dynamics: Frequent fire was the predominant natural disturbance in this system, which is now dependent on management with prescribed fire. Component communities naturally burned every few years, many averaging as often as every 3 years. Fires are naturally low to moderate in intensity. They burn above-ground parts of herbs and shrubs but have little effect on the fire-tolerant trees. Vegetation recovers very quickly from fire; the perennial species resprout quickly. Many herbaceous plants have their flowering triggered by burning. Frequent fires help maintain more species richness at small sample scales, compared to pinelands of the other regions (Carr et al. 2010). In the absence of fire, hardwoods increase. *Quercus* spp. and shrubs, kept to low density and mostly reduced to shrub size by fire, become tall and dense and can suppress *Pinus palustris* regeneration. Herb layer density and diversity decline without occasional fire. Frequent fire requires a mix of fine fuels composed both of herbaceous (primarily grasses) fine fuels and *Pinus palustris* leaf litter. Consequently, thinning the *Pinus palustris* canopy to low basal area or opening too large gaps, particularly in absence of *Aristida beyrichiana,* can lead to rapid hardwood encroachment due to lack of abundant and continuous fuels necessary for frequent fire (K. Kirkman pers. comm.). Only on the most excessively drained coarse sands does the vegetation not undergo substantial structural alteration and reduction in species richness after a number of years without burning. This is due to the infertile soils. This structural alteration occurs more slowly on these infertile soils, but due to the slow accumulation of fuels, lack of fire can become more pronounced.

Canopies are believed to naturally be multi-aged, consisting of a fine mosaic of small even-aged groves driven by gap-phase regeneration. *Pinus palustris* is shade-intolerant and slow to reach reproductive age but is very long-lived. *Pinus palustris* seedlings can survive under a gap opening in canopy >35%. However, they will not move out of grass stage unless the gap fraction is >60%. Because these canopy gaps have less needle fall, the frequent fires which burn there are less intense, which permits *Pinus palustris* seedlings to survive. *Pinus palustris* can also stay in the sapling stage for decades and still take advantage of a gap opening to move into the canopy (Kirkman and Mitchell 2006).

Component Associations:

- *Pinus palustris - Pinus (echinata, taeda) / Quercus (marilandica, laevis) / Schizachyrium scoparium* Woodland (CEGL008491, G3)
- *Pinus palustris - Pinus (echinata, taeda) / Schizachyrium tenerum - Vernonia angustifolia* Woodland (CEGL004774, G2G3)
- *Pinus palustris / Asimina angustifolia / Aristida beyrichiana - Schizachyrium scoparium - Dyschoriste oblongifolia* Woodland (CEGL004485, G2G3)
- *Pinus palustris / Quercus falcata / Cornus florida / Aristida beyrichiana* Woodland (CEGL004945, G1G2)
- *Pinus palustris / Quercus falcata / Cornus florida / Schizachyrium scoparium* Woodland (CEGL003575, G3)
- *Pinus palustris / Quercus incana / Sporobolus clandestinus* Woodland (CEGL004957, G1G2)
- *Pinus palustris / Quercus laevis / Aristida beyrichiana - Pityopsis aspera* Woodland (CEGL003583, G3)
- *Pinus palustris / Quercus laevis / Schizachyrium scoparium - Rhynchosia cytisoides* Woodland (CEGL003587, G3)
- *Pinus palustris / Quercus laevis / Serenoa repens - Clinopodium coccineum* Woodland (CEGL003601, G2)
- *Pinus palustris / Quercus laevis / Serenoa repens / Aristida condensata* Woodland (CEGL003588, G2)
- *Pinus palustris / Quercus marilandica / Schizachyrium scoparium - Schizachyrium tenerum - Rhexia alifanus* Woodland (CEGL003598, G2G3)
- *Pinus palustris / Quercus pumila / Aristida beyrichiana* Woodland (CEGL007749, G2G3)
- *Pinus palustris / Schizachyrium scoparium - Coreopsis tripteris - Baptisia bracteata var. leucophaea* Woodland (CEGL004955, G2)
- *Pinus palustris / Schizachyrium scoparium - Verbesina aristata* Loamhill Woodland (CEGL008452, G2G3)

DISTRIBUTION

Range: This system formerly occupied an extensive range across the southern parts of Alabama, northern Panhandle of Florida (north of the Cody Scarp), southern Mississippi, and southwestern Georgia and was also present in limited areas of Louisiana. It has been greatly reduced in its extent, with much of its range now occupied by agriculture or by planted stands of *Pinus taeda*. In southwestern Mississippi, this system is apparently absent (or very rare and limited) west of 91 degrees W longitude to the limits of the alluvial plain and northwest of a line running approximately from the intersection of 31 degrees N latitude and 91 degrees W longitude, northeastward to the city of Jackson, Mississippi. This is consistent with the ranges of "Oak-Pine" vegetation versus "Longleaf-Loblolly-Slash Pines" (generally equivalent to this system) in Shantz and Zon (1924). In southwest Georgia, this ecological system occurs in Coastal Plain areas which drain to the Gulf of Mexico.

EAST GULF COASTAL PLAIN MARITIME FOREST (CES203.503)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); East Gulf Coastal Plain; Coast
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2380; ESLF 4323; ESP 1380

CONCEPT

Summary: This system encompasses a mosaic of woody vegetation present on barrier islands and near-coastal strands along the northern Gulf of Mexico, from the Florida panhandle to southern Mississippi. Examples may include forests and/or shrublands that are found in somewhat more protected environments than East Gulf Coastal Plain Dune and Coastal Grassland (CES203.500). Such areas include relatively stabilized coastal dunes, sometimes with a substantial shell component. Vegetation structure and composition are influenced by salt spray, extreme disturbance events, and the distinctive climate of the immediate coast. Stands may be dominated by a variety of needle-leaved and broad-leaved evergreen trees, including *Pinus clausa, Pinus elliottii var. elliottii, Pinus palustris, Quercus virginiana, Sabal palmetto, Carya glabra*, and *Carya pallida*. Wetland inclusions may be dominated by *Taxodium ascendens* and *Magnolia virginiana*. The most heavily salt-influenced examples may appear pruned or sculpted.

DESCRIPTION

Environment: This system is found on barrier islands and near-coastal strands, on stable dune-and-swale topography in somewhat more protected environments along the northern Gulf of Mexico. More specifically, these areas are generally landward of the foredune and transitional backdune zones. Examples may include forests and/or shrublands that are found in somewhat more protected environments than adjacent dune and coastal grassland vegetation. The system typically includes a series of stabilized dunes and interdune swales oriented parallel to the coastline. Soils are primarily wind- and wave-deposited, well-drained quartz sands of Appalachian origin (Drehle 1973, Johnson and Barbour 1990), sometimes with a substantial shell component, that have been stabilized long enough to support trees and shrubs. As the forest establishes, soil temperature fluctuations moderate and humus begins to build up over the well-drained sands, contributing to moisture retention and leading to more mesic conditions, especially in swales where soil moisture is typically higher (FNAI 1990).

Vegetation: Stands may be dominated by a variety of needle-leaved and broad-leaved evergreen trees, including *Pinus clausa, Pinus elliottii var. elliottii, Pinus palustris, Quercus virginiana, Sabal palmetto, Carya glabra*, and *Carya pallida*. Wetland inclusions may be dominated by *Taxodium ascendens* and *Magnolia virginiana*. Understory trees and shrubs may include *Quercus geminata, Quercus myrtifolia, Ilex vomitoria, Serenoa repens, Morella cerifera, Ilex glabra, Vaccinium arboreum, Juniperus virginiana, Zanthoxylum clava-herculis, Sideroxylon lanuginosum, Persea borbonia, Conradina canescens*, and *Callicarpa americana*. Herbs may include *Spartina patens, Juncus roemerianus*, and *Panicum virgatum*. Wetland inclusions may contain *Cladium mariscus ssp. jamaicense*.

Dynamics: The maritime environment for these forests is extremely dynamic, even though they occur on the most stable portions of barrier islands. Maritime forest systems remain subject to periodic severe physical stresses. The environment for these forests may be severely altered or destroyed by geologic processes such as the slow movement of dunes or their destruction by storms and hurricanes. Sand movement may also create new sites for this system to occupy or degrade them through erosion or sand burial. Chronic salt spray (sea salt aerosol), as well as intense salt spray during storms are important influences on vegetation structure and composition; however, the extent to which plant communities found in this system are shaped by salt spray varies. The most heavily salt-influenced examples of these systems may appear pruned or sculpted. Extreme salt spray or saltwater flooding in storms can severely disturb vegetation, though it recovers if the landforms have not been altered. Fire may have naturally occurred infrequently in this system, but probably was not an important factor. Mature *Quercus virginiana* trees are fire-resistant when mature, and their litter also does not easily burn (Stalter and Odum 1993).

Hurricanes frequently make landfall in the northern Gulf of Mexico and have a significant impact on coastal systems. Even when they

do not make landfall in the region, the storm surge and wave action generated by an off-shore storm can have a significant impact. For example, a total of 112 hurricanes made landfall from Wakulla County, Florida, to Hancock County, Mississippi, during the period 1926 to 2005 (Jarrell et al. 1992 with updates); 36 major hurricanes (Category 3 or higher) made landfall along the Gulf Coast from Louisiana to the Florida Panhandle between 1851 and 2004 (Blake et al. 2005). Hurricane-associated storm surges can overwash the dune system and cause significant erosion and/or sand burial of maritime forests (Landfire 2007a).

The role of fire in this system is poorly documented. The majority of this system occurs on narrow barrier islands along the northern Gulf of Mexico. FNAI (1990) indicates that the mesic conditions and insular locations of well-developed maritime hammock communities inhibit natural fires, which occur no more frequently than once every 26 to 100 years. Mature *Quercus virginiana* trees are fire-resistant when mature, and their litter also does not easily burn (Stalter and Odum 1993). Liu et al. (2003), in their study of sediment cores from Little Lake, Alabama, suggested that wildfires have been common in the coastal ecosystems in Alabama; however, they offered no frequency estimates. They did suggest a correlation between hurricanes and fire. This correlation was also supported by Meyers and van Lear (1998) who suggest that interactions between hurricanes and fires once played a major role in the development of ecosystems in the southern U.S., influencing their composition, structure, and pattern on the landscape (Landfire 2007a).

Component Associations:
- *Pinus clausa - Quercus geminata - Quercus hemisphaerica / Quercus myrtifolia* Forest (CEGL004942, G1G2)
- *Pinus clausa / Ceratiola ericoides / Cladonia* spp. Woodland (CEGL004668, G1G2)
- *Pinus clausa / Quercus geminata - Quercus myrtifolia - Conradina canescens* Woodland (CEGL003554, G2)
- *Pinus elliottii var. elliottii - (Pinus palustris) / Ilex vomitoria - Serenoa repens - Morella cerifera* Woodland (CEGL004658, G2G3)
- *Pinus elliottii var. elliottii / Serenoa repens - Ilex glabra - Morella cerifera - Ilex vomitoria* Woodland (CEGL004680, G3)
- *Pinus elliottii var. elliottii / Spartina patens - Juncus roemerianus - (Panicum virgatum)* Woodland (CEGL004958, G3?)
- *Quercus geminata / Serenoa repens - Ilex vomitoria - (Sideroxylon lanuginosum)* Forest (CEGL007019, G2?)
- *Quercus virginiana - (Juniperus virginiana) - Zanthoxylum clava-herculis / Sideroxylon lanuginosum* Woodland (CEGL003523, G2G3)
- *Quercus virginiana - (Pinus elliottii var. elliottii, Sabal palmetto) / Persea borbonia - Callicarpa americana* Forest (CEGL007032, G2)
- *Quercus virginiana - Pinus clausa / Carya (glabra, pallida) / Serenoa repens* Forest (CEGL004976, G2Q)
- *Quercus virginiana / Vaccinium arboreum - Ilex vomitoria* Forest (CEGL007028, G2G3)
- *Taxodium ascendens / Magnolia virginiana / Cladium mariscus ssp. jamaicense* Forest (CEGL004914, G1)

DISTRIBUTION

Range: This system is found along the northern Gulf of Mexico, from the Florida panhandle to southern Mississippi, restricted to the most coastward part of the "Gulf Coast Flatwoods" (Ecoregion 75a of EPA (2004)).

EAST GULF COASTAL PLAIN NORTHERN DRY UPLAND HARDWOOD FOREST (CES203.483)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2307; ESLF 4113; ESP 1307

CONCEPT

Summary: This system represents dry, upland, predominantly hardwood forests of limited portions of the East Gulf Coastal Plain of western Kentucky and Tennessee, northern Mississippi and Alabama. The core range of this type lies within the Northern Hilly Coastal Plain (EPA Level IV Ecoregion 65e), which includes the Northern Pontotoc Ridge (222Cf), Upper Loam Hills (222Cg), and Northern Loessal Hills (222Ce) Ecomap subsections. These areas occupy the eastern margin of the Upper East Gulf Coastal Plain where elevation is greatest and influence of loess is less than adjacent areas to the west. The vegetation has been broadly considered distinct from other coastal plain forests but has received almost no specific study. Although vastly forested when compared to the loess plains to the west, most of the vegetation is recovering from one or more forms of severe disturbance. *Quercus alba* dominates the upland forests which have been studied in a limited portion of this area, but communities have not been described to the same detail as in other ecological systems.

Classification Comments: The range of this system overlaps with East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506) in the Fall Line Hills (Ecoregion 65i) of Alabama and in the Southern Hilly Gulf Coastal Plain (Ecoregion 65d) of Mississippi and may overlap to some degree with Southern Coastal Plain Dry Upland Hardwood Forest (CES203.560) at its southern boundary as well. In parts of the overlapping range (including the Oakmulgee Ranger District of the Talladega National Forest), these types occur in a mosaic which is difficult to interpret environmentally and ecologically (A. Schotz pers. comm.). The vegetation of this system has received almost no specific study and is extremely poorly documented.

Similar Ecological Systems:
- East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506)
- Southern Interior Low Plateau Dry-Mesic Oak Forest (CES202.898)

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer
- White Oak: 53 (Eyre 1980) Finer

DESCRIPTION

Environment: The most northern examples (e.g., western Tennessee and Kentucky) occur along the eastern margin of the East Gulf Coastal Plain where elevation is greatest and influence of loess is minimal, and where they occur as predominantly slope forests in relatively deep, dissected stream valleys. The vegetation in this region has been broadly considered distinct from other coastal plain forests (Bryant et al. 1993, Fralish and Franklin 2002) but has received almost no specific study (Franklin and Kupfer 2004). Although vastly forested when compared to the loess plains to the west (USGS 1992), most of the vegetation is recovering from one or more forms of severe disturbance (Franklin and Kupfer 2004). *Quercus alba* dominates the upland forests which have been studied in a limited portion of this area (Franklin and Kupfer 2004), but communities have not been described to the same detail as in other ecological systems.

Vegetation: Stands may contain *Aesculus pavia, Carya alba, Carya glabra, Carya pallida, Carya* spp., *Celtis laevigata, Iris verna var. smalliana, Kalmia latifolia, Liquidambar styraciflua, Liriodendron tulipifera, Ostrya virginiana, Oxydendrum arboreum, Quercus alba, Quercus falcata, Quercus marilandica, Quercus muehlenbergii, Quercus pagoda, Quercus stellata, Quercus velutina, Styrax grandifolius, Vaccinium arboreum, Vaccinium* spp., and *Vaccinium stamineum.*

Dynamics: Fire suppression and the resulting greater understory density and resulting cooler conditions on the forest floor affect this system.

Component Associations:
- *Quercus alba - Carya glabra - Carya alba / Aesculus pavia* Forest (CEGL007225, G4?)
- *Quercus alba - Carya glabra* / Mixed Herbs Coastal Plain Forest (CEGL007226, G4?)
- *Quercus falcata - Quercus alba - Carya alba / Oxydendrum arboreum / Vaccinium stamineum* Forest (CEGL007244, G4G5)
- *Quercus falcata - Quercus stellata - Carya alba / Vaccinium* spp. Coastal Plain Forest (CEGL007246, G4?)
- *Quercus muehlenbergii - Carya* spp. / *Ostrya virginiana* Upper East Gulf Coastal Plain Forest (CEGL003903, G3)
- *Quercus pagoda - (Quercus falcata) / Ostrya virginiana* Forest (CEGL003871, G3?)
- *Quercus prinus - Carya* spp. - *Quercus velutina / Vaccinium arboreum / Iris verna var. smalliana* Forest (CEGL007261, G3G4)
- *Quercus prinus - Quercus* spp. / *Vaccinium arboreum - (Kalmia latifolia, Styrax grandifolius)* Forest (CEGL007700, G4)

- *Quercus stellata - Quercus marilandica - Carya (alba, pallida)* Upper East Gulf Coastal Plain Woodland (CEGL003952, G2G3)
- *Quercus velutina - Carya pallida - Tilia americana var. heterophylla / Celtis laevigata / Aesculus pavia* Forest (CEGL008565, G3G4)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506)
- East Gulf Coastal Plain Northern Loess Plain Oak-Hickory Upland (CES203.482)
- South-Central Interior / Upper Coastal Plain Flatwoods (CES203.479)

Adjacent Ecological System Comments: To the west this system grades into East Gulf Coastal Plain Northern Loess Plain Oak-Hickory Upland (CES203.482). The two types are similar and may be difficult to distinguish where they come together. The loess plain type is believed to be more mesic and richer floristically due to the influence of the loessal soils. However, it is also rare due to the fertility of the soils for agriculture. More work is needed to better quantify the differences between these types and their exact boundaries.

DISTRIBUTION

Range: This system is found in the Coastal Plain of western Kentucky and Tennessee, ranging south to northern Mississippi and Alabama.
Divisions: 203:C
Nations: US
Subnations: AL, KY, MS, TN

EAST GULF COASTAL PLAIN NORTHERN LOESS BLUFF FOREST (CES203.481)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Loess deposit (undifferentiated); Forest and Woodland (Treed); Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2327; ESLF 4133; ESP 1327

CONCEPT

Summary: This system is largely confined to steep bluffs bordering the northern portion of the eastern edge of the Mississippi River Alluvial Plain. The geology is typically mapped as the Jackson Formation. These bluffs extend up to 150 m (500 feet) in elevation and from 30 to 60 m (100-200 feet) above the adjacent plain. They consist of a belt of Pleistocene and Tertiary eolian deposits that are often deeply eroded and very steep, with fertile topsoil and abundant moisture. The vegetation is often richer than surrounding non-loessal areas, or those with only thin loess deposits. The forests found on these bluffs are intermediate in soil moisture for the region and may best be thought of as mesic. The vegetation may sometimes be referred to as western mesophytic forest and may share some superficial similarities with cove forests of the Interior Highlands. In many cases, these bluffs provide habitat for plant species that are rare or absent from other parts of the Coastal Plain. The composition of these forests changes from north to south along the bluffs; more southerly examples are represented by the East Gulf Coastal Plain Southern Loess Bluff Forest (CES203.556), and these would contain *Magnolia grandiflora* as an important component. As currently defined this system ranges northward from about 32 degrees N latitude (where the Big Black River cuts through the bluffs), and occurs only in the westernmost portions of the Upper East Gulf Coastal Plain, including northern and central Mississippi, western Tennessee, and western Kentucky, being restricted to the northern part of the Loess Bluff Hills (EPA Ecoregion 74a).
Classification Comments: Similar ecological systems include East Gulf Coastal Plain Southern Loess Bluff Forest (CES203.556) which occurs further southward in the East Gulf Coastal Plain and has greater dominance by broad-leaved and needle-leaved evergreen trees, Southern Coastal Plain Mesic Slope Forest (CES203.476), and East Gulf Coastal Plain Northern Mesic Hardwood Slope Forest (CES203.477). There are other mixed deciduous mesic systems in the West Gulf Coastal Plain as well as other mesic forest systems to the east of this one, in areas other than the loess bluffs.
Similar Ecological Systems:
- East Gulf Coastal Plain Northern Mesic Hardwood Slope Forest (CES203.477)
- East Gulf Coastal Plain Southern Loess Bluff Forest (CES203.556)
- Southern Coastal Plain Mesic Slope Forest (CES203.476)

Related Concepts:
- Beech - Sugar Maple: 60 (Eyre 1980) Finer
- Coastal Plain Mesophytic Cane Forest (Evans 1991) Finer
- Northern Red Oak: 55 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is largely confined to the lower portions of steep bluffs east of the Mississippi River. These bluffs consist of a belt of Pleistocene and Tertiary eolian deposits (Braun 1950) that are often deeply eroded and very steep, with fertile topsoil and abundant moisture (Miller and Neiswender 1987). The core of this is mapped as the Jackson Formation (Hardeman 1966) and corresponds more broadly with Ecoregion 74a (Bluff Hills) (EPA 2004). These bluffs border the eastern edge of the Mississippi River Alluvial Plain from about 32 degrees N latitude (where the Big Black River cuts through the bluffs) northward to western Tennessee and Kentucky. Examples may extend up to 150 m (500 feet) in elevation and from 30 to 60 m (100-200 feet) above the adjacent Mississippi Alluvial Plain. In Tennessee the loess soils may be 9-27.5 m (30-90 feet deep) (Springer and Elder 1980).
Vegetation: Examples of this system have deciduous canopies dominated by *Fagus grandifolia* or this species in combination with *Quercus alba*. The most mesic stands may lack codominance by *Quercus* spp. In addition, a variety of other hardwood species may also be found in the overstory, including *Liriodendron tulipifera, Liquidambar styraciflua, Acer rubrum, Nyssa sylvatica, Fraxinus americana, Magnolia acuminata* (of local distribution), and *Pinus taeda* (in more southern stands). This system is defined as being north of the range of *Magnolia grandiflora*, which excludes the "Beech-Magnolia" forests of the southern loess bluffs. Some subcanopy components (in addition to canopy species) include *Carpinus caroliniana, Diospyros virginiana, Oxydendrum arboreum, Cornus florida, Acer barbatum, Magnolia macrophylla, Ostrya virginiana, Ulmus alata*, and *Ilex opaca*. Other shrubs and woody vines include *Decumaria barbara, Rhododendron canescens, Toxicodendron radicans, Vitis rotundifolia*, and *Smilax glauca*. Important herbs include *Polystichum acrostichoides, Woodwardia areolata, Osmunda cinnamomea, Mitchella repens*, and *Hexastylis arifolia*. In many cases, these bluffs provide habitat for plant species that are rare or absent from other parts of the Coastal Plain, such as *Magnolia acuminata, Aralia racemosa*, and *Hydrophyllum canadense* (Chester et al. 1997).
Dynamics: These are stable, generally fire-sheltered forests. These forests probably generally exist naturally as old-growth forests, with canopy dynamics dominated by gap-phase regeneration. As modeled here, replacement disturbance is over 60% and more likely

due to weather-related events than fire. Included among these are windthrow, lightning, and ice damage, as well as the inclusion of the erosion and mass wastage (Bryant et al. 1993) that give the bluffs their characteristic steepness. Widespread insect or disease mortality has not been reported. Wind/weather/stress replacement frequency is modeled near 240 years, replacement fire return at approximately 385 years, and all fire return frequency at about 85 years. "Open" structure is uncommon, even when defined as canopy closure less than 81%, and may be created by mixed-severity fire. Surface fire may maintain open conditions, but it does not transition closed classes. Disturbance is presumed to mirror mixed mesophytic forest, occurring primarily in small gaps (less than one-quarter acre), although the occurrence of aggregates of intolerant species suggests that larger scale disturbances occasionally play a role (Landfire 2007a). In addition, periodic droughts may cause death of or stress to moisture-requiring canopy trees. There is presumably some natural disturbance from the effects of windstorms, which are relatively frequent in the range of this system.

Component Associations:
- *Fagus grandifolia - Quercus (alba, rubra) / Acer barbatum / Asimina triloba* Forest (CEGL004072, G2G3)
- *Quercus pagoda - Quercus nigra* Forest (CEGL004109, G3?)

DISTRIBUTION

Range: This system is endemic to the loess bluffs ("Bluff Hills" [Ecoregion 74a] of EPA (2004)) along the eastern edge of the Mississippi River Alluvial Plain in Mississippi, Tennessee, and Kentucky.

EAST GULF COASTAL PLAIN NORTHERN LOESS PLAIN OAK-HICKORY UPLAND (CES203.482)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Loess deposit (undifferentiated); Forest and Woodland (Treed); Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2306; ESLF 4112; ESP 1306

CONCEPT

Summary: This is the former matrix hardwood system flanking the loess bluffs of the most northern portions of the Upper East Gulf Coastal Plain of western Tennessee, western Kentucky, possibly southern Illinois, and northern Mississippi. The core distribution of this system is mapped as the Loess Plains (EPA Ecoregion 74b). Extensive forests once covered this broad area of generally flat to rolling uplands. Most have been cleared for agriculture due to the rich, productive soils derived from relatively thick loess deposits. The areal extent of this forested system has been so heavily reduced that the component community types remain undocumented and speculative at best. Typical stands would contain oaks and other hardwoods. Some typical canopy dominants include *Quercus falcata, Quercus alba, Carya alba, Quercus stellata, Quercus marilandica*, and *Quercus velutina*. Scattered successional stands would be dominated by *Juniperus virginiana var. virginiana*. In addition, *Liquidambar styraciflua* and *Liriodendron tulipifera* may be present.
Classification Comments: The southern boundary of this system has not been clearly delineated; Omernik (EPA 2004) Ecoregion 74b extends farther south than the presumed boundary of this system. For now, the boundary is assumed to occur in northern Mississippi at the latitude of the junction of Omernik (EPA 2004) Ecoregion 65e and Ecoregion 65d (ca. 34 degrees N). To the east, this system grades into East Gulf Coastal Plain Northern Dry Upland Hardwood Forest (CES203.483). The two types may be similar and difficult to distinguish where they come together, but the former is believed to be more mesic and richer floristically due to the influence of the loessal soils. However, it is also rare due the fertility of the soils for agriculture. More work is needed to better quantify the differences between these types and their exact boundaries.
Similar Ecological Systems:
- East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506)

Related Concepts:
- Acidic Subxeric Forest (Evans 1991) Broader
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: The habitat for this system is a broad area of generally flat to rolling uplands. Soils included in this system in western Tennessee are rich, productive, and silty, being derived from relatively thick loess deposits. Most of the soils have fragipans and some are poorly drained (Springer and Elder 1980).
Vegetation: Typical stands would contain oaks and other hardwoods. Some typical canopy dominants include *Quercus falcata, Quercus alba, Carya alba, Quercus stellata, Quercus marilandica*, and *Quercus velutina*. Scattered successional stands would be dominated by *Juniperus virginiana var. virginiana*. In addition, *Liquidambar styraciflua* and *Liriodendron tulipifera* may be present.
Dynamics: Most of the landscape in which this was the matrix system was cleared of forests for settlement and agriculture during the nineteenth and early twentieth century and very few sites remain in primary forest condition. Fire frequency and severity are classified as Fire Regime Group I, with frequent, low-intensity surface fires. The mean fire-return interval (MFRI) is about 15 years with wide year-to-year and within-type variation related to moisture cycles, degree of sheltering, and proximity to more fire-prone vegetation types. Anthropogenic fire may have contributed to presettlement fire frequency (Landfire 2007a). When sites are cleared for settlement or agriculture, *Liquidambar styraciflua* is a major component of the replacement successional forest, in addition to other wind-blown or bird-dispersed trees such as *Acer rubrum, Celtis* spp., *Fraxinus americana, Juglans nigra, Juniperus virginiana, Liquidambar styraciflua, Liriodendron tulipifera, Prunus serotina, Robinia pseudoacacia, Sassafras albidum, Ulmus americana*, and the exotic *Ailanthus altissima*. In addition, *Baccharis halimifolia* is a native increaser shrub that will colonize disturbed sites.

Component Associations:
- *Quercus falcata - Quercus alba - Carya alba / Oxydendrum arboreum / Vaccinium stamineum* Forest (CEGL007244, G4G5)

SPATIAL CHARACTERISTICS

Spatial Summary: Historically a matrix system which dominated the landscape; in current condition only exists in small isolated patches.
Adjacent Ecological Systems:
- East Gulf Coastal Plain Jackson Plain Prairie and Barrens (CES203.353)
- East Gulf Coastal Plain Northern Dry Upland Hardwood Forest (CES203.483)
- East Gulf Coastal Plain Northern Mesic Hardwood Slope Forest (CES203.477)
- South-Central Interior / Upper Coastal Plain Flatwoods (CES203.479)

• South-Central Interior / Upper Coastal Plain Wet Flatwoods (CES203.480)

Adjacent Ecological System Comments: Included within this former matrix system were patches of other systems including East Gulf Coastal Plain Jackson Plain Prairie and Barrens (CES203.353), South-Central Interior / Upper Coastal Plain Wet Flatwoods (CES203.480), and South-Central Interior / Upper Coastal Plain Flatwoods (CES203.479). It is bordered on the west by East Gulf Coastal Plain Northern Mesic Hardwood Slope Forest (CES203.477) and to the east by East Gulf Coastal Plain Northern Dry Upland Hardwood Forest (CES203.483).

DISTRIBUTION

Range: This system would have occupied the most northern portions of the Upper East Gulf Coastal Plain of western Tennessee, western Kentucky, possibly southern Illinois, and northern Mississippi. Its core distribution is mapped by EPA (2004) as the Loess Plains (EPA Ecoregion 74b). Today it is reduced to remnant forest patches in a largely agricultural landscape.

EAST GULF COASTAL PLAIN NORTHERN MESIC HARDWOOD SLOPE FOREST (CES203.477)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Slope; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2325; ESLF 4131; ESP 1325

CONCEPT

Summary: This system includes mesic deciduous hardwood forests of inland portions of the East Gulf Coastal Plain, including Alabama, Mississippi, western Kentucky, and western Tennessee. This system covers parts of the more mesic forests in the coastal plain portion of the Western Mesophytic Forest Region referred to as mesophytic mixed hardwoods, as well as mesic forests in the adjacent "Oak-Pine-Hickory" region to the south. Examples of this system occur on slopes and ravines between dry uplands and stream bottoms. Mesic forests of the loess bluffs are treated in separate ecological systems, being confined to that landform of steep bluffs and ravines on deep loess. The most characteristic feature of the vegetation in some examples may be *Fagus grandifolia*, but a variety of other hardwood species may also be found in the overstory, and *Fagus grandifolia* may not always be present. Some stands may be dominated by *Fagus grandifolia* and *Quercus alba*, others by *Quercus alba* or *Quercus pagoda* with other mesic hardwoods. In addition, *Pinus taeda* may be common in some examples in the southern portion of the range and, depending on previous disturbance and site conditions, may be locally dominant [see CEGL004763]. To the south this system is replaced by Southern Coastal Plain Mesic Slope Forest (CES203.476), which is within the range of *Pinus glabra* and *Magnolia grandiflora*.
Classification Comments: Southern Coastal Plain Mesic Slope Forest (CES203.476) is a similar mesic forest system to the south of this one in the East Gulf Coastal Plain with greater dominance by broad-leaved evergreen trees. The systems of the loess bluffs to the west of this one, bordering the Mississippi River Alluvial Plain, are treated as distinct and are more extensive and continuous in their extent both vertically and latitudinally [see East Gulf Coastal Plain Northern Loess Bluff Forest (CES203.481) and East Gulf Coastal Plain Southern Loess Bluff Forest (CES203.556)]. One association now (2005) included here (*Quercus alba - Fagus grandifolia / Hydrangea quercifolia - Viburnum acerifolium / Carex picta - Polystichum acrostichoides* Forest (CEGL007213)) has the majority of its occurrences in the interior regions (southern Cumberland Plateau, Ridge and Valley), but its flora contains some Coastal Plain elements as well as more interior ones. It is from a "transition region" where *Quercus rubra* may be present in parts of the upper Coastal Plain and conversely some more southerly affiliated species (e.g., *Decumaria barbara*) range farther north. This association is now affiliated with two different ecological systems.
Similar Ecological Systems:
- East Gulf Coastal Plain Northern Loess Bluff Forest (CES203.481)
- East Gulf Coastal Plain Southern Loess Bluff Forest (CES203.556)
- Southern Coastal Plain Mesic Slope Forest (CES203.476)

DESCRIPTION

Environment: This system occurs along the eastern margin of the Upper Coastal Plain where elevation is greatest and influence of loess is minimal where stands occur as predominantly slope forests in relatively deep, dissected stream valleys. The vegetation in this region has been broadly considered distinct from other coastal plain forests (Bryant et al. 1993, Fralish and Franklin 2002) but has received almost no specific study (Franklin and Kupfer 2004). Although vastly forested when compared to the loess plains to the west (USGS 1992), most of the vegetation is recovering from one or more forms of severe disturbance (Franklin and Kupfer 2004). *Quercus alba* dominates the upland forests, examples of which have been studied in a limited portion of this area by Franklin and Kupfer (2004), but these communities have not been described to the same detail as other ecological systems.
Vegetation: The most characteristic feature of the vegetation is a high cover value for *Fagus grandifolia*, but a variety of other hardwood species may also be found in the overstory. Stands are mesic, and some may be dominated by *Fagus grandifolia* and *Quercus alba*, others by *Quercus alba* or *Quercus pagoda* with other mesic hardwoods. This system is defined as being north of the range of *Magnolia grandiflora*, which excludes the "Beech-Magnolia" forests of the deeper south. From north to south, there is some floristic variability in the component floristics of this system. *Quercus rubra* will be of greater importance north of 35 degrees N latitude, and *Pinus taeda* conversely of greater importance to the south of this boundary. The core concept of this system consists of association types in which *Quercus* spp. can be present in the canopy, but are not dominant; but some may exhibit codominance by

Fagus grandifolia and *Quercus alba* or other mesic *Quercus* spp. Other important canopy components include *Liriodendron tulipifera, Liquidambar styraciflua, Acer rubrum, Nyssa sylvatica, Fraxinus americana, Magnolia acuminata* (of local distribution), *Magnolia virginiana*, and *Pinus taeda*. Some subcanopy components (in addition to canopy species) include *Carpinus caroliniana, Diospyros virginiana, Oxydendrum arboreum, Cornus florida, Acer barbatum, Magnolia macrophylla* (to the south), *Ostrya virginiana, Ulmus alata*, and *Ilex opaca*. Other shrubs and woody vines include *Decumaria barbara, Rhododendron canescens, Toxicodendron radicans, Vitis rotundifolia*, and *Smilax glauca*. Important herbs include *Polystichum acrostichoides, Woodwardia areolata, Osmunda cinnamomea, Mitchella repens*, and *Hexastylis arifolia*. This system is found north of the distribution of *Pinus glabra* and *Magnolia grandiflora*, which will be absent.

Dynamics: These are stable, generally fire-sheltered forests. There is presumably some natural disturbance from the effects of hurricanes (to the south), or from other windstorms, which are relatively frequent in the range of this system. Most of the vegetation is recovering from one or more forms of severe anthropogenic disturbance (Franklin and Kupfer 2004). Infrequent, low-intensity surface fires and rare mosaic or replacement fires are typical in this system (Fire Regime Group III) (Landfire 2007a). The mean fire-return interval (MFRI) is about 35 years with wide year-to-year and within-type variation related to moisture cycles, degree of sheltering, and proximity to more fire-prone vegetation types. Anthropogenic fire is also part of this variation. Exposure to occasional fires and severe storms may create some canopy disturbances, which can be followed by waves of tree recruitment, growth, and death resulting in changes in the density and structure of tree populations and in consequent fluctuations in forest species composition. Periodic droughts will cause death of or stress to moisture-requiring canopy trees.

Component Associations:
- *Fagus grandifolia - Acer saccharum - Liriodendron tulipifera* Unglaciated Forest (CEGL002411, G4?)
- *Fagus grandifolia - Liriodendron tulipifera / Euonymus americanus / Athyrium filix-femina ssp. asplenioides* Forest (CEGL007201, G4)
- *Fagus grandifolia - Quercus alba / Cornus florida* Forest (CEGL007881, G4)
- *Pinus taeda - Quercus alba / Chasmanthium sessiliflorum* Forest (CEGL004763, G3G4)
- *Quercus alba - Carya (alba, ovata) - Liriodendron tulipifera - (Quercus phellos) / Cornus florida* Forest (CEGL007709, G4)
- *Quercus alba - Carya glabra - Carya alba / Aesculus pavia* Forest (CEGL007225, G4?)
- *Quercus alba - Fagus grandifolia / Hydrangea quercifolia - Viburnum acerifolium / Carex picta - Polystichum acrostichoides* Forest (CEGL007213, G3G4)
- *Quercus alba - Quercus rubra - Carya (alba, ovata) / Cornus florida* Acidic Forest (CEGL002067, G3)
- *Quercus pagoda - Quercus (michauxii, shumardii)* Forest (CEGL004545, G3G4)
- *Quercus pagoda - Quercus nigra* Forest (CEGL004109, G3?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- East Gulf Coastal Plain Northern Loess Plain Oak-Hickory Upland (CES203.482)

DISTRIBUTION

Range: This system is found in northern and inland portions of the East Gulf Coastal Plain, including Alabama, Mississippi, western Kentucky, and western Tennessee. It does not occur in Arkansas. This area is equivalent to the coastal plain portion of the Western Mesophytic Forest Region of Braun (1950) and the "Oak-Pine-Hickory" region of Greller (1988).

EAST GULF COASTAL PLAIN SOUTHERN LOESS BLUFF FOREST (CES203.556)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Loess deposit (undifferentiated); Forest and Woodland (Treed); Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2329; ESLF 4135; ESP 1329

CONCEPT

Summary: This system of upland hardwood-dominated forests is defined as including both the steep loess bluffs bordering the eastern edge of the Mississippi River Alluvial Plain, ranging from south-central Mississippi to southeastern Louisiana, as well as hardwood vegetation of the "Loess Plains" immediately to the east of these bluffs and ravines. The vegetation is often richer than surrounding non-loessal areas, or those with only thin loess deposits. At least in some examples of this system, tree species normally associated with bottomland habitats are found to be abundant or even dominant in non-flooded uplands. In many cases, the bluffs provide habitat "refugia" for plant species that are more common to the north. The general composition of these forests along the bluffs changes from north to south; the more northerly examples are represented in this classification by East Gulf Coastal Plain Northern Loess Bluff Forest (CES203.481), north of the range of *Magnolia grandiflora* and *Pinus glabra*. As currently defined this system ranges from about 32 degrees N latitude (where the Big Black River dissects the bluffs) southward and is restricted to the southern part of the Loess Bluff Hills (EPA Ecoregion 74a).
Classification Comments: The vegetation of this system has been poorly studied and documented, and few associations have currently been described in the USNVC for this system. More information is needed. This system meets East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506) farther to the east in Louisiana and Mississippi.
Similar Ecological Systems:
- East Gulf Coastal Plain Northern Loess Bluff Forest (CES203.481)
- East Gulf Coastal Plain Northern Mesic Hardwood Slope Forest (CES203.477)
- Southern Coastal Plain Mesic Slope Forest (CES203.476)

Related Concepts:
- White Oak: 53 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occupies upland loess bluffs, ravines, and adjacent plains that are considerably higher in elevation than the adjacent Mississippi River Alluvial Plain. These bluffs consist of a belt of Pleistocene and Tertiary eolian deposits (Braun 1950) that are often deeply eroded and very steep, with fertile topsoil and abundant moisture. In many cases, the bluffs provide habitat "refugia" for plant species that are more common to the north (Delcourt and Delcourt 1975).
Vegetation: Forest stands of the southern loess bluffs are characteristically dominated by *Fagus grandifolia* and *Magnolia grandiflora*, with *Quercus pagoda*, *Liquidambar styraciflua*, and other hardwood species, along with *Pinus glabra* and *Pinus taeda*. Vegetation of the loess plains would more likely be dominated by *Quercus pagoda*, *Liquidambar styraciflua*, and other hardwood species, along with *Pinus taeda*.
Dynamics: Considering the southern bluffs in conjunction with a portion of the adjacent plains, along with proximity to the Gulf of Mexico, stands of this system tend to be somewhat less stable and more fire-prone than the bluffs alone to the north (Landfire 2007a). As modeled here, replacement disturbance has roughly equal probability of occurring by either fire or weather-related events. The latter include windthrow, lightning and ice damage, as well as the inclusion of the erosion and mass wastage that give the bluffs their characteristic steepness. Widespread insect or disease mortality has not been reported. Wind/weather/stress replacement frequency is modeled near 220 years, replacement fire return at approximately 215 years, and all fire return frequency at about 40 years. "Open" structure is uncommon, even when defined as canopy closure <81%, and may be created by mixed-severity fire. Surface fire may maintain open conditions, but it does not transition closed classes. Disturbance is presumed to occur primarily in small gaps (less than one-half acre). The presence of aggregates of intolerant species suggests that larger scale disturbances occasionally play a role, likely more so on the plains (Landfire 2007a). Periodic droughts will cause death of or stress to moisture-requiring canopy trees.

Component Associations:
- *(Fagus grandifolia) - Quercus pagoda - Magnolia grandiflora / Hydrangea quercifolia / Cystopteris protrusa - Thelypteris kunthii* Forest (CEGL007461, G3?)
- *Fagus grandifolia - Quercus alba - Liquidambar styraciflua / Magnolia grandiflora / Smilax pumila - Hexastylis arifolia* Forest (CEGL007210, G4)
- *Quercus alba - Quercus nigra - Carya pallida - (Quercus pagoda) / Magnolia (grandiflora, macrophylla)* Forest (CEGL004775, G3G4)
- *Quercus shumardii - Quercus pagoda - Fraxinus americana / Ostrya virginiana - Cornus florida / Trillium ludovicianum* Forest (CEGL007272, G1)

DISTRIBUTION

Range: This system is endemic to the loess bluffs ("Bluff Hills" [Ecoregion 74a] of EPA (2004)) and the immediately adjacent Southern Rolling Plains (western portion of EPA Ecoregion 74c) along the eastern edge of the Mississippi River Alluvial Plain in southwestern Mississippi and adjacent Louisiana.
Divisions: 203:C
Nations: US

EAST-CENTRAL TEXAS PLAINS POST OAK SAVANNA AND WOODLAND (CES205.679)

CLASSIFIERS

Classification Status: Standard

Primary Division: Eastern Great Plains (205)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Loam Soil Texture; Sand Soil Texture
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2519; ESLF 4158; ESP 1519

CONCEPT

Summary: This ecological system is found in east-central Texas in a broad, northeast/southwest-trending band located west of the Upper West Gulf Coastal Plain, northwest of the Coastal Prairie, and east and south of the Blackland Prairie ecoregions. It exhibits some floristic and physiognomic variation across this northeast-southwest gradient, losing some eastern species and picking up some species with more western affinities. It is distinguished from the nearby prairie by the higher density of trees and diversity of woody species. The system differs from the floristically similar Crosstimbers Oak Forest and Woodland (CES205.682) in that it generally occurs on Tertiary (primarily Eocene) geologic formations on the east-central Texas Plains, while the related Crosstimbers ecological system occupies Cretaceous and older formations of the interior plains. Floristically, Post Oak Savanna (at least north of the Colorado River) contains species of more eastern affinities such as *Callicarpa americana, Sassafras albidum, Cornus florida, Vaccinium arboreum, Ulmus alata,* and particularly *Ilex vomitoria,* the latter species being absent from Crosstimbers Oak Forest and Woodland (CES205.682). Post Oak Savanna generally occurs on sandy or loamy soils, often underlain by a claypan subsoil. Rainfall ranges from about 120 cm in the northeastern part of the range to about 70 cm in the southwest, where it becomes increasingly erratic. Therefore moisture is often limiting during part of the growing season. The system was historically characterized as having significant areas of graminoid cover with species composition resembling that of nearby prairie systems, punctuated by short, stunted woodlands and forests dominated by *Quercus stellata* and *Quercus marilandica*. Drought, grazing, and fire are the primary natural processes that affect this system. Much of this system has been impacted by conversion to improved pasture or crop production. Overgrazing and fire suppression have led to increased woody cover on most extant occurrences and the invasion of some areas by problematic brush species such as *Juniperus virginiana var. virginiana* and *Prosopis glandulosa* in the southern part of the system's range. These factors have also led to decreases in native grass cover allowing for annual grasses and forbs to invade.
Classification Comments: Vegetation of East-Central Texas Plains Xeric Sandyland (CES205.897) can be embedded within the matrix-forming East-Central Texas Plains Post Oak Savanna and Woodland (CES205.679). East-Central Texas Plains Xeric Sandyland (CES205.897) was formerly called Crosstimbers Southern Xeric Sandhill but has been renamed to reflect this relationship.
Similar Ecological Systems:
- Crosstimbers Oak Forest and Woodland (CES205.682)--is found to the west of this system.
- East-Central Texas Plains Xeric Sandyland (CES205.897)--has an overlapping range but occupies sandier soils.

DESCRIPTION

Environment: This system is typically located on irregular plains in the East Central Texas Plains (Level III Ecoregion 33) of EPA (Griffith et al. 2004), comprised of sedimentary formations of Tertiary age, including Eocene sands such the Queen City, Sparta, and Carrizo sands, as well as the Wilcox and Claiborne groups. The system also occupies other Tertiary formations such as the Goliad and Willis formations, as well as portions of the Quaternary Willis Formation. This system occupies gently rolling to hilly topography. It is moderately dissected by drainages. It usually occurs on sandy to sandy loam soils, often with a marked clay subsurface horizon. Soils of this system are generally Alfisols, are typically acidic to neutral, and range from shallow to moderately deep. Typical Ecological Sites include Claypan Savannah, Claypan Prairie, Sandy Loam, Sandy, and Deep Sand (Elliott 2011). Rainfall ranges from about 120 cm in the northeastern part of the range to about 70 cm in the southwest, where it becomes increasingly erratic.

Vegetation: This system represents a transition from the woodlands and forests of East Texas to the prairies to the west, specifically the Blackland Prairie. Savannas and woodlands are typically dominated by *Quercus stellata, Quercus marilandica,* and *Carya texana*. Large areas of woodland, particularly in the south and east, are dominated or codominated by *Quercus fusiformis* or *Quercus virginiana* (east of the Brazos River). Other species, such as *Quercus incana* (on more xeric sites), *Ulmus alata, Ulmus crassifolia, Quercus nigra, Juniperus virginiana,* and *Prosopis glandulosa,* can also be present in the overstory. To the east, *Quercus falcata, Quercus nigra, Liquidambar styraciflua, Pinus echinata, Pinus taeda,* and *Carya alba* may be conspicuous in the overstory. Shrubs may attain significant cover in the understory, with species including *Ilex vomitoria* (often dominant), *Callicarpa americana, Sideroxylon lanuginosum, Crataegus* spp., *Ilex decidua, Toxicodendron radicans, Smilax bona-nox, Juniperus virginiana,* and *Symphoricarpos orbiculatus*. To the south, this system grades into vegetation more characteristic of southern Texas, with *Quercus fusiformis* and *Prosopis glandulosa* becoming the primary overstory components, and shrubs of southern Texas such as *Acacia rigidula, Forestiera angustifolia, Condalia hookeri, Colubrina texensis, Eysenhardtia texana, Opuntia engelmannii var. lindheimeri,* and *Diospyros texana* becoming increasingly conspicuous understory components. To the east, *Vaccinium arboreum, Morella cerifera, Diospyros virginiana,* and *Cornus florida* may be common components of the understory. On some sites, *Ilex vomitoria* can form a nearly continuous, sometimes impenetrable, dense shrub layer. Mid- and tallgrass species, including *Schizachyrium scoparium, Sorghastrum nutans,* and *Panicum virgatum*, are frequent in the understory where light penetration supports herbaceous cover, and also form prairie patches within the savanna, particularly on tighter soils. Other grasses present include *Andropogon gerardii, Bothriochloa laguroides ssp. torreyana, Paspalum plicatulum* (to the south), *Nassella leucotricha, Dichanthelium* spp., *Aristida* spp., and *Sporobolus cryptandrus*. Non-native grass species such as *Bothriochloa ischaemum var. songarica, Paspalum notatum,* and *Cynodon dactylon* may dominate some sites. Forbs are often conspicuous and may include species such as *Croton capitatus, Gaillardia pulchella, Monarda punctata, Rudbeckia hirta, Phlox drummondii, Commelina erecta, Acalypha radians, Verbesina virginica, Aphanostephus skirrhobasis, Froelichia gracilis, Cnidoscolus texanus,* and many others (Elliott 2011).
Dynamics: Drought, grazing, and fire are the primary natural processes that affect this system. This system is intricately tied with some occurrences of West Gulf Coastal Plain Herbaceous Seep and Bog (CES203.194). The sandy soils and underlying geologic strata that support this system serve as recharge areas for groundwater that supports seeps and bogs along hillsides and at the heads of drainages supporting West Gulf Coastal Plain Herbaceous Seep and Bog.

Component Associations:
- *Quercus stellata - Quercus marilandica - (Carya texana)* Forest (CEGL002074, G4)
- *Quercus stellata - Quercus marilandica - Carya texana - (Quercus shumardii, Quercus velutina)* Forest (CEGL002324, G3G5)
- *Quercus stellata - Quercus marilandica / Schizachyrium scoparium* Woodland (CEGL002147, G4)
- *Quercus stellata - Ulmus alata* Forest (CEGL004546, GNR)
- *Quercus virginiana - Quercus stellata / Schizachyrium scoparium - Paspalum plicatulum* Woodland (CEGL002155, G3)

DISTRIBUTION

Range: This ecological system is found in east-central Texas in a broad, northeast/southwest-trending band located west of the Upper West Gulf Coastal Plain, northwest of the Coastal Prairie, and east and south of the Blackland Prairie ecoregions. An arm extends along the Red River in north Texas.

EASTERN BOREAL BALSAM FIR-WHITE SPRUCE-PAPER BIRCH FOREST (CES103.421)

CLASSIFIERS

Classification Status: Standard

Land Cover Class: Forest and Woodland
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
National Mapping Codes: ESLF 4343

CONCEPT

Summary: This ecological system represents the mesic boreal forests of eastern Canada, ranging from northwestern Ontario east to the Atlantic Provinces. The low-elevation forests are dominated by *Picea glauca* and *Abies balsamea*. *Picea mariana* is often present, along with occasional *Pinus banksiana*. Codominant boreal hardwoods include *Populus tremuloides* and *Betula papyrifera*. Northern hardwoods are essentially absent. The shrub and herb layers are variable, decreasing as the percent conifer cover increases. Common shrub species include *Alnus viridis, Corylus cornuta, Diervilla lonicera,* and *Lonicera canadensis*. The moss layer ranges from discontinuous to continuous. These upland forests typically occur on loamy soils over bedrock in scoured bedrock uplands and loamy, rocky, or sandy soils on glacial moraines, till plains and outwash plains. Moisture conditions range from well-drained to somewhat poorly drained. Wetter sites may contain *Alnus incana ssp. rugosa, Calamagrostis canadensis,* and *Equisetum* spp. This is the matrix mesic forest type of eastern Canada. This group may include earlier-successional patches, in which *Populus* spp. and *Betula* spp. are dominant or mixed with *Picea* and *Abies*, that will develop into spruce-fir forests. Blowdowns with subsequent gap regeneration are the most frequent form of natural disturbance, with large-scale fires important at longer return intervals. Insect infestations, in particular by *Choristoneura fumiferana* (spruce budworm), also can impact this group.
Classification Comments: A separate aspen-birch system is not recognized in this region; and this system is directly comparable to the group concept (G638).
Similar Ecological Systems:
- Atlantic Boreal Balsam Fir Wet Forest (CES103.433)
- Central Boreal White Spruce-Balsam Fir-Paper Birch Forest (CES103.427)
- Laurentian-Acadian Sub-boreal Mesic Balsam Fir-Spruce Forest (CES103.426)

Related Concepts:
- Balsam Fir: 5 (Eyre 1980) Finer
- White Spruce: 201 (Eyre 1980) Finer

DESCRIPTION

Environment: These upland forests typically occur on loamy soils over bedrock in scoured bedrock uplands and loamy, rocky, or sandy soils on glacial moraines, till plains and outwash plains. Moisture conditions range from well-drained to somewhat poorly drained. Climate is boreal. Soils are typically neutral to acidic, shallow sandy, sandy loam, or loamy sand. Some examples occur on heavier, mesic silty or clay loams that are more alkaline in nature.
Vegetation: *Picea glauca* typically dominates on drier sites or is codominant with *Abies balsamea* on more mesic sites. In some mesic to wet-mesic examples, *Abies balsamea* dominates. This group includes several successional stages, including earlier-successional patches in which *Populus* spp. and *Betula* spp. are dominant. Mid-successional stands often contain stands mixed with *Picea* and *Abies* that will develop into spruce-fir forests. The shrub and herb layers are variable, decreasing as the percent conifer cover increases. Common shrub species include *Acer spicatum, Corylus cornuta, Diervilla lonicera,* and *Lonicera canadensis*. The composition and density of the herbaceous layer can vary among associations and locations. Typically, *Aralia nudicaulis, Eurybia macrophylla, Clintonia borealis*, and *Maianthemum canadense* are common understory species. The moss layer ranges from discontinuous to continuous. Wetter sites may contain *Alnus incana ssp. rugosa, Calamagrostis canadensis*, and *Equisetum* spp.
Dynamics: These forests are affected by windthrow, insect defoliation, and infrequent fires. Selective herbivory by moose (*Alces americanus*) can alter the composition and structure and favor browse-tolerant species such as *Picea glauca*. These forests typically regenerate from gap-phase dynamics.

DISTRIBUTION

Range: This system ranges from northwestern Ontario to eastern Canada.

EASTERN BOREAL BLACK SPRUCE-JACK PINE FOREST (CES103.422)

CLASSIFIERS

Classification Status: Standard

Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
National Mapping Codes: ESLF 4405

CONCEPT

Summary: This conifer forest ecological system is found on nutrient-poor soils in a variety of topographic settings. It ranges from northwestern Ontario to Newfoundland and Labrador. Soils are loamy to sandy, varying from nutrient-poor, thin soil over bedrock to deeper soils, sometimes sandy. Sites are typically dry-mesic. The dominant fire regime varies from 50-100 years. *Picea mariana* and *Pinus banksiana* are characteristic overstory species over much of the range. Canopy structure is mostly closed but can be partially open. Conifers typically dominate the canopy, but boreal hardwoods (*Populus tremuloides, Betula papyrifera*) may codominate. As time since fire increases, *Picea mariana* may dominate. Tree regeneration includes *Abies balsamea, Betula papyrifera, Populus tremuloides,* and *Picea mariana*. The shrub and field layers can be very open to somewhat dense (5-75% cover). Characteristic low-shrub and herb species include *Amelanchier* spp., *Vaccinium angustifolium, Diervilla lonicera, Cornus canadensis, Linnaea borealis, Doellingeria umbellata (= Aster umbellatus),* and *Eurybia macrophylla*. Older *Picea mariana* stands may be strongly dominated by feathermosses.
Classification Comments: In Quebec, C. Morneau (pers. comm. 2009) made the following comments: "First, *Picea mariana* is far more common than *Pinus banksiana* in the boreal forest. Second, forests composed of a mixture of *Picea mariana* and *Abies balsamea* with a feathermoss carpet on the ground are very common east of 74 degrees W longitude and north of 48 degrees N latitude where climate undergoes a maritime influence and where *Pinus banksiana* gradually becomes absent. Third, the most common forest type in the northern part of the boreal forest (north of 51-52 degrees N latitude) is *Picea mariana* / lichen woodland characterized by an open spruce cover (15-40% cover) and a lichen carpet (*Cladina* spp.) on the ground" [these stands will be placed in a northern North American subarctic woodland group (under development)].

At this time, this system excludes xeric *Pinus banksiana* and *Picea mariana* stands, which are placed in their own system, Eastern Boreal Jack Pine - Black Spruce Dry Woodland (CES103.423), which is found on dry, poor sites, where there is a low density of *Picea mariana* and *Pinus banksiana* trees, resulting in a woodland condition. Lichens are dominant. Woodland physiognomy, plus lichen rather than feathermoss dominance, distinguish that system from this system, where feathermosses and herbs are more abundant.

Similar Ecological Systems:
- Central Boreal Jack Pine-Black Spruce Forest (CES103.428)
- Eastern Boreal Jack Pine-Black Spruce Dry Woodland (CES103.423)
- Laurentian-Acadian Sub-boreal Dry-Mesic Pine-Black Spruce-Hardwood Forest (CES103.425)

Related Concepts:
- Black Spruce: 12 (Eyre 1980) Intersecting
- Jack Pine: 1 (Eyre 1980) Intersecting

DESCRIPTION

Environment: Soils are loamy to sandy, varying from nutrient-poor, thin soil over bedrock to deeper soils, sometimes sandy. Sites are typically on dry-mesic to dry sites, but not commonly found on xeric sandplains or bedrock sites.
Vegetation: *Picea mariana* and *Pinus banksiana* are characteristic overstory species. Canopy structure is mostly closed but can be partially open. Conifers typically dominate the canopy; boreal hardwoods (*Populus tremuloides, Betula papyrifera*) may codominate but are typically less than 25% cover. As time since fire increases, *Picea mariana* may dominate. Tree regeneration of somewhat more moisture-preferring trees may be common and includes *Abies balsamea, Betula papyrifera, Populus tremuloides*, and *Picea mariana*. Ground layer is not lichen-dominated and contains at least 5%, and as much as 75%, cover by herbs and shrubs, and feathermosses are common, up to 100% cover in some stands. Characteristic low-shrub and herb species include *Amelanchier* spp., *Vaccinium angustifolium, Diervilla lonicera, Cornus canadensis, Linnaea borealis, Doellingeria umbellata (= Aster umbellatus),* and *Eurybia macrophylla*. Older *Picea mariana* stands may be strongly dominated by feathermosses.
Dynamics: The dominant fire regime varies from 50-100 years.

DISTRIBUTION

Range: This system ranges from northwestern Ontario (perhaps eastern Manitoba) to Newfoundland and Labrador.
Nations: CA
Subnations: LB, MB?, NF, ON, QC

EASTERN BOREAL JACK PINE-BLACK SPRUCE DRY WOODLAND (CES103.423)

CLASSIFIERS

Classification Status: Standard

Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
National Mapping Codes: ESLF 4344

CONCEPT

Summary: This conifer woodland ecological system is found throughout the eastern boreal region of Canada. It occurs on dry nutrient-poor sandplains and along rocky ridges, often adjacent to rivers and lakes, and along talus slopes. The canopy ranges from patchy to continuous and is dominated by a mix of primarily conifer and hardwood species. In some examples, canopy trees may be stunted. *Picea mariana* and *Pinus banksiana* are the most frequent conifer species. Hardwood species vary in cover from 25-90% of the canopy. Most common are *Betula papyrifera* and *Populus* spp. In areas of open bedrock, species typical of bedrock outcrops and shallow soils can be found. The nonvascular layer can be absent or present with up to 30% cover. In the open bedrock areas, this layer consists mainly of the lichens and mosses. Infrequent fire is the primary dynamic, with catastrophic fires occurring approximately every 150-200 years with surface fires every 50-200 years.

Similar Ecological Systems:
- Central Boreal Jack Pine-Black Spruce Dry Woodland (CES103.429)
- Eastern Boreal Black Spruce-Jack Pine Forest (CES103.422)
- Laurentian-Acadian Sub-boreal Dry-Mesic Pine-Black Spruce-Hardwood Forest (CES103.425)
- Northern Dry Jack Pine-Red Pine-Hardwood Woodland (CES103.424)

Related Concepts:
- Black Spruce: 12 (Eyre 1980) Intersecting
- Jack Pine: 1 (Eyre 1980) Intersecting

DESCRIPTION

Environment: Examples of this system occur on rocky ridgetops, high slopes, and terraces sometimes along rivers or lakeshores. These areas are dry, well-drained sites, often with exposed bedrock. Soils range from bare bedrock and talus slopes to rocky, shallow loams and deep sands. Those stands on bedrock may have occasional cracks in the underlying bedrock resulting in pockets of relatively deep (15-20 cm) soil. Bare rock (with crustose lichens) can cover up to 50% of the area.

Vegetation: The canopy ranges from scattered trees to a moderately dense canopy. Stands are a mix of conifer species, occasionally with hardwood species. In some examples, canopy trees may be stunted. The conifers in most examples are dominated by *Picea mariana* and *Pinus banksiana*. Hardwood species vary in cover from 25-90% of the canopy, with *Betula papyrifera* and *Populus* spp. occurring more commonly. Shrubs may be absent to dense and include *Diervilla lonicera, Corylus cornuta, Juniperus communis,* and *Vaccinium angustifolium*. Herbaceous species vary across the range of this type. The nonvascular layer can be absent or present with up to 30% cover. In the open bedrock areas, this layer consists mainly of lichens and mosses. Lichen species may include *Cladina rangiferina (= Cladonia rangiferina)* and *Cladina mitis (= Cladonia mitis)*. Mosses include *Dicranum* spp., *Pleurozium schreberi*, and *Polytrichum* spp.

DISTRIBUTION

Range: This system ranges from northwestern Ontario (possibly eastern Manitoba) to Quebec, Newfoundland and Labrador.
Nations: CA
Subnations: LB, MB?, NF, ON, QC
TNC Ecoregions: 48:?, 141:?

EASTERN GREAT PLAINS TALLGRASS ASPEN PARKLAND (CES205.688)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Eastern Great Plains (205)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Lakeplain; Forest and Woodland (Treed); Woody-Herbaceous; Sandplains/Glacial Outwash or Flats; Glaciated
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2331; ESLF 4137; ESP 1331

CONCEPT

Summary: This system is found primarily on part of the Glacial Lake Agassiz plain in northwestern Minnesota, ranging into southern Canada. Calcareous glacial drift overlain with lacustrine soils ranging from loamy to gravelly is characteristic of the lakeplain within the range of this system. Historically this system included a mosaic of tallgrass prairie, wet prairie, brush prairie and aspen-oak woodlands. It is dominated by *Populus tremuloides* with scattered *Quercus macrocarpa* and *Betula papyrifera*. Shrubs such as willow (*Salix* spp.) and hazel (*Corylus* spp.) are also common. The dominant tallgrass species is *Andropogon gerardii* often associated with *Sorghastrum nutans, Calamagrostis* spp., and *Sporobolus heterolepis*. Fire is the most important natural dynamic in this system and helps maintain the open parkland or brush nature of this system. Wind and grazing are also important dynamics. Conversion to agriculture and fire suppression have decreased the range of this system and allowed more shrubs and trees to establish.
Similar Ecological Systems:
- Northwestern Great Plains Aspen Forest and Parkland (CES303.681)--biogeography and understory species separate. NW Great Plains system has a more mixed understory with *Stipa, Bouteloua,* and *Festuca*. *Festuca* would be a good differential genus.

Related Concepts:
- Aspen: 16 (Eyre 1980) Finer
- Bur Oak: 42 (Eyre 1980) Finer
- Paper Birch: 18 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs largely on the lakeplain of Glacial Lake Agassiz. This landscape is very flat with soils ranging from fine to somewhat coarse. Drainage is moderate to poor at most sites.
Dynamics: The interaction of fire and regional climate shaped this system. Aspen parklands occur on the margin of the northern prairies and northern forests. The climate will support tallgrass, tree and shrub species, and aspen parklands are a mix of these lifeforms. Frequent fires favor the spread of tallgrass species and reduce woody cover (Svedarsky et al. 1986). Sites not burned as often, due to a fire-protected position on the landscape or to a reduction in fire frequency across the entire landscape, tend to become dominated by trees and shrubs. An average fire-return interval of 10-15 years was estimated by Landfire modelers (Landfire 2007a), though individual areas would have burned less or more often. This system occurs on a very flat landscape and minor variations in topography can create wet prairie or wet shrub pockets within the parkland.

Component Associations:
- *Betula papyrifera / Corylus cornuta* Forest (CEGL002079, G2G3)
- *Populus tremuloides - Quercus macrocarpa - Salix* spp. / *Andropogon gerardii* Shrubland (CEGL002182, G2G3)
- *Populus tremuloides / Corylus americana* Forest (CEGL002063, G5)
- *Populus tremuloides / Corylus* spp. / *Andropogon gerardii* Woodland (CEGL005205, G4G5)
- *Quercus macrocarpa - Populus tremuloides / Corylus* spp. Woodland (CEGL002139, G4?)
- *Salix petiolaris - (Betula pumila) / Spartina pectinata - Carex pellita* Shrubland (CEGL002434, G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Northern Tallgrass Prairie (CES205.686)
- Northwestern Great Plains Aspen Forest and Parkland (CES303.681)

DISTRIBUTION

Range: This system is found primarily on part of the Glacial Lake Agassiz plain in northwestern Minnesota, ranging into southern Canada.
Divisions: 201:P; 205:C
Nations: CA, US
Subnations: MB, MN, ND
Map Zones: 39:P, 40:C, 41:P
USFS Ecomap Regions: 222N:CC, 251A:PP
TNC Ecoregions: 35:C, 46:?, 47:P, 66:P

EASTERN SERPENTINE WOODLAND (CES202.347)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Rock Outcrops/Barrens/Glades; Serpentine; Unglaciated; Ultramafic with low Ca:Mg ratio
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2375; ESLF 4318; ESP 1375

CONCEPT

Summary: This system consists of distinct vegetation associated with ultramafic rock substrates in the Piedmont and Blue Ridge of the eastern United States. The bedrock is serpentinite, dunite, or other ultramafic rocks. The soil has unusual and extreme chemical composition that includes strongly skewed calcium-to-magnesium ratios and often high levels of heavy metals such as chromium. Most examples are open woodlands with *Pinus rigida*, *Pinus virginiana*, and/or *Quercus alba, Quercus marilandica*, and *Quercus stellata* in the often stunted canopy. Extreme edaphic conditions lead to locally xerophytic growing conditions that contribute to relatively open canopies and a ground cover dominated by prairie grasses and a variety of forbs. Disjunct species from drier regions and some endemic plant taxa are often present. The unusual and extreme soil chemistry determines the underlying floristics and distinctive flora of the type, but fire frequency, extent, and severity determine the physiognomy of particular examples over time.
Classification Comments: While details of flora vary widely among the scattered examples of this system, all associations have in common a composition that is distinct from communities on other substrates and that is more xeric in aspect. Serpentine substrates support distinctive barren vegetation in most places where they occur. This system is distinguished from serpentine barrens in other regions because of the distinctive flora, as well as the climate, lack of glaciation, and other factors distinct to this region. A closely related Piedmont system, Piedmont Hardpan Woodland and Forest (CES202.268), may be only incompletely distinguished from this system. In this Appalachian system *Pinus rigida / Schizachyrium scoparium - Packera plattensis* Wooded Herbaceous Vegetation (CEGL006084) occurs in both the Appalachians and in the Piedmont.

Ultramafic rock substrate is apparently not sufficient to create this system. Some Piedmont areas with ultramafic rock outcrops on the most mesic sites support mesic forest vegetation not distinguishable from that on other substrates. It may be that these outcrops have less extreme chemistry, or that sufficient moisture levels or a long period without natural disturbance in the form of fire will override the effects of chemistry. The presence of unusually xerophytic or barren vegetation should be the defining characteristic of this system.

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Virginia Pine: 79 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in a variety of topographic settings, perhaps excluding only alluvial sites. The bedrock is serpentinite, dunite, or other ultramafic rocks. The soil has unusual and extreme chemical composition that includes strongly skewed calcium-to-magnesium ratios and often high levels of heavy metals such as chromium. Owing to a high level of toxic metals and a deficiency in nutrients, serpentine outcrops are ecologically unique and provide habitat for many plant species that grow nowhere else. The soil may be shallow and rocky, or deep, and is usually very clayey. Seepage may be present locally.
Vegetation: Vegetation is generally an open woodland of pines or xerophytic hardwoods. The dominant vegetation is more xerophytic and more open than the topographic setting, soil moisture, and climate would suggest, and contrasts strongly with adjacent vegetation on other kinds of rock. *Pinus rigida* and *Pinus virginiana* are frequent canopy dominants, but *Quercus marilandica*, *Quercus alba*, and *Quercus stellata* dominate some examples. There is generally not a well-developed understory. Shrubs may be sparse to dense. The herb layer is usually dense; grasses, including prairie elements such as *Schizachyrium scoparium, Andropogon gerardii*, and/or *Sorghastrum nutans*, usually dominate, but a number of forbs may be present. In the northern portion of this system's range in Pennsylvania and Maryland, *Phlox subulata* and the endemic *Symphyotrichum depauperatum* are characteristic; in the southern Appalachian portion of its range, *Packera plattensis, Hexastylis arifolia var. ruthii*, and *Thalictrum macrostylum* are characteristic. Often, paradoxical mixtures of xerophytic and mesophytic species are present, though the overall plant composition is characteristic of a drier setting. Disjunct species from drier regions and some endemic plant taxa are often present. There is one site where *Pinus palustris* occurs over serpentine (Burks Mountain, Columbus County, Georgia), but this is classed as a "Piedmont Longleaf" site.
Dynamics: Although the unique soil chemistry is the crucial determining factor for this system, fire is generally a crucial process influencing species composition and vegetation structure. The unusual and extreme soil chemistry determines the underlying floristics and distinctive flora of the type, but fire frequency, extent, and severity determine the physiognomy of particular examples over time. Without fire, vegetation can sometimes become dense enough to suppress or eliminate the distinctive herbaceous layer, as well as

turning a distinctive savanna or woodland structure into dense forest. Southern pine beetle (*Dendroctonus frontalis*) damage is an important factor in examples dominated by *Pinus* species.

Component Associations:
- *(Quercus stellata) / Schizachyrium scoparium - Packera plattensis - Parthenium auriculatum - Phemeranthus piedmontanus* Wooded Herbaceous Vegetation (CEGL006084, G1)
- *Acer rubrum - Pinus virginiana - Pinus rigida / Smilax* spp. Serpentine Forest (CEGL006439, G1G2)
- *Acer rubrum - Quercus* spp. / *Smilax* spp. Serpentine Forest (CEGL006438, G1G2)
- *Deschampsia caespitosa - Vernonia noveboracensis* Herbaceous Vegetation (CEGL006316, G1)
- *Juniperus virginiana - Pinus virginiana / Smilax rotundifolia* Serpentine Forest (CEGL006440, G1G2)
- *Pinus rigida - Quercus alba / Sporobolus heterolepis - Andropogon gerardii* Woodland (CEGL003768, G1)
- *Pinus rigida - Quercus stellata / Andropogon gerardii - Packera paupercula* Woodland (CEGL004968, G1)
- *Pinus virginiana - Pinus rigida - Quercus stellata / Ceanothus americanus - Kalmia latifolia / Thalictrum revolutum* Woodland (CEGL007721, G1)
- *Quercus alba / Physocarpus opulifolius / Packera plattensis - Hexastylis arifolia var. ruthii* Forest (CEGL007296, G1)
- *Schizachyrium scoparium - Sporobolus heterolepis* Serpentine Herbaceous Vegetation (CEGL006442, G1G2)
- *Sorghastrum nutans - Schizachyrium scoparium* Serpentine Herbaceous Vegetation (CEGL006441, G1G2)

SPATIAL CHARACTERISTICS

Spatial Summary: Small- to large-patch system, most examples covering a few dozen acres at most. The largest, in Maryland, is 2000 acres.
Size: Most examples naturally cover a few to perhaps several dozen acres. A few in Pennsylvania and Maryland are 100-200 acres, with one Maryland site covering 2000 acres.
Adjacent Ecological System Comments: May be bordered by any other system appropriate for the region, often with abrupt boundaries at geologic contacts. Ultramafic rocks are often associated with mafic rocks such as amphibolite, so systems with basic soils are likely to be associated.

DISTRIBUTION

Range: This system is widely scattered throughout the Southern and Central Appalachians and Piedmont, from Pennsylvania to North Carolina.
Divisions: 202:C
Nations: US
Subnations: MD, NC, PA, VA
Map Zones: 57:C, 59:C, 60:C, 61:C

EDWARDS PLATEAU DRY-MESIC SLOPE FOREST AND WOODLAND (CES303.656)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Midslope; Forest and Woodland (Treed); Broad-Leaved Deciduous Tree; Broad-Leaved Evergreen Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2523; ESLF 4331; ESP 1523

CONCEPT

Summary: This system occurs on dry to mesic, middle slopes of the rolling uplands and escarpments of the Edwards Plateau and similar sites in the adjacent Blackland Prairie region. The canopy is typically dominated or codominated by deciduous trees, including *Quercus buckleyi, Quercus sinuata var. breviloba, Ulmus crassifolia,* and/or *Celtis laevigata var. reticulata*. *Quercus fusiformis* and *Juniperus ashei* are often present and are sometimes codominant with deciduous species of this system. Canopy closure is variable, and this system can be expressed as forests or woodlands. The shrub layer may be well-represented, especially where the overstory canopy is discontinuous. Species such as *Aesculus pavia var. flavescens, Cercis canadensis var. texensis, Forestiera pubescens, Ungnadia speciosa, Ceanothus herbaceus, Sophora secundiflora, Rhus* spp., *Vitis* spp., and *Garrya ovata* may be present in the shrub layer. With the large amount of exposed rock, frequent accumulation of leaf litter, and significant canopy closure, herbaceous cover is generally sparse, with *Carex planostachys* often present. Woodland forbs such as *Tinantia anomala, Chaptalia texana, Nemophila phacelioides, Salvia roemeriana, Lespedeza texana*, and various ferns may also be present, these often being patchy in distribution.
Classification Comments: Further field investigation is needed to better develop the association-level information for this system.
Similar Ecological Systems:
- Edwards Plateau Limestone Savanna and Woodland (CES303.660)--is typically expressed as a mixed evergreen-deciduous woodland or forest characterized by *Quercus fusiformis* and/or *Juniperus ashei*. It occurs on rolling uplands and dry to xeric slopes.
- Edwards Plateau Mesic Canyon (CES303.038)--is currently described as limited to steep, narrow canyons that support more mesic forests. It is limited in extent to steep canyons bordering the Balcones Escarpment.

Related Concepts:
- Ashe Juniper - Redberry (Pinchot) Juniper: 66 (Eyre 1980) Finer
- Edwards Plateau: Ashe Juniper Slope Forest (901) [CES303.656.1] (Elliott 2011) Finer
- Edwards Plateau: Live Oak Slope Forest (902) [CES303.656.2] (Elliott 2011) Finer
- Edwards Plateau: Oak / Ashe Juniper Slope Forest (903) [CES303.656.4] (Elliott 2011) Finer
- Edwards Plateau: Oak / Hardwood Slope Forest (904) [CES303.656.6] (Elliott 2011) Finer

DESCRIPTION

Environment: This system occurs on dry-mesic, primarily north- and east-facing limestone slopes in the Edwards Plateau of Texas. In the adjacent Blackland Prairie region, it is found on limestone chalk cuestas (Elliott 2011). Stones and boulders are conspicuous on the soil surface. Soils are generally dark clay to clay loam and shallow. Steep Rocky and Steep Adobe Ecological Sites may be associated with this system (Elliot 2011).
Vegetation: The canopy is typically dominated or codominated by deciduous trees, including *Quercus buckleyi, Quercus laceyi, Quercus sinuata var. breviloba, Fraxinus texensis, Ulmus crassifolia, Prunus serotina var. eximia, Juglans major,* and/or *Celtis laevigata var. reticulata*. *Quercus fusiformis* and *Juniperus ashei* are often present and are sometimes codominant with deciduous species of this system. Canopy closure is variable, and this system can be expressed as forests or woodlands. The shrub layer may be well-represented, especially where the overstory canopy is discontinuous. Species such as *Aesculus pavia var. flavescens, Cercis canadensis var. texensis, Forestiera pubescens, Ungnadia speciosa, Ceanothus herbaceus, Frangula caroliniana, Sophora secundiflora, Viburnum rufidulum, Rhus* spp., *Vitis* spp., and *Garrya ovata* may be present in the shrub layer. With the large amount of exposed rock, frequent accumulation of leaf litter, and significant canopy closure, herbaceous cover is generally sparse, with *Carex planostachys* often present. Woodland forbs such as *Tinantia anomala, Chaptalia texana, Nemophila phacelioides, Salvia roemeriana, Lespedeza texana*, and various ferns may also be present, if patchy (Elliott 2011).

Component Associations:
- *Juniperus ashei - Quercus buckleyi* Woodland (CEGL004172, G4)
- *Muhlenbergia reverchonii - Bouteloua hirsuta var. pectinata - Carex microdonta* Herbaceous Vegetation (CEGL004520, G3?)
- *Quercus buckleyi - Fraxinus texensis - Juniperus ashei* Forest (CEGL002135, G3)
- *Quercus laceyi - Juniperus ashei* Woodland (CEGL002136, G2)

SPATIAL CHARACTERISTICS

Spatial Summary: This system often forms deciduous bands at midslope on hills in the Edwards Plateau of Texas.
Adjacent Ecological Systems:
- Edwards Plateau Carbonate Glade and Barrens (CES303.655)

- Edwards Plateau Cliff (CES303.653)
- Edwards Plateau Floodplain Terrace (CES303.651)
- Edwards Plateau Limestone Savanna and Woodland (CES303.660)
- Edwards Plateau Limestone Shrubland (CES303.041)
- Edwards Plateau Mesic Canyon (CES303.038)
- Edwards Plateau Riparian (CES303.652)
- Edwards Plateau Upland Depression (CES303.654)

Adjacent Ecological System Comments: The predominantly evergreen Edwards Plateau Limestone Savanna and Woodland (CES303.660) occurs on adjacent drier upland ridges, flats and upper slopes. Very steep and moist canyons of the Edwards Plateau are classified as Edwards Plateau Mesic Canyon (CES303.038).

DISTRIBUTION

Range: This system is expected to occur on dry-mesic slopes in the Edwards Plateau and Lampasas Cutplain.
Divisions: 303:C
Nations: US
Subnations: TX

EDWARDS PLATEAU LIMESTONE SAVANNA AND WOODLAND (CES303.660)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Ridge/Summit/Upper Slope; Sedimentary Rock; Temperate [Temperate Continental]; Unglaciated; Alkaline Soil; Calcareous; Ustic
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2383; ESLF 4326; ESP 1383

CONCEPT

Summary: This upland system occurs primarily on soils derived from chalk or limestone of Cretaceous or Pennsylvanian origin in the Edwards Plateau; it forms the matrix within this ecoregion. It can also occur on limestone in the shortgrass regions of Texas and north into Oklahoma in areas such as the Arbuckle Mountains. This system is typified by a mosaic of evergreen oak forests, woodlands and savannas over shallow soils of rolling uplands and upper slopes within the Edwards Plateau and Lampasas Cutplain. *Quercus fusiformis* or *Juniperus ashei* typically dominate the canopy of this system. Other species may include *Quercus buckleyi, Quercus laceyi, Quercus stellata, Ulmus crassifolia, Fraxinus texensis, Quercus sinuata, Quercus vaseyana, Sophora secundiflora, Mahonia trifoliolata,* and *Diospyros texana*. Physiographic expression of this system varies from dense mottes (patches of forest where canopy cover approaches 100%) interspersed with grasslands to open savannalike woodlands with scattered individual or small groups of trees. Understories can contain various shrubs and graminoids, including *Cercis canadensis var. texensis, Forestiera pubescens, Sideroxylon lanuginosum, Diospyros texana, Rhus trilobata, Bouteloua* spp., *Schizachyrium scoparium, Nassella leucotricha, Carex planostachys, Aristida purpurea, Aristida oligantha, Liatris mucronata, Stillingia texana, Symphyotrichum ericoides, Hedyotis nigricans, Monarda citriodora,* and *Salvia texana*. Grasslands dominated by *Schizachyrium scoparium* occur in small patches within more closed woodlands and in larger patches between mottes or in open savannalike woodlands with scattered trees. Grasslands in this system tend to grade from shortgrass communities in the west to mixedgrass communities to the east. Substrate (limestone) determines the range of this system within given examples. Some disturbed areas of the western plateau are now dominated by mesquite woodland. Natural mesquite woodlands are believed to have occurred on the deeper soils of adjacent riparian systems.
Classification Comments: Distribution in Oklahoma needs to be reviewed. This system is described as a mosaic of grassland and woodland or forest communities.
Similar Ecological Systems:
- Edwards Plateau Dry-Mesic Slope Forest and Woodland (CES303.656)
- Edwards Plateau Limestone Shrubland (CES303.041)
- Llano Uplift Acidic Forest, Woodland and Glade (CES303.657)

Related Concepts:
- Ashe Juniper - Redberry (Pinchot) Juniper: 66 (Eyre 1980) Finer
- Edwards Plateau: Ashe Juniper Motte and Woodland (1101) [CES303.660.1] (Elliott 2011) Finer
- Edwards Plateau: Deciduous Oak / Evergreen Motte and Woodland (1103) [CES303.660.4] (Elliott 2011) Finer
- Edwards Plateau: Live Oak Motte and Woodland (1102) [CES303.660.2] (Elliott 2011) Finer
- Edwards Plateau: Oak / Hardwood Motte and Woodland (1104) [CES303.660.5] (Elliott 2011) Finer
- Edwards Plateau: Post Oak Motte and Woodland (1114) [CES303.660.6] (Elliott 2011) Finer
- Edwards Plateau: Savanna Grassland (1107) [CES303.660.9] (Elliott 2011) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is primarily found on Cretaceous limestones of the Edwards Plateau and Limestone (also referred to as Lampasas) Cutplain, but also associated with Pennsylvanian limestones of the Palo Pinto Formation and Winchell, Ranger, Home Creek limestone in the vicinity of Palo Pinto County, as well as on Cretaceous chalk formations in the northern Blackland Prairie and Cretaceous limestones of the western Crosstimbers and Rolling Plains. It ranges north into Oklahoma and is found on rolling to level upland topography, often on plateau tops, but also on gentle slopes. Soils are generally loams, clay loams, or clays, often with limestone parent material apparent. Low Stony Hill, Adobe, Clay Loam, and Shallow Ecological Sites are commonly associated with this system (Elliott 2011). Soil moisture and topography influence this system.
Vegetation: This forest and woodland system is dominated by species such as *Quercus fusiformis, Quercus laceyi, Quercus vaseyana, Juniperus ashei*, or *Pinus remota*. Other species may include *Quercus buckleyi, Ulmus crassifolia, Fraxinus texensis, Quercus sinuata,* and *Diospyros texana*. Certain uplands may have mottes of *Quercus fusiformis* dominating a savannalike woodland. Physiographic expression varies from dense mottes (patches of forest where canopy cover approaches 100%) interspersed with large or small grassland patches to open savannalike woodlands with scattered individual or small groups of trees. Understories can contain various shrubs and graminoids, including *Cercis canadensis var. texensis, Forestiera pubescens, Sideroxylon lanuginosum, Diospyros*

texana, Rhus trilobata, Mahonia trifoliolata, Sophora secundiflora, Opuntia engelmannii var. lindheimeri, and *Opuntia leptocaulis (= Cylindropuntia leptocaulis)*. Grasses and forbs include *Bouteloua* spp., *Schizachyrium scoparium, Sorghastrum nutans, Bouteloua curtipendula, Bothriochloa barbinodis, Bothriochloa laguroides ssp. torreyana, Nassella leucotricha, Hilaria belangeri, Buchloe dactyloides (= Bouteloua dactyloides), Andropogon gerardii, Bouteloua hirsuta, Bouteloua rigidiseta, Muhlenbergia reverchonii, Muhlenbergia lindheimeri, Carex planostachys, Aristida purpurea, Aristida oligantha, Liatris mucronata, Stillingia texana, Symphyotrichum ericoides, Hedyotis nigricans, Monarda citriodora*, and *Salvia texana*. Grasslands dominated by *Schizachyrium scoparium* occur in small patches within more closed woodlands and in larger patches between mottes or in open savannalike woodlands with scattered trees. Grasslands in this system tend to grade from shortgrass communities in the west to mixedgrass communities to the east. Substrate (limestone) determines the range of this system within given examples. The herbaceous stratum is often dominated by non-native grass species, especially *Bothriochloa ischaemum var. songarica*.
Dynamics: Substrate (limestone) and topographic position primarily influence this system. Fire, grazing and browsing may also influence this system.

Component Associations:
- *Hilaria belangeri - Bouteloua curtipendula* Herbaceous Vegetation (CEGL002238, G3?)
- *Juniperus ashei - Quercus buckleyi* Woodland (CEGL004172, G4)
- *Juniperus ashei - Quercus sinuata var. breviloba* Woodland (CEGL004170, G4)
- *Muhlenbergia reverchonii - Bouteloua hirsuta var. pectinata - Carex microdonta* Herbaceous Vegetation (CEGL004520, G3?)
- *Pinus remota - Juniperus ashei - Quercus* spp. Woodland (CEGL002124, G2G3)
- *Quercus fusiformis - Quercus buckleyi - Ulmus crassifolia / Schizachyrium scoparium* Woodland (CEGL004168, GNR)
- *Quercus fusiformis - Quercus buckleyi / Quercus sinuata - (Juniperus ashei)* Woodland (CEGL004215, GNR)
- *Quercus fusiformis / Hilaria belangeri* Woodland (CEGL002116, GNR)
- *Quercus fusiformis / Schizachyrium scoparium* Woodland (CEGL002115, G2G4)
- *Quercus sinuata var. breviloba* Scrub (CEGL004453, G2G3)
- *Quercus stellata - (Quercus marilandica, Ulmus crassifolia) / Schizachyrium scoparium* Woodland (CEGL004176, GNR)
- *Schizachyrium scoparium - (Sorghastrum nutans) - Sporobolus compositus var. compositus - Liatris mucronata* Herbaceous Vegetation (CEGL004211, GNR)
- *Schizachyrium scoparium - Bouteloua curtipendula - Nassella leucotricha* Herbaceous Vegetation (CEGL004070, GNR)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Edwards Plateau Carbonate Glade and Barrens (CES303.655)
- Edwards Plateau Cliff (CES303.653)
- Edwards Plateau Dry-Mesic Slope Forest and Woodland (CES303.656)
- Edwards Plateau Floodplain Terrace (CES303.651)
- Edwards Plateau Limestone Shrubland (CES303.041)
- Edwards Plateau Mesic Canyon (CES303.038)
- Edwards Plateau Riparian (CES303.652)
- Edwards Plateau Upland Depression (CES303.654)
- Llano Uplift Acidic Forest, Woodland and Glade (CES303.657)

Adjacent Ecological System Comments: A common component of Edwards Plateau Limestone Savanna and Woodland (CES303.660), *Quercus buckleyi*, is conspicuously absent from Llano Uplift Acidic Forest, Woodland and Glade (CES303.657).

DISTRIBUTION

Range: This system is found primarily within the Edwards Plateau ecoregion but can extend north into Oklahoma and into portions of the Southern Shortgrass region of Texas.
Divisions: 303:C

EDWARDS PLATEAU MESIC CANYON (CES303.038)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Canyon Mosaic; Forest and Woodland (Treed); Toeslope/Valley Bottom; Ustic; Flood Scouring; Canyon
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Moss/Lichen (Nonvascular); Temperate [Temperate Continental]; Alkaline Soil; Calcareous; Landslide
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2524; ESLF 4153; ESP 1524

CONCEPT

Summary: This system is largely endemic to the Edwards Plateau ecoregion and occurs on canyon bottoms, mesic lower slopes and steep canyons, primarily in the Southern Balcones Escarpment, but also in the Eastern Balcones Escarpment. This system also includes cliff faces and lower slopes of boxed canyons occurring as narrow, sometimes long bands in areas often with seeps where moisture is consistently more available than on adjacent slopes. The tree canopy is generally closed. Common components include *Ulmus crassifolia, Juglans major, Quercus buckleyi, Quercus laceyi, Prunus serotina var. eximia* (becoming less common to the north), *Fraxinus texensis* (dominant in the northeastern plateau), *Quercus muehlenbergii*, and *Acer grandidentatum*. Canyon bottoms may have scattered *Quercus macrocarpa*. Substrate (limestone) and topographic position (north and east aspects and lower slopes) are the dominant characteristics of this system. Small seepage areas are often dominated by *Adiantum capillus-veneris*, with *Thelypteris ovata var. lindheimeri* on nearby moist habitats. Other prominent species include *Buddleja racemosa, Ungnadia speciosa*, and *Toxicodendron radicans ssp. eximium*. Fire probably plays little role in the system, while grazing and browsing (by native as well as exotic ungulates) may play an important role in recruitment and understory composition. Adjacent, drier slopes are usually dominated by various *Quercus* species and *Juniperus ashei*.

Similar Ecological Systems:
- Edwards Plateau Cliff (CES303.653)--represents sparsely vegetated cliff faces and could be considered a part this system and may not be justified as distinct from it.
- Edwards Plateau Dry-Mesic Slope Forest and Woodland (CES303.656)--represents dry-mesic slopes in the Edwards Plateau characterized by woodlands often dominated by *Quercus buckleyi*.

- Edwards Plateau Mixed Deciduous Mesic Canyon (not mapped) [CES303.038.2] (Elliott 2011) Finer
- Sugar Maple: 27 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is largely endemic to the Edwards Plateau ecoregion. Examples are associated with lower Cretaceous limestones of the Edwards Plateau, often on the Glen Rose or related formations. This system occurs on mesic lower slopes (toeslopes), canyon bottoms, and onto the margins of adjacent valleys of small drainages, primarily in the Southern Balcones Escarpment, but also in the Eastern Balcones Escarpment (also on the Limestone Cutplain). Occurrences are generally found in steep canyons where insolation is minimal, or on lower positions on northern- or eastern-facing slopes. This system also includes areas of cliff faces and lower slopes of boxed canyons occurring as narrow, sometimes long bands in areas often with seeps where moisture is consistently more available than on adjacent slopes. Soils are rich loams, often very rocky, with little soil development. It includes Steep Rocky Ecological Site, in part (Elliott 2011).

Vegetation: The tree canopy is generally closed. Composition is variable among examples, depending on moisture status. Common components include *Ulmus crassifolia, Juglans major, Quercus buckleyi, Quercus laceyi, Prunus serotina var. eximia* (becoming less common to the north), *Fraxinus texensis* (dominant in the northeastern plateau), *Quercus muehlenbergii*, and *Acer grandidentatum*. Canyon bottoms may have scattered *Quercus macrocarpa*. Small seepage areas are often dominated by *Adiantum capillus-veneris*, with *Thelypteris ovata var. lindheimeri* on nearby moist habitats. Other prominent species include *Buddleja racemosa, Ungnadia speciosa*, and *Toxicodendron radicans ssp. eximium*. Mesic examples are characterized by the presence of *Acer grandidentatum*, with *Quercus muehlenbergii* as a common associate, along with *Ulmus crassifolia, Juglans major, Quercus buckleyi, Quercus laceyi, Prunus serotina var. eximia* (becoming less common to the north), and *Fraxinus texensis* (dominant in the northeastern plateau). Mesic herbaceous indicators such as *Aquilegia canadensis* and *Clematis texensis* may be present in these examples (Elliott 2011).

Dynamics: Substrate (limestone) and topographic position (northern and eastern aspects and lower slopes) are the dominant characteristics of this system. Fire probably plays little role in the system, while grazing and browsing (by native as well as exotic ungulates) may play an important role in recruitment and understory composition.

Component Associations:
- *Acer grandidentatum - (Quercus muehlenbergii) / Carex edwardsiana* Lampasas Cutplain Forest (CEGL002319, G2)
- *Acer grandidentatum - Quercus muehlenbergii - Quercus laceyi / Carex edwardsiana - Chaetopappa effusa* Southern Edwards

Plateau Forest (CEGL004931, G2)
- *Adiantum capillus-veneris - (Thelypteris ovata var. lindheimeri, Thelypteris kunthii)* Herbaceous Vegetation (CEGL004514, G2)
- *Muhlenbergia reverchonii - Bouteloua hirsuta var. pectinata - Carex microdonta* Herbaceous Vegetation (CEGL004520, G3?)
- *Quercus laceyi - Juniperus ashei* Woodland (CEGL002136, G2)
- *Quercus muehlenbergii - Juglans major - (Ulmus rubra) / Verbesina virginica* Forest (CEGL004927, G2G3)

Spatial Characteristics

Adjacent Ecological Systems:
- Edwards Plateau Carbonate Glade and Barrens (CES303.655)
- Edwards Plateau Cliff (CES303.653)
- Edwards Plateau Dry-Mesic Slope Forest and Woodland (CES303.656)
- Edwards Plateau Floodplain Terrace (CES303.651)
- Edwards Plateau Limestone Savanna and Woodland (CES303.660)
- Edwards Plateau Limestone Shrubland (CES303.041)
- Edwards Plateau Riparian (CES303.652)
- Edwards Plateau Upland Depression (CES303.654)
- Llano Uplift Acidic Forest, Woodland and Glade (CES303.657)

Distribution

Range: Largely endemic to the Edwards Plateau ecoregion and occurs on canyon bottoms, mesic lower slopes and steep canyons, primarily in the Southern Balcones Escarpment, but also in the Eastern Balcones Escarpment.

FLORIDA LONGLEAF PINE SANDHILL (CES203.284)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Xeric; Very Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2356; ESLF 4259; ESP 1356

CONCEPT

Summary: This system represents stands of *Pinus palustris* on excessively well-drained, sandy soils in the Outer Coastal Plain and adjacent Inner Coastal Plain of Florida. This includes the "high pine islands" of central Florida, as well as vegetation of extensive areas of sand in the Florida Panhandle, north of the Cody Scarp, including at Eglin Air Force Base (with greater than 100,000 hectares of this ecological system). In central Florida on the Ocala National Forest, these stands are found in relation with sand pine scrub vegetation. This system is represented by larger patches of *Pinus palustris* sandhills, generally ranging from 60 to 4000 hectares in size. In addition to the largest extent at Eglin Air Force Base, examples also occur on the Ocala National Forest, the southern end of the Lake Wales Ridge, the Brooksville Ridge, and in other parts of the Florida Peninsula. Fire is absolutely essential to maintain this system, without which it may be almost completely replaced by scrub vegetation, hardwood trees, *Pinus taeda*, or other non-*Pinus palustris*-dominated vegetation.

Related Concepts:
- Longleaf Pine: 70 (Eyre 1980) Finer
- Sandhill (FNAI 1990) Broader

DESCRIPTION

Environment: Surface soils tend to be coarse, with <5% composition of finer-textured particles (silt and clay), and very low organic content and low moisture-holding capacity. Soils are typically Entisols (Psamments), with very limited profile development. In the Florida Panhandle soils can be Ultisols. Some soil series associated with this system include the Astatula series (Kalisz 1982), as well as the Lakeland, Tavares, and Orsino series (Abrahamson et al. 1984). Candler is the most extensive soil on sandhills on the ridges of Central Florida (S. Carr pers. comm.) In some cases on the Ocala National Forest the soils may be unusually dark in color at the surface, which has been attributed, in part, to the presence of charcoal. Soils are strongly acidic (pH 4.7-5.0). Some Central Florida sites have silt or clay in the subsoil contributing to significantly higher extractable bases at the surface when compared to nearby scrub sites (Kalisz 1982). Excluded are areas with a "shallow sand cap" (K. Outcault pers. comm.). On Eglin Air Force Base in the western Florida Panhandle, this ecological system occurs on deep sands on the Citronelle Formation. Psamments are the dominant soil suborder in the areas of Florida where this system is found (NRCS n.d.).

Vegetation: Stands of this system typically lack a well-developed subcanopy, especially in contrast to surrounding *Pinus clausa* scrub vegetation. However, the shrub layer may be well-developed, even under frequent fire conditions, and appears to be dominated by sprouts of *Quercus laevis* and *Quercus myrtifolia*. A rich herbaceous layer is present. Characteristic species in this stratum are *Aristida beyrichiana* and *Licania michauxii*. In addition, a number of species found primarily in central Florida may also be present, among the most frequent of which is *Chapmannia floridana*. Other geographically limited species may include *Sabal etonia, Polygonella ciliata,* and *Arnoglossum floridanum*.

Dynamics: Fire is absolutely essential to maintain this system, without which it may be almost completely replaced by scrub vegetation (in the Florida Peninsula), hardwood trees, *Pinus taeda*, or other non-*Pinus palustris*-dominated vegetation.

Component Associations:
- *Bigelowia nuttallii - Schizachyrium scoparium - Eurybia hemispherica* Florida Sandstone Herbaceous Vegetation (CEGL004946, G1)
- *Pinus palustris / Quercus (incana, margarettiae) / Aristida beyrichiana - Asimina angustifolia* Woodland (CEGL008586, G2?)
- *Pinus palustris / Quercus (laevis, myrtifolia) / Aristida beyrichiana - Chapmannia floridana* Woodland (CEGL008569, G2)
- *Pinus palustris / Quercus laevis - Quercus geminata / Ceratiola ericoides* Woodland (CEGL004491, G1G2)
- *Pinus palustris / Quercus laevis / Aristida beyrichiana - Pityopsis aspera* Woodland (CEGL003583, G3)
- *Pinus palustris / Quercus laevis / Schizachyrium scoparium - Rhynchosia cytisoides* Woodland (CEGL003587, G3)

SPATIAL CHARACTERISTICS

Spatial Summary: This system represents larger patches of *Pinus palustris* Sandhills (in Florida), ranging from 60 to 4000 hectares in size.

Adjacent Ecological Systems:
- Central Florida Pine Flatwoods (CES203.382)
- Central Florida Wet Prairie and Herbaceous Seep (CES203.491)
- Florida Peninsula Inland Scrub (CES203.057)

Adjacent Ecological System Comments: Adjacent to Central Florida Wet Prairie and Herbaceous Seep (CES203.491) and Central Florida Pine Flatwoods (CES203.382). It can be surrounded by Florida Peninsula Inland Scrub (CES203.057).

DISTRIBUTION

Range: This ecological system is found in the Outer Coastal Plain and adjacent Inner Coastal Plain of Florida, including the central Florida Peninsula (Ocala National Forest, Brooksville Ridge, southern end of the Lake Wales Ridge) (Abrahamson et al. 1984) and the Florida Panhandle, mainly north of the Cody Scarp (e.g., Eglin Air Force Base).

GREAT BASIN PINYON-JUNIPER WOODLAND (CES304.773)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Foothill(s); Lowland [Foothill]; Piedmont; Plateau; Forest and Woodland (Treed); Ridge/Summit/Upper Slope; Aridic; Pinus monophylla, Juniperus osteosperma
Non-Diagnostic Classifiers: Sideslope; Temperate [Temperate Continental]; Alkaline Soil; Long Disturbance Interval; F-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2019; ESLF 4206; ESP 1019

CONCEPT

Summary: This ecological system occurs on dry mountain ranges of the Great Basin region and eastern foothills of the Sierra Nevada south in scattered locations throughout southern California. It is typically found at lower elevations ranging from 1600-2600 m. These woodlands occur on warm, dry sites on mountain slopes, mesas, plateaus and ridges. Severe climatic events occurring during the growing season, such as frosts and drought, are thought to limit the distribution of pinyon-juniper woodlands to relatively narrow altitudinal belts on mountainsides. Woodlands dominated by a mix of *Pinus monophylla* and *Juniperus osteosperma*, pure or nearly pure occurrences of *Pinus monophylla*, or woodlands dominated solely by *Juniperus osteosperma* comprise this system, but in some regions of southern California, *Juniperus osteosperma* is replaced by *Juniperus californica*. *Cercocarpus ledifolius* is a common associate. On the east slope of the Sierras in California, *Pinus jeffreyi* and *Juniperus occidentalis var. australis* may be components of these woodlands. Understory layers are variable. Associated species include shrubs such as *Arctostaphylos patula, Artemisia arbuscula, Artemisia nova, Artemisia tridentata, Cercocarpus ledifolius, Cercocarpus intricatus, Coleogyne ramosissima, Yucca brevifolia, Quercus gambelii, Quercus turbinella, Quercus john-tuckeri, Juniperus californica, Quercus chrysolepis*, and bunch grasses *Hesperostipa comata, Festuca idahoensis, Pseudoroegneria spicata, Leymus cinereus (= Elymus cinereus),* and *Poa fendleriana*. This system occurs at lower elevations than Colorado Plateau Pinyon-Juniper Woodland (CES304.767) where sympatric.

HAWAI'I LOWLAND DRY FOREST (CES412.408)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Tropical/Subtropical [Tropical Xeric]
Non-Diagnostic Classifiers: Broad-Leaved Evergreen Tree; Broad-Leaved Evergreen Shrub
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2813; ESLF 4291; ESP 1813

CONCEPT

Summary: This ecological system occurs on dry slopes of the main islands generally from 15-1000 m (50-3280 feet) elevation, but it may extend to 1500 m (4920 feet). Stands typically occur on the leeward sides of islands where there is a strong rainshadow effect from high mountains that reduce precipitation from moisture-laden trade winds. Annual rainfall is generally 500-2000 mm. Substrates include well-drained, sandy loam soils derived from volcanic ash or cinder and weathered 'a'Ã¢ or pÃ¢hoehoe basaltic lava. Vegetation is characterized by an open to dense tree layer typically dominated or codominated by a variety of mostly evergreen trees and diverse shrubs, ferns and lianas depending on location and age of stands. Lowland dry and mesic forests are exceptionally rich in tree species. Widespread species *Metrosideros polymorpha* is a constituent or may codominate in relatively young stands. Late-seral stands are dominated by *Diospyros sandwicensis* and, less commonly, *Colubrina oppositifolia*. In driest settings supporting trees, summer deciduous *Erythrina sandwicensis* may dominate. Presence of diagnostic tree species such as *Acacia koaia, Erythrina sandwicensis, Gardenia brighamii, Hibiscadelphus* spp., *Kokia* spp., *Nesoluma polynesicum, Reynoldsia sandwicensis*, or the shrubs *Achyranthes* spp., *Nototrichium* spp., or *Tephrosia* spp. indicate this dry lowland system. Other characteristics trees include *Canthium odoratum, Alphitonia ponderosa, Nestegis sandwicensis, Pleomele* spp., *Rauvolfia sandwicensis, Santalum* spp., *Sophora chrysophylla, Pouteria sandwicensis*, and *Sapindus oahuensis*. Native shrubs include *Dodonaea, Styphelia, Osteomeles, Sida, Waltheria, Nothocestrum* spp., *Myrsine lanaiensis, Wikstroemia* spp., *Plumbago zeylanica, Senna gaudichaudii, Plectranthus parviflorus (= Plectranthus australis), Lipochaeta* spp., *Tetramolopium* spp., and *Chamaesyce* spp. Native vines include *Ipomoea* spp., *Bonamia menziesii*, and *Canavalia* spp. Native ferns include *Doryopteris* and *Pellaea ternifolia*. Almost all native lowland dry forests have been degraded and include some invasive exotic woody species such as *Lantana camara, Leucaena leucocephala, Schinus terebinthifolius*, and widespread exotic grasses such as *Andropogon virginicus, Pennisetum setaceum*, and *Schizachyrium condensatum*. Where substrate is rocky, lichens are often common.

Similar Ecological Systems:

- Hawai'i Montane-Subalpine Dry Forest and Woodland (CES412.402)

DESCRIPTION

Environment: This lowland ecological system occurs over a broad moisture range from very dry to seasonally mesic zones (Zones 2, 3, and 4) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). It occurs on dry slopes of the main islands generally from 15-1000 m (50-3280 feet) elevation, but it may extend to 1500 m (4920 feet) (Gagne and Cuddihy 1990). Stands typically occur on the leeward sides of islands where there is a strong rainshadow effect from high mountains that reduce precipitation from moisture-laden trade winds. Annual rainfall is generally 500-2000 mm. Substrates include well-drained, sandy loam soils derived from volcanic ash or cinder and weathered 'a'Ã¢ or pÃ¢hoehoe basaltic lava.

Vegetation: Vegetation is characterized by an open to dense tree layer typically dominated or codominated by a variety of mostly evergreen trees and diverse shrubs, ferns and lianas depending on location and age of stands. Lowland dry and mesic forests are exceptionally rich in tree species. Widespread species *Metrosideros polymorpha* is a constituent or may codominate in relatively young stands. Late-seral stands are dominated by *Diospyros sandwicensis* and, less commonly, *Colubrina oppositifolia*. In driest settings supporting trees, summer deciduous *Erythrina sandwicensis* may dominate. Presence of diagnostic tree species such as *Acacia koaia, Erythrina sandwicensis, Gardenia brighamii, Hibiscadelphus* spp., *Kokia* spp., *Nesoluma polynesicum, Reynoldsia sandwicensis*, or the shrubs *Achyranthes* spp., *Nototrichium* spp., or *Tephrosia* spp. indicate this dry lowland system. Other characteristics trees include *Canthium odoratum, Alphitonia ponderosa, Nestegis sandwicensis, Pleomele* spp., *Rauvolfia sandwicensis, Santalum* spp., *Sophora chrysophylla, Pouteria sandwicensis*, and *Sapindus oahuensis*. Native shrubs include *Dodonaea, Styphelia, Osteomeles, Sida, Waltheria, Nothocestrum* spp., *Myrsine lanaiensis, Wikstroemia* spp., *Plumbago zeylanica, Senna gaudichaudii, Plectranthus parviflorus (= Plectranthus australis), Lipochaeta* spp., *Tetramolopium* spp., and *Chamaesyce* spp. Native vines include *Ipomoea* spp., *Bonamia menziesii*, and *Canavalia* spp. Native ferns include *Doryopteris* and *Pellaea ternifolia*. Almost all native lowland dry forests have been degraded and include some invasive exotic woody species such as *Lantana camara, Leucaena leucocephala, Schinus terebinthifolius*, and widespread exotic grasses such as *Andropogon virginicus, Pennisetum setaceum*, and *Schizachyrium condensatum*. Where substrate is rocky, lichens are often common.

Dynamics: Severe weather (windthrow), drought, fire, landslides, and rats could all suppress reproduction or induce gaps, lowering tree cover; repeated fire could convert forest to shrubland and grassland. Wood harvested from dry forest for fuel could open closed forest.

Component Associations:
- *Acacia koaia* Lowland Dry Forest (CEGL008024, G1)
- *Diospyros sandwicensis - Colubrina oppositifolia* Lowland Dry Forest (CEGL008025, G1)
- *Diospyros sandwicensis* Lowland Dry Forest (CEGL008027, G3)
- *Erythrina sandwicensis* Lowland Dry Woodland (CEGL008036, G3)
- *Metrosideros polymorpha* Lowland Dry Forest (CEGL008029, G3)
- *Nestegis sandwicensis / Diospyros sandwicensis* Lowland Dry Forest (CEGL008031, G1)
- *Sapindus oahuensis* Lowland Dry Forest (CEGL008015, G1)

DISTRIBUTION

Range: This lowland forest ecological system occurs on dry slopes of the main Hawai'ian Islands, except for Kaho'olawe.

HAWAI'I LOWLAND MESIC FOREST (CES412.411)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Tropical/Subtropical [Tropical Pluviseasonal]
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2814; ESLF 4292; ESP 1814

CONCEPT

Summary: This ecological system occurs on mesic slopes of Hawai'i, Moloka'i, Maui, Kaua'i and O'ahu, from 30 to 1500 m (100-4920 feet) elevation, typically from 250 to1000 m (820-3280 feet). Stands are found in the mesic seasonal zone between the dry leeward and wet windward climates. Sites are considered mesic; too dry to support rainforests, but typically do not experience extended periods of drought like the dry forests. These mesic sites have relatively even precipitation throughout the year or have a distinct, seasonally dry period. Annual rainfall is 1200-2500 mm (47-98 inches) and falls largely from October to March. Substrates are highly variable but are generally well-drained and include steep, rocky talus, shallow to deep soils over weathered rock and gravelly alluvium, rocky shallow organic muck. Vegetation is variable, ranging from an open to dense, mostly evergreen tree layer 2-20 m tall. There is often diverse canopy, subcanopy and tall-shrub layers with lianas. As with lowland dry forest, tree diversity is very high. *Metrosideros polymorpha, Acacia koa, Diospyros sandwicensis, Nestegis sandwicensis, Pleomele* spp., and *Pritchardia kaalae* dominate or codominate. Diagnostic species of this system include the trees *Antidesma pulvinatum, Cryptocarya mannii, Alectryon macrococcus, Charpentiera* spp., *Flueggea neowawraea, Rhus sandwicensis, Pisonia* spp., and shrub and vine species *Ctenitis squamigera, Doodia* spp., and *Strongylodon ruber*. Other characteristic species in these diverse mesic forests may include *Antidesma platyphyllum, Bobea* spp., *Coprosma* spp., *Gardenia* spp., *Hibiscus* spp., *Melicope* spp., *Myrsine* spp., *Nothocestrum* spp., *Psychotria* spp., *Ochrosia* spp., *Pandanus tectorius, Pipturus albidus, Pittosporum* spp., *Rauvolfia* spp., *Santalum* spp., *Syzygium sandwicense, Xylosma hawaiiensis, Tetraplasandra* spp., *Zanthoxylum hawaiiense*, and drier forest species such as *Chamaesyce celastroides, Sophora chrysophylla*, and *Myoporum sandwicense*. The understory is variable and may be dominated by sedges and ferns or shrubs. The tree fern *Cibotium* spp. is typically absent. Common shrubs and vines include *Alyxia oliviformis, Cyanea* spp., *Delissea* spp., *Dodonaea viscosa, Eugenia* spp., *Freycinetia arborea, Hedyotis* spp., *Lobelia* spp., *Styphelia tameiameiae*, and *Vaccinium dentatum*. Common ferns and fern allies present are *Asplenium nidus, Dicranopteris linearis, Pteris* spp., and graminoids *Carex* spp. Exotic trees *Morella faya, Psidium* spp., and *Schinus terebinthifolius* are often present in disturbed stands. Fire-adapted exotic grasses such as *Oplismenus hirtellus* and *Pennisetum setaceum* are invasive and threaten these forests by increasing fire intensity, frequency and size.

Similar Ecological Systems:

- Hawai'i Mesic Coastal Forest (CES412.417)

DESCRIPTION

Environment: This lowland ecological system occurs mostly within the seasonally mesic and moist mesic zones (Zones 4 and 5) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007), but may extend into the moderately dry (Zone 3) at lower elevation (<300 m). This ecological system occurs on mesic slopes of Hawai'i, Moloka'i, Maui, Kaua'i and O'ahu, from 30 to 1500 m (100-4920 feet) elevation, typically from 250 to1000 m (820-3280 feet). Stands are found in the mesic seasonal zone between the dry leeward and wet windward climates. Sites are considered mesic; too dry to support rainforests, but typically do not experience extended periods of drought like the dry forests. These mesic sites have relatively even precipitation throughout the year or have a distinct, seasonally dry period. Annual rainfall is 1200-2500 mm (47-98 inches) and falls largely from October to March. Substrates are highly variable but are generally well-drained and include steep, rocky talus, shallow to deep soils over weathered rock and gravelly alluvium, and rocky shallow organic muck.

Vegetation: Vegetation is variable, ranging from an open to dense, mostly evergreen tree layer 2-20 m tall. There is often diverse canopy, subcanopy and tall-shrub layers with lianas. As with lowland dry forest, tree diversity is very high. *Metrosideros polymorpha, Acacia koa, Diospyros sandwicensis, Nestegis sandwicensis, Pleomele* spp., and *Pritchardia kaalae* dominate or codominate. Diagnostic species of this system include the trees *Antidesma pulvinatum, Cryptocarya mannii, Alectryon macrococcus, Charpentiera* spp., *Flueggea neowawraea, Rhus sandwicensis, Pisonia* spp., and shrub and vine species *Ctenitis squamigera, Doodia* spp., and *Strongylodon ruber*. Other characteristic species in these diverse mesic forests may include *Antidesma platyphyllum, Bobea* spp., *Coprosma* spp., *Gardenia* spp., *Hibiscus* spp., *Melicope* spp., *Myrsine* spp., *Nothocestrum* spp., *Psychotria* spp., *Ochrosia* spp., *Pandanus tectorius, Pipturus albidus, Pittosporum* spp., *Rauvolfia* spp., *Santalum* spp., *Syzygium sandwicense, Xylosma hawaiiensis, Tetraplasandra* spp., *Zanthoxylum hawaiiense*, and drier forest species such as *Chamaesyce celastroides, Sophora chrysophylla*, and *Myoporum sandwicense*. The understory is variable and may be dominated by sedges and ferns or shrubs. The tree fern *Cibotium* spp. is typically absent. Common shrubs and vines include *Alyxia oliviformis, Cyanea* spp., *Delissea* spp., *Dodonaea viscosa, Eugenia* spp., *Freycinetia arborea, Hedyotis* spp., *Lobelia* spp., *Styphelia tameiameiae*, and *Vaccinium dentatum*. Common ferns and fern allies present are *Asplenium nidus, Dicranopteris linearis, Pteris* spp., and graminoids *Carex* spp. Exotic trees *Morella faya, Psidium*

spp., and *Schinus terebinthifolius* are often present in disturbed stands. Fire-adapted exotic grasses such as *Oplismenus hirtellus* and *Pennisetum setaceum* are invasive and threaten these forests by increasing fire intensity, frequency and size.

HAWAI'I LOWLAND RAINFOREST (CES412.226)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Tropical/Subtropical [Tropical Pluvial]; Broad-Leaved Evergreen Tree; Tree Fern
Non-Diagnostic Classifiers: Sideslope; Toeslope/Valley Bottom
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2808; ESLF 4293; ESP 1808

CONCEPT

Summary: Hawai'i Lowland Rainforest occurs on all the main islands except Ni'ihau and Kaho'olawe. Lowland wet forests are thought to have been the predominant original vegetation of the windward lowlands on the larger main islands. The system typically occurs on windward slopes high enough to intercept orographic rainfall resulting from rising moist tradewind air, but also occurs in a relatively narrow high precipitation band on the leeward side of the Big Island resulting from Kona storms. Soils vary throughout the island chain, from gray acidic clays on older islands to thin organic mucks over lava flows and ash beds on Hawai'i. The canopy is dominated by *Metrosideros polymorpha* or, in some forests, by *Acacia koa* where it attains heights up to 40 m. On some islands, this system forms a distinct belt above *Acacia*-dominated mesic forest. Diversity in the lowland rainforest is high, and *Metrosideros* and *Acacia* at times form an emergent layer over a diverse layer of native trees and an understory of native ferns, herbs, shrubs and vines. Important taxa in this rainforest system include *Alyxia oliviformis, Antidesma platyphyllum, Broussaisia arguta, Cheirodendron* spp., *Cibotium* spp., *Coprosma* spp., *Cyrtandra* spp., *Dicranopteris linearis, Diospyros sandwicensis, Freycinetia arborea, Hedyotis* spp., *Ilex anomala, Korthalsella* spp., *Machaerina* spp., *Melicope* spp., *Myrsine* spp., *Peperomia* spp., *Pittosporum* spp., *Psychotria* spp., *Sadleria* spp., *Smilax melastomifolia*, and in some areas *Pritchardia* spp. Native trees that occur in the understory include *Psychotria hawaiiensis* (kopiko) and *Antidesma platyphyllum* (hame). The endemic liana (*Freycinetia arborea*) is often abundant in these forests. Species that act as epiphytes include *Astelia menziesiana, Peperomia* spp., *Adenophorus, Huperzia*, and *Elaphoglossum* spp.

In the upper reaches of the lowland ohi'a forest on the island of Hawai'i, the understory is dominated by tree ferns or *Cibotium* spp. (hapu'u) which form a distinct closed layer beneath the trees. A more open *Metrosideros* forest with other scattered native trees and a dense ground cover of the indigenous mat-forming *Dicranopteris linearis* (uluhe) and other related ferns (*Diplopterygium pinnatum, Sticherus owhyensis*) is seen on steep ridges and valley walls of Kaua'i, O'ahu, Moloka'i, Maui, and the Kohola Mountains of Hawai'i Island. *Freycinetia, Antidesma platyphyllum, Perrottetia*, and *Bobea* are constituents restricted largely to the lowland zone.
Classification Comments: The boundary between the lowland and montane wet forests in Hawai'i is not generally agreed upon by all botanists and ecologists, and it may be variable on different islands. A clear picture of pre-human vegetation is complicated by the extreme disturbance the lowlands have suffered. Nonetheless, roughly 1000 m elevation marks the transition between the warmer lowlands and the cooler montane zone.

DESCRIPTION

Environment: Hawai'i Lowland Rainforest occurs on all the main islands except Ni'ihau and Kaho'olawe. Lowland wet forests are thought to have been the predominant original vegetation of the windward lowlands on the larger main islands. The system typically occurs on windward slopes high enough to intercept orographic rainfall resulting from rising moist tradewind air, but also occurs in a relatively narrow high precipitation band on the leeward side of the Big Island resulting from Kona storms. Climate is moderately wet to very wet (Zones 6 and 7) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). Elevations range from 100-1200 m (328-3935 feet). Annual rainfall ranges from 1500 to over 5000 mm, sometimes less on sheltered sites. Soils vary throughout the island chain, from gray acidic clays on older islands to thin organic mucks over lava flows and ash beds on Hawai'i.
Vegetation: The canopy is dominated by *Metrosideros polymorpha* or, in some forests, by *Acacia koa* where it attains heights up to 40 m. On some islands, this system forms a distinct belt above *Acacia*-dominated mesic forest. Diversity in the lowland rainforest is high, and *Metrosideros* and *Acacia* at times form an emergent layer over a diverse layer of native trees beneath the *Metrosideros* canopy, and an understory of native ferns, herbs, shrubs and vines, including *Alyxia oliviformis, Antidesma platyphyllum, Broussaisia arguta, Cheirodendron* spp., *Cibotium* spp., *Coprosma* spp., *Cyrtandra* spp., *Dicranopteris linearis, Diospyros sandwicensis, Freycinetia arborea, Hedyotis* spp., *Ilex anomala, Korthalsella* spp., *Machaerina* spp., *Melicope* spp., *Myrsine* spp., *Peperomia* spp., *Pittosporum* spp., *Psychotria* spp., *Sadleria* spp., *Smilax melastomifolia*, and in some areas *Pritchardia* spp. Native trees that occur in the understory include *Psychotria hawaiiensis* (kopiko) and *Antidesma platyphyllum* (hame). The endemic *Freycinetia arborea* (liama) is often abundant in these forests. Species that act as epiphytes include *Astelia menziesiana, Peperomia* spp., *Adenophorus, Huperzia*, and *Elaphoglossum* spp. In the upper reaches of the lowland ohi'a forest on the island of Hawai'i, the understory is dominated by tree ferns or *Cibotium* spp. (hapu'u) which form a distinct closed layer beneath the trees. A more open *Metrosideros* forest with other scattered native trees and a dense ground cover of the indigenous mat-forming *Dicranopteris linearis* (uluhe) and other related ferns (*Diplopterygium pinnatum, Sticherus owhyensis*) is seen on steep ridges and valley walls of Kaua'i, O'ahu, Moloka'i, Maui, and the Kohola Mountains of Hawai'i Island (Cuddihy and Stone 1990). *Freycinetia, Antidesma platyphyllum,*

Perrottetia, and *Bobea* are constituents restricted largely to the lowland zone.
Dynamics: The lowland wet forest historically (pre-Polynesian times) was more widespread below 1000 m (3280 feet) elevation on the larger islands in windward areas with deep soils before being subjected to cultivation by Hawaiians. Where lands cultivated by Hawaiians were not subsequently used for agriculture, grazing, or urban development, they were invaded by species of Polynesian introduction, particularly *Aleurites moluccana* (kukui) and by later post-European introductions such as *Psidium cattleianum* (strawberry guava). Disturbances in this system include landslides in wet valleys, flood, lava flows, storms, rat predation, and fire. Major storms, particularly hurricanes will often open up the tree canopy. Although most of the species found in the tree canopy, subcanopy, and understory will still be present, *Dicranopteris linearis*, and taxa such as *Cibotium* and *Sadleria* may temporarily increase in cover because of the increased light levels with the more open canopy.

Component Associations:
- *Acacia koa / Metrosideros polymorpha - Dicranopteris linearis* Lowland Wet Forest (CEGL008005, G3)
- *Dicranopteris linearis* Wet Herbaceous Mat (CEGL008048, G4)
- *Metrosideros polymorpha / Cheirodendron* spp. Lowland Wet Forest (CEGL008000, G3)
- *Metrosideros polymorpha / Cibotium* spp. Lowland Wet Forest (CEGL008001, G3)
- *Metrosideros polymorpha / Dicranopteris* spp. Lowland Wet Shrubland (CEGL008049, G3)
- *Metrosideros polymorpha / Freycinetia arborea* Lowland Wet Forest (CEGL008002, G3)
- *Metrosideros polymorpha / Pandanus tectorius* Lowland Wet Forest (CEGL008003, G3)
- *Pritchardia martii* Lowland Wet Forest (CEGL008004, G2)

HAWAI'I MESIC COASTAL FOREST (CES412.417)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Shoreline; Tropical/Subtropical [Tropical Pluviseasonal]; Salt Spray; Coast
Non-Diagnostic Classifiers: Lowland [Lowland]; Beach (Substrate)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2812; ESLF 4294; ESP 1812

CONCEPT

Summary: This ecological system is restricted to the windward sides of the larger main islands that intercept sufficient orographic rainfall to maintain a forest condition, yet are influenced strongly by coastal factors such as salt spray. A few representatives can be found in the northwestern Hawaiian Islands. Coastal mesic volcanic substrates are often dominated by *Pandanus tectorius* (hala). Native plant associates in coastal mesic forest may include coastal shrubs, forbs and grasses. They are now relatively uncommon, having been largely replaced by alien species, but a diverse flora once likely existed. Remnant native constituents such as *Lipochaeta succulenta* (nehe) may dominate the understory and forest edges. In areas with annual rainfall of 1800-3800 mm on Hawai'i, recent lava flows exposed to salt spray are believed to have undergone succession involving eventual replacement of colonizing *Metrosideros polymorpha* (Ã´hi'a) by hala. Included in this system are the highly fragmented *Pritchardia* (loula) coastal forests, which occur on windward sea cliffs of Moloka'i, Huelo Islet, and Nihoa Island in the northwestern Hawaiian Islands.
Classification Comments: Planted coconut groves occur after Hawaiian colonization.
Similar Ecological Systems:
- Hawai'i Dry Coastal Strand (CES412.418)
- Hawai'i Lowland Mesic Forest (CES412.411)
- Hawai'i Wet-Mesic Coastal Strand (CES412.419)

DESCRIPTION

Environment: This mesic coastal forest ecological system occurs within the moderately dry, seasonal mesic, moist mesic, and moderately wet zones (Zones 3, 4, 5 and 6) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This ecological system is restricted to the windward sides of the larger main islands that intercept sufficient orographic rainfall to maintain a forest condition, yet are influenced strongly by coastal factors such as salt spray. A few representatives can be found in the northwestern Hawaiian Islands. Coastal mesic volcanic substrates are often dominated by *Pandanus tectorius* (hala).
Vegetation: Native plant associates in coastal mesic forest may include coastal shrubs, forbs and grasses. They are now relatively uncommon, having been largely replaced by alien species, but a diverse flora once likely existed. Remnant native constituents such as *Lipochaeta succulenta* (nehe) may dominate the understory and forest edges. In areas with annual rainfall of 1800-3800 mm on Hawai'i, recent lava flows exposed to salt spray are believed to have undergone succession involving eventual replacement of colonizing *Metrosideros polymorpha* (Ã´hi'a) by *Pandanus tectorius* (hala) (Atkinson 1970, as cited in Wagner et al. 1999).

Component Associations:
- *Pandanus tectorius* Coastal Mesic Forest (CEGL008032, G3)
- *Pritchardia hillebrandii* Coastal Mesic Forest (CEGL008033, G1)
- *Pritchardia remota* Coastal Dry Forest (CEGL008035, G1)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Hawai'i Dry Coastal Strand (CES412.418)
- Hawai'i Lowland Mesic Forest (CES412.411)
- Hawai'i Wet-Mesic Coastal Strand (CES412.419)

Adjacent Ecological System Comments: This system occurs adjacent to lowland mesic forest and may grade into it; both include a component of *Pandanus*, but this coastal forest is influenced by coastal spray/salinity-adapted species.

DISTRIBUTION

Range: This ecological system is known from the windward sides of the larger main islands that intercept sufficient orographic rainfall to maintain a forest condition, yet are influenced strongly by coastal factors such as salt spray. It also occurs on cliffs of Huelo Islet, Moloka'i, and Nihoa Island in the northwestern Hawai'ian Islands.

HAWAI'I MONTANE CLOUD FOREST (CES412.217)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Forest and Woodland (Treed); Ridge; Ridge/Summit/Upper Slope; Tropical/Subtropical [Tropical Pluvial]; Tree Fern; Epiphyte
Non-Diagnostic Classifiers: Broad-Leaved Evergreen Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2809; ESLF 4295; ESP 1809

CONCEPT

Summary: Hawai'i Montane Cloud Forest occurs between 1065 and 1830 m (3500-6000 feet) elevation as a large-patch mosaic on windward aspects of all the high islands that receive evenly distributed orographically derived rainfall exceeding 2500 mm (99 inches) annually. Montane cloud forests are defined by the regular presence of clouds, low stature of the tree canopy, the abundance of epiphytes, and the significant proportion by which those passing clouds contribute fog water (fog drip) to total annual precipitation (up to 1073 mm [42 inches]). Regular fog drip sustains relatively constant streamflow and shallow groundwater hydrology in montane forests, particularly during dry seasons. Hawai'i cloud forests occur on older volcanic substrates that are nutrient-poor and lateritic due to leaching. They generally have a gley layer 10 to 70 cm (4-28 inches) thick with an organic overlay that varies from 10 to 30 cm (4-12 inches) deep. This ecological system is rich in species, with multiple species represented in each of several genera of shrubs and ferns. Vegetation is dominated by low-statured *Metrosideros polymorpha* and *Cheirodendron* spp. (specifically *Cheirodendron platyphyllum* on O'ahu and *Cheirodendron dominii* on Kaua'i), which form a low to medium-height canopy from 3 to 40 m tall. Subdominant tree species include *Ilex anomala, Alyxia oliviformis*, and shrubs *Clermontia* spp., *Cyanea* spp., *Dubautia platyphylla, Korthalsella* spp., *Myrsine* spp., *Trematolobelia* spp., *Smilax melastomifolia, Stenogyne* spp., *Phyllostegia* spp., and *Vaccinium* sp. This system supports an abundance of epiphytic shrubs, ferns, mosses and bryophytes. Species that act as epiphytes include *Astelia menziesiana, Peperomia* spp., and thick mats of bryophytes. Ferns include *Dicranopteris linearis, Cibotium* spp., *Astelia, Adenophorus* and *Elaphoglossum* spp. Cloud forests are distinguished from montane rainforests by the presence of a low-statured tree canopy and the ground-level clouds for a portion of nearly every day. Cloud forests generally support more epiphytes than montane rainforests.
Classification Comments: Hawai'i Montane Cloud Forest is similar to Hawai'i Montane Rainforest (CES412.215), but this community is generally found only on wet wind-exposed upper slopes of the major Hawaiian Islands and is characterized by a low-statured tree canopy and thick mats of bryophytes and epiphytes.
Similar Ecological Systems:
- Hawai'i Montane Rainforest (CES412.215)

DESCRIPTION

Environment: Hawai'i Montane Cloud Forest occurs between 1065 and 1830 m (3500-6000 feet) elevation as a large-patch mosaic on windward aspects of all the high islands that receive evenly distributed orographically derived rainfall exceeding 2500 mm (99 inches) annually. Climate is generally very wet (Zone 7) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). Montane cloud forests are defined by the regular presence of clouds, low stature of the tree canopy, the abundance of epiphytes, and the significant proportion by which those passing clouds contribute fog water (fog drip) to total annual precipitation (up to 1073 mm [42 inches]). Regular fog drip sustains relatively constant streamflow and shallow groundwater hydrology in montane forests, particularly during dry seasons. Hawai'i cloud forests occur on older volcanic substrates that are nutrient-poor and lateritic due to leaching. They generally have a gley layer 10 to 70 cm (4-28 inches) thick with an organic overlay that varies from 10 to 30 cm (4-12 inches) deep.
Vegetation: This ecological system is rich in species, with multiple species represented in each of several genera of shrubs and ferns. Vegetation is dominated by low-statured *Metrosideros polymorpha* and *Cheirodendron* spp. (specifically *Cheirodendron platyphyllum* on O'ahu and *Cheirodendron dominii* on Kaua'i), which form a low to medium-height canopy from 3 to 40 m tall. Subdominant tree species include *Ilex anomala, Alyxia oliviformis*, and shrubs *Clermontia* spp., *Cyanea* spp., *Dubautia platyphylla, Korthalsella* spp., *Myrsine* spp., *Trematolobelia* spp., *Smilax melastomifolia, Stenogyne* spp., *Phyllostegia* spp., and *Vaccinium* sp. This system supports an abundance of epiphytic shrubs, ferns, mosses and bryophytes. Species that act as epiphytes include *Astelia menziesiana, Peperomia* spp., and thick mats of bryophytes. Ferns include *Dicranopteris linearis, Cibotium* spp., *Astelia, Adenophorus* and *Elaphoglossum* spp.
Dynamics: The major disturbance factors in this system are from climatic factors, particularly hurricanes and drought. After a hurricane, the tree canopy will be opened up, although most of the species found in the tree canopy, subcanopy, and understory will still be present. Species such as *Dicranopteris linearis* may temporarily increase in cover because of the increased light levels with the more open canopy.

Component Associations:

- *Metrosideros polymorpha - Cheirodendron trigynum* / (*Cibotium* spp.) Montane Wet Forest (CEGL008008, G3)
- *Metrosideros polymorpha / Cibotium* spp. Montane Wet Forest (CEGL008009, G3)
- *Metrosideros polymorpha* / Mixed Shrub Montane Wet Forest (CEGL008007, G3)

CONCEPT

Summary: Hawai'i Montane Rainforest encompasses a mosaic of rainforest and shrublands between 1100 and 2200 m (3600-7000 feet) elevation on all of the high islands. Montane rainforest occurs as a large-patch mosaic on windward areas that receive evenly distributed orographically derived rainfall exceeding 2500 mm (99 inches) annually. Stands also occur in a relatively narrow high precipitation band on the leeward side of the Big Island resulting from Kona storms. The climate is warm, with frequent afternoon fog often generating fog drip. Soils generally have a gley horizon 10 to 70 cm (4-28 inches) deep, underlain by lateritic weathered basalt and overlain with organic hummus ranging from 10 to 30 cm (4-12 inches) deep.

Across the range of the ecological system, vegetation varies in height, structural complexity and species richness. Forests can be dominated by *Metrosideros polymorpha, Cibotium* spp. (tree fern) in some areas, or by a tall, well-stratified canopy of *Acacia koa* (koa) in other areas. At higher elevations on Maui and Hawai'i, *Metrosideros* forms a 5- to 8-m canopy that is relatively simple floristically. Canopy height becomes as low as 2 m in poorly drained areas and along bog margins. At the lower elevational limit, montane rainforests merge with Hawai'i Lowland Rainforest (CES412.226). At the upper elevational limit on Hawai'i and Maui, they quickly grade into *Acacia / Sophora* forest and other mesic communities. Montane rainforests frequently support a large mass of epiphytic mosses, ferns, and other plants. Common codominant and associated species include *Cheirodendron* spp., *Astelia menziesiana, Carex alligata, Clermontia* spp., *Cyrtandra* spp., *Dicranopteris* spp., *Psychotria* spp., *Pteridium aquilinum, Rubus* spp., *Urera glabra*, and *Vaccinium calycinum*. Plants that act as epiphytes include *Astelia menziesiana, Carex alligata, Elaphoglossum* spp., *Metrosideros polymorpha, Peperomia* spp., *Vaccinium calycinum*, and others. Montane rainforests differ from cloud forests by the lack of ground-level clouds nearly every day. Cloud forests support more epiphytes than montane rainforests.
Classification Comments: The boundary between the lowland and montane wet forests in Hawai'i is not generally agreed upon by all botanists and ecologists, and it may be variable on different islands. A clear picture of pre-human vegetation is complicated by the extreme disturbance the lowlands have suffered. Nonetheless, roughly 1000 m elevation marks the transition between the warmer lowlands and the cooler montane zone.
Similar Ecological Systems:
- Hawai'i Montane Cloud Forest (CES412.217)

DESCRIPTION

Environment: Montane rainforest occurs as a large-patch mosaic on windward areas that receive evenly distributed orographically-derived rainfall exceeding 2500 mm (99 inches) annually. Stands also occur in a relatively narrow high precipitation band on the leeward side of the Big Island resulting from Kona storms. Climate is moderately wet to very wet (Zones 6 and 7) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007).There is also frequent afternoon fog often generating fog drip. Soils generally have a gley horizon 10 to 70 cm (4-28 inches) deep, underlain by lateritic weathered basalt and overlain with organic hummus ranging from 10 to 30 cm (4-12 inches) deep.
Vegetation: Across the range of the ecological system, vegetation varies in height, structural complexity and species richness. Forests can be dominated by *Metrosideros polymorpha, Cibotium* spp. (tree fern) in some areas, or by a tall, well-stratified canopy of *Acacia koa* (koa) in other areas. At higher elevations on Maui and Hawai'i, *Metrosideros* forms a 5- to 8-m canopy that is relatively simple floristically. Canopy height becomes as low as 2 m in poorly drained areas and along bog margins. Montane rainforests frequently support a large mass of epiphytic mosses, ferns, and other plants. Common codominant and associated species include *Cheirodendron* spp., *Astelia menziesiana, Carex alligata, Clermontia* spp., *Cyrtandra* spp., *Dicranopteris* spp., *Psychotria* spp., *Pteridium aquilinum, Rubus* spp., *Urera glabra*, and *Vaccinium calycinum*. *Cheirodendron* spp. (olapa) are often codominant in low-statured, wind-stunted forests of peaks and ridges, areas almost continually brushed by clouds (Cuddihy et al. 1990). Plants that act as epiphytes include *Astelia menziesiana, Carex alligata, Elaphoglossum* spp., *Metrosideros polymorpha, Peperomia* spp., *Vaccinium calycinum*, and others.
Dynamics: The major disturbance factors in this system are from climatic factors, particularly hurricanes and drought, or periodic and widespread dieback of the *Metrosideros* tree canopy that has been documented for the islands of Hawai'i and Maui. After major storms or drought, the tree canopy will often be opened up. Although most of the species found in the tree canopy, subcanopy, and understory will still be present, *Dicranopteris linearis*, and taxa such as *Cibotium* and *Sadleria* may temporarily increase in cover because of the increased light levels with the more open canopy. On the island of Hawai'i, lava flows periodically run through forests on the flanks of Mauna Loa and Hualalai volcanoes. The invasive *Morella faya (= Myrica faya)* has formed closed-canopy dominance

in some montane rainforests on Hawai'i and Maui. The invasive *Passiflora mollissima* is a problem within this ecological system on Kaua'i and Hawai'i.

Component Associations:
- *Acacia koa / Metrosideros polymorpha - Cibotium* spp. Montane Wet Forest (CEGL008006, G3)
- *Carex alligata* Montane Wet Herbaceous Vegetation (CEGL008091, G3)
- *Metrosideros polymorpha / Cibotium* spp. Montane Wet Forest (CEGL008009, G3)
- *Metrosideros polymorpha / Dicranopteris linearis* Montane Wet Woodland (CEGL008041, G3)
- *Metrosideros polymorpha* / Mixed Shrub Montane Wet Forest (CEGL008007, G3)

HAWAI'I MONTANE-SUBALPINE DRY FOREST AND WOODLAND (CES412.402)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Forest and Woodland (Treed); Tropical/Subtropical [Tropical Xeric]; Very Shallow Soil
Non-Diagnostic Classifiers: Mountainside; Saddle; Broad-Leaved Evergreen Tree; Broad-Leaved Evergreen Shrub
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2815; ESLF 4297; ESP 1815

CONCEPT

Summary: This ecological system occurs on dry slopes of higher mountains of Maui and Hawai'i, from 1000-2900 m (3280-9510 feet) elevation. An inversion layer of warmer air forms 50-70% of the time between 1600 and 3000 m that dramatically reduces precipitation at higher elevations. This is because the wet trade winds generally do not rise above 1900 m (6230 feet) and are deflected around the mountains, leaving upper slopes too dry to support rain forests. Stands also occur at lower elevations on the leeward sides of islands where there is a strong rainshadow effect. Annual rainfall is generally 300-1200 mm. Many sites are wind-exposed. Substrates include cinder, well-drained, sandy loam soils derived from volcanic ash, and weathered 'a'Ã¢ or pÃ¢hoehoe basaltic lava with little soil development. Vegetation is characterized by an open to dense tree layer dominated or codominated by *Metrosideros polymorpha, Sophora chrysophylla, Myoporum sandwicense, Acacia koa, Chamaesyce celastroides,* or *Chamaesyce olowaluana*. *Acacia koa* forests are tallest (up to 18 m), and *Sophora - Myoporum* and *Chamaesyce* forests range from 3-5 m tall, and up to 10 m in some places. Diagnostic taxa for this system are *Chamaesyce olowaluana, Sophora chrysophylla* and species of *Exocarpos* shrubs. Other trees include *Myrsine lanaiensis, Santalum* spp., and *Zanthoxylum hawaiiense*. *Dodonaea viscosa, Styphelia tameiameiae, Chenopodium oahuense,* and *Vaccinium* spp. frequently form a sparse to moderately dense shrub layer up to 3 m tall. Other shrubs may include *Bidens menziesii, Coprosma ernodeoides, Dubautia ciliolata, Dubautia linearis, Geranium cuneatum, Geranium multiflorum, Osteomeles anthyllidifolia, Silene* spp., and *Tetramolopium* spp. Native graminoids (e.g., *Gahnia* spp.) usually have less than 10% cover and ferns (e.g., *Pteridium aquilinum*) are present, but contribute low cover especially at higher elevations. Native grasses include *Eragrostis atropioides*. Fire-adapted exotic grasses such as *Pennisetum setaceum* are invasive and threaten these dry shrublands by increasing fire intensity, frequency and size. The exotic rosette forb *Verbascum thapsus* is a common in many stands.

DESCRIPTION

Environment: This montane to subalpine ecological system occurs within the very dry and moderately dry zones (Zones 2 and 3) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This ecological system occurs on dry slopes of higher mountains of Maui and Hawai'i, from 1000-2900 m (3280-9510 feet) elevation. An inversion layer of warmer air forms 50-70% of the time between 1600 and 3000 m that dramatically reduces precipitation at higher elevations (Gagne and Cuddihy 1990). This is because the wet trade winds generally do not rise above 1900 m (6230 feet) and are deflected around the mountains, leaving upper slopes too dry to support rain forests (Mueller-Dombois and Fosberg 1998). Stands also occur at lower elevations on the leeward sides of islands where there is a strong rainshadow effect. Annual rainfall is generally 300-1200 mm. Many sites are wind-exposed. Substrates include cinder, well-drained, sandy loam soils derived from volcanic ash, and weathered 'a'Ã¢ or pÃ¢hoehoe basaltic lava with little soil development.
Vegetation: Vegetation is characterized by an open to dense tree layer dominated or codominated by *Metrosideros polymorpha, Sophora chrysophylla, Myoporum sandwicense, Acacia koa, Chamaesyce celastroides,* or *Chamaesyce olowaluana*. *Acacia koa* forests are tallest (up to 18 m), and *Sophora - Myoporum* and *Chamaesyce* forests range from 3-5 m tall, and up to 10 m in some

places. Diagnostic taxa for this system are *Chamaesyce olowaluana, Sophora chrysophylla*, and species of *Exocarpos* shrubs. Other trees include *Myrsine lanaiensis, Santalum* spp., and *Zanthoxylum hawaiiense*. *Dodonaea viscosa, Styphelia tameiameiae, Chenopodium oahuense*, and *Vaccinium* spp. frequently form a sparse to moderately dense shrub layer up to 3 m tall. Other shrubs may include *Bidens menziesii, Coprosma ernodeoides, Dubautia ciliolata, Dubautia linearis, Geranium cuneatum, Geranium multiflorum, Osteomeles anthyllidifolia, Silene* spp., and *Tetramolopium* spp. Native graminoids(e.g., *Gahnia* spp., *Eragrostis atropioides*) usually have less than 10% cover and ferns (e.g., *Pteridium aquilinum*) are present but contribute low cover, especially at higher elevations. Fire-adapted exotic grasses such as *Pennisetum setaceum* are invasive and threaten these dry woodlands by increasing fire intensity, frequency and size (Castillo 1997). The exotic rosette forb *Verbascum thapsus* is common in many stands.
Dynamics: This is a structurally diverse system that varies depending on pioneer substrates. On basalt lava, ohi'a is the pioneer species with a mixture of sparse ferns, grasses, and shrubs. Then shrubs such as *Dodonaea viscosa, Styphelia tameiameiae, Chenopodium oahuense*, and *Vaccinium* spp. form a layer with shrubby and tree *Metrosideros polymorpha*. As more ash blows in, other tree species may colonize, such as *Sophora chrysophylla, Myoporum sandwicense, Acacia koa, Chamaesyce celastroides*, or *Chamaesyce olowaluana* forming an open tree canopy and eventually a closed tree canopy.

On cinder and ash deposits, shrubs such as *Dodonaea viscosa, Styphelia tameiameiae, Chenopodium oahuense*, grasses and ferns colonize barren substrates. *Sophora chrysophylla* and *Myoporum sandwicense* become established as the shrub layer closes and stands resemble climax dry shrubland with scattered trees. Grasses may be present with up to 40% cover. *Sophora chrysophylla* and *Myoporum sandwicense* continue to grow and form an open tree canopy with a moderately dense shrub layer and a grass layer (up to 20% cover). Eventually the *Sophora chrysophylla* and *Myoporum sandwicense* tree canopy closes. This late-seral tree canopy may become mixed with or in time dominated by *Acacia koa, Chamaesyce celastroides*, or *Chamaesyce olowaluana*.

Component Associations:
- *Acacia koa / Sophora chrysophylla* Montane Dry Forest (CEGL008019, G1)
- *Chamaesyce celastroides* Montane Dry Woodland (CEGL008037, G1)
- *Chamaesyce olowaluana* Montane Dry Woodland (CEGL008038, G1)
- *Metrosideros polymorpha* Montane Dry Woodland (CEGL008042, G3)
- *Metrosideros polymorpha* Subalpine Dry Woodland (CEGL008043, G3)
- *Sophora chrysophylla / Myoporum sandwicense* Subalpine Dry Forest (CEGL008021, G1)
- *Sophora chrysophylla* Subalpine Dry Woodland (CEGL008047, G2)

HAWAI'I MONTANE-SUBALPINE MESIC FOREST (CES412.406)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Forest and Woodland (Treed); Tropical/Subtropical [Tropical Pluviseasonal]
Non-Diagnostic Classifiers: Mountainside
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2816; ESLF 4298; ESP 1816

CONCEPT

Summary: This ecological system occurs on mesic montane and subalpine slopes of Kaua'i, Maui and Hawai'i, from 900-2000 m (2950-6560 feet) elevation. Stands are found in the zone of mesic, seasonal precipitation between the dry leeward and wet windward climates. Sites are too dry to support rainforests, but do not experience extended periods of drought like the dry forests. Annual rainfall is generally 1000-2500 mm, with some areas experiencing a distinct dry period. Substrates include deep volcanic ash soils and trachyte, rocky mucks, and silty loams derived from weathered 'a'Ã¢ lava. Vegetation is characterized by an open to dense, mostly evergreen tree layer 10-35 m tall. There are often diverse subcanopy and tall-shrub layers with lianas. *Metrosideros polymorpha, Acacia koa*, or *Nestegis sandwicensis* dominate or codominate with other trees (e.g., *Santalum* spp., *Sapindus* spp.). *Sapindus saponaria* is a diagnostic species of this mesic system. Other trees may be present such as *Coprosma* spp., *Ilex anomala, Melicope* spp., *Myoporum sandwicense, Myrsine* spp., *Nothocestrum breviflorum, Pipturus albidus, Pisonia brunoniana, Pittosporum* spp., *Psychotria hawaiiensis, Zanthoxylum hawaiiense*, and drier forest species such as *Chamaesyce celastroides* and *Sophora chrysophylla*. The understory is variable and may be dominated by sedges and ferns or shrubs. Tree ferns (*Cibotium* spp.) are typically much less prominent than in wet forest. Common shrubs include *Clermontia* spp., *Cyanea* spp., *Dodonaea viscosa, Hedyotis* spp., *Rubus hawaiensis, Stenogyne* spp., and *Styphelia tameiameiae*. Common ferns and fern allies present include *Dryopteris wallichiana, Microlepia strigosa, Nephrolepis cordifolia, Melicope* spp. (= *Pelaea* spp.), *Sadleria* spp., and graminoids *Carex* spp. and *Uncinia uncinata*. Exotic trees *Morella faya, Psidium* spp., and *Schinus terebinthifolius* are often present in disturbed stands. Fire-adapted exotic grasses such as *Holcus lanatus, Pennisetum clandestinum*, and *Pennisetum setaceum* are invasive and threaten these forests by increasing fire intensity, frequency and size.
Similar Ecological Systems:
- Hawai'i Montane-Subalpine Dry Forest and Woodland (CES412.402)
- Hawai'i Montane-Subalpine Dry Shrubland (CES412.403)
- Hawai'i Subalpine Mesic Shrubland (CES412.404)

DESCRIPTION

Environment: This montane to subalpine ecological system occurs within the seasonally mesic and moist mesic zones (Zones 4 and 5) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This ecological system occurs on mesic montane and subalpine slopes of Kaua'i, Maui and Hawai'i, from 900-2000 m (2950-6560 feet) elevation. Stands are found in the zone of mesic, seasonal precipitation between the dry leeward and wet windward climates. Sites are too dry to support rainforests, but do not experience extended periods of drought like the dry forests (Gagne and Cuddihy 1990). Annual rainfall is generally 1000-2500 mm, with some areas experiencing a distinct dry period. Substrates include deep volcanic ash soils and trachyte, rocky mucks, and silty loams derived from weathered 'a'Ã¢ lava (Gagne and Cuddihy 1990).
Vegetation: Vegetation is characterized by an open to dense, mostly evergreen tree layer 10-35 m tall. There are often diverse subcanopy and tall-shrub layers with lianas. *Metrosideros polymorpha, Acacia koa*, or *Nestegis sandwicensis* dominate or codominate with other trees (e.g., *Santalum* spp., *Sapindus* spp.). *Sapindus saponaria* is a diagnostic species of this mesic system. Other trees may be present such as *Coprosma* spp., *Ilex anomala, Melicope* spp., *Myoporum sandwicense, Myrsine* spp., *Nothocestrum breviflorum, Pipturus albidus, Pisonia brunoniana, Pittosporum* spp., *Psychotria hawaiiensis, Zanthoxylum hawaiiense*, and drier forest species such as *Chamaesyce celastroides* and *Sophora chrysophylla*. The understory is variable and may be dominated by sedges and ferns or shrubs. Tree ferns (*Cibotium* spp.) are typically much less prominent than in wet forest. Common shrubs include *Clermontia* spp., *Cyanea* spp., *Dodonaea viscosa, Hedyotis* spp., *Rubus hawaiensis, Stenogyne* spp., and *Styphelia tameiameiae*. Common ferns and fern allies present include *Dryopteris wallichiana, Microlepia strigosa, Nephrolepis cordifolia, Melicope* spp. (= Pelaea spp.), *Sadleria* spp., and graminoids *Carex* spp. and *Uncinia uncinata*. Exotic trees *Morella faya, Psidium* spp., and *Schinus terebinthifolius* are often present in disturbed stands. Fire-adapted exotic grasses such as *Holcus lanatus, Pennisetum clandestinum*, and *Pennisetum setaceum* are invasive and threaten these forests by increasing fire intensity, frequency and size.
Dynamics: Major disturbances are storms, lava flow, lava or lightning-ignited fire.

Component Associations:
- *Acacia koa / Metrosideros polymorpha - Sapindus saponaria* Montane Mesic Forest (CEGL008016, G1)
- *Acacia koa / Metrosideros polymorpha* Montane Mesic Forest (CEGL008017, G1)

- *Acacia koa / Santalum paniculatum* Montane Mesic Forest (CEGL008018, G1)
- *Metrosideros polymorpha* Montane Mesic Forest (CEGL008020, G3)
- *Nestegis sandwicensis* Montane Mesic Woodland (CEGL008044, G1)

INTER-MOUNTAIN BASINS ASPEN-MIXED CONIFER FOREST AND WOODLAND (CES304.776)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Needle-Leaved Tree; Broad-Leaved Deciduous Tree; Aspen - Conifer Mix
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Sideslope; Toeslope/Valley Bottom; Temperate [Temperate Continental]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2061; ESLF 4302; ESP 1061

CONCEPT

Summary: This ecological system occurs on montane slopes and plateaus in Utah, western Colorado, northern Arizona, eastern Nevada, southern Idaho, western Wyoming, and in north-central Montana in the Big Snowy Mountains. It also occurs in localized settings in the Klamath Mountains of California, as well as in the Sierra Nevada and adjacent Great Basin mountains (Inyo, White, Warner, and Modoc Plateau). Elevations range from 1700 to 2800 m. Occurrences are typically on gentle to steep slopes on any aspect but are often found on clay-rich soils in intermontane valleys. Soils are derived from alluvium, colluvium and residuum from a variety of parent materials but most typically occur on sedimentary rocks. The tree canopy is composed of a mix of deciduous and coniferous species, codominated by *Populus tremuloides* and conifers, including *Pseudotsuga menziesii, Abies concolor, Abies lasiocarpa, Abies magnifica, Picea engelmannii, Picea glauca X engelmannii, Picea pungens, Pinus contorta, Pinus flexilis, Pinus jeffreyi, Pinus contorta var. murrayana*, and *Pinus ponderosa*. As the occurrences age, *Populus tremuloides* is slowly reduced until the conifer species become dominant. Common shrubs include *Amelanchier alnifolia, Prunus virginiana, Acer grandidentatum, Symphoricarpos oreophilus, Juniperus communis, Paxistima myrsinites, Rosa woodsii, Spiraea betulifolia, Symphoricarpos albus*, or *Mahonia repens*. Herbaceous species include *Bromus carinatus, Calamagrostis rubescens, Carex geyeri, Elymus glaucus, Poa* spp., and *Achnatherum, Hesperostipa, Nassella*, and/or *Piptochaetium* spp. (= *Stipa* spp.), *Achillea millefolium, Arnica cordifolia*, Asteraceae spp., *Erigeron* spp., *Galium boreale, Geranium viscosissimum, Lathyrus* spp., *Lupinus argenteus, Mertensia arizonica, Mertensia lanceolata, Maianthemum stellatum, Osmorhiza berteroi (= Osmorhiza chilensis)*, and *Thalictrum fendleri*. Most occurrences at present represent a late-seral stage of aspen changing to a pure conifer occurrence. Nearly a hundred years of fire suppression and livestock grazing have converted much of the pure aspen occurrences to the present-day aspen-conifer forest and woodland ecological system. This is the typical meadow edge aspen-conifer setting in the Sierra Nevada where frequently, due to fire suppression, the conifers are replacing aspens.

Related Concepts:
- Aspen Woodland (411) (Shiflet 1994) Intersecting
- Aspen: 217 (Eyre 1980) Intersecting

DESCRIPTION

Environment: The aspen-conifer forest and woodland ecological system is very similar to the aspen forest ecological system with regards to environmental characteristics. It is usually found on montane slopes and plateaus in western Wyoming, Idaho, Utah, and eastern Nevada. Elevations range from 1700 to 2800 m. Climate is temperate with cold winters. Mean annual precipitation is greater than 38 cm and typically greater than 50 cm. Occurrences are typically on gentle to steep slopes on any aspect. Soils are derived from alluvium, colluvium and residuum from a variety of parent materials, but most typically occur on sedimentary rocks.

Distribution of this ecological system is primarily limited by adequate soil moisture required to meet its high evapotranspiration demand (Mueggler 1988). Secondarily, its range is limited by the length of the growing season or low temperatures (Mueggler 1988). Topography is variable; sites range from level to steep slopes. Aspect varies according to the limiting factors. Occurrences at high elevations are restricted by cold temperatures and are found on warmer southern aspects. At lower elevations aspen is restricted by lack of moisture and is found on cooler north aspects and mesic microsites. The soils are typically deep and well-developed with rock often absent from the soil. Soil texture ranges from sandy loam to clay loam. Parent materials are variable and may include sedimentary, metamorphic or igneous rocks, but it appears to grow best on limestone, basalt, and calcareous or neutral shales (Mueggler 1988).

Vegetation: The open to moderately closed, mixed evergreen needle-leaved and deciduous broad-leaved tree canopy is composed of short to moderately tall trees and is codominated by *Populus tremuloides* and conifers, including *Pseudotsuga menziesii, Abies concolor, Abies lasiocarpa, Picea engelmannii, Picea pungens, Pinus contorta, Pinus flexilis*, and *Pinus ponderosa*. As the occurrences age, *Populus tremuloides* is slowly reduced until the conifer species becomes dominant (Mueggler 1988). The sparse to moderately dense understory may be structurally complex and includes tall-shrub, short-shrub and herbaceous layers, or it may be simple with just an herbaceous layer. Because of the open growth form of *Populus tremuloides*, more light can penetrate the canopy than in a pure conifer occurrence. Typically the understory is denser in younger occurrences that are dominated by *Populus tremuloides* and in more mesic sites with open canopies. If present, the tall-shrub layer may be dominated by *Amelanchier alnifolia, Prunus virginiana*, or *Acer grandidentatum*, and short-shrub layer by *Symphoricarpos oreophilus, Juniperus communis*, or *Mahonia*

repens. Other common shrubs include *Paxistima myrsinites, Rosa woodsii, Spiraea betulifolia, Symphoricarpos albus,* and in wet areas *Salix scouleriana*. Where dense, the herbaceous layer is often dominated by graminoids such as *Bromus carinatus, Calamagrostis rubescens, Carex geyeri, Elymus glaucus, Poa* spp., and *Achnatherum, Hesperostipa, Nassella,* and/or *Piptochaetium* spp. (= *Stipa* spp.). More sparse herbaceous layers are generally a more even mixture of forbs such as *Achillea millefolium, Arnica cordifolia, Eucephalus engelmannii (= Aster engelmannii), Erigeron speciosus, Fragaria vesca, Galium boreale, Geranium viscosissimum, Lathyrus* spp., *Lupinus argenteus, Mertensia arizonica, Mertensia lanceolata, Maianthemum stellatum, Osmorhiza berteroi (= Osmorhiza chilensis),* and *Thalictrum fendleri*. Annuals are typically uncommon. The exotic species *Poa pratensis* and *Taraxacum officinale* are more common in livestock-impacted occurrences (Mueggler 1988).

Dynamics: *Populus tremuloides* is thin-barked and readily killed by fire. It is a fire-adapted species that generally needs a large disturbance to establish and maintain dominance in a forest. These mixed forests are generally seral and, in the absence of stand-replacing disturbance such as fire, will slowly convert to a conifer-dominated forest (Mueggler 1988). The natural fire-return interval is approximately 20 to 50 years for seral occurrences (Hardy and Arno 1996). Intervals that approach 100 years are typical of late-seral occurrences (Hardy and Arno 1996). Although the young conifer trees in these occurrences are susceptible to fire, older individuals develop self-pruned lower branches and develop a thick corky bark that makes them resistant to ground fires. Most of the occurrences sampled by Mueggler (1988) had a history of livestock grazing, as evidenced by relative abundance of the exotics *Taraxacum officinale, Poa pratensis,* and other grazing-tolerant plants, and the scarcity of grazing-susceptible plants (Mueggler 1988). Most occurrences that we see today represent a late-seral stage of aspen changing to a pure conifer occurrence. Nearly a hundred years of fire suppression and livestock grazing have converted much of the pure aspen occurrences to the present-day aspen-conifer forest and woodland ecological system.

Component Associations:

- *Pinus contorta var. murrayana - Populus tremuloides / Artemisia tridentata / Poa pratensis* Forest (CEGL008669, GNR)

INTER-MOUNTAIN BASINS CURL-LEAF MOUNTAIN-MAHOGANY WOODLAND AND SHRUBLAND (CES304.772)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Aridic; Cercocarpus ledifolius
Non-Diagnostic Classifiers: Foothill(s); Piedmont; Plateau; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Sideslope; Temperate [Temperate Continental]; Long Disturbance Interval; F-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2062; ESLF 4303; ESP 1062

CONCEPT

Summary: This ecological system occurs in hills and mountain ranges of the Intermountain West basins from the eastern foothills of the Sierra Nevada northeast to the foothills of the Bighorn Mountains. It typically occurs from 600 m to over 2650 m in elevation on rocky outcrops or escarpments and forms small- to large-patch stands in forested areas. Most stands occur as shrublands on ridges and steep rimrock slopes, but they may be composed of small trees in steppe areas. Scattered junipers or pines may also occur. This system includes both woodlands and shrublands dominated by *Cercocarpus ledifolius*. *Artemisia tridentata ssp. vaseyana, Purshia tridentata,* with species of *Arctostaphylos, Ribes*, or *Symphoricarpos* are often present. Undergrowth is often very sparse and dominated by bunch grasses, usually *Pseudoroegneria spicata* and *Festuca idahoensis*. *Cercocarpus ledifolius* is a slow-growing, drought-tolerant species that generally does not resprout after burning and needs the protection from fire that rocky sites provide.
Related Concepts:

- Curlleaf Mountain-Mahogany - Bluebunch Wheatgrass (322) (Shiflet 1994) Finer

DESCRIPTION

Environment: Curl-leaf mountain-mahogany (*Cercocarpus ledifolius var. intermontanus*) communities are usually found on upper slopes and ridges between 2135 and 3200 m (7000-10,500 feet) elevations (NRCS 2003), although northern stands may occur as low as 610 m (2000 feet) (Marshall 1995). In western Nevada, curl-leaf mountain-mahogany may occur down to 1525 m (5000 feet) or lower and be restricted to northwestern and especially northeastern aspects at drier, lower edge of range. Most stands occur on rocky shallow soils and outcrops, with mature stand cover between 10-55%. In the absence of fire, old stands may occur on somewhat deeper soils, with more than 55% cover.
Dynamics: LANDFIRE model information: Fire: Curl-leaf mountain-mahogany does not resprout and is easily killed by fire (Marshall 1995). It is a primary early-successional colonizer rapidly invading bare mineral soils after disturbance. Fires are not common in early-seral stages, when there is little fuel, except in chaparral. Replacement fires (MFRI=150-500 years) become more common in mid-seral stands, where herbs and smaller shrubs provide ladder fuels. By late succession, two classes and fire regimes are possible depending on the history of mixed-severity and surface fires. In the presence of surface fire (MFRI=50 years) and past mixed-severity fires in younger classes, the stand will adopt a savanna-like woodland structure with a grassy understory, spiny phlox, and currant. Trees can become very old and will rarely show fire scars. In late, closed stands, the absence of herbs and small forbs makes replacement fires uncommon (MFRI of 500 years), requiring extreme winds and drought, because thick duff provides fuel for more intense fires. Mixed-severity fires (MFRI=50-200 years) are present in all classes, except the late closed one, and more frequent in the mid-development classes.

Ungulate herbivory: Heavy browsing by native medium-sized and large mammals reduces mountain-mahogany productivity and reproduction (NRCS 2003). This is an important disturbance in early- and mid-seral stages, when mountain-mahogany seedlings are becoming established. Browsing by small mammals has been documented (Marshall 1995), but is relatively unimportant and was incorporated as a minor component of native herbivory mortality.

Avian-caused mortality: In western Nevada for ranges in close proximity to the Sierra Nevada, sapsuckers drilling of young curl-leaf mountain-mahogany has been observed to cause stand-replacement mortality (C. Ross, NV BLM, pers. comm.).

Windthrow and snow creep on steep slopes are also sources of mortality.

Component Associations:
- *Artemisia arbuscula - Cercocarpus ledifolius / Pseudoroegneria spicata - Poa secunda* Scrub (CEGL001487, G4Q)
- *Cercocarpus ledifolius / Artemisia tridentata ssp. vaseyana* Woodland (CEGL001022, G3)
- *Cercocarpus ledifolius / Artemisia tridentata* Woodland (CEGL000960, G3G4)
- *Cercocarpus ledifolius / Calamagrostis rubescens* Woodland (CEGL000961, G2)
- *Cercocarpus ledifolius / Festuca idahoensis* Woodland (CEGL000962, G3)
- *Cercocarpus ledifolius / Holodiscus dumosus* Woodland (CEGL000963, G1G2)
- *Cercocarpus ledifolius / Leymus salinus ssp. salmonis* Woodland (CEGL000964, G2Q)
- *Cercocarpus ledifolius / Mahonia repens* Scrub (CEGL000965, GNR)

- *Cercocarpus ledifolius / Prunus virginiana* Scrub (CEGL000966, G4)
- *Cercocarpus ledifolius / Pseudoroegneria spicata - Festuca idahoensis* Woodland (CEGL000968, G3G4)
- *Cercocarpus ledifolius / Pseudoroegneria spicata* Scrub (CEGL000967, G4Q)
- *Cercocarpus ledifolius / Quercus gambelii* Woodland (CEGL005359, GNR)
- *Cercocarpus ledifolius / Symphoricarpos longiflorus* Scrub (CEGL000969, G4)
- *Cercocarpus ledifolius / Symphoricarpos oreophilus* Woodland (CEGL000970, G2)

SPATIAL CHARACTERISTICS

Spatial Summary: Because these communities are restricted to rock outcrops and thin soils, stands usually occur on a small scale, and are spatially separated from each other by other communities that occur on different aspects or soil types. A few curl-leaf mountain-mahogany stands may be much larger than 100 acres.

INTER-MOUNTAIN BASINS SUBALPINE LIMBER-BRISTLECONE PINE WOODLAND (CES304.790)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Forest and Woodland (Treed); Ridge; Ridge/Summit/Upper Slope; Temperate [Temperate Continental]; Xeric; Pinus longaeva, P. flexilis
Non-Diagnostic Classifiers: Calcareous
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2020; ESLF 4207; ESP 1020

CONCEPT

Summary: This ecological system extends from the Mojave Desert and Sierra Nevada across the central Great Basin to the central Wasatch and western Uinta mountains. These open woodlands are typically found on high-elevation ridges and rocky slopes above subalpine forests and woodlands. Site are harsh, exposed to desiccating winds with rocky substrates and a short growing season that limit plant growth. Parent materials include dolomitic, limestone or granitic rocks. Occurrences can be found on all aspects but are more common on southwestern exposures on steep convex slopes and ridges between 2530 and 3600 m (8300-12,000 feet). Stands are strongly dominated by *Pinus flexilis* and/or *Pinus longaeva*. *Pinus monophylla* may be present in lower-elevation stands. If present, shrub and herbaceous layers are generally sparse and composed of xeric shrubs, graminoids and cushion plants. Associated species may include *Antennaria rosea, Arenaria kingii, Artemisia tridentata, Cercocarpus intricatus, Chamaebatiaria millefolium, Cymopterus cinerarius, Elymus elymoides, Erigeron pygmaeus, Eriogonum ovalifolium, Festuca brachyphylla, Koeleria macrantha, Leptodactylon pungens, Ribes cereum,* or *Ribes montigenum*.
Related Concepts:
- Bristlecone Pine: 209 (Eyre 1980) Broader
- Limber Pine: 219 (Eyre 1980) Intersecting

DESCRIPTION

Environment: The bristlecone pine-limber pine woodland ecological system denotes some of the driest and windiest sites capable of supporting trees other than *Juniperus*. Sites are typically xeric on exposed, windswept rocky slopes and ridges. It can be found on all aspects but is more common on southwestern exposures on steep convex slopes and ridges between 2530 and 3600 m (8300-12,000 feet). It commonly represents a topographic or edaphic climax within the *Abies lasiocarpa* and upper *Pseudotsuga menziesii* zones. This system occurs on a variety of substrates but is best represented on residuum and colluvium derived from limestone and dolomite or Tertiary and Cretaceous sandstone. A characteristic feature is the predominance of bare soil; almost all sites have between 25 and 50% bare ground. Consequently, litter accumulations are slight and intermittent. Most sites are droughty, with gravel in the shallow subsurface horizons. Surface textures vary depending upon parent material. Steep slopes, high-intensity summer convection storms, and only partial ground cover for interception often result in severe sheet erosion of fine particles. This usually leads to the development of gravel pavements. Additional erosion can be expected from wind action. High insolation and wind during the winter usually result in reduced snowpack accumulations. However, soils can be expected to freeze.
Dynamics: Both *Pinus longaeva* and *Pinus flexilis* are short-statured, slow-growing, long-lived trees that are intolerant of shade. *Pinus longaeva* may attain nearly 4900 years in age and 12 m in height, whereas *Pinus flexilis* may live 1000 years and attain 18 m in height. Bristlecone pine branches retain needles for as long as 30 years, whereas limber pine needles are lost after only several years. Bristlecone pine trees produce dense, resinous wood that is resistant to rot and disease. Mature trees have massive, contorted trunks with mostly dead and gnarled wood (Sawyer et al. 2009). Tree-ring data over the last 4000 years indicate that droughts of 200 years or more have occurred.

Natural regeneration of *Pinus flexilis* appears to be closely associated with caching of the large wingless seeds, primarily by Clark's nutcracker (*Nucifraga columbiana*) (Lanner and Vander Wall 1980). Germination of cached seeds often results in the multi-stemmed clumps characteristic of these sites, although the species may produce multiple stems from boles damaged near the ground. Germination and rooting will sometimes be restricted to crevices in rock. *Pinus longaeva* has smaller winged seeds that are wind-disseminated. However, caching by nutcrackers does take place, especially when other *Pinus* species are also available (Dr. R. Lanner pers. comm.). The longevity of individuals enables stands to persist for centuries between times of favorable seedling establishment (Keeley and Zedler 1998). Stands are subject to long, intense droughts.

Stands vary from tens to hundreds of acres in size with stand-replacement fires ranging from 1/10th acre to 100 acres (Landfire 2007a). These pines have relatively thin bark adapted to survive only low-severity surface fires. However, fires seldom consume whole stands due to the open to sparse nature of the tree canopy and abundant bare ground. When fires occur on high-elevation sites, they are usually small, low-severity surface fires (Bradley et al. 1992). The sparsity of shrubs, forbs, grasses, and litter, in addition to the widely spaced trees, usually means that fire does not carry easily. Individual trees may be ignited and damaged or killed from lightning strikes, but seldom is an entire stand burned except when fire is spread via high winds. At lower elevations surface fuels should be more abundant and could allow for spreading surface fires (Kilpatrick and Biondi 2013).

Pinus longaeva and *Pinus flexilis* are both experiencing mountain pine beetle (*Dendroctonus ponderosae*) infestations throughout much of their ranges (Lanner 1983). Logan and Powell (2001) provide information on the ecology and management of mountain pine beetles in high-elevation ecosystems. Gibson et al. (2008) reported recently detected mortality of *Pinus longaeva* in the Great Basin, including 100 acres in 2005, 60 acres in 2006, and 300 acres in 2007, all within the Snake Range in east-central Nevada (aerial detection surveys). Western dwarf mistletoe (*Arceuthobium campylopodum*) infests Great Basin bristlecone pines in southern Nevada and Utah (Mathiasen and Hawksworth 1990).

Component Associations:
- *Abies concolor var. concolor - Pinus ponderosa - Pinus longaeva* Forest (CEGL002736, GNR)
- *Pinus flexilis / Cercocarpus ledifolius* Woodland (CEGL000804, G4)
- *Pinus flexilis / Festuca idahoensis* Woodland (CEGL000805, G5)
- *Pinus flexilis / Juniperus communis* Woodland (CEGL000807, G5)
- *Pinus flexilis / Juniperus osteosperma* Woodland (CEGL000808, G3)
- *Pinus flexilis / Mahonia repens* Woodland (CEGL000811, G3?)
- *Pinus longaeva* Woodland (CEGL002380, GNR)

Spatial Characteristics

Adjacent Ecological System Comments: Adjacent vegetation at high elevations includes alpine meadows and shrublands and subalpine forests dominated by *Picea, Abies,* or *Pseudotsuga*. Adjacent montane occurrences are dominated by *Pinus ponderosa, Pinus contorta,* or *Pseudotsuga menziesii*. At lower elevations adjacent vegetation may include *Juniperus*-dominated woodland and savannas; shrublands dominated by species of *Artemisia, Cercocarpus,* or *Purshia tridentata*.

Distribution

INTERIOR HIGHLANDS UNGLACIATED FLATWOODS (CES202.454)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Matrix, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Hardpan; Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 4339

CONCEPT

Summary: This system represents hardwood- or pine-hardwood-dominated flatwoods of the Ozarks, Arkansas Valley, and Ouachitas of Arkansas, adjacent Missouri and possibly Oklahoma. Sites are high, fairly level and generally unflooded but seasonally saturated. There is some local variability in the expression of this system along a hydrologic/microtopographic gradient. The elevated ridges or pimple mounds are better drained and retain less moisture than do the lower areas, although both occur in a tight local mosaic. The soils appear to have well-developed subsurface hardpans, the impermeability of which contributes to shallowly perched water tables during portions of the year when precipitation is greatest and evapotranspiration is lowest. Soil moisture fluctuates widely throughout the growing season, from saturated to very dry, a condition sometimes referred to as xerohydric. Fire was an important natural process in this system, and well-burned examples tend to be relatively open-canopied with well-developed herbaceous layers.

Similar Ecological Systems:
- Lower Mississippi River Flatwoods (CES203.193)
- South-Central Interior / Upper Coastal Plain Flatwoods (CES203.479)
- South-Central Interior / Upper Coastal Plain Wet Flatwoods (CES203.480)
- West Gulf Coastal Plain Nonriverine Wet Hardwood Flatwoods (CES203.548)

DESCRIPTION

Environment: This system occupies level or nearly level ground on upland plains, flat ridgetops, and floodplain terraces. Soils are usually deep but with an impermeable or slowly permeable hardpan or fragipan which creates a shallow perched water table. It is seasonally wet in winter and spring, becoming very dry in summer and autumn. Sites are high, fairly level and generally not flooded, but seasonally saturated. There is some local variability in the expression of this system along a hydrologic/microtopographic gradient. The elevated ridges or pimple mounds are better drained and retain less moisture than do the lower areas, although both occur in a tight local mosaic. The soils appear to have well-developed subsurface hardpans, the impermeability of which contributes to shallowly perched water tables during portions of the year when precipitation is greatest and evapotranspiration is lowest. Soil moisture fluctuates widely throughout the growing season, from saturated to very dry, a condition sometimes referred to as xerohydric. Fire was an important natural process in this system, and well-burned examples tend to be relatively open-canopied with well-developed herbaceous layers (Nelson 2005).

Vegetation: These are hardwood- or pine-hardwood-dominated forests or woodlands. *Quercus phellos* is typically dominant or codominant except in the occurrences that are seasonally driest, where *Quercus stellata* is dominant. *Pinus echinata* may be dominant or codominant with *Quercus phellos* in sites of intermediate moisture. The medium tree canopy is somewhat open-grown with a somewhat open to mostly closed canopy (70-90% cover). The understory is poorly developed. Ground cover is variable with a low to medium diversity consisting of plants characteristic of dry soils on higher ground and wet soils in depressions.

Dynamics: Hydrology is the most important ecosystem process. Fire is of variable importance, i.e., it was very frequent and important in large sites ranging from very dry to moderately dry, but less frequent and less important on the wettest sites, where long-duration saturation leads to shallow rooting depths and consequent susceptibility to windthrow. Therefore, communities of wettest sites are more likely to be closed forest and uneven-aged whereas intermediate to very dry sites may be more likely to be woodland, perhaps even-aged. Drought and, in the past, gazing by bison and elk also influenced the woodland structure and composition (Nelson 2005).

Component Associations:
- *Quercus phellos - Quercus similis* Flatwoods Forest (CEGL007112, G3?)
- *Quercus stellata / Cinna arundinacea* Flatwoods Forest (CEGL002405, G2G3)

SPATIAL CHARACTERISTICS

Spatial Summary: Small to large patch in Arkansas; Nelson (2005) says it can be matrix in Missouri.

Adjacent Ecological Systems:
- Central Interior Highlands and Appalachian Sinkhole and Depression Pond (CES202.018)
- Ozark Prairie and Woodland (CES202.326)
- Ozark-Ouachita Shortleaf Pine-Oak Forest and Woodland (CES202.313)

Adjacent Ecological System Comments: Topographic relief and soil profile that affect seasonal moisture regime control transition to a different system. The system may grade into wet depressional ponds (CES202.018). As topography becomes more undulating to hilly and hardpan is lost, it may grade into Ozark-Ouachita Shortleaf Pine - Oak Forest and Woodland (CES202.313). It exists on

margins of prairies (CES202.326) where there is still a hardpan, but slightly more undulation than in typical prairie.

DISTRIBUTION

Range: This system is found in the Ozarks, Arkansas Valley, and Ouachitas of Arkansas, adjacent Missouri and possibly Oklahoma
Divisions: 202:C
Nations: US
Subnations: AR, MO, OK?

KLAMATH-SISKIYOU LOWER MONTANE SERPENTINE MIXED CONIFER WOODLAND (CES206.917)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Serpentine; Mediterranean [Mediterranean Pluviseasonal-Oceanic]; Ultramafic with low Ca:Mg ratio
Non-Diagnostic Classifiers: Montane [Lower Montane]; Xeric
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2021; ESLF 4208; ESP 1021

CONCEPT

Summary: This system occurs throughout the Klamath-Siskiyou region below 1500 m (4550 feet) elevation on thin, rocky, ultramafic (gabbro, peridotite, serpentinite) soils below winter snow accumulations and typically experiences hot and dry summers. Soils are not always rocky; they can be loamy, up to 76 cm (30 inches) in depth, and can be heavy clay. Not all ultramafic outcrops support distinct vegetation; only those with very low Ca:Mg ratios impact biotic composition. These woodlands are highly variable and spotty in distribution. These sites are more productive and can support large-statured (dbh, height) trees, although they tend to be widely spaced. Common species include *Pseudotsuga menziesii, Pinus sabiniana, Pinus lambertiana, Pinus jeffreyi, Pinus attenuata, Lithocarpus densiflorus var. echinoides, Calocedrus decurrens, Arctostaphylos* spp., *Quercus vacciniifolia,* and *Xerophyllum tenax*. Perennial grasses such as *Festuca idahoensis* may also be characteristic. *Chamaecyparis lawsoniana* communities can occur within occurrences of this system in mesic and linear riparian zones. Herbaceous-dominated serpentine fens (and bogs) are treated in Mediterranean California Serpentine Fen (CES206.953).
Classification Comments: It has been proposed to merge this system with the similar Klamath-Siskiyou Upper Montane Serpentine Mixed Conifer Woodland (CES206.914), as they are similar in composition and structure. For now, they are kept as separate systems pending further review and comment from California ecologists.
Similar Ecological Systems:
- Klamath-Siskiyou Xeromorphic Serpentine Savanna and Chaparral (CES206.150)

Related Concepts:
- Knobcone Pine: 248 (Eyre 1980) Intersecting
- Port Orford-Cedar: 231 (Eyre 1980) Intersecting

DESCRIPTION

Environment: This system occurs throughout the Klamath-Siskiyou region below 1500 m (4550 feet) elevation on thin, rocky, ultramafic (gabbro, peridotite, serpentinite) soils below winter snow accumulations and typically experiences hot and dry summers. Soils are not always rocky; they can be loamy, up to 76 cm (30 inches) in depth, and can be heavy clay. Not all ultramafic outcrops support distinct vegetation; only those with very low Ca:Mg ratios impact biotic composition. Soils on ultramafics are usually shallow and skeletal, with little profile development. Ultramafic soils impose the following stresses on plants: imbalance of calcium and magnesium, magnesium toxicity, low availability of molybdenum, toxic levels of heavy metals, sometime high alkalinity, low concentrations of some essential nutrients, and low soil water storage capacity (Kruckeberg 1984, Sanchez-Mata 2007). In some cases, the steepness of the slopes and general sparseness of the vegetation result in continual erosion.
Dynamics: Sites are productive and can support large-statured trees, although they will generally be widely spaced. Trees tend to grow very slowly due to the soil chemistry and textural characteristics which limit available nutrients.

Several important trees in this systems are fire-adapted, but the system as a whole is an edaphically-controlled type. Fire regimes vary depending on the slope position, elevation, fire history, and successional stage. *Chamaecyparis lawsoniana*-dominated stands have a low frequency of stand-replacing fires with an age class distribution showing >50% of stands are more than 300 years old (Jimerson et al. 1995). Other forest types in this system have more frequent stand-replacing fires. *Pseudotsuga menziesii* woodlands age class distribution shows >80% of stands were older than 175 years. *Pinus jeffreyi* occurs on drier sites and has more frequent fires, age classes are evenly distributed from young to old; while *Pinus lambertiana* has highest age class frequency of stands <175 years. *Pinus lambertiana* stands burn more frequently due to upper slope positions (Jimerson et al. 1995). Native dwarf mistletoe (*Arceuthobium* spp.) infest many trees within this system; generally they do not cause mortality but weaken trees sufficiently for bark or engraver beetles or wood borers to successfully attack and kill the tree.

Parker (1990) suggests that species growing on serpentine sites may suffer greater mortality and poorer recruitment after a fire than the same species on adjacent sandstone soils. Landfire (2007a): This type has a very limited distribution and consequently limited information for fire occurrence history. Adjacent mixed conifer forest types have similar characteristics and are detailed below. Surface and mixed-severity fires occur at an average of about 10-15 years (Taylor and Skinner 1998, 2003, Sensenig 2002). Kilgore and Taylor (1979) reported a FRI=19-39 years (N/NE aspects), which may favor mixed fires. Replacement fires with longer (70-110 years) return intervals are possible (Frost and Sweeney 2000). With historic fire regimes, insect outbreaks may have been much reduced compared to current conditions. Snow breakage occurs in the mid-seral closed state about every 5 years. While model is

aspatial, most medium- and high-severity fire may actually occur on mid and upper slope positions (Taylor and Skinner 1998, Taylor 2000, Bekker and Taylor 2001).

Component Associations:

KLAMATH-SISKIYOU UPPER MONTANE SERPENTINE MIXED CONIFER WOODLAND (CES206.914)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Forest and Woodland (Treed); Mediterranean [Mediterranean Pluviseasonal-Oceanic]; Ultramafic with low Ca:Mg ratio; Very Shallow Soil; Ustic
Non-Diagnostic Classifiers: Serpentine; Needle-Leaved Tree; Broad-Leaved Evergreen Tree; Broad-Leaved Evergreen Shrub
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2022; ESLF 4209; ESP 1022

CONCEPT

Summary: This system occurs throughout the Klamath - Siskiyou region above 1500 m (4550 feet) elevation on thin, rocky, ultramafic (gabbro, peridotite, serpentinite) soils in dry-mesic conditions. Not all ultramafic outcrops support distinct vegetation; only those with very low Ca:Mg ratios impact biotic composition. Although ultramafics may be relatively dry and have a moderate to high grass component, they do not burn often where the serpentine syndrome [see Kruckeberg (1984)] is severe. The problem is not just the calcium:magnesium ratio, but heavy metals and sometimes high clay content limit biomass production. These systems are highly variable and spotty in distribution. Common species include *Pinus monticola, Pinus balfouriana, Quercus vacciniifolia, Pinus jeffreyi, Ceanothus pumilus, Arctostaphylos* spp., *Lithocarpus densiflorus var. echinoides, Abies X shastensis (= Abies magnifica var. shastensis*), and *Chamaecyparis nootkatensis*. Stands of stunted (up to 12 m [40 feet]) but straight *Pinus contorta* are also possible. *Chamaecyparis lawsoniana* communities can occur in this system in mesic and linear riparian zones. Herbaceous-dominated serpentine fens (and bogs) are treated in Mediterranean California Serpentine Fen (CES206.953).
Classification Comments: It has been proposed to merge this system with the similar Klamath-Siskiyou Lower Montane Serpentine Mixed Conifer Woodland (CES206.917), as they are similar in composition and structure. For now, they are kept as separate systems pending further review and comment from California ecologists.

LAURENTIAN-ACADIAN NORTHERN HARDWOOD FOREST (CES201.564)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Forest and Woodland (Treed); Eutrophic Soil; Mesotrophic Soil; Broad-Leaved Tree; Acer saccharum - Betula spp.
Non-Diagnostic Classifiers: Lowland; Ridge/Summit/Upper Slope; Sideslope; Glaciated; Circumneutral Soil; Acidic Soil; Shallow Soil; Deep Soil; Mineral: W/ A-Horizon >10 cm; Loam Soil Texture; Udic; Long Disturbance Interval; W-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2302; ESLF 4108; ESP 1302

CONCEPT

Summary: These northern hardwood forests range across New England and adjacent Canada, south to northern Pennsylvania and west to Minnesota. They occur in various dry-mesic to wet-mesic settings at low to moderate elevations (generally <610 m [2000 feet]) throughout the Laurentian-Acadian Division. *Acer saccharum, Betula alleghaniensis*, and *Fagus grandifolia* are the dominant trees (the latter only east of northern Wisconsin). *Tsuga canadensis* or, in the Northeast, *Picea rubens* are common minor canopy associates. *Ostrya virginiana* is frequent but not dominant. Oak is a minor component and absent from northern regions. Successional stands may be dominated by *Populus tremuloides, Betula papyrifera, Acer rubrum, Fraxinus americana, Prunus serotina,* sometimes with scattered *Pinus strobus*. Soils range from moderately nutrient-poor to quite enriched, with associated shifts in the herb flora. This system can include large expanses of rich forest in areas of limestone or similar bedrock, as well as forests that are relatively poor floristically in areas of granitic (or similar) bedrock or acidic till. Blowdowns or snow and ice loading, with subsequent gap regeneration, are the most frequent form of natural disturbance.
Classification Comments: An east-west separation between the Laurentian and Acadian regions was considered, but the hardwoods component is essentially similar (though beech drops out in the most western part of this system). It appears to be more of a gradient, with beech and hobblebush dropping out and fire frequency probably a little greater in the western portion. A possible split at Lake Michigan could be considered if one could make a better case than just beech. Hemlock-hardwood inclusions in the East may be part of this system where the matrix and surroundings are predominantly hardwood, but where hemlock and pine are prevalent, as in ravines or cool slopes, Laurentian-Acadian Pine-Hemlock-Hardwood Forest (CES201.563) is the appropriate system.
Similar Ecological Systems:
- Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565)--is primarily coniferous though portions may have hardwoods present or codominant; *Picea rubens* is characteristic in the Acadian region and *Picea mariana* associations are also attributed.
- Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593)--occurs southward of this type; the two overlap in parts of Pennsylvania, New York and the Connecticut Valley.
- Laurentian-Acadian Pine-Hemlock-Hardwood Forest (CES201.563)--is primarily coniferous and often on lower slopes or ravines.
- North-Central Interior Beech-Maple Forest (CES202.693)

LAURENTIAN-ACADIAN NORTHERN PINE-(OAK) FOREST (CES201.719)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Laurentian-Acadian (201)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2362; ESLF 4265; ESP 1362

CONCEPT

Summary: This is a pine-dominated, or occasionally pine-oak, forest system that is typically found on nutrient-poor soils, or on moderately rich soils in the upper Midwest, northeastern U.S., and adjacent Canada, in a variety of topographic settings. Soils are loamy to sandy, varying from thin soil over bedrock to deeper soils, sometimes sandy. Sites are xeric to subxeric, but less strongly than barrens and sandplains. The dominant fire regime varies from 100-200 years for *Pinus strobus* and *Pinus resinosa*. Other boreal conifers, or in the East *Picea rubens*, may occasionally be present. Canopy structure is mostly closed but can be partially open. Conifers typically dominate the canopy, but codominates may include hardwoods, especially *Quercus rubra* or *Acer rubrum*, but also *Populus tremuloides* or *Betula papyrifera*. The shrub and field layers can be somewhat dense to sparse.
Classification Comments: This system is dominated by white pine and red pine forests, which are found primarily in the Great Lakes and sub-boreal region, but extend eastward to Acadia. Where *Pinus strobus* is a codominant with *Tsuga canadensis*, stands most typically are placed within Laurentian-Acadian Pine-Hemlock-Hardwood Forest (CES201.563).
Similar Ecological Systems:
- Central Appalachian Dry Oak-Pine Forest (CES202.591)
- Laurentian Pine-Oak Barrens (CES201.718)
- Laurentian-Acadian Pine-Hemlock-Hardwood Forest (CES201.563)--is more mesic; red pine and jack pine are good differential species for CES201.719 versus CES201.563.

LAURENTIAN-ACADIAN PINE-HEMLOCK-HARDWOOD FOREST (CES201.563)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Pinus spp. - Tsuga canadensis
Non-Diagnostic Classifiers: Sideslope; Glaciated; Mesotrophic Soil; Acidic Soil; Shallow Soil; Deep Soil; Mineral: W/ A-Horizon >10 cm; Loam Soil Texture; Sand Soil Texture; Udic; Very Long Disturbance Interval; F-Landscape/Medium Intensity; W-Patch/Medium Intensity; Needle-Leaved Tree; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2366; ESLF 4308; ESP 1366

CONCEPT

Summary: This north-temperate forest system ranges from the northeastern U.S. and adjacent Canada west to the Great Lakes and upper Midwest. The mesic to dry-mesic forests usually occur on low-nutrient soils at low elevations, mostly less than 610 m (2000 feet). Canopy dominants include *Pinus strobus, Tsuga canadensis*, and *Quercus rubra* in varying percentages. *Acer rubrum* is also quite common; *Betula lenta* may be common at the southern periphery of this system's range. *Quercus velutina* and *Quercus alba* are essentially absent from this system, being more representative of systems in the Central Interior-Appalachian Division to the south. This is a widespread, matrix forest type for the more temperate portions of this division. Gap replacement and infrequent fire are the major natural regeneration modes.
Classification Comments: *Tsuga canadensis* is useful to separate this system from Laurentian-Acadian Northern Pine-(Oak) Forest (CES201.719), but does not always occur in this system. Hemlock draws in USFS Section 222L (Baraboo) could be considered as remnants of this system rather than an inclusion in the hardwood matrix, as they are very distinctive from the surrounding forest and have the northern representative flora. In the East, northern hardwoods other than beech, e.g., sugar maple, are rarely found in this system. This system and Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593) grade into one another in southern New York and northern Pennsylvania; the presence of *Liriodendron tulipifera* is diagnostic for the Division 202 Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593).
Similar Ecological Systems:
- Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593)--is the counterpart to this system as one moves southward; also can have more northern hardwood species than usually seen in this system.
- Laurentian-Acadian Northern Hardwood Forest (CES201.564)
- Laurentian-Acadian Northern Pine-(Oak) Forest (CES201.719)--occurs in slightly to considerably drier settings and rarely has hemlock. Fire return interval is shorter too. May have red pine.

LAURENTIAN-ACADIAN SUB-BOREAL ASPEN-BIRCH FOREST (CES103.020)

CLASSIFIERS

Classification Status: Standard

Primary Division: Boreal (103)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Boreal [Boreal Continental]; Intermediate Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2301; ESLF 4107; ESP 1301

CONCEPT

Summary: These early-successional boreal hardwood forests and woodlands are widespread throughout the eastern hemi-boreal region of Canada, extending into parts of the Laurentian-Acadian region, but more localized eastward. They originate naturally after fires and blowdowns, but more commonly originate after logging of conifer or mixed conifer-hardwood systems. *Populus tremuloides* and *Betula papyrifera* are the most important tree species. This system is maintained by repeated disturbance within 50-year return intervals and would otherwise succeed to conifer systems. Localized stands of mixed conifer-hardwoods (pines and spruces) can occur in this type, but are more typically part of conifer systems.
Classification Comments: As defined here, these are deciduous forest-dominated systems; mixed conifer-hardwoods areas will go in the appropriate conifer forest system. In addition, this system is primarily eastern hemi-boreal, because some northern hardwood species do occur; in the Laurentian-Acadian region, successional aspen-birch or red maple stands would be placed within the appropriate mature Laurentian-Acadian forest system (e.g., aspen-birch stands in Maine are placed within Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565). The perspective here is that *Picea rubens* (red spruce) is not a boreal species; stands of *Picea rubens* often contain many typical northern hardwood associates, rather than *Populus tremuloides* or *Betula papyrifera*. It is not clear how naturally this system occurs in the upper Midwest given catastrophic fires in the 1800s-early 1900s; is the extensive aspen-birch found in northern Minnesota this system or should those be considered part of northern hardwoods or spruce-fir? A workable approach for now would be to restrict this system to northernmost Minnesota and southern Lake Superior [see USFS Ecomap Regions].

The original "Boreal Aspen-Birch Forest" system was not well defined in Canada. As described it only covered the hemi-boreal region of eastern Canada. It has been renamed to reflect that concept. This system is closely related to Eastern Hemi-Boreal Mesic Balsam Fir-Spruce Forest (CES103.426), and within the IVC these are part of Eastern Hemi-Boreal Mesic Balsam Fir - Spruce - Hardwood Forest Group (G048). It may be that a series of aspen-birch systems separate from the spruce-fir systems, are needed for Eastern Boreal, Central Hemi-Boreal, Central Boreal, Western Boreal and Western Hemi-Boreal regions of the North American Boreal Forest. Or, conversely, this system (CES103.020) could be lumped within Eastern Hemi-Boreal Mesic Balsam Fir-Spruce Forest (CES103.426), and the distinction treated here and elsewhere at the alliance level, below system.
Similar Ecological Systems:
- Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565)--occurs farther east and does not overlap.

LAURENTIAN-ACADIAN SUB-BOREAL DRY-MESIC PINE-BLACK SPRUCE-HARDWOOD FOREST (CES103.425)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Land Cover Class: Forest and Woodland
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
National Mapping Codes: ESLF 4336

CONCEPT

Summary: This hemi-boreal forest ecological system is found on dry-mesic nutrient-poor soils in a variety of topographic settings. It ranges from northwestern Ontario to eastern Canada, and southward into Minnesota, the Great Lakes region, and very locally into northwestern Maine. Soils are loamy to sandy, varying from nutrient-poor, thin soils over bedrock to deeper soils, sometimes sandy. Sites are typically dry-mesic. The dominant fire regime varies from 50-100 years. *Pinus banksiana, Pinus resinosa,* and *Picea mariana* are characteristic overstory species, with *Pinus strobus* occasionally common, over much of the range, but east of the Great Lakes, *Picea mariana* becomes increasingly dominant with *Abies balsamea* as an important associate. Canopy structure is mostly closed but can be partially open. Conifers typically dominate the canopy, but boreal hardwoods (*Populus tremuloides, Betula papyrifera*) may codominate. As time since fire increases, *Picea mariana* may dominate. Tree regeneration includes *Abies balsamea, Betula papyrifera, Populus tremuloides*, and *Picea mariana*. The shrub and field layers can be very open to somewhat dense (5-75% cover). Characteristic low-shrub and herb species include *Amelanchier* spp., *Vaccinium angustifolium, Diervilla lonicera, Cornus canadensis, Linnaea borealis, Doellingeria umbellata (= Aster umbellatus)*, and *Eurybia macrophylla*. Older *Picea mariana* stands may be strongly dominated by feathermosses.
Classification Comments: In Quebec (C. Morneau pers. comm. 2009), *Picea mariana* is far more common than *Pinus banksiana* in the boreal forest. Secondly, forests composed of a mixture of *Picea mariana* and *Abies balsamea* with a feathermoss carpet on the ground are very common east of 74 degrees W longitude and north of 48 degrees N latitude where climate undergoes a maritime influence and where *Pinus banksiana* gradually becomes absent. *Picea mariana - Picea rubens / Rhododendron canadense / Cladina* spp. Woodland (CEGL006421), in the present system, represents spruce-lichen woodlands at the boreal-temperate forest interface.

At this time, this system excludes xeric *Pinus banksiana* and *Picea mariana* stands, which are placed in their own system, Eastern Hemi-Boreal Dry Jack Pine - Red Pine - Hardwood Woodland (CES103.424), found on dry, poor sites, where there is a low density of *Pinus banksiana* trees resulting in a woodland condition. Lichens are dominant. Woodland physiognomy and lichen dominance distinguish that system from this system, which has more of a closed canopy and feathermosses and herbs are more abundant. See also Minnesota DNR (2003), which separates Northern Dry-Sand Pine Woodland (FDn12) and Northern Dry-Bedrock Pine-(Oak) Woodland (FDn22), and belong with CES103.424, from the dry-mesic *Pinus banksiana* and *Picea mariana* Forests and Woodlands (FDn32 and FDn33), which belong with this system.

Placement of *Populus tremuloides - (Populus grandidentata)* Rocky Woodland (CEGL002487) in this system needs review.
Similar Ecological Systems:
- Eastern Boreal Black Spruce-Jack Pine Forest (CES103.422)
- Eastern Boreal Jack Pine-Black Spruce Dry Woodland (CES103.423)
- Northern Dry Jack Pine-Red Pine-Hardwood Woodland (CES103.424)

Related Concepts:
- Black Spruce: 12 (Eyre 1980) Intersecting
- Jack Pine - Black Spruce (Heinselman 1973) Finer
- Jack Pine - Fir, Black Spruce - Feathermoss (Heinselman 1973) Finer
- Jack Pine: 1 (Eyre 1980) Intersecting

DESCRIPTION

Environment: Soils are loamy to sandy, varying from nutrient-poor, thin soil over bedrock to deeper soils, sometimes sandy. Sites are typically on dry-mesic to dry sites, but not commonly found on xeric sandplains or bedrock sites.
Vegetation: *Pinus banksiana* and *Picea mariana* are characteristic overstory species. In the Upper Great Lakes region, *Pinus banksiana* may intermix with *Pinus resinosa*. Canopy structure is mostly closed but can be partially open. Conifers typically dominate the canopy, but boreal hardwoods (*Populus tremuloides, Betula papyrifera*) may codominate. As time since fire increases, *Picea mariana* may dominate. Tree regeneration includes *Abies balsamea, Betula papyrifera, Populus tremuloides,* and *Picea mariana*. Characteristic low-shrub and herb species include *Amelanchier* spp., *Vaccinium angustifolium, Diervilla lonicera, Cornus canadensis, Linnaea borealis, Doellingeria umbellata (= Aster umbellatus)*, and *Eurybia macrophylla*. Older *Picea mariana* stands may be strongly dominated by feathermosses (Minnesota DNR 2003).

DISTRIBUTION

Range: This system ranges from northwestern Ontario to eastern Canada, and southward into Minnesota, the Great Lakes region, and very locally into northwestern Maine.

LAURENTIAN-ACADIAN SUB-BOREAL MESIC BALSAM FIR-SPRUCE FOREST (CES103.426)

CLASSIFIERS

Conf.: 1 - Strong
Classification Status: Standard
Land Cover Class: Forest and Woodland
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
National Mapping Codes: ESLF 4337

CONCEPT

Summary: This ecological system represents the mesic southern or hemi-boreal eastern boreal forest, ranging from northwestern Ontario to eastern Canada's Atlantic provinces and extending into the U.S. in northeastern Minnesota, Isle Royale, and near-coastal areas of Lake Superior shores in northern Wisconsin and Michigan. The low-elevation forests are dominated by *Picea glauca* and *Abies balsamea*. *Picea mariana* is often present, along with occasional *Pinus banksiana*. Codominant boreal hardwoods include *Populus tremuloides* and *Betula papyrifera*. Northern hardwoods, such as *Acer saccharum* and *Tilia americana* are relatively minor. The shrub and herb layers are variable, decreasing as the percent conifer cover increases. Common shrub species include *Acer spicatum, Alnus viridis, Corylus cornuta, Diervilla lonicera*, and *Lonicera canadensis*. The moss layer ranges from discontinuous to continuous. These upland forests typically occur on loamy soils over bedrock in scoured bedrock uplands and loamy, rocky, or sandy soils on glacial moraines, till plains and outwash plains, and moisture conditions range from well-drained to somewhat poorly drained. Wetter sites may contain *Alnus incana ssp. rugosa, Calamagrostis canadensis*, and *Equisetum* spp. This is the matrix forest type in many parts of its range. This group may include earlier-successional patches, in which *Populus* spp. and *Betula* spp. are dominant or mixed with *Picea* and *Abies*, that will develop into spruce-fir forests. Blowdown with subsequent gap regeneration is the most frequent form of natural disturbance, with large-scale fires important at longer return intervals. Insect infestations, in particular by *Choristoneura fumiferana* (spruce budworm), also can impact this group.
Classification Comments: The transition zone from the Boreal (including hemi-boreal) Forest formation (where *Abies balsamea* is the dominant tree species) to the Cool Temperate Forest (where *Acer saccharum* is the dominant tree species) is difficult to untangle, but depends on the increasing abundance of northern hardwood tree species and more cool-temperate shrubs and herbs. Where these species occur with the boreal conifers, they are placed in 1.B.2 Cool Temperate Forest Formation (F008). Forest associations typical of this transition zone are mixedwood associations dominated by *Betula alleghaniensis* or *Acer rubrum* and *Abies balsamea* or *Acer rubrum* and *Abies balsamea*. These associations are currently placed in Cool Temperate Forest under Sub-Boreal Mesic Fir - Yellow Birch - Hardwoods Forest (CES103.434). In Quebec (C. Morneau pers. comm. 2009), the most northerly cool temperate transition zone extends between 47 degrees N latitude and 49 degrees N latitude, including Bas-St. Laurent and Gaspesie regions.

A separate aspen-birch system is recognized in the eastern hemi-boreal region, Eastern Hemi-Boreal Aspen-Birch Forest (CES103.020), though these are lumped together at the group level (G048).

Similar Ecological Systems:
- Atlantic Boreal Balsam Fir Wet Forest (CES103.433)
- Eastern Boreal Balsam Fir-White Spruce-Paper Birch Forest (CES103.421)--represents the core mesic spruce-fir forests of the eastern boreal region, with temperate and transitional species, such as *Acer spicatum* and *Betula alleghaniensis*, absent.

Related Concepts:
- Balsam Fir: 5 (Eyre 1980) Finer
- Boreal Forest (Kost et al. 2007) Broader
- Boreal Forest (Curtis 1959) Broader. The bulk of Curtis's concept fits well with this type, but he also included stands further inland in Wisconsin, that appear to contain a large abundance of northern hardwoods, and those stands probably fit better with Sub-Boreal Mesic Fir - Yellow Birch - Hardwoods Forest (CES103.434).
- Boreal Forest (Wisconsin DNR 2009a) Broader
- Fir-Birch (Heinselman 1996) Finer
- White Spruce: 201 (Eyre 1980) Finer

DESCRIPTION

Environment: These upland forests typically occur on loamy soils over bedrock in scoured bedrock uplands and loamy, rocky, or sandy soils on glacial moraines, till plains and outwash plains (Minnesota DNR 2003). Moisture conditions range from well-drained to somewhat poorly drained. Climate typically is characterized by cool, even temperatures, shorter growing season, and deep and sometimes severe winter snowfall. In the southern part of their range in the Great Lakes states, they occur along northern Great Lakes shorelines and on islands in Lake Superior. Cold temperate to boreal. Soils are typically neutral to acidic, shallow sandy, sandy-loam, or loamy-sand. Some examples occur on heavier, mesic silty or clay loams that are more alkaline in nature. Along Great Lakes shorelines, these soils overlay limestone or volcanic bedrock.
Vegetation: *Picea glauca* typically dominates on drier sites or is codominant with *Abies balsamea* on more mesic sites. In some mesic to wet-mesic examples, *Abies balsamea* dominates. This group includes several successional stages, including earlier-successional patches in which *Populus* spp. and *Betula* spp. are dominant. Mid-successional stands often contain stands mixed with *Picea* and *Abies*, that will develop into spruce-fir forests. The shrub and herb layers are variable, decreasing as the percent conifer cover increases. Common shrub species include *Acer spicatum, Corylus cornuta, Diervilla lonicera*, and *Lonicera canadensis*. The composition and density of the herbaceous layer can vary among associations and location. Typically, *Aralia nudicaulis, Eurybia*

macrophylla, *Clintonia borealis*, and *Maianthemum canadense* are common understory species. The moss layer ranges from discontinuous to continuous. Wetter sites may contain *Alnus incana ssp. rugosa*, *Calamagrostis canadensis*, and *Equisetum* spp. Additional diagnostic shrub and herb species of this hemi-boreal type will be added through further analyses.
Dynamics: These forests are affected by windthrow, insect defoliation, and infrequent fires. Forests closer to the Great Lakes shorelines occur on shallower soils and are more likely to experience more serious windthrow and snap-off of larger trees. Mammalian herbivory also can impact forest stands. Selective herbivory by white-tailed deer and moose (*Alces americanus*) can alter the composition and structure and favor browse-tolerant species such as *Picea glauca*. These forests typically regenerate from gap-phase dynamics.

DISTRIBUTION

Range: This system ranges in Canada from northwestern Ontario (possibly eastern Manitoba) to eastern Canada's Atlantic provinces and extending into the U.S. in northeastern Minnesota, Isle Royale, and near-coastal areas of Lake Superior shores in northern Wisconsin and Michigan. Its range westward is marked by a shift towards greater *Picea glauca* dominance and lower *Abies balsamea* dominance.

LLANO UPLIFT ACIDIC FOREST, WOODLAND AND GLADE (CES303.657)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Isolated Wetland [Strictly Isolated]
Non-Diagnostic Classifiers: Inselberg; Forest and Woodland (Treed); Woody-Herbaceous; Herbaceous; Moss/Lichen (Nonvascular); Ridge/Summit/Upper Slope; Rock Outcrops/Barrens/Glades; Granitic Rock; Metamorphic Rock; Igneous Rock; Temperate [Temperate Continental]; Depressional; Unglaciated; Bald; Acidic Soil; Sand Soil Texture
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2410; ESLF 7159; ESP 1410

CONCEPT

Summary: This upland matrix system occurs primarily on coarse soils derived from the weathering of underlying Precambrian granites in the Llano Uplift region of Texas. The underlying intrusive granitic bedrock substrate determines the range of this system. It is composed of a mosaic of vegetation types, including closed-canopy forests, open woodlands, savannas and sparsely vegetated rock outcrops. Common trees include *Quercus marilandica, Quercus fusiformis, Quercus stellata, Carya texana, Ulmus crassifolia*, and *Prosopis glandulosa*. Subcanopy species may include *Diospyros texana, Aloysia gratissima, Ungnadia speciosa, Ziziphus obtusifolia var. obtusifolia, Eysenhardtia texana, Aesculus glabra var. arguta, Opuntia engelmannii var. lindheimeri (= Opuntia lindheimeri), Yucca elata, Nolina texana*, and *Opuntia leptocaulis*. Grasslands may be dominated by *Schizachyrium scoparium, Sorghastrum nutans, Panicum virgatum, Bouteloua hirsuta, Bouteloua curtipendula, Nassella leucotricha, Bothriochloa laguroides*, and *Plantago wrightiana*. Granitic glades and barrens are sparsely vegetated by crustose and foliose lichens, several ferns and fern allies, and cacti. This system also includes small (up to 16 m in diameter) shallow depressions that hold rainwater and support wetland flora including the Texas endemic, *Isoetes lithophila*.
Classification Comments: This ecological system is defined to include a diversity of vegetation occurring on granitic outcrops and on soils that have developed over these outcrops in central Texas. In comparison to other areas of the U.S. where sparsely vegetated glades and barrens may be defined separately from the woodland surrounding them and/or the woodland separately from the forest (e.g., Southern Piedmont Granite Flatrock and Outcrop (CES202.329) just includes the sparsely vegetated barrens), these different vegetation types are included together here because they occur as an ecological complex or mosaic and they share floristic and geologic affinities that set them apart from the surrounding landscape. In the central mineral region of central Texas, granite glades and barrens are surrounded by areas of deeper soils derived from granite that support denser herbaceous or woody vegetation that includes many species found sparsely on the glades. In the eastern U.S. xeric granite outcrops are generally separated from one another by large areas of mesic to dry-mesic forests, whereas the granitic outcrops in central Texas are separated from one another by areas of coarse soils derived from the underlying granite. In addition, the xeric nature of the granite outcrops in the eastern U.S. is a stark contrast to the other vegetation in this humid temperate environment. Whereas, west of the dry line, the moisture availability of the granite outcrops in central Texas is not as starkly contrasted with the surrounding landscape. This has been suggested as a reason why the granite glades of central Texas do not support the degree of endemism that is found on the granite outcrops of the eastern U.S. (Walters and Wyatt 1982). The relationship of this ecological system to the granite glades and woodlands occurring in Oklahoma (currently included in Crosstimbers Oak Forest and Woodland (CES205.682)) needs to be further explored.

Currently this system includes dry woodlands on shallow soil and mesic woodlands on deeper soil. The more mesic woodlands tend to support *Carya texana* which is generally absent in other areas on the plateau. Further investigation is needed to determine if the mesic and dry components should be classified as two separate systems.

Similar Ecological Systems:

DESCRIPTION

Environment: This system is restricted to the Llano Uplift, also known as the central mineral region of Texas. Though named as an uplift because it is an intrusion of Precambrian metamorphic rocks and large granitic massifs, this area is generally lower in elevation than the surrounding Edwards Plateau (Walters and Wyatt 1982, Riskind and Diamond 1988). At a regional scale, it is a topographic bowl, though rock outcrops such as Enchanted Rock often produce dramatic increases in elevation at a local scale. Aside from these

massif intrusions, topography is generally level to rolling. The substrate of granites, gneisses and schists determines the range of this system in central Texas. Elevation ranges from 251 to 686 m above sea level (825-2250 feet). Rainfall averages about 76 cm (30 inches), peaking in May or June and September. The central mineral region occupies approximately 1.5 million hectares in central Texas (Riskind and Diamond 1988). Mineralogy of the granitic material varies, with hornblende schist, graphite schist, quartz-feldspar gneiss and quartz-plagioclase-microcline rock common (Riskind and Diamond 1988). Soils are generally sandy loams, with gravelly soils common. They are generally acidic and coarse, resulting from weathering of the underlying granite. Many areas of exposed bedrock are present. Most frequently encountered Ecological Sites include Shallow Granite, Sandy Loam, Red Savannah, Gravelly Sandy Loam, Shallow Ridge, Granite Gravel, Sandstone Hill, and Granite Hill (Elliott 2011).

Vegetation: This system is typified by a mosaic of vegetation types, including mixed oak forests and savannas over coarse soils and sparsely vegetated areas on rock outcrops. Species such as *Quercus marilandica, Quercus fusiformis, Quercus stellata, Carya texana, Ulmus crassifolia,* and *Prosopis glandulosa* may dominate the canopy of this system. Some areas are characterized by dense forest patches (mottes) of *Quercus fusiformis*, with various mixtures of other oaks and shrubs surrounded by open grasslands. Subcanopy species may include *Diospyros texana, Aloysia gratissima, Ungnadia speciosa, Ziziphus obtusifolia var. obtusifolia, Eysenhardtia texana, Aesculus glabra var. arguta, Opuntia engelmannii var. lindheimeri (= Opuntia lindheimeri), Yucca elata, Nolina texana,* and *Opuntia leptocaulis*. The ground flora may contain *Schizachyrium scoparium, Sorghastrum nutans, Panicum virgatum, Bouteloua hirsuta, Bouteloua curtipendula, Nassella leucotricha, Eragrostis intermedia, Croton monanthogynus,* and *Plantago wrightiana*. In addition to oak woodlands and grasslands, this system also includes granitic glades and barrens. These are sparsely vegetated areas characterized by crustose and foliose lichens, several ferns and fern allies, and cacti, including *Cheilanthes lindheimeri, Pellaea ternifolia, Selaginella arenicola ssp. riddellii, Selaginella peruviana, Selaginella wrightii, Echinocereus reichenbachii,* and *Echinocereus triglochidiatus (= Echinocereus coccineus)*. Other species that may occur in cracks and crevices or slight depressions with shallow, gravelly soil include *Eriogonum tenellum, Lechea san-sabeana, Sedum nuttallianum, Tripogon spicatus, Plantago wrightiana, Talinum parviflorum, Helenium amarum, Campanula reverchonii, Aphanostephus skirrhobasis,* and *Hypericum gentianoides*. Small-scale shallow vernal pools formed within barrens by weathering of the granitic surface support *Crassula aquatica, Sedum nuttallianum, Talinum parviflorum, Eleocharis montevidensis, Elatine brachysperma, Juncus diffusissimus, Allium canadense, Nothoscordum bivalve, Cooperia drummondii, Lepuropetalon spathulatum, Isoetes melanopoda,* and the Texas endemic *Isoetes lithophila*. Larger pools often exhibit a pattern of zonation of the vegetation as soil accumulates in the center. Crevices in the rock outcrops tend to support scattered, stunted individuals of trees and shrubs found in the adjacent woodland. Endemics or near-endemics occurring within this ecological system include *Isoetes lithophila, Campanula reverchonii, Eriogonum tenellum var. ramosissimum, Elatine brachysperma, Valerianella texana, Packera texensis, Tradescantia pedicellata, Brazoria enquistii, Indigofera miniata (= var. texana),* and *Tripogon spicatus*.

Dynamics: This ecological system is a complex of vegetation types. The different physiognomies are maintained by an interaction between site conditions and disturbance dynamics. The forest patches, woodlands, savannas and grasslands are thought to have been maintained historically by various fire frequencies and intensities. In the absence of natural or prescribed fire, increased cover of woody vegetation has increased in some occurrences. Native grazing may have also played a role in preventing woody encroachment though the rough terrain of much of this system would have limited the extent of native grazers.

Component Associations:
- *Hilaria belangeri - Bouteloua curtipendula* Herbaceous Vegetation (CEGL002238, G3?)
- *Quercus fusiformis - (Quercus stellata) / Schizachyrium scoparium* Granite Woodland (CEGL004937, G2?)
- *Quercus fusiformis / Schizachyrium scoparium* Woodland (CEGL002115, G2G4)
- *Sedum nuttallianum - Selaginella peruviana* Granitic Outcrop Sparse Vegetation (CEGL004396, G2)

Spatial Characteristics

Spatial Summary: This system is the matrix system of the Llano Uplift area (EPA ecoregion 30b) of central Texas.

Size: As a complex, this system covered large areas (>2000 ha), but occurrences of individual physiognomies (forests, woodlands, grasslands, barrens) may occur as large (50-2000 ha) or small (1-50 ha) patches.

Adjacent Ecological Systems:
- Edwards Plateau Floodplain Terrace (CES303.651)
- Edwards Plateau Limestone Savanna and Woodland (CES303.660)
- Edwards Plateau Limestone Shrubland (CES303.041)
- Edwards Plateau Mesic Canyon (CES303.038)
- Edwards Plateau Riparian (CES303.652)

Adjacent Ecological System Comments: This system is found adjacent to Edwards Plateau Limestone Savanna and Woodland (CES303.660), Edwards Plateau Limestone Shrubland (CES303.041), and is dissected by Edwards Plateau Mesic Canyon (CES303.038), Edwards Plateau Riparian (CES303.652), and Edwards Plateau Floodplain (CES303.651). A common component of Edwards Plateau Limestone Savanna and Woodland (CES303.660), *Quercus buckleyi*, is conspicuously absent from Llano Uplift Acidic Forest, Woodland and Glade (CES303.657).

Distribution

Range: This system is restricted to the Llano Uplift region of Texas.

Divisions: 303:C

Nations: US

Subnations: TX

LOWER MISSISSIPPI RIVER DUNE POND (CES203.189)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Dune (Substrate); Sand Soil Texture
National Mapping Codes: ESLF 4151

CONCEPT

Summary: This system represents distinctive wetlands that are called "sand ponds" in Arkansas. They occur in isolated depressions in the context of sand dunes and related eolian features of the lower Mississippi River Alluvial Valley in Missouri and Arkansas. These depressions have silty bottoms and may be connected to the local aquifer or have a perched water table. The margins of these ponds are rimmed by *Quercus phellos* and also have *Quercus lyrata*. These Pleistocene dunes were overlooked or unrecognized until the late 1970s (Saucier 1978). These dunes are west of Crowley's Ridge and near the Black and White rivers, above the normal flood level of the Mississippi. Examples in Missouri occur amidst a series of low-lying, anastomosing channels that have helped to protect them from extensive alteration more typical in Arkansas where the uplands have been largely cleared.
Classification Comments: These depressions in the dune fields are one of the principal habitats for the rare shrub *Lindera melissifolia* (Heineke 1987). The dunes consist of a layer of sand or sandy loam over an impervious sublayer. This large area of eolian sand dunes occurs "mainly in a long band to the west of Crowley's Ridge" and occupies approximately 1000 square kilometers (400 square miles) in discrete fields of up to 78 square kilometers (30 square miles) each (Heineke 1987).

Quercus lyrata - Quercus palustris / Acer rubrum var. drummondii / Itea virginica - Cornus foemina - (Lindera melissifolia) Forest (CEGL004778), a wetland type, occurs in isolated depressions in the dunes that may be connected to the local aquifer or have a perched water table (T. Foti pers. comm.).
Related Concepts:

LOWER MISSISSIPPI RIVER DUNE WOODLAND AND FOREST (CES203.531)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Dune (Substrate); Sand Soil Texture
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2381; ESLF 4324; ESP 1381

CONCEPT

Summary: This system represents the vegetation of sand dunes and related eolian features of the lower Mississippi River Alluvial Valley in Missouri and Arkansas. These Pleistocene dunes were overlooked or unrecognized until the late 1970s (Saucier 1978). This fact coupled with long periods of weathering and human disturbance, as well as proximity to a terrace mapped as "prairie" in General Land Office records, has led to considerable confusion regarding this type (T. Foti pers. comm.). These dunes are west of Crowley's Ridge and near the Black and White rivers, above the normal flood level of the Mississippi. Examples in Missouri occur amidst a series of low-lying, anastomosing channels that have helped to protect them from extensive alteration more typical in Arkansas where the uplands have been largely cleared. The uppermost portions of the dunes support a xeric community similar to sandhills of the West Gulf Coastal Plain (WGCP), but are outside the natural range of *Quercus incana*, a diagnostic species typical of the WGCP examples. Instead the dunes support very open *Quercus stellata* woodlands with *Schizachyrium scoparium* and abundant lichen cover (presumably *Cladonia* spp.), along with *Opuntia* sp. Less edaphically extreme slopes support more closed-canopied forests in which *Quercus stellata* is still important, along with *Quercus falcata* and possibly other species. In many instances, distinctive wetlands imbedded within this system are also present (Lower Mississippi River Dune Pond (CES203.189)). Called "sand ponds" in Arkansas, these depressions have silty bottoms and perched water tables. The margins of these ponds are rimmed by *Quercus phellos* and have *Quercus lyrata* (Heineke 1987).
Classification Comments: Heineke (1987) states that this large area of eolian sand dunes occurs "mainly in a long band to the west of Crowley's Ridge," and occupies approximately 1000 square kilometers (400 square miles) in discrete fields of up to 78 square kilometers (30 square miles) each. The dunes consist of a layer of sand or sandy loam over an impervious sublayer (Heineke 1987). Depressions in the dune fields (e.g., Lower Mississippi River Dune Pond (CES203.189)) are one of the principal habitats for the rare shrub *Lindera melissifolia*.

MADREAN ENCINAL (CES305.795)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Sierra Madre (305)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Tropical/Subtropical [Tropical Xeric]; Xeric; F-Patch/Medium Intensity; Broad-Leaved Evergreen Tree; Graminoid; Quercus arizonica, Q. emoryi, Q. grisea, Q. oblongifolia Q. toumeyi
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Shrubland (Shrub-dominated); Sideslope; Intermediate Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2023; ESLF 4210; ESP 1023

CONCEPT

Summary: Madrean Encinal occurs on foothills, canyons, bajadas and plateaus in the Sierra Madre Occidentale and Sierra Madre Orientale in Mexico, extending north into Trans-Pecos Texas, southern New Mexico and sub-Mogollon Arizona. These woodlands are dominated by Madrean evergreen oaks along a low-slope transition below Madrean Lower Montane Pine-Oak Forest and Woodland (CES305.796) and Madrean Pinyon-Juniper Woodland (CES305.797). Lower elevation stands are typically open woodlands or savannas where they transition into desert grasslands, chaparral or in some cases desertscrub. Common evergreen oak species include *Quercus arizonica, Quercus emoryi, Quercus intricata, Quercus grisea, Quercus oblongifolia, Quercus toumeyi*, and in Mexico *Quercus chihuahuensis* and *Quercus albocincta*. Madrean pine, Arizona cypress, pinyon and juniper trees may be present but do not codominate. Chaparral species such as *Arctostaphylos pungens, Cercocarpus montanus, Purshia* spp., *Garrya wrightii, Quercus turbinella, Frangula betulifolia (= Rhamnus betulifolia)*, or *Rhus* spp. may be present but do not dominate. The graminoid layer is usually prominent between trees in grassland or steppe that is dominated by warm-season grasses such as *Aristida* spp., *Bouteloua gracilis, Bouteloua curtipendula, Bouteloua rothrockii, Digitaria californica, Eragrostis intermedia, Hilaria belangeri, Leptochloa dubia, Muhlenbergia* spp., *Pleuraphis jamesii*, or *Schizachyrium cirratum*, species typical of Apacherian-Chihuahuan Semi-Desert Grassland and Steppe (CES302.735). This system includes seral stands dominated by shrubby Madrean oaks typically with a strong graminoid layer. In transition areas with drier chaparral systems, stands of chaparral are not dominated by Madrean oaks; however, Madrean Encinal may extend down along drainages.
Classification Comments: Although some stands may be shrubby especially in the north, E. Muldavin (pers. comm.) says encinal is considered woodland in Mexico.
Similar Ecological Systems:
- Apacherian-Chihuahuan Semi-Desert Grassland and Steppe (CES302.735)

Related Concepts:

- Western Live Oak: 241 (Eyre 1980) Broader

DESCRIPTION

Vegetation: Stands of this system are dominated by evergreen oak species including *Quercus arizonica, Quercus emoryi, Quercus intricata, Quercus grisea, Quercus oblongifolia, Quercus toumeyi*, and in Mexico *Quercus chihuahuensis* and *Quercus albocincta*. Madrean pine, Arizona cypress, pinyon and juniper trees may be present but do not codominate. Chaparral species such as *Arctostaphylos pungens, Cercocarpus montanus, Purshia* spp., *Garrya wrightii, Quercus turbinella, Frangula betulifolia (= Rhamnus betulifolia)*, or *Rhus* spp. may be present but do not dominate. The graminoid layer is usually prominent between trees in grassland or steppe that is dominated by warm-season grasses such as *Aristida* spp., *Bouteloua gracilis, Bouteloua curtipendula, Bouteloua rothrockii, Digitaria californica, Eragrostis intermedia, Hilaria belangeri, Leptochloa dubia, Muhlenbergia* spp., *Pleuraphis jamesii*, or *Schizachyrium cirratum*. These species are also typical of Apacherian-Chihuahuan Semi-Desert Grassland and Steppe (CES302.735).

Component Associations:
- *Cupressus arizonica / Quercus hypoleucoides* Forest (CEGL000352, G2)
- *Cupressus arizonica / Quercus turbinella* Forest (CEGL000353, G2G3)
- *Quercus arizonica / Bouteloua curtipendula* Woodland (CEGL000680, G3)
- *Quercus arizonica / Muhlenbergia emersleyi* Woodland (CEGL000681, G4)
- *Quercus emoryi / Arctostaphylos pungens* Woodland (CEGL000682, GNR)

Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Montane]; Tropical/Subtropical [Tropical Xeric]; Shallow Soil; Xeric; F-Patch/High Intensity; Needle-Leaved Tree; Evergreen Sclerophyllous Shrub; Quercus arizonica, Q. emoryi, Q. grisea, Q. oblongifolia Q. toumeyi; Pinus discolor, P. leiophylla, P. engelmannii
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Ridge/Summit/Upper Slope; Sideslope; Intermediate Disturbance Interval; Xeromorphic Shrub
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2024; ESLF 4211; ESP 1024

CONCEPT

Summary: This system occurs on mountains and plateaus in the Sierra Madre Occidentale and Sierra Madre Orientale in Mexico, Trans-Pecos Texas, southern New Mexico and Arizona, generally south of the Mogollon Rim. These forests and woodlands are composed of Madrean pines (*Pinus arizonica, Pinus engelmannii, Pinus leiophylla*, or *Pinus strobiformis*) and evergreen oaks (*Quercus arizonica, Quercus emoryi*, or *Quercus grisea*) intermingled with patchy shrublands on most mid-elevation slopes (1500-2300 m elevation). Other tree species include *Cupressus arizonica, Juniperus deppeana, Pinus cembroides, Pinus discolor, Pinus ponderosa* (with Madrean pines or oaks), and *Pseudotsuga menziesii*. Subcanopy and shrub layers may include typical encinal and chaparral species such as *Agave* spp., *Arbutus arizonica, Arctostaphylos pringlei, Arctostaphylos pungens, Garrya wrightii, Nolina* spp., *Quercus hypoleucoides, Quercus rugosa*, and *Quercus turbinella*. Some stands have moderate cover of perennial graminoids such as *Muhlenbergia emersleyi, Muhlenbergia longiligula, Muhlenbergia virescens*, and *Schizachyrium cirratum*. Fires are frequent with perhaps more crown fires than ponderosa pine woodlands, which tend to have more frequent ground fires on gentle slopes.

Similar Ecological Systems:
- Madrean Mesic Canyon Forest and Woodland (CES302.454)

Related Concepts:
- Western Live Oak: 241 (Eyre 1980) Intersecting

DESCRIPTION

Vegetation: These forests and woodlands are composed of Madrean pines (*Pinus arizonica, Pinus engelmannii, Pinus leiophylla*, or *Pinus strobiformis*) and evergreen oaks (*Quercus arizonica, Quercus emoryi*, or *Quercus grisea*) intermingled with patchy shrublands on most mid-elevation slopes (1500-2300 m elevation). Other tree species include *Cupressus arizonica, Juniperus deppeana, Pinus cembroides, Pinus discolor, Pinus ponderosa* (with Madrean pines or oaks), and *Pseudotsuga menziesii*. Subcanopy and shrub layers may include typical encinal and chaparral species such as *Agave* spp., *Arbutus arizonica, Arctostaphylos pringlei, Arctostaphylos pungens, Garrya wrightii, Nolina* spp., *Quercus hypoleucoides, Quercus rugosa*, and *Quercus turbinella*. Some stands have moderate cover of perennial graminoids such as *Muhlenbergia emersleyi, Muhlenbergia longiligula, Muhlenbergia virescens*, and *Schizachyrium cirratum*.

MADREAN MESIC CANYON FOREST AND WOODLAND (CES302.454)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Warm Desert (302)
Land Cover Class: Forest and Woodland
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
National Mapping Codes: ESLF 4342

CONCEPT

Summary: These woodlands of the Trans-Pecos mountains occur in canyons and along streams, sometimes occupying benches, terraces, and adjacent lower slopes with coarse, rocky substrate. The canopy may be variously dominated by a number of coniferous, broad-leaved evergreen, and deciduous components depending on phytogeography, elevation, and availability of groundwater. Occurrences may be dominated by evergreen conifers *Pinus* spp., *Juniperus* spp., *Pseudotsuga menziesii*, and/or *Cupressus arizonica* or codominated by a mix of evergreen conifers and evergreen and deciduous hardwoods, including *Quercus* sp., *Acer grandidentatum, Quercus muehlenbergii, Quercus gravesii*, and *Fraxinus velutina*. In addition these woodlands may also contain a shrubland component.
Classification Comments: Formerly, this previously undescribed system had components that may have been included in Madrean Lower Montane Pine-Oak Forest and Woodland (CES305.796), Madrean Upper Montane Conifer-Oak Forest and Woodland (CES305.798), North American Warm Desert Lower Montane Riparian Woodland and Shrubland (CES302.748), or Rocky Mountain Bigtooth Maple Ravine Woodland (CES306.814).
Similar Ecological Systems:
- Madrean Lower Montane Pine-Oak Forest and Woodland (CES305.796)
- Madrean Upper Montane Conifer-Oak Forest and Woodland (CES305.798)
- North American Warm Desert Lower Montane Riparian Woodland and Shrubland (CES302.748)
- Rocky Mountain Bigtooth Maple Ravine Woodland (CES306.814)

DESCRIPTION

Environment: This system is found in montane canyons and stream terraces on various geological strata of the Trans-Pecos mountains, particularly limestone and igneous formations. The system often occupies local alluvium, both fine and coarse, and sometimes Quaternary alluvium as mapped. It may be expected to occur on Canyon (Mountain Savannah), Foothill Slope, Draw, Limestone Canyon, Mountain Loam, Limestone Hill & Mountain, and Igneous Hill & Mountain Ecological Sites.
Vegetation: Canopy species may include *Pseudotsuga menziesii* (lacking in the Davis Mountains), *Pinus ponderosa var. scopulorum, Pinus arizonica var. stormiae* (in the Chisos Mountains), *Pinus cembroides, Pinus edulis* (in the Guadalupe Mountains), *Cupressus arizonica, Juniperus deppeana, Juniperus flaccida* (in the Chisos Mountains), *Quercus emoryi, Quercus rugosa, Quercus hypoleucoides, Quercus graciliformis, Quercus gravesii, Quercus muehlenbergii*, and *Quercus grisea*. Species such as *Ungnadia speciosa, Acer grandidentatum, Fraxinus velutina, Prunus serotina var. virens, Arbutus xalapensis, Ostrya knowltonii* (in the Guadalupe Mountains), and/or *Ostrya virginiana var. chisosensis* (in the Chisos Mountains) may be present in more mesic situations, such as perennial water sources. Shrubs that may be present include *Salvia regla, Juglans microcarpa, Nolina erumpens, Dasylirion leiophyllum, Agave havardiana, Agave parryi ssp. neomexicana, Mahonia haematocarpa, Garrya ovata, Ceanothus greggii, Crataegus tracyi, Cercocarpus montanus, Sambucus nigra ssp. cerulea, Frangula betulifolia, Philadelphus* spp., and *Vitis arizonica*. The herbaceous layer is patchy with species such as *Piptochaetium fimbriatum, Bouteloua curtipendula, Poa strictiramea, Muhlenbergia rigida, Muhlenbergia emersleyi, Bothriochloa laguroides ssp. torreyana*, and *Schizachyrium scoparium*.

DISTRIBUTION

Range: This system occurs in the mountains of the Trans-Pecos region of Texas and adjacent New Mexico.

MADREAN PINYON-JUNIPER WOODLAND (CES305.797)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Sierra Madre (305)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Tropical/Subtropical [Tropical Xeric]; Shallow Soil; Xeric; F-Patch/Medium Intensity; Needle-Leaved Tree; Evergreen Sclerophyllous Shrub; Pinus cembroides, Juniperus deppeana
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Shrubland (Shrub-dominated); Sideslope; Intermediate Disturbance Interval; Broad-Leaved Evergreen Tree; Xeromorphic Shrub
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2025; ESLF 4212; ESP 1025

CONCEPT

Summary: This system occurs on foothills, mountains and plateaus in the Sierra Madre Occidentale and Sierra Madre Orientale in Mexico, Trans-Pecos Texas, southern New Mexico and Arizona, generally south of the Mogollon Rim. Substrates are variable, but soils are generally dry and rocky. The presence of *Pinus cembroides, Pinus discolor*, or other Madrean trees and shrubs is diagnostic of this woodland system. *Juniperus coahuilensis, Juniperus deppeana, Juniperus pinchotii, Juniperus monosperma,* and/or *Pinus edulis* may be present to dominant. Madrean oaks such as *Quercus arizonica, Quercus emoryi, Quercus grisea*, or *Quercus mohriana* may be codominant. *Pinus ponderosa* is absent or sparse. If present, understory layers are variable and may be dominated by shrubs or graminoids.
Classification Comments: According to USFS TES mapping (USDA 2001), *Quercus grisea* woodlands (Madrean Encinal) occur on both sides of the Guadalupe Mountains and in the southeastern portion of the Sacramento Mountains. This suggests that the associated pinyon and juniper woodlands are Madrean Pinyon-Juniper Woodland (CES305.797).
Related Concepts:

MADREAN UPPER MONTANE CONIFER-OAK FOREST AND WOODLAND (CES305.798)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Sierra Madre (305)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Montane]; Forest and Woodland (Treed); Tropical/Subtropical [Tropical Xeric]; Xeric; F-Patch/Medium Intensity; Abies coahuilensis, Quercus hypoleucoides, Q. rugosa
Non-Diagnostic Classifiers: Sideslope; Toeslope/Valley Bottom; Mesotrophic Soil; Deep Soil; Sand Soil Texture; Long Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2026; ESLF 4213; ESP 1026

CONCEPT

Summary: This ecological system occurs at the upper elevations in the Sierra Madre Occidentale and Sierra Madre Orientale of Mexico. In the U.S., it is restricted to north and east aspects at high elevations (1980-2440 m) in the Sky Islands (Chiricahua, Huachuca, Pinaleno, Santa Catalina, and Santa Rita mountains) and along the Nantanes Rim. It is more common in Mexico and does not occur north of the Mogollon Rim. The vegetation is characterized by large- and small-patch forests and woodlands dominated by *Pseudotsuga menziesii*, *Abies coahuilensis*, or *Abies concolor* and Madrean oaks such as *Quercus arizonica*, *Quercus emoryi*, *Quercus grisea*, *Quercus hypoleucoides*, *Quercus rugosa*, and *Quercus toumeyi*. If *Quercus gambelii* is prominent in the shrub layer, then other Madrean elements are present. This system may include stands of *Quercus gravesii* woodlands. It is similar to Southern Rocky Mountain Dry-Mesic Montane Mixed Conifer Forest and Woodland (CES306.823) which typically lacks Madrean elements.
Classification Comments: Texas experts for mapzone 26 feel that this system does not occur in that zone.
Similar Ecological Systems:
- Madrean Mesic Canyon Forest and Woodland (CES302.454)
- Southern Rocky Mountain Dry-Mesic Montane Mixed Conifer Forest and Woodland (CES306.823)

Component Associations:
- *Juniperus deppeana - Quercus X pauciloba* Woodland (CEGL005370, GNR)
- *Pseudotsuga menziesii / Quercus hypoleucoides* Forest (CEGL000453, G3)
- *Pseudotsuga menziesii / Quercus rugosa* Forest (CEGL000454, G2)

DISTRIBUTION

Range: This system is found in the Sierra Madre Occidentale and Sierra Madre Orientale of Mexico. In the U.S., it is restricted to north and east aspects at high elevations (1980-2440 m) in the Sky Islands (Chiricahua, Huachuca, Pinaleno, Santa Catalina, and Santa Rita mountains) and along the Nantanes Rim.

MEDITERRANEAN CALIFORNIA DRY-MESIC MIXED CONIFER FOREST AND WOODLAND (CES206.916)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Forest and Woodland (Treed); Mediterranean [Mediterranean Xeric-Oceanic]; Ustic; Needle-Leaved Tree
Non-Diagnostic Classifiers: F-Patch/Low Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2027; ESLF 4214; ESP 1027

CONCEPT

Summary: These mixed-conifer forests, always with at least two conifer species codominating, occur on all aspects in lower montane zones (600-1800 m elevation in northern California; 1200-2150 m in southern California). This system occurs in a variety of topo-edaphic positions, such as upper slopes at higher elevations, canyon sideslopes, ridgetops, and south- and west-facing slopes which burn relatively frequently. Often, several conifer species co-occur in individual stands. *Pseudotsuga menziesii, Pinus ponderosa*, and *Calocedrus decurrens* are the most common conifers. Other conifers that can occasionally be present include *Pinus jeffreyi, Pinus attenuata*, and *Pinus lambertiana* (not as common in this as in Mediterranean California Mesic Mixed Conifer Forest and Woodland (CES206.915)). Common subcanopy trees include *Quercus chrysolepis* and *Quercus kelloggii*. *Arbutus menziesii* and *Lithocarpus densiflorus* may be common with the oaks in northern areas. *Pseudotsuga macrocarpa* and *Pinus coulteri* can be present but are not dominant species in this system in the Transverse Ranges of southern California. Codominant *Abies concolor - Calocedrus decurrens* communities in southern California are also included in this system. In the Transverse Ranges, where Great Basin and Mojavean elements are transitioning into the montane zones, *Juniperus californica* and *Pinus monophylla* can be mixed with the other conifers. Understories are variable, except in the Sierra Nevada, where in some stands there can be dense understory mats of *Chamaebatia foliolosa* (and other low, spreading shrubs) which foster relatively high-frequency, low-intensity ground fires. In Oregon, shrubs such as *Holodiscus discolor, Toxicodendron rydbergii, Mahonia nervosa, Mahonia aquifolium*, and *Symphoricarpos mollis* are common in addition to graminoids such as *Festuca californica*, *Elymus glaucus*, and *Danthonia californica*. In the north, where *Calocedrus decurrens* and *Pinus ponderosa* drop out, this system shifts to North Pacific Dry Douglas-fir-(Madrone) Forest and Woodland (CES204.845).
Classification Comments: This forest is more dense, with a greater richness of canopy tree species than Mediterranean California Lower Montane Black Oak-Conifer Forest and Woodland (CES206.923).
Similar Ecological Systems:
- Sierran-Intermontane Desert Western White Pine-White Fir Woodland (CES204.101)

Related Concepts:
- Interior Ponderosa Pine: 237 (Eyre 1980) Intersecting
- Pacific Douglas-fir: 229 (Eyre 1980) Intersecting
- Pacific Ponderosa Pine - Douglas-fir: 244 (Eyre 1980) Intersecting
- Pacific Ponderosa Pine: 245 (Eyre 1980) Intersecting
- Sierra Nevada Mixed Conifer: 243 (Eyre 1980) Intersecting
- White Fir: 211 (Eyre 1980) Intersecting

DESCRIPTION

Dynamics: Historically, frequent and low-intensity fires maintained these woodlands. Due to fire suppression, the majority of these forests now have closed canopies, whereas in the past, a moderately high fire frequency (every 20-30 years) formerly maintained an open forest of many conifers.

Component Associations:
- *Abies concolor - Pinus ponderosa / Amelanchier alnifolia* Forest (CEGL000014, G2)
- *Abies concolor / Amelanchier alnifolia / Anemone deltoidea* Forest (CEGL000010, G2?)
- *Pinus lambertiana - Pinus ponderosa - Pseudotsuga menziesii / Festuca californica* Forest (CEGL000065, G1)
- *Pinus ponderosa - Calocedrus decurrens - Quercus chrysolepis / Chamaebatia foliolosa* Forest (CEGL008674, G4?)
- *Pinus ponderosa - Calocedrus decurrens - Quercus kelloggii* Forest (CEGL008673, G4?)
- *Pinus ponderosa - Calocedrus decurrens / Chamaebatia foliolosa* Forest (CEGL008672, G4?)
- *Pinus ponderosa - Quercus kelloggii / Arctostaphylos viscida* Woodland (CEGL008694, G4?)
- *Pseudotsuga menziesii - Abies concolor - Calocedrus decurrens* Forest (CEGL005813, G3?)
- *Pseudotsuga menziesii - Pinus ponderosa - Calocedrus decurrens* Forest (CEGL008684, G3?)
- *Pseudotsuga menziesii - Quercus chrysolepis* Forest (CEGL005814, G3?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Mediterranean California Mesic Mixed Conifer Forest and Woodland (CES206.915)

Adjacent Ecological System Comments: This system occurs sympatrically with Mediterranean California Mesic Mixed Conifer Forest and Woodland (CES206.915) but is found on lower, drier, warmer, or more exposed sites in comparison to the mesic system.

DISTRIBUTION

Range: This system occurs in lower montane zones (600-1800 m elevation in northern California; 1200-2150 m in southern California), including the eastern Klamath-Siskiyou, interior Coast Ranges, Transverse Ranges and Sierra Nevada.
Divisions: 206:C
Nations: US
Subnations: CA, NV, OR

MEDITERRANEAN CALIFORNIA LOWER MONTANE BLACK OAK-CONIFER FOREST AND WOODLAND (CES206.923)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Toeslope/Valley Bottom; Franciscan Formation Soils; Deep Soil; Mineral: W/ A-Horizon >10 cm
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Ustic; Short Disturbance Interval; F-Patch/Low Intensity; Quercus kelloggii
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2030; ESLF 4217; ESP 1030

CONCEPT

Summary: This ecological system is found throughout California's middle and inner North Coast Ranges, as well as the southern and eastern Klamath Mountains from 600-1600 m (1800-4850 feet) elevation, and the lower slopes of the western Sierra Nevada. It occurs in valleys and lower slopes on a variety of parent materials, including granitics, metamorphic and Franciscan metasedimentary parent material and deep, well-developed soils. It is characterized by woodlands or forests of *Pinus ponderosa* with one or more oaks, including *Quercus kelloggii*, *Quercus garryana*, *Quercus wislizeni*, or *Quercus chrysolepis*. *Pseudotsuga menziesii* may co-occur with *Pinus ponderosa*, particularly in the North Coast Ranges and Klamath Mountains. On most sites, the oaks are dominant, forming a dense subcanopy under a more open canopy of the conifers. On many sites, *Quercus kelloggii* is the dominant; in late-seral stands on more mesic sites, conifers such as *Pinus ponderosa* or *Pseudotsuga menziesii* will form a persistent emergent canopy over the oak. Stands may have shrubby understories (in the Klamath Mountains and Sierra Nevada) and, more rarely, grassy understories (in North Coast Ranges). Common shrubs include *Arctostaphylos viscida*, *Arctostaphylos manzanita*, *Ceanothus integerrimus*, and *Toxicodendron diversilobum*. Grasses can include *Festuca californica*, *Festuca idahoensis*, and *Melica* spp. Historical fire in this system was likely high frequency but of low intensity. Conifer species, such as *Pseudotsuga menziesii*, become more abundant with wildfire suppression.
Classification Comments: The floristic and geographic transition from this system to North Pacific Oak Woodland (CES204.852) needs to be further detailed. This system generally has lower tree species richness in the canopy and a lower canopy density than Mediterranean California Dry-Mesic Mixed Conifer Forest and Woodland (CES206.916), although the oaks can form a dense subcanopy in the mixed conifer system.
Similar Ecological Systems:
- California Lower Montane Blue Oak-Foothill Pine Woodland and Savanna (CES206.936)
- Mediterranean California Mixed Evergreen Forest (CES206.919)

Related Concepts:
- California Black Oak: 246 (Eyre 1980) Intersecting
- Interior Ponderosa Pine: 237 (Eyre 1980) Intersecting
- Pacific Ponderosa Pine - Douglas-fir: 244 (Eyre 1980) Intersecting. Douglas-fir and/or Ponderosa over oaks in the Klamaths and south are included in this ecological system.
- Pacific Ponderosa Pine: 245 (Eyre 1980) Intersecting. Ponderosa over oaks in the Klamaths and south are included in this ecological system.

DESCRIPTION

Dynamics: LANDFIRE model information: Historical fire frequency was 5 to 30 years in this type. Fire intensities were probably low in open stands but increased in severity as woodland vegetation transitioned to a denser, closed-canopy type along watercourses. Vegetation is fire-tolerant and therefore fire severity is low. The natural fire regime was a type I regime in the upland. With the more dense vegetation and the occurrence of fuel ladders, fire severity would become mixed. The fire regime may reflect a type III in this more mesic habitat.

Insects and disease may impact individual trees (ponderosa pine) locally. Armillaria root rot, western pine beetle, western oak looper, western tent caterpillar, and the pine engraver have the greatest potential for damage.

Component Associations:
- *Pinus ponderosa - Calocedrus decurrens - Quercus chrysolepis / Chamaebatia foliolosa* Forest (CEGL008674, G4?)
- *Pinus ponderosa - Quercus kelloggii / Arctostaphylos viscida* Woodland (CEGL008694, G4?)

MEDITERRANEAN CALIFORNIA MESIC MIXED CONIFER FOREST AND WOODLAND (CES206.915)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Toeslope/Valley Bottom; Mediterranean [Mediterranean Xeric-Oceanic]; Udic
Non-Diagnostic Classifiers: Long (>500 yrs) Persistence; Forest and Woodland (Treed); F-Patch/Low Intensity; Sequoiadendron giganteum
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2028; ESLF 4215; ESP 1028

CONCEPT

Summary: This ecological system occurs in cool ravines and north-facing slopes (typically with 100-150 cm annual precipitation; 50% as snow). It is found from 800-1000 m (2400-3000 feet) elevation in the Sierra Nevada and 1250-2200 m (3800-6700 feet) in the Klamath Mountains. The most characteristically co-occurring conifers are *Abies concolor var. lowiana, Calocedrus decurrens*, and *Pinus lambertiana*. *Pinus jeffreyi, Pinus ponderosa*, and *Pseudotsuga menziesii* occur frequently but are not dominant. In limited locations in the central Sierra Nevada, *Sequoiadendron giganteum* dominates, usually with *Abies concolor*, and at the highest elevations also with *Abies magnifica*. *Acer macrophyllum* is common in lower elevation mesic pockets; *Chrysolepis chrysophylla* also occurs in the western Klamaths. Common understory species include *Corylus cornuta, Cornus nuttallii*, and at higher elevations *Chrysolepis sempervirens*. In areas of recent fire or other disturbance, *Arctostaphylos patula, Ceanothus integerrimus, Ceanothus cordulatus, Ceanothus parvifolius*, and *Ribes* spp. are more common. Fire of highly variable patch size and return interval maintains the structure of these woodlands
Classification Comments: The presence of *Abies concolor* with other conifers is a strong indicator for this system in central California's Coast and Transverse ranges.

MEDITERRANEAN CALIFORNIA MIXED EVERGREEN FOREST (CES206.919)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Franciscan Formation Soils; Broad-Leaved Evergreen Tree
Non-Diagnostic Classifiers: Montane [Lower Montane]; Ustic; F-Patch/Low Intensity; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2043; ESLF 4230; ESP 1043

CONCEPT

Summary: This ecological system occurs from the Santa Cruz Mountains (and locally in the Santa Lucia Mountains), California, north into southwestern Oregon throughout the outer and middle Coast Ranges on Franciscan Formation soils (metasedimentary sandstones, schists, and shales) with moderate to high rainfall. This system occurs just inland from the redwood belt of this region. It also occurs in southern California in more mesic, protected, cooler sites of the Transverse and Peninsular ranges. Historic fire frequency in this system was higher than for redwood-dominated systems (every 50-100 years). It is characterized by mixes of coniferous and broad-leaved evergreen trees. Characteristic trees include *Pseudotsuga menziesii, Quercus chrysolepis, Lithocarpus densiflorus, Arbutus menziesii, Umbellularia californica*, and *Chrysolepis chrysophylla*. On the eastern fringe of this system, in the western Siskiyous, other conifers occur such as *Pinus ponderosa* and *Chamaecyparis lawsoniana*. In southern California (Transverse and Peninsular ranges), *Pseudotsuga macrocarpa* replaces *Pseudotsuga menziesii* but co-occurs with *Quercus chrysolepis* and sometimes *Quercus agrifolia*. *Calocedrus decurrens* is occasional. In the southern portion of the range, *Lithocarpus densiflorus, Arbutus menziesii, Umbellularia californica*, and *Chrysolepis chrysophylla* become less important or are absent. In the Santa Lucia Mountains, stands of *Abies bracteata* are included in this system and are an unusual and unique component. These stands are a mixture of *Abies bracteata* and *Quercus chrysolepis*. The more northerly stands tend to have dense or diverse shrub understories, with *Corylus cornuta, Vaccinium ovatum, Rhododendron macrophyllum, Gaultheria shallon, Quercus sadleriana, Mahonia nervosa*, and *Toxicodendron diversilobum* being common. Southern stands are less diverse and more sparse; *Toxicodendron diversilobum* is the most constant shrub, with *Ribes* spp. occasionally present, along with much *Polystichum munitum*. Especially in the south, stands are restricted to fire-protected sites (extremely steep, northerly, mesic slopes and coves) where fires from adjacent chaparral systems do not carry.
Classification Comments: In northern California, especially around Point Reyes, there are stands dominated by *Umbellularia californica*. These nearly pure stands are a part of this system, as it is a disturbance-driven species and grows rapidly with full sunlight. With time and succession, other trees will succeed into the canopy. This is in contrast to small patches or individuals of *Umbellularia californica* in some of the various chaparral systems. Here there are no chaparral shrubs in the understory. The presence of *Lithocarpus densiflorus* in mixed stands of pine and oak is the indicator species for this system in many places in the Coast Ranges throughout northern and central California.

MEDITERRANEAN CALIFORNIA MIXED OAK WOODLAND (CES206.909)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Sideslope; Mediterranean [Mediterranean Xeric-Oceanic]; Shallow Soil; F-Patch/Medium Intensity; Quercus kelloggii; Quercus garryana var. breweri
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Xeric; Intermediate Disturbance Interval; Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2029; ESLF 4216; ESP 1029

CONCEPT

Summary: This ecological system is found throughout the Sierra Nevada and Coast Range foothills and lower montane elevations from 600-1600 m (1800-4850 feet) on steep, rocky slopes where snow and cold temperatures occur. Fire frequency and intensity drive composition of this system, with *Quercus chrysolepis* dominant with less frequent fires. With frequent annual burning (at lower elevations and on warmer sites), this system is an open to dense woodland of large oaks with well-developed grassy understories of native perennial bunchgrass. The predominant oaks with the higher frequency fires include *Quercus kelloggii* and *Quercus garryana*, with *Quercus garryana var. garryana* codominant in the central and northern Coast Ranges and *Quercus garryana var. breweri* often codominant in the northwestern Coast Ranges as well as portions of the Sierra Nevada. *Quercus chrysolepis* becomes dominant with less frequent fires (but in Oregon this species is not important and occurs in a different system, either Mediterranean California Mixed Evergreen Forest (CES206.919) or Mediterranean California Dry-Mesic Mixed Conifer Forest and Woodland (CES206.916)). The perennial bunchgrass component includes *Festuca idahoensis, Festuca californica, Elymus glaucus,* and *Danthonia californica* (close to the coast). A variety of native forbs also occur. Other characteristic species include *Toxicodendron diversilobum, Juniperus occidentalis*, and *Ceanothus cuneatus*. This system is similar to North Pacific Oak Woodland (CES204.852) but does not include a conifer component, and *Quercus garryana* is not the only oak.

Similar Ecological Systems:
- North Pacific Oak Woodland (CES204.852)

Related Concepts:
- California Black Oak: 246 (Eyre 1980) Broader
- Canyon Live Oak: 249 (Eyre 1980) Undetermined
- Oregon White Oak: 233 (Eyre 1980) Intersecting. Oregon white oak does occur occasionally as a dominant in this ecological system.

DESCRIPTION

Dynamics: LANDFIRE model information: Fire Regime I, primarily short-interval (e.g., <10 years) surface fires. Surface fires every 3-10 years maintained an open savanna-like structure. Fires can be mixed-severity, especially when closed-canopy conditions or additional species such as conifers and shrubs are present. Native burning was a significant factor in fire frequency of this type, but return intervals may increase significantly with a little distance from native settlements and valley bottoms.

Component Associations:
- *Quercus chrysolepis - Umbellularia californica* Forest (CEGL008604, G4?)
- *Quercus chrysolepis / Arctostaphylos patula* Forest (CEGL008601, G3?)

MEDITERRANEAN CALIFORNIA RED FIR FOREST (CES206.913)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Forest and Woodland (Treed); Mediterranean [Mediterranean Pluviseasonal-Oceanic]; Deep Soil; Ustic; Long Disturbance Interval; Abies magnifica (= var. magnifica)
Non-Diagnostic Classifiers: Sideslope; Toeslope/Valley Bottom; Sand Soil Texture; F-Patch/High Intensity; W-Patch/High Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2032; ESLF 4219; ESP 1032

CONCEPT

Summary: This ecological system includes high-elevation (1600-2700 m [4850-9000 feet]) forests and woodlands dominated by *Abies magnifica (= var. magnifica), Abies X shastensis (= Abies magnifica var. shastensis),* and/or *Abies procera*. This system is typically found on deep, well-drained soils throughout this elevation zone from the central Sierra Nevada north and west into southern Oregon. Heavy snowpack is a major source of soil moisture throughout the growing season. The limiting factors can be either cold-air drainages or ponding, or coarser soils (pumice versus ash, for example). Other conifers that can occur in varying mixtures with *Abies magnifica* include *Pinus contorta var. murrayana, Pinus monticola, Tsuga mertensiana, Pinus jeffreyi,* and *Abies concolor*. At warmer and lower sites of the North Coast Ranges and Sierra Nevada, *Abies concolor* can codominate with *Abies magnifica*. *Pinus contorta* in Oregon indicates lower productivity where it intergrades with *Abies X shastensis*. This system ranges from dry to moist, and some sites have mesic indicator species, such as *Ligusticum grayi* or *Thalictrum fendleri*. Common understory species include *Quercus vacciniifolia, Ribes viscosissimum, Chrysolepis sempervirens, Ceanothus cordulatus* (in seral stands), *Vaccinium membranaceum, Symphoricarpos mollis,* and *Symphoricarpos rotundifolius*. Characteristic forbs include *Eucephalus breweri, Pedicularis semibarbata,* and *Hieracium albiflorum*. This system commonly occurs above mixed conifer forests with *Abies concolor* and overlaps in elevation with forests and woodlands of *Pinus contorta var. murrayana*. On volcanic sites of lower productivity, stands may be more open woodland in structure and with poor-site understory species such as *Wyethia mollis*. Driving ecological processes include occasional blow-down, insect outbreaks and stand-replacing fire.

Related Concepts:
- Red Fir: 207 (Eyre 1980) Equivalent

DESCRIPTION

Dynamics: Stand-replacing fire is important but so are moderately frequent (about once every 40 years) low- to moderate-severity fires. The whole system is characterized by a "moderate-severity fire regime" (Agee 1993), i.e., high variability in severity and moderate frequency of fires. See also Chappell and Agee (1996), Pitcher (1987), and Taylor and Halpern (1991) for documentation of fire regime in these forests. Windthrow causes tree-sized gaps that release already established individuals in the understory.

TNC model information: At higher elevations and in the southern Sierra Nevada, fuels are relatively more discontinuous than northern locations because the terrain is broken up by natural breaks such as rock outcrops, lava reefs, wet meadows, etc. Fuels may be more continuous at the northern end of the range, where this vegetation type is found at lower elevations. Primarily Fire Regime Group III, but because of slow fuel accumulation rates, it is possible to have 35- to 150-year frequency surface fire in some classes (lower frequency for these settings as a whole). The discontinuous nature of the fuels limits the extent of fires, and while fires may burn less often, they may burn at high severities. Larger and more frequent moderate-intensity fires occur on average every 60-70 years. High-intensity crown fires are rare, occurring every few hundred years; overall mean fire-return interval is approximately 35-50 years (Pitcher 1987, Skinner 2000, Taylor 2000, Bekker and Taylor 2001). Replacement fire likely varies with slope position (upper slope > midslope > lower slope), and landscapes with greater topographic variation are likely to experience more stand-replacement fires. A considerable range of values has been reported in the literature for mixed and surface fires (Taylor and Halpern 1991, Taylor 1993, Bekker and Taylor 2001, Taylor and Solem 2001).

Component Associations:
- *(Abies concolor) - Abies X shastensis / Symphoricarpos mollis* Forest (CEGL000033, GU)

MEDITERRANEAN CALIFORNIA SUBALPINE WOODLAND (CES206.910)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Temperate [Temperate Oceanic]; Very Shallow Soil; W-Landscape/High Intensity; Krummholz
Non-Diagnostic Classifiers: Montane [Upper Montane]; Ridge/Summit/Upper Slope
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2033; ESLF 4220; ESP 1033

CONCEPT

Summary: This ecological system occurs on ridges and rocky slopes around timberline at 2900 m (9500 feet) elevation in the southern Sierra Nevada and Transverse and Peninsular ranges, up to 3500 m (11,500 feet) in the Sierra Nevada, and 2450 m (8000 feet) in the southern Cascades. Tree species often occur as krummholz growth forms with a wind-pruned, prostrate, and/or shrublike appearance, but in more protected sites they form true woodland physiognomy. Stands are dominated by *Pinus albicaulis* and/or *Pinus contorta var. murrayana*; other important conifers and locally dominant species include *Pinus balfouriana* (only in the Klamath Mountains and southern Sierra Nevada where it may replace *Pinus albicaulis*), *Pinus flexilis* (but only in small patches on the eastern flank of the Sierra Nevada escarpment when it does occur), *Pinus monticola* (not in Transverse or Peninsular ranges), and *Juniperus occidentalis var. australis* (mostly in the central and southern Sierra Nevada but not in the Klamath Mountains). Important shrubs include *Arctostaphylos nevadensis, Chrysolepis sempervirens*, and *Holodiscus discolor (= Holodiscus microphyllus)*. Grasses and forbs include *Carex rossii, Carex filifolia, Poa wheeleri, Eriogonum incanum, Penstemon newberryi*, and *Penstemon davidsonii*. Due to landscape position and very thin soils, these are harsh sites exposed to desiccating winds with ice and snow blasts, and rocky substrates. In addition, a short growing season limits plant growth. The highest tree diversity occurs in the Klamath Mountains, with sometimes five or more conifers sharing codominance in one stand.

Similar Ecological Systems:
- Sierra Nevada Subalpine Lodgepole Pine Forest and Woodland (CES206.912)

Related Concepts:
- California Mixed Subalpine: 256 (Eyre 1980) Intersecting
- Western Juniper - Big Sagebrush - Bluebunch Wheatgrass (107) (Shiflet 1994) Intersecting. *Juniperus occidentalis var. australis* woodlands are included in this ecological system of the Sierras.
- Western Juniper: 238 (Eyre 1980) Intersecting. *Juniperus occidentalis var. australis* stands are an important compoenent of this ecological system.
- Whitebark Pine: 208 (Eyre 1980) Intersecting. Whitebark pine stands are a component of this ecological system.

Component Associations:
- *Juniperus occidentalis var. australis - Cercocarpus ledifolius / Artemisia tridentata* Woodland (CEGL003150, G3?)
- *Juniperus occidentalis var. australis / Artemisia tridentata* Woodland (CEGL003151, G3?)

MIDDLE ROCKY MOUNTAIN MONTANE DOUGLAS-FIR FOREST AND WOODLAND (CES306.959)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: RM Montane Mesic Mixed Conifer; Moderate (100-500 yrs) Persistence; Montane [Montane]; Montane [Lower Montane]; Forest and Woodland (Treed); Aridic; Intermediate Disturbance Interval; F-Patch/Medium Intensity; F-Landscape/Medium Intensity; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2166; ESLF 4266; ESP 1166

CONCEPT

Summary: This ecological system occurs throughout the middle Rocky Mountains of central and southern Idaho (Lemhi, Beaverhead and Lost River ranges), south and east into the greater Yellowstone region, and south and east into the Wind River, Gros Ventre and Bighorn ranges of Wyoming. It extends north into Montana on the east side of the Continental Divide, north to about the McDonald Pass area, and also into the Rocky Mountain Front region of Montana. This is a *Pseudotsuga menziesii*-dominated system without the maritime floristic composition; these are forests and woodlands occurring in the central Rockies where the southern monsoon influence is less and maritime climate regime is not important. This system includes extensive *Pseudotsuga menziesii* forests, occasionally with *Pinus flexilis* on calcareous substrates, and *Pinus contorta* at higher elevations. True firs, such as *Abies concolor, Abies grandis*, and *Abies lasiocarpa*, are absent in these occurrences, but *Picea engelmannii* can occur in some stands. Understory components include shrubs such as *Physocarpus malvaceus, Juniperus communis, Symphoricarpos oreophilus*, and *Mahonia repens*, and graminoids such as *Calamagrostis rubescens, Carex rossii*, and *Leucopoa kingii*. The fire regime is of mixed severity with moderate frequency. This system often occurs at the lower treeline immediately above valley grasslands, or sagebrush steppe and shrublands. Sometimes there may be a "bath-tub ring" of *Pinus ponderosa* at lower elevations or *Pinus flexilis* between the valley non-forested and the solid *Pseudotsuga menziesii* forest. In the Wyoming Basins, this system occurs as isolated stands of *Pseudotsuga menziesii*, with *Artemisia tridentata, Pseudoroegneria spicata, Leucopoa kingii*, and *Carex rossii*.

MISSISSIPPI DELTA MARITIME FOREST (CES203.513)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Coast
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2384; ESLF 4327; ESP 1384

CONCEPT

Summary: This system includes forests on barrier islands and spits formed during the deltaic shifts of the Mississippi River. It also includes the woody vegetation of salt domes in the Mississippi River deltaic plain. Since natural deltaic processes have been altered, barrier islands are no longer being formed in the Mississippi Delta region and existing barrier islands are undergoing subsidence and beach erosion. Some documented stands that apparently pertain to this system are found on Native American middens (shell mounds) located in the salt marshes of Hancock County, Mississippi. This system currently includes one forested beach ridge located at Grande Isle in Louisiana.

Related Concepts:
- Live Oak: 89 (Eyre 1980) Finer

DESCRIPTION

Environment: This system includes forests on barrier islands and spits formed during the deltaic shifts of the Mississippi River. It also includes the woody vegetation of salt domes in the Mississippi River deltaic plain. Some documented stands that apparently pertain to this system are found on Native American middens (shell mounds) located in the salt marshes of Hancock County, Mississippi (Eleuterius and Otvos 1979). This system also includes one forested beach ridge located at Grande Isle in Louisiana.
Dynamics: The maritime environment for these forests is extremely dynamic and may be severely altered or destroyed by geologic processes, including catastrophic destruction by storms. Fire may have naturally occurred infrequently in this system, but probably was not an important factor. Mature *Quercus virginiana* trees are fire-resistant when mature, and their litter also does not easily burn (Stalter and Odum 1993). Maritime forest systems remain subject to periodic severe physical stresses, although less than coastal dune and grassland systems. Vegetation structure and composition are influenced by salt spray (sea salt aerosol) and extreme disturbance events such as hurricanes, erosion, accretion and sand burial. Chronic salt spray, as well as intense salt spray during storms are important influences on vegetation structure and composition; however, the extent to which plant communities found in this system are shaped by salt spray varies. The most heavily salt-influenced examples of these systems may appear pruned or sculpted. Extreme salt spray or saltwater flooding in storms can severely disturb vegetation, though it recovers if the landforms have not been altered.

Hurricanes frequently make landfall in the northern Gulf of Mexico region, and have a significant impact on coastal systems. Even when they do not make landfall, the storm surge and wave action generated by an off-shore storm can have a significant impact. A total of 112 hurricanes made landfall from Wakulla County, Florida, to Hancock County, Mississippi, during the period 1926 to 2005 (Jarrell et al. 1992 with updates). From the period 1851 to 2004, 36 major hurricanes (Category 3 or higher) made landfall along the Gulf Coast from Louisiana to the Florida Panhandle (Blake et al. 2005). Hurricane-associated storm surges can overwash the dune system and cause significant erosion and/or sand burial of maritime forests. Personal observations along coastal areas of the Florida panhandle region in 2005 revealed large areas of vegetation extending several hundred yards inland that were killed or significantly impacted by saltwater inundation (Landfire 2007a).

The role of fire in this system is poorly documented. The majority of this system occurs on narrow barrier islands along the northern Gulf of Mexico. FNAI (1990) indicates that the mesic conditions and insular locations of well-developed maritime hammock communities inhibit natural fires, which occur no more frequently than once every 26 to 100 years. Liu et. al. (2003), in their study of sediment cores from Little Lake, Alabama, suggested that wildfires have been common in the coastal ecosystems in Alabama; however, they offered no frequency estimates. They did suggest a correlation between hurricanes and fire. This correlation was also supported by Meyers and van Lear (1998) who suggest that hurricane-fire interactions once played a major role in the development of ecosystems in the southern U.S., influencing their composition, structure, and pattern on the landscape (Landfire 2007a).

The following fire-return interval estimates were based on the Huffman and Platt (2004) study of fire scars on slash pines on Little St. George Island (Florida) and the return interval in similar ecological systems on the mainland. Fires were primarily light surface fires occurring every four years during the growing season. More intense replacement fires may have occurred following hurricanes, when more fuel was available as a result of storm damage. There is little fuel to sustain surface fires in the *Quercus/Ceratiola ericoides*-dominated ridges. Fires in this vegetation type are typically replacement fires that burn through the shrub crowns. The return interval here was estimated at 25 to 100 years, and may have occurred following a hurricane or other intense storm-related event when more fuel was available and fire intensity was higher (Landfire 2007a).

Component Associations:
- *Quercus virginiana - Magnolia grandiflora - Quercus pagoda - Celtis laevigata / Sabal minor* Forest (CEGL007467, G1)

- *Quercus virginiana* Forest (CEGL007831, G1Q)

DISTRIBUTION

Range: This system is apparently restricted to Louisiana. It is found on barrier islands and spits formed during the deltaic shifts of the Mississippi River.

MISSISSIPPI RIVER ALLUVIAL PLAIN DRY-MESIC LOESS SLOPE FOREST (CES203.071)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Unglaciated
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Loess; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2509; ESLF 4155; ESP 1509

CONCEPT

Summary: This system of dry-mesic upland forests occurs most extensively on west-facing loess slopes on southern Crowley's Ridge, with more limited occurrences on northern Crowley's Ridge and in the erosional slopes and hills that bound the Grand Prairie terrace of Arkansas and Macon Ridge in Louisiana and Arkansas. The vegetation is very distinctive from that of the adjacent alluvial plain, and the sites themselves, which occur on distinct slopes that rise above the alluvial plain surface, also contrast sharply with it. Occurrences of this system generally comprise dry-mesic forests that occupy west-facing slopes and narrow, "finger" ridgetops in a highly dissected landscape. In many cases, these slopes provide habitat for plant species that are uncommon in other parts of the alluvial plain. Forests on the ridgetops are dominated by *Quercus alba, Quercus rubra* (Crowley's Ridge only), *Quercus falcata, Quercus pagoda, Quercus stellata, Carya texana, Quercus shumardii*, and *Quercus velutina*.
Classification Comments: This system is best developed on southern Crowley's Ridge where loess is most pronounced and is more isolated and less extensive elsewhere. More associations may need to be developed.
Similar Ecological Systems:
- Crowley's Ridge Mesic Loess Slope Forest (CES203.079)
- Crowley's Ridge Sand Forest (CES203.072)

Related Concepts:
- Dry-mesic Loess/Glacial Till Forest (Nelson 2005) Broader
- Shortleaf Pine - Oak: 76 (Eyre 1980) Finer
- Shortleaf Pine: 75 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: These forests occur on narrow ridgetops and slopes in a highly dissected environment. The system is best documented from southern Crowley's Ridge, Arkansas (Cross County south through Phillips County), with additional occurrences on the northern ridge, on the eastern border of the Grand Prairie terrace in Arkansas, on Macon Ridge (Louisiana/Arkansas) and probably on other upland sites within the alluvial plain, including Missouri and extreme western Kentucky and Tennessee. Loess soil is a characteristic and diagnostic component of the environment of this system.
Vegetation: This system consists of forests that are typically dominated by oaks and other hardwoods. Depending upon local soil moisture and other factors, canopy composition can vary from *Quercus stellata*- and *Quercus falcata*-dominated on the driest sites to *Quercus alba* and other oaks on more mesic sites. Associated species in the subcanopy and understory vary along this moisture gradient.
Dynamics: These are fire-maintained forests. In Arkansas, they generally lie to the east of hydroxeric Pleistocene terrace flatwoods or prairies (now usually converted to cropland) that burned frequently. Those fires would have continued into these dry to dry-mesic forests. There is presumably also some natural disturbance from the effects of windstorms and collapse of the fragile loess.

This loess forest type is Fire Regime Group III, surface fires with return intervals of 30 to 100 or more years. Mixed-severity fires will occur approximately every 100 years, opening the canopy with increased mortality. This effect may also be achieved by recurrent, severe insect defoliations or droughts. Straight-line winds or microbursts may cause blowdowns on a scale of 1 to 100 acres. Stand-replacement fires happen very infrequently (Landfire 2007a).

Component Associations:
- *Quercus alba - Quercus falcata - Quercus velutina / Ostrya virginiana* Forest (CEGL004068, G1G2)
- *Quercus stellata - Quercus falcata / Ostrya virginiana* Forest (CEGL004064, G1)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Lower Mississippi Alluvial Plain Grand Prairie (CES203.549)

DISTRIBUTION

Range: This system is endemic to well-drained sites on Crowley's Ridge (Arkansas, Missouri) and Macon Ridge (Louisiana/Arkansas), along the eastern slopes of the Grand Prairie terrace in Arkansas, and perhaps other such sites in the Mississippi River Alluvial Plain, including Missouri and extreme western Kentucky and Tennessee.

MONTANE BOREAL WHITE AND BLACK SPRUCE FOREST (CES105.800)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Boreal [Boreal Continental]; Glaciated; Long Disturbance Interval [Seasonality/Spring Disturbance]
Non-Diagnostic Classifiers: Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Acidic Soil
National Mapping Codes: ESLF 4274

CONCEPT

Summary: This ecological system is more common north and west of the Northern Rockies, and is truly a boreal forest type; it is considered only peripheral to the Rocky Mountain Division. The montane *Picea glauca* and *Picea mariana* forests in the Northern Rockies represent the southernmost extent of these expansive boreal forests. The southern limit appears to be related to July mean temperatures exceeding 65 degrees F and maximum of 75 degrees F, and where annual precipitation drops below 38-50 cm (15-20 inches). *Picea glauca* associations found in Banff, Jasper, Kootenay and Yoho national parks occur on gentle to moderate slopes and are generally very mature stands. Canopy ranges from closed to open forests, usually with a shrub understory, although some stands have only an herbaceous carpet. Other tree species that may be codominant in the upper canopy include *Picea mariana, Picea engelmannii X glauca, Pseudotsuga menziesii, Abies lasiocarpa,* and *Larix occidentalis*. Undergrowth components include *Rosa acicularis, Dasiphora fruticosa ssp. floribunda, Shepherdia canadensis, Menziesia ferruginea,* and *Cornus canadensis*. Herbaceous species include *Equisetum arvense* and *Triglochin maritima* and the bryophytes *Abietinella abietina (= Thuidium abietinum)* and *Hylocomium splendens*.
Classification Comments: In Alaska systems classification work, mixed white and black spruce upland forests were combined into Western North American Boreal Mesic Black Spruce Forest (CES105.107).
Similar Ecological Systems:
- Western North American Boreal Mesic Black Spruce Forest (CES105.107)
- Western North American Boreal White Spruce Forest (CES105.104)
- Western North American Boreal White Spruce-Hardwood Forest (CES105.106)

NORTH PACIFIC BROADLEAF LANDSLIDE FOREST AND SHRUBLAND (CES204.846)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Broad-Leaved Deciduous Tree
Non-Diagnostic Classifiers: Montane [Montane]; Lowland [Foothill]; Lowland [Lowland]; Temperate [Temperate Continental]
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2063; ESLF 4304; ESP 1063

CONCEPT

Summary: These forests and shrublands occur throughout the northern Pacific mountains and lowlands, becoming less prominent in the northern half of this region. They occur on steep slopes and bluffs that are subject to mass movements on a periodic basis. They are found in patches of differing age associated with different landslide events. The vegetation is deciduous broadleaf forests, woodlands, or shrublands, sometimes with varying components of conifers. *Alnus rubra* and *Acer macrophyllum* are the major tree species. *Rubus spectabilis, Rubus parviflorus, Ribes bracteosum,* and *Oplopanax horridus* are some of the major shrub species. Shrublands tend to be smaller in extent than woodlands or forests. Small patches of sparsely vegetated areas or herbaceous-dominated vegetation (especially *Petasites frigidus*) also often occur as part of this system. On earthflows, once stable, vegetation may succeed to dominance by conifers.
Classification Comments: Early-successional shrubby patches dominated by *Alnus* or *Acer* not associated with landslide disturbance are removed from this system and are placed within the forest types they are successional to, for example see North Pacific Maritime Dry-Mesic Douglas-fir-Western Hemlock Forest (CES204.001). More stable patches generally belong to North Pacific Montane Shrubland (CES204.087). For other disturbance driven shrublands, see North Pacific Avalanche Chute Shrubland (CES204.854). This system has not been determined to occur in Alaska, so for now that state is removed from its distribution.

NORTH PACIFIC DRY DOUGLAS-FIR-(MADRONE) FOREST AND WOODLAND (CES204.845)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); F-Patch/Medium Intensity; Pseudotsuga menziesii; Arbutus menziesii
Non-Diagnostic Classifiers: Lowland [Foothill]; Temperate [Temperate Oceanic]
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2035; ESLF 4222; ESP 1035

CONCEPT

Summary: This system is most common in the Puget Trough - Willamette Valley ecoregion but also occurs in adjacent ecoregions. It occupies small patches associated with dry sites or larger areas in prairie landscapes. This system historically had moderate- to low-severity fires moderately frequently. Historically, these communities were either part of larger forested landscapes or occupied sheltered topographic positions in prairie-dominated landscapes. They now also occur on some sites that formerly supported prairies or tall shrublands (*Corylus cornuta*) with scattered trees. In the mountains, this type occurs locally on dry sites within dry to mesic (for the coastal areas) climates up to about 1220 m (4000 feet) elevation. This is a forest or woodland primarily dominated by the long-lived conifer *Pseudotsuga menziesii*. The evergreen broadleaf *Arbutus menziesii*, the short-lived conifer *Pinus contorta*, the broadleaf deciduous *Acer macrophyllum*, and the shade-tolerant conifer *Abies grandis* are local dominant or codominant species. These sites are too dry and warm or have been too frequently and extensively burned for anything more than small amounts of *Tsuga heterophylla* or *Thuja plicata* to be present as regeneration. *Arbutus menziesii* dominance is favored by high-severity fires on sites where it occurs, and *Pseudotsuga menziesii* can be locally eliminated by logging and hot fire or repeated high-severity fires. *Calocedrus decurrens* is absent. *Abies grandis* can be an important subcanopy or sapling tree, especially in and around the Willamette Valley and in the driest portions of the Georgia Basin (Coastal Douglas-fir Zone).
Classification Comments: Originally named Dry Douglas-Fir and Madrone Forest and Woodland, name changed as many areas occur without madrone. However, note that the description states we can have madrone stands with no Douglas-fir; these are less common than the former.

NORTH PACIFIC DRY-MESIC SILVER FIR-WESTERN HEMLOCK-DOUGLAS-FIR FOREST (CES204.098)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Tsuga heterophylla - Abies amabilis
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2174; ESLF 4272; ESP 1174

CONCEPT

Summary: This forested system occurs only in the Pacific Northwest mountains, primarily west of the Cascade Crest. It generally occurs in an elevational band between *Pseudotsuga menziesii - Tsuga heterophylla* forests and *Tsuga mertensiana* forests. It dominates mid-montane dry to mesic maritime and some submaritime climatic zones from northwestern British Columbia to northwestern Oregon. In British Columbia and in the Olympic Mountains, this system occurs on the leeward side of the mountains only. In the Washington Cascades, it occurs on both windward and leeward sides of the mountains (in other words, it laps over the Cascade Crest to the "eastside"). Stand-replacement fires are regular with mean return intervals of about 200-500 years. Fire frequency tends to decrease with increasing elevation and continentality but still remains within this typical range. A somewhat variable winter snowpack that typically lasts for 2-6 months is characteristic. The climatic zone within which it occurs is sometimes referred to as the "rain-on-snow" zone because of the common occurrence of major winter rainfall on an established snowpack. *Tsuga heterophylla* and/or *Abies amabilis* dominate the canopy of late-seral stands, though *Pseudotsuga menziesii* is usually also common because of its long life span, and *Chamaecyparis nootkatensis* can be codominant, especially at higher elevations. *Abies procera* forests (usually mixed with silver fir) are included in this system and occur in the Cascades from central Washington to central Oregon and rarely in the Coast Range of Oregon. *Pseudotsuga menziesii* is a common species (unlike the mesic western hemlock-silver fir forest system) that regenerates after fires and therefore is frequent as a codominant, except at the highest elevations; the prevalence of this species is an important indicator in relation to the related climatically wetter North Pacific Mesic Western Hemlock-Silver Fir Forest (CES204.097). *Abies lasiocarpa* sometimes occurs as a codominant on the east side of the Cascades and in submaritime British Columbia. Understory species that tend to be more common or unique in this type compared to the wetter North Pacific Mesic Western Hemlock-Silver Fir Forest (CES204.097) include *Achlys triphylla*, *Mahonia nervosa*, *Xerophyllum tenax*, *Vaccinium membranaceum*, *Rhododendron macrophyllum*, and *Rhododendron albiflorum*. *Vaccinium ovalifolium*, while still common, only dominates on more moist sites within this type, unlike in the related type where it is nearly ubiquitous.
Classification Comments: Unlike North Pacific Mesic Western Hemlock-Silver Fir Forest (CES204.097), the dominant natural process here is stand-replacing fires which occur on average every 200-500 years. Where old-growth does exist, it is mostly "young old-growth" 200-500 years in age. Natural-origin stands less than 200 years old are also common. More mixed-severity fires occur to the south in this system, so structure, patch size and proportions will be different; further north is more stand-replacing fires. In mapzone 7 this system will get modeled as 2 different BpS because of the differences in regimes. In Oregon there are more mixed-severity fires.

Similar Ecological Systems:
- Alaskan Pacific Maritime Western Hemlock Forest (CES204.840)
- North Pacific Mesic Western Hemlock-Silver Fir Forest (CES204.097)

Related Concepts:

Adjacent Ecological Systems:

- North Pacific Maritime Dry-Mesic Douglas-fir-Western Hemlock Forest (CES204.001)
- North Pacific Maritime Mesic-Wet Douglas-fir-Western Hemlock Forest (CES204.002)

DISTRIBUTION

Range: This system only occurs in the Pacific Northwest mountains, on the leeward side of coastal mountains in both British Columbia and in the Olympic Mountains of Washington. It occurs throughout most of the Washington Cascades on both west and east sides (sporadically on the east) and in the western Cascades of northern to central Oregon. It occurs very sporadically in the Willapa Hills of southwestern Washington and in the northern Oregon Coast Range. This type may also occur on the east side of the Oregon Cascades north of 45 degrees North latitude (Mount Hood National Forest - Hood River and Barlow ranger districts, and possibly the northern edge of Warm Springs Reservation in part of the McQuinn Strip).

NORTH PACIFIC HYPERMARITIME WESTERN RED-CEDAR-WESTERN HEMLOCK FOREST (CES204.842)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Temperate [Temperate Hyperoceanic]; Tsuga heterophylla, Thuja plicata
Non-Diagnostic Classifiers: Lowland [Lowland]
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2178; ESLF 4271; ESP 1178

CONCEPT

Summary: These forests occupy the outer coastal portions of British Columbia, southeastern Alaska, and northwestern Washington. Their center of distribution is the central coast of British Columbia, as *Thuja plicata* approaches its northernmost limit in the southern half of southeastern Alaska. These forests occur mainly on islands but also fringe the mainland. They are generally less than 25 km from saltwater; elevation ranges from 0 to 600 m, and below 245 m in Alaska (above 200 m, *Chamaecyparis nootkatensis* replaces *Thuja plicata*). The climate is hypermaritime, with cool summers, very wet winters, abundant fog, and without a major snowpack. Fire is absent from this system in Alaska and rare throughout the rest of the range. These forests are influenced by gap disturbance processes and intense windstorms and not much by fire. The terrain is mostly gentle to rolling, of low topographic relief, and often rocky. Soils typically have a distinct humus layer overlying mineral horizons or bedrock; where the system is best developed in central British Columbia, the humus layers are very thick (mean 17-35 cm). Soils are often imperfectly drained, but this is not a wetland system. *Thuja plicata* and *Tsuga heterophylla* are the dominant tree species throughout, and *Chamaecyparis nootkatensis* joins them from northern Vancouver Island north. Canopy cover of trees is typically over 60%. *Pinus contorta* and *Tsuga mertensiana* can be present in some locations in the central and northern portion of the range. *Abies amabilis* occurs in British Columbia and northern Washington stands but is not typically found in southeastern Alaska. In Washington, nearly pure stands of *Tsuga heterophylla* are common and seem to be associated with microsites most exposed to intense windstorms. A shrub layer of *Gaultheria shallon*, *Vaccinium ovalifolium*, and *Menziesia ferruginea* is usually well-developed. The fern *Blechnum spicant* in great abundance is typical of hypermaritime conditions. *Oxalis oregana* (absent in Alaska) is important in the understory of moist sites in Washington. *Polystichum munitum* occurs at the northern end of its range in southeastern Alaska on well-drained sites. The abundance of *Thuja plicata* in relation to other conifers is one of the diagnostic characters of these forests; the other is the low abundance of *Pseudotsuga menziesii* (absent in Alaska) and *Picea sitchensis*. Where these forests are best developed, they occur in a mosaic with forested wetlands, bogs, and Sitka spruce forests (the latter in riparian areas and on steep, more productive soils).
Classification Comments: Yellow-cedar usually replaces western red-cedar in southern southeast Alaska at an elevation of about 152 m (500 feet). When yellow-cedar is mixed with western hemlock, and western red-cedar has dropped out, the occurrence is classified as North Pacific Mesic Western Hemlock-Yellow-cedar Forest (CES204.843). Below 152 m elevation, western red-cedar predominates; however, yellow-cedar may be present.

DESCRIPTION

Environment: These forests occur mainly on islands but also fringe the mainland and coastal fjords. They are generally less than 25 km from saltwater; elevation ranges from 0 to 600 m, and below 245 m in Alaska (above 200 m, *Chamaecyparis nootkatensis* replaces *Thuja plicata*). Climate is characterized by moist mild air from the Pacific. Frequent winter storms produce abundant precipitation as they encounter rising mountain slopes. In summer, large high-pressure areas off the coast produce prolonged spells of fine weather (Taylor 1997). The climate is classified as hypermaritime, with cool summers, very wet winters, abundant fog, and without a major snowpack (Meidinger and Pojar 1991). Rainfall is relatively high for the region at 254-380 cm (100-150 inches) rain annually, rarely as snow (Landfire 2007a). The terrain is mostly gentle to rolling, of low topographic relief, and often rocky. This type generally occurs on relatively old, acidic, humic soils with a distinct humus layer overlying mineral horizons or bedrock; where the system is best developed in central British Columbia, the humus layers are very thick (mean 17-35 cm) (Banner et al. 1993, Green and Klinka 1994, Steen and Coupe 1997). Soils are often imperfectly drained, but this is not a wetland system. Where these forests are best developed, they occur in a mosaic with forested wetlands, bogs, and Sitka spruce forests (the latter in riparian areas and on steep, more productive soils). This system represents the upper end of the productivity gradient within the Cedar-Hemlock Ecological Zone and the lower end of the Western Hemlock Ecological Zone (DeMeo et al. 1992).

Dynamics: Fire is absent from this system in Alaska and rare throughout the rest of the range, e.g., British Columbia's north coast (Banner et al. 1993, Landfire 2007a). These forests are primarily influenced by gap disturbance processes (gaps created by the death of individual trees, or small patches due to disease, insect damage and treefall following mortality). On the most exposed areas of the coastline, occasional hurricane force winds and severe storms result in major windthrow events. Less severe winds may cause breakage or early blowdown of diseased trees. The ground surface often has pit-and-mound microtopography that is formed by windthrow events. Storms are generally from the southwest and sweep across the low country of southwestern Washington, and strike either the front range of the Cascades or the southwest face of the Olympics. Wind damage tends to repeat at certain locations either due to direct exposure or due to the funneling of winds around topographic features. Wind damage tends to be more significant on the coast than further inland. Studies by USFS in southeastern Alaska show lots of broken boles as cause of tree mortality (Hennon 2008).

NORTH PACIFIC INTERIOR ASPEN FOREST (CES207.360)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane
National Mapping Codes: ESLF 4165

CONCEPT

Summary: This ecological system encompasses non-seral *Populus tremuloides* forests of the central interior of British Columbia.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC INTERIOR DRY DOUGLAS-FIR FOREST (CES207.362)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland
National Mapping Codes: ESLF 4412

CONCEPT

Summary: This ecological system encompasses forests dominated by *Pseudotsuga menziesii* that are limited to the southern interior region of British Columbia. Sites are generally level to moderately sloping with medium-textured soils. Douglas-fir dominates the overstory and tree regeneration in most stands. *Populus tremuloides* may appear within the matrix of *Pseudotsuga menziesii*. Undergrowth has sparse to moderate shrub cover, and several grass species and low-growing dry-land forbs. Moss cover is typically patchy.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC INTERIOR LODGEPOLE PINE-WHITEBARK PINE FOREST (CES207.363)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane
National Mapping Codes: ESLF 4404

CONCEPT

Summary: This ecological system encompasses dry and cold forests of the central interior of British Columbia dominated by *Pinus contorta* and *Pinus albicaulis*. These occur on rocky upper slopes and crests where soils are skeletal or shallow and drainage is very rapid. This system also occurs on flacio-fluvial deposits on lower slopes and level areas with sandy skeletal soils. Forests consist of stunted and scatted *Pinus albicaulis* with some *Abies lasiocarpa, Tsuga heterophylla*, or *Pinus contorta*. Shrub layers consist only of *Lonicera involucrata* and regenerating *Tsuga heterophylla* and *Abies lasiocarpa*. Herb layers are very sparse. Ground lichens can be codominated by feathermosses. This system is distinguished from North Pacific Sub-boreal Dry Lodgepole Pine Forest (CES207.344) by the presence of *Pinus albicaulis*.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

DESCRIPTION

Environment: These dry and cold forests of the central interior of British Columbia occur on rocky upper slopes and crests where soils are skeletal or shallow and drainage is very rapid (Banner et al. 1993, Steen and Coupe 1997). This system also occurs on flacio-fluvial deposits on lower slopes and level areas with sandy skeletal soils. The climate is typically very cold in winter and dry in summer. Some sites have little snow accumulation because of high winds and sublimation.
Dynamics: There is very little information available about vegetation dynamics directly related to this ecological system; much of the below has been inferred from the similar system, Northern Rocky Mountain Subalpine Woodland and Parkland (CES306.807), and what is known about lodgepole and whitebark pine ecology and dynamics. The major disturbance processes in this system are fire, insect pests, and possibly windthrow or snow avalanches. Both of the dominant pines are shade-intolerant, post-disturbance (generally fire) colonizers, but their regeneration strategies are quite different.

Pinus contorta is an aggressively colonizing, shade-intolerant conifer which usually occurs in lower subalpine forests in the major ranges of the western United States and Canada. Establishment is episodic and linked to stand-replacing disturbances, primarily fire. The incidence of serotinous cones varies within and among varieties of *Pinus contorta*, being most prevalent in Rocky Mountain populations (*Pinus contorta var. latifolia*). Closed, serotinous cones appear to be strongly favored by fire and allow rapid colonization of fire-cleared substrates (Burns and Honkala 1990a). Hoffman and Alexander (1980, 1983) report that in stands where *Pinus contorta* exhibits a multi-aged population structure, with regeneration occurring, there is typically a higher proportion of trees bearing nonserotinous cones. The dominance of *Pinus contorta* with *Pinus albicaulis* in this system is related to fire history and topo-edaphic conditions (Pfister et al. 1977, Steele et al. 1981). Following stand-replacing fires, *Pinus contorta* will rapidly colonize and develop into dense stands of even-aged trees. Over time, many of these stands can succeed to dominance by other more shade-tolerant conifer species. Where *Pinus contorta* is the dominant in this system, the occurrence is likely to be early- to mid-successional, which developed following fires.

Pinus albicaulis is a slow-growing, long-lived conifer that is common at higher elevations in the upper subalpine zone. It typically occurs in a mosaic of tree islands and meadows where it often colonizes sites and creates habitat for less hardy tree species. In lower subalpine forests, it is a seral species, establishing after a large disturbance such as stand-replacing fire or avalanche, or it is restricted to dry, rocky ridges where it competes well with shade-tolerant tree species. Without disturbance it will be overtopped in 100-120

years by faster growing, shade-tolerant species such as *Abies lasiocarpa*, *Tsuga mertensiana*, and *Tsuga heterophylla*. Although crown fires and hot surface fires kill *Pinus albicaulis*, it tolerates low-intensity surface fires that will kill the shade-tolerant understory. Fire intervals range from 30-300 years.

Birds and small mammals often eat and cache the large, wingless whitebark pine seeds and are responsible for the dispersal of this species. Most important is the Clark's nutcracker (*Nucifraga columbiana*), which can transport the seeds long distances and cache them on exposed windswept and burned-over sites (Tomback et al. 1990, Tomback 1998); *Pinus albicaulis* is one of only 8 pine species in the world with bird-dispersed seeds. This results in the regeneration of pines in clumps from forgotten caches (Eyre 1980, Steele et al. 1983, Burns and Honkala 1990a, Schmidt and McDonald 1990). Nutcrackers tend to cache seeds at some distance from the parent trees, and they are attracted to open sites for seed caching; this results in dispersal of whitebark pine to new sites (Tomback et al. 1990).

DISTRIBUTION

Range: This ecological system occurs entirely within central interior British Columbia.
Divisions: 207:C
Nations: CA

NORTH PACIFIC INTERIOR MESIC WESTERN HEMLOCK-WESTERN RED-CEDAR FOREST (CES207.387)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane
National Mapping Codes: ESLF 4413

CONCEPT

Summary: This ecological system represents the interior analog to the coastal version of this forest. Here *Tsuga heterophylla* and *Thuja plicata* are mixed with *Pinus contorta, Picea galuca X engelmannii* (hybrid white spruce0, and *Abies lasiocarpa*. These forests are located well within the interior, occurring primarily in the Interior Cedar-Hemlock Zone (ICH) of the Prince George Forest Region of British Columbia, in and around the Rocky Mountain Trench. The shrub, forb and grass species in the understory are a mix of Rocky Mountain and interior species such as *Acer glabrum, Spiraea betulifolia*, and *Gymnocarpium dryopteris*.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC INTERIOR MESIC-WET ROCHE SPRUCE-MIXED CONIFER FOREST (CES207.388)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland
National Mapping Codes: ESLF 4414

CONCEPT

Summary: This ecological system encompasses interior forests limited to the Interior Cedar-Hemlock Zone (ICH) very wet and wet cold variants. Forests are dominated by *Tsuga heterophylla* with *Abies lasiocarpa*, Roche spruce, the hybrid of *Picea sitchensis* with either *Picea engelmannii* or *Picea glauca*, and *Pinus contorta*. Understories tend to be rich and very mesic.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC LOWLAND MIXED HARDWOOD-CONIFER FOREST (CES204.073)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Needle-Leaved Tree; Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 4333

CONCEPT

Summary: This lowland mixed hardwood - conifer forest system occurs throughout the Pacific Northwest. It occurs on valley terraces, margins, and slopes at low elevations in the mountains of the Pacific Northwest Coast and interior valleys west of the high Cascade Mountains. These forests are composed of large conifers, including *Pseudotsuga menziesii, Thuja plicata, Abies grandis, Tsuga heterophylla*, and/or *Picea sitchensis*, with deciduous hardwood trees present and usually codominant. Major dominant broadleaf species are *Acer macrophyllum, Quercus garryana, Alnus rubra, Frangula purshiana*, and *Cornus nuttallii*. Conifers tend to increase with succession in the absence of major disturbance although the hardwoods, particularly *Acer macrophyllum*, persist in the overstory. The understory is characterized by deciduous shrubs such as *Acer circinatum, Corylus cornuta, Oemleria cerasiformis, Rubus ursinus, Symphoricarpos albus*, and *Toxicodendron diversilobum*, but evergreen shrubs, including *Gaultheria shallon* and *Mahonia nervosa* and forbs, such as *Polystichum munitum* and *Oxalis oregana*, can be dominant.

DESCRIPTION

Environment: In some places, hardwoods are truly only found in early-seral conditions. This is more true the farther north you get, so in Washington, there are a few places where hardwoods persist, outside of the dry Douglas fir - madrone forests around the Willamette Valley, Puget Trough and the western Oregon Interior Valleys. In the Coast Range and Cascades, there are hardwoods (mostly alder and bigleaf maple) found in most of the valley toeslopes. They also occur in areas with exposed talus, exposed rocks, and in dry places, and often with Oregon white oak and Oregon ash. This mix of deciduous hardwoods and conifers is a climax forest in many areas, while in others it is successional, with the conifers completely overtaking the hardwoods after 200 years or so without disturbance.

Component Associations:
- *Abies grandis - Acer macrophyllum / Symphoricarpos albus* Forest (CEGL000519, G3Q)
- *Acer macrophyllum - Pseudotsuga menziesii / Acer circinatum / Polystichum munitum* Forest (CEGL003394, G4)
- *Acer macrophyllum - Pseudotsuga menziesii / Corylus cornuta / Hydrophyllum tenuipes* Forest (CEGL000517, G3)
- *Acer macrophyllum / Acer circinatum* Forest (CEGL000560, G4G5)
- *Acer macrophyllum / Rubus spectabilis* Forest (CEGL000561, G4)

NORTH PACIFIC MARITIME DRY-MESIC DOUGLAS-FIR-WESTERN HEMLOCK FOREST (CES204.001)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Temperate [Temperate Oceanic]; Tsuga heterophylla, Pseudotsuga menziesii
Non-Diagnostic Classifiers: Montane
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2037; ESLF 4224; ESP 1037

CONCEPT

Summary: This ecological system comprises much of the major lowland forests of western Washington, northwestern Oregon, eastern Vancouver Island, and the southern Coast Ranges in British Columbia. In southwestern Oregon, it becomes local and more small-patch in nature. It occurs throughout low-elevation western Washington, except on extremely dry or moist to very wet sites. In Oregon, it occurs on the western slopes of the Cascades, around the margins of the Willamette Valley, and in the Coast Ranges. These forests occur on the drier to intermediate moisture habitats and microhabitats within the Western Hemlock Zone of the Pacific Northwest. Climate is relatively mild and moist to wet. Mean annual precipitation is mostly 90-254 cm (35-100 inches) (but as low as 20 inches in the extreme rainshadow) falling predominantly as winter rain. Snowfall ranges from rare to regular, and summers are relatively dry. Elevation ranges from sea level to 610 m (2000 feet) in northern Washington to 1067 m (3500 feet) in Oregon. Topography ranges from relatively flat glacial tillplains to steep mountainous terrain. This is generally the most extensive forest in the lowlands on the west side of the Cascades and forms the matrix within which other systems occur as patches. Throughout its range it occurs in a mosaic with North Pacific Maritime Mesic-Wet Douglas-fir-Western Hemlock Forest (CES204.002); in dry areas it occurs adjacent to or in a mosaic with North Pacific Dry Douglas-fir-(Madrone) Forest and Woodland (CES204.845), and at higher elevations it intermingles with either North Pacific Dry-Mesic Silver Fir-Western Hemlock-Douglas-fir Forest (CES204.098) or North Pacific Mesic Western Hemlock-Silver Fir Forest (CES204.097).

Overstory canopy is dominated by *Pseudotsuga menziesii*, with *Tsuga heterophylla* generally present in the subcanopy or as a canopy dominant in old-growth stands. *Abies grandis*, *Thuja plicata*, and *Acer macrophyllum* codominants are also represented. In the driest climatic areas, *Tsuga heterophylla* may be absent, and *Thuja plicata* takes its place as a late-seral or subcanopy tree species. *Gaultheria shallon*, *Mahonia nervosa*, *Rhododendron macrophyllum*, *Linnaea borealis*, *Achlys triphylla*, and *Vaccinium ovatum* typify the poorly to well-developed shrub layer. *Acer circinatum* is a common codominant with one or more of these other species. The fern *Polystichum munitum* can be codominant with one or more of the evergreen shrubs on sites with intermediate moisture availability (mesic). If *Polystichum munitum* is thoroughly dominant or greater than about 40-50% cover, then the stand is probably in the more moist North Pacific Maritime Mesic-Wet Douglas-fir-Western Hemlock Forest (CES204.002). Young stands may lack *Tsuga heterophylla* or *Thuja plicata*, especially in the Puget Lowland. *Tsuga heterophylla* is generally the dominant regenerating tree species. Other common associates include *Acer macrophyllum*, *Abies grandis*, and *Pinus monticola*. In southwestern Oregon, *Pinus lambertiana*, *Calocedrus decurrens*, and occasionally *Pinus ponderosa* may occur in these forests. Soils are generally well-drained and are mesic to dry for much of the year. This is in contrast to North Pacific Maritime Mesic-Wet Douglas-fir-Western Hemlock Forest (CES204.002), which occurs on sites where soils remain moist to subirrigated for much of the year and fires were less frequent. Fire is (or was) the major natural disturbance. In the past (pre-1880), fires were less commonly high-severity, typically mixed-severity or moderate-severity, with natural return intervals of 100 years or less in the driest areas, to a few hundred years in areas with more moderate to wet climates. In the drier climatic areas (central Oregon Cascades, Puget Lowlands, Georgia Basin), this system was typified by a (mixed) moderate-severity fire regime involving occasional stand-replacing fires and more frequent moderate-severity fires. This fire regime would create a complex mosaic of stand structures across the landscape.

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- East Cascades Mesic Montane Mixed-Conifer Forest and Woodland (CES204.086)
- North Pacific Dry Douglas-fir-(Madrone) Forest and Woodland (CES204.845)
- North Pacific Dry-Mesic Silver Fir-Western Hemlock-Douglas-fir Forest (CES204.098)
- North Pacific Maritime Mesic-Wet Douglas-fir-Western Hemlock Forest (CES204.002)
- North Pacific Mesic Western Hemlock-Silver Fir Forest (CES204.097)

Adjacent Ecological System Comments: In dry areas it occurs adjacent to or in a mosaic with North Pacific Dry Douglas-fir-(Madrone) Forest and Woodland (CES204.845) and at higher, moister elevations intermingles with either North Pacific Dry-Mesic Silver Fir-Western Hemlock-Douglas-fir Forest (CES204.098) or North Pacific Mesic Western Hemlock-Silver Fir Forest (CES204.097). Throughout its range it occurs in a mosaic with North Pacific Maritime Mesic-Wet Douglas-fir-Western Hemlock Forest (CES204.002).

DISTRIBUTION

Range: This system comprises the major lowland and low montane forests of western Washington, northwestern Oregon, and southwestern British Columbia. In British Columbia and Washington, it is uncommon to absent on the windward side of the coastal mountains where fire is rare. It also occurs locally in far southwestern Oregon (Klamath ecoregion) as small to large patches.

NORTH PACIFIC MARITIME MESIC SUBALPINE PARKLAND (CES204.837)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Late-lying snowpack; Montane [Upper Montane]; Tsuga mertensiana
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Temperate [Temperate Continental]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2038; ESLF 4225; ESP 1038

CONCEPT

Summary: This ecological system occurs throughout the mountains of the Pacific Northwest, from the southern Cascades of Oregon to the mountains of southeastern Alaska bordering British Columbia. It occurs at the transition zone of forest to alpine, forming a subalpine forest-meadow ecotone. Mountain hemlock forests, as they approach treeline, become open patches of mature-height trees surrounded by mesic and wet meadows rich in dwarf-shrubs and forbs. Clumps of trees to small patches of forest interspersed with low shrublands and meadows characterize this system. Krummholz often occurs near the upper elevational limit of this system where it grades into alpine vegetation. Associations include woodlands, forested, and subalpine meadow types. It occurs on the west side of the Cascade Mountains and is a transitional open forest into the true alpine on the interior side of the Coastal Mountains of British Columbia where deep, late-lying snowpack is the primary environmental factor. Major tree species are *Tsuga mertensiana, Abies amabilis, Chamaecyparis nootkatensis*, and *Abies lasiocarpa*. This system includes British Columbia Hypermaritime and Maritime Parkland (*Tsuga mertensiana*). Dominant dwarf-shrubs include *Phyllodoce empetriformis, Cassiope mertensiana*, and *Vaccinium deliciosum*. Dominant herbaceous species include *Lupinus arcticus ssp. subalpinus, Valeriana sitchensis, Carex spectabilis*, and *Polygonum bistortoides*. There is very little disturbance, either windthrow or fire. The major process controlling vegetation is the very deep long-lasting snowpacks (deepest in the North Pacific region) limiting tree regeneration. Trees get established only in favorable microsites (mostly adjacent to existing trees) or during drought years with low snowpack. It is distinguished from more interior dry parkland primarily by the presence of *Tsuga mertensiana* or *Abies amabilis* and absence or paucity of *Pinus albicaulis* and *Larix lyallii*.
Classification Comments: This system includes what the Alaska Natural Heritage Program called Maritime Subalpine Fir-Mountain Hemlock Forest. It is very localized in its occurrence in Alaska, occurring in the eastern portion of the panhandle at high elevations.

NORTH PACIFIC MARITIME MESIC-WET DOUGLAS-FIR-WESTERN HEMLOCK FOREST (CES204.002)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Temperate [Temperate Oceanic]; Tsuga heterophylla, Pseudotsuga menziesii
Non-Diagnostic Classifiers: Montane
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2039; ESLF 4226; ESP 1039

CONCEPT

Summary: This ecological system is a significant component of the lowland and low montane forests of western Washington, northwestern Oregon, and southwestern British Columbia. It occurs throughout low-elevation western Washington, except on extremely dry sites and in the hypermaritime zone near the outer coast where it is rare. In Oregon, it occurs on the western slopes of the Cascades, around the margins of the Willamette Valley, and on the west side of the Coast Ranges, and is reduced to locally small patches in southwestern Oregon. In British Columbia, it occurs on the eastern (leeward) side of Vancouver Island, commonly and rarely on the windward side, and in the southern Coast Ranges. These forests occur on moist habitats and microhabitats, mainly lower slopes or valley landforms, within the Western Hemlock Zone of the Pacific Northwest. They differ from North Pacific Maritime Dry-Mesic Douglas-fir-Western Hemlock Forest (CES204.001) primarily in having more hydrophilic undergrowth species, moist to subirrigated soils, high abundance of shade- and moisture-tolerant canopy trees, as well as higher stand productivity, due to higher soil moisture and lower fire frequency. Climate is relatively mild and moist to wet. Mean annual precipitation is mostly 90-254 cm (35-100 inches) (but as low as 20 inches in the extreme rainshadow) predominantly as winter rain. Snowfall ranges from rare to regular (but consistent winter snowpacks are absent or minimal), and summers are relatively dry. Elevation ranges from sea level to 610 m (2000 feet) in northern Washington to 1067 m (3500 feet) in Oregon. Topography ranges from relatively flat glacial tillplains to steep mountainous terrain. This is an extensive forest in the lowlands on the west side of the Cascades. In some wetter climatic areas, it forms the matrix within which other systems occur as patches, especially riparian wetlands. In many rather drier climatic areas, it occurs as small to large patches within a matrix of North Pacific Maritime Dry-Mesic Douglas-fir-Western Hemlock Forest (CES204.001); in dry areas, it can occur adjacent to or in a mosaic with North Pacific Dry Douglas-fir-(Madrone) Forest and Woodland (CES204.845), and at higher elevations it intermingles with either North Pacific Dry-Mesic Silver Fir-Western Hemlock-Douglas-fir Forest (CES204.098) or North Pacific Mesic Western Hemlock-Silver Fir Forest (CES204.097).

Overstory canopy is dominated by *Pseudotsuga menziesii*, *Tsuga heterophylla*, and/or *Thuja plicata*, as well as *Chamaecyparis lawsoniana* in western Oregon, away from the coast. *Pseudotsuga menziesii* is usually at least present to more typically codominant or dominant. *Acer macrophyllum* and *Alnus rubra* (the latter primarily where there has been historic logging disturbance) are commonly found as canopy or subcanopy codominants, especially at lower elevations. In a natural landscape, small patches can be dominated in the canopy by these broadleaf trees for several decades after a severe fire. *Polystichum munitum, Oxalis oregana, Rubus spectabilis*, and *Oplopanax horridus* typify the poorly to well-developed herb and shrub layers. *Gaultheria shallon, Mahonia nervosa, Rhododendron macrophyllum*, and *Vaccinium ovatum* are often present but are generally not as abundant as the aforementioned indicators; except where *Chamaecyparis lawsoniana* is a canopy codominant, they may be the dominant understory. *Acer circinatum* is a very common codominant as a tall shrub. Forested stands with abundant *Lysichiton americanus*, an indicator of seasonally flooded or saturated soils, belong in North Pacific Hardwood-Conifer Swamp (CES204.090). Stands included are best represented on lower mountain slopes of the coastal ranges with high precipitation, long frost-free periods, and low fire frequencies. Young stands may lack *Tsuga heterophylla* or *Thuja plicata*, especially in the Puget Lowland. *Tsuga heterophylla* is generally the dominant regenerating tree species. Other common associates include *Abies grandis*, which can be a codominant especially in the Willamette Valley - Puget Trough - Georgia Basin ecoregion. Soils are moist to somewhat wet but not saturated for much of the year and are well-drained to somewhat poorly drained. Typical soils for *Polystichum* sites would be deep, fine- to moderately coarse-textured, and for *Oplopanax* sites, soils typically have an impermeable layer at a moderate depth. Both types of soils are well-watered from upslope sources, seeps, or hyperheic sources. This is in contrast to North Pacific Maritime Dry-Mesic Douglas-fir-Western Hemlock Forest (CES204.001), which occurs on well-drained soils, south-facing slopes, and dry ridges and slopes where soils remain mesic to dry for much of the year. Fire is (or was) the major natural disturbance in all but the wettest climatic areas. In the past (pre-1880), fires were less commonly high-severity, typically mixed-severity or moderate-severity, with natural return intervals of a few hundred to several hundred years. This system was formerly supported by occasional, stand-replacing fires. More frequent moderate-severity fires would generally not burn these moister microsites.

Classification Comments: Stands dominated or codominated with *Chamaecyparis lawsoniana* that are within 25 km (15 miles) of the coast are part of either California Coastal Redwood Forest (CES206.921) (extreme southern Oregon and northern California) or North Pacific Seasonal Sitka Spruce Forest (CES204.841) (central and northern coastal Oregon). Stands in these areas may or may not have redwood or Sitka spruce present. Stands away for the coast and not on serpentine soils are considered part of North Pacific Maritime Mesic-Wet Douglas-fir-Western Hemlock Forest (CES204.002).

NORTH PACIFIC MESIC WESTERN HEMLOCK-SILVER FIR FOREST (CES204.097)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Forest and Woodland (Treed); Temperate [Temperate Oceanic]; Tsuga heterophylla - Abies amabilis
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2042; ESLF 4229; ESP 1042

CONCEPT

Summary: This forested system occurs only in the Pacific Northwest mountains entirely west of the Cascade Crest from coastal British Columbia to Washington, and probably occurs in southeastern Alaska. It generally occurs in an elevational band between *Pseudotsuga menziesii - Tsuga heterophylla* or hypermaritime zone forests and *Tsuga mertensiana* forests. It dominates mid-montane maritime climatic zones on the windward side of Vancouver Island, the Olympic Peninsula, and the wettest portions of the North Cascades in Washington (north of Snoqualmie River). A somewhat variable winter snowpack that typically lasts for 2-6 months is characteristic. The climatic zone within which it occurs is sometimes referred to as the "rain-on-snow" zone because of the common occurrence of major winter rainfall on an established snowpack. *Tsuga heterophylla* and/or *Abies amabilis* dominate the canopy of late-seral stands, and *Chamaecyparis nootkatensis* can be codominant, especially at higher elevations. *Thuja plicata* is also common and sometimes codominates in British Columbia. In Alaska, *Abies amabilis* occurs in nearly pure stands and in mixture with *Picea sitchensis* and *Tsuga heterophylla*. *Pseudotsuga menziesii* is relatively rare to absent in this system, as opposed to the similar but drier North Pacific Dry-Mesic Silver Fir-Western Hemlock-Douglas-fir Forest (CES204.098). The major understory dominant species is *Vaccinium ovalifolium*. Understory species that help distinguish this system from the drier silver fir system (they are much more common here) include *Oxalis oregana, Blechnum spicant,* and *Rubus pedatus*. Windthrow is a common small-scale disturbance in this system, and gap creation and succession are important processes.
Classification Comments: Jan Henderson suggests using 90 inches mean precipitation at sea level (with modification for topographic moisture) to distinguish wet and dry silver fir systems. Fire regime is significantly different at regional scale between the dry and mesic; this difference appears to be consistent throughout the range of the types. The mesic rarely, if ever, burns; it is dominated by what is sometimes called "old old-growth" stands that run from 700 to over 1000 years in age. Research in British Columbia indicates these coastal rainforests may burn an average of once every 2000 years. The major processes then are small-scale gap dynamics, not stand-replacement fires. This difference is related to climate, not site moisture, with the mesic having a very wet climate that is more coastal, less continental, with cooler summers, and warmer winters on average.

DESCRIPTION

Dynamics: Stand-replacing fires are relatively infrequent to absent, with return intervals of several hundred or more years. More mixed-severity fires occur in the southern parts of this system, so that forest structure, patch size and proportions will be different from northern stands. Further north, stand-replacing fires are also infrequent but are a more common fire event.

Component Associations:
- *Abies amabilis / Menziesia ferruginea* Forest (CEGL000224, G4)
- *Abies amabilis / Oplopanax horridus* Forest (CEGL000004, G5)
- *Abies amabilis / Polystichum munitum* Forest (CEGL000006, G4)
- *Abies amabilis / Rhododendron albiflorum* Forest (CEGL000225, G5)
- *Abies procera / Oxalis oregana* Forest (CEGL003444, G1)
- *Tsuga heterophylla - Abies amabilis - (Chamaecyparis nootkatensis) / Vaccinium alaskaense* Forest (CEGL002850, G3?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:

- North Pacific Maritime Mesic-Wet Douglas-fir-Western Hemlock Forest (CES204.002)

DISTRIBUTION

Range: This system occurs only in the Pacific Northwest mountains (Coastal and westside Cascades). It occurs on the windward side of coastal mountains in both British Columbia and in the Olympic Mountains and north Cascade Range of Washington. It may also extend north to about 56 degrees north latitude in southeastern Alaska. *Abies amabilis* has a limited distribution in Alaska, apparently confined to the extreme southern mainland and a few islands south of 56 degrees north latitude.

NORTH PACIFIC MESIC WESTERN HEMLOCK-YELLOW-CEDAR FOREST (CES204.843)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Temperate [Temperate Oceanic]; Chamaecyparis nootkatensis
Non-Diagnostic Classifiers: Lowland
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2040; ESLF 4227; ESP 1040

CONCEPT

Summary: This system occurs throughout southeastern Alaska but appears to be more common in central southeastern Alaska. It is more common on the islands than on the mainland and is less common on northern Chichagof Island than on southern Chichagof and Baranof islands. It occurs at all elevations below the Mountain Hemlock Zone and is most abundant on somewhat poorly to moderately drained slopes. In the southern part of southeastern Alaska, this system generally occupies the upper edge of the Western Hemlock Zone, from 305-610 m (1000-2000 feet) elevation. On non-alluvial low-elevation sites, *Chamaecyparis nootkatensis* abundance increases as soil drainage becomes poorer. Poor drainage results in fewer trees and, therefore, more understory light, allowing yellow-cedar to survive and reproduce despite competition from western hemlock. *Chamaecyparis nootkatensis* is more tolerant of poor soil drainage than *Tsuga heterophylla*. *Chamaecyparis nootkatensis* is a codominant with *Tsuga heterophylla* in stands with moderately open (50-70%) canopies. Yellow-cedar cover typically ranges from 5-50% and rarely dominates the overstory. *Picea sitchensis* may be an overstory component. The canopy is typically multilayered, with *Tsuga heterophylla* dominating the lower layers. This system intergrades with *Tsuga mertensiana* forests, and *Tsuga mertensiana* may occur in transitional stands. The shrub layer is relatively well-developed (>50%) in late-seral stands and includes *Vaccinium ovalifolium* and *Menziesia ferruginea*, with *Lysichiton americanus* and *Coptis* spp. as consistently present herbaceous species. *Blechnum spicant* is the most common fern, while *Dryopteris expansa* is nearly absent from this type. This system is distinguished by the codominance of *Chamaecyparis nootkatensis* and *Tsuga heterophylla* and the absence or rarity of *Thuja plicata*, *Picea sitchensis*, and *Abies amabilis*.
Classification Comments: This system is found only in southeastern Alaska. Poorly drained, low-productivity woodlands of *Chamaecyparis nootkatensis* are placed into a different system.

CONCEPT

Summary: This forested ecological system occurs throughout the mountains of the North Pacific, from the southern Cascades of Oregon north to southwestern British Columbia. It is the predominant forest of subalpine elevations in the coastal mountains of British Columbia, western Washington and western Oregon. It also occurs on mountain slopes on the outer coastal islands of British Columbia. It lies between the Western Hemlock, Pacific Silver Fir, or Shasta Red Fir zones and the Subalpine Parkland or Alpine Tundra Zone, at elevations ranging from 300 to 2300 m (1000-7500 feet). The lower and upper elevational limits decrease from south to north and from east to west. The climate is generally characterized by short, cool summers, rainy autumns and long, cool, wet winters with heavy snow cover for 5-9 months. The heavy snowpack is ubiquitous, but at least in southern Oregon and perhaps the eastern Cascades, summer drought is more significant. Fire is very rare or absent across the majority of the range of the system. *Tsuga mertensiana* is one of the dominant tree species throughout, and *Abies amabilis* becomes an important associated species in the southern portion of the range (British Columbia, Washington, and northwestern Oregon). *Tsuga heterophylla* often occurs at lower elevations in this system but is much less abundant than *Tsuga mertensiana*. *Chamaecyparis nootkatensis* occurs in the more coastal portions, while *Abies lasiocarpa* is found inland and becomes increasingly common near the transition to the Subalpine Fir-Engelmann Spruce Zone in the Cascades and British Columbia. On the leeward side of the Cascades, this is usually a dense canopy composed of *Abies lasiocarpa* and *Tsuga mertensiana*, with some *Picea engelmannii* or *Abies amabilis*. In the Cascades of central to southern Oregon, *Abies X shastensis* is typically present and often codominant. *Picea sitchensis* and *Thuja plicata* are occasionally present. Deciduous trees are rare. Common understory species include *Vaccinium ovalifolium, Menziesia ferruginea, Elliottia pyroliflorus*, and *Blechnum spicant*. Parklands (open woodlands or sparse trees with dwarf-shrub or herbaceous vegetation) are not part of this system but of North Pacific Maritime Mesic Subalpine Parkland (CES204.837) or Alaskan Pacific Maritime Subalpine Mountain Hemlock Woodland (CES204.143).

Classification Comments: Farther inland, *Tsuga mertensiana* becomes limited to the coldest and wettest pockets of the more continental subalpine fir forests, described from the eastern Cascades and northern Rocky Mountains. In the northern Rocky Mountains of northern Idaho and Montana, *Tsuga mertensiana* occurs as patches within the matrix of Rocky Mountain Subalpine Mesic-Wet Spruce-Fir Forest and Woodland (CES306.830) only in the most maritime of environments and is included in the spruce-fir system. In the northern Rocky Mountains, this forest system is codominated by *Abies lasiocarpa* and/or *Picea engelmannii*. Mountain hemlock forests in Alaska are placed into Alaskan Pacific Maritime Mountain Hemlock Forest (CES204.142) or Alaskan Pacific Maritime Subalpine Mountain Hemlock Woodland (CES204.143).

DESCRIPTION

Dynamics: In the more summer-dry climatic areas (Cascades), occasional high-severity fires occur, with return intervals of 400-600 years (J. Kertis pers. comm. 2006, K. Kopper pers. comm. 2006). On drier sites, *Abies lasiocarpa* and *Pinus contorta* can be the first forests to develop after stand-replacing fire. These early-seral stages, with lodgepole pine dominant in the upper canopy, could be classified and mapped as Rocky Mountain Lodgepole Pine Forest (CES306.820) but should be considered part of this system if other tree species listed above are present, as it will succeed as a mixed pine type, then mountain hemlock becomes characteristic. Landfire VDDT models: R#ABAMup.

Component Associations:
- *Abies lasiocarpa - (Pinus contorta) / Lupinus arcticus ssp. subalpinus* Woodland (CEGL000316, G2)
- *Tsuga mertensiana - Abies amabilis / Caltha leptosepala ssp. howellii* Forest (CEGL000501, G3)
- *Tsuga mertensiana - Abies amabilis / Elliottia pyroliflorus* Woodland (CEGL000503, G3G4)
- *Tsuga mertensiana - Abies amabilis / Oplopanax horridus* Forest (CEGL000507, G3G4)

NORTH PACIFIC OAK WOODLAND (CES204.852)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Temperate [Temperate Oceanic]; Quercus garryana
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2008; ESLF 4101; ESP 1008

CONCEPT

Summary: This ecological system is limited to the southern portions of the North Pacific region. It occurs primarily in the Puget Trough and Willamette Valley but trickles down into the Klamath ecoregion and into California. This system is associated with dry, predominantly low-elevation sites and/or sites that experienced frequent presettlement fires. In the Willamette Valley, soils are mesic yet well-drained, and the type is clearly large patch in nature. In the Puget Lowland and Georgia Basin, this system is primarily found on dry sites, typically either shallow bedrock soils or deep gravelly glacial outwash soils. It occurs on various soils in the interior valleys of the Klamath Mountains, and on shallow soils of "bald hill" toward the coast. Even where more environmentally limited, the system is strongly associated with a pre-European settlement, low-severity fire regime. Succession in the absence of fire tends to favor increased shrub dominance in the understory, increased tree density, and increased importance of conifers, with the end result being conversion to a conifer forest. The vegetation ranges from savanna and woodland to forest dominated by deciduous broadleaf trees, mostly *Quercus garryana*. Codominance by the evergreen conifer *Pseudotsuga menziesii* is common, and *Pinus ponderosa* is important in some stands. In the south, common associates also include *Quercus kelloggii* and *Arbutus menziesii*. This system merges into Mediterranean California Lower Montane Black Oak-Conifer Forest and Woodland (CES206.923) on sites that support more conifer cover, and into Mediterranean California Mixed Oak Woodland (CES206.909) in the southern portion of its distribution. This system is borderline between small patch and large patch in its dynamics.
Classification Comments: East of the Cascade Crest is a different system dominated by Oregon white oak (i.e., East Cascades Oak-Ponderosa Pine Forest and Woodland (CES204.085)). While *Quercus garryana* does occur in California, it is uncertain that this system (a Garry oak-dominated woodland) does not occur that far south. Garry oak in California may be mostly shrubby form around the edges of balds or else mixed into woodlands dominated by other species; this needs further review.
Similar Ecological Systems:
- Mediterranean California Mixed Oak Woodland (CES206.909)

Related Concepts:
- Oregon White Oak: 233 (Eyre 1980) Equivalent

DESCRIPTION

Environment: This type is associated with dry, predominantly low-elevation sites and/or sites that experienced frequent presettlement fires. In the Willamette Valley, soils are mesic yet well-drained, and the type is clearly large patch in nature. In the Puget Lowland and Georgia Basin, this system is primarily found on dry sites, typically either on shallow bedrock soils or deep gravelly glacial outwash soils. It occurs on various soils in the interior valleys of the Klamath Mountains, and on shallow soils of "bald hills" toward the coast.
Dynamics: Even where more environmentally limited, the system is strongly associated with a pre-European settlement, low-severity fire regime. Succession in the absence of fire tends to favor increased shrub dominance in the understory, increased tree density, and increased importance of conifers, with the end result being conversion to a conifer forest. Landfire (2007a) model: Fire Regime I, primarily short-interval (e.g., <10 years) surface fires. Surface fires every 3-10 years maintained an open savanna-like structure. Fires can be mixed-severity especially when closed-canopy conditions or additional species such as conifers and shrubs are present. Native American burning was a significant factor in fire frequency of this type, but fire frequency may have decreased significantly with a little distance from native settlements and valley bottoms. Landfire VDDT models: #R OWOA Oregon White Oak applies to southern occurrences. Dissemination of acorns by squirrels and chipmunks is thought to be the most important long-distance dispersal mechanism for the oaks (WNHP 2011).

Component Associations:
- *Pseudotsuga menziesii - Quercus garryana / Melica subulata* Forest (CEGL003355, G1)
- *Pseudotsuga menziesii - Quercus garryana / Symphoricarpos albus* Woodland (CEGL000929, G2G3)
- *Quercus garryana / Carex inops - Camassia quamash* Woodland (CEGL000548, G1)
- *Quercus garryana / Ceanothus cuneatus / Festuca idahoensis* Woodland (CEGL000930, G2)
- *Quercus garryana / Symphoricarpos albus / Carex inops* Woodland (CEGL003358, G2)
- *Quercus garryana / Symphoricarpos albus / Polystichum munitum* Forest (CEGL003353, G2)
- *Quercus garryana / Toxicodendron diversilobum / Elymus glaucus* Woodland (CEGL000932, G2)
- *Quercus garryana / Viburnum ellipticum - Toxicodendron diversilobum* Woodland (CEGL003354, G1)

Spatial Characteristics

Spatial Summary: This system is borderline between small patch and large patch in its dynamics.

Adjacent Ecological Systems:

- Mediterranean California Lower Montane Black Oak-Conifer Forest and Woodland (CES206.923)
- Mediterranean California Mixed Oak Woodland (CES206.909)

Adjacent Ecological System Comments: This system merges into Mediterranean California Lower Montane Black Oak-Conifer Forest and Woodland (CES206.923) on sites that support more conifer cover, and into Mediterranean California Mixed Oak Woodland (CES206.909) in the southern portion of its distribution.

Distribution

Range: This system occurs primarily in the Puget Trough and Willamette Valley and extends southward at low elevations in the Klamath Mountains on both sides of the Oregon/California stateline.

NORTH PACIFIC SEASONAL SITKA SPRUCE FOREST (CES204.841)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Temperate [Temperate Hyperoceanic]; Picea sitchensis
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2036; ESLF 4223; ESP 1036

CONCEPT

Summary: This ecological system is restricted to the hypermaritime climatic areas near the Pacific Coast from Point Arena, California, north to northern Vancouver Island, British Columbia. These forests are typically dominated or codominated by *Picea sitchensis* and often have a mixture of other conifers present, such as *Tsuga heterophylla, Thuja plicata, Pseudotsuga menziesii*, or *Chamaecyparis nootkatensis*. *Tsuga heterophylla* is very often codominant. In the southern extent (in Oregon, but not in California), *Abies grandis, Acer circinatum, Alnus rubra, Acer macrophyllum, Chamaecyparis lawsoniana*, and *Frangula purshiana (= Rhamnus purshiana)* can be associates, while *Chamaecyparis nootkatensis* is completely absent. Wet coastal environments that support stands of *Chamaecyparis lawsoniana* in the absence of *Picea sitchensis* are also part of this system. The understory is rich with shade-tolerant shrubs and ferns, including *Gaultheria shallon, Vaccinium ovatum, Polystichum munitum, Dryopteris* spp., and *Blechnum spicant*, as well as a high diversity of mosses and lichens. This ecological system is restricted to the hypermaritime climatic areas near the Pacific Coast from Point Arena, California, north to northern Vancouver Island and Smith Sound on the mainland coast of British Columbia. They are generally limited to areas within 25 km or so of saltwater and are most abundant along the coast of Vancouver Island, southern portions of coastal mainland British Columbia, and the Olympic Peninsula of Washington. This ecosystem is defined as the "Seasonal Rain Forest" by Wolf et al. (1995), as the climate has abundant rainfall in the winter months and very little in the summer months. At the northern boundary this Sitka spruce forest ecosystem merges into Alaska Maritime Sitka Spruce (CES204.151) which has more continuous year-round rainfall and lacks Douglas-fir. North Pacific Seasonal Sitka Spruce Forest (CES204.841) occurs on outermost coastal fringe where salt spray is prominent, riparian terraces and valley bottoms near the coast where there is major fog accumulation, and on steep, well-drained productive slopes not directly adjacent to the outer coast but within the hypermaritime zone. Annual precipitation ranges from 65 to 550 cm, with the majority falling as rain. Winter rains can be heavy. When summer drought occurs it is typically short in duration and ameliorated by frequent, dense coastal fog and cloud cover. In fact the fog belt becomes more and more important in the southern half of this ecosystem's distribution. In Washington and Oregon, it is found mostly below 300 m elevation. It also occurs as a very narrow strip or localized patches along the southern Oregon and northern California coasts. The disturbance regime is mostly small-scale windthrow or other gap mortality processes (though there are occasional widespread intense windstorms) and very few fires, the latter mainly in Oregon.

Classification Comments: Stands dominated or codominated with *Chamaecyparis lawsoniana* that are within 25 km (15 miles) of the coast are part of either California Coastal Redwood Forest (CES206.921) (extreme southern Oregon and northern California) or North Pacific Seasonal Sitka Spruce Forest (CES204.841) (central and northern coastal Oregon). Stands in these areas may or may not have redwood or Sitka spruce present. Stands away for the coast and not on serpentine soils are considered part of North Pacific Maritime Mesic-Wet Douglas-fir-Western Hemlock Forest (CES204.002).

DESCRIPTION

Environment: From Vancouver Island south, the forest is not confined to fjords, but a marked orographic effect from the Coast and Cascade ranges limits its interior extent. At its southern extent, the zone narrows again, confined to the fog belt not by mountains but by moisture. It is restricted to the hypermaritime climatic areas (Meidinger and Pojar 1991) near the Pacific coast, along a fog belt from Point Arena, California, north to northern Vancouver Island, British Columbia. These forests are generally restricted to areas within 25 km of saltwater and are most abundant along the coast of Vancouver Island, southern portions of coastal British Columbia, and the Olympic Peninsula of Washington. Sites include the outermost coastal fringe where salt spray is prominent, riparian terraces and valley bottoms near the coast where there is major fog accumulation, and in the northern half of its range starting in central British Columbia, steep, well-drained productive slopes not directly adjacent to the outer coast but within the hypermaritime zone (Banner et al. 1993, Green and Klinka 1994, Steen and Coupe 1997). Annual precipitation ranges from 65 to 550 cm, with the majority falling as rain. Winter rains can be heavy. The climate has more seasonal rainfall than coastal areas to the north, with a pronounced drought in summer months. Summer drought does occur, but it is typically short in duration and ameliorated by frequent, dense coastal fog and cloud cover. This forest type also dominates lower elevations (to 350 m) on the leeward side of the Queen Charlotte Islands in British Columbia. In Washington and Oregon, it is found mostly below 300 m elevation. It also occurs as a very narrow strip or localized patches along the southern Washington, Oregon and northern California coasts.

Dynamics: The disturbance regime is mostly small-scale windthrow or other gap mortality processes (though there are occasional widespread intense windstorms) and very few fires, the latter mainly in Oregon. Sitka spruce acts as an early colonizer of disturbed sites, such as land slumps, fluvial deposits, recently deglaciated areas. Seeds germinate best on bare mineral soil, a mixture of mineral soil and organic soil, and nurse-logs (Sawyer et al. 2009). Landfire (2007a) model: The disturbance regime is mostly small-scale windthrow or other gap mortality processes (though there are occasional widespread intense windstorms) and very few fires, the latter mainly in Oregon. Where fire does occur, it is usually stand-replacing, with a fire return interval of 300-1000 years or longer. In most of the range of the type, windthrow is a more significant catastrophic disturbance than wildfire. Windthrow "rotation" is estimated to be between 100-200 years, (but can be up to 1000 years due to patchiness). The effects of windthrow are strongly correlated with topography and adjacent land use (e.g., clearcuts). Landfire VDDT models: R#SSHE Sitka spruce - hemlock.

Component Associations:

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- California Coastal Closed-Cone Conifer Forest and Woodland (CES206.922)
- California Coastal Redwood Forest (CES206.921)
- North Pacific Hypermaritime Western Red-cedar-Western Hemlock Forest (CES204.842)

Adjacent Ecological System Comments: From Washington north, it occurs as patches within a matrix or mosaic of North Pacific Hypermaritime Western Red-cedar-Western Hemlock Forest (CES204.842) and wetlands. In California, it occurs adjacent to California Coastal Redwood Forest (CES206.921) and California Coastal Closed-Cone Conifer Forest and Woodland (CES206.922).

DISTRIBUTION

Range: This ecological system is restricted to the hypermaritime climatic areas near the Pacific coast from Point Arena, California, north to northern Vancouver Island and Smith Sound on the mainland coast of British Columbia (S. Saunders pers. comm. 2013), where it merges with its northern counterpart, Alaskan Pacific Maritime Sitka Spruce Forest (CES204.151).

NORTH PACIFIC SUB-BOREAL MESIC HYBRID WHITE SPRUCE-DOUGLAS-FIR FOREST (CES207.350)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Plateau
National Mapping Codes: ESLF 4410

CONCEPT

Summary: This ecological system encompasses forests of the southern interior occurring in southern positions and lower elevations with respect to the other variants. Winter precipitation is relatively low for the region, with snowpacks generally accumulating up to about 2 m in depth. Forests are dominated by a combination of *Pseudotsuga menziesii*, *Pinus contorta*, and *Picea glauca X engelmannii* (hybrid white spruce). In the interior portions of British Columbia, Douglas-fir may increase with global warming. This system may be a subset of the mesic hybrid white spruce system, but it is separated due to the predominance of Douglas-fir and as a warmer climate indicator. Undergrowth is rich, with 30% shrub cover, 80% moss cover and 50% herbaceous layer.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC SUB-BOREAL SUBALPINE FIR-HYBRID WHITE SPRUCE PARKLAND (CES207.358)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]
National Mapping Codes: ESLF 4411

CONCEPT

Summary: This ecological system encompasses forests of the central interior subalpine altitudes transitioning into the alpine. Parklands are clumps of full-height trees of *Picea glauca X engelmannii* (hybrid white spruce) and *Abies lasiocarpa*, with wet and mesic meadows in the openings between tree patches.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC WOODED VOLCANIC FLOWAGE (CES204.883)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Rock Outcrops/Barrens/Glades; Very Shallow Soil; Lava Flow
Non-Diagnostic Classifiers: Escarpment; Long (>500 yrs) Persistence; Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Temperate [Temperate Continental]; Butte
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2173; ESLF 4329; ESP 1173

CONCEPT

Summary: This ecological system is found from foothill to subalpine elevations and includes woodland to sparsely vegetated landscapes (generally >10% plant cover) on recent lava flows, excessively well-drained lahars, debris avalanches and pyroclastic flows. The characteristic feature of this system is the substrate limiting characteristic that creates an environment for a more open vegetation than the surrounding closed matrix forest. Examples are recent lava flows (3500-8200 years ago) on the north side of Mount Adams (andecite) and the big lava beds (basalt) south of Indian Heaven west of Mount Adams, Washington, and lahars (200-2000 years old) at Old Maid Flat west of Mount Hood, Oregon. These areas support open to sparse tree cover; characteristic species include *Pseudotsuga menziesii, Pinus contorta, Pinus monticola,* and *Abies lasiocarpa*. Tree cover can range from scattered (5%) up to 70% or occasionally even more. There may be scattered to dense shrubs present, such as *Acer circinatum, Vaccinium membranaceum, Arctostaphylos uva-ursi* (very characteristic), *Mahonia nervosa, Amelanchier alnifolia,* and *Xerophyllum tenax*. Soil development is limited, and mosses and lichens often cover the soil or rock surface.
Classification Comments: This system will include areas that fit the sparsely vegetated system type definition but are included here and delineated by the boundary of lava or other volcanic flowage. Elevation range (>3350 m) for this system is great, but the specialized substrate is the overriding factor defining it. These are mid-stages of primary succession that differ in degree of forest cover, soil development and productivity. Early primary succession on these substrates are included in North Pacific Active Volcanic Rock and Cinder Land (CES204.092). Later primary succession stages (increased soil development) are included in appropriate matrix forest systems.
Related Concepts:
- Lodgepole Pine: 218 (Eyre 1980) Intersecting

SPATIAL CHARACTERISTICS

Size: Big lava bed in Washington approx. 16,000 acres; Mount Adams north side approx. 8000 acres. Can also be quite small, e.g., lahar at Longmire on Mount Rainier less than 100 acres.

DISTRIBUTION

Range: This uncommon system is found in the east and west Cascades of Washington and Oregon, and may occur in small patches in northern California in the vicinity of Mount Lassen or Mount Shasta.
Divisions: 204:C
Nations: US
Subnations: CA?, OR, WA

NORTH-CENTRAL INTERIOR BEECH-MAPLE FOREST (CES202.693)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Glaciated; Acer saccharum - Fagus grandifolia
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2313; ESLF 4119; ESP 1313

CONCEPT

Summary: This system is found primarily along the southern Great Lakes ranging from central Indiana to southern Ontario. It is typically found on flat to rolling uplands to steep slopes with rich loam soils over glacial till. This system is characterized by a dense tree canopy that forms a thick layer of humus and leaf litter leading to a dense and rich herbaceous layer. *Acer saccharum* and *Fagus grandifolia* comprise up to 80% of the canopy. Canopy associates can include *Quercus rubra*, *Tilia americana*, and *Liriodendron tulipifera* with *Carpinus caroliniana* and *Ostrya virginiana* common in the understory and subcanopy. The relative dominance of sugar maple compared to other tree species varies across the range of this system based on regional climate and microclimate. The herbaceous layer is very diverse and typically includes spring ephemerals. Some common species include *Arisaema triphyllum*, *Osmorhiza claytonii*, *Polygonatum biflorum*, and *Trillium grandiflorum*. The primary natural disturbance influencing this system includes wind-driven gap dynamics. Conversion to agriculture has significantly decreased the range of this system, and very few large stands remain intact.
Classification Comments: North-Central Interior Wet Flatwoods (CES202.700) may co-occur in close proximity to this system on clay-plain landscapes. This is on richer sites than the corresponding Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593).
Similar Ecological Systems:
- Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593)--occurs on poorer sites.
- Laurentian-Acadian Northern Hardwood Forest (CES201.564)--can have inclusions of richer stands. Eastern rich forests CEGL005008 are placed in CES201.564, and range for that system includes Mapzones 41, 50, 51.
- North-Central Interior Maple-Basswood Forest (CES202.696)--less beech.
- South-Central Interior Mesophytic Forest (CES202.887)-- present system is in glaciated landscape; this one (CES202.887) is not.

Related Concepts:
- Beech - Sugar Maple: 60 (Eyre 1980) Finer
- Sugar Maple - Beech - Yellow Birch: 25 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is typically found on flat to rolling uplands to steep slopes with rich loam soils over glacial till. It occurs principally on medium- or fine-textured ground moraine, medium- or fine-textured end moraine, and silty/clayey glacial lakeplains. Sand dunes and sandy lakeplains can support these systems where proximity to the Great Lakes modifies local climate (within 10-20 miles of the shore, evapotranspiration conditions are suitable for mesic forest). Prevalent topographic positions of this community are gentle to moderate slopes and level areas with moderate to good drainage. Where mesic southern forest occurs on steeper slopes, it is often associated with northern to eastern exposures which receive low amounts of direct sunlight and are characterized by a cool, moist microclimate.

It can occur on a variety of soil types, but loam is the predominant texture. The diversity of soils which can support this system include sand, sandy loam, loamy sand, loam, silt loam, silty clay loam, clay loam, and clay. Soils are typically well-drained with high water-holding capacity and high nutrient and soil organism content. High soil fertility is maintained by nutrient inputs from the decomposition of deciduous leaves which enrich the top layer of soil (Cohen 2004).
Dynamics: Small-gap development and replacement due to tree death is the prevalent disturbance factor influencing this system. Catastrophic fire and/or wind can impact this system over long return intervals but are rare. Tree canopy tends to be closed so understory plants receive little light after leaf-out in the spring. This system could form large stands or be part of a large forested landscape in conjunction with other forested types, resulting in a relatively high proportion of forest interior to forest edge.

Component Associations:
- *Acer saccharum - Fagus grandifolia - Betula* spp. / *Maianthemum canadense* Forest (CEGL005004, G4G5)
- *Fagus grandifolia - Acer saccharum* Glaciated Midwest Forest (CEGL005013, G2G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- North-Central Interior Wet Flatwoods (CES202.700)

Adjacent Ecological System Comments: North-Central Interior Wet Flatwoods (CES202.700) may co-occur in close proximity to this system on clay-plain landscapes.

DISTRIBUTION

NORTH-CENTRAL INTERIOR DRY OAK FOREST AND WOODLAND (CES202.047)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Outwash plain; Forest and Woodland (Treed); Sand Soil Texture; Intermediate Disturbance Interval; F-Patch/Medium Intensity
Non-Diagnostic Classifiers: Outwash terrace; Acidic Soil; Ustic; Xeric
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2311; ESLF 4117; ESP 1311

CONCEPT

Summary: This system is found throughout the glaciated regions of the Midwest, typically in gently rolling to flat landscapes. It can occur on uplands within the prairie matrix or within the context of dry-mesic oak-hickory forests and oak savannas. These are common on rolling glacial moraines and outwash plains. Soils are typically well-drained to excessively drained Mollisols or Alfisols that range from sand to sandy loam in texture. Historically, this type was quite extensive in Michigan, Indiana, Illinois, Missouri, Iowa, Wisconsin, and Minnesota. It is distinguished from other forested systems within the region by a dry edaphic condition that is transitional between dry prairies, oak barrens, or savannas and dry-mesic oak-hickory forests and woodlands. Forest cover can range from dense to moderately open canopy. Fire-resistant oak species, in particular *Quercus velutina, Quercus macrocarpa, Quercus coccinea*, and *Quercus ellipsoidalis*, dominate the overstory. *Carya glabra, Prunus serotina*, and *Sassafras albidum* are also common in portions of the range of this system. Depending on range of distribution and overstory canopy density, the understory may include species such as *Gaylussacia baccata* (in Michigan, Wisconsin, and Minnesota), *Vaccinium angustifolium*, and *Rhus aromatica*, and/or a mixture of woodland and grassland species, including *Schizachyrium scoparium, Deschampsia flexuosa*, and *Carex pensylvanica*. Extreme drought, along with periodic ground and crown fire events, constitute the main natural processes for this type and likely maintained a more open canopy structure that supported oak regeneration. In fact, many current examples of this type have resulted from long-term fire suppression and conversion of oak barrens to these forests and woodlands. Fire suppression may also account for examples of this system with the more dry-mesic understory. It likely has allowed for other associates such as *Quercus rubra* and *Fraxinus americana* to become more prevalent. Extensive conversion for agriculture in the surrounding landscape with more productive soils has fragmented and isolated examples of this system. It is found primarily within the "corn belt" of the United States, and remaining large areas of this system are likely under considerable pressure due to conversion to pastureland and urban development.

Classification Comments: This system is related to North-Central Interior Dry-Mesic Oak Forest and Woodland (CES202.046), which has white oak, red oak, and bur oak, and occurs on somewhat deeper soils; the present system has oak savannas and oak-hickory and occurs on sandplains. Applying this concept difference to drawing lines on the ground can be tricky.

Similar Ecological Systems:
- North-Central Interior Dry-Mesic Oak Forest and Woodland (CES202.046)

Related Concepts:
- Northern Pin Oak: 14 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: This system can occur on uplands within the prairie matrix or within the context of dry-mesic oak-hickory forests and oak savannas. These are common on rolling glacial moraines and outwash plains and, less frequently, old dunes. Soils are typically well-drained to excessively drained Mollisols or Alfisols that range from sand to sandy loam in texture. Dry soils or landscape position (steep slopes, upper slopes, south- or west-facing aspect) favor the formation of this system. Historically, this type was quite extensive in Michigan, Indiana, Illinois, Missouri, Iowa, Wisconsin, and Minnesota. It is distinguished from other forested systems within the region by a dry edaphic condition that is transitional between dry prairies, oak barrens, or savannas and dry-mesic oak-hickory forests and woodlands.

Vegetation: Forest cover can range from a dense to moderately open canopy. Fire-resistant oak species, in particular *Quercus velutina, Quercus macrocarpa, Quercus coccinea*, and *Quercus ellipsoidalis*, dominate the overstory. *Carya glabra, Prunus serotina*, and *Sassafras albidum* are also common in portions of the range of this system. Depending on range of distribution and overstory canopy density, the understory may include species such as *Gaylussacia baccata* (in MI, WI, and MN), *Vaccinium angustifolium*, and *Rhus aromatica*, and/or a mixture of woodland and grassland species, including *Schizachyrium scoparium, Deschampsia flexuosa*, and *Carex pensylvanica*.

Dynamics: Extreme drought, along with periodic ground and crown fire events, constitute the main natural processes for this type and likely maintained a more open canopy structure that supported oak regeneration. In fact, many current examples of this type have resulted from long-term fire suppression and conversion of oak barrens to these forests and woodlands. Frequency of fires necessary to maintain this system varied, largely depending on soil fertility and drainage, with more fertile and mesic sites requiring more frequent

fires. Fire-return intervals of 5-20 years would typically maintain a woodland or oak grub shrubland, while fire-return intervals of 20-50 years would typically maintain a closed canopy oak forest (Landfire 2007a). Fire suppression may also account for examples of this system with the more dry-mesic understory. It likely has allowed for other associates such as *Quercus rubra* and *Fraxinus americana* to become more prevalent.

Component Associations:
- *Quercus ellipsoidalis - (Quercus macrocarpa)* Forest (CEGL002077, G4?)
- *Quercus velutina - (Quercus ellipsoidalis) - Quercus alba / Deschampsia flexuosa* Woodland (CEGL005029, GNR)
- *Quercus velutina - Quercus alba - Carya (glabra, ovata)* Forest (CEGL002076, G4?)
- *Quercus velutina - Quercus alba / Vaccinium (angustifolium, pallidum) / Carex pensylvanica* Forest (CEGL005030, G4?)
- *Quercus velutina / Carex pensylvanica* Forest (CEGL002078, G4?)

NORTH-CENTRAL INTERIOR DRY-MESIC OAK FOREST AND WOODLAND (CES202.046)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Udic; F-Patch/Low Intensity; Quercus - Carya
Non-Diagnostic Classifiers: Footslope; Glaciated uplands; Kame moraine; Lakeplain; Moraine; Temperate [Temperate Continental]; Mesotrophic Soil; Loam Soil Texture
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2310; ESLF 4116; ESP 1310

CONCEPT

Summary: This system is found throughout the glaciated regions of the Midwest, typically in gently rolling landscapes. It can occur on uplands within the prairie matrix and near floodplains, or on rolling glacial moraines and among kettle-kame topography. Soils are typically well-drained Mollisols or Alfisols that range from loamy to sandy loam or even coarse sands in texture. Historically, this type was quite extensive in Michigan, Indiana, Illinois, Missouri, Iowa, Wisconsin, and Minnesota. Well over 700,000 hectares likely occurred in southern Michigan alone (ca. 1800). It is distinguished from other forested systems within the region by a dry-mesic edaphic condition that is transitional between dry oak forests and woodlands and mesic hardwood forests, such as maple-basswood forests. Forest cover can range from a dense to moderately open canopy and there is commonly a dense shrub layer. Fire-resistant oak species, in particular *Quercus macrocarpa, Quercus rubra*, and/or *Quercus alba*, dominate the overstory. *Carya* spp., including *Carya ovata, Carya cordiformis*, and *Carya alba (= Carya tomentosa)*, are diagnostic in portions of the range of this system. Depending on site location and overstory canopy density, the understory may include species such as *Amelanchier* spp., *Aralia nudicaulis, Corylus americana, Desmodium glutinosum, Maianthemum stellatum, Osmunda claytoniana, Phryma leptostachya, Trillium grandiflorum*, and *Viburnum acerifolium*. Occasionally, prairie grasses such as *Andropogon gerardii* and *Panicum virgatum* may be present. Fire constitutes the main natural process for this type and likely maintained a more open canopy structure to support oak regeneration. Historic fire frequency was likely highest in the prairie-forest border areas. Fire suppression may account for the more closed oak forest examples of this system with the more mesic understory. It likely has allowed for other associates, such as *Acer saccharum, Acer rubrum, Celtis occidentalis, Liriodendron tulipifera, Ostrya virginiana*, and *Juglans nigra*, to become more prevalent, especially in upland areas along floodplains. Periodic drought, intensified by local conditions, such as slope, southern exposure, or sandy soil, also inhibit growth of mesophytic trees. Extensive conversion for agriculture has fragmented this system. Continued fire suppression has also resulted in succession to mesic hardwoods, such that in many locations, no oak species are regenerating. Remaining large areas of this system are likely under considerable pressure due to conversion to agriculture, pastureland, and urban development.
Classification Comments: This is the predominant oak system for the upper Midwest, and is more extensive on the landscape than the related North-Central Interior Dry Oak Forest and Woodland (CES202.047).

DESCRIPTION

Environment: This system can occur on uplands within the prairie matrix and near floodplains, or on rolling glacial moraines and kettle-kame topography. Soils are typically well-drained Mollisols or Alfisols that range from loamy to sandy loam or even coarse sands in texture. Historically, this type was quite extensive in Michigan, Indiana, Illinois, Missouri, Iowa, Wisconsin, and Minnesota. Well over 700,000 hectares likely occurred in southern Michigan alone (ca. 1800). It is distinguished from other forested systems within the region by a dry-mesic edaphic condition that is transitional between dry oak forests and woodlands and mesic hardwood forests, such as maple-basswood forests.
Vegetation: Forest cover can range from a dense to moderately open canopy and there is commonly a dense shrub layer. Fire-resistant oak species, in particular *Quercus macrocarpa, Quercus rubra*, and/or *Quercus alba*, dominate the overstory. *Carya* spp., including *Carya ovata*, *Carya cordiformis*, and *Carya alba (= Carya tomentosa)*, are diagnostic in portions of the range of this system. Depending on site location and overstory canopy density, the understory may include species such as *Corylus americana, Amelanchier* spp., *Maianthemum stellatum, Caulophyllum thalictroides, Laportea canadensis, Trillium grandiflorum, Aralia nudicaulis*, and *Urtica dioica*. Occasionally, prairie grasses such as *Andropogon gerardii* and *Panicum virgatum* may be present. Fire

suppression likely has allowed for other associates, such as *Acer saccharum, Celtis occidentalis, Liriodendron tulipifera, Ostrya virginiana,* and *Juglans nigra,* to become more prevalent, especially in upland areas along floodplains.
Dynamics: Fire constitutes the main natural process for this type and frequent surface fires combined with uncommon crown fires maintained a more open canopy and subcanopy structure to allow oak regeneration. Historic fire frequency was highest in the prairie-forest border areas and declined further from prairies and behind natural firebreaks. Frequency of fires necessary to maintain this system varied, largely depending on soil fertility and drainage, with more fertile and mesic sites requiring more frequent fires. Fire-return intervals of 15-25 years would typically maintain a woodland, while fire-return intervals of 25-50 years would typically maintain a closed-canopy oak forest (Landfire 2007a). Fire suppression accounts for many of the more closed oak forest examples of this system with the more mesic understory (Abrams 1992, Lorimer 2001). Fire suppression has allowed for other associates, such as *Acer saccharum, Celtis occidentalis, Juglans nigra, Liriodendron tulipifera, Ostrya virginiana,* and invasive shrubs, to become more prevalent, especially in more mesic upland areas or along floodplains (Rogers et al. 2008). Periodic drought, intensified by local conditions like slope, southern exposure, or sandy soil, also inhibit growth of mesophytic trees. Some stands currently in this system were more open savanna stands but fire suppression has allowed them to succeed to the more close-canopy oak woodland or forest. A continued lack of fire in many of those stands will result in succession to more mesophytic forest types. Gap-phase dynamics producing multi-structured, uneven-aged stands operate most noticeably in North-Central Interior Beech-Maple Forest (CES202.693) but also influence succession in this system. Canopy gap formation originates through localized stem breakage resulting from wind (Runkle 1982), glaze or ice storms (Lemon 1961), attack by oak wilt fungus (*Chalara quercina*), and episodic defoliation caused by insects such as gypsy moth (*Lymantria dispar*).

Component Associations:
- *Acer saccharum - Quercus muehlenbergii* Forest (CEGL005010, GNR)
- *Quercus alba - (Carya ovata) / Carex pensylvanica* Glaciated Woodland (CEGL002134, G1Q)

NORTH-CENTRAL INTERIOR MAPLE-BASSWOOD FOREST (CES202.696)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Sideslope; Toeslope/Valley Bottom; Mesotrophic Soil; Deep Soil; Loam Soil Texture
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2314; ESLF 4120; ESP 1314

CONCEPT

Summary: This system is primarily found in the prairie forest border region of Minnesota, Wisconsin, and Iowa, but it can range north into northern Minnesota and Wisconsin and south to central Illinois, central Missouri, and eastern Kansas. This forest system is distinguished by underlying mesic soils and the predominance of mesic deciduous species forming a moderately dense to dense canopy. Examples of this system occur on valley slopes and bottoms often with northern or eastern aspects. Soils are moderately well-drained, fertile, and medium to deep loams that have developed from glacial till or loess parent material. *Acer saccharum* typifies this system, with *Tilia americana, Quercus rubra*, and *Ostrya virginiana* as common associates. The dense canopy allows for a rich mixture of shrub and herbaceous species in the understory. Examples of common herbaceous species include *Anemone quinquefolia, Adiantum pedatum, Arisaema triphyllum*, and *Sanicula* spp. Spring ephemeral herbaceous species are characteristic of this system, including *Aplectrum hyemale, Cardamine* spp., *Claytonia virginica, Dicentra cucullaria, Diplazium pycnocarpon, Erythronium americanum, Hydrastis canadensis, Phlox divaricata*, and *Trillium flexipes*. Dynamic processes such as wind and fire can impact this system over long return cycles; however, the most immediate threats to remaining examples of this system are grazing, unsustainable logging, and conversion to agriculture.
Classification Comments: Where *Quercus alba* is prominent in the upper Midwest, this system can be difficult to separate from related oak-dominated systems [see Effigy Mounds NPS map (Hop et al. 2005)]. *Quercus alba* in combination with *Acer saccharum*, and with a more mesic understory, is classified as the present system.
Similar Ecological Systems:
- North-Central Interior Beech-Maple Forest (CES202.693)

Related Concepts:
- Eastern Upland Oak Bluff Forest (Rolfsmeier and Steinauer 2010) Broader
- Northern Red Oak: 55 (Eyre 1980) Finer
- Sugar Maple - Basswood: 26 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is found primarily on mesic soils that are moderately well-drained and fertile. These are mostly moderate to deep loams that have developed from glacial till or loess. This system occurs near the prairie-forest border, and the closer to this border, the stronger the association this system has with natural firebreaks. These sites are typically on the east and north sides of rivers, lakes, and wetlands and topographically protected areas on valley slopes and bottoms often with northern or eastern aspects (Kucera and McDermott 1955, Grimm 1984, Moran n.d.).
Vegetation: Mesic deciduous trees form a moderately dense to dense canopy in examples of this system. *Acer saccharum* is the most common tree species forming the majority of the canopy and sapling layers. Common associates include *Tilia americana, Quercus rubra*, and *Ostrya virginiana*. The understory contains a rich mixture of shrub and herbaceous species such as *Anemone quinquefolia, Adiantum pedatum, Arisaema triphyllum*, and *Sanicula* spp. This system is found west and north of where *Fagus grandifolia* is a reliable and dominant member of the canopy.
Dynamics: Wind and fire can impact this system over long return intervals but are rare. Small-gap development and replacement due to tree death is more frequent than catastrophic fire or wind (Bray 1956, Grimm 1984). Tree canopy tends to be closed so understory plants receive little light after leaf-out in the spring. Old-growth stands may not vary greatly in species composition from mature managed forest but have different structural characteristics, including more snags, coarse woody debris, and large trees (McHale et al. 1999). This provides different habitats for wildlife and other non-plant species. This system could form large stands or be part of a large forested landscape in conjunction with other forested types, resulting in a relatively high proportion of forest interior to forest edge.

Component Associations:
- *Acer saccharum - Acer nigrum - Tilia americana - Quercus rubra / Ostrya virginiana* Forest (CEGL002061, G3G4)
- *Acer saccharum - Tilia americana / Ostrya virginiana - Carpinus caroliniana* Forest (CEGL002062, G3G4)
- *Quercus rubra - (Acer saccharum, Quercus alba)* Forest (CEGL005017, G4?)

NORTHEASTERN INTERIOR DRY-MESIC OAK FOREST (CES202.592)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Acidic Soil; Quercus - Carya
Non-Diagnostic Classifiers: Sideslope; Toeslope/Valley Bottom; Mineral: W/ A-Horizon >10 cm; Loam Soil Texture; Ustic; F-Patch/Medium Intensity; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2303; ESLF 4109; ESP 1303

CONCEPT

Summary: These oak-dominated forests are one of the matrix forest systems in the northeastern and north-central U.S. Occurring in dry-mesic settings, they are typically closed-canopy forests, though there may be areas of patchy-canopy woodlands. They cover large expanses at low to mid elevations, where the topography is flat to gently rolling, occasionally steep. Soils are mostly acidic and relatively infertile but not strongly xeric. Local areas of calcareous bedrock, or colluvial pockets, may support forests typical of richer soils. Oak species characteristic of dry-mesic conditions (e.g., *Quercus rubra, Quercus alba, Quercus velutina*, and *Quercus coccinea*) and *Carya* spp. are dominant in mature stands. *Quercus prinus* may be present but is generally less important than the other oak species. *Castanea dentata* was a prominent tree before chestnut blight eradicated it as a canopy constituent. *Acer rubrum, Betula lenta*, and *Betula alleghaniensis* may be common associates; *Acer saccharum* is occasional. With a long history of human habitation, many of the forests are early- to mid-successional, where *Pinus strobus, Pinus virginiana*, or *Liriodendron tulipifera* may be dominant or codominant. Within these forests, hillslope pockets with impeded drainage may support small isolated wetlands, including non-forested seeps or forested wetlands with *Acer rubrum, Quercus bicolor*, or *Nyssa sylvatica* characteristic.
Classification Comments: The oak-dominated forest matrix in this region spans a range of elevational and moisture regimes, reflected in different ecological systems. Those in drier settings, within the general range of this system, are placed in either Allegheny-Cumberland Dry Oak Forest and Woodland (CES202.359) or Central Appalachian Dry Oak-Pine Forest (CES202.591).
Similar Ecological Systems:
- Allegheny-Cumberland Dry Oak Forest and Woodland (CES202.359)--is somewhat more xeric and confined to the Southern Unglaciated Allegheny Plateau.
- Central Appalachian Dry Oak-Pine Forest (CES202.591)--is also more xeric and with *Quercus prinus* generally more important.
- Southern Appalachian Oak Forest (CES202.886)--is an equivalent system to the south (in the Southern Blue Ridge, EPA 66).

DESCRIPTION

Environment: These oak-dominated forests are one of the matrix forest systems in the northeastern and north-central U.S. Occurring in dry-mesic settings, they are typically closed-canopy forests, though there may be areas of patchy-canopy woodlands. They cover large expanses at low to mid elevations, where the topography is flat to gently rolling, occasionally steep. The typical landscape position is midslope to toeslope, transitioning to more xeric systems on the upper slopes and ridges. Soils are acidic and relatively infertile but not strongly xeric.
Vegetation: Mature stands are dominated by oak species characteristic of dry-mesic conditions (e.g., *Quercus rubra, Quercus alba, Quercus velutina*, and *Quercus coccinea*), along with various *Carya* spp. *Quercus prinus* may be present but is generally less important than the other oak species. *Castanea dentata* was a prominent tree before chestnut blight eradicated it as a canopy constituent. *Acer rubrum* and *Betula lenta* are frequently common associates. Local areas of calcareous bedrock may support forests typical of richer soils (e.g., with *Acer saccharum* and/or *Quercus muehlenbergii*). Common shrubs include *Viburnum acerifolium, Hamamelis virginiana, Corylus* spp., and *Smilax* spp., as well as heaths such as *Kalmia latifolia, Vaccinium* spp., and *Gaylussacia* spp. Herbs, forbs, and ferns are usually sparse to moderate in density.
Dynamics: This system is naturally dominated by stable, uneven-aged forests, with canopy dynamics dominated by gap-phase regeneration. Most oaks are long-lived, with typical age of mortality ranging from 200 to 400 years. *Quercus coccinea* and *Quercus velutina* are shorter-lived with typical ages being approximately 50 to 100 years, while *Quercus alba* can live as long as 600 years. Extreme wind or ice storms occasionally create larger canopy openings.

This forest system is characterized by low-severity surface fires that cause variable structure and composition based on fire frequency and intensity. The great majority of historical fires were generated by Native Americans.

Open woodlands developed within a moderate burning regime, (fire-return intervals of 5 to 15 years), and canopy closure occurred with greater fire-return intervals. Shade-tolerant, fire-sensitive trees such as *Acer saccharum* regenerated beneath oak-hickory canopies when fire was excluded over several decades. With continued fire exclusion, *Acer saccharum* and other late-successional species gradually replaced overstory oaks and hickories as forest gaps closed (Sutherland et al. 2003), generating a mosaic of vegetation types formed with varying fire history (Cutter and Guyette 1994). A recent study on fire history of a *Quercus rubra* stand in West Virginia revealed that fire intervals ranged from 7 to 32 years from 1846 to 2002, in contrast to intervals of 7 to 15 years prior to the fire control era. These results were consistent with previous research in the oak forests of Ohio, Maryland, and Missouri (Schuler and McClain 2003).

Component Associations:
- *Fagus grandifolia - Betula lenta - Quercus (alba, rubra) / Carpinus caroliniana* Forest (CEGL006921, GNR)
- *Liriodendron tulipifera - Pinus strobus - Tsuga canadensis - Quercus (rubra, alba) / Polystichum acrostichoides* Forest (CEGL006304, G4?)
- *Pinus strobus - Quercus (rubra, velutina) - Fagus grandifolia* Forest (CEGL006293, G5)
- *Quercus (alba, rubra, velutina) - Carya* spp. / *Viburnum acerifolium* Forest (CEGL006336, G4G5)
- *Quercus (rubra, velutina, alba) - Betula lenta - (Pinus strobus)* Forest (CEGL006454, G4G5)
- *Quercus alba - Carya glabra - Fraxinus americana / Cercis canadensis / Muhlenbergia sobolifera - Elymus hystrix* Forest (CEGL006216, G3)
- *Quercus alba - Quercus rubra - Carya (alba, ovata) / Cornus florida* Acidic Forest (CEGL002067, G3)
- *Quercus alba - Quercus rubra - Carya alba / Cornus florida / Vaccinium stamineum / Desmodium nudiflorum* Piedmont Forest (CEGL008475, G4G5)

- *Quercus alba - Quercus rubra - Quercus prinus - Acer saccharum / Lindera benzoin* Forest (CEGL002059, GNR)
- *Quercus bicolor / Vaccinium corymbosum / Carex stipata* Forest (CEGL006241, GNR)
- *Quercus muehlenbergii - Quercus (alba, rubra) - Carya cordiformis / Viburnum prunifolium* Forest (CEGL004793, G3G4)
- *Quercus prinus - Quercus rubra - Carya ovalis / Carex pensylvanica - (Calamagrostis porteri)* Forest (CEGL008516, G3G4)
- *Quercus prinus - Quercus rubra / Hamamelis virginiana* Forest (CEGL006057, G5)
- *Quercus rubra - Acer saccharum / Ostrya virginiana / Cardamine concatenata* Forest (CEGL008517, G4)
- *Quercus rubra - Carya (glabra, ovata) / Ostrya virginiana / Carex lucorum* Forest (CEGL006301, G4)
- *Quercus rubra - Carya (ovata, ovalis) - Fraxinus americana / Actaea racemosa - Hydrophyllum virginianum* Forest (CEGL008518, G3G4)
- *Quercus rubra - Quercus prinus - Carya ovalis / (Cercis canadensis) / Solidago (caesia, curtisii)* Forest (CEGL008514, G3G4)
- *Tilia americana - Fraxinus americana / Acer pensylvanicum - Ostrya virginiana / Parthenocissus quinquefolia - Impatiens pallida* Woodland (CEGL008528, G3)

SPATIAL CHARACTERISTICS

Spatial Summary: These were historically among the most important matrix forests of the Northeast. They cover extensive areas where conditions are not extreme. Upslope they may grade into more xeric oak ridge systems or rocky oak-pine forests/woodlands. Mesic cove forest systems may be embedded within this matrix in protected draws. Small pocket wetlands, not discriminated as separate systems, may also occur within these forests.

Adjacent Ecological Systems:
- Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593)
- Central Appalachian Dry Oak-Pine Forest (CES202.591)
- Southern and Central Appalachian Cove Forest (CES202.373)

Adjacent Ecological System Comments: Dry-mesic oak forests often occur on hilltops and sideslopes. Though often contiguous, patches of this system are often interdigitated with other systems, especially Southern and Central Appalachian Cove Forest (CES202.373) and Central Appalachian Dry Oak-Pine Forest (CES202.591). At the highest elevations, this system may grade into Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593). Small patches of other communities, such as rock outcrops and mountain wetlands, are sometimes embedded within this system.

DISTRIBUTION

Range: This system is found from southern New York west through Ohio and Pennsylvania and south to Virginia. It does not extend to the southernmost part of Virginia, except in the Ridge and Valley.

Divisions: 202:C

Nations: US

Subnations: MD, NJ, NY, OH, PA, VA, WV

NORTHEASTERN INTERIOR PINE BARRENS (CES202.590)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Sandplains/Glacial Outwash or Flats; Glaciated; Oligotrophic Soil; Acidic Soil; Sand Soil Texture; F-Landscape/Medium Intensity; Pinus rigida
Non-Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Ustic
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2354; ESLF 4257; ESP 1354

CONCEPT

Summary: These pine barrens occur on glacial sandplains of the inland regions of the northeastern U.S., with a disjunction to the distinctive till plain shrublands in the Poconos of eastern Pennsylvania. Substrates include outwash plains, stabilized sand dunes, and glacial till. The soils are consequently coarse-textured, acidic, mostly well-drained to xeric, and low in nutrients. *Pinus rigida* is the usual dominant, and cover may range from closed-canopy forest to (more typically) open woodlands. *Quercus rubra, Pinus strobus,* and *Betula populifolia* are common associates. A tall-shrub layer of *Quercus ilicifolia* and/or *Quercus prinoides* is commonly present, although portions of some barrens (or occasionally the entire barrens) lack the scrub oak component. A well-developed low-shrub layer is typical, with lowbush *Vaccinium* spp., *Gaylussacia baccata,* and *Comptonia peregrina* characteristic, with *Rhododendron canadense* characteristic on the slightly more mesic microsites of the Poconos. The system is often a physiognomic patchwork, ranging from nearly closed-canopy forest to open pine woodlands, to scrub oak shrublands, to herbaceous/dwarf-shrub frost pockets. Grassy areas dominated by *Schizachyrium scoparium* with *Lupinus perennis, Lespedeza capitata,* and other forbs provide habitat for several rare invertebrates. Small changes in elevation can create pockets with saturated soil, where shrubs such as *Corylus americana, Cephalanthus occidentalis, Vaccinium corymbosum,* and *Alnus* spp. form dense cover. These barrens always have a history of recurrent fires, and fire is required to maintain them.
Classification Comments: This system can include patches, or sometimes larger areas, of mesic pitch pine - shrub vegetation. For instance, Pennsylvania's "mesic till barrens" are somewhat less dry than the typical barrens in this system, but fit otherwise. Elsewhere in these barrens, wet pitch pine pockets can occur in (usually small) topographic depressions.
Similar Ecological Systems:
- Laurentian Pine-Oak Barrens (CES201.718)--is centered around the Great Lakes.
- Northern Atlantic Coastal Plain Pitch Pine Barrens (CES203.269)

Related Concepts:
- Bear Oak: 43 (Eyre 1980) Finer
- Eastern White Pine: 21 (Eyre 1980) Finer
- Pitch Pine - Heath Barren (Gawler and Cutko 2010) Finer
- Pitch Pine - Scrub Oak Barren (Gawler and Cutko 2010) Finer
- Pitch Pine: 45 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is confined to flat to gently rolling plains with sandy soils that are coarse-textured, acidic, mostly well-drained to xeric, and low in nutrients.
Dynamics: Fire regime includes frequent stand-replacing events and lower intensity surface fires. Periodic severe wildfires with 40- to 100-year intervals have produced oak-pine mixtures over extensive areas of uplands, while more frequent severe fires have created mixtures of pitch pine and shrub oaks. Pitch pine younger than 20-40 years may produce stump sprouts after top-killing fire (Andresen 1959). If not top-killed, pines may recover from fire by sprouting from branches and trunk. Pitch pine has. Additionally, pitch pine is quick to maturity and to produce seeds. Frequent fires of moderate to high intensity/severity eventually eliminate all other tree species except for scrub oak and pitch pine, which has thick, fire-resistant bark and is a prolific seed producer. Fires, especially large wildfires, have been a major factor in the development of the present differences among forest stands on similar sites in the Pine Barrens. Abandoned upland sites generally progress from a grass or shrubland (MFRI of 2-3? years) to pitch pine/scrub oak woodland (5-25 years) to pure pitch pine forest with heath/oak scrublands (30-60 years) to pitch pine/tree-sized oak forest (60-100 years) to oak-hickory forest (100-200 years) (Landfire 2007a).

Component Associations:
- *Pinus rigida - Quercus (velutina, prinus)* Forest (CEGL006290, GNR)
- *Pinus rigida - Quercus ilicifolia - Rhododendron canadense* Woodland (CEGL006157, G1)
- *Pinus rigida / Quercus ilicifolia / Lespedeza capitata* Woodland (CEGL006025, G2)
- *Pinus rigida / Quercus ilicifolia / Piptatherum pungens* Woodland (CEGL006203, G2)
- *Pinus rigida / Vaccinium* spp. - *Gaylussacia baccata* Woodland (CEGL005046, G3G5)
- *Pinus strobus - Pinus resinosa - Pinus rigida* Forest (CEGL006259, G4G5)

- *Vaccinium angustifolium / Schizachyrium scoparium - Carex lucorum* Shrub Herbaceous Vegetation (CEGL006393, GNR)

Spatial Characteristics

Size: As an order of magnitude, generally a few hundred to a 1000-2000 acres.
Adjacent Ecological System Comments: Wetland pockets are common, and vary from small to large. Outwash Plain Pondshores and Basin Peatlands are characteristic wetland systems that may be embedded in pine barrens.

Distribution

Range: This system is restricted to interior south-central New England; Colchester, Vermont; eastern New York; and the Pennsylvania Poconos.
Divisions: 202:C

NORTHERN ATLANTIC COASTAL PLAIN HARDWOOD FOREST (CES203.475)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Long Disturbance Interval; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2324; ESLF 4130; ESP 1324

CONCEPT

Summary: This ecological system is comprised of dry hardwood forests largely dominated by oaks, ranging from sandy glacial and outwash deposits of Cape Cod, Massachusetts, and Long Island, New York, south to the Coastal Plain portions of Maryland and Virginia south to about the James River. *Quercus alba, Quercus prinus, Quercus coccinea,* and *Quercus rubra* are typical, and *Ilex opaca* is sometimes present. *Pinus* species may be codominant in some areas, for example the mixture of oaks with *Pinus virginiana* or *Pinus echinata* on very xeric, relict inland dunes. In the northern half of the range, conditions can grade to dry-mesic, reflected in the local abundance of *Fagus grandifolia*. These forests occur on acidic, sandy to gravelly soils with a thick duff layer, often with an ericaceous shrub layer. From New Jersey south to Virginia, this system also includes oak-beech/heath forests on steep slopes.
Classification Comments: This system grades into other hardwood types of the northeastern U.S. as one moves inland and northward. North of Cape Cod, similar forests are treated as part of Central Appalachian Dry Oak-Pine Forest (CES202.591). In Delaware and New York these coastal forests are apparently distinct (fauna, flora and substrate are distinct) from more inland forests. The southern part of this type's range overlaps with Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242); where they overlap, they are separated based on moisture regime, with the drier forests (often with an ericaceous shrub layer) going to this type.

Similar Ecological Systems:
- Central Appalachian Dry Oak-Pine Forest (CES202.591)--similar forests found north of Cape Cod.
- Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242)

NORTHERN ATLANTIC COASTAL PLAIN MARITIME FOREST (CES203.302)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Coast
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2379; ESLF 4322; ESP 1379

CONCEPT

Summary: This system encompasses a range of woody vegetation present on barrier islands, maritime shores and near-coastal strands, from Fisherman's Island, Virginia (the northern range limit of *Quercus virginiana*) northward to the extent of the Atlantic Coastal Plain. It includes forests and shrublands whose structure and composition are influenced by proximity to marine environments, including both upland and wetland. Vegetation includes narrow bands of forests with often stunted trees with contorted branches and dense vine layers. A range of trees may be present depending upon actual location and degree of protection from most extreme maritime influences. Common trees include *Prunus serotina, Pinus taeda, Ilex opaca, Quercus stellata, Juniperus virginiana, Pinus rigida, Pinus virginiana, Amelanchier canadensis*, and *Celtis occidentalis*. These trees are also found in less extreme or non-maritime settings; this system is distinguished as much by the structure of the vegetation as its composition. *Morella pensylvanica* is a characteristic shrub, and *Smilax rotundifolia* and *Vitis rotundifolia* are characteristic vines. *Morella cerifera* is often present south of central New Jersey.
Classification Comments: In New York this concept includes Maritime Holly Forest, Maritime Post Oak Forest, Maritime Beech Forest, Maritime Red Cedar Forest (Edinger et al. 2002).
Similar Ecological Systems:
- Central Atlantic Coastal Plain Maritime Forest (CES203.261)
- Northern Atlantic Coastal Plain Dune and Swale (CES203.264)

Related Concepts:
- Beech - Sugar Maple: 60 (Eyre 1980) Finer
- Black Oak: 110 (Eyre 1980) Finer
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Loblolly Pine - Hardwood: 82 (Eyre 1980) Finer
- Loblolly Pine: 81 (Eyre 1980) Finer
- Northern Red Oak: 55 (Eyre 1980) Finer
- Pitch Pine: 45 (Eyre 1980) Finer
- Sassafras - Persimmon: 64 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer
- White Oak: 53 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in marine coastal areas on sandy soils, usually in low interdunal areas behind primary or secondary dunes. In the glaciated portion of the range, it also occurs on till or morainal bluffs fronting the ocean, or on drowned drumlins on coastal islands. Examples also occur on sill or sand deposits in salt marsh islands. Soils range from well-drained on higher topographic positions to mesic in lower positions.
Vegetation: Vegetation includes narrow bands of forest with often stunted trees with contorted branches and wilted leaves and dense vine layers (Edinger et al. 2002). A range of trees may be present depending upon actual location and degree of protection from most extreme maritime influences. Species range from deciduous hardwoods to pitch pine and Virginia pine. A rare pitch pine variant is found in Delaware (Cape Henlopen) and New York.
Dynamics: Salt spray, high winds, dune deposition, sand shifting and blasting, and occasional overwash during extreme disturbance events.

Component Associations:
- *Acer rubrum / Rhododendron viscosum - Clethra alnifolia* Forest (CEGL006156, GNR)
- *Amelanchier canadensis - Viburnum* spp. - *Morella pensylvanica* Scrub Forest (CEGL006379, GNR)

NORTHERN ATLANTIC COASTAL PLAIN PITCH PINE BARRENS (CES203.269)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Xeric; F-Patch/High Intensity; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2355; ESLF 4258; ESP 1355

CONCEPT

Summary: This system is comprised of a group of dry pitch pine woodlands and forests of deep sandy soils ranging from Cape Cod (Massachusetts) south through Long Island (New York) and the famous Pine Barrens of the New Jersey Coastal Plain, with occasional occurrences north to southernmost Maine and south to the Anacostia watershed (Maryland). The vegetation is characterized by a tree canopy of *Pinus rigida* with a tall-shrub layer dominated by *Quercus ilicifolia* and a low-shrub layer characterized by *Vaccinium pallidum* and/or *Vaccinium angustifolium*. The system is heavily influenced by fire, the composition and structure of its components varying with fire frequency. In general, tree oaks are more prevalent in those stands having a longer fire-return interval; fire frequencies of 8-10 years foster the growth of "pine plains," i.e., dwarf pine stands 1 m in height. Pine barrens with a history of more-or-less biennial burns for lowbush blueberry production may have very few trees and be characterized as sandplain grasslands. Dwarf-shrubs such as *Arctostaphylos uva-ursi*, *Vaccinium angustifolium*, *Vaccinium pallidum*, and *Hudsonia ericoides* typify the field layer of pine plains and sandplain grasslands. *Schizachyrium scoparium* is the most common grass (in close proximity to the coast, it may be represented by its close relative *Schizachyrium littorale*).

Scrub oak stands may occur without pine cover, particularly in low-lying areas that do not intersect the water table, where cold-air drainage inhibits pine growth. North of the glacial boundary, heathlands characterized by *Arctostaphylos uva-ursi*, *Corema conradii*, and *Morella pensylvanica*, and grasslands characterized by *Schizachyrium littorale*, *Schizachyrium scoparium*, and *Danthonia spicata* occur as small (or occasionally large) patches. The Pine Barrens of New Jersey are very similar in structure and composition to those north of the glacial boundary but are characterized by additional species, such as *Quercus marilandica*, *Quercus stellata*, *Pyxidanthera barbulata*, *Leiophyllum buxifolium*, and others. Where the water table is close to the surface, pitch pine lowland vegetation (described as a separate system) occurs.

Classification Comments: This system includes the New Jersey Pine Barrens, the uniqueness of which has long been recognized, and the system is well-studied and summarized in a number of recent treatments (Forman 1979, Buckhholz and Good 1982, Gibson et al. 1999).

Similar Ecological Systems:
- Northeastern Interior Pine Barrens (CES202.590)--occurs farther inland and lacks coastal elements.
- Northern Atlantic Coastal Plain Heathland and Grassland (CES203.895)

Related Concepts:

- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: This system typically occurs on deep well-drained sand deposits. In the coastal regions of the glaciated Northeast, it occurs on outwash plains and morainal deposits. In New Jersey, it occurs on Cohansey sand, which is sometimes overlain with hilltop gravel deposits.

Vegetation: The uniqueness of the New Jersey Pine Barrens flora has long been recognized (Stone 1911, Harshberger 1916). More recent treatments by Forman (1979) and Buckhholz and Good (1982) have compiled much of the available information. *Pinus rigida* is the dominant and characteristic species of this system. It may be found in well-developed tree form or as a short-statured, shrubby ecotype. *Pinus rigida* may occur as the sole dominant or occur with a variety of oak species, especially *Quercus marilandica*, *Quercus stellata*, and *Quercus ilicifolia*. In some examples *Pinus echinata* may co-occur.

Dynamics: Different fire frequencies and intensities interrupt succession, accounting for variations in forest composition. Periodic severe wildfires with 40- to 100-year intervals have produced oak-pine mixtures over extensive areas of uplands, while more frequent severe fires have created mixtures of pitch pine and shrub oaks. The most frequent and severe fires have created the pine plains (Landfire 2007a).

Component Associations:
- *Gaylussacia baccata - Vaccinium angustifolium - Arctostaphylos uva-ursi / Schizachyrium littorale* Dwarf-shrubland (CEGL006066, G3)

- *Morella pensylvanica / Schizachyrium littorale - Danthonia spicata* Shrub Herbaceous Vegetation (CEGL006067, G2)
- *Pinus (rigida, echinata) - Quercus coccinea / Ilex opaca* Woodland (CEGL006115, GNR)
- *Pinus rigida - (Pinus echinata) / Quercus (marilandica, ilicifolia) / Vaccinium pallidum* Woodland (CEGL006383, G2?)
- *Pinus rigida - Quercus coccinea - Quercus falcata / (Quercus marilandica) / Gaylussacia frondosa* Woodland (CEGL006329, G2G3)
- *Pinus rigida - Quercus coccinea / Vaccinium pallidum - (Morella pensylvanica)* Woodland (CEGL006381, GNR)
- *Pinus rigida - Quercus ilicifolia / Arctostaphylos uva-ursi* Shrubland (CEGL006097, G1Q)
- *Pinus rigida - Quercus marilandica / Corema conradii* Shrubland (CEGL006148, G2)
- *Pinus rigida / Carex pensylvanica* Woodland (CEGL006385, GNR)
- *Pinus rigida / Quercus (marilandica, ilicifolia) / Pyxidanthera barbulata* Woodland (CEGL006051, G2)
- *Pinus rigida / Quercus ilicifolia - Kalmia angustifolia / Pyxidanthera barbulata* Woodland (CEGL006384, G1)
- *Pinus rigida / Quercus ilicifolia / Morella pensylvanica* Woodland (CEGL006315, G3)
- *Quercus ilicifolia - Quercus prinoides* Shrubland (CEGL006111, GNR)
- *Quercus prinus - Quercus velutina / Gaylussacia frondosa* Forest (CEGL006334, GNR)
- *Vaccinium angustifolium / Schizachyrium scoparium - Carex lucorum* Shrub Herbaceous Vegetation (CEGL006393, GNR)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Northern Atlantic Coastal Plain Basin Peat Swamp (CES203.522)
- Northern Atlantic Coastal Plain Pond (CES203.518)
- Northern Atlantic Coastal Plain Riverine Peat Swamp (CES203.070)

Adjacent Ecological System Comments: Coastal Plain ponds and Atlantic white-cedar swamps may be embedded in these pine barrens.

DISTRIBUTION

Range: This system is found in the Atlantic Coastal Plain from Delaware Bay northward through the New Jersey Coastal Plain and Long Island (New York) to Cape Cod, Massachusetts, with peripheral occurrences in Pennsylvania (historic), New Hampshire (historic), and southern Maine (Kennebunk Plains and Wells Barren).

NORTHERN CALIFORNIA MESIC SUBALPINE WOODLAND (CES206.911)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Temperate [Temperate Oceanic]; Udic
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Sideslope
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2044; ESLF 4231; ESP 1044

CONCEPT

Summary: This ecological system occurs on ridges and rocky slopes around timberline at 2600 m (7900 feet) elevation in the central Sierra Nevada and 2450 m (8000 feet) in the southern Cascades. These woodlands are found on concave or mesic slopes in areas with long-lasting snowpack and better soil development than other drier and more exposed subalpine woodlands. The tree canopy is characterized by *Tsuga mertensiana* and may include *Abies magnifica, Abies procera, Pinus albicaulis,* and *Pinus monticola*. Mesic-site shrubs will include *Cassiope mertensiana, Phyllodoce breweri, Phyllodoce empetriformis, Vaccinium membranaceum*, and others. *Juniperus communis* is found in most stands of the northern Sierra Nevada. *Penstemon davidsonii*, as well as patches of grasses, sedges, and forbs grade into adjacent meadows.

Similar Ecological Systems:
- Sierra Nevada Subalpine Lodgepole Pine Forest and Woodland (CES206.912)

Related Concepts:
- California Mixed Subalpine: 256 (Eyre 1980) Intersecting
- Mountain Hemlock: 205 (Eyre 1980) Intersecting. Mountain hemlock stands are a component of subalpine parklands.
- Whitebark Pine: 208 (Eyre 1980) Intersecting. Whitebark pine stands are a component of this ecological system.

Component Associations:
- *Pinus albicaulis - Tsuga mertensiana* / Mixed Herbaceous Woodland (CEGL003132, G2G4)
- *Pinus albicaulis / Penstemon davidsonii* Woodland (CEGL003134, G3G4)
- *Tsuga mertensiana - Pinus contorta var. murrayana - Pinus albicaulis* Forest (CEGL008692, GNR)
- *Tsuga mertensiana - Pinus contorta var. murrayana - Pinus monticola* Forest (CEGL008691, G3?)
- *Tsuga mertensiana - Pinus contorta var. murrayana / Carex rossii* Forest (CEGL008690, G3?)
- *Tsuga mertensiana - Pinus contorta var. murrayana / Phyllodoce breweri* Forest (CEGL008689, G3?)
- *Tsuga mertensiana - Pinus contorta var. murrayana* Forest (CEGL008688, G3G4)
- *Tsuga mertensiana - Pinus monticola* Forest (CEGL008687, G3)
- *Tsuga mertensiana / Arabis platysperma* Forest (CEGL008686, GNR)
- *Tsuga mertensiana* / Sparse Understory Forest (CEGL008685, G3G4)

DISTRIBUTION

NORTHERN DRY JACK PINE-RED PINE-HARDWOOD WOODLAND (CES103.424)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Land Cover Class: Forest and Woodland
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
National Mapping Codes: ESLF 4278

CONCEPT

Summary: This conifer woodland is found throughout the eastern southern or hemi-boreal regions of eastern Canada, extending into the Upper Midwest and Northeast parts of the United States. It occurs on dry nutrient-poor sand plains and along rocky ridges, often adjacent to rivers and lakes, and along talus slopes. The canopy ranges from patchy to continuous and is dominated by a mix of primarily conifer and hardwood species. In some examples, canopy trees may be stunted. *Pinus banksiana* is the most frequent conifer species, although *Pinus resinosa, Pinus strobus, Picea mariana,* or *Picea glauca* can be common and may dominate some sites. Hardwood species vary in cover from 25-90% of the canopy. *Quercus ellipsoidalis* is a restricted dominant in the Midwest part of the range of this system, along with *Quercus macrocarpa* and *Quercus rubra*. More common are *Betula papyrifera* and *Populus* spp. In areas of open bedrock, species typical of bedrock outcrops and shallow soils can be found and include *Danthonia spicata, Poa alsodes, Elymus trachycaulus (= Agropyron trachycaulum), Maianthemum canadense, Schizachne purpurascens*, and *Oryzopsis asperifolia*. The nonvascular layer can be absent or present with up to 30% cover. In the open bedrock areas, this layer consists mainly of the lichens and mosses. Infrequent fire is the primary dynamic, with catastrophic fires occurring approximately every 150-200 years with surface fires every 50-200 years.

Similar Ecological Systems:
- Central Boreal Jack Pine-Black Spruce Dry Woodland (CES103.429)
- Eastern Boreal Jack Pine-Black Spruce Dry Woodland (CES103.423)
- Laurentian-Acadian Sub-boreal Dry-Mesic Pine-Black Spruce-Hardwood Forest (CES103.425)

Related Concepts:
- FDn12 Northern Dry-Sand Pine Woodland (Minnesota DNR 2003) Finer
- FDn22 Northern Dry-Bedrock Pine (Oak) Woodland (Minnesota DNR 2003) Finer

DESCRIPTION

Environment: Examples of this system occur on rocky ridgetops, high slopes, and terraces sometimes along rivers or lakeshores, including Great Lakes shorelines. These areas are dry, well-drained sites, often with exposed bedrock. Soils range from bare bedrock and talus slopes to rocky, shallow loams and deep sands. Those stands on bedrock may have occasional cracks in the underlying bedrock resulting in pockets of relatively deep (15-20 cm) soil. Bare rock (with crustose lichens) can cover up to 50% of the area.
Vegetation: The canopy ranges from scattered trees to a moderately dense canopy. Stands are a mix of conifer species, occasionally with hardwood species. In some examples, canopy trees may be stunted. The conifers in most examples are dominated by *Pinus banksiana*. *Pinus resinosa, Pinus strobus, Picea mariana,* or *Picea glauca* can be common and may dominate some sites. Hardwood species vary in cover from 25-90% of the canopy. *Quercus ellipsoidalis* is a restricted dominant in the Midwest part of the range, with *Quercus macrocarpa* or *Quercus rubra, Betula papyrifera,* and *Populus* spp. occurring more commonly. Shrubs may be absent to dense and include *Amelanchier* spp., *Diervilla lonicera, Corylus cornuta, Juniperus communis, Prunus pensylvanica, Salix bebbiana,* and *Vaccinium angustifolium.* Herbaceous species vary across the range of this type. Some typical species include *Danthonia spicata, Poa alsodes, Elymus trachycaulus (= Agropyron trachycaulum), Maianthemum canadense, Schizachne purpurascens*, and *Oryzopsis asperifolia*. The nonvascular layer can be absent or present with up to 30% cover. In the open bedrock areas, this layer consists mainly of the lichens and mosses. Lichen species may include *Cladina rangiferina (= Cladonia rangiferina)* and *Cladina mitis (= Cladonia mitis)*. Mosses include *Dicranum* spp., *Pleurozium schreberi,* and *Polytrichum* spp.

DISTRIBUTION

Range: This system ranges in Canada from northwestern Ontario (possibly eastern Manitoba) to eastern Canada's Atlantic provinces and extending into the U.S. in northeastern Minnesota, Isle Royale, and near-coastal areas of Lake Superior shores in northern Wisconsin and Michigan.

NORTHERN ROCKY MOUNTAIN DRY-MESIC MONTANE MIXED CONIFER FOREST (CES306.805)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Montane]; Forest and Woodland (Treed); Ustic; Short Disturbance Interval; F-Patch/Low Intensity; Needle-Leaved Tree; Abies grandis - Mixed
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Montane [Lower Montane]; Sideslope; Toeslope/Valley Bottom; Temperate [Temperate Continental]; Mesotrophic Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2045; ESLF 4232; ESP 1045

CONCEPT

Summary: This ecological system is composed of highly variable montane coniferous forests found in the interior Pacific Northwest, from southernmost interior British Columbia, eastern Washington, eastern Oregon, northern Idaho, western and north-central Montana, and south along the east slope of the Cascades in Washington and Oregon. In central Montana it occurs on mountain islands (the Snowy Mountains). This system is associated with a submesic climate regime with annual precipitation ranging from 50 to 100 cm, with a maximum in winter or late spring. Winter snowpacks typically melt off in early spring at lower elevations. Elevations range from 460 to 1920 m. Most occurrences of this system are dominated by a mix of *Pseudotsuga menziesii* and *Pinus ponderosa* (but there can be one without the other) and other typically seral species, including *Pinus contorta, Pinus monticola* (not in central Montana), and *Larix occidentalis* (not in central Montana). *Picea engelmannii* (or *Picea glauca* or their hybrid) becomes increasingly common towards the eastern edge of the range. The nature of this forest system is a matrix of large patches dominated or codominated by one or combinations of the above species; *Abies grandis* (a fire-sensitive, shade-tolerant species not occurring in central Montana) has increased on many sites once dominated by *Pseudotsuga menziesii* and *Pinus ponderosa*, which were formerly maintained by low-severity wildfire. Presettlement fire regimes may have been characterized by frequent, low-intensity ground fires that maintained relatively open stands of a mix of fire-resistant species. Under present conditions the fire regime is mixed severity and more variable, with stand-replacing fires more common, and the forests are more homogeneous. With vigorous fire suppression, longer fire-return intervals are now the rule, and multi-layered stands of *Pseudotsuga menziesii, Pinus ponderosa*, and/or *Abies grandis* provide fuel "ladders," making these forests more susceptible to high-intensity, stand-replacing fires. They are very productive forests which have been priorities for timber production. They rarely form either upper or lower timberline forests. Understories are dominated by graminoids, such as *Pseudoroegneria spicata, Calamagrostis rubescens, Carex geyeri*, and *Carex rossii*, that may be associated with a variety of shrubs, such as *Acer glabrum, Juniperus communis, Physocarpus malvaceus, Symphoricarpos albus, Spiraea betulifolia*, or *Vaccinium membranaceum* on mesic sites. *Abies concolor* and *Abies grandis X concolor* hybrids in central Idaho (the Salmon Mountains) are included here but have very restricted range in this area. *Abies concolor* and *Abies grandis* in the Blue Mountains of Oregon are probably hybrids of the two and mostly *Abies grandis*.
Classification Comments: Need to re-assess the concept of this system in relation to Northern Rocky Mountain Western Larch Savanna (CES306.837) and East Cascades Mesic Montane Mixed-Conifer Forest and Woodland (CES204.086). In PNV (PAGs) concept, this is mostly *Pseudotsuga menziesii*, moist *Pinus ponderosa* series, dry *Abies grandis* or warm, dry *Abies lasiocarpa* series in the Canadian Rockies, northern Middle Rockies, East Cascades and Okanagan ecoregions. Everett et al. (2000) indicate that in the eastern Cascades of Washington this system forms fire polygons due to abrupt north and south topography with presettlement fire-return intervals of 11-12 years typically covering less than 810 ha. Currently, fires have 40- to 45-year return intervals with thousands of hectares in size. Northern Rocky Mountain Western Larch Savanna (CES306.837) is a large-patch type that occurs typically within this matrix or Northern Rocky Mountain Mesic Montane Mixed Conifer Forest (CES306.802) matrix. We need to define the percent cover of larch over 50% or over 75% relative cover of all trees for an occurrence to be placed in Northern Rocky Mountain Western Larch Savanna (CES306.837). This needs to be relative because these look(ed) like ponderosa savanna in places. East Cascades Mesic Montane Mixed-Conifer Forest and Woodland (CES204.086) has North Pacific floristic composition, and is mostly east Cascades ecoregion, peripheral in Okanagan ecoregion, and west Cascades. PAGs most of the *Abies grandis*, dry western red-cedar and western hemlock in the east Cascades. Environmentally, it is equivalent to Northern Rocky Mountain Mesic Montane Mixed Conifer Forest (CES306.802). Contrasting this system (CES306.805) with Rocky Mountain Subalpine Dry-Mesic Spruce-Fir Forest and Woodland (CES306.828) and Rocky Mountain Subalpine Mesic-Wet Spruce-Fir Forest and Woodland (CES306.830) is important in the Middle Rockies ecoregion and Oregon.
Similar Ecological Systems:
- East Cascades Mesic Montane Mixed-Conifer Forest and Woodland (CES204.086)
- North Pacific Interior Dry-Mesic Mixed Conifer Forest (CES207.152)
- Northern Rocky Mountain Western Larch Savanna (CES306.837)
- Rocky Mountain Subalpine Dry-Mesic Spruce-Fir Forest and Woodland (CES306.828)
- Rocky Mountain Subalpine Mesic-Wet Spruce-Fir Forest and Woodland (CES306.830)
- Sierran-Intermontane Desert Western White Pine-White Fir Woodland (CES204.101)

NORTHERN ROCKY MOUNTAIN MESIC MONTANE MIXED CONIFER FOREST (CES306.802)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Long (>500 yrs) Persistence; Forest and Woodland (Treed); Udic; Very Long Disturbance Interval; F-Landscape/Medium Intensity; Needle-Leaved Tree; Tsuga heterophylla and Thuja plicata
Non-Diagnostic Classifiers: Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Sideslope; Toeslope/Valley Bottom; Temperate [Temperate Continental]; Glaciated; Mesotrophic Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2047; ESLF 4234; ESP 1047

CONCEPT

Summary: This ecological system occurs in the northern Rockies of western Montana west into northeastern Washington and southern British Columbia. These are vegetation types dominated by *Tsuga heterophylla* and *Thuja plicata* in most cases, found in areas influenced by incursions of mild, wet, Pacific maritime air masses. Much of the annual precipitation occurs as rain, but where snow does occur, it can generally be melted by rain during warm winter storms. Occurrences generally are found on all slopes and aspects but grow best on sites with high soil moisture, such as toeslopes and bottomlands. At the periphery of its distribution, this system is confined to moist canyons and cooler, moister aspects. Generally these are moist, non-flooded or upland sites that are not saturated yearlong. Along with *Tsuga heterophylla* and *Thuja plicata*, *Pseudotsuga menziesii* commonly shares the canopy, and *Pinus monticola*, *Pinus contorta*, *Abies grandis*, *Taxus brevifolia*, and *Larix occidentalis* are major associates. Mesic *Abies grandis* associations are included in this system, and *Abies grandis* is often the dominant in these situations; *Tsuga heterophylla* and *Thuja plicata* can both be absent. *Cornus nuttallii* may be present in some situations. *Picea engelmannii*, *Abies lasiocarpa*, and *Pinus ponderosa* may be present but only on the coldest or warmest and driest sites. *Linnaea borealis*, *Paxistima myrsinites*, *Alnus incana*, *Acer glabrum*, *Spiraea betulifolia*, *Symphoricarpos hesperius (= Symphoricarpos mollis ssp. hesperius)*, *Cornus canadensis*, *Rubus parviflorus*, *Menziesia ferruginea*, and *Vaccinium membranaceum* are common shrub species. The composition of the herbaceous layer reflects local climate and degree of canopy closure; it is typically highly diverse in all but closed-canopy conditions. Important forbs and ferns include *Actaea rubra*, *Anemone piperi*, *Aralia nudicaulis*, *Asarum caudatum*, *Clintonia uniflora*, *Coptis occidentalis*, *Thalictrum occidentale*, *Tiarella trifoliata*, *Trientalis borealis*, *Trillium ovatum*, *Viola glabella*, *Gymnocarpium dryopteris*, *Polystichum munitum*, and *Adiantum pedatum*. Typically, stand-replacement, fire-return intervals are 150-500 years, with moderate-severity fire intervals of 50-100 years.

NORTHERN ROCKY MOUNTAIN PONDEROSA PINE WOODLAND AND SAVANNA (CES306.030)

CLASSIFIERS

Classification Status: Standard

Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Ridge/Summit/Upper Slope; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Sand Soil Texture; Aridic; Intermediate Disturbance Interval [Periodicity/Polycyclic Disturbance]; F-Patch/Medium Intensity; Needle-Leaved Tree; Graminoid; Pinus ponderosa with grassy understory; Pinus ponderosa with shrubby understory
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Montane [Montane]; Montane [Lower Montane]; Forest and Woodland (Treed); Temperate [Temperate Continental]; Circumneutral Soil; F-Landscape/Low Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2053; ESLF 4240; ESP 1053

CONCEPT

Summary: This inland Pacific Northwest ecological system occurs in the foothills of the northern Rocky Mountains in the Columbia Plateau region and west along the foothills of the Modoc Plateau and eastern Cascades into southern interior British Columbia. These woodlands and savannas occur at the lower treeline/ecotone between grasslands or shrublands and more mesic coniferous forests typically in warm, dry, exposed sites. Elevations range from less than 500 m in British Columbia to 1600 m in the central Idaho mountains. Occurrences are found on all slopes and aspects; however, moderately steep to very steep slopes or ridgetops are most common. This ecological system generally occurs on glacial till, glacio-fluvial sand and gravel, dune, basaltic rubble, colluvium, to deep loess or volcanic ash-derived soils, with characteristic features of good aeration and drainage, coarse textures, circumneutral to slightly acidic pH, an abundance of mineral material, rockiness, and periods of drought during the growing season. In the Oregon "pumice zone" this system occurs as matrix-forming, extensive woodlands on rolling pumice plateaus and other volcanic deposits. These woodlands in the eastern Cascades, Okanagan and northern Rockies regions receive winter and spring rains, and thus have a greater spring "green-up" than the drier woodlands in the central Rockies. *Pinus ponderosa* (primarily *var. ponderosa*) is the predominant conifer; *Pseudotsuga menziesii* may be present in the tree canopy but is usually absent. In southern interior British Columbia, *Pseudotsuga menziesii* or *Pinus flexilis* may form woodlands or fire-maintained savannas with and without *Pinus ponderosa var. ponderosa* at the lower treeline transition into grassland or shrub-steppe. The understory can be shrubby, with *Artemisia tridentata, Arctostaphylos patula, Arctostaphylos uva-ursi, Cercocarpus ledifolius, Physocarpus malvaceus, Purshia tridentata, Symphoricarpos oreophilus* or *Symphoricarpos albus, Prunus virginiana, Amelanchier alnifolia,* and *Rosa* spp. common species. Understory vegetation in the true savanna occurrences is predominantly fire-resistant grasses and forbs that resprout following surface fires; shrubs, understory trees and downed logs are uncommon. These more open stands support grasses such as *Pseudoroegneria spicata, Hesperostipa* spp., *Achnatherum* spp., dry *Carex* species (*Carex inops*), *Festuca idahoensis,* or *Festuca campestris.* The more mesic portions of this system may include *Calamagrostis rubescens* or *Carex geyeri*, species more typical of Northern Rocky Mountain Dry-Mesic Montane Mixed Conifer Forest (CES306.805). Mixed fire regimes and surface fires of variable return intervals maintain these woodlands typically with a shrub-dominated or patchy shrub layer, depending on climate, degree of soil development, and understory density. This includes the northern race of Interior Ponderosa Pine old-growth (USFS Region 6, USFS Region 1). Historically, many of these woodlands and savannas lacked the shrub component as a result of 3- to 7-year fire-return intervals.
Classification Comments: Hot, dry Douglas-fir types with grass are included here. Rocky Mountain Ponderosa Pine Woodland (CES306.827) and Southern Rocky Mountain Ponderosa Pine Savanna (CES306.826) contain mostly *Pinus ponderosa var. scopulorum* and *Pinus arizonica var. arizonica (= Pinus ponderosa var. arizonica).* The FRIS site describes different varieties of *Pinus ponderosa* and associated species. Johansen and Latta (2003) have mapped the distribution of the two varieties using mitochondrial DNA. They hybridize along the Continental Divide in Montana backing up the FRIS information. Another ponderosa pine system remains to be defined and described for the woodlands and savannas occurring in central and eastern Montana and the Black Hills region. These "northwestern Great Plains ponderosa pine woodlands" are likely to have a floristic component that is more northern Great Plains mixedgrass in nature, as well as being open woodlands generally found in a grassland matrix. Further work is need to identify the geographic and conceptual boundaries between Northern Rocky Mountain Ponderosa Pine Woodland and Savanna (CES306.030) and the northwestern Great Plains system.

Meeting of Pacific Northwest ecologists for Landfire concluded that the "true savanna" of high-frequency / low-intensity fires and grassy understories is now minimally in existence. Most areas that may have been savanna in the past are now more nearly closed-canopy woodlands/forests. Conclusion was that these true savannas should be included with this woodland system, rather than with the climatically-edaphically controlled Northern Rocky Mountain Foothill Conifer Wooded Steppe (CES306.958). Hence, the "true fire-maintained savanna" is included in this woodland system.

Louisa Evers (pers. comm. 2006) notes that she has not found any evidence that ponderosa pine savanna existed historically in north-central and central Oregon. In north-central Oregon, the savanna would have been oak or pine-oak. In central Oregon, it may well have been western juniper. Condition surveys of the Cascades Forest Reserve and General Land Office survey notes suggest that

ponderosa pine formed a woodland with grassy understories, but still was often referred to as open-parklike. Conversely pine-oak and Douglas-fir-oak savannas appeared to have once been quite common in the Willamette Valley (and are classified in North Pacific Oak Woodland (CES204.852)).

Similar Ecological Systems:

- Northwestern Great Plains-Black Hills Ponderosa Pine Woodland and Savanna (CES303.650)
- Southern Rocky Mountain Ponderosa Pine Savanna (CES306.649)
- Southern Rocky Mountain Ponderosa Pine Woodland (CES306.648)

- Ponderosa Pine - Grassland (110) (Shiflet 1994) Intersecting
- Ponderosa Pine - Shrubland (109) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This ecological system within the region occurs at the lower treeline/ecotone between grasslands or shrublands and more mesic coniferous forests typically in warm, dry, exposed sites at elevations ranging from 500-1600 m (1600-5248 feet). These woodlands receive winter and spring rains, and thus have a greater spring "green-up" than the drier ponderosa woodlands in the Colorado and New Mexico Rockies. In eastern Washington, precipitation varies from 36-76 cm (14-30 inches) with most occurring as snowfall (WNHP 2011). It can occur on all slopes and aspects; however, it commonly occurs on moderately steep to very steep slopes or ridgetops. This ecological system generally occurs on most geological substrates from weathered rock to glacial deposits to eolian deposits (e.g., glacial till, glacio-fluvial sand and gravel, dunes, basaltic rubble, colluvium, to deep loess or volcanic ash-derived soils) (WNHP 2011). Characteristic soil features include good aeration and drainage, coarse textures, circumneutral to slightly acidic pH, an abundance of mineral material, and periods of drought during the growing season. Some occurrences may occur as edaphic climax communities on very skeletal, infertile and/or excessively drained soils, such as pumice, cinder or lava fields, and scree slopes. In the Oregon "pumice zone" this system occurs as matrix-forming, extensive woodlands on rolling pumice plateaus and other volcanic deposits. Surface textures are highly variable in this ecological system ranging from sand to loam and silt loam. Exposed rock and bare soil consistently occur to some degree in all the associations.

Dynamics: Summer drought and frequent, low-severity fires create woodlands composed of widely spaced, large trees with small scattered clumps of dense, even-aged stands which regenerated in forest gaps or were protected from fire due to higher soil moisture or topographic protection. Closed-canopy or dense stands were also part of the historical range of stand variability but under natural disturbance regimes are a minor component of that landscape. Mixed fire regimes and surface fires of variable return intervals maintain these woodlands typically with a shrub-dominated or patchy shrub layer, depending on climate, degree of soil development, and understory density. Historically, many of these woodlands and savannas lacked the shrub component as a result of low-severity but high-frequency fires (2 - to 10-year fire-return intervals). Some sites, because of low productivity, naturally lacked a dense shrub understory. Mixed-severity fires had a return interval of 25-75 years while stand-replacing fire occurred at an interval of >100 years (Arno 1980, Fischer and Bradley 1987). The latter two intervals only occurred on 20-25% of stands within the landscape while surface fires were the dominant fire regime on over 75% of stands (Landfire 2007a). Presettlement fires were triggered by lightning strikes or deliberately set fires by Native Americans. Landfire VDDT models: R#PIPOm.

Pinus ponderosa is a drought-resistant, shade-intolerant conifer which usually occurs at lower treeline in the major ranges of the western United States. Establishment of ponderosa pine is erratic and believed to be linked to periods of adequate soil moisture and good seed crops as well as fire frequencies, which allow seedlings to reach sapling size.

Western pine beetle is another significant disturbance and especially affects larger trees. Bark beetle outbreaks are highly related to stand density. Denser stands in relation to site capacity will favor outbreaks, which will decrease as trees are thinned (Landfire 2007a). Mistletoe can cause tree mortality in young and small trees. Fires and insect outbreaks resulted in a landscape consisting of a mosaic of open forests of large trees (most abundant patch), small denser patches of trees, and openings (Franklin et al. 2008). White-headed woodpecker, pygmy nuthatch, and flammulated owl are indicators of healthy ponderosa pine woodlands. All of these birds prefer mature trees in an open woodland setting (Jones 1998, Levad 1998 Winn 1998, as cited in Rondeau 2001).

Component Associations:

National Mapping Codes: EVT 2046; ESLF 4233; ESP 1046

CONCEPT

Summary: This ecological system of the Northern Rockies, Cascade Range, and northeastern Olympic Mountains is typically a high-elevation mosaic of stunted tree clumps, open woodlands, and herb- or dwarf-shrub-dominated openings, occurring above closed forest ecosystems and below alpine communities. It includes open areas with clumps of *Pinus albicaulis*, as well as woodlands dominated by *Pinus albicaulis* or *Larix lyallii*. In the Cascade Range and northeastern Olympic Mountains, the tree clump pattern is one manifestation, but these are also woodlands with an open canopy, without a tree clump/opening patchiness to them; in fact, that is quite common with *Pinus albicaulis*. The climate is typically very cold in winter and dry in summer. In the Cascades and Olympic Mountains, the climate is more maritime in nature and wind is not as extreme. The upper and lower elevational limits, due to climatic variability and differing topography, vary considerably; in interior British Columbia, this system occurs between 1000 and 2100 m elevation, and in northwestern Montana, it occurs up to 2380 m. Landforms include ridgetops, mountain slopes, glacial trough walls and moraines, talus slopes, landslides and rockslides, and cirque headwalls and basins. Some sites have little snow accumulation because of high winds and sublimation. *Larix lyallii* stands generally occur at or near upper treeline on north-facing cirques or slopes where snowfields persist until June or July. In this harsh, often windswept environment, trees are often stunted and flagged from damage associated with wind and blowing snow and ice crystals, especially at the upper elevations of the type. The stands or patches often originate when *Picea engelmannii, Larix lyallii*, or *Pinus albicaulis* colonize a sheltered site such as the lee side of a rock. *Abies lasiocarpa* can then colonize in the shelter of the *Picea engelmannii* and may form a dense canopy by branch-layering. Major disturbances are windthrow and snow avalanches. Fire is known to occur infrequently in this system, at least where woodlands are present; lightning damage to individual trees is common, but sparse canopies and rocky terrain limit the spread of fire.

These high-elevation coniferous woodlands are dominated by *Pinus albicaulis, Abies lasiocarpa,* and/or *Larix lyallii*, with occasional *Picea engelmannii*. In the Cascades and Olympics, *Abies lasiocarpa* sometimes dominates the tree layer without *Pinus albicaulis*, though in this dry parkland *Tsuga mertensiana* and *Abies amabilis* are largely absent. The undergrowth is usually somewhat depauperate, but some stands support a near sward of heath plants, such as *Phyllodoce glanduliflora, Phyllodoce empetriformis, Empetrum nigrum, Cassiope mertensiana,* and *Kalmia polifolia,* and can include a slightly taller layer of *Ribes montigenum, Salix brachycarpa, Salix glauca, Salix planifolia, Vaccinium membranaceum, Vaccinium myrtillus,* or *Vaccinium scoparium* that may be present to codominant. The herbaceous layer is sparse under dense shrub canopies or may be dense where the shrub canopy is open or absent. *Vahlodea atropurpurea (= Deschampsia atropurpurea), Luzula glabrata var. hitchcockii,* and *Juncus parryi* are the most commonly associated graminoids.

In the mountains of northwestern and west-central Wyoming, where this upper-treeline system reaches the edge of its geographic range, the vegetation usually has the form of an open woodland, and only rarely as scattered groves of trees. At the highest elevations, *Pinus albicaulis* usually has a wind-stunted shrub form. On lower, more favorable sites, upright but wind-shaped *Pinus albicaulis* forms woodlands, sometimes with *Pinus contorta* as a codominant or even the dominant species. With decrease in altitude, where this system merges into the subalpine forests, *Picea engelmannii* and *Abies lasiocarpa* become common tree species as well.
Classification Comments: There is a proposal to either split the dry, subalpine *Pinus albicaulis* woodlands of the Blue Mountains (Oregon) and northern Nevada into a different system; or else to include them in Rocky Mountain Subalpine-Montane Limber-Bristlecone Pine Woodland (CES306.819). For Landfire, these *Pinus albicaulis* woodlands were included in this subalpine parkland system, but ecologically and floristically they are more similar to Rocky Mountain dry subalpine woodlands. In addition, there is a proposal and discussion that tree ribbon spruce-fir woodlands in scattered ranges of southern Wyoming are more ecologically "parklands"; possibly those areas could be included in this system.

DESCRIPTION

Environment: The climate is typically very cold in winter and dry in summer. In the Cascades and Olympic Mountains, the climate is more maritime in nature and wind is not as extreme. The upper and lower elevational limits, due to climatic variability and differing topography, vary considerably; in interior British Columbia, this system occurs between 1000 and 2100 m elevation, and in northwestern Montana, it occurs up to 2380 m. Landforms include ridgetops, mountain slopes, glacial trough walls and moraines, talus slopes, landslides and rockslides, and cirque headwalls and basins. Some sites have little snow accumulation because of high winds and sublimation. In west-central Wyoming, this system occurs on various landforms over an elevational range from 2230 to 3200 m. It is not tied to particular aspects (Steele et al. 1983).

Dynamics: In this harsh, often windswept environment, trees are often stunted and flagged from damage associated with wind and blowing snow and ice crystals, especially at the upper elevations of the type. The stands or patches often originate when *Picea engelmannii*, *Larix lyallii*, or *Pinus albicaulis* colonize a sheltered site such as the lee side of a rock. *Abies lasiocarpa* can then colonize in the shelter of the *Picea engelmannii* and may form a dense canopy by branch-layering. Major disturbances are windthrow and snow avalanches. Fire is known to occur infrequently in this system, at least where woodlands are present; lightning damage to individual trees is common, but sparse canopies and rocky terrain limit the spread of fire. *Larix lyallii* is a very slow-growing, long-lived tree, with individuals up to 1000 years in age. It is generally shade-intolerant; however, extreme environmental conditions limit potentially competing trees. In the Cascades and Olympic Mountains, the climate is more maritime in nature and wind is not as extreme, but summer drought is a more important process than in the related North Pacific Maritime Mesic Subalpine Parkland (CES204.837). In northwestern and west-central Wyoming, *Pinus albicaulis* is the initial colonizer, and trees of other species become established in the micro-sites that it creates (Callaway 1998, cited in Greater Yellowstone Coordinating Committee 2011). In the highest-elevation stands where *Pinus albicaulis* usually is the only tree present, vegetation dynamics are relatively simple: stands start out with rather dense overstories and sparse undergrowths, and develop more open overstories and denser undergrowths over time. At lower elevations, *Pinus contorta* dominates some stands soon after fire, and the long-lived, more shade-tolerant *Pinus albicaulis* become dominant over time (Steele et al. 1983). As in the Pacific Northwest, fire has, in the past, been a minor process (compared to the subalpine forests at lower elevations): lightning starts many fires, but they rarely spread (Steele et al. 1983).

NORTHERN ROCKY MOUNTAIN WESTERN LARCH SAVANNA (CES306.837)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Forest and Woodland (Treed); Udic; Very Long Disturbance Interval; F-Landscape/Medium Intensity; Other Floristics/Dominants [User-defined]
Non-Diagnostic Classifiers: Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Sideslope; Toeslope/Valley Bottom; Temperate [Temperate Continental]; Mesotrophic Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2010; ESLF 4103; ESP 1010

CONCEPT

Summary: This ecological system is restricted to the interior montane zone of the Pacific Northwest in northern Idaho and adjacent Montana, Washington, Oregon, and in southeastern interior British Columbia. It also appears in the east Cascades of Washington. Winter snowpacks typically melt off in early spring at lower elevations. Elevations range from 680 to 2195 m (2230-7200 feet), and sites include drier, lower montane settings of toeslopes and ash deposits. This system is composed of open-canopied "savannas" of the deciduous conifer *Larix occidentalis*, which may have been initiated following stand-replacing crownfires of other conifer systems, but are maintained by a higher frequency, surface-fire regime. These savannas are found in settings where low-intensity, high-frequency fires create open larch woodlands, often with the undergrowth dominated by low-growing *Arctostaphylos uva-ursi, Calamagrostis rubescens, Linnaea borealis, Spiraea betulifolia, Vaccinium caespitosum*, or *Xerophyllum tenax*. Less frequent or absence of fire creates mixed-dominance stands with often shrubby undergrowth; *Vaccinium caespitosum* is common, and taller shrubs can include *Acer glabrum, Ceanothus velutinus, Shepherdia canadensis, Physocarpus malvaceus, Rubus parviflorus*, or *Vaccinium membranaceum*. Fire suppression has led to invasion of the more shade-tolerant tree species *Abies grandis, Abies lasiocarpa, Picea engelmannii*, or *Tsuga* spp. and loss of much of the single-story canopy woodlands.
Classification Comments: Stands initiated following crownfires in areas with stand-replacing fire frequencies greater than 150 years are included in the more mesic adjacent forest systems (Northern Rocky Mountain Mesic Montane Mixed Conifer Forest (CES306.802) and Northern Rocky Mountain Dry-Mesic Montane Mixed Conifer Forest (CES306.805)). This is a fire-dependant system and was much more extensive in the past; it is now very patchy in distribution. Most *Larix occidentalis* is a seral component of the dry-mesic mixed montane forest.
Similar Ecological Systems:
- Northern Rocky Mountain Dry-Mesic Montane Mixed Conifer Forest (CES306.805)

Related Concepts:
- Western Larch: 212 (Eyre 1980) Broader

DESCRIPTION

Dynamics: *Larix occidentalis* is a long-lived species (in excess of 700 years in the northern Rocky Mountains), and thus stands fitting this concept are themselves long-persisting; the life of *Larix*-dominated stands probably does not much exceed 250 years due to various mortality sources and the ingrowth of shade-tolerant species. Occurrences of this ecological system are generated by stand-replacing fire, the fire-return interval for which is speculated to be on the order of 80 to 200 years. These sites may be maintained in a seral status for hundreds of years due to the fact that *Larix occidentalis* is a long-lived species and the understory is often dominated by *Pseudotsuga*, which will grow into the upper canopy. The potential dominants *Abies lasiocarpa, Picea engelmannii*, or *Abies grandis* are slow to establish on these sites and grow slowly presenting the distinct probability, given the fire-return intervals for this type, that the "climax" (long-term stable) condition is never realized.

It has been noted in northern Idaho that, following disturbance (particularly logging) in some mesic-site occurrences, *Larix occidentalis* does not necessarily succeed itself, the first tree-dominated successional stages being dominated by *Pseudotsuga menziesii*, *Pinus contorta*, or less frequently by more shade-tolerant species (Cooper et al. 1987); this response is a consequence of the episodic nature of favorable cone crop years in *Larix occidentalis*.

Landfire VDDT models: #RMCONm and #RMCONdy classes B, C, & D.

Component Associations:
- *Larix occidentalis / Clintonia uniflora - Xerophyllum tenax* Forest (CEGL005881, GNR)
- *Larix occidentalis / Clintonia uniflora* Forest (CEGL005880, GNR)
- *Larix occidentalis / Vaccinium caespitosum / Clintonia uniflora* Forest (CEGL005883, GNR)
- *Larix occidentalis / Vaccinium caespitosum* Forest (CEGL005882, GNR)

DISTRIBUTION

Range: This ecological system is restricted to the interior montane zone of the Pacific Northwest in northern Idaho and adjacent Montana, Washington, Oregon, and in southeastern interior British Columbia. It also appears in the east Cascades of Washington.

NORTHWESTERN GREAT PLAINS HIGHLAND WHITE SPRUCE WOODLAND (CES303.957)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Temperate [Temperate Continental]; Picea glauca
Non-Diagnostic Classifiers: Montane [Montane]; Forest and Woodland (Treed); Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2048; ESLF 4235; ESP 1048

CONCEPT

Summary: This uncommon system is limited to relatively high-elevation outliers of montane environments in the northwestern Great Plains. Best known areas of this system are small portions of the Black Hills of Wyoming and South Dakota and the Cypress Upland of southern Alberta and Saskatchewan. These highland areas have a cooler climate than surrounding mixedgrass prairie. In the Black Hills, these woodlands occur as small or large patches within the ponderosa pine matrix, from about 1740 to 2135 m (5700-7000 feet); at lower elevations, they are restricted to north-facing slopes. At the higher elevations, they are found on level or gently sloping areas. In other locations, this woodland system is limited to sideslopes and depressions, likely adjoining riparian zones, where snow is well-retained. Soils vary widely from deep to quite shallow. *Picea glauca* is the characteristic conifer, but other trees can include *Pinus ponderosa, Populus tremuloides*, and *Betula papyrifera*. Undergrowth shrubs typically include *Arctostaphylos uva-ursi, Juniperus communis, Linnaea borealis, Symphoricarpos albus*, and *Vaccinium scoparium*. Disturbance regimes are not well-documented for this system, but likely include periodic windthrow as well as fire spreading from adjacent, lower elevation woodlands and grasslands.

DESCRIPTION

Environment: This system is limited to relatively high-elevation outliers of montane environments in the northwestern Great Plains of the U.S. and southern Canada. These highland areas have a cooler and more mesic climate than surrounding mixedgrass prairie. In the Black Hills, these woodlands occur as small or large patches within the ponderosa pine matrix, from about 1740 to 2135 m (5700-7000 feet) elevation; at lower elevations, they are restricted to north-facing slopes. At the higher elevations, they are found on level or gently sloping areas. In other locations, this woodland system is limited to sideslopes and depressions, likely adjoining riparian zones, where snow is well-retained. Geology is generally dominated by limestone, granite, slate and schist. Soils vary widely from deep to quite shallow. In the Cypress Hills of Alberta and Saskatchewan, the elevations where this system is found range up to 1466 m; generally these woodlands occur on north-facing slopes or near small springs and seeps.
Dynamics: Disturbance regimes are not well-documented for this system, but likely include periodic windthrow as well as fire spreading from adjacent, lower elevation or drier woodlands and grasslands. There is some debate about whether mixed-severity fire would have occurred in this type based on tree-ring and historical evidence; estimated at a 100-year return interval (Landfire 2007a). Stand-replacing disturbances are primarily associated with climatic fluctuations and include fire and insect (in late-development classes only, mountain pine beetles create larger patch sizes; Ips beetles create smaller patches). Snowbreak and windthrow events may occur. The majority of the insect outbreaks generally occur in late-development stands but in periods of drought (such as that which the forest is currently experiencing), tree mortality is occurring in ponderosa pine that are less than 18 cm (7 inches) dbh. Surface and stand-replacing fire events occur in this system. Stand-replacing fires were likely most common in higher elevation and northern slopes that were primarily dominated by spruce, with surface fires occurring most often in the moist ponderosa pine.

Component Associations:
- *Picea glauca / Linnaea borealis* Forest (CEGL000382, G2G3)
- *Picea glauca / Vaccinium scoparium* Forest (CEGL000383, G1G2)
- *Picea glauca* Alluvial Black Hills Forest (CEGL002057, G2G3)

DISTRIBUTION

Range: This system is limited to relatively high-elevation outliers of montane environments in the northwestern Great Plains. Best known areas of this system are small portions of the Black Hills of Wyoming and South Dakota and the Cypress Upland of southern Alberta and Saskatchewan. It may also occur in very small stands of the Bighorn Mountains of north-central Wyoming and south-central Montana.

NORTHWESTERN GREAT PLAINS-BLACK HILLS PONDEROSA PINE WOODLAND AND SAVANNA (CES303.650)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Ridge/Summit/Upper Slope; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Sand Soil Texture; Aridic; Intermediate Disturbance Interval [Periodicity/Polycyclic Disturbance]; F-Patch/Medium Intensity; Needle-Leaved Tree; Pinus ponderosa with grassy understory; Pinus ponderosa with shrubby understory
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2179; ESLF 4280; ESP 1179

CONCEPT

Summary: This system occurs throughout the Great Plains Division along areas that border the Rocky Mountain Division and into the central Great Plains. The expansion of this system into the central Great Plains may be due to fire suppression. These can be physiognomically variable, ranging from very sparse patches of trees on drier sites, to nearly closed-canopy forest stands on north slopes or in draws where available soil moisture is higher. This system occurs primarily on gentle to steep slopes along escarpments, buttes, canyons, rock outcrops or ravines and can grade into one of the Great Plains canyon systems or the surrounding prairie system. Soils typically range from well-drained loamy sands to sandy loams formed in colluvium, weathered sandstone, limestone, scoria or eolian sand. This system is primarily dominated by *Pinus ponderosa* but may include a sparse to relatively dense understory of *Juniperus scopulorum, Thuja*, or *Cercocarpus* with just a few scattered trees. Deciduous trees are an important component in some areas (western Dakotas, Black Hills) and are sometimes codominant with the pines, including *Fraxinus pennsylvanica, Betula papyrifera, Quercus macrocarpa, Ulmus americana, Acer negundo*, and *Populus tremuloides*. Along the Missouri Breaks in north-central Montana, woodlands dominated by *Pseudotsuga menziesii* are in similar ecological settings as *Pinus ponderosa* in the Great Plains and are included in this system. In the breaks where it occurs, *Pseudotsuga menziesii* has a very open canopy over grassy undergrowth, predominantly composed of *Pseudoroegneria spicata*, with little to no shrubs present. Important or common shrub species with ponderosa pine can include *Arctostaphylos uva-ursi, Mahonia repens, Yucca glauca, Symphoricarpos* spp., *Prunus virginiana, Juniperus communis, Juniperus horizontalis, Amelanchier alnifolia, Rhus trilobata*, and *Physocarpus monogynus*. The herbaceous understory can range from sparse to a dense layer with species typifying the surrounding prairie system, with mixedgrass species common, such as *Andropogon gerardii, Bouteloua curtipendula, Carex inops ssp. heliophila, Carex filifolia, Danthonia intermedia, Koeleria macrantha, Nassella viridula, Oryzopsis asperifolia, Pascopyrum smithii, Piptatherum micranthum*, and *Schizachyrium scoparium*. Timber cutting and other disturbances have degraded many examples of this system within the Great Plains, however, some good examples may occur along the Pine Ridge escarpment and Pine Ridge district of the Nebraska National Forest in Nebraska.
Classification Comments: In this Great Plains region, what were previously called Northern Rocky Mountain Foothill Conifer Wooded Steppe (CES306.958), Southern Rocky Mountain Ponderosa Pine Woodland (CES303.648) and Southern Rocky Mountain Ponderosa Pine Savanna (CES306.826) are now included in this new system. Physiognomically, this is a variable system, with everything from sparse woodlands on breaks and scoria bluffs to dense closed-canopy stands in the Black Hills included.

Southern Rocky Mountain Ponderosa Pine Woodland (CES306.648) is now defined to occur in the montane zones of the Bighorns (USFS section M331B) and Laramie Range (USFS section M331I) and to the west and south of these mountains. It will also occur in other isolated mountain ranges of central Wyoming, but not in eastern Wyoming. It does not occur farther north than Wyoming; all Montana ponderosa pine woodlands are placed into either this Northwest Great Plains system or into Northern Rocky Mountain Ponderosa Pine Woodland and Savanna (CES306.030), as appropriate. The southern extent is hard to determine, but farther south in Colorado, there is more *Juniperus, Pinus edulis*, and *Quercus gambelii*. This system certainly occurs in New Mexico, but stands at the Black Mesa in western Oklahoma and in southeastern Colorado may also be viewed as having the southwestern affinities.

In the Pine Escarpments of Nebraska, pine communities can range from open canopies with grassy understories to more closed canopies. Included within these areas are also several rocky outcrops, which probably should be included within the system as they are often intermingled with the savanna. The more closed-canopy examples may be more similar to Southern Rocky Mountain Ponderosa Pine Woodland (CES306.648) but are included in this system for now.
Similar Ecological Systems:
- Northern Rocky Mountain Foothill Conifer Wooded Steppe (CES306.958)
- Northern Rocky Mountain Ponderosa Pine Woodland and Savanna (CES306.030)
- Southern Rocky Mountain Ponderosa Pine Savanna (CES306.649)
- Southern Rocky Mountain Ponderosa Pine Woodland (CES306.648)

Related Concepts:
- Interior Ponderosa Pine: 237 (Eyre 1980) Intersecting
- Northwestern Great Plains Pine Woodland (Rolfsmeier and Steinauer 2010) Equivalent

DESCRIPTION

Dynamics: Marriot and Faber-Langendoen (2000) report different fire regimes for ponderosa pine communities in the Black Hills, with their "Dry Group" more typically having frequent surface fires and the "Mesic Group" having infrequent catastrophic fires (every 100-200 years). The Dry Group of associations includes lower elevation foothill savanna associations, and the mesic group somewhat higher elevation, north-slope, swale associations. K. Kindscher (pers. comm. 2007) believes that almost all of the stands in Nebraska were there at the time of settlement and are not a result of pine expansion due to fire suppression; in addition, at least some have disappeared, such as the one in southern Nebraska (Franklin County). It is possible, however, that some areas of this system have expanded in size due to fire suppression, but this needs substantiation.

Component Associations:
- *Pinus ponderosa / Carex inops ssp. heliophila* Woodland (CEGL000849, G3G4)
- *Pinus ponderosa / Juniperus horizontalis* Woodland (CEGL000860, G3?)
- *Pinus ponderosa / Oryzopsis asperifolia* Woodland (CEGL002123, G3G4Q)
- *Pinus ponderosa / Pascopyrum smithii* Woodland (CEGL000188, G3G4)
- *Pinus ponderosa / Physocarpus monogynus* Forest (CEGL000190, G3)
- *Pinus ponderosa / Prunus virginiana* Forest (CEGL000192, G3G4)
- *Pinus ponderosa / Quercus macrocarpa* Woodland (CEGL000873, G3)
- *Pinus ponderosa / Schizachyrium scoparium* Woodland (CEGL000201, G3G4)
- *Pinus ponderosa / Symphoricarpos occidentalis* Forest (CEGL000204, G3)

SPATIAL CHARACTERISTICS

Spatial Summary: These ponderosa pine occurrences are typically found in the matrix of the Great Plains grassland systems. They are often surrounded by mixedgrass or tallgrass prairie, in places where available soil moisture is higher or soils are more coarse and rocky. In some cases, these woodlands or savannas may occur where fire suppression has allowed trees to become established (in areas where deciduous trees are more abundant (Girard et al. 1987)). These are typically not in the same setting as Rocky Mountain ponderosa pine, where ponderosa pine forms woodlands at lower treeline and grades into mixed montane conifer systems at higher elevations (it did not make sense to keep Black Hills ponderosa woodlands with the Rocky Mountain system, so they are included here).

Floristically, these pine stands have a graminoid component that is strongly related to mixedgrass or tallgrass Great Plains floristics. The shrub component is not very diagnostic, as most of the important shrubs are commonly also important in Rocky Mountain ponderosa pine or Douglas-fir systems.

DISTRIBUTION

Range: This system is found in central and eastern Montana, the western Dakotas, eastern Wyoming (east of the Bighorns), the Black Hills, and south into the Sand Hills of Nebraska and northeastern Colorado (north of Pawnee National Grasslands to Cedar Point near Limon and south). In Montana, it occurs along the Missouri River breaks, around the Little Belts and Snowy mountains, in south-central Montana between the Bighorns and the Black Hills (along the Tongue and Powder rivers), and other areas of eastern Montana. In Wyoming, it is found around the Black Hills and Bear Lodge Mountains, and in isolated areas of eastern Wyoming on bluffs and rock outcrops, and along "breaks." Whether this system occurs in Kansas is uncertain.

OUACHITA MONTANE OAK FOREST (CES202.306)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Forest and Woodland (Treed); Ozark/Ouachita; Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2312; ESLF 4118; ESP 1312

CONCEPT

Summary: This system represents hardwood forests of the highest elevations of the Ouachita, Rich, and Black Fork mountains of Arkansas and Oklahoma (about 790-850 m [2600-2800 feet]). Vegetation consists of either forests or open woodlands dominated by *Quercus alba* or *Quercus stellata*. Canopy trees are often stunted due to the effects of ice, wind and cold conditions, in combination with fog, shallow soils over rock, and periodic severe drought. Some stands form almost impenetrable thickets.
Classification Comments: *Quercus alba - Carya alba / Ostrya virginiana / Carex pensylvanica - Schizachyrium scoparium* Forest (CEGL007818) is taller and less influenced by wind and ice. It is no longer included in this system.
Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer
- White Oak: 53 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is restricted to the highest elevations of the Ouachita, Rich, and Black Fork mountains of Arkansas and Oklahoma (about 790-850 m [2600-2800 feet]). Ecological factors include the effects of ice, wind and cold, in combination with fog, shallow soils over rock, and periodic severe drought.
Vegetation: The vegetation of this system consists of either forests or open woodlands dominated by *Quercus alba* or *Quercus stellata*. Some examples may have *Quercus marilandica var. ashei*; herb layers may contain *Carex pensylvanica* and/or *Carex ouachitana*. In addition, *Quercus rubra, Quercus stellata, Carya texana,* and *Quercus marilandica* may occur as minor components of the canopy. Associated woody species of minor importance include *Amelanchier arborea, Acer rubrum var. rubrum, Sassafras albidum, Vaccinium pallidum, Vaccinium stamineum, Rubus* spp., *Nyssa sylvatica, Hamamelis virginiana, Rhus copallinum, Rhus glabra, Pinus echinata, Chionanthus virginicus, Ulmus alata, Smilax* spp., and *Rubus* spp. The ground layer may have a mosaic of sedge-dominated and lichen/moss-dominated areas. In addition to *Carex pensylvanica* and *Carex ouachitana*, herbaceous species include *Carex albicans var. albicans, Carex nigromarginata, Deschampsia flexuosa, Schizachyrium scoparium, Elymus* spp., *Maianthemum racemosum, Hypericum* sp., *Baptisia* sp., *Cynoglossum virginianum var. virginianum, Agalinis* sp., *Dichanthelium* spp., *Solidago ulmifolia*, and *Solidago* spp.
Dynamics: Canopy trees are often stunted due to the effects of ice, wind and cold conditions, in combination with fog, shallow soils over rock, and periodic severe drought.

Component Associations:
- *Quercus alba / Carex pensylvanica - Carex ouachitana* Dwarf Forest (CEGL002433, G1)
- *Quercus stellata - Quercus marilandica var. ashei* Interior Highlands Scrub Woodland (CEGL003884, G2)

DISTRIBUTION

Range: This system is found at the highest elevations of the Ouachita, Rich, and Black Fork mountains of Arkansas and Oklahoma (about 790-850 m [2600-2800 feet]).

OZARK-OUACHITA DRY OAK WOODLAND (CES202.707)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Ozark/Ouachita
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Woody-Herbaceous
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2364; ESLF 4306; ESP 1364

CONCEPT

Summary: This system occurs in the Ozark and Ouachita Highlands and far western portions of the Interior Low Plateau regions along gentle to steep slopes and over bluff escarpments with southerly to westerly aspects. Parent material can range from calcareous to acidic with very shallow, well- to excessively well-drained soils, sometimes with a fragipan that causes "xero-hydric" moisture conditions. Historically, this system primarily exhibited a woodland structure with related composition and processes, but now most stands have a more closed canopy. Oak species such as *Quercus stellata*, *Quercus marilandica*, and *Quercus coccinea* dominate this system with an understory of grassland species such as *Schizachyrium scoparium* and shrub species such as *Vaccinium arboreum*. Drought stress is the major dynamic influencing and maintaining this system. Some examples are flatwoods with fragipans; in these examples *Quercus stellata* is the major dominant. In addition, *Quercus alba, Quercus falcata*, and/or *Carya texana* may be present in some stands.
Classification Comments: Dry-mesic to mesic oaks were separated from dry oak per the suggestion of Missouri [see Ozark-Ouachita Dry-Mesic Oak Forest (CES202.708)]. This separation may need to be further reviewed.
Similar Ecological Systems:
- Ouachita Novaculite Glade and Woodland (CES202.314)
- Ozark-Ouachita Dry-Mesic Oak Forest (CES202.708)
- Ozark-Ouachita Shortleaf Pine-Oak Forest and Woodland (CES202.313)

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs along gentle to steep slopes and over bluff escarpments with southerly to westerly aspects in the Ozark and Ouachita Highlands and far western portions of the Interior Low Plateau regions. Parent material can range from calcareous to acidic with very shallow, well- to excessively well-drained soils, sometimes with a fragipan that causes "xero-hydric" moisture conditions. Conditions are drier than those of the dry oak woodlands.
Vegetation: Oak species such as *Quercus stellata, Quercus marilandica*, and *Quercus coccinea* dominate this system with an understory of grassland species such as *Schizachyrium scoparium* and shrub species such as *Vaccinium arboreum*. Drought stress is the major dynamic influencing and maintaining this system. On flatwoods with fragipans, *Quercus stellata* is the major dominant. *Quercus alba, Quercus falcata*, and/or *Carya texana* may be present in some stands. Other species that may be present include *Schizachyrium scoparium, Ulmus alata*, and *Vaccinium arboreum*.

Component Associations:
- *Quercus alba - Quercus stellata - Quercus velutina / Schizachyrium scoparium* Woodland (CEGL002150, G2G3)
- *Quercus falcata - Quercus alba - Quercus stellata - Quercus velutina* Forest (CEGL005018, G3G5)
- *Quercus marilandica / Vaccinium arboreum / Danthonia spicata* Scrub Woodland (CEGL002425, G3G4)
- *Quercus stellata - Quercus marilandica - Carya (glabra, texana) / Vaccinium arboreum* Forest (CEGL002075, G4)
- *Quercus stellata - Quercus marilandica - Quercus velutina - Carya texana / Schizachyrium scoparium* Woodland (CEGL002149, G2G3)
- *Quercus velutina - Carya (alba, glabra) / Vaccinium arboreum* Forest (CEGL004987, G2G3Q)
- *Quercus velutina - Quercus coccinea - Carya texana* Ozark Forest (CEGL002399, GNR)

DISTRIBUTION

Range: This system occurs in the Western Interior Highlands of the Ozark, Ouachita, and western Interior Low Plateau regions.

OZARK-OUACHITA DRY-MESIC OAK FOREST (CES202.708)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Ozark/Ouachita
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Quercus - Carya
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2304; ESLF 4110; ESP 1304

CONCEPT

Summary: This system is found throughout the Ozark and Ouachita Highlands ranging to the western edge of the Interior Low Plateau. It is the matrix system of this region and occurs on dry-mesic to mesic, gentle to moderately steep slopes. Soils are typically moderately to well-drained and more fertile than those associated with oak woodlands. A closed canopy of oak species (*Quercus rubra* and *Quercus alba*) often associated with hickory species (*Carya* spp.) typifies this system. *Acer saccharum* (or *Acer barbatum* to the south) may occur on more mesic examples of this system. Wind, drought, lightning, and occasional fires can influence this system.
Classification Comments: Dry-mesic to mesic oaks were separated from dry oak (Ozark-Ouachita Dry Oak Woodland (CES202.707)) per the suggestion of Missouri. This separation may need to be further reviewed. Likewise, the distribution of this system versus the one farther north (North-Central Interior Dry-Mesic Oak Forest and Woodland (CES202.046)) needs to be reviewed. Currently the glacial line separates the two systems.
Similar Ecological Systems:
- Ouachita Novaculite Glade and Woodland (CES202.314)
- Ozark-Ouachita Dry Oak Woodland (CES202.707)
- Ozark-Ouachita Shortleaf Pine-Oak Forest and Woodland (CES202.313)

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Sugar Maple: 27 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer
- White Oak: 53 (Eyre 1980) Finer

DESCRIPTION

Environment: This is the matrix system of this region and occurs on dry-mesic to mesic, gentle to moderately steep slopes. Soils are typically moderately to well-drained and more fertile than those associated with oak woodlands.
Vegetation: A closed canopy of oak species (*Quercus rubra, Quercus muehlenbergii,* and *Quercus alba*) often associated with hickory species (*Carya* spp.) typifies this system. *Acer saccharum* (or *Acer barbatum* to the south) may occur in more mesic examples. Some stands in the western edge of the Interior Low Plateau (eastern range limit of the system) may contain *Quercus prinus*. Some other species which may be present include *Carex pensylvanica, Carya alba, Carya cordiformis, Carya glabra, Carya ovata, Cercis canadensis, Cornus florida, Fagus grandifolia, Fraxinus americana, Gleditsia triacanthos, Gymnocladus dioicus, Hybanthus concolor, Juglans nigra, Juniperus virginiana, Lindera benzoin, Liquidambar styraciflua, Maclura pomifera, Ostrya virginiana, Quercus alba, Quercus falcata, Quercus marilandica, Quercus shumardii, Quercus velutina, Schizachyrium scoparium, Smilax* spp., *Ulmus americana, Ulmus serotina,* and *Vitis aestivalis*.
Dynamics: Wind, drought, lightning, and occasional fires can influence this system.

Component Associations:
- *Acer saccharum - Quercus muehlenbergii / Cotinus obovatus* Forest (CEGL004795, G2G3Q)
- *Juniperus virginiana - Quercus (alba, stellata) - Carya texana* Forest (CEGL004803, GNR)
- *Quercus alba - Carya alba / Ostrya virginiana / Carex pensylvanica - Schizachyrium scoparium* Forest (CEGL007818, G3Q)
- *Quercus alba - Quercus rubra - Carya (alba, ovata) / Cornus florida* Acidic Forest (CEGL002067, G3)
- *Quercus alba - Quercus rubra - Quercus muehlenbergii / Cercis canadensis* Forest (CEGL002070, G4G5)
- *Quercus alba - Quercus velutina - Carya alba / Desmodium nudiflorum* Ozark Forest (CEGL004270, G4)
- *Quercus alba / Cornus florida* Unglaciated Forest (CEGL002066, G4?)
- *Quercus falcata - Carya alba - Carya ovata* Forest (CEGL004543, G3Q)
- *Quercus muehlenbergii - Quercus shumardii* Forest (CEGL004602, G2G4)
- *Quercus prinus / Smilax* spp. Forest (CEGL005022, G4)
- *Quercus rubra - Quercus shumardii* Forest (CEGL004796, G3?)
- *Quercus velutina - Quercus alba - Carya (glabra, ovata)* Forest (CEGL002076, G4?)
- *Vitis aestivalis* Vine-Shrubland (CEGL003890, G2G3)

DISTRIBUTION

Range: This system is found throughout the Ozark and Ouachita Highlands, reaching to the western Interior Low Plateau of Illinois.

OZARK-OUACHITA MESIC HARDWOOD FOREST (CES202.043)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Ozark/Ouachita
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Toeslope/Valley Bottom
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2334; ESLF 4140; ESP 1334

CONCEPT

Summary: This system is found on lower slopes, toeslopes and valley bottoms within the Ozark and Ouachita regions, as well as on north slopes. In the Ozarks, *Quercus rubra* increases in abundance compared to dry-mesic habitats, and *Acer saccharum* is sometimes a leading dominant. On more alkaline moist soils, *Quercus muehlenbergii, Tilia americana,* and *Cercis canadensis* may be common. In the Boston Mountains, mesic forests may also be common on protected slopes and terraces next to streams. Here, *Fagus grandifolia* may be the leading dominant, with codominants of *Acer saccharum, Liquidambar styraciflua, Tilia americana, Magnolia acuminata, Magnolia tripetala,* and others. Similar habitats occur in the western Ouachita Mountains.

Similar Ecological Systems:
- South-Central Interior Mesophytic Forest (CES202.887)

Related Concepts:
- Beech - Sugar Maple: 60 (Eyre 1980) Finer
- Northern Red Oak: 55 (Eyre 1980) Finer
- Sugar Maple: 27 (Eyre 1980) Finer

DESCRIPTION

Environment: This system may be found on a wide range of topographic positions. It includes mixed mesophytic forests, seeps/springs and smaller riparian areas. This system is found on primarily north- and east-facing aspects, lower slopes, toeslopes, small valley bottoms and terraces, as well as other protected slopes and ravines along intermittent and/or ephemeral streams. Distribution is influenced by local conditions affecting moisture, aspect, elevation and soil productivity. Closed conditions are multiple canopy usually late-seral forests. Stands of this system are generally small, isolated, and/or disjunct and are generally "embedded" in a larger landscape matrix. These communities are maintained primarily through naturally occurring circumstances such as aspect, elevation, soil moisture conditions, and soil productivity, except for mortality or other disturbance-induced openings or gaps.

Vegetation: Dominant or characteristic trees in examples of this system may include *Quercus alba, Quercus rubra, Acer barbatum, Acer saccharum, Fagus grandifolia, Liquidambar styraciflua, Quercus muehlenbergii,* and *Tilia americana*. The understory may contain *Cercis canadensis, Magnolia tripetala,* and/or *Magnolia acuminata*. Some common shrubs include *Asimina triloba* and *Lindera benzoin*. Stands will typically have diverse ground layers. Some typical herbs include *Podophyllum peltatum* and *Hybanthus concolor*.

Dynamics: This type has a lower fire frequency than drier (uphill) types and experiences primarily low-intensity surface fire with occasional mosaic (mixed-severity) or replacement fire. Mean fire-return interval (MFI) is about 25 years with wide year-to-year and within-type variation related to moisture cycles, degree of sheltering and proximity to more fire-prone types. Anthropogenic fire is considered and contributes to within-type MFRI variation. Drought and moisture cycles play a strong role interacting with fire and insect and disease damage. Other natural disturbances may include wind and ice (Landfire 2007a).

Component Associations:
- *Acer (barbatum, saccharum) - Juglans nigra - Fraxinus americana / Hybanthus concolor* Forest (CEGL007811, G2)
- *Acer (saccharum, barbatum) - Quercus rubra - Carya cordiformis / Asimina triloba* Forest (CEGL002060, G3)
- *Fagus grandifolia - Acer saccharum - Liriodendron tulipifera* Unglaciated Forest (CEGL002411, G4?)
- *Fagus grandifolia - Quercus rubra - Tilia americana var. caroliniana / Magnolia tripetala / Podophyllum peltatum* Forest (CEGL007823, G3G4)
- *Quercus alba - Quercus rubra - Acer saccharum - Carya cordiformis / Lindera benzoin* Forest (CEGL002058, G3?)
- *Quercus muehlenbergii - Acer saccharum* Southeastern Oklahoma Forest (CEGL004662, G2G4)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Ozark-Ouachita Shortleaf Pine-Bluestem Woodland (CES202.325)
- Ozark-Ouachita Shortleaf Pine-Oak Forest and Woodland (CES202.313)

DISTRIBUTION

Range: This system is found within the Ozarks and Ouachita Mountains of Missouri, Arkansas, and Oklahoma.

Divisions: 202:C
Nations: US
Subnations: AR, MO, OK
Map Zones: 44:C, 49:P

OZARK-OUACHITA SHORTLEAF PINE-BLUESTEM WOODLAND (CES202.325)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Ozark/Ouachita; Very Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2507; ESLF 4281; ESP 1507

CONCEPT

Summary: This system represents woodlands of the Ouachita and Ozark mountains region of Arkansas, adjacent Oklahoma, and southern Missouri in which *Pinus echinata* is the canopy dominant, and the understory is characterized by *Andropogon gerardii*, *Schizachyrium scoparium*, and other prairie plants. Although examples of this system occur throughout this region, there is local variation in the extent to which they were present. The center of distribution is the northern and western Ouachita Mountains, and it is best developed in large, dry, and flat to gently undulating portions of the landscape which carry fire well, creating extensive natural fire compartments. In the Ouachitas, the system occurs on the northern Hogback Ridges excluding the Novaculite areas to the south. These are large, gently sloping, east/west-trending ridges of sandstone and shale, the south-facing slopes of which constitute large fire compartments. In nearly all examples, *Pinus echinata* occurs with a variable mixture of hardwood species. The exact composition of the hardwoods is much more closely related to aspect and topographic factors than is the pine component. In the Ozark Highlands this system is less extensive but was historically prominent where sandstone-derived soils are common. In Missouri and Oklahoma, this system occurs on gently dissected upland cherty plains (in addition to sandstone ridges).
Classification Comments: This system is primarily confined to gently to moderately sloping, upland plains and is distinguished from Ozark-Ouachita Shortleaf Pine-Oak Forest and Woodland (CES202.313), which occurs on more steeply dissected ridges and steep southwest-facing slopes. The abundance of prairie flora also distinguishes this system from the shortleaf pine-oak woodland.
Similar Ecological Systems:
- East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506)
- Ozark-Ouachita Shortleaf Pine-Oak Forest and Woodland (CES202.313)
- Southern Appalachian Low-Elevation Pine Forest (CES202.332)

Related Concepts:
- Shortleaf Pine - Oak: 76 (Eyre 1980) Intersecting
- Shortleaf Pine: 75 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs throughout the Ouachita and Ozark mountains region, and there is some local variation in the extent to which it is present. The system is best developed in large portions of the landscape which are flat to gently undulating and which would carry fire well, creating extensive natural fire compartments. In the Ouachitas, the system occurs on the northern Hogback Ridges, which are large, gently sloping, east/west-trending ridges of sandstone and shale, the south-facing slopes of which constitute large fire compartments. In nearly all examples, *Pinus echinata* occurs with a variable mixture of hardwood species. The exact composition of the hardwoods is much more closely related to aspect and topographic factors than is the pine component. In the Ozark Highlands this system is less extensive but was historically prominent where sandstone-derived soils are common. In Missouri and Oklahoma, this system occurs on gently dissected upland cherty plains (in addition to sandstone ridges). This system is primarily confined to gently to moderately sloping, upland plains (larger fire compartments) and is thereby distinguished from shortleaf pine-oak woodland, which occurs on more steeply dissected ridges and steep southwest-facing slopes (smaller fire compartments). In the Ouachitas, the primary pine-bluestem landscape lies to the north of the two tallest ridges, Blackfork Mountain and Rich Mountain, which form a rainshadow by orographic lifting of the moisture-laden winds from the Gulf of Mexico that strongly influence the climate of this region; precipitation on those ridges can be as high as 147 cm (58 inches) annually, while just to the north, it may fall to 117 cm (46 inches) (T. Foti pers. comm. 2013).
Vegetation: In the northern part of this geographic area *Pinus echinata*, xeric oaks and some hickory dominate the overstory with a high percentage of oak on steep north slopes and on *Quercus stellata* flats. Associated species include *Quercus marilandica* and *Carya alba* on drier sites and to the west *Carya texana*. In some examples of this system, the aggregate importance of hardwoods may be greater than pine, especially on subxeric and mesic sites (Dale and Ware 1999). Pine is often the canopy emergent on upper slopes. Stand density increases with available moisture. Typical shrubs may include *Vaccinium arboreum*, *Vaccinium pallidum*, and *Vaccinium stamineum*, but these patches are rare. Various bluestem grasses, legumes and other forbs dominate the understory (herbaceous layer).
Dynamics: This system is Fire Regime Group I (Landfire 2007a), with frequent surface fires. Area fire frequency is 3 to 4 years, and the mean fire-return interval ranges from 1 to 12 years (Masters et al. 1995). Annual fire was common historically, such as in the 1800s. Replacement and mixed-severity fires are infrequent, every 100 to 1000 years. Stand-replacement fires occurred mostly under extreme drought conditions during the growing season. The impact of native ungulate grazing (buffalo and elk) was negligible, but

fire generally maintained these open woodlands. Drought and moist cycles play a strong role interacting with both fire and native grazing. Other disturbance types include ice storms, wind events, and insect infestations. These disturbances can add significantly to downed woody debris, which can add fuel and increase fire intensity when that downed material is dry and burns. *Pinus echinata* has shorter needles and is not as susceptible to ice as *Pinus taeda*, which is more common further south in Arkansas.

Fire is an important dynamic process, which maintains open woodland conditions and can promote oak and pine regeneration. Today the region consists largely of closed-canopy forests, though relatively frequent fires prior to Euro-American settlement created and maintained forests, woodlands, savannas and glades (Stambaugh and Guyette 2006). Prior to 1820, fires were most frequent in areas with low topographic roughness, such as flat or gently sloping lands away from ravines and creeks (Stambaugh and Guyette 2008). For the next hundred years, fires increased as population increased (Stambaugh and Guyette 2006, 2008), until about 1930 when very effective fire-suppression practices began (Guldin et al. 2005). During the 1800s, these fires helped maintain *Pinus echinata* woodlands with floristically rich understory vegetation of prairie grasses and forbs (Hedrick et al. 2007). There is a very low rate of fire ignitions from lightning strikes in the area, nearly all ignitions are caused by people (Stambaugh and Guyette 2006).

Component Associations:
- *Pinus echinata - Quercus alba / Schizachyrium scoparium* Woodland (CEGL002394, G3G4)
- *Pinus echinata - Quercus stellata - Quercus marilandica / Schizachyrium scoparium* Woodland (CEGL002393, G2G3)
- *Pinus echinata* / Rock Outcrop Interior Highland Woodland (CEGL002402, G2G3)
- *Pinus echinata / Schizachyrium scoparium - Solidago ulmifolia - Monarda russeliana - Echinacea pallida* Woodland (CEGL007815, G1G2)

OZARK-OUACHITA SHORTLEAF PINE-OAK FOREST AND WOODLAND (CES202.313)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Ozark/Ouachita; Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2367; ESLF 4310; ESP 1367

CONCEPT

Summary: This system represents forests and woodlands of the Ouachita and Ozark mountains region of Arkansas, adjacent Oklahoma, and southern Missouri in which *Pinus echinata* is an important or dominant component. Although examples of this system occur throughout this region, there is local variation in the extent to which they were present. For example, in the Ozark Highlands, this system was historically prominent only in the southeastern part where sandstone-derived soils were common, and in the southern part on soils derived from chert, being excluded from or diminished in other areas by non-conducive soils. In contrast, pine was virtually ubiquitous in the historical forests of the Ouachitas. In nearly all cases (at least in the Ouachitas), *Pinus echinata* occurs with a variable mixture of hardwood species. The exact composition of the hardwoods is much more closely related to aspect and topographic factors than is the pine component. In some examples of this system, the aggregate importance of hardwoods may be greater than pine, especially on subxeric and mesic sites.
Classification Comments: This system (CES202.313) is distinguished from the equivalent Appalachian system (CES202.332) at its western extent in central Tennessee by the absence of *Pinus virginiana* and *Quercus prinus*, which do not cross the Mississippi River.
Similar Ecological Systems:

- Ozark-Ouachita Dry Oak Woodland (CES202.707)
- Ozark-Ouachita Dry-Mesic Oak Forest (CES202.708)
- Ozark-Ouachita Shortleaf Pine-Bluestem Woodland (CES202.325)
- Southern Appalachian Low-Elevation Pine Forest (CES202.332)

Related Concepts:
- Shortleaf Pine - Oak: 76 (Eyre 1980) Intersecting
- Shortleaf Pine: 75 (Eyre 1980) Finer

DESCRIPTION

Environment: In the Ozark Highlands, this system was historically prominent only in the southeastern part, where sandstone derived soils were common (USFS 1999) and in the southern part on soils derived from chert; being limited in other areas by non-conducive soils. In contrast, pine was "virtually ubiquitous in the historical forests of the Ouachitas" (USFS 1999). In nearly all cases (at least in the Ouachitas), Pinus echinata occurs with a variable mixture of hardwood species. The exact composition of the hardwoods is much more closely related to aspect and topographic factors than is the pine component (Dale and Ware 1999).
Vegetation: Stands of this system typically contain *Pinus echinata* with various oak species, including *Quercus alba, Quercus rubra, Quercus falcata, Quercus stellata, Quercus velutina,* and *Quercus marilandica*. In some examples of this system, the aggregate importance of hardwoods may be greater than pine, especially on subxeric and mesic sites (Dale and Ware 1999). Typical shrubs include *Vaccinium arboreum, Vaccinium pallidum,* and *Vaccinium stamineum*. Characteristic herbs include *Schizachyrium scoparium, Chasmanthium sessiliflorum, Solidago ulmifolia, Monarda russeliana,* and *Echinacea pallida*.
Dynamics: Fire is an important dynamic process, which maintains open woodland conditions and can promote oak and pine regeneration. Fires have historically occurred more frequently than once every 10 years (Hedrick et al. 2007). Today the region consists largely of closed-canopy forests, though relatively frequent fires prior to Euro-American settlement created and maintained forests, woodlands, savannas and glades (Stambaugh and Guyette 2006). Prior to 1820, fires were most frequent in areas with relatively low topographic roughness, such as flat or gently sloping lands away from ravines and creeks (Stambaugh and Guyette 2008). For the next hundred years, fires increased as population increased (Stambaugh and Guyette 2006, 2008), until about 1930 when very effective fire-suppression practices began (Guldin et al. 2005). During the 1800s, these fires helped maintain *Pinus echinata* and hardwood forests with floristically rich understory vegetation of grasses and forbs (Hedrick et al. 2007). There is a very low rate of fire ignitions from lightning strikes in the Ozark Highlands area, nearly all ignitions are caused by people (Stambaugh and Guyette 2006). However, fires started by lightning could become very large, since ignitions may occur associated with drought, high winds, drying fuels, and decreasing humidity. The number of lightning strike-initiated wildfires is higher in the Ouachita Mountains and Boston Mountains. In these areas, presettlement wildland fires were ignited by Native Americans and by lightning (Foti and Glenn 1990). Other disturbances include wind, tornados, drought, and ice storms. These disturbances can open forest canopies and add significantly to downed woody debris, which can add fuel and lead to increased fire intensity when that downed material is dry and burns. *Pinus echinata* has shorter needles and is not as susceptible to ice as *Pinus taeda*, which is more common further south in

Arkansas.

Component Associations:
- *Pinus echinata - Quercus (alba, rubra) / Vaccinium (arboreum, pallidum) / Schizachyrium scoparium - Chasmanthium sessiliflorum - Solidago ulmifolia* Forest (CEGL007489, G3G4)

PIEDMONT HARDPAN WOODLAND AND FOREST (CES202.268)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Clay Soil Texture; Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2342; ESLF 4149; ESP 1342

CONCEPT

Summary: This system of the southern Piedmont occurs in places where a particularly dense clay hardpan has developed over a range of typically mafic rocks, sometimes with more limited areas of shallow glade-like vegetation. In the deeper soil portions of this system, the density of the clay, in combination with its shrink-swell properties, limits water and root penetration into the soil and creates xeric conditions for plants despite the presence of deep soil. Possibly most typical expression of this system in North Carolina is an open forest or woodland of *Quercus stellata*, with *Quercus marilandica* as a characteristic associate. The open canopy leads to a better developed herb layer than in most Piedmont forests, one that is usually grassy. In Virginia, typical canopy trees include *Quercus alba, Carya glabra*, and *Fraxinus americana*. Some of these sites may have once supported open prairies or prairie savannas when they burned more frequently. Fire was probably once the most important natural dynamic process, but the universal elimination of fire in the Piedmont makes this difficult to observe on most of the modern landscape.
Classification Comments: This system is distinguished from others in the Piedmont by occurrence on distinctive substrates. These include hardpan soils in the Triassic basins, as well as on soils derived from gabbro and on acidic metasediments in the Carolina Slate Belt. Despite the contrast in vegetation, this system will sometimes grade quite gradually into Piedmont Upland Depression Swamp (CES202.336), with which it often co-occurs.

DESCRIPTION

Environment: This system occurs in places in the southern Piedmont where a particularly dense clay hardpan, typically composed of Montmorillonite, has developed. The substrate is typically mafic igneous or metamorphic rock (gabbro, basalt, diabase, or amphibolite) but occasionally is slate. The density of the clay, or its shrink-swell properties, limits penetration of water into the soil and limits penetration of roots, creating xeric conditions for plants despite the presence of deep soil. These areas generally occur on unusually flat uplands but may occur on tops of narrower ridges. Only a minority of these substrates form the distinctive soil conditions of this system. Local topography that promotes runoff is important to forming this system. Areas with these soil conditions but with concave topography perch water and support Piedmont depressional wetlands. Soils in most examples are basic or circumneutral, but those formed from slate are somewhat acidic. In Virginia and adjacent Maryland, this system occupies one of the largest Triassic basins in eastern North America. It includes a mix of sedimentary rocks, especially siltstone, mixed with igneous intrusions. The igneous rocks weather to form more mafic soils, while the sedimentary rocks are more acidic. The local landscape may best be thought of as a lowland, in comparison with the surrounding and prevailing topography.
Vegetation: Vegetation consists of xerophytic species, most typically consisting of open forests or woodlands of *Quercus stellata*, with *Quercus marilandica* as a characteristic associate in North Carolina. In Virginia and adjacent Maryland, *Quercus alba, Fraxinus americana*, and *Carya glabra* are common canopy components. The open canopy leads to a better developed herb layer than in most Piedmont forests, one that is usually grassy. Some of these sites may have once supported open prairies or prairie savannas when they burned more frequently. A significant flora of shade-intolerant herbs with prairie affinities is present in open areas on these soils to support this idea. In contrast to upland forests of adjacent portions of the Virginia Piedmont, there is a pronounced difference in the abundance of hickory present (Farrell and Ware 1991, Ware 1992).
Dynamics: Fire was probably once the most important natural dynamic process, but the universal elimination of fire in the Piedmont makes this difficult to determine. Both the drier character of the sites and the distinctive soil conditions interact with one another to retard woody succession. These factors would presumably have interacted with the fire regime to promote more open vegetation on

these sites. This would presumably lead to a greater probability that these open woodland conditions would prevail for a longer period than they would on more typical soils. Fire would have kept canopies open by limiting the growth of trees and would have promoted a more diverse, grass-dominated herb layer. Bison may have once been a significant influence on this system. These sites are now of more limited extent and it is harder to determine how these factors operated in the larger landscape.

Component Associations:
- *Carya glabra - Quercus (rubra, prinus) - Fraxinus americana / Viburnum rafinesquianum / Piptochaetium avenaceum* Forest (CEGL006209, G1G2)

- *Sporobolus vaginiflorus var. ozarkanus - Diodia teres - Croton willdenowii - Ruellia humilis* Herbaceous Vegetation (CEGL004276, G1)

SPATIAL CHARACTERISTICS

Spatial Summary: Large-patch system.
Size: Occurs in large patches, ranging up to dozens of acres.
Adjacent Ecological Systems:
- Piedmont Upland Depression Swamp (CES202.336)
- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)

Adjacent Ecological System Comments: Piedmont Upland Depression Swamp (CES202.336) occurs on similar soils with topography that limits runoff of rainwater. Most are surrounded by basic soil associations of Southern Piedmont Dry Oak-(Pine) Forest (CES202.339) on less extreme soils.

DISTRIBUTION

Range: As currently known, this system is found in the Piedmont of Maryland, Virginia, North Carolina, South Carolina and Georgia. Its status in Alabama is not known. Its occurrence may be more frequent in the Triassic basins, but it is not restricted to them.
Divisions: 202:C
Nations: US
Subnations: GA, MD, NC, SC, VA
Map Zones: 54:C, 59:C, 60:C, 61:C

ROCKY MOUNTAIN ASPEN FOREST AND WOODLAND (CES306.813)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Long Disturbance Interval; F-Patch/Medium Intensity; F-Landscape/Medium Intensity; Broad-Leaved Deciduous Tree; Populus tremuloides
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Temperate [Temperate Continental]; Mesotrophic Soil; Shallow Soil; Mineral: W/ A-Horizon <10 cm; Ustic
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2011; ESLF 4104; ESP 1011

CONCEPT

Summary: This widespread ecological system is more common in the southern and central Rocky Mountains but occurs in the montane and subalpine zones throughout much of the western U.S. and north into Canada. An eastern extension occurs along the Rocky Mountains foothill front and in mountain "islands" in Montana (Big Snowy and Highwood mountains), and the Black Hills of South Dakota. In California, this system is only found on the east side of the Sierra Nevada adjacent to the Great Basin. Large stands are found in the Inyo and White mountains, while small stands occur on the Modoc Plateau. In western Alberta, it occurs only in the Upper Foothills subregion, and north of there transitions to Western North American Boreal Mesic Birch-Aspen Forest (CES105.108). Elevations generally range from 1525 to 3050 m (5000-10,000 feet), but occurrences can be found at lower elevations in some regions, especially in the Canadian Rockies. Distribution of this ecological system is primarily limited by adequate soil moisture required to meet its high evapotranspiration demand. Secondarily, it is limited by the length of the growing season or low temperatures. These are upland forests and woodlands dominated by *Populus tremuloides* without a significant conifer component (<25% relative tree cover). The understory structure may be complex with multiple shrub and herbaceous layers, or simple with just an herbaceous layer. The herbaceous layer may be dense or sparse, dominated by graminoids or forbs. In California, *Symphyotrichum spathulatum (= Aster occidentalis)* is a common forb. Associated shrub species include *Symphoricarpos* spp., *Rubus parviflorus, Amelanchier alnifolia*, and *Arctostaphylos uva-ursi*. Occurrences of this system originate and are maintained by stand-replacing disturbances such as avalanches, crown fire, insect outbreak, disease and windthrow, or clearcutting by man or beaver, within the matrix of conifer forests. It differs from Northwestern Great Plains Aspen Forest and Parkland (CES303.681), which is limited to plains environments.
Classification Comments: The scattered occurrences in Trans-Pecos of Texas are of interest as they represent disjunct outliers of the type occurring under highly limited circumstances.
Similar Ecological Systems:
- Northwestern Great Plains Aspen Forest and Parkland (CES303.681)--is limited to plains environments.

Related Concepts:
- Aspen Woodland (411) (Shiflet 1994) Broader
- Aspen: 217 (Eyre 1980) Broader

DESCRIPTION

Environment: Climate is temperate with a relatively long growing season, typically cold winters and deep snow. Mean annual precipitation is greater than 15 inches and typically greater than 20 inches, except in semi-arid environments where occurrences are restricted to mesic microsites such as seeps or large snow drifts. Distribution of this ecological system is primarily limited by adequate soil moisture required to meet its high evapotranspiration demand (Mueggler 1988). Secondarily, its range is limited by the length of the growing season or low temperatures (Mueggler 1988). Topography is variable, sites range from level to steep slopes. Aspect varies according to the limiting factors. Occurrences at high elevations are restricted by cold temperatures and are found on warmer southern aspects. At lower elevations occurrences are restricted by lack of moisture and are found on cooler north aspects and mesic microsites. The soils are typically deep and well developed with rock often absent from the soil. Soil texture ranges from sandy loam to clay loams. Parent materials are variable and may include sedimentary, metamorphic or igneous rocks, but it appears to grow best on limestone, basalt, and calcareous or neutral shales (Mueggler 1988).
Vegetation: Occurrences have a somewhat closed canopy of trees of 5-20 m tall that is dominated by the cold-deciduous, broad-leaved tree *Populus tremuloides*. Conifers that may be present but never codominant include *Abies concolor, Abies lasiocarpa, Picea engelmannii, Picea pungens, Pinus ponderosa*, and *Pseudotsuga menziesii*. Conifer species may contribute up to 15% of the tree canopy before the occurrence is reclassified as a mixed occurrence. Because of the open growth form of *Populus tremuloides*, enough light can penetrate for lush understory development. Depending on available soil moisture and other factors like disturbance, the understory structure may be complex with multiple shrub and herbaceous layers, or simple with just an herbaceous layer. The herbaceous layer may be dense or sparse, dominated by graminoids or forbs. Common shrubs include *Acer glabrum, Amelanchier alnifolia, Artemisia tridentata, Juniperus communis, Prunus virginiana, Rosa woodsii, Shepherdia canadensis, Symphoricarpos oreophilus*, and the dwarf-shrubs *Mahonia repens* and *Vaccinium* spp. The herbaceous layers may be lush and diverse. Common

graminoids may include *Bromus carinatus, Calamagrostis rubescens, Carex siccata (= Carex foenea), Carex geyeri, Carex rossii, Elymus glaucus, Elymus trachycaulus, Festuca thurberi, Hesperostipa comata*, and *Leymus innovatus* in northern occurrences. Associated forbs may include *Achillea millefolium, Eucephalus engelmannii (= Aster engelmannii), Delphinium* spp., *Geranium viscosissimum, Heracleum sphondylium, Ligusticum filicinum, Lupinus argenteus, Osmorhiza berteroi (= Osmorhiza chilensis), Pteridium aquilinum, Rudbeckia occidentalis, Thalictrum fendleri, Valeriana occidentalis, Wyethia amplexicaulis*, and many others. Exotic grasses such as the perennials *Poa pratensis* and *Bromus inermis* and the annual *Bromus tectorum* are often common in occurrences disturbed by grazing.

Dynamics: Occurrences in this ecological system often originate, and are likely maintained, by stand-replacing disturbances such as crown fire, disease and windthrow, or clearcutting by man or beaver. The stems of these thin-barked, clonal trees are easily killed by ground fires, but they can quickly and vigorously resprout in densities of up to 30,000 stems per hectare (Knight 1993). The stems are relatively short-lived (100-150 years), and the occurrence will succeed to longer-lived conifer forest if undisturbed. Occurrences are favored by fire in the conifer zone (Mueggler 1988). With adequate disturbance a clone may live many centuries. Although *Populus tremuloides* produces abundant seeds, seedling survival is rare because of the long moist conditions required to establish are rare in the habitats that it occurs in. Superficial soil drying will kill seedlings (Knight 1993).

Component Associations:

SPATIAL CHARACTERISTICS

Size: This system is not actually very extensive in the Oregon Cascades and probably non-existent in the Coast Ranges. It is not very extensive in western Washington either. Most patches may be too small to map. Many may be relict stands from another climate, just barely hanging on. In the Cascades this system occurs as a small-patch type, not large-patch.

Adjacent Ecological Systems:

- Rocky Mountain Bigtooth Maple Ravine Woodland (CES306.814)

DISTRIBUTION

Range: This system is more common in the central and southern Rocky Mountains extending south to the Sacramento Mountains, however, it occurs in the montane and subalpine zones throughout much of the western U.S. and north into Canada, as well as west into California. Elevations generally range from 1525 to 3050 m (5000-10,000 feet), but occurrences can be found at lower elevations in some regions. Very small occurrences may be found in a few scattered locations of the Trans-Pecos of Texas.

ROCKY MOUNTAIN BIGTOOTH MAPLE RAVINE WOODLAND (CES306.814)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Ravine; Stream terrace (undifferentiated); Toeslope; Mineral: W/ A-Horizon <10 cm; Unconsolidated; Broad-Leaved Deciduous Tree; Acer grandidentatum; Colluvial slope
Non-Diagnostic Classifiers: Montane [Montane]; Montane [Lower Montane]; Forest and Woodland (Treed); Toeslope/Valley Bottom; Temperate [Temperate Continental]; Mesotrophic Soil; Landslide
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2012; ESLF 4105; ESP 1012

CONCEPT

Summary: This ecological system occurs in cool ravines, on toeslopes and slump benches associated with riparian areas in the northern and central Wasatch Range and Tavaputs Plateau extending into southern Idaho, as well as in scattered localities in southwestern Utah, central Arizona and New Mexico and the Trans-Pecos of Texas. Substrates are typically rocky colluvial or alluvial soils with favorable soil moisture. These woodlands are dominated by *Acer grandidentatum* but may include mixed stands codominated by *Quercus gambelii* or with scattered conifers. Some stands may include *Acer negundo* or *Populus tremuloides* as minor components. It also occurs on steeper, north-facing slopes at higher elevations, often adjacent to Rocky Mountain Gambel Oak-Mixed Montane Shrubland (CES306.818) or Rocky Mountain Aspen Forest and Woodland (CES306.813).
Classification Comments: In the Trans-Pecos of Texas, this system is a cool ravine woodland type generally occupying lower slope positions. It forms a patchy narrow band on lower slopes that may include *Quercus muehlenbergii*, *Acer grandidentatum*, *Fraxinus* sp., *Prunus serotina*, and *Arbutus xalapensis*. Some of these stands may be included in North American Warm Desert Lower Montane Riparian Woodland and Shrubland (CES302.748) or the broader group North American Warm Desert Riparian Systems (CES302.612). Also look at Madrean Lower Montane Pine-Oak Forest and Woodland (CES305.796).

FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2049; ESLF 4236; ESP 1049

CONCEPT

Summary: This ecological system occurs in foothill and lower montane zones in the Rocky Mountains from northern Montana south to central Colorado and on escarpments across Wyoming extending out into the western Great Plains. Elevation ranges from 1000-2400 m. It occurs generally below continuous forests of *Pseudotsuga menziesii* or *Pinus ponderosa* and can occur in large stands well within the zone of continuous forests in the northeastern Rocky Mountains. It is restricted to shallow soils and fractured bedrock derived from a variety of parent material, including limestone, sandstone, dolomite, granite and colluvium. Soils have a high rock component (typically over 50% cover) and are coarse- to fine-textured, often gravelly and calcareous. Slopes are typically moderately steep to steep. At higher elevations, it is limited to the most xeric aspects on rock outcrops, and at lower elevations to the relatively mesic north aspects. Fire is infrequent and spotty because rocky substrates prevent a continuous vegetation canopy needed to spread. Vegetation is characterized by an open-tree canopy or patchy woodland that is dominated by either *Pinus flexilis, Juniperus osteosperma,* or *Juniperus scopulorum*. *Pinus edulis* is not present. A sparse to moderately dense short-shrub layer, if present, may include a variety of shrubs, such as *Arctostaphylos uva-ursi, Artemisia nova, Artemisia tridentata, Cercocarpus ledifolius, Cercocarpus montanus, Dasiphora fruticosa ssp. floribunda, Ericameria nauseosa, Juniperus horizontalis, Purshia tridentata, Rhus trilobata, Rosa woodsii, Shepherdia canadensis* (important in Montana stands), *Symphoricarpos albus,* or *Symphoricarpos oreophilus*. Herbaceous layers are generally sparse, but range to moderately dense, and are typically dominated by perennial graminoids such as *Bouteloua gracilis, Festuca idahoensis, Festuca campestris, Danthonia intermedia, Leucopoa kingii, Hesperostipa comata, Koeleria macrantha, Piptatherum micranthum, Poa secunda,* or *Pseudoroegneria spicata*. Within this ecological system, there may be small patches of grassland or shrubland composed of some of the above species. In Wyoming, some limber pine stands are found up to 2440 m (8000 feet) elevation and are still included in this system.

ROCKY MOUNTAIN LODGEPOLE PINE FOREST (CES306.820)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Acidic Soil; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Ustic; Long Disturbance Interval; F-Patch/High Intensity [Seasonality/Fall Fire]; F-Landscape/High Intensity; Needle-Leaved Tree; Pinus contorta
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Forest and Woodland (Treed); Sideslope; Toeslope/Valley Bottom; Temperate [Temperate Continental]
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2050; ESLF 4237; ESP 1050

CONCEPT

Summary: This ecological system is widespread in upper montane to subalpine elevations of the Rocky Mountains, Intermountain West region, north into the Canadian Rockies and east into mountain "islands" of north-central Montana. These are subalpine forests where the dominance of *Pinus contorta* is related to fire history and topo-edaphic conditions. Following stand-replacing fires, *Pinus contorta* will rapidly colonize and develop into dense, even-aged stands. Most forests in this ecological system occur as early- to mid-successional forests which developed following fires. This system includes *Pinus contorta*-dominated stands that, while typically persistent for >100-year time frames, may succeed to spruce-fir; in the southern and central Rocky Mountains it is seral to Rocky Mountain Subalpine Dry-Mesic Spruce-Fir Forest and Woodland (CES306.828). More northern occurrences are seral to Rocky Mountain Subalpine Mesic-Wet Spruce-Fir Forest and Woodland (CES306.830). Soils supporting these forests are typically well-drained, gravelly, coarse-textured, acidic, and rarely formed from calcareous parent materials. These forests are dominated by *Pinus contorta* with shrub, grass, or barren understories. Sometimes there are intermingled mixed conifer/*Populus tremuloides* stands, with the latter occurring with inclusions of deeper, typically fine-textured soils. The shrub stratum may be conspicuous to absent; common species include *Arctostaphylos uva-ursi, Ceanothus velutinus, Linnaea borealis, Mahonia repens, Menziesia ferruginea* (in northern occurrences), *Purshia tridentata, Rhododendron albiflorum* (in northern occurrences), *Spiraea betulifolia, Spiraea douglasii, Shepherdia canadensis, Vaccinium caespitosum, Vaccinium scoparium, Vaccinium membranaceum, Symphoricarpos albus*, and *Ribes* spp. In southern interior British Columbia, this system is usually an open lodgepole pine forest found extensively between 500 and 1600 m elevation in the Columbia Range. In the Interior Cedar Hemlock and Interior Douglas-fir zones, *Tsuga heterophylla* or *Pseudotsuga menziesii* may be present. In Alberta, species composition indicates the transition to more boreal floristics, including such species as *Empetrum nigrum, Ledum groenlandicum, Leymus innovatus*, and more abundant lichens or mosses such as *Cladina* spp., *Hylocomium splendens*, and *Pleurozium schreberi*.

DESCRIPTION

Dynamics: *Pinus contorta* is an aggressively colonizing, shade-intolerant conifer which usually occurs in lower subalpine forests in the major ranges of the western United States. Establishment is episodic and linked to stand-replacing disturbances, primarily fire. The incidence of serotinous cones varies within and between varieties of *Pinus contorta*, being most prevalent in Rocky Mountain populations. Closed, serotinous cones appear to be strongly favored by fire, and allow rapid colonization of fire-cleared substrates (Burns and Honkala 1990a). Hoffman and Alexander (1980, 1983) report that in stands where *Pinus contorta* exhibits a multi-aged population structure, with regeneration occurring, there is typically a higher proportion of trees bearing nonserotinous cones.

Component Associations:
- *Ceanothus velutinus* Shrubland (CEGL002167, GNR)
- *Chamerion angustifolium* Rocky Mountain Herbaceous Vegetation (CEGL005856, G4G5)
- *Pinus contorta / Arnica cordifolia* Forest (CEGL000135, G4?)
- *Pinus contorta / Carex geyeri* Forest (CEGL000141, G4?)
- *Pinus contorta / Ceanothus velutinus* Forest (CEGL000145, G4)
- *Pinus contorta / Clintonia uniflora - Xerophyllum tenax* Woodland (CEGL005921, G4G5)
- *Pinus contorta / Clintonia uniflora* Forest (CEGL005916, G5)

DISTRIBUTION

Range: This system occurs at upper montane to subalpine elevations of the Rocky Mountains, Intermountain West region, north into the Canadian Rockies, and east onto mountain "islands" of north-central Montana. In Washington, this system occurs mostly on the east side of the Cascade Crest. In Oregon, this system only occurs in the Blue Mountains; all Oregon Cascades lodgepole pine forests are included in other systems.

ROCKY MOUNTAIN POOR-SITE LODGEPOLE PINE FOREST (CES306.960)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Acidic Soil; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Ustic; Long Disturbance Interval; F-Patch/High Intensity [Seasonality/Fall Fire]; F-Landscape/High Intensity; Needle-Leaved Tree; Pinus contorta
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2167; ESLF 4267; ESP 1167

CONCEPT

Summary: This ecological system is widespread but patchy in distribution in upper montane to subalpine elevations of the Rocky Mountains and Intermountain region. These are subalpine forests, occasionally found in the montane zone, where the dominance of *Pinus contorta* is related to topo-edaphic conditions and nutrient-poor soils. These include excessively well-drained pumice deposits, glacial till and alluvium on valley floors where there is cold-air accumulation, warm and droughty shallow soils over fractured quartzite bedrock, and shallow moisture-deficient soils with a significant component of volcanic ash. Pumice soils at lower elevations of the pumice zone of Oregon support this system. Soils on these sites are typically well-drained, gravelly, coarse-textured, acidic, and rarely formed from calcareous parent materials. Following stand-replacing fires, *Pinus contorta* will rapidly colonize and develop into dense, even-aged stands and then persist on these sites that are too extreme for other conifers to establish. In some cases, stands are open to dense and may be multi-aged, not just even-aged. These forests are dominated by *Pinus contorta* with shrub, grass, or barren understories. Sometimes there are intermingled mixed conifer/*Populus tremuloides* stands, with the latter occurring with inclusions of deeper, typically fine-textured soils. In central Oregon, *Pseudotsuga menziesii, Pinus ponderosa*, and *Abies concolor* may be present, and *Populus tremuloides* may be present as small patches. The shrub stratum may be conspicuous to absent; common species include *Arctostaphylos uva-ursi, Artemisia tridentata, Juniperus communis, Ceanothus velutinus, Linnaea borealis, Mahonia repens, Purshia tridentata, Spiraea betulifolia, Shepherdia canadensis, Vaccinium scoparium, Symphoricarpos albus*, and *Ribes* spp. Some open stands with very sparse understories can experience a form of mixed-severity burning via cigarette burning along downed logs (insufficient fuels between logs to carry fire). Depending on the arrangement and loading of logs to living trees, either mortality or fire-scarring may occur.
Classification Comments: The higher elevation *Pinus contorta* forests of the southern Cascades are included in Sierra Nevada Subalpine Lodgepole Pine Forest and Woodland (CES206.912).
Related Concepts:
- Lodgepole Pine: 218 (Eyre 1980) Broader

DESCRIPTION

Dynamics: *Pinus contorta* is an aggressively colonizing, shade-intolerant conifer which usually occurs in lower subalpine forests in the major ranges of the western United States. Establishment is episodic and linked to stand-replacing disturbances, primarily fire. The incidence of serotinous cones varies within and between varieties of *Pinus contorta*, being most prevalent in Rocky Mountain populations. Closed, serotinous cones appear to be strongly favored by fire and allow rapid colonization of fire-cleared substrates (Burns and Honkala 1990a). Hoffman and Alexander (1980, 1983) report that, in stands where *Pinus contorta* exhibits a multi-aged population structure with regeneration occurring, there is typically a higher proportion of trees bearing nonserotinous cones.

Past clearcutting has expanded this type into ponderosa pine forests south of Bend, Oregon, by creating frost pockets that favor lodgepole pine establishment.

Component Associations:
- *Artemisia tridentata ssp. vaseyana / Achnatherum occidentale* Shrubland (CEGL001033, G2)

- *Pinus contorta var. latifolia / Purshia tridentata / Achnatherum occidentale ssp. occidentale* Woodland (CEGL000162, G3)
- *Pinus contorta var. latifolia / Purshia tridentata / Festuca idahoensis* Woodland (CEGL000160, G3)

DISTRIBUTION

Range: This system is found in the upper montane to subalpine elevations of the Rocky Mountains from north-central Colorado north and west into Wyoming, Montana, Idaho, Oregon and Washington, as well as the Intermountain region (northeastern Nevada and north-central Utah). In north-central Montana (mapzone 20), it may occur on appropriate habitats (intrusive volcanics, very nutrient-poor) within "island" mountain ranges (Big Snowy and Highwood mountains). In central Wyoming, it may occur in the Ferris Mountains and possibly north into the Bighorns.

ROCKY MOUNTAIN SUBALPINE DRY-MESIC SPRUCE-FIR FOREST AND WOODLAND (CES306.828)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: RM Subalpine Mesic Spruce-Fir; Long (>500 yrs) Persistence; Montane [Upper Montane]; Forest and Woodland (Treed); Acidic Soil; Ustic; Very Long Disturbance Interval [Seasonality/Summer Disturbance]; F-Patch/High Intensity; F-Landscape/High Intensity; Needle-Leaved Tree; Abies lasiocarpa - Picea engelmannii
Non-Diagnostic Classifiers: Montane [Montane]; Ridge/Summit/Upper Slope; Sideslope; Temperate [Temperate Continental]; Mesotrophic Soil; Shallow Soil; Mineral: W/ A-Horizon >10 cm; W-Patch/Medium Intensity; W-Landscape/Low Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2055; ESLF 4242; ESP 1055

CONCEPT

Summary: Engelmann spruce and subalpine fir forests comprise a substantial part of the subalpine forests of the Cascades and Rocky Mountains from southern British Columbia east into Alberta, and south into New Mexico and the Intermountain region. They also occur on mountain "islands" of north-central Montana. They are the matrix forests of the subalpine zone, with elevations ranging from 1275 m in its northern distribution to 3355 m in the south (4100-11,000 feet). They often represent the highest elevation forests in an area. Sites within this system are cold year-round, and precipitation is predominantly in the form of snow, which may persist until late summer. Snowpacks are deep and late-lying, and summers are cool. Frost is possible almost all summer and may be common in restricted topographic basins and benches. Despite their wide distribution, the tree canopy characteristics are remarkably similar, with *Picea engelmannii* and *Abies lasiocarpa* dominating either mixed or alone. *Pseudotsuga menziesii* may persist in occurrences of this system for long periods without regeneration. *Pinus contorta* is common in many occurrences, and patches of pure *Pinus contorta* are not uncommon, as well as mixed conifer/*Populus tremuloides* stands. In some areas, such as Wyoming, *Picea engelmannii*-dominated forests are on limestone or dolomite, while nearby codominated spruce-fir forests are on granitic or volcanic rocks. Upper elevation examples may have more woodland physiognomy, and *Pinus albicaulis* can be a seral component. What have been called "ribbon forests" or "tree islands" by some authors are included here; they can be found at upper treeline in many areas of the Rockies, including the central and northern ranges in Colorado and the Medicine Bow and Bighorn ranges of Wyoming. These are more typically islands or ribbons of trees, sometimes with a krummholz form, with open-meadow areas in a mosaic. These patterns are controlled by snow deposition and wind-blown ice. Xeric species may include *Juniperus communis, Linnaea borealis, Mahonia repens,* or *Vaccinium scoparium*. In the Bighorn Mountains, *Artemisia tridentata* is a common shrub. More northern occurrences often have taller, more mesic shrub and herbaceous species, such as *Empetrum nigrum, Rhododendron albiflorum*, and *Vaccinium membranaceum*. Disturbance includes occasional blowdown, insect outbreaks and stand-replacing fire. Mean return interval for stand-replacing fire is 222 years as estimated in southeastern British Columbia.
Classification Comments: It has been proposed to split out the tree island or ribbon forests of high timberline in the drier mountain ranges of north-central Colorado, southern Wyoming and north-central Wyoming (the Bighorns) into a new Southern Rocky Mountain Parkland system. With further discussion, this may be implemented, but for now these areas are still included in this existing system.
Similar Ecological Systems:
- Northern Rocky Mountain Dry-Mesic Montane Mixed Conifer Forest (CES306.805)
- Rocky Mountain Subalpine Mesic-Wet Spruce-Fir Forest and Woodland (CES306.830)

- Engelmann Spruce - Subalpine Fir: 206 (Eyre 1980) Broader

DESCRIPTION

Dynamics: *Picea engelmannii* can be very long-lived, reaching 500 years of age. *Abies lasiocarpa* decreases in importance relative to *Picea engelmannii* with increasing distance from the region of Montana and Idaho where maritime air masses influence the climate. Fire is an important disturbance factor, but fire regimes have a long return interval and so are often stand-replacing. *Picea engelmannii* can rapidly recolonize and dominate burned sites, or can succeed other species such as *Pinus contorta* or *Populus tremuloides*. Due to great longevity, *Pseudotsuga menziesii* may persist in occurrences of this system for long periods without regeneration. Old-growth characteristics in *Picea engelmannii* forests will include treefall and windthrow gaps in the canopy, with large downed logs, rotting woody material, tree seedling establishment on logs or on mineral soils unearthed in root balls, and snags. Landfire VDDT models: #RSPFI.

Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: RM Subalpine Dry-Mesic Spruce-Fir; Long (>500 yrs) Persistence; Montane [Upper Montane]; Forest and Woodland (Treed); Acidic Soil; Udic; Very Long Disturbance Interval [Seasonality/Summer Disturbance]; F-Patch/High Intensity; F-Landscape/Medium Intensity; Abies lasiocarpa - Picea engelmannii
Non-Diagnostic Classifiers: Montane [Montane]; Sideslope; Toeslope/Valley Bottom; Temperate [Temperate Continental]; Mesotrophic Soil; Shallow Soil; Mineral: W/ A-Horizon >10 cm
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2056; ESLF 4243; ESP 1056

CONCEPT

Summary: This is a high-elevation system of the Rocky Mountains, dry eastern Cascades and eastern Olympic Mountains dominated by *Picea engelmannii* and *Abies lasiocarpa*. It extends westward into the northeastern Olympic Mountains and the northeastern side of Mount Rainier in Washington, and as far east as mountain "islands" of north-central Montana. It also occurs northward into the Upper Foothills subregion of western Alberta. *Picea engelmannii* is generally more important in southern forests than those in the Pacific Northwest. Occurrences are typically found in locations with cold-air drainage or ponding, or where snowpacks linger late into the summer, such as north-facing slopes and high-elevation ravines. They can extend down in elevation below the subalpine zone in places where cold-air ponding occurs (as low as 970 m [3180 feet] in the Canadian Rockies); northerly and easterly aspects predominate. These forests are found on gentle to very steep mountain slopes, high-elevation ridgetops and upper slopes, plateau-like surfaces, basins, alluvial terraces, well-drained benches, and inactive stream terraces. In the northern Rocky Mountains of northern Idaho and Montana, *Tsuga mertensiana* occurs as small to large patches within the matrix of this mesic spruce-fir system and only in the most maritime of environments (the coldest and wettest of the more Continental subalpine fir forests). In the Olympics and northern Cascades, the climate is more maritime than typical for this system, but due to the lower snowfall in these rainshadow areas, summer drought may be more significant than snowpack in limiting tree regeneration in burned areas. *Picea engelmannii* is rare in these areas. Mesic understory shrubs include *Menziesia ferruginea, Vaccinium membranaceum, Rhododendron albiflorum, Amelanchier alnifolia, Rubus parviflorus, Ledum glandulosum, Phyllodoce empetriformis*, and *Salix* spp. Herbaceous species include *Actaea rubra, Maianthemum stellatum, Cornus canadensis, Erigeron eximius, Gymnocarpium dryopteris, Rubus pedatus, Saxifraga bronchialis, Tiarella* spp., *Lupinus arcticus ssp. subalpinus, Valeriana sitchensis*, and graminoids *Luzula glabrata var. hitchcockii* or *Calamagrostis canadensis*. In Alberta, species composition indicates the transition to more boreal floristics, including such species as *Ledum groenlandicum* and *Leymus innovatus*, and more abundant mosses such as *Hylocomium splendens* and *Pleurozium schreberi*. Disturbances include occasional blowdown, insect outbreaks (30-50 years), mixed-severity fire, and stand-replacing fire (every 150-500 years). The more summer-dry climatic areas also have occasional high-severity fires.
Classification Comments: This system is similar to Rocky Mountain Subalpine Dry-Mesic Spruce-Fir Forest and Woodland (CES306.828) but is distinguished by its occurrence on mesic to wet microsites within the matrix of the drier (and warmer) subalpine spruce-fir or lodgepole pine forests. The microsites include north-facing slopes, swales or ravines, toeslopes, cold pockets, and other locations where available soil moisture is higher or lasts longer into the growing season. This system is NOT confined to the northern Rocky Mountains or Pacific Northwest (it is not geographically defined, rather by topographic settings in the subalpine).

While the name of this system suggests a Rocky Mountain distribution, floristic affinities of Engelmann spruce-subalpine fir forests in western Washington and the Oregon Cascades are such that the spruce-fir forests of those regions are included in this system. The subalpine fir-dominated forests of the northeastern Olympic Mountains and the northeastern side of Mount Rainier are included here. They are more similar to subalpine fir forests on the eastern slopes of the Cascades than they are to mountain hemlock forests.

Diagnostic Classifiers: Upper Treeline; Ridge/Summit/Upper Slope; Calcareous; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Aridic; W-Patch/High Intensity; W-Landscape/High Intensity; Needle-Leaved Tree; Pinus flexilis, P. aristata
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Forest and Woodland (Treed); Temperate [Temperate Continental]; Alkaline Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2057; ESLF 4244; ESP 1057

CONCEPT

Summary: This ecological system occurs throughout the Rocky Mountains, south of Montana, on dry, rocky ridges and slopes near upper treeline above the matrix spruce-fir forest. It extends down to the lower montane in the northeastern Great Basin mountains where dominated by *Pinus flexilis*. Sites are harsh, exposed to desiccating winds, with rocky substrates and a short growing season that limit plant growth. Higher-elevation occurrences are found well into the subalpine-alpine transition on wind-blasted, mostly west-facing slopes and exposed ridges. Calcareous substrates are important for *Pinus flexilis*-dominated communities in the northern Rocky Mountains and possibly elsewhere. The open tree canopy is often patchy and is strongly dominated by *Pinus flexilis* or *Pinus aristata* with the latter restricted to southern Colorado, northern New Mexico and the San Francisco Mountains in Arizona. In the Wyoming Rockies and northern Great Basin, *Pinus albicaulis* is found in some occurrences, but is a minor component. Other trees such as *Juniperus* spp., *Pinus contorta, Pinus ponderosa*, or *Pseudotsuga menziesii* are occasionally present. *Arctostaphylos uva-ursi, Cercocarpus ledifolius, Juniperus communis, Mahonia repens, Purshia tridentata, Ribes montigenum*, or *Vaccinium* spp. may form an open shrub layer in some stands. The herbaceous layer, if present, is generally sparse and composed of xeric graminoids, such as *Calamagrostis purpurascens, Festuca arizonica, Festuca idahoensis, Festuca thurberi*, or *Pseudoroegneria spicata*, or more alpine plants.
Classification Comments: This system is distinguished from lower montane and foothill limber pine stands in Wyoming and Montana. The foothill system (Rocky Mountain Foothill Limber Pine-Juniper Woodland (CES306.955)) is found at the lower treeline, below the zone of continuous *Pinus ponderosa* or *Pseudotsuga menziesii* woodlands and forest, and extends out into the eastern portions of these states in the foothill zones of mountain ranges, along rock outcrops, breaks along rivers, and on sheltered sites where soil moisture is slightly higher than surrounding grasslands.

This system needs to be more clearly distinguished from Northern Rocky Mountain Subalpine Woodland and Parkland (CES306.807), which also includes woodlands of *Pinus flexilis* and *Pinus albicaulis* and occurs in similar environmental settings of the northern Rocky Mountains, particularly northwestern Wyoming, Montana, and north into Alberta and British Columbia. There is a proposal to include the dry, subalpine *Pinus albicaulis* woodlands of the Blue Mountains (Oregon) and northern Nevada into this system, Rocky Mountain Subalpine-Montane Limber-Bristlecone Pine Woodland (CES306.819). For Landfire, these *Pinus albicaulis* woodlands were included in the subalpine parkland system, but ecologically and floristically they are more similar to Rocky Mountain dry subalpine woodlands.

DESCRIPTION

Environment: This system is found throughout the Rocky Mountains, south of Montana, on dry, rocky ridges and slopes near upper treeline above the matrix spruce-fir forest. It extends down to the lower montane in the northeastern Great Basin mountains. Sites are harsh, exposed to desiccating winds with rocky substrates and a short growing season that limit plant growth. Higher elevation occurrences are found well into the subalpine - alpine transition on wind-blasted, mostly south- to west-facing slopes and exposed ridges. *Pinus aristata* forests are typically found on steep, south-facing slopes from 2700 to 3700 m (8850-12,140 feet) elevation. *Pinus flexilis* woodlands occupy similar habitats, but may occur at lower elevations than *Pinus aristata*. When found in the same landscape, stands dominated by *Pinus aristata* occur at higher elevation.
Dynamics: Both *Pinus flexilis* and *Pinus aristata* are short-statured, slow-growing, long-lived species in which individuals may live for 1000 or more years in fire-protected areas. They are adapted to cold, drought and extremely windy conditions with flexible branches that likely reduce wind damage. Fire is an important source of disturbance that facilitates stand regeneration in this system. Older woodlands are often broadly even-aged stands where seedlings are nearly absent, while areas that have recently burned may have abundant seedlings. Bristlecone pine is somewhat more tolerant of fire than is limber pine; however, both species appear to depend on fire for regeneration. Post-fire regeneration of bristlecone pine tends to be near burn edges and/or under surviving trees (Coop and Schoettle 2011). Regeneration of limber pine on burned areas is largely due to the germination of seeds cached primarily by Clark's nutcrackers (*Nucifraga columbiana*) and jays (i.e., corvid family), but also small mammals such as squirrels (Lanner and

Vander Wall 1980, Tomback 2001, Lanner 2007, CNHP 2010b). Dispersal of the smaller winged seeds of bristlecone pine is primarily by wind, but seeds are likely to also be dispersed by birds (Coop and Schoettle 2011).

Fire occurrence in this ecosystem is low frequency and mixed severity. In the absence of wind, fires are likely limited in extent (two acres or less). Understories are often sparse, with little to carry fires across the surface (Landfire 2007a). Stand-replacement fires are usually wind-driven, especially in mid- and late-serial classes. Landfire (2007a) review estimated replacement fires occurring between 35-100+ years and 200+ years (Fire Regime Groups IV and V) with surface fires occurring every 1000 years. However, in northern New Mexico, some open stands transition into subalpine grasslands and have more frequent, less severe fires (Coop and Schoettle 2011).

SIERRA NEVADA SUBALPINE LODGEPOLE PINE FOREST AND WOODLAND (CES206.912)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Mediterranean [Mediterranean Xeric-Oceanic]; Shallow Soil; Xeric; Short Disturbance Interval [Periodicity/Irregular Disturbance]; Pinus contorta
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Acidic Soil; Sand Soil Texture; F-Patch/High Intensity; Avalanche; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2058; ESLF 4245; ESP 1058

CONCEPT

Summary: This ecological system is widespread in glacial basins at upper montane to subalpine elevations of the central and northern Sierra Nevada and Transverse and Peninsular ranges where cold-dry conditions exist (1800-2450 m [6000-8000 feet] in the north and 2450-3600 m [8000-12,000 feet] in the south). It also occurs on extensive broad ridges and pumice plateaus of the southern Cascades in Oregon (the broad ridges that form the Cascade crest in southern Oregon tend to be dominated by extensive stands of lodgepole pine). Soils are often shallow and coarse-textured. These forests and woodlands are dominated by *Pinus contorta var. murrayana* with shrub, grass or barren understories. Avalanche as well as tree mortality from insect outbreak and disease, drought and associated wildfire are drivers of community structure and composition. Understories are open, with scattered shrubs and herbaceous species, which do not carry fire should one get started. Trees can be very large and old and can attain diameters of 1.2 m (4 feet). Associated plant species include *Arctostaphylos nevadensis, Ceanothus cordulatus, Cercocarpus ledifolius* (although not that common, just occasional in drier sites), *Chrysolepis sempervirens, Phyllodoce breweri*, and *Ribes montigenum.* Common graminoids include *Poa wheeleri, Carex filifolia, Carex rossii*, and *Carex exserta*. Fire-return intervals are many hundreds of years. This system occurs in less severe settings than Mediterranean California Subalpine Woodland (CES206.910) and Northern California Mesic Subalpine Woodland (CES206.911) and is made up of trees that are not usually krummholz. Avalanches are less of a factor except in association with the volcanic peaks. Low-elevation stands of *Pinus contorta* in the pumice zone of Oregon are included in Rocky Mountain Poor-Site Lodgepole Pine Forest (CES306.960).

Similar Ecological Systems:
- Mediterranean California Subalpine Woodland (CES206.910)
- Northern California Mesic Subalpine Woodland (CES206.911)

Related Concepts:
- Lodgepole Pine: 218 (Eyre 1980) Broader

DESCRIPTION

Dynamics: LANDFIRE model information: Disturbance patterns have been poorly studied in Sierran lodgepole pine. Sierran lodgepole has been described as not being a fire type (Barbour and Minnich 2000) or as having long intervals between fires (Keeley 1980, Parker 1986, Potter 1998). Avalanche as well as tree mortality from insect outbreak and disease, drought and associated wildfire are the main drivers of community structure and composition. Somewhat similar wet lodgepole types in the Klamath Mountains and Oregon had a fire-return interval range of 70-100 years. Season of fire is generally late summer to early fall. Stand-replacement fire occurs at long interval, resulting in low stand complexity. Mixed-severity fire occurs when fuel conditions remain moist and result in mixed-age stands. Very infrequently, surface fires can occur. Forest understory is typically sparse with few shrubs and low to moderate herbaceous cover. Fuel is considered sparse (Parker 1986, van Wagtendonk 1991). Stands in the southern Sierra Nevada have been described as self-perpetuating (regeneration from treefall gaps) with long intervals between fires (Keeley 1980, Parker 1986, Potter 1998). Sparse fuels are believed to limit ignition and fire spread (Parker 1986). In contrast, fire history studies from dry subalpine lodgepole pine forest in the southern Sierra Nevada have found moderate fire-return intervals in some stands (Keifer 1991, Caprio 2008 and unpubl. data). Intervals ranged from 31-74 years (Chagoopa Plateau, Sequoia National Park and Palisades Canyon, Kings Canyon National Park). Fire severity was mixed and ranged from understory burns on areas up to 100s of ha to high-severity crown fires in patches up to 10s of ha (FRG of III). Season of fires was late summer or early fall. Seasonal fire scar positions on Chagoopa and Palisades (SEKI) was 40.7% and 15% latewood and 59.3% and 80% dormant, respectively (Caprio unpubl. data). Other important disturbance agents in this system include the lodgepole needle miner, windthrow and stress from extreme climatic events.

Component Associations:
- *Pinus albicaulis - Pinus contorta var. latifolia / Penstemon laetus* Forest (CEGL000130, G2)
- *Pinus contorta var. murrayana / Artemisia tridentata* Forest (CEGL005812, G3?)
- *Pinus contorta var. murrayana / Carex exserta* Forest (CEGL008667, G4)
- *Pinus contorta var. murrayana / Carex rossii* Forest (CEGL002749, G3?)
- *Pinus contorta var. murrayana / Ledum glandulosum* Forest (CEGL008668, G3)

- *Pinus contorta var. murrayana / Ligusticum grayi* Forest (CEGL002747, G4?)
- *Pinus contorta var. murrayana / Penstemon newberryi* Woodland (CEGL002748, G3?)
- *Pinus contorta var. murrayana* / Sparse Understory Forest (CEGL003069, G4?)
- *Pinus contorta var. murrayana* / Sparse Understory Woodland (CEGL003070, G3G4)

DISTRIBUTION

Range: This system occurs in glacial basins at upper montane to subalpine elevations of the central and northern Sierra Nevada and Transverse and Peninsular ranges where cold-dry conditions exist (1800-2450 m [6000-8000 feet] in the north and 2450-3600 m [8000-12,000 feet] in the south). It also extends south into Baja California, Mexico, in the San Pedro Martir Mountains.

If present in Oregon, the most likely location is the southern Oregon Cascades. The broad ridges that form the Cascade Crest in southern Oregon tend to be dominated by extensive stands of lodgepole pine (south of Crater Lake and north maybe to Mount Bachelor). There are also relatively large areas of lodgepole pine along the broad crest from Mt. Jefferson to a little ways north of Olallie Butte that may also fit this type better than the Rocky Mountain lodgepole pine type, as these stands are more likely dominated by *Pinus contorta var. murrayana* than var. *latifolia*. Understory species are probably different from those listed, however.

SIERRAN-INTERMONTANE DESERT WESTERN WHITE PINE-WHITE FIR WOODLAND (CES204.101)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Very Shallow Soil; Aridic; Short Disturbance Interval; F-Patch/Low Intensity; F-Landscape/Low Intensity; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2172; ESLF 4269; ESP 1172

CONCEPT

Summary: This interior Pacific Northwest ecological system occurs on the Modoc Plateau and Warner Mountains of California, north into the Fremont National Forest along the east slope of the southern Cascades in Oregon, and may also occur in isolated high-elevation ranges of northern Nevada. These forests and woodlands range from just above the zone of ponderosa pine in the montane zone, to the upper montane zone. Elevations range from 1370 m to over 2135 m (4500-7000 feet). Occurrences are found on all slopes and aspects, although more frequently on drier areas, including northwest- and southeast-facing slopes, but also occurs on northerly slopes and ridges. This ecological system generally occurs on basalts, andesite, glacial till, basaltic rubble, colluvium, or volcanic ash-derived soils, and sometimes on granitics (Carson Range). These soils have characteristic features of good aeration and drainage, coarse textures, circumneutral to slightly acidic pH, an abundance of mineral material, rockiness, and periods of drought during the growing season. Climatically, this system occurs somewhat in the rainshadow of the Sierras and Cascades and has a more continental regime, similar to the northern Great Basin. This system tends to be more woodland than forest in character, and the undergrowth is more open and drier, with little shrub or herbaceous cover. Tree regeneration is less prolific than in other mixed-montane conifer systems of the Cascades, Sierras and California Coast Ranges. *Pinus monticola* is the dominant conifer in most places, but *Abies concolor var. lowiana* is usually present, at least in the understory, and occasionally as the dominant in the canopy, replacing *Pinus monticola*, particularly at lower elevations, and *Pinus ponderosa* is also often present. In the Warner Mountains, the *Abies concolor var. lowiana* stands range from 1675 to 2135 m (5500-7000 feet) in elevation, and the mixed *Pinus monticola - Abies concolor* is usually above 2135 m (7000 feet). Mixed stands with *Pinus contorta*, in moister locations, as well as *Pinus jeffreyi* and sometimes *Populus tremuloides* occasionally occur. Southern stands (around Babbitt Peak and in the Carson Range) can sometime have *Abies magnifica* in them, sometimes replacing *Abies concolor*. These forests and woodlands are marked by the absence of *Pseudotsuga menziesii*, *Pinus lambertiana*, and *Calocedrus decurrens*, and the generally drier, continental climatic conditions. In addition, the overall floristic affinities are with the Great Basin rather than Pacific Northwest. Understories are typically open, with moderately low shrub cover and diversity, and include *Arctostaphylos patula*, *Arctostaphylos nevadensis*, *Chrysolepis sempervirens*, *Ceanothus* sp., and *Ribes viscosissimum*. Common herbaceous taxa include *Arnica cordifolia*, *Festuca* sp., *Poa nervosa*, *Carex inops*, *Pyrola picta*, and *Hieracium albiflorum*. In openings, *Wyethia mollis* can be abundant.
Classification Comments: An alternative name could be Modoc Plateau Western White Pine - White Fir Woodland. This system is very similar to Mediterranean California Dry-Mesic Mixed Conifer Forest and Woodland (CES206.916), Mediterranean California Mesic Mixed Conifer Forest and Woodland (CES206.915) and Northern Rocky Mountain Dry-Mesic Montane Mixed Conifer Forest (CES306.805). Justification for splitting this system includes the following: it is *Abies concolor var. lowiana* (as opposed to being grand fir, which is found further east and north; hence it's probably not the northern Rocky Mountain system); it lacks Douglas-fir completely which is an important component of the Californian mixed conifer systems in the Sierras; and the understory composition suggests it is drier (due to: lower elevations? volcanic-derived ash/tuff soils? rainshadow of the Cascades?) than the Californian systems.

Similar Ecological Systems:
- Mediterranean California Dry-Mesic Mixed Conifer Forest and Woodland (CES206.916)
- Mediterranean California Mesic Mixed Conifer Forest and Woodland (CES206.915)
- Northern Rocky Mountain Dry-Mesic Montane Mixed Conifer Forest (CES306.805)

Related Concepts:
- Western White Pine: 215 (Eyre 1980) Intersecting. White pine is a major component.
- White Fir: 211 (Eyre 1980) Intersecting. White fir (*Abies concolor ssp. lowiana*) is a major component of this ecological system.

DESCRIPTION

Dynamics: The open nature of the stands suggests regeneration and establishment is slow and sporadic. Stand-replacing events are not frequent; most fire is probably partial stand disturbance. These stands are relatively high elevation, and there are generally widely spaced large and somewhat fire-resistant individuals. Also the discontinuous understory and only patchy regeneration suggests non-stand-replacing fire as the norm., rather patchy burns with isolated trees surviving regularly. Local windthrow, insects, disease (blister rust), and individual lightning strikes probably make up most of the disturbances.

Component Associations:
- *Abies concolor - Pinus monticola / Ribes viscosissimum* Forest (CEGL000260, G2)

- *Pinus monticola / Achnatherum occidentale* Woodland (CEGL008622, G3)

DISTRIBUTION

Range: This ecological system is found in the transition zone from the northern Sierra Nevada of California and Oregon, east into the Modoc Plateau and Intermountain region of northwestern Nevada. It is found in the Fremont National Forest east of Lake View in Oregon, and in the Modoc Plateau and Warner Mountains of California. It continues farther south in California to the Diamond Mountains south of Honey Lake (a northeast extension of the Sierras), on Babbitt Peak between Lake Tahoe and Sierra Valley, and also in the Carson Range in Nevada east of Lake Tahoe Scattered stands may occur on Hart Mountain and Steens Mountain in Oregon and possibly a few isolated places in the northern Great Basin and the Jarbridge Mountains of Nevada.

SOUTH FLORIDA HARDWOOD HAMMOCK (CES411.287)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Alkaline Soil; Broad-Leaved Evergreen Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2333; ESLF 4139; ESP 1333

CONCEPT

Summary: This rockland tropical hammock system, as currently defined, occurs only in extreme southern Florida. It consists of upland hardwood forest on elevated ridges of limestone in three discrete major regions; the Keys, southeastern Big Cypress, and the Miami Rock Ridge. Tropical hardwood species are diagnostic of the system. Among the species likely to be encountered throughout are *Bursera simaruba, Coccoloba diversifolia*, and *Eugenia axillaris*. *Quercus laurifolia* is one of the few temperate species which attains prominence in this system. These forests tend to have a dense canopy that produces deeper shade, less evaporation, and lower air temperature than surrounding vegetation. This microclimate, in combination with high water tables, tends to keep humidity levels high. A number of orchid and bromeliad species thrive in such conditions. Unlike most coastal plain systems, fire is a major threat to South Florida Hardwood Hammock (CES411.287). For this reason, many examples occur alongside natural firebreaks.

Related Concepts:

- Coastal Rock Barren (FNAI 1990) Intersecting
- Live Oak: 89 (Eyre 1980) Finer
- Rockland Hammock (FNAI 1990) Finer
- Tropical Hammock (Snyder et al. 1990) Equivalent
- Tropical Hardwoods: 105 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in three discrete regions of south Florida. Underlying geology and soils are somewhat different among these regions, and the juxtaposition of the system may be somewhat unique. Generally, soils are highly organic with uneven and widely ranging thickness (Snyder et al. 1990). These forests tend to have a dense canopy that produces deeper shade, less evaporation, and lower air temperature than surrounding vegetation. This microclimate, in combination with high water tables, tends to keep humidity levels high and the community quite mesic (FNAI 1990). Unlike most coastal plain ecological systems, fire is a major threat to South Florida Hardwood Hammock (CES411.287). For this reason, many examples occur alongside natural firebreaks, such as the leeward side of exposed limestone (Robertson 1955), moats created by limestone solution (Duever et al. 1986), and elevated outcrops above marshes, scrub cypress, or sometimes mangrove swamps (Snyder et al. 1990).

Vegetation: There tends not to be strong dominance in these forests, so the principal species list can be long. Tropical hardwood species are diagnostic of the system, although few are common or dominant in all regions where these hammocks occur (Snyder et al. 1990). Among the species likely to be encountered throughout are *Bursera simaruba, Coccoloba diversifolia*, and *Eugenia axillaris*. The northward ranges of these species are limited by the incidence of frosts (Drew and Schomer 1984). Other typical dominant tree species, in no real order, are *Metopium toxiferum, Swietenia mahagoni, Zanthoxylum fagara, Gymnanthes lucida (= Ateramnus lucidus), Piscidia piscipula*, and *Pithecellobium keyense* (T. Armentano pers. comm.). Other species can include *Lysiloma latisiliquum, Nectandra coriacea, Ficus aurea, Sideroxylon foetidissimum, Eugenia foetida, Guapira discolor, Coccoloba uvifera, Thrinax morrisii, Thrinax radiata, Erithalis fruticosa, Krugiodendron ferreum, Casasia clusiifolia, Erithalis fruticosa, Byrsonima lucida*, and *Capparis flexuosa*.

Dynamics: Groundwater and seasonal pooling and drying of the soil are important dynamics. There is organic soil accumulation, thick in some areas and thin in others. Solution-eroded limestone provides wet pockets and dry patches in the environment. Thick organic soil helps maintain high levels of moisture in the system. Hurricanes are a part of the natural dynamics of this ecological system. Fire is very infrequent, due to the protection of this ecological system, many examples occur alongside natural firebreaks.

Component Associations:

- *Bursera simaruba - Swietenia mahagoni - Lysiloma latisiliquum / Nectandra coriacea - Coccoloba diversifolia* Forest (CEGL007003, G1G2)
- *Casasia clusiifolia - Guapira discolor - Pithecellobium keyense - Metopium toxiferum / Solanum bahamense / Hymenocallis latifolia* Forest (CEGL007005, G1)
- *Conocarpus erectus - Sideroxylon celastrinum - Erithalis fruticosa - Manilkara jaimiqui ssp. emarginata* Forest (CEGL007058, G1)
- *Ficus aurea - Sideroxylon foetidissimum - Bursera simaruba / Eugenia foetida - Guapira discolor - Nectandra coriacea* Forest (CEGL007001, G1)
- *Metopium toxiferum - Eugenia foetida - Coccoloba uvifera - Thrinax morrisii / Erithalis fruticosa* Forest (CEGL007008, G2)
- *Metopium toxiferum - Eugenia foetida - Krugiodendron ferreum - Swietenia mahagoni / Capparis flexuosa* Forest (CEGL007007,

G2)
- *Metopium toxiferum - Thrinax morrisii - Byrsonima lucida / Schizachyrium* spp. Woodland (CEGL003503, G1)
- *Morella cerifera - Ilex cassine - Quercus virginiana - Serenoa repens* Shrubland (CEGL003788, G2)
- *Opuntia stricta - Acanthocereus tetragonus - Evolvulus convolvuloides - Indigofera oxycarpa* Shrubland (CEGL003872, G1)
- *Pteridium caudatum* Herbaceous Vegetation (CEGL004259, GNR)
- *Sideroxylon foetidissimum - Sideroxylon salicifolium - Ficus aurea - Quercus virginiana - Celtis laevigata* Forest (CEGL007004, G1Q)
- *Strumpfia maritima* Florida Keys Shrubland (CEGL003794, G1)
- *Thrinax radiata - Casasia clusiifolia - Erithalis fruticosa* Forest (CEGL004711, G1Q)

SOUTH FLORIDA PINE ROCKLAND (CES411.367)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Circumneutral Soil; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2360; ESLF 4263; ESP 1360

CONCEPT

Summary: This system includes pinelands of extreme south Florida growing on limestone. The uniqueness of the flora associated with this type has long been recognized, including the number of endemic and West Indian species. Many plant and animal taxa found in this system are restricted to it, including many of south Florida's endemic plants. Unlike pinelands elsewhere in the southeastern coastal plain, *Pinus elliottii var. densa* is the only native pine species in this system. Understory vegetation consists of many hardwood species, including a number with tropical origins, and the herbaceous flora is species-rich and fire-adapted.

Similar Ecological Systems:
- South Florida Pine Flatwoods (CES411.381)--is also dominated nearly exclusively by *Pinus elliottii var. densa* in the canopy, but is on more acidic substrates (e.g., sand) and lacks much of the diversity and tropical characteristics of the understory.

Related Concepts:
- Coastal Rock Barren (FNAI 1990) Intersecting
- Pine Forest (Duever et al. 1986) Broader
- Pine Rockland (FNAI 1990) Equivalent
- South Florida Slash Pine: 111 (Eyre 1980) Undetermined

DESCRIPTION

Environment: In southeast Florida this system occurs on Miami Oolitic Limestone, while in the Big Cypress region (southwest Florida) it is found on outcrops of Tamiami Limestone. Pinnacle rock is characteristic of some sites; these are solution-formed irregular limestone features which stick up in places.
Vegetation: *Pinus elliottii var. densa* is the only native pine species in this system. It has been estimated that nearly one-third of the taxa found in this system are restricted to it, including half of south Florida's endemic plants (Stout and Marion 1993). The range of this system is largely outside the natural range of *Pinus serotina*, *Pinus elliottii var. elliottii*, and *Pinus palustris*.
Dynamics: Historical accounts show that fire has been frequent over the past several hundred years, perhaps as often as every 1-4 years (Wade et al. 1980, Bergh and Wisby 1996, Slocum et al. 2003). Without fire, after 15-20 years, hardwoods will be numerous and quite large (Wade et al. 1980). In the absence of fire, this system may be replaced by hardwoods species within several decades (Stout and Marion 1993). High winds from hurricanes are an infrequent, natural disturbance. Pine rockland in the Florida Keys can be subjected to storm surge associated with hurricanes (Saha et al. 2011).

Component Associations:
- *Pinus elliottii var. densa / Coccothrinax argentata - Thrinax morrisii* Woodland (CEGL003532, G1)
- *Pinus elliottii var. densa / Sabal palmetto / Schizachyrium rhizomatum - Muhlenbergia filipes - Rhynchospora divergens* Tropical Woodland (CEGL003533, G1G2)
- *Pinus elliottii var. densa / Sabal palmetto / Serenoa repens* Woodland (CEGL003534, G2?)
- *Pinus elliottii var. densa / Serenoa repens - Tetrazygia bicolor - Guettarda scabra* Woodland (CEGL003538, G1)
- *Pinus elliottii var. densa / Sideroxylon salicifolium - Chrysobalanus icaco - Ilex cassine* Woodland (CEGL003535, G2?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- South Florida Depression Pondshore (CES411.054)

DISTRIBUTION

Range: Davis (1943) mapped this system, which occurred primarily on the Miami ridge bordering the Everglades, with disjunct examples found in the Big Cypress Swamp. Davis estimated there once was 180,000 acres of "Miami region pine" (Davis 1943). McPherson's (1986) map of Big Cypress shows "pine forest," which includes both pine rocklands and pine flatwoods, scattered across the unit. It may be possible to differentiate based on soil type or geology, the pine rockland being in the southeast part of Big Cypress. In the Florida Keys it is found on Big Pine Key, No Name Key, Little Pine Key, Cudjoe Key, and Upper Sugarloaf Key. There has been an estimated 98% decline in the amount of pine rockland habitat on the Miami Rock Ridge in southern Florida, outside of the Everglades National Park where Long Pine Key is protected (Noss et al. 1995, Enge et al. 2002). About 6200 ha (15,000 acres) of pine rockland remain (Enge et al. 2002).

FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2326; ESLF 4132; ESP 1326

CONCEPT

Summary: This system represents mostly *Quercus stellata* dominated "xerohydric flatwoods" of limited flat areas of the most inland portions of the East Gulf Coastal Plain in western Kentucky, as well as in the nearby Shawnee Hills in the western Interior Low Plateau. The core of the area is referred to as the Jackson Purchase or "Jackson Plain." There is some local variability in the expression of this system along a hydrologic/microtopographic gradient. The elevated areas are composed of somewhat coarser-textured soils and retain less moisture than do the lower areas, although both occur in a tight local mosaic. The soils appear to have well-developed subsurface hardpans. Thus, soil moisture fluctuates widely throughout the growing season, from saturated to very dry.
Classification Comments: The component associations are poorly known and described. More work is needed to clarify which types are present.
Similar Ecological Systems:
- Interior Highlands Unglaciated Flatwoods (CES202.454)
- South-Central Interior / Upper Coastal Plain Wet Flatwoods (CES203.480)

Related Concepts:
- Flatwoods (Evans 1991) Broader
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer

DESCRIPTION

Environment: The soils appear to have well-developed subsurface hardpans, the impermeability of which contributes to shallowly perched water tables during portions of the year when precipitation is greatest and evapotranspiration is lowest (not due to overbank flooding). Thus, soil moisture fluctuates widely throughout the growing season, from saturated to very dry, a condition sometimes referred to as xerohydric (Evans 1991). Examples of this system occur along the northeastern flank of the Upper East Gulf Coastal Plain ecoregion where loess deposits thin out and gravelly or sandy soils predominate. Examples occur on relatively high flat areas that are not directly affected by overbank flooding. These environments include ancient Quaternary or Tertiary post-glacial meltwater lakebeds and high terraces of the Upper Gulf Coastal Plain. The most typical soil is Okaw Silt Loam. The same system is found in the Shawnee Hills of Kentucky (M. Evans pers. comm. 2006). The lakes were originally formed by glacial damming of the Ohio River. It could also occur on upland plains and flat ridgetops (KSNPC 2009).
Vegetation: Stands of this system are dominated by *Quercus stellata*, a somewhat fire-tolerant oak. In addition, *Quercus alba, Carya ovata, Carya glabra*, and *Quercus velutina* may be present. The presence of *Quercus falcata* indicates longer fire-return times. The presence of *Quercus imbricaria* indicates that the stands were formerly more open. *Pinus* spp. are not prevalent in this area, but could invade from nearby plantations. Herbaceous cover is sparse to moderate; leaf litter is the dominant ground cover. Some shrubs include *Crataegus viridis, Ilex decidua*, and *Ulmus alata*. Characteristic grasses could include *Schizachyrium scoparium, Sorghastrum nutans*, and *Andropogon* spp. Some other typical herbs include *Manfreda virginica, Croton willdenowii, Danthonia spicata, Porteranthus stipulatus*, and *Pycnanthemum tenuifolium* (Hendricks et al. 1991). Lower areas (drainage ways and depressions) have *Quercus michauxii, Quercus pagoda, Quercus phellos, Liquidambar styraciflua*, or even *Taxodium distichum*. Local herb dominance in depressions is of wetland species such as *Juncus* spp. and *Carex* spp. For this related and possibly juxtaposed wetland vegetation, see South-Central Interior / Upper Coastal Plain Wet Flatwoods (CES203.480).
Dynamics: Fire was an important natural process in this system, and well-burned examples tend to be relatively open-canopied with well-developed herbaceous layers (M. Evans pers. comm.). The natural dynamics of wetness and drought and the patchy variation in soil wetness probably led to patchy fires in this habitat. Due to subsurface hardpans, tree rooting is restricted which makes trees more prone to windthrow. High wind and ice storms contribute to forest openings (Landfire 2007a).

Component Associations:
- *Quercus stellata / (Danthonia spicata, Croton willdenowii)* Woodland (CEGL005057, G1)
- *Quercus stellata / Cinna arundinacea* Flatwoods Forest (CEGL002405, G2G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- East Gulf Coastal Plain Northern Dry Upland Hardwood Forest (CES203.483)
- East Gulf Coastal Plain Northern Loess Plain Oak-Hickory Upland (CES203.482)

Adjacent Ecological System Comments: East Gulf Coastal Plain Northern Dry Upland Hardwood Forest (CES203.483).

DISTRIBUTION

Range: This system occurs in limited areas of the most inland portions of the East Gulf Coastal Plain in western Kentucky and adjacent Tennessee (the "Jackson Purchase" or "Jackson Plain" region; 222Cb; 74b in part), as well as in the nearby "Shawnee Hills" of the Interior Low Plateau (222Dh, 222Di; 72c) of Kentucky and adjacent Indiana. The core of the area from which this system was initially described is referred to as the Jackson Purchase or "Jackson Plain," where these areas have long been recognized as a distinctive subdivision within this region (Davis 1923, Bryant and Martin 1988). It is known from the Clarks River National Wildlife Refuge (KSNPC 2009).

SOUTH-CENTRAL INTERIOR MESOPHYTIC FOREST (CES202.887)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Sideslope; Unglaciated; Eutrophic Soil; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2321; ESLF 4127; ESP 1321

CONCEPT

Summary: These high-diversity, predominately deciduous forests occur on deep and enriched soils (in some cases due to, or enhanced by, the presence of limestone or related base-rich geology), in non-montane settings and usually in somewhat protected landscape positions such as coves or lower slopes. The core distribution of this system lies in the Cumberland and Allegheny plateaus, extending into the adjacent southern Ridge and Valley and portions of the Interior Low Plateau where it is located entirely south of the glacial boundary. Dominant species include *Acer saccharum, Fagus grandifolia, Liriodendron tulipifera, Tilia americana, Quercus rubra, Magnolia acuminata*, and *Juglans nigra*. *Tsuga canadensis* may be a component of some stands, although its abundance is being rapidly reduced by the hemlock woolly adelgid (*Adelges tsugae*). Trees may grow very large in undisturbed areas. The herb layer is very rich, often with abundant spring ephemerals. Many examples may be bisected by small streams.
Classification Comments: Southern and Central Appalachian Cove Forest (CES202.373) (Ecoregions 51 and 59) is being treated as a separate system. The concept of this type (CES202.887) is more-or-less consistent with the "Mixed Mesophytic Communities" of both the Mixed Mesophytic Forest Region and the non-coastal plain portion of the Western Mesophytic Forest Region, extending north into unglaciated portions of the Beech-Maple Forest Region, of Braun (1950) and Greller (1988). There is much variability in different examples of this system across its range, with the composition of some occurrences in the escarpment of the Cumberland Plateau approaching that of examples of Southern and Central Appalachian Cove Forest (CES202.373). The Allegheny Front is adopted as the divide between these two similar systems: material to the west goes to this system, and material to the east goes to Southern and Central Appalachian Cove Forest (CES202.373). In limited areas of the region, some stands may contain hemlock (*Tsuga canadensis*). These are noteworthy on a local basis, as the tree is less well distributed in the range of this system than it is in corresponding environments at higher elevation in the Appalachians or to the north.
Similar Ecological Systems:
- Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593)--found to the north and east.
- North-Central Interior Beech-Maple Forest (CES202.693)--is an equivalent system of glaciated terrain to the north.
- Ozark-Ouachita Mesic Hardwood Forest (CES202.043)
- Southern and Central Appalachian Cove Forest (CES202.373)--is found in adjacent regions to the east.

- *Tsuga canadensis - Fagus grandifolia - Acer saccharum / (Hamamelis virginiana, Kalmia latifolia)* Forest (CEGL005043, G3?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Allegheny-Cumberland Dry Oak Forest and Woodland (CES202.359)
- Southern Interior Low Plateau Dry-Mesic Oak Forest (CES202.898)

DISTRIBUTION

Range: This system occurs in southeastern Ohio east to Virginia, West Virginia, Kentucky, Tennessee, Georgia, and Alabama, with disjunct occurrences in unglaciated southwestern Pennsylvania and southwestern New York. This range is more-or-less consistent with the "Mixed Mesophytic" and "Western Mesophytic" (non-coastal plain portion only) forest regions of Braun (1950) and Greller (1988), although it does extend into unglaciated portions of the "Beech-Maple" region to the north. Thus, this system is most extensive in the Cumberland and Allegheny plateaus, as well as the unglaciated Interior Low Plateau, and becomes relatively limited in extent towards its western limit in the Ozark Hills of Illinois, and towards its northern limit in southwestern New York.. It is replaced in the Upper East Gulf Coastal Plain by other systems. Its range also includes the southern Ridge and Valley from Tennessee (and adjacent southwestern Virginia) to Alabama. Parts of the Cumberland Mountains (EPA 69 in Kentucky and Tennessee) are instead occupied by Southern and Central Appalachian Cove Forest (CES202.373). North-Central Interior Beech-Maple Forest (CES202.693) replaces this one in EPA 72b of Indiana.

SOUTHEAST FLORIDA COASTAL STRAND AND MARITIME HAMMOCK (CES411.369)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2337; ESLF 4143; ESP 1337

CONCEPT

Summary: This ecological system occurs as a narrow band of hardwood forest and shrublands along the Atlantic coast of southeastern Florida (approximately Volusia County southward). It is found on stabilized, old, coastal dunes, often with substantial shell components. The vegetation is characterized by hardwood species with tropical affinities, such as *Guapira discolor* and *Exothea paniculata*. As such, the northern extent of this type is limited by periodic freezes. This system is closely related to both inland tropical hammocks and southwest Florida maritime hammocks, and may share some species overlap with each.
Classification Comments: This system may be distinguished from southwest Florida maritime hammocks by geographic location, presence of certain indicator species lacking from southwest type (*Guapira discolor* and *Exothea paniculata*), and relatively harsher coastal exposure. It is distinguished from maritime hammocks further north which contain temperate species including *Persea borbonia, Quercus virginiana, Magnolia grandiflora*, and *Juniperus virginiana var. silicicola* (Johnson and Muller 1993a). Thatch palms (*Thrinax morrisii, Thrinax radiata*) are found in rockland hammocks, but absent from maritime hammocks.
Similar Ecological Systems:
- Southwest Florida Coastal Strand and Maritime Hammock (CES411.368)

- Live Oak: 89 (Eyre 1980) Finer
- Maritime Hammock (FNAI 1990) Intersecting
- Southern Scrub Oak: 72 (Eyre 1980) Finer
- Tropical Hardwoods: 105 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs along the coast on stabilized, old coastal dunes, often with substantial shell components. The northern extent of this type is limited by periodic freezes.
Dynamics: The northern extent of this type is limited by periodic freezes and lack of cold tolerance of tropical plants, such as *Guapira discolor* and *Exothea paniculata* (Johnson and Muller 1993a). Maritime hammocks are relatively stable forest communities, as long as the canopy remains intact and the underlying landform is stable (FNAI 1990). Surface fires may help to maintain the open understory (Landfire 2007a). The shrub-dominated, coastal strand communities are considered ecotonal, and historically burned more frequently than maritime hammocks, possibly every 4-5 years (Austin and Coleman-Marois 1977). However, there is some disagreement on this point. There is little information on natural fire frequency in coastal strand (FNAI 2010a). The low stature of strand is due to the influence of storms and the ongoing salt spray pruning (FNAI 2010a). Fire is not needed to explain the shrub-dominated vegetation of coastal strands (Landfire 2007a).

SOUTHEASTERN INTERIOR LONGLEAF PINE WOODLAND (CES202.319)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2351; ESLF 4254; ESP 1351

CONCEPT

Summary: This system encompasses the fire-maintained non-Coastal Plain woodlands and forests where *Pinus palustris* is a dominant or codominant canopy species. Its current range includes the outer Piedmont of Georgia and the Carolinas and various parts of Alabama, including the Talladega upland region (quartzite-slate transition) and the Cumberland Plateau, as well as, at least historically, the intervening Ridge and Valley. Examples occur on rolling to somewhat mountainous upland slopes in North Carolina, South Carolina, Georgia, and Alabama. They are believed to naturally be open woodlands with grassy ground cover, but many are now closed forests with dense shrubs or with little ground cover. *Pinus palustris* is either dominant, codominant, or present in circumstances that indicate former dominance or codominance. *Pinus echinata, Quercus coccinea, Quercus falcata, Quercus marilandica, Quercus prinus, Quercus stellata,* and *Quercus velutina* are frequent associates, often codominating. *Carya pallida* and *Sassafras albidum* are also frequent trees. Some of the most frequently encountered grasses include *Andropogon* spp., *Chasmanthium laxum, Danthonia spicata, Dichanthelium commutatum (= Panicum commutatum), Panicum virgatum, Piptochaetium avenaceum, Schizachyrium scoparium,* and *Sorghastrum nutans*. Important forbs include *Coreopsis major, Euphorbia corollata, Helianthus microcephalus, Pityopsis graminifolia, Solidago odora, Tephrosia virginiana,* and the fern *Pteridium aquilinum*.
Classification Comments: This system is closely related to the upland longleaf pine systems of the Coastal Plain, with which it shares the ecological importance of fire, much of its flora and presumably fauna, and probably canopy dynamics. It is distinguished by the distinctive non-Coastal Plain soils and landscape, with its greater topographic relief, and by some floristic and compositional differences. It probably had less frequent natural fire and a somewhat more mixed canopy, with additional pine species in addition to oaks.

This system is distinguished from all other Piedmont and interior systems in having *Pinus palustris*, an indicator of frequent fire, as a dominant species. However, universal logging and fire suppression have blurred the distinction and have made many former examples indistinguishable from one of these other systems. This system should be recognized where there remains evidence of its past occurrence in the form of remnant flora.

Similar Ecological Systems:
- East Gulf Coastal Plain Interior Upland Longleaf Pine Woodland (CES203.496)
- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)

Related Concepts:
- Longleaf Pine: 70 (Eyre 1980) Finer
- Longleaf Pine: Clayey and Rocky Uplands, Piedmont and Montane Uplands (Peet 2006) Equivalent

DESCRIPTION

Environment: This system occurs in upland settings, which may range from gently rolling to rugged and mountainous. Geologic substrates vary. Most portions are dry, but occasional moist areas and seepage wetlands occur. The primary influence on the system is frequent fire, associated with a location near a fire-prone portion of the Coastal Plain or with other factors. Apparently once widespread along the Fall-line, remnants are now largely limited to two clusters, in eastern Alabama and adjacent Georgia and in south-central North Carolina. The former occurs on rugged terrain associated with the extension of geologic belts of the Blue Ridge. The latter is on gently to moderately rolling topography of metasedimentary and volcanic rocks. Most common on the poorest soils in the Piedmont of eastern Alabama, *Pinus palustris* was "a prominent constituent of the upland forests of nearly every county" but, by the first half of the twentieth century, "grew too scattered to be logged economically" (Harper 1943). About 35% of the original forest there was estimated to have been evergreen; the most common pines were *Pinus taeda, Pinus palustris,* and *Pinus echinata* (Harper 1943). However, this estimate is likely to have been low, since much *Pinus palustris* logging, turpentining and regeneration failure had already occurred prior to Harper's time (J.M. Varner pers. comm.). Today, montane *Pinus palustris* occurs mainly on ridgelines and south to southwesterly slopes (USFWS 2005), but was previously found on nearly all upland sites surveyed in Coosa County, Alabama (Reed 1905). In northwest Georgia, *Pinus palustris* occurs above 300 m (1000 feet) elevation, and it occurs up to nearly 600 m (2000 feet) in Talladega County, Alabama (Harper 1905).

Vegetation: Vegetation consists of open woodlands or forests. *Pinus palustris* is either dominant, codominant, or present in circumstances that indicate former dominance or codominance. *Pinus echinata, Pinus taeda, Quercus falcata, Quercus stellata, Quercus prinus, Quercus coccinea,* and *Quercus velutina* are frequent associates, often codominating. Alteration of fire regimes and universal logging have made the natural condition of the vegetation somewhat uncertain. Almost certainly *Pinus palustris* was more abundant than it usually is at present, but very likely some component of other pines and oaks was present. Under conditions of

frequent fire, understories and shrub layers were sparse and the grassy herb layer dense. Some of the most frequently encountered grasses include *Schizachyrium scoparium, Sorghastrum nutans, Andropogon* spp., *Chasmanthium laxum*, and *Panicum virgatum*. Some frequent forbs include *Tephrosia virginiana, Solidago odora*, and *Pteridium aquilinum* (Andrews 1917, Peet 2006). Other frequently dominant species, such as *Piptochaetium avenaceum* and *Danthonia spicata*, are not characteristic of Coastal Plain longleaf pine systems. Many other grasses and forbs are shared with the upland longleaf pine systems of the Coastal Plain. There is no evidence that *Aristida stricta* or *Aristida beyrichiana* were present in stands of this system, as these species are confined to the coastal plains. In remnant examples, where fire suppression has affected vegetation structure, the ground cover is often shrubby, with dense ericaceous shrubs leaving little space for herbs. Examples that have been burned recently often have ground cover dominated by shrubs and hardwood sprouts, with somewhat increased herb cover.

Dynamics: The dynamics of this system are strongly dominated by fire. The needles of *Pinus palustris* are an important fuel source for low-intensity fires. Fires probably once occurred at frequencies similar to those in the Coastal Plain but more frequently than in any other Piedmont ecological system. Evidence suggests fire frequencies of once every two to four years, with some annual fires (Bale 2009). Modern fire suppression has allowed *Pinus taeda* and *Quercus* spp. to increase in density, along with shrubs, and has resulted in the decrease in cover and diversity of the herb layer. Reproduction of *Pinus palustris* has been largely eliminated by the lack of fire, and the rooting of feral hogs (*Sus scrofa*). Where the canopy was also logged, *Pinus palustris* has often been completely eliminated, leaving the system indistinguishable from logged examples of Southern Piedmont Dry Oak-(Pine) Forest (CES202.339). Because *Pinus palustris* and some of the canopy species naturally associated with it are fairly resilient to fire, and many have the ability to sprout, reintroduction of fire can return this system to its natural composition and structure, but only gradually. Despite frequent fire, canopy dynamics were probably naturally dominated by gap-phase regeneration, with trees reproducing in small to medium-sized gaps created by wind storms and hot spots in fires. *Pinus palustris* is a long-lived tree, which continues to produce greater numbers of cones after age 100.

Component Associations:
- *(Pinus palustris) / Quercus georgiana* Woodland (CEGL007029, G2Q)
- *Pinus palustris - Pinus echinata - (Pinus virginiana) / Quercus marilandica - (Quercus prinus) / Vaccinium pallidum* Woodland (CEGL008437, G2)
- *Pinus palustris - Pinus echinata / Quercus coccinea - Quercus georgiana* Woodland (CEGL004432, G1Q)
- *Pinus palustris - Pinus echinata / Schizachyrium scoparium - Manfreda virginica* Serpentine Woodland (CEGL003608, G1)

- *Pinus palustris / Rhus aromatica / Salvia urticifolia - Piptochaetium avenaceum* Basic Woodland (CEGL007018, G1)
- *Quercus prinus - Pinus palustris* Forest (CEGL004060, G2G3)

Spatial Characteristics

Spatial Summary: This system was once a large-patch to matrix system, locally dominating the landscape matrix. Remnants are mostly large patches, some up to hundreds of acres or possibly even more.

Size: This system naturally occurs as a large-patch system, or as matrix system in limited areas. Contiguous examples or complexes of related patches of thousands of acres probably once occurred. Remnants are mostly large to medium patches. Occurrences over 1000 acres are present in Alabama, and patches up to 400 acres are present in North Carolina.

Adjacent Ecological Systems:
- Piedmont Seepage Wetland (CES202.298)
- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)

Adjacent Ecological System Comments: Examples are interfingered or associated with various mesic and floodplain or bottomland systems. Upland systems such as Southern Piedmont Dry Oak-(Pine) Forest (CES202.339) sometimes occur adjacent to remnants, especially on more rugged terrain. It is not always clear which oak-hickory forests are true examples of that system and which represent longleaf pine systems that have been degraded beyond recognition.

Distribution

Range: This system once occurred in parts of the mostly outer Piedmont, from central North Carolina to Alabama, where it extends into the adjacent Ridge and Valley in northeastern Alabama and northwest Georgia. More extensive areas are now largely, if not exclusively, restricted to south-central North Carolina (outer Piedmont) and to eastern Alabama (Talladega upland), as well as the Cumberland Plateau and at least historically, the Ridge and Valley of Alabama. Smaller remnants are found in very limited areas of South Carolina and Georgia (such as Pine Mountain).

SOUTHERN AND CENTRAL APPALACHIAN COVE FOREST (CES202.373)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2318; ESLF 4124; ESP 1318

CONCEPT

Summary: This system consists of mesophytic hardwood or hemlock-hardwood forests of sheltered topographic positions in the Southern Blue Ridge and central Appalachian Mountains. Examples are generally found on concave slopes that promote moist conditions. The system includes a mosaic of acidic and "rich" coves that may be distinguished by individual plant communities based on perceived differences in soil fertility and species richness (rich examples have higher diversity and density in the herbaceous layer). Both acidic and rich coves may occur in the same site, with the acidic coves potentially creeping out of the draw-up to at least midslope on well-protected north-facing slopes. Characteristic species in the canopy include *Aesculus flava, Acer saccharum, Fraxinus americana, Tilia americana, Liriodendron tulipifera, Halesia tetraptera, Tsuga canadensis, Fagus grandifolia, Magnolia acuminata,* and *Magnolia fraseri.*

Classification Comments: This system is best distinguished from others in its range by the combination of sheltered topography, low elevation, and mesophytic flora with high species richness. Canopies can sometimes become depauperate after repeated logging. It is presently defined as not including rich, mesophytic "cove" forests of the Cumberland Plateau and Interior Low Plateau, even though some of these approach or exceed Appalachian examples in their species composition and or their "coveyness." This will be interpreted as variability within South-Central Interior Mesophytic Forest (CES202.887). The Allegheny Front is adopted as the divide between these two similar systems: material to the west goes to South-Central Interior Mesophytic Forest (CES202.887), and material to the east goes to this system.

Similar Ecological Systems:
- Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593)
- South-Central Interior Mesophytic Forest (CES202.887)--found in adjacent regions to the west, out of the mountains, with a more matrix landscape character.
- Southern Piedmont Mesic Forest (CES202.342)--found in adjacent regions to the east.

DESCRIPTION

Environment: This mixed mesophytic forest system occurs on moist, topographically protected areas such as coves, V-shaped valley bottoms and ravines, and north- and east-facing toeslopes in a dissected landscape. It generally occurs below 1525 m (5000 feet) elevation. The dissected topography creates strong gradients in microclimate and soil moisture and fertility at the local (watershed) scale (Hutchins et al. 1976, Iverson et al. 1997, Morris and Boerner 1998). This forest type developed primarily on mesic, sheltered landscape positions (e.g., lower slopes, coves, ravines) but also occurred on some dry-mesic slopes, where presumably fire was infrequent (Wade et al. 2000). This system has two primary components, an acidic cove of lower soil fertility that ranges from the lowest slope positions up the slope on north-facing protected slopes, and a rich, high-fertility cove forest that tends to occur only at the lowest slope positions. Both are sheltered from wind and may be shaded by topography, promoting moist conditions. Local slopes are usually concave. Bedrock may be of virtually any type. Acidic rocks, such as felsic igneous and metamorphic rocks, support rich cove forests in a more limited range of sites than do basic rocks, such as mafic metamorphic rocks or marble. Soils may be rocky or fine-textured, and may be residual, alluvial, or colluvial. In the southern Appalachians, the hemlock "phase" of this ("acidic cove forest") often occurs between "richer" examples of Southern and Central Appalachian Cove Forest (CES202.373) in the lowest areas and Southern Appalachian Oak Forest (CES202.886) on the midslopes.

Vegetation: This system is among the most diverse in the United States, containing more than 30 canopy tree species. Vegetation consists of forests dominated by various combinations of mesophytic species, usually with many different species of primarily deciduous trees present. *Acer saccharum, Liriodendron tulipifera, Tilia americana, Tilia americana var. heterophylla, Fraxinus americana, Aesculus flava, Fagus grandifolia, Betula lenta, Magnolia acuminata, Magnolia fraseri, Quercus rubra, Halesia*

tetraptera, Prunus serotina, and *Tsuga canadensis* are the most frequent dominant canopy species (Braun 1950, Muller 1982). Witness tree data (from early land surveys) and studies of old-growth forests suggest that mixed-oak forests were generally more abundant on the landscape than mixed-mesophytic forests prior to European settlement (Beatley 1959, McCarthy et al. 1987, Abrams et al. 1995, Dyer 2001, McCarthy et al. 2001, Rentch et al. 2003). Canopies are generally very diverse, with all species potentially occurring in one 20x50-meter plot in rich cove areas. A well-developed herb layer, often very dense and usually high in species richness, is present in all but the acid coves. Well-developed and fairly diverse subcanopy and shrub layers are often also present in all but the acid coves. Ulrey (1999) listed *Caulophyllum thalictroides, Actaea racemosa (= Cimicifuga racemosa), Laportea canadensis, Osmorhiza claytonii, Sanguinaria canadensis, Viola canadensis, Acer saccharum, Aesculus flava, Carya cordiformis,* and *Tilia americana var. heterophylla* as characteristic species.

Dynamics: This system is naturally dominated by stable, uneven-aged forests, with canopy dynamics dominated by gap-phase regeneration on a fine scale. Occasional extreme wind or ice events may disturb larger patches. In the absence of frequent or catastrophic disturbance, environmental gradients formed by the dissected topography determine forest composition (Hutchins et al. 1976, Muller 1982, Iverson et al. 1997, Dyer 2001). Most of the component species are among the less fire-tolerant in the region. The mixed-mesophytic forest type is fire regime class III, surface fires with return intervals 30-100+ years (Wade et al. 2000). Mixed-severity fires may occur approximately every 500 years opening the canopy with increased mortality. Straight-line winds or microbursts may cause blowdowns on a scale of one to 100 acres. Stand-replacement fires happen very infrequently. Current composition and structure of this system is influenced by the absence of fire, deer herbivory, and non-native invasive species (plants, animals, insects and disease). The absence of fire is causing an expansion of some of the characteristic mesic taxa out of coves, potentially replacing previous oak-dominated vegetation on drier and more exposed sites than those typically associated with "mesic" vegetation.

Component Associations:

- *Acer (nigrum, saccharum) - Tilia americana / Asimina triloba / Jeffersonia diphylla - Caulophyllum thalictroides* Forest (CEGL008412, G4G5)
- *Acer saccharum - Fraxinus americana - Tilia americana - Liriodendron tulipifera / Actaea racemosa* Forest (CEGL006237, G4?)
- *Aesculus flava - Acer saccharum - (Fraxinus americana, Tilia americana var. heterophylla) / Hydrophyllum canadense - Solidago flexicaulis* Forest (CEGL007695, G3G4)
- *Betula alleghaniensis - Tilia americana var. heterophylla / Acer spicatum / Ribes cynosbati / Dryopteris marginalis* Forest (CEGL004982, G2G3)
- *Diphylleia cymosa - Saxifraga micranthidifolia - Laportea canadensis* Herbaceous Vegetation (CEGL004296, G3)
- *Impatiens (capensis, pallida) - Monarda didyma - Rudbeckia laciniata var. humilis* Herbaceous Vegetation (CEGL004293, G3)
- *Liriodendron tulipifera - Betula lenta - Tsuga canadensis / Rhododendron maximum* Forest (CEGL007543, G5)
- *Liriodendron tulipifera - Fraxinus americana - (Tilia americana, Aesculus flava) / Actaea racemosa - Laportea canadensis* Forest (CEGL007710, G4)
- *Liriodendron tulipifera - Pinus strobus - Tsuga canadensis - Quercus (rubra, alba) / Polystichum acrostichoides* Forest (CEGL006304, G4?)
- *Liriodendron tulipifera - Quercus rubra - Fraxinus americana / Asimina triloba / Actaea racemosa - Uvularia perfoliata* Forest (CEGL006186, G4?)
- *Liriodendron tulipifera - Quercus rubra - Magnolia acuminata / Cornus florida* Forest (CEGL008510, G5?)
- *Liriodendron tulipifera - Tilia americana var. heterophylla - (Aesculus flava) / Actaea racemosa* Forest (CEGL007291, G4?)
- *Pinus strobus - Tsuga canadensis / Rhododendron maximum - (Leucothoe fontanesiana)* Forest (CEGL007102, G4)
- *Quercus alba - Quercus rubra - Carya ovalis / Acer saccharum / Polystichum acrostichoides* Forest (CEGL007233, G4)
- *Quercus rubra - Tilia americana var. heterophylla - (Halesia tetraptera var. monticola) / Collinsonia canadensis - Prosartes lanuginosa* Forest (CEGL007878, G3?)
- *Tilia americana var. heterophylla - Aesculus flava - Acer saccharum / Cystopteris bulbifera - Asarum canadense* Forest (CEGL006472, G3G4)
- *Tilia americana var. heterophylla - Fraxinus americana - (Ulmus rubra) / Sanguinaria canadensis - (Aquilegia canadensis, Asplenium rhizophyllum)* Forest (CEGL007711, G2G3)
- *Tsuga canadensis - (Fagus grandifolia, Tilia americana var. heterophylla) / Magnolia tripetala* Forest (CEGL008407, G4)
- *Tsuga canadensis - Halesia tetraptera - (Fagus grandifolia, Magnolia fraseri) / Rhododendron maximum / Dryopteris intermedia* Forest (CEGL007693, G2)
- *Tsuga canadensis - Quercus prinus - Liriodendron tulipifera / Kalmia latifolia - (Rhododendron catawbiense)* Forest (CEGL008512, G4)
- *Tsuga canadensis / Rhododendron maximum - (Clethra acuminata, Leucothoe fontanesiana)* Forest (CEGL007136, G3G4)

SPATIAL CHARACTERISTICS

Spatial Summary: Large-patch system commonly occurring in a landscape mosaic with several other systems. On slopes it forms a mosaic with fire-prone Central Appalachian Dry Oak-Pine Forest (CES202.591), where these forests are restricted to the most protected coves.

Size: Most individual patches are tens to sometimes a few hundred acres. Because it frequently occurs in mosaics with other systems, separation distance for occurrences has a strong effect on the size of occurrences. Complexes of thousands of acres of this system are possible.

Adjacent Ecological Systems:

- Central Appalachian Dry Oak-Pine Forest (CES202.591)
- Northeastern Interior Dry-Mesic Oak Forest (CES202.592)
- Southern and Central Appalachian Bog and Fen (CES202.300)
- Southern Appalachian Low-Elevation Pine Forest (CES202.332)
- Southern Appalachian Montane Cliff and Talus (CES202.330)
- Southern Appalachian Oak Forest (CES202.886)
- Southern Appalachian Seepage Wetland (CES202.317)
- Southern Appalachian Spray Cliff (CES202.288)

Adjacent Ecological System Comments: This system is usually bordered by Southern Appalachian Oak Forest (CES202.886) in the Southern Blue Ridge. The border with adjacent systems is gradational. It may also contain small embedded patches of Southern Appalachian Montane Cliff and Talus (CES202.330) or other small-patch systems. In the southern Appalachians, the "richer" phase of Southern and Central Appalachian Cove Forest (CES202.373) occurs downslope from the hemlock "phase" ("acidic cove forests") and tends to be more mesic and more species-rich than the hemlock-dominated areas. Southern Appalachian Oak Forest (CES202.886) occurs upslope from this system and tends to be drier and even less diverse than the hemlock areas, which may grade into Southern Appalachian Low-Elevation Pine Forest (CES202.332) in especially dry occurrences. On slopes it forms a mosaic with fire-prone Central Appalachian Dry Oak-Pine Forest (CES202.591), where these forests are restricted to the most protected coves.

DISTRIBUTION

Range: This system occurs in the southern and central Appalachian Mountains, ranging into the Cumberland Mountains of Kentucky and Tennessee. This range is more-or-less consistent with the "Oak-Chestnut" forest region of Braun (1950) and Greller (1988), versus the "Mixed Mesophytic" and "Western Mesophytic" forest regions to the west.

SOUTHERN APPALACHIAN LOW-ELEVATION PINE FOREST (CES202.332)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Acidic Soil; Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2353; ESLF 4256; ESP 1353

CONCEPT

Summary: This ecological system consists of *Pinus echinata*- and *Pinus virginiana*-dominated forests in the lower elevation Southern Appalachians and adjacent Piedmont and Cumberland Plateau, extending into the Interior Low Plateau of Indiana, Kentucky and Tennessee. Examples can occur on a variety of topographic and landscape positions, including ridgetops, upper and midslopes, as well as lower elevations (generally below 700 m [2300 feet]) in the Southern Appalachians such as mountain valleys. Examples occur on a variety of acidic bedrock types. Frequent, low-intensity fires coupled with severe fires may have been the sole factor favoring the occurrence of this system instead of hardwood forests in the absence of fire. Under current conditions, stands are dominated by *Pinus echinata* or *Pinus virginiana*. *Pinus rigida* may sometimes be present. Hardwoods are sometimes abundant, especially dry-site oaks such as *Quercus falcata*, *Quercus prinus*, and *Quercus coccinea*, but also *Carya glabra, Acer rubrum*, and others. The shrub layer may be well-developed, with *Gaylussacia baccata, Kalmia latifolia, Rhododendron minus, Vaccinium pallidum,* or other acid-tolerant species most characteristic. Herbs are usually sparse but may include *Pityopsis graminifolia* and *Tephrosia virginiana*.
Classification Comments: This system and its component associations are among the least studied in the southern Appalachians (Harrod and White 1999). Settlement, universal logging, pine beetle outbreaks, and fire suppression potentially have altered their character and blurred their boundaries more than most systems in the region. The situation is further complicated by the potential for pine-dominated forests to have been both created and destroyed in different places by these disturbances. Obviously successional pine forests associated with the recovery of heavily logged or plowed slopes and valleys are grouped into the matrix Central and Southern Appalachian Montane Oak Forest (CES202.596).

The relationship between this system and Southern Appalachian Montane Pine Forest and Woodland (CES202.331) may need further clarification. Southern Appalachian Low-Elevation Pine Forest (CES202.332) is distinguished by its occurrence as large patches on lower terrain (generally below 700 m [2300 feet]) and less extreme topography. The vegetation of the two systems may overlap due to the factors outlined above, but pitch pine and Table Mountain pine are more typical of the former, while shortleaf pine and Virginia pine are more typical of the latter.

Presently the shortleaf pine-dominated vegetation of the Interior Low Plateau (ILP), including examples in southern Indiana and the Tennessee portion of Land Between the Lakes, is included in this system. Frost (1998) treats the ILP region in a different fire-return-interval class than the core range of this system, although local variation may overwhelm the broad regional differences. If more detailed information becomes available to document important ecological differences between these areas, a new system may be required.

This system (CES202.332) at its western extent in central Tennessee and Kentucky would be distinguished from equivalent Ozarkian systems (e.g., Ozark-Ouachita Shortleaf Pine-Oak Forest and Woodland (CES202.313)) by the presence of *Pinus virginiana* and *Quercus prinus*, which do not cross the Mississippi River.
Similar Ecological Systems:
- Allegheny-Cumberland Dry Oak Forest and Woodland (CES202.359)
- Central and Southern Appalachian Montane Oak Forest (CES202.596)
- Ozark-Ouachita Shortleaf Pine-Bluestem Woodland (CES202.325)
- Ozark-Ouachita Shortleaf Pine-Oak Forest and Woodland (CES202.313)
- Southern Appalachian Montane Pine Forest and Woodland (CES202.331)
- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)

Related Concepts:
- Appalachian Pine-Oak Forest (Evans 1991) Finer
- Eastern White Pine: 21 (Eyre 1980) Finer
- Shortleaf Pine - Oak: 76 (Eyre 1980) Finer
- Shortleaf Pine: 75 (Eyre 1980) Finer
- Virginia Pine: 79 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on ridgetops, upper and midslopes, in mountain valleys and the lower ranges. It is found on south- and southwest-facing slopes (Whittaker 1956). Bedrock may be a variety of types, but the system may be limited to acidic substrates. Fire is undoubtedly a very important and necessary influence.

Vegetation: Vegetation consists of closed to open forests or woodlands dominated by *Pinus echinata* or *Pinus virginiana*. *Pinus rigida* may sometimes be present. Hardwoods are sometimes abundant, especially dry-site oaks such as *Quercus falcata, Quercus prinus*, and *Quercus coccinea*, but also *Carya glabra, Acer rubrum*, and others. An extensive hardwood component may partly be the result of fire suppression. The shrub layer may be well-developed, with *Vaccinium pallidum, Gaylussacia baccata*, or other acid-tolerant species most characteristic. Herbs are usually sparse but may include *Pityopsis graminifolia* and *Tephrosia virginiana*. Herbs probably were more abundant and shrubs less dense when fires occurred more frequently, and the communities of this system may have been grassy under more natural conditions, with *Schizachyrium scoparium* being a typical component, possibly with *Danthonia* sp.
Dynamics: Fire is clearly an important influence on the dynamics of this ecological system, and frequent, low-intensity fires coupled with occasional severe fires (Harrod and White 1999) are thought to have been the primary factor leading to the occurrence of this system rather than hardwood forests on dry sites in the absence of fire. Fires probably were frequent and of low intensity, or a mix of low and higher intensity. Over many decades, accumulation of dead biomass can predispose these forests to catastrophic fire. However, even in the absence of fire, successional changes are normally restricted (possibly ending with oak domination) because most sites are infertile and dry (Murphy and Nowacki 1997). Fire probably is important for determining the balance of the two pine species, the component of hardwoods, and the overall vegetation structure. *Pinus echinata* is fairly resilient to fire once mature, while *Pinus virginiana* individuals are fairly susceptible to fire but well-adapted to establishing in areas opened by intense fire.

Southern pine beetles (*Dendroctonus frontalis*) are an important disturbance and threat in this system, at least under present conditions and severe outbreaks can kill all the pines without creating the conditions for the pines to regenerate. Effects of logging and past clearing as well as lack of fire make understanding of this system's natural character and dynamics difficult. An extensive hardwood component may partly be the result of lack of fire. Some pine-dominated areas appear to be successional stands established in former hardwood forests after logging or cultivation, and would not be expected to have the same dynamics or ecosystem characteristics as natural pine forests maintained by fire. In natural pine forests, logging may allow pines to regenerate or may change the composition to weedy hardwoods. This might also alter canopy composition as well as structure. In many cases, several prescribed fires or a combination of fire and thinning treatments will be necessary to restore these ecosystems (Elliott and Vose 2005).

Component Associations:
- *Pinus echinata - Quercus (prinus, falcata) / Oxydendrum arboreum / Vaccinium pallidum* Forest (CEGL007493, G3G4)
- *Pinus echinata - Quercus alba / Vaccinium pallidum / Hexastylis arifolia - Chimaphila maculata* Forest (CEGL008427, G3G4)
- *Pinus echinata - Quercus prinus - Quercus stellata / Vaccinium pallidum / Pityopsis graminifolia var. latifolia* Woodland (CEGL004445, G2?)
- *Pinus echinata - Quercus prinus / Rhododendron minus / Vaccinium pallidum* Forest (CEGL007496, G2G3)
- *Pinus echinata - Quercus stellata - Quercus marilandica / Vaccinium pallidum* Woodland (CEGL003765, G4?)
- *Pinus echinata - Quercus stellata - Quercus prinus - Carya glabra / (Danthonia spicata, Piptochaetium avenaceum)* Forest (CEGL007500, G3?)
- *Pinus echinata / Schizachyrium scoparium* Appalachian Woodland (CEGL003560, G2)
- *Pinus echinata / Vaccinium (pallidum, stamineum) - Kalmia latifolia* Forest (CEGL007078, G4?)
- *Pinus strobus / Kalmia latifolia - (Vaccinium stamineum, Gaylussacia ursina)* Forest (CEGL007100, G2G3)
- *Pinus virginiana - (Pinus rigida, Pinus pungens) / Schizachyrium scoparium* Forest (CEGL008500, G3G4)
- *Pinus virginiana - Pinus (rigida, echinata) - (Quercus prinus) / Vaccinium pallidum* Forest (CEGL007119, G3)

SPATIAL CHARACTERISTICS

Spatial Summary: Probably naturally a large-patch system, covering thousands of acres. Most remnants in relatively natural condition are probably small patches
Size: Natural size distribution not well-known, but probably a large-patch system with patches or complexes covering hundreds to thousands of acres. The current distribution of patch size is also not well-known. Size of defined occurrences may be strongly affected by standards for condition and separation distances. In some parts of the Interior Low Plateau, this system consists of smaller patches or linear strips along acidic (sandstone, cherty limestone) clifflines.
Adjacent Ecological Systems:
- Southern and Central Appalachian Cove Forest (CES202.373)
- Southern Appalachian Montane Cliff and Talus (CES202.330)
- Southern Appalachian Montane Pine Forest and Woodland (CES202.331)
- Southern Appalachian Oak Forest (CES202.886)

Adjacent Ecological System Comments: Probably usually bordered and intermixed with Southern Appalachian Oak Forest (CES202.886). Southern and Central Appalachian Cove Forest (CES202.373) may be present in more mesic areas. This system may also intergrade into Southern Appalachian Montane Pine Forest and Woodland (CES202.331) at high elevations.

DISTRIBUTION

Range: This system is found primarily in the Appalachian regions of Kentucky and the Southern Blue Ridge in northern Georgia, western North Carolina, southeastern Tennessee, the Cumberlands of Alabama, parts of the Interior Low Plateau (e.g., the Knobs Region of Kentucky and southern Indiana and the western Highland Rim of Tennessee), and southwestern Virginia.

SOUTHERN APPALACHIAN MONTANE PINE FOREST AND WOODLAND (CES202.331)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Forest and Woodland (Treed); Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2352; ESLF 4255; ESP 1352

CONCEPT

Summary: This system consists of predominantly evergreen woodlands (or more rarely forests) occupying very exposed, convex, often rocky south- and west-facing slopes, ridge spurs, crests, and clifftops in the Central Appalachians, Southern Ridge and Valley and Southern Blue Ridge. They occur at moderate to upper elevations (450-1200 m [1500-4000 feet]), with the more southerly examples at the higher elevations. In the Southern Blue Ridge, this system is best developed above 700 m (2300 feet) in elevation. The underlying rock is acidic and sedimentary or metasedimentary (e.g., quartzites, sandstones and shales). The soils are very infertile, shallow and droughty. A thick, poorly decomposed duff layer, along with dead wood and highly volatile ericaceous shrubs, creates a strongly fire-prone habitat. Most examples are dominated by *Pinus pungens*, often with *Pinus rigida* and/or *Pinus virginiana*, and occasionally *Tsuga caroliniana*. The canopy is usually patchy to open, but areas of closed canopy may be present, especially where *Tsuga caroliniana* is prominent. Fire is a very important ecological process in this system. Pines may be able to maintain dominance due to edaphic conditions, such as very shallow soil or extreme exposure in some areas which can produce sustained drought conditions, but most sites appear eventually to succeed to oak dominance in the absence of fire. Fire is also presumably a strong influence on vegetation structure, producing a more open woodland canopy structure and more herbaceous ground cover.
Classification Comments: This system is related to Central Appalachian Pine-Oak Rocky Woodland (CES202.600), which is distinguished by a mixed or deciduous canopy and absence of *Pinus pungens*. Stands with *Pinus echinata* present are generally accommodated by Southern Appalachian Low-Elevation Pine Forest (CES202.332). The relationship between these two systems may need further clarification. This system is distinguished by occurrence as small patches on the most extreme topography, as well as by the species of pines dominating. However, *Pinus echinata* may codominate in Southern Appalachian Low-Elevation Pine Forest (CES202.332) at times. Sites that would support this system under a natural fire regime, but which have lost the pines by logging, southern pine beetle or senescence in the absence of fire, should probably be regarded as degraded examples of this system. However, they become virtually indistinguishable from Southern Appalachian Oak Forest (CES202.886) and Central Appalachian Pine-Oak Rocky Woodland (CES202.600) over time.
Similar Ecological Systems:

- Virginia Pine: 79 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on ridgetops, usually only on the sharpest and narrowest spur ridges, and adjacent convex upper slopes. These sites are the extreme of convex landforms. Rapid drainage of rainfall and exposure to wind, sun and lightning are probably the important characteristics. Bedrock may be of any acidic type, including felsic igneous and metamorphic rocks, sandstone and quartzite. Soils are shallow and rocky residual soils. Fire appears to be an important factor.
Vegetation: Vegetation consists of open forests or woodlands dominated by *Pinus pungens*, often with *Pinus rigida* or less commonly *Tsuga caroliniana*, and sometimes with *Pinus virginiana* or rarely *Pinus echinata* codominant. In examples that have not had fire in a long time, *Quercus prinus, Quercus coccinea*, or other oaks are usually present and are sometimes abundant, as are *Nyssa sylvatica* and *Acer rubrum*. *Castanea dentata* may also have once been abundant. A dense heath shrub layer is almost always present. *Kalmia latifolia* is the most typical dominant, but species of *Rhododendron, Vaccinium*, or *Gaylussacia* may be dominant. Herbs are usually sparse but probably were more abundant and shrubs less dense when fires occurred more frequently.
Dynamics: Fire is apparently a very important process in this system (Harrod and White 1999). Pines may be able to maintain dominance due to shallow soils and extreme exposure in some areas, but most sites appear eventually to succeed to oak dominance in the absence of fire. Fire is also presumably a strong influence on vegetation structure, producing a more open woodland canopy structure and more herbaceous ground cover. Occurrence in highly exposed sites may make this system more prone to ignition, but most fires probably spread from adjacent oak forests. Fires could be expected to show more extreme behavior in this system than in

oaks forests under similar conditions, due to the flammability of the vegetation and the dry, windy and steep location. Both intense catastrophic fires and lower-intensity fires probably occurred naturally. Natural occurrences probably include both even-aged and uneven-aged canopies.

Southern pine beetles are an important factor in this system, at least under present conditions. Beetle outbreaks can kill all the pines without creating the conditions for the pines to regenerate. If the pines are lost, the distinction between this system and Southern Appalachian Oak Forest (CES202.886) or Central Appalachian Pine-Oak Rocky Woodland (CES202.600) becomes blurred.

Component Associations:
- *Pinus pungens - Pinus rigida - (Quercus prinus) / Kalmia latifolia - Vaccinium pallidum* Woodland (CEGL007097, G3)
- *Pinus rigida - (Pinus pungens) / Rhododendron catawbiense - Kalmia latifolia / Galax urceolata* Woodland (CEGL004985, G2)
- *Pinus rigida / Schizachyrium scoparium - Sorghastrum nutans - Baptisia tinctoria* Woodland (CEGL003617, G2?)
- *Pinus virginiana - Pinus (rigida, echinata) - (Quercus prinus) / Vaccinium pallidum* Forest (CEGL007119, G3)
- *Tsuga caroliniana - Pinus (rigida, pungens, virginiana)* Forest (CEGL006178, G2)
- *Tsuga caroliniana / Kalmia latifolia - Rhododendron catawbiense* Forest (CEGL007139, G2)

SPATIAL CHARACTERISTICS

Spatial Summary: Large- to small-patch system, occurring as a frequent part of the landscape mosaic.
Size: Occurs as a large- to small-patch system. Contiguous bodies probably once covered dozens to 100 or more acres. Patches often occur in complexes with other systems. Size of defined occurrences may be strongly affected by separation distances for occurrences.
Adjacent Ecological Systems:
- Southern Appalachian Grass and Shrub Bald (CES202.294)
- Southern Appalachian Low-Elevation Pine Forest (CES202.332)
- Southern Appalachian Montane Cliff and Talus (CES202.330)
- Southern Appalachian Oak Forest (CES202.886)

Adjacent Ecological System Comments: This system is almost always bordered and intermixed with Southern Appalachian Oak Forest (CES202.886). Distinctions are made more difficult by the suppression of fire and subsequent invasion of less fire-tolerant species such as *Acer rubrum* and *Nyssa sylvatica*. Generally speaking, communities with a heavy component of pine (at least 25 or 50% of canopy, and with some *Pinus pungens*) are categorized as Southern Appalachian Montane Pine Forest and Woodland (CES202.331), whereas communities with a much smaller component of pines are considered Southern Appalachian Oak Forest (CES202.886). At the highest elevations that this system is seen, it may intergrade with Southern Appalachian Grass and Shrub Bald (CES202.294).

DISTRIBUTION

Range: This system is centered on the Southern Blue Ridge, from northern Georgia and South Carolina north through Virginia, with outlying occurrences north through the Central Appalachians to a small incursion in the northern Blue Ridge of south-central Pennsylvania.

SOUTHERN APPALACHIAN NORTHERN HARDWOOD FOREST (CES202.029)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Broad-Leaved Tree
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2309; ESLF 4115; ESP 1309

CONCEPT

Summary: This system consists of hardwood forests of the higher elevation zones of the Southern Appalachians, generally above 1372 m (4500 feet) elevation. Included are classic northern hardwood forests, dominated by various combinations of mesophytic hardwoods, which interfinger with high-elevation oak forests downslope or on more exposed aspects. The combination of elevation and aspect provides habitat for this system. Included in this system are limited areas locally known as "beech gaps" and "boulderfields." Stands are dominated by various combinations of Appalachian mesophytic trees, including *Betula alleghaniensis, Fagus grandifolia, Aesculus flava, Acer saccharum*, and *Tsuga canadensis*. *Prunus serotina* and *Tilia americana var. heterophylla* are occasionally abundant. *Quercus rubra* may be present but is not dominant. In Kentucky, this system is of extremely limited extent, being restricted to areas above about 1100-1160 m (3600-3800 feet) elevation on Black Mountain, the highest elevation in Kentucky, which is apparently higher in elevation than adjacent areas in Tennessee and Virginia.
Classification Comments: This system does not include high-elevation *Quercus rubra* associations, which are placed in related Central and Southern Appalachian Montane Oak Forest (CES202.596). Even though they may occur in the same elevational zone as the mesophytic northern hardwood forests, they occupy a different habitat (drier and more exposed aspects), and comprise a different set of plant associations. They differ from the mesophytic northern hardwood forests in the dominance of oaks and the probable importance of fire as a process. The border of this system with adjacent systems is usually gradational. The transition to Central and Southern Appalachian Spruce-Fir Forest (CES202.028) that often adjoins at higher elevation is marked by a gradual shift in canopy dominance from hardwoods to conifers. The transition to lower elevation hardwood forest systems is similarly marked by a gradual turnover of dominant trees but may be more subtle because more species are shared. The transition to Southern and Central Appalachian Cove Forest (CES202.373) is particularly gradual, being marked mainly by the addition of species without loss of species. The non-forested systems that occur in the same elevational zone may have transition zones of open woody vegetation, though some have sharp borders. In relatively undisturbed stands, the canopy composition and structure are the best way to determine the boundary of this system.

This system is similar to the northern hardwood forests of the northeastern U.S., i.e., Laurentian-Acadian Northern Hardwood Forest (CES201.564), but differs in having a southern mountain climate (shorter winters, less extreme cold temperatures, shorter summer days), lacking a history of glaciation, and in having a flora and fauna with many southern Appalachian endemics. A few characteristic dominants of the northern hardwoods are lacking, including *Betula papyrifera* and *Populus tremuloides*. It differs from Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593) in its more montane setting and its flora and fauna having many southern Appalachian endemics. The northern hardwoods in the Ridge and Valley are primarily included in CES202.593. The northern boundary of this system follows a gradual northward transition through central and northern Virginia.
Similar Ecological Systems:
- Appalachian (Hemlock)-Northern Hardwood Forest (CES202.593)
- Central and Southern Appalachian Montane Oak Forest (CES202.596)--generally occupies more exposed and drier aspects and becomes more prominent at lower elevations.
- Southern Appalachian Oak Forest (CES202.886)

Related Concepts:
- Hemlock - Yellow Birch: 24 (Eyre 1980) Finer
- Northern Hardwood Forest (Schafale and Weakley 1990) Broader
- Sugar Maple - Beech - Yellow Birch: 25 (Eyre 1980) Undetermined

DESCRIPTION

Environment: The habitat for this system in the Southern Blue Ridge includes cooler, moister slopes and more-or-less concave landforms, at elevations from 1220-1680 m (4000-5500 feet), occasionally extending up to nearly 1830 m (6000 feet). It is most prevalent on north- to east-facing slopes, but can occur on a variety of landforms and aspects within this elevational range, tending to be more predominant towards its upper limits, where it transitions to spruce- or spruce-hardwood-dominated types. Elevation and orographic effects make the climate cool and wet, with significant moisture input from fog as well as high rainfall. Strong winds, ice glaze, and extreme cold may occur but are less important than in Central and Southern Appalachian Spruce-Fir Forest (CES202.028). Soils are generally very rocky, with the matrix ranging from well-weathered parent material to coarse colluvial boulder deposits. Soils are probably moist but not saturated most of the time. Any kind of bedrock may be present. Limited areas support boulderfields. In

related areas of Kentucky (in the highest elevations of the Cumberlands), this system is of extremely limited extent. Its elevational range is lower than in the Southern Blue Ridge, being restricted to areas above about 1100-1160 m (3600-3800 feet) elevation on Black Mountain. These are the highest elevations in Kentucky and are apparently higher in elevation than adjacent areas in Tennessee and Virginia, which apparently lack examples of this system.

Vegetation: Vegetation consists of forests dominated by various combinations of *Betula alleghaniensis*, *Fagus grandifolia*, *Aesculus flava*, *Acer saccharum*, and *Tsuga canadensis*. *Prunus serotina* and *Tilia americana var. heterophylla* are occasionally abundant. *Quercus rubra* may be present but is not dominant; it dominates the warmer, more exposed aspects in this elevational range, and these stands are part of Central and Southern Appalachian Montane Oak Forest (CES202.596), not Southern Appalachian Northern Hardwood Forest (CES202.029). Lower strata usually include a dense herb layer and often a well-developed deciduous shrub layer as well. Limited areas may have a dense evergreen shrub layer. Plant species richness ranges from fairly high to very low.

Dynamics: This system is naturally dominated by stable, uneven-aged forests, with canopy dynamics dominated by gap-phase regeneration on a fine to medium scale. Occasional extreme wind or ice events disturb larger patches on exposed slopes. Fire appears to be uncommon under natural conditions, perhaps extremely rare in the more mesic portions. In contrast, fire may be important in regeneration of *Quercus rubra* in stands of Central and Southern Appalachian Montane Oak Forest (CES202.596), and may be crucial in maintaining its dominance in these drier sites. Many *Quercus rubra* forests now appear to be succeeding to mesophytic hardwoods in the absence of fire. Little is known about natural fire behavior. Fires are likely to be low in intensity because of limited flammability of the vegetation and prevailing moist conditions, but most of the component tree species are probably not very tolerant of fire.

Component Associations:

- *Aesculus flava - Betula alleghaniensis - Acer saccharum / Acer spicatum / Caulophyllum thalictroides - Actaea podocarpa* Forest (CEGL004973, G3)
- *Betula alleghaniensis - (Tsuga canadensis) / Rhododendron maximum / (Leucothoe fontanesiana)* Forest (CEGL007861, G3)
- *Betula alleghaniensis - Acer saccharum - Aesculus flava / Acer pensylvanicum / Trillium grandiflorum* Forest (CEGL004417, G2G3Q)
- *Betula alleghaniensis - Fagus grandifolia - Aesculus flava / Viburnum lantanoides / Eurybia chlorolepis - Dryopteris intermedia* Forest (CEGL007285, G3G4)
- *Betula alleghaniensis / Ribes glandulosum / Polypodium appalachianum* Forest (CEGL006124, G2G3)
- *Fagus grandifolia / Carex pensylvanica - Ageratina altissima var. roanensis* Forest (CEGL006130, G1)

Spatial Characteristics

Spatial Summary: Large-patch to local matrix system, dominating the landscape of fairly high mountain ranges and occurring as a broad elevational zone on the highest. Small-patch systems may be embedded. It may be interfingered with Central and Southern Appalachian Montane Oak Forest (CES202.596) particularly between 1220-1372 m (4000-4500 feet) elevation.

Size: The size of patches is variable, being interfingered with montane oak vegetation in some cases, or occurring in larger more continuous patches in others. In the highest ranges, it occupies a broad elevational zone on the flanks. On somewhat lower mountain ranges, it dominates the mountaintops. Natural patches covered thousands to maybe 10,000 to 20,000 acres. A few remnant patches of thousands of acres remain, along with patches of hundreds of acres.

Adjacent Ecological Systems:

- Central and Southern Appalachian Montane Oak Forest (CES202.596)
- Central and Southern Appalachian Spruce-Fir Forest (CES202.028)
- High Allegheny Wetland (CES202.069)
- Southern and Central Appalachian Bog and Fen (CES202.300)
- Southern Appalachian Grass and Shrub Bald (CES202.294)
- Southern Appalachian Rocky Summit (CES202.327)
- Southern Appalachian Seepage Wetland (CES202.317)

Adjacent Ecological System Comments: Central and Southern Appalachian Montane Oak Forest (CES202.596) most typically interfingers at intermediate elevations and adjoins at lower ones. Central and Southern Appalachian Spruce-Fir Forest (CES202.028) may adjoin or interfinger at higher elevation. Small-patch systems such as Southern Appalachian Rocky Summit (CES202.327), Southern Appalachian Seepage Wetland (CES202.317), Southern and Central Appalachian Bog and Fen (CES202.300), and Southern Appalachian Grass and Shrub Bald (CES202.294) may be embedded.

Distribution

Range: This system is primarily found in the Southern Blue Ridge, where it ranges from northwestern Georgia, western North Carolina and eastern Tennessee northward to southern Virginia. In Kentucky, this system is restricted to the Cumberland Mountains in the extreme southeastern corner of that state.

SOUTHERN APPALACHIAN OAK FOREST (CES202.886)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Ridge/Summit/Upper Slope; Unglaciated; Broad-Leaved Deciduous Tree; Quercus - Carya
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2315; ESLF 4121; ESP 1315

CONCEPT

Summary: This system consists of predominantly dry-mesic (to dry) forests occurring on open and exposed topography at lower to mid elevations in the Southern Blue Ridge and Southern Ridge and Valley ecoregions. This is the upland forest that characterizes much of the lower elevations of these areas. Substrates of stands included in this system can range from acidic to circumneutral or basic, and the vegetation varies accordingly. Bedrock may be of any type. Soils are usually deep residual soils but are often rocky. Some shallow soils and colluvium may be present locally within the group, but shallow soils tend to produce environments that are more extreme and have a larger component of various pine species. Typically, the vegetation consists of forests dominated by oaks, especially *Quercus prinus, Quercus alba, Quercus rubra, Quercus velutina*, and *Quercus coccinea*, with varying amounts of *Carya* spp., *Nyssa sylvatica, Acer rubrum*, and other species such as *Pinus strobus* and *Fraxinus americana*. Historically, *Castanea dentata* was a dominant or codominant in many of these communities until its virtual elimination by the chestnut blight fungus (*Cryphonectria parasitica*] during the early 1900s. Some areas (usually on drier sites) now have dense evergreen ericaceous shrub layers of *Kalmia latifolia*, with *Rhododendron* spp. on more mesic sites. Some other areas have deciduous ericad layers, sometimes consisting of *Vaccinium* spp. or *Gaylussacia* spp. This system concept also includes many successional communities that have been impacted by logging or agriculture, such as types dominated by *Liriodendron tulipifera, Pinus* spp., and *Robinia pseudoacacia*. This system is naturally dominated by stable, uneven-aged forests, with canopy dynamics dominated by gap-phase regeneration. Most oaks are long-lived with typical age of mortality ranging from 200 to 400 years. Scarlet and black oaks are shorter lived with typical ages being approximately 50 to 100 years, while white oaks can live as long as 600 years.
Classification Comments: This system is distinguished from the oak forests of the Piedmont by substantial floristic differences that probably are determined by biogeography as well as climate and topography. Compositional differences were more pronounced in the past, when *Castanea dentata* was a major species in this system and not in Piedmont oak forests. This system is distinguished from most other systems in its primary range by the canopy dominance of oaks (other than strong dominance by red oak) without a large component of yellow pines (*Pinus echinata, Pinus virginiana, Pinus pungens*) in the canopy. It shares those characteristics with Allegheny-Cumberland Dry Oak Forest and Woodland (CES202.359), which might be thought of as a subtype of this system on the more exposed and acidic substrates. The environment is intermediate within the region in topography and moisture. Northward this system grades into Northeastern Interior Dry-Mesic Oak Forest (CES202.592), which occurs in similar environmental conditions. This southern Appalachian system is characterized by the presence, in most occurrences, of plant species of southern Appalachian affinity, such as *Magnolia fraseri, Gaylussacia ursina, Rhododendron calendulaceum*, etc.
Similar Ecological Systems:
- Allegheny-Cumberland Dry Oak Forest and Woodland (CES202.359)--may represent a narrower concept subset of this.
- Central and Southern Appalachian Montane Oak Forest (CES202.596)
- Central Appalachian Dry Oak-Pine Forest (CES202.591)
- Northeastern Interior Dry-Mesic Oak Forest (CES202.592)
- Southern Appalachian Montane Pine Forest and Woodland (CES202.331)
- Southern Appalachian Northern Hardwood Forest (CES202.029)

Related Concepts:

DESCRIPTION

Environment: Occurs on open slopes, ridgetops, lower elevation peaks, and higher parts of broad valley bottoms, at low to moderate elevations. Bedrock may be of any type. Soils are usually deep residual soils, but are often rocky. Some shallow soils, colluvium, and other soils may be present locally within the system, but shallow soils tend to produce environments that are more extreme and have a larger component of *Pinus* spp. than this system. Moisture levels are intermediate for the region. Soil chemistry and topography are important determinants of different associations within the system. Topography, elevation, and soil depth are the most important

factors separating this system from others.

Vegetation: Vegetation consists of forests dominated by *Quercus* species, most typically *Quercus prinus, Quercus alba*, and *Quercus coccinea*, with varying amounts of *Carya* spp., *Acer rubrum*, and other species. Less typical are stands dominated by other species, such as *Pinus strobus*, or other hardwood species. *Castanea dentata* was once dominant or codominant in many of these forests. Subcanopies and shrub layers are usually well-developed. Some associations have dense evergreen shrub layers, while others have open shrub layers. Herbs, forbs and ferns are usually sparse to moderate in density.

Dynamics: This system is naturally dominated by stable, uneven-aged forests, with canopy dynamics dominated by gap-phase regeneration. Extreme wind or ice storms occasionally create larger canopy openings. Fire occurred fairly frequently in presettlement times, though there is some dispute whether most of the fires were natural or anthropogenic in origin (Abrams 1992, Delcourt and Delcourt 1997). Fires were usually low-intensity surface fires. The dominant species are fairly fire-tolerant, making most fires non-catastrophic. Fire may be important for favoring oak dominance over more mesophytic tree species within some of the topographic range of this system. Fire also can be expected to have a moderate effect on vegetation structure, producing a somewhat more open canopy and less dense understory and shrub layer than currently seen in most examples. Fire frequency or intensity may be important for determining the boundary between this system and both the more mesic and the drier systems. Virtually all examples have been strongly affected by the introduction of the chestnut blight, which killed all of the *Castanea dentata* trees, eliminating it as a canopy dominant. Past logging affected most occurrences by changing canopies to an even-aged, or more even-aged, structure. Extreme wind or ice storms occasionally create larger canopy openings. Virtually all examples have been strongly affected by introduction of chestnut blight, which killed all the American chestnut trees, eliminating it as a canopy dominant. The introduction, and now widespread establishment, of gypsy moth (*Lymantria dispar*) that favors oaks as food has also affected these forests by causing widespread mortality of overstory trees depending on topographic position and precipitation amounts around defoliation events. Past logging, and now lack of fire, has affected most occurrences by changing canopies to an even-aged, or more even-aged, structure with an understory of shade-tolerant but fire-intolerant species such as *Pinus strobus, Acer rubrum*, and *Acer pensylvanicum*. The removal of American chestnut from the overstory of these forests is thought to have benefited *Carya* spp., and their persistence and continued recruitment in contemporary oak-hickory forests may reflect fire exclusion in recent decades.

Component Associations:

- *Pinus strobus - Quercus (coccinea, prinus) / (Gaylussacia ursina, Vaccinium stamineum)* Forest (CEGL007519, G4)
- *Pinus strobus - Quercus alba - (Carya alba) / Gaylussacia ursina* Forest (CEGL007517, G3G4)
- *Quercus (prinus, coccinea) / Kalmia latifolia / (Galax urceolata, Gaultheria procumbens)* Forest (CEGL006271, G5)
- *Quercus alba - Quercus (rubra, prinus) / Rhododendron calendulaceum - Kalmia latifolia - (Gaylussacia ursina)* Forest (CEGL007230, G4G5)
- *Quercus alba - Quercus coccinea - Quercus falcata / Kalmia latifolia - Vaccinium pallidum* Forest (CEGL007691, G2G3)
- *Quercus alba - Quercus falcata / Vaccinium (arboreum, hirsutum, pallidum)* Forest (CEGL008567, G3G4)

- *Quercus alba - Quercus rubra - Quercus prinus / Collinsonia canadensis - Podophyllum peltatum - Amphicarpaea bracteata* Forest (CEGL007692, G3)
- *Quercus alba / Kalmia latifolia* Forest (CEGL007295, G2Q)
- *Quercus muehlenbergii - Quercus (alba, rubra) - Carya cordiformis / Viburnum prunifolium* Forest (CEGL004793, G3G4)
- *Quercus prinus - (Quercus coccinea) / Carya pallida / Vaccinium arboreum - Vaccinium pallidum* Forest (CEGL008431, G4G5)
- *Quercus prinus - (Quercus rubra) - Carya* spp. / *Oxydendrum arboreum - Cornus florida* Forest (CEGL007267, G4G5)
- *Quercus prinus - Carya ovata - Quercus rubra / Acer saccharum* Forest (CEGL007268, G4?)
- *Quercus prinus - Quercus rubra - Carya* spp. *- Fraxinus americana / Cercis canadensis / Solidago sphacelata* Forest (CEGL008549, G3?)
- *Quercus prinus - Quercus rubra / Rhododendron maximum / Galax urceolata* Forest (CEGL006286, G4)
- *Quercus rubra - Acer rubrum / Pyrularia pubera / Thelypteris noveboracensis* Forest (CEGL006192, G4?)
- *Quercus rubra - Quercus muehlenbergii / Hamamelis virginiana / Polymnia canadensis* Forest (CEGL007215, G1Q)
- *Sassafras albidum - Quercus* spp. Forest (CEGL004096, G5)
- *Vitis aestivalis* Vine-Shrubland (CEGL003890, G2G3)

SPATIAL CHARACTERISTICS

Spatial Summary: Matrix system, covering a majority of the landscape over large areas.

Size: Occurs as a large-patch to matrix system. Contiguous bodies of tens of thousands of acres once occurred. The oak forests probably make up slightly more than 50% of the landscape in all but the higher elevations of the region. Size of existing occurrences may be strongly affected by separation distances for occurrences. A few remaining occurrences over 10,000 acres are probably present.

Adjacent Ecological Systems:

- Central and Southern Appalachian Montane Oak Forest (CES202.596)
- Southern and Central Appalachian Cove Forest (CES202.373)
- Southern and Central Appalachian Mafic Glade and Barrens (CES202.348)
- Southern Appalachian Granitic Dome (CES202.297)
- Southern Appalachian Low-Elevation Pine Forest (CES202.332)
- Southern Appalachian Montane Cliff and Talus (CES202.330)
- Southern Appalachian Montane Pine Forest and Woodland (CES202.331)

Adjacent Ecological System Comments: This system is almost always bordered by Southern and Central Appalachian Cove Forest (CES202.373) in more mesic sites. It is often bordered by Southern Appalachian Low-Elevation Pine Forest (CES202.332) on more exposed topography. It may grade into Central and Southern Appalachian Montane Oak Forest (CES202.596) at the highest elevations. Various rock outcrop systems may be present as embedded small patches.

DISTRIBUTION

Range: This system ranges throughout the southern Appalachians, from northern Georgia and South Carolina north into the Southern Blue Ridge of Virginia to the Roanoke River in the Blue Ridge, and slightly farther south in the Ridge and Valley. It occurs in very limited montane outliers in the Piedmont, and possibly on Pine/Black mountain in Kentucky.

SOUTHERN ATLANTIC COASTAL PLAIN DRY AND DRY-MESIC OAK FOREST (CES203.241)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Long Disturbance Interval; Broad-Leaved Tree
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2335; ESLF 4141; ESP 1335

CONCEPT

Summary: This system encompasses oak-dominated forests of somewhat fire-sheltered dry to dry-mesic sites in the Mid-Atlantic and South Atlantic coastal plains from southeastern Virginia to Georgia. Sites where this system occurs are somewhat protected from most natural fires by some combination of steeper topography, isolation from the spread of fire, and limited flammability of the vegetation. If fires were more frequent, the vegetation would likely be replaced by more fire-tolerant southern pines, especially *Pinus palustris*.

Classification Comments: There remains some uncertainty how this system and other dry and dry-mesic hardwood systems should be divided. There is a broad gradient in climate and species composition from north to south and west. The boundaries at the north edge of the Mid-Atlantic Coastal Plain ecoregion and at the break between the South Atlantic Coastal Plain and East Gulf Coastal Plain ecoregions are boundaries of convenience to create breaks in this broad gradient. Better boundaries may be possible. Differences from comparable systems in the Piedmont are sometimes fairly subtle, and species that differentiate them in one part of the range many not work in other parts. In particular, some species that are excluded from the Coastal Plain farther south are common components farther north. The boundary with Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242) and with adjacent *Pinus palustris*-dominated systems may be blurred by fire suppression.

- White Oak: 53 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in dry-mesic to dry but not xeric sites, generally on upper to midslopes in bluff systems, but occasionally it occurs on broader uplands or on the highest parts of non-flooded river terraces. Soils are generally acidic, though calcareous soils occur occasionally (as in Carya glabra - Tilia americana var. caroliniana - Acer barbatum / Trillium maculatum Forest (CEGL004747)). Soils are loamy to clayey and well-drained but not excessively drained. Similar sites with coarse sandy soils tend to support other ecological systems, in part due to the influence of more frequent fire. Sites are somewhat protected from most natural fires by steep topography and by limited flammability of the vegetation. Fires that penetrate them are generally low in intensity and have fairly limited ecological effect.

Vegetation: Vegetation consists of forests dominated by combinations of upland oaks, particularly *Quercus alba, Quercus falcata,* and *Quercus stellata*. In the northern part of the range, *Quercus rubra* may be a component, while in the southern part, evergreen species such as *Quercus nigra* or *Quercus hemisphaerica* become more prominent. Hickories (*Carya* spp.) are also prominent, including *Carya alba, Carya glabra,* and *Carya pallida*. Other woody plants may include *Tilia americana var. caroliniana, Acer barbatum, Aesculus pavia, Osmanthus americanus var. americanus, Ilex glabra, Ilex opaca, Vaccinium arboreum, Vaccinium elliottii,* and *Clethra alnifolia*. Some typical herbs are *Trillium maculatum* and *Chasmanthium sessiliflorum.* There is some variation in composition with aspect and degree of exposure to fire. *Pinus echinata* may be present in some stands, particularly on drier south- and west-facing slopes but is typically not dominant. *Pinus taeda* is sometimes present, but it is unclear if it is a natural component or has entered only as a result of past cutting. More mesophytic species such as *Fagus grandifolia* and *Magnolia grandiflora* are absent or are confined to the understory. Analogous systems on the Gulf Coastal Plain have pine as a natural component, and this may be true for some examples of this system as well, where occasional fires may allow them to regenerate. A well-developed shrub layer may be present, with *Vaccinium* spp. and *Gaylussacia* spp. most typical. The herb layer is generally sparse, and species richness tends to be low. In examples where fires have occurred, the understory is open and savannalike and dominated by grasses and forbs rather than shrubs.

Dynamics: Fire is intermediate in frequency in this system, being less frequent than in adjacent *Pinus palustris*-dominated stands, and more frequent than in mesic hardwood stands below. This fire regime is an important factor separating it from adjacent *Pinus palustris*-dominated systems. If fire does penetrate, it is likely to be low in intensity and have somewhat limited ecological effects.

However, there is some evidence that this system has expanded into areas once occupied by *Pinus palustris* as fire has been suppressed (Ware et al. 1993). There may have been a shifting boundary between these systems, driven by variation in fire frequency. These forests probably generally naturally existed as old-growth forests, with canopy dynamics dominated by gap-phase regeneration. However, exposure to occasional fires and hurricanes may create more frequent and larger canopy disturbances than analogous systems inland.

Frequent surface fires occurred on a 5- to 10-year return interval from both lightning and Native American ignitions. These frequent light surface fires would have maintained a grassy understory and kept more fire-tolerant hardwoods and shrubs from capturing the understory and forming a midstory layer. Lightning fires occurred primarily during the spring dry season (April and May) with a secondary peak of Native American and settler burning during the fall (October and November) (Landfire 2007a). Occasionally, during extensive droughts, mixed-severity or stand-replacement fires did occur, especially in drier stand dominated of codominated by *Pinus echinata*.

Local blowdown winds associated with thunderstorms created gaps on a small but continual basis. More extensive regional disturbances included tropical storms during the growing season and ice storms during winter (in the northern part of the range). Dense stands of middle to older aged pines (where present) were susceptible to periodic mortality from bark beetle epidemics (Landfire 2007a).

Component Associations:
- *Carya glabra - Tilia americana var. caroliniana - Acer barbatum / Trillium maculatum* Forest (CEGL004747, G2G3)
- *Quercus alba - Carya alba / Oxydendrum arboreum - Ilex opaca / Gaylussacia frondosa - Symplocos tinctoria - Vaccinium stamineum* Coastal Plain Forest (CEGL004321, G3G4)
- *Quercus alba - Carya glabra - Carya alba / Aesculus pavia* Forest (CEGL007225, G4?)
- *Quercus alba - Carya glabra* / Mixed Herbs Coastal Plain Forest (CEGL007226, G4?)
- *Quercus alba - Quercus (margarettiae, rubra, stellata) / Vaccinium pallidum* Sandhill Forest (CEGL007766, G2?)
- *Quercus alba - Quercus nigra - Quercus falcata / Ilex opaca / Clethra alnifolia - Arundinaria gigantea ssp. tecta* Forest (CEGL007862, G4?)
- *Quercus falcata - Quercus stellata - Carya alba / Vaccinium* spp. Coastal Plain Forest (CEGL007246, G4?)
- *Quercus hemisphaerica - Magnolia grandiflora - Carya (glabra, pallida) / Vaccinium arboreum / Chasmanthium sessiliflorum* Forest (CEGL004788, G3G4)
- *Quercus hemisphaerica - Pinus taeda - (Quercus nigra) / Osmanthus americanus var. americanus / Ilex glabra* Forest (CEGL007022, G2G3)

SPATIAL CHARACTERISTICS

Spatial Summary: Occurs in mosaics with small-patch systems, or as small isolated patches surrounded by wetlands.
Size: Generally occurs as small to medium patches, of a few to dozens of acres. Mosaics may contain up to several hundred acres in close proximity.
Adjacent Ecological Systems:
- Southeastern Coastal Plain Cliff (CES203.398)
- Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242)

Adjacent Ecological System Comments: Most commonly associated with Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242). Naturally grades to adjacent *Pinus palustris*-dominated systems on drier or flatter sites, but virtually no examples remain with this association intact.

DISTRIBUTION

Range: This system ranges from southeastern Virginia (south of the James River) south to southeastern Georgia in the Atlantic Coastal Plain.
Divisions: 203:C
Nations: US
Subnations: GA, NC, SC, VA
Map Zones: 55:C, 58:C, 60:C

SOUTHERN ATLANTIC COASTAL PLAIN MARITIME FOREST (CES203.537)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Coast
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2382; ESLF 4325; ESP 1382

CONCEPT

Summary: This system encompasses a range of woody vegetation present on stabilized upland dunes of barrier islands and near-coastal strands, from central South Carolina (from approximately the Cooper River) southward to Volusia County, Florida. It includes vegetation whose structure and composition are influenced by salt spray, extreme disturbance events, and the distinctive climate of the immediate coast. Examples are known from the barrier islands of Georgia and Florida, such as Big Talbot Island, Florida, and probably Sapelo Island, Georgia. Most typical stands are dominated by oaks, primarily *Quercus virginiana* and/or *Quercus geminata*. Vegetation may also include different woodland communities often dominated by southern pine species. *Pinus palustris, Pinus serotina,* and *Pinus elliottii var. elliottii* are all important in documented examples. These examples tend to have densely shrubby subcanopies and understories with species such as *Quercus virginiana, Quercus geminata, Quercus hemisphaerica, Quercus chapmanii, Quercus myrtifolia,* and *Magnolia grandiflora*. Unlike maritime vegetation to the north, this system may be more heavily influenced by natural fire regimes that may help to explain the predominance of the fire-tolerant pine species. It has been postulated that the natural fire-return interval is from 20 to 30 years.

Similar Ecological Systems:
- Central Atlantic Coastal Plain Maritime Forest (CES203.261)--occurs to north.
- Southern Atlantic Coastal Plain Dune and Maritime Grassland (CES203.273)

DESCRIPTION

Environment: The primary range of this system coincides with the Sea Islands, a chain of more than 100 low islands off the Atlantic coast of South Carolina, Georgia, and northern Florida, extending from the Cooper River to the St. Johns River. Many of these islands have a long history of human use and occupation, including Spanish missions and garrisons in the 16th century. In addition, the Sea Islands were the first important cotton-growing area in North America. The degree to which this system has been altered by these events is unknown.

This system is found on these islands and associated near-coastal strands, on stable dune and swale topography in somewhat more protected environments. These areas are generally landward of the foredune and transitional backdune zones. Examples typically include forests and/or shrublands that are found in somewhat more protected environments than adjacent dune and coastal grassland vegetation. The system typically includes a series of stabilized dunes and interdune swales oriented parallel to the coastline. Soils are primarily wind- and wave-deposited, well-drained quartz sands of Appalachian origin (Drehle 1973, Johnson and Barbour 1990), sometimes with a substantial shell component, that have been stabilized long enough to support trees and shrubs. As the forest establishes, soil temperature fluctuations moderate and humus begins to build up over the well-drained sands, contributing to moisture retention and leading to more mesic conditions, especially in swales where soil moisture is typically higher (FNAI 1990).

Vegetation: Most typical stands are dominated by oaks, primarily *Quercus virginiana* and/or *Quercus geminata*. Vegetation may also include different woodland communities often dominated by southern pine species. *Pinus palustris, Pinus serotina,* and *Pinus elliottii var. elliottii* are all important in documented examples. These examples tend to have densely shrubby subcanopies and understories with species such as *Quercus virginiana, Quercus geminata, Quercus hemisphaerica, Quercus chapmanii, Quercus myrtifolia,* and *Magnolia grandiflora*.

Dynamics: Maritime forests occur in the most stable portions of barrier islands, but the maritime environment is still extremely dynamic. Wind events and hurricanes will have significant impacts on this system. The environment for these forests may be severely altered or destroyed by geologic processes, such as the slow movement of dunes or their catastrophic destruction by storms. Sand movement may also create new sites for this system to occupy. Extreme salt spray or saltwater flooding in storms can severely disturb

vegetation, though it recovers if the landforms have not been altered. Mature *Quercus virginiana* trees are fire-resistant when mature, and their litter also does not easily burn (Stalter and Odum 1993). Fire may have occurred naturally yet infrequently in this system, but probably was not an important factor.

The vegetation of this system has a structure and composition that is influenced by salt spray (sea salt aerosol), extreme disturbance events, and the distinctive climate of the immediate coast. Extreme salt spray or saltwater flooding in storms can severely disturb vegetation, although the vegetation recovers if the landforms have not been altered. Unlike maritime vegetation to the north, this system may be more heavily influenced by natural fire regimes that may help to explain the predominance of the fire-tolerant pine species. It has been postulated that the natural fire frequency is from 20 to 30 years.

SOUTHERN ATLANTIC COASTAL PLAIN MESIC HARDWOOD FOREST (CES203.242)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Long Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2343; ESLF 4150; ESP 1343

CONCEPT

Summary: This upland system of the Atlantic Coastal Plain ranges from Delaware south to interior Georgia in a variety of moist but non-wetland sites that are naturally sheltered from frequent fire. Such sites include lower slopes and bluffs along streams and rivers in dissected terrain, mesic flats between drier pine-dominated uplands and floodplains, and local topographic high areas within bottomland terraces or nonriverine wet flats. Soil textures are variable in both texture and pH. The vegetation consists of forests dominated by combinations of trees that include a significant component of mesophytic deciduous hardwood species, such as *Fagus grandifolia* or *Acer barbatum*. Its southern limit is generally exclusive of the natural range of *Pinus glabra* and *Magnolia grandiflora*. Upland and bottomland oaks at the mid range of moisture tolerance are usually also present, particularly *Quercus alba*, but sometimes also *Quercus pagoda*, *Quercus falcata*, *Quercus michauxii*, *Quercus shumardii*, or *Quercus nigra*. *Pinus taeda* is sometimes present, but it is unclear if it is a natural component or has entered only as a result of past cutting. Analogous systems on the Gulf Coastal Plain have pine as a natural component, and this may be true for some examples of this system. Understories are usually well-developed. Shrub and herb layers may be sparse or moderately dense. Within its range, *Sabal minor* may be a prominent shrub. Species richness may be fairly high in basic sites but is fairly low otherwise.

Classification Comments: There remains some uncertainty how this system and other mesic hardwood systems should be divided. There is a broad gradient in climate and species composition from north to south and west. The boundaries at the northern edge of its range (the Chesapeake Bay Lowlands TNC ecoregion) and at the break between the South Atlantic Coastal Plain and East Gulf Coastal Plain ecoregions are boundaries of convenience to create breaks in this broad gradient. At the southern end, the boundary has been better determined (April 2006) to exclude areas within the combined ranges of *Pinus glabra* and *Magnolia grandiflora*, making this system deciduous rather than mixed evergreen-deciduous. Differences from mesic forests of the Piedmont are sometimes fairly subtle, and species that differentiate them in one part of the range many not work in other parts. In particular, some species that are excluded from the Coastal Plain farther south are common components farther north. In MD and DC, this system can extend into the Piedmont, straddling the fall zone where the Coastal Plain and Piedmont meet. Besides the variation across the range of this system, there are two sets of distinctions within it that may be worthy of consideration for defining separate systems. Acidic and basic substrates have substantial floristic differences. Variants on upland slopes, nonriverine swamp islands, and high ridges in bottomlands could be recognized as separate systems, or the latter two could be treated as part of the systems that surround them. However, the difference between ecological processes in uplands and wetlands separates those surrounded by wetland systems from the surrounding systems. This is especially true in the case of floodplains, which have flood-carried nutrient input as well as wetness as a difference. Floristic differences may exist between these variants, but they are subtle and do not appear to be definitive.

Similar Ecological Systems:
- Atlantic Coastal Plain Brownwater Stream Floodplain Forest (CES203.248)
- Northern Atlantic Coastal Plain Hardwood Forest (CES203.475)
- Southern Coastal Plain Mesic Slope Forest (CES203.476)
- Southern Piedmont Mesic Forest (CES202.342)

Related Concepts:
- Sugar Maple: 27 (Eyre 1980) Finer
- White Oak: 53 (Eyre 1980) Finer
- Yellow-Poplar: 57 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs in a variety of moist non-wetland sites that are naturally sheltered from frequent fire. The distribution of these forests is determined by the interaction of local topography and soil texture. Most common are lower slope and bluff examples along streams and rivers in dissected terrain, but some examples occur on mesic flats between drier pine-dominated uplands and floodplains or on local high areas within bottomland terraces or nonriverine wet flats. Soils cover the full range of mineral soil textures, except the coarsest sands. Richer and more mesic stands occur in more strongly concave and finer-textured areas. Soils are not saturated for any significant time during the growing season and seldom, if ever, are extremely dry. Soils developed from calcareous materials or rich alluvium may be basic; others are strongly acidic. Sites are protected from most natural fires by steep topography or by surrounding extensive areas of non-flammable vegetation (Batista and Platt 1997).

Vegetation: Stands of this system include a significant component of mesophytic species such as *Fagus grandifolia* or *Acer barbatum*. Upland and bottomland oaks at the mid range of moisture tolerance are usually also present, particularly *Quercus alba*, but

sometimes also *Quercus falcata, Quercus michauxii, Quercus shumardii,* or *Quercus nigra*. Other hardwood components include *Liriodendron tulipifera, Liquidambar styraciflua, Carya cordiformis, Nyssa sylvatica,* and *Magnolia tripetala*. *Pinus taeda* is sometimes present, but it is unclear if it is a natural component or has entered only as a result of past removal of the hardwood canopy and subsequent invasion. Analogous systems on the Gulf Coastal Plain have pine as a natural component, and this may be true for some examples of this system. Understories are usually well-developed. Shrub and herb layers may be sparse or moderately dense, with the herb layer being forb-dominated. Some typical smaller trees and shrubs include *Cornus florida, Symplocos tinctoria, Oxydendrum arboreum, Hamamelis virginiana, Morus rubra,* and *Stewartia malacodendron*. Within its range, *Sabal minor* may be a prominent shrub. Some stands may contain *Arundinaria gigantea*. Some typical herbs include *Mitchella repens* and *Hexastylis arifolia*. Species richness may be fairly high in basic sites but is fairly low otherwise.

Dynamics: Fire is naturally infrequent to absent in this system. Sites are protected from most natural fires by steep topography or by surrounding extensive areas of non-flammable vegetation (Landfire 2007a). If fire does penetrate, it is likely to be low in intensity but may have significant ecological effects. These forests probably generally exist naturally as old-growth forests, with canopy dynamics dominated by gap-phase regeneration. However, exposure to occasional fires and severe storms may create more frequent and larger canopy disturbances than analogous systems inland. Storm-related disturbance can be followed by waves of tree recruitment, growth, and death resulting in changes in the density and structure of tree populations and in consequent fluctuations in forest species composition. Disturbances in these forests appear to be critical for both regeneration and change in older stands (Batista and Platt 1997). Periodic droughts will cause death of or stress to moisture-requiring canopy trees.

Component Associations:

- *Aquilegia canadensis - Asplenium X heteroresiliens* Herbaceous Vegetation (CEGL004269, G1?)
- *Fagus grandifolia - Acer barbatum - Quercus muehlenbergii / Sanguinaria canadensis* Forest (CEGL007181, G2?)
- *Fagus grandifolia - Liriodendron tulipifera - Carya cordiformis / Lindera benzoin / Podophyllum peltatum* Forest (CEGL006055, G4?)
- *Fagus grandifolia - Quercus (alba, rubra) - Liriodendron tulipifera / (Ilex opaca var. opaca) / Polystichum acrostichoides* Forest (CEGL006075, G5)
- *Fagus grandifolia - Quercus alba - (Acer barbatum)* / Mixed Herbs Forest (CEGL007206, G4)
- *Fagus grandifolia - Quercus alba - Quercus laurifolia / Galax urceolata* Forest (CEGL007863, G4?)
- *Fagus grandifolia - Quercus nigra* Forest (CEGL007211, G3)
- *Fagus grandifolia - Quercus rubra / Cornus florida / Polystichum acrostichoides - Hexastylis virginica* Forest (CEGL008465, G3G4)
- *Quercus alba - Carya glabra - Carya alba / Aesculus pavia* Forest (CEGL007225, G4?)
- *Quercus alba - Quercus (michauxii, nigra) / Ilex opaca / Chasmanthium laxum* Forest (CEGL007845, G3G4)
- *Quercus alba - Quercus velutina - Carya alba / Cornus florida / Chimaphila maculata* Forest (CEGL007278, G3G4)
- *Quercus falcata - Quercus phellos / Ilex opaca* Forest (CEGL006390, GNR)
- *Quercus hemisphaerica - Tilia americana var. caroliniana - Magnolia grandiflora / Aesculus pavia - Ilex vomitoria* Forest (CEGL007470, G2G3)
- *Quercus muehlenbergii / Cercis canadensis / Dichanthelium boscii - Bromus pubescens - Erigeron pulchellus var. pulchellus - Aquilegia canadensis* Forest (CEGL007748, G1)
- *Quercus pagoda - Carya cordiformis / Chasmanthium sessiliflorum - Verbesina virginica* Forest (CEGL004092, G2?)
- *Quercus virginiana - Celtis laevigata - Tilia americana var. caroliniana / Aesculus pavia - Ilex vomitoria* Forest (CEGL007282, G1)
- *Quercus virginiana - Quercus pagoda - Magnolia grandiflora - Carya glabra / Ilex opaca* Forest (CEGL007850, G1Q)

Spatial Characteristics

Spatial Summary: Large-patch system, occurring in mosaics with other small-patch systems, or as small isolated patches surrounded by wetlands.

Size: Generally occurs as small to large patches, of a few to dozens of acres. Mosaics may contain up to several hundred acres in close proximity.

Adjacent Ecological Systems:

- Central Appalachian Dry Oak-Pine Forest (CES202.591)
- Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265)
- Northern Atlantic Coastal Plain Hardwood Forest (CES203.475)
- Southeastern Coastal Plain Cliff (CES203.398)
- Southern Atlantic Coastal Plain Dry and Dry-Mesic Oak Forest (CES203.241)
- Southern Atlantic Coastal Plain Nonriverine Swamp and Wet Hardwood Forest (CES203.304)
- Southern Atlantic White-cedar Peatland Forest (CES203.068)

Adjacent Ecological System Comments: Most commonly associated with Southern Atlantic Coastal Plain Dry and Dry-Mesic Oak Forest (CES203.241) and various floodplain systems. Less commonly associated with Southern Atlantic Coastal Plain Nonriverine Swamp and Wet Hardwood Forest (CES203.304). Floodplain systems often occur below this system. In MD and DC, where this system occurs along the fall zone, it may be found below ridges and hilltops supporting Central Appalachian Dry Oak-Pine Forest (CES202.591) and adjacent to steep slopes supporting Northern Atlantic Coastal Plain Hardwood Forest (CES203.475).

Distribution

Range: This system ranges from Delaware south to central Georgia in the Atlantic Coastal Plain. Its southern limit is generally

exclusive of the natural range of *Pinus glabra* as mapped by Kossuth and Michael (1990) and *Magnolia grandiflora* as mapped by Outcalt (1990).

SOUTHERN COASTAL PLAIN DRY UPLAND HARDWOOD FOREST (CES203.560)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2330; ESLF 4136; ESP 1330

CONCEPT

Summary: This is one of three hardwood-dominated systems found in the East Gulf Coastal Plain and adjacent areas of central Florida. This type is found in the Southern Coastal Plain and Southeastern Plains (EPA Level III Ecoregion 75 and parts of 65). Examples attributable to this type are typically deciduous or mixed evergreen oak-dominated forests, often with a pine component present. Although the southern portion of the range of this system overlaps Southern Coastal Plain Oak Dome and Hammock (CES203.494), the latter is dominated by evergreen oak species, and the two should not be confused. The core range of this type extends northward to the approximate historical range of *Pinus palustris*; although most deciduous species do not mimic this range, this boundary does appear to be a reasonable demarcation boundary north of which *Quercus alba* becomes more abundant and south of which *Quercus hemisphaerica* is more diagnostic. Like all hardwood systems of this region, examples occur within a landscape matrix historically occupied by pine-dominated uplands and consequently this system only occurred in fire-sheltered locations in naturally small to large patches. Examples of this system tend to occur on sites intermediate in moisture status (mostly dry to dry-mesic), although occasionally very dry (xeric) stands may also be included. Toward the northern range limits of this system, it may have been less restricted to small patches in fire-protected locations, and may have been formerly more prevalent on the landscape even in areas heavily influenced by fire.

Important tree species vary geographically and according to previous disturbance. *Quercus hemisphaerica* is a typical species in many examples, with *Quercus stellata*, *Quercus falcata*, and *Quercus alba* less frequently encountered, but dominant in some stands. The overstory of some examples may be quite diverse, with hickories and other hardwood species often present. Typically mesic sites, as indicated by species indicative of these conditions (e.g., *Fagus grandifolia*), are covered under other systems. *Pinus taeda* is sometimes present, but it is unclear if it is a natural component or has entered only as a result of past cutting. *Pinus glabra* or *Pinus echinata* may also be present in some examples. Stands may be found on slopes above rivers and adjacent to sinkholes, as well as other fire-infrequent habitats including narrow bands between mesic slopes below and pine-dominated flats above.
Classification Comments: As currently conceived, the Alabama range of this type extends throughout the Southern Hilly Gulf Coastal Plain (Ecoregion 65d), as mapped by the U.S. Environmental Protection Agency (EPA 2004) northward across the Black Belt and into the Fall Line Hills (Ecoregion 65i) to approximately Tuscaloosa (A. Schotz pers. comm.). To the north it is eventually replaced by East Gulf Coastal Plain Northern Dry Upland Hardwood Forest (CES203.483), but along this northern range it occurs in a mosaic with CES203.483 as well as East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506). In Mississippi the range extends almost to the same latitude, but this range is confined to Ecoregion 65d.
Similar Ecological Systems:
- Southern Coastal Plain Oak Dome and Hammock (CES203.494)

Related Concepts:
- Southern Scrub Oak: 72 (Eyre 1980) Finer
- Upland Hardwood Forest (FNAI 1990) Finer
- Upland Mixed Forest (FNAI 1990) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer

DESCRIPTION

Environment: Topographically, these sites tend to occur on upper to mid slopes, but occasionally on broader uplands with reduced fire frequencies. A range of soils may be present from loamy and clayey to coarse sands, but are generally well-drained but not excessively drained. Soils are generally acidic, though calcareous soils occur occasionally. Sites are somewhat protected from most natural fires by steep topography and by limited flammability of the vegetation.
Vegetation: Vegetation consists of forests dominated by combinations of upland oaks, particularly *Quercus alba, Quercus falcata, Quercus stellata, Quercus margarettiae*, and other species. There is some variation between the composition of northern versus southern examples in which evergreen species such as *Quercus nigra* and *Quercus hemisphaerica* become more prominent. Hickories (*Carya alba, Carya glabra*) may be present. There is some variation in composition with aspect and degree of exposure to fire. More mesophytic species such as *Fagus grandifolia* and *Magnolia grandiflora* are absent or are confined to the understory. *Pinus echinata* may be present in some stands, particularly on drier south- and west-facing slopes, but is typically not dominant. *Pinus taeda* is sometimes present, but it is unclear if it is a natural component or has entered only as a result of past cutting. Some examples of this system will have pine (*Pinus echinata, Pinus glabra, Pinus taeda*) as a natural component, where occasional fires may allow them to regenerate. In most examples, the understory is well-developed. A well-developed shrub layer may be present, with *Vaccinium* spp.

and *Gaylussacia* spp. most typical. The herb layer is generally sparse; species richness tends to be low but may be richer if fire has played a role in shaping the structure and composition of the stand. The most likely grass taxa (found in open-understory examples) are *Schizachyrium scoparium, Andropogon* spp., *Chasmanthium* spp., *Dichanthelium* spp., and *Danthonia sericea*.

Dynamics: Sites where this system occurs almost invariably grade upslope into pine-dominated systems, especially stands containing *Pinus palustris* and, to a lesser extent, *Pinus echinata*. If these sites were burned more frequently, the vegetation would likely be replaced by more fire-tolerant southern pines. Fires that penetrate stands of this type are generally low in intensity and have fairly limited ecological effect. In general, more frequent or intense fire would move the vegetation on the site toward more fire-tolerant components. Conversely, with the prolonged complete absence of fire, less fire-tolerant species could invade, causing the vegetation to resemble the more mesic slope forests below.

Frequent surface fires occurred on a 4- to 8-year return interval from both lightning and Native American ignitions. These frequent light surface fires maintained the grassy understory and kept more fire-tolerant hardwoods and shrubs from capturing the understory and forming a midstory layer. Lightning fires occurred primarily during the spring dry season (April and May) with a secondary peak of Native American and settler burning during the fall (October and November) (Landfire 2007a). Occasionally, during extensive droughts, mixed-severity or stand-replacement fires did occur, especially in drier *Pinus echinata*-dominated stands. Local thunderstorms created gaps on a small but continual basis. More extensive regional disturbances included tropical storms during the growing season and ice storms during winter (in the northern part of the range). Dense stands of middle to older aged *Pinus* species (where present) were susceptible to periodic mortality from bark beetle epidemics (Landfire 2007a).

Component Associations:

- *Quercus falcata - Quercus stellata - Carya alba / Vaccinium* spp. Coastal Plain Forest (CEGL007246, G4?)
- *Quercus hemisphaerica - Carya glabra - Magnolia grandiflora / Sabal etonia* Forest (CEGL003792, G2?)
- *Quercus hemisphaerica - Carya glabra / Oxydendrum arboreum / Sebastiania fruticosa / Carex baltzellii* Forest (CEGL007023, G2G3)
- *Quercus hemisphaerica - Magnolia grandiflora - Carya (glabra, pallida) / Vaccinium arboreum / Chasmanthium sessiliflorum* Forest (CEGL004788, G3G4)
- *Quercus hemisphaerica - Quercus (falcata, nigra) / Ilex opaca - Vaccinium arboreum / Cnidoscolus stimulosus* Forest (CEGL007751, G4)
- *Quercus velutina - Carya pallida - (Pinus echinata) / Vaccinium arboreum / Yucca filamentosa* Forest (CEGL008553, G3G4)

Spatial Characteristics

Spatial Summary: Examples occur within a landscape matrix historically occupied by pine-dominated uplands and therefore typically occur in somewhat fire-sheltered locations in naturally small to large patches. Toward the northern range limits of this system, it may have been less restricted to small patches in fire-protected locations, and may have been formerly more prevalent on the landscape even in areas heavily influenced by fire.

Adjacent Ecological Systems:

- East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506)

Distribution

Range: This system is found in the East Gulf Coastal Plain and adjacent areas of central Florida ranging northward into central Mississippi and Alabama.

SOUTHERN COASTAL PLAIN LIMESTONE FOREST (CES203.502)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Circumneutral Soil; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2328; ESLF 4134; ESP 1328

CONCEPT

Summary: This system represents dry to dry-mesic deciduous forests of the East Gulf Coastal Plain where limestone, marl, or other calcareous substrates occur near enough to the surface to influence vegetation composition. Examples are most common in the Black Belt region of Alabama and Mississippi, but are also present in more isolated patches in other portions of the region, including western Alabama, eastern Georgia, and southwestern middle Tennessee. Generally, the vegetation consists of forests and woodlands on well-developed, deep soils. Related, but physiognomically distinct, vegetation surrounding rock outcrops and calcareous prairies is accommodated within other ecological systems.
Classification Comments: Examples have been found in the Atlantic Coastal Plain which has led to a range expansion. South Carolina Heritage (B. Pittman/K. Boyle pers. comm.) has an ongoing study related to these communities in that state.
Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Sugar Maple: 27 (Eyre 1980) Finer

DESCRIPTION

Environment: Stands typically occur on ridges and upper to middle slopes of the southern coastal plains where limestone, marl, or other calcareous substrates occur near enough to the surface to influence vegetation composition.
Vegetation: Typical stands are dominated by oaks and hickories, particularly species which are indicative of finer-textured soils and/or a higher base status in the soil (e.g., *Carya carolinae-septentrionalis, Quercus muehlenbergii, Quercus pagoda, Quercus shumardii, Quercus stellata*). Other hardwood trees include *Fraxinus americana, Liquidambar styraciflua, Acer barbatum*, and *Aesculus glabra*. The rare *Carya myristiciformis* may also be found in some stands. Understory trees may include *Fraxinus americana* and *Juniperus virginiana var. virginiana*. Early-successional or fire-suppressed stands may exhibit greater dominance by *Juniperus virginiana*. More nutrient-rich or fire-sheltered stands may exhibit dominance or codominance by *Fraxinus americana, Tilia americana* (most commonly *var. caroliniana*, but *var. heterophylla* along the Chattahoochee River), and/or *Acer barbatum*. Understory trees may include smaller examples of canopy species in addition to *Aesculus pavia var. pavia*, *Cercis canadensis, Cornus florida*, *Ostrya virginiana*, and *Ulmus alata*. Shrubs and woody vines may include *Arundinaria gigantea, Berchemia scandens, Bignonia capreolata, Cocculus carolinus, Cornus drummondii, Crataegus* spp., *Euonymus americanus, Euonymus atropurpureus, Frangula caroliniana, Hydrangea quercifolia, Ilex decidua, Menispermum canadense, Parthenocissus quinquefolia, Ptelea trifoliata, Sideroxylon lycioides, Staphylea trifolia, Symphoricarpos orbiculatus, Toxicodendron radicans, Viburnum* spp., and *Vitis* spp. Some typical herbs include *Chasmanthium laxum, Chasmanthium sessiliflorum, Dichanthelium boscii, Lithospermum tuberosum, Polystichum acrostichoides, Sanicula* spp., *Solidago auriculata, Spigelia marilandica, Trillium* spp., and *Verbesina virginica*. The ground layers of some stands may exhibit dominance by native warm-season grasses and other graminoids, including *Schizachyrium scoparium, Andropogon* spp., *Danthonia* spp., and *Carex cherokeensis*. In addition, *Tillandsia usneoides* may be present as an epiphyte.
Dynamics: Fire frequency and intensity are factors determining the relative mixture of deciduous hardwood versus evergreen trees in this system. Frequent surface fires occurred on a 5- to 10-year return interval from both lightning and Native American ignitions. These frequent light surface fires maintained the grassy understory and kept hardwoods and shrubs from dominating the understory and forming a midstory layer. Lightning fires occurred primarily during the spring dry season (April and May) with a secondary peak of Native American and settler burning during the fall (October and November) (Landfire 2007a). Occasionally, during extensive droughts, mixed-severity or stand-replacement fires did occur, especially in drier stands, or those containing *Juniperus virginiana* or rarely with *Pinus* species (e.g., *Pinus taeda* and/or *Pinus echinata*). In addition, local thunderstorm-caused blowdowns created gaps on a small but continual basis. More extensive regional disturbances included tropical storms during the growing season and ice storms during winter (in the northern part of the range). Dense stands of middle to older aged pines (where present) were susceptible to periodic mortality from bark beetle epidemics, and younger *Juniperus virginiana* trees were killed by periodic droughts.

Component Associations:
- *Acer barbatum - Aesculus glabra - Carya myristiciformis - Quercus shumardii - Quercus muehlenbergii* Forest (CEGL004671, G1G2)
- *Aquilegia canadensis - Asplenium heterochroum - Polymnia laevigata - Urtica chamaedryoides* Herbaceous Vegetation (CEGL004268, G1?)
- *Fagus grandifolia - Magnolia grandiflora - Fraxinus americana / Acer barbatum - Cercis canadensis - Ostrya virginiana* Forest

(CEGL007458, G1G2)
- *Fraxinus americana - Juglans nigra - Ulmus rubra / Acer barbatum - Ostrya virginiana / Ptelea trifoliata* Forest (CEGL007180, G2)
- *Quercus (pagoda, shumardii) - Liquidambar styraciflua / Verbesina virginica - Solidago auriculata* Forest (CEGL008585, G3G4)
- *Quercus muehlenbergii - (Quercus sinuata) - Carya* spp. / *Sabal minor / Carex cherokeensis - Chasmanthium sessiliflorum* Forest (CEGL004023, G2)
- *Quercus muehlenbergii - Quercus shumardii - Carya (carolinae-septentrionalis, ovata)* Forest (CEGL007808, G3)
- *Quercus shumardii - Fraxinus americana - Carya* spp. / *Juniperus virginiana var. virginiana* Forest (CEGL004685, G2?)
- *Quercus shumardii - Quercus pagoda - Fraxinus americana / Ostrya virginiana - Cornus florida / Trillium ludovicianum* Forest (CEGL007272, G1)
- *Tilia americana (var. caroliniana, var. heterophylla) - Acer barbatum - Fraxinus americana / Arundinaria gigantea / Tillandsia usneoides* Forest (CEGL008557, G2G3)

Spatial Characteristics

Adjacent Ecological Systems:
- East Gulf Coastal Plain Interior Shortleaf Pine-Oak Forest (CES203.506)

Distribution

Range: This system occurs in the East Gulf (and rarely the Atlantic) Coastal Plain, most commonly in the Black Belt region of Alabama and Mississippi. It is also present in more isolated patches in other portions of the region, including western Alabama, eastern Georgia, and marginally in southwestern middle Tennessee.

SOUTHERN COASTAL PLAIN MESIC SLOPE FOREST (CES203.476)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Slope; Long Disturbance Interval; Broad-Leaved Evergreen Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2357; ESLF 4260; ESP 1357

CONCEPT

Summary: This forested system of the southern East Gulf and Atlantic coastal plains occurs on steep slopes, bluffs, or sheltered ravines where fire is naturally rare, generally within the natural range of *Pinus glabra* and *Magnolia grandiflora*. Stands are mesic, and vegetation typically includes species such as *Fagus grandifolia, Magnolia grandiflora, Illicium floridanum,* and other species rarely encountered outside this system in the region. Related forests which occur on deep loess soils along the western margin of the region are classified as East Gulf Coastal Plain Southern Loess Bluff Forest (CES203.556). Some component associations are also found in temporarily flooded floodplains adjacent to these slopes, but this is primarily an upland system. The system also includes essentially upland vegetation of Pleistocene terraces, although these are conceptually transitional to creek floodplain systems.
Classification Comments: East Gulf Coastal Plain Northern Mesic Hardwood Slope Forest (CES203.477) is a similar mesic forest system to the north of this one in the Upper East Gulf Coastal Plain that has greater dominance by deciduous trees. The systems of the loess bluffs to the west of this one, bordering the Mississippi River Alluvial Plain, are treated as distinct and are more extensive and continuous in their extent both vertically and latitudinally [see East Gulf Coastal Plain Northern Loess Bluff Forest (CES203.481) and East Gulf Coastal Plain Southern Loess Bluff Forest (CES203.556)]. To the north of the combined ranges of *Pinus glabra* and *Magnolia grandiflora* in the Atlantic Coastal Plain, this system is replaced by Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242).
Similar Ecological Systems:
- East Gulf Coastal Plain Northern Loess Bluff Forest (CES203.481)
- East Gulf Coastal Plain Northern Mesic Hardwood Slope Forest (CES203.477)
- East Gulf Coastal Plain Southern Loess Bluff Forest (CES203.556)
- Southeastern Coastal Plain Cliff (CES203.398)
- Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242)

Related Concepts:
- Loblolly Pine - Hardwood: 82 (Eyre 1980) Finer
- Slope Forest (FNAI 1990) Intersecting
- White Oak: 53 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is restricted to steep slopes, bluffs, or sheltered ravines where fire is naturally rare. This mesic habitat is confined to very limited, fire-sheltered areas within the natural ranges of *Pinus glabra* (Kossuth and Michael 1990) and *Magnolia grandiflora* (Outcalt 1990). This system occurs in a variety of moist, non-wetland sites that are naturally sheltered from frequent fire. These are typically narrow bands of vegetation between floodplain forests and upland communities dominated by *Pinus palustris* (Batista and Platt 1997). Most common are lower slope, bluff, and ravine examples along streams and rivers in dissected terrain, but some examples occur on mesic flats between drier pine-dominated uplands and floodplains or on local high areas within bottomland terraces or nonriverine wet flats. There may be larger patches where side -drains join larger streams. Under closed-canopy conditions, fire may only partially penetrate this system from adjacent uplands. Soils are typically deep, fine-textured, and moderately well-drained. Soils cover the full range of mineral soil textures, except for the coarsest sands. Soils are not saturated for any significant time during the growing season and seldom, if ever, are extremely dry. Soils developed from calcareous materials or rich alluvium may be basic; others are strongly acidic. Richer and more mesic stands occur in more strongly concave and finer-textured areas. Sites are normally protected from most natural fires by steep topography or by surrounding extensive areas of non-flammable vegetation. This system occurs in a region of mild winters, high annual rainfall and high evapotranspiration, as well as a high likelihood of hurricane landfall (Ware et al. 1993). These forests may represent relicts derived from the early Tertiary flora (Batista and Platt 1997).
Vegetation: Stands are mesic, and vegetation typically includes species such as *Fagus grandifolia, Magnolia grandiflora, Pinus glabra,* and other species rarely encountered outside this system in the region. All woody strata contain a mixture of evergreen and deciduous species. Canopies are diverse; in addition to the aforementioned taxa, other canopy taxa may include *Quercus alba, Quercus pagoda, Quercus michauxii, Quercus falcata, Quercus shumardii, Quercus velutina, Quercus laurifolia, Quercus nigra, Quercus hemisphaerica, Pinus echinata, Pinus taeda, Nyssa sylvatica, Fraxinus americana, Carya alba* (in the north), *Carya glabra, Ulmus alata, Ulmus americana, Ulmus rubra, Liriodendron tulipifera,* and *Liquidambar styraciflua* (NatureServe Ecology unpubl. data 2003). The presence of *Pinus taeda* is normal at lower frequencies, but higher ones may indicate past disturbance or removal of the hardwood canopy and subsequent invasion. Additional subcanopy taxa may include *Acer barbatum, Acer rubrum, Oxydendrum*

arboreum, Carpinus caroliniana ssp. caroliniana, Ostrya virginiana, Prunus caroliniana, Prunus serotina, Symplocos tinctoria, Magnolia macrophylla (rare to the west), *Halesia diptera, Styrax grandifolius, Sassafras albidum, Ilex opaca, Hamamelis virginiana, Magnolia pyramidata, Tilia americana var. caroliniana, Zanthoxylum clava-herculis, Crataegus marshallii, Morus rubra,* and *Cornus florida*. The shrub layer can be very diverse. Trees support lianas and epiphytes. Shrubs and woody vines include *Illicium floridanum, Hydrangea quercifolia, Arundinaria gigantea, Halesia diptera, Aesculus pavia, Calycanthus floridus var. floridus, Toxicodendron radicans, Parthenocissus quinquefolia, Viburnum rufidulum, Ilex vomitoria, Berchemia scandens, Vitis rotundifolia, Decumaria barbara, Callicarpa americana, Symplocos tinctoria, Ampelopsis arborea, Frangula caroliniana, Smilax tamnoides (= Smilax hispida), Gelsemium sempervirens, Sabal minor, Schisandra glabra, Lindera benzoin, Asimina parviflora, Cornus drummondii, Bignonia capreolata,* and *Euonymus americanus*. Except in gaps, herbs are scarce (Batista and Platt 1997). Herbs and herbaceous vines include *Thelypteris kunthii, Cystopteris protrusa, Viola walteri, Polystichum acrostichoides, Galium obtusum, Chasmanthium sessiliflorum, Aristolochia serpentaria, Trillium foetidissimum, Desmodium nudiflorum, Lithospermum tuberosum, Boehmeria cylindrica, Ageratina altissima var. altissima, Sanicula canadensis, Sanicula marilandica, Arisaema dracontium, Tillandsia usneoides, Cryptotaenia canadensis, Adiantum pedatum, Passiflora lutea, Cynoglossum virginianum, Botrychium virginianum, Ranunculus recurvatus, Mikania scandens,* and *Clematis crispa* (NatureServe Ecology unpubl. data 2003).
Dynamics: These are stable, fire-sheltered forests. Fire is naturally infrequent to absent in this system. Sites are protected from most natural fires by steep topography or by surrounding extensive areas of non-flammable vegetation (Landfire 2007a). If fire does penetrate, it is likely to be low in intensity but may have significant ecological effects. These forests probably generally exist naturally as old-growth forests, with canopy dynamics dominated by gap-phase regeneration. There is presumably some natural disturbance from the effects of hurricanes, which are relatively frequent in the range of this system, creating more frequent and larger canopy disturbances than analogous systems inland. Hurricanes can be followed by waves of tree recruitment, growth, and death resulting in changes in the density and structure of tree populations and in consequent fluctuations in forest species composition. Disturbances in these forests appear to be critical for both regeneration and change in older stands (Batista and Platt 1997). Periodic droughts will cause death of or stress to moisture-requiring canopy trees.

Component Associations:
- *(Fagus grandifolia) - Quercus pagoda - Magnolia grandiflora / Hydrangea quercifolia / Cystopteris protrusa - Thelypteris kunthii* Forest (CEGL007461, G3?)
- *Fagus grandifolia - Magnolia grandiflora - Fraxinus americana / Acer barbatum - Cercis canadensis - Ostrya virginiana* Forest (CEGL007458, G1G2)
- *Fagus grandifolia - Magnolia grandiflora - Pinus glabra - (Magnolia macrophylla) / (Illicium floridanum) / Hexastylis arifolia* Forest (CEGL007460, G3)
- *Fagus grandifolia - Magnolia grandiflora - Quercus michauxii - Quercus nigra / Rhododendron canescens* Forest (CEGL004965, G2G3)
- *Fagus grandifolia - Magnolia grandiflora - Quercus pagoda - Acer barbatum - Pinus taeda* Forest (CEGL004963, G1G2)
- *Fagus grandifolia - Magnolia grandiflora / Ilex opaca - (Persea borbonia) / Mitchella repens* Forest (CEGL007459, G2G3)
- *Fagus grandifolia - Magnolia grandiflora / Ostrya virginiana / Aesculus parviflora* Forest (CEGL008554, G2?)
- *Fagus grandifolia - Pinus glabra - Magnolia grandiflora / Serenoa repens* Forest (CEGL004977, G2G3)
- *Fagus grandifolia - Quercus alba - Liquidambar styraciflua / Magnolia grandiflora / Smilax pumila - Hexastylis arifolia* Forest (CEGL007210, G4)
- *Fagus grandifolia - Quercus alba / Symplocos tinctoria* East Gulf Coastal Plain Forest (CEGL003859, G3G4)
- *Pinus taeda - Quercus alba / Chasmanthium sessiliflorum* Forest (CEGL004763, G3G4)
- *Quercus (pagoda, shumardii) - Liquidambar styraciflua / Verbesina virginica - Solidago auriculata* Forest (CEGL008585, G3G4)
- *Quercus alba - Carya glabra - Carya alba / Aesculus pavia* Forest (CEGL007225, G4?)
- *Quercus alba - Quercus nigra - Carya pallida - (Quercus pagoda) / Magnolia (grandiflora, macrophylla)* Forest (CEGL004775, G3G4)
- *Quercus pagoda - Quercus (michauxii, shumardii) - Magnolia grandiflora - (Tilia americana var. caroliniana) / Sabal minor* Forest (CEGL007712, G2?)
- *Tilia americana (var. caroliniana, var. heterophylla) - Acer barbatum - Fraxinus americana / Arundinaria gigantea / Tillandsia usneoides* Forest (CEGL008557, G2G3)

DISTRIBUTION

Range: This mesic upland system of the southern (Atlantic and Gulf) coastal plains is found in suitable conditions from southern South Carolina south to northern Florida and west to (and including) the loessal plains of Mississippi and Louisiana. Its range is generally congruent with the natural range of *Pinus glabra* as mapped by Kossuth and Michael (1990) and *Magnolia grandiflora* as mapped by Outcalt (1990).

SOUTHERN COASTAL PLAIN OAK DOME AND HAMMOCK (CES203.494)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Long Disturbance Interval; Broad-Leaved Evergreen Tree
National Mapping Codes: ESLF 4275

CONCEPT

Summary: This small-patch system occurs in the Southern Coastal Plain (EPA ecoregion 75). Examples are known from some more inland portions of this region as well as the Southeastern Plain (EPA ecoregion 65) in Georgia and Alabama. Relatively dense stands of *Quercus virginiana* and/or *Quercus geminata* are diagnostic of this system. Examples often occupy locally distinct microhabitats that differ from the surrounding landscape, such as shallow depressions or slight topographic highs in a predominantly *Pinus palustris* -dominated landscape. Although embedded in a matrix of vegetation with extremely frequent fire regimes, patches of this system are subject to only infrequent or rare fire events. Under more frequent fire regimes, these sites would likely be occupied by *Pinus palustris*. It has been postulated that winter burning regimes have allowed this type to expand. A range of soil and moisture conditions may be present. More mesic examples have relatively thin soils (to 50 cm) above clay, while xeric examples occupy deep (>130 cm) well-drained sands. Dominant plants of mesic examples include *Quercus virginiana* and *Quercus hemisphaerica*, along with *Diospyros virginiana*. Vines including *Campsis radicans* and *Smilax* spp. dominate the sparse ground cover. In xeric examples, dominants include *Quercus geminata, Pinus palustris, Quercus virginiana, Aristida beyrichiana*, and *Stylisma humistrata*. This system is low in plant species diversity compared to most other habitats in the region.
Classification Comments: More diverse stands of upland hardwoods occurring in the same ecoregions should generally be treated under Southern Coastal Plain Dry Upland Hardwood Forest (CES203.560). The core range of this system lies farther south than CES203.560. Closely related stands of vegetation may also occur in near-coastal environments where they are more obviously influenced by maritime disturbances; these are treated under different ecological systems. In Alabama examples of this system are of very limited extent, but occur inland as far as 60 miles or so from the coast; it is also known from bluffs along the Mobile-Tensas (A. Schotz pers. comm.).
Similar Ecological Systems:

DESCRIPTION

Environment: Examples are thickets or groves of *Quercus* species in a *Pinus* spp.-dominated landscape (Myers 1990). These typically occupy locally distinct microhabitats that differ from the surrounding landscape, such as shallow depressions or slight topographic highs in a predominantly *Pinus palustris*-dominated landscape. A range of soil and moisture conditions may be present. As currently defined, this system includes examples across a moisture gradient from mesic to xeric, ranging across parts of the southeastern coastal plains from Georgia to Mississippi. In Georgia, more mesic examples of this system have relatively thin soils (to 50 cm) above clay, while xeric examples occupy deep (>130 cm) well-drained sands (Drew et al. 1998). In Florida, the xeric hammock typically develops on excessively drained sands where fire exclusion has allowed for the establishment of an oak canopy (FNAI 2010a). This may occur naturally, when the area has isolation from, or significant barriers to, fire. This can also occur as the result of human intervention, as at old homesites where fire was excluded for many years. In these areas, xeric hammock is found as small patches within or near sandhill or scrub. Xeric hammock can also occur on high islands within flatwoods or even on a high, well-drained ridge within a floodplain. Xeric hammock can occur on barrier islands and in other coastal situations, as an advanced successional stage of coastal scrub.

Along and near the east coast of Florida, from Cape Canaveral and northward, there is more shell or humus in the sand, and a tendency to have hammocks containing *Quercus virginiana* with coastal strand rather than scrub; on the other hand, where there is more dry acidic sand, scrub occurs nearer the coast and *Quercus geminata* hammocks are found further back from the coast (A. Johnson pers. comm.).
Vegetation: This concept covers both xeric and more mesic types of oak domes and hammocks. In the more xeric examples (Xeric Hammock of FNAI 2010a), the canopy is more-or-less closed and dominated by *Quercus geminata*, although *Quercus chapmanii, Quercus hemisphaerica, Quercus incana, Quercus laevis*, and *Quercus margarettiae* may also be common. An emergent canopy of pine, either *Pinus clausa, Pinus elliottii*, or *Pinus palustris* may be present (FNAI 2010a). *Quercus myrtifolia* may form a clonal shrub layer. *Aristida beyrichiana* and *Stylisma humistrata* may also be present. Hammocks that are intermediate in moisture status may have

some live oak (*Quercus virginiana*) in the canopy. According to Drew et al. (1998), the dominant taxa of mesic examples are *Quercus hemisphaerica*, *Quercus nigra*, and *Quercus virginiana*, along with *Diospyros virginiana*. *Campsis radicans* and *Smilax* spp. dominate the sparse ground cover. Examples of this system are low in plant species diversity compared to other habitats in the region. Cabbage palms are a diagnostic component of examples of this system in central Florida (A. Johnson pers. comm.).

Dynamics: Although embedded in a matrix of vegetation with extremely frequent fire regimes, patches of this system are subject to only infrequent or rare fire events. Under more frequent fire regimes, these sites would likely be occupied by *Pinus palustris*. Myers (1990) postulated that winter -burning regimes have allowed for the expansion of this type. *Quercus geminata* and *Quercus myrtifolia* are both clonal species which establish large rhizome systems capable of quickly resprouting following injury. Xeric hammocks, whether natural or anthropogenic, result from years of fire exclusion, maintained and further enhanced by incombustible oak litter and a sparsity of herbs. The thick bark of *Quercus geminata* makes these trees somewhat resistant to fire. Once they form a canopy that shades the understory, the trees generate a layer of leaf litter that covers open patches of sand and leads to more shaded, mesic ground conditions. The resulting shaded habitat can allow more fire-intolerant species such as *Magnolia grandiflora* to establish (Daubenmire 1990). Once the canopy is greater than 2 m high, even hot summer burns may not be sufficient to kill the dome, which can become established after only 7 to 16 years of fire exclusion (Guerin 1993). At that stage, oaks would only be killed through a catastrophic burn during dry conditions. Otherwise, the spread of oaks could be halted through mechanical removal or the use of herbicides if the management intent is the re-establishment of the fire-maintained community that was replaced by the xeric hammock. Xeric hammocks also form from long unburned oak scrub (Laessle 1958). There is a dynamic tension between the *Quercus*-dominated patches and the *Pinus*-dominated matrix. Oak domes are a natural part of the landscape, but can also result from human-caused fire exclusion. Near the coast, these communities are affected by salt spray (sea salt aerosol). At and near the coast, salt spray maintains the *Quercus geminata* at shrub height as much as does fire; one may observe a gradient of increasingly taller *Quercus geminata* as you move inland and the effect of salt spray becomes diminished (A. Johnson pers. comm.).

Component Associations:

- *Quercus geminata / Sabal etonia* Forest (CEGL008599, G2G3)
- *Quercus geminata / Vaccinium arboreum* Forest (CEGL003564, G3)
- *Quercus hemisphaerica - Carya glabra - (Quercus virginiana)* Forest (CEGL004506, G2G3)
- *Quercus hemisphaerica - Quercus geminata / Persea borbonia - Osmanthus americanus* Forest (CEGL004787, G2G3)
- *Quercus nigra - Quercus geminata / Lyonia ferruginea - Serenoa repens* Forest (CEGL003665, G2?)
- *Quercus virginiana - Quercus (hemisphaerica, nigra) / Serenoa repens* Forest (CEGL004408, G3?)
- *Quercus virginiana / Vaccinium arboreum - Ilex vomitoria* Forest (CEGL007028, G2G3)

DISTRIBUTION

Range: This system occurs in Florida, adjacent Georgia and in very limited areas of Alabama (A. Schotz pers. comm.).
Divisions: 203:C
Nations: US
Subnations: AL, FL, GA, MS
Map Zones: 55:C, 56:C, 99:C

SOUTHERN INTERIOR LOW PLATEAU DRY-MESIC OAK FOREST (CES202.898)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2305; ESLF 4111; ESP 1305

CONCEPT

Summary: This system of upland hardwood-dominated forests occurs in the Interior Low Plateau region of the southeastern United States along ridgetops and slopes of various aspects. The system includes essentially all upland hardwood stands of the region except for mesic hardwood forests (which are accommodated by South-Central Interior Mesophytic Forest (CES202.887)). The floristic expression of different stands included in this system varies considerably with aspect and soil type. Included here are a variety of associations ranging along a moisture gradient from submesic to drier ones. The submesic to dry-mesic expressions tend to be found on midslopes with northerly to easterly aspects, and the drier ones on southerly to westerly aspects and on broad ridges. Parent material can range from calcareous to acidic with very shallow, well- to excessively well-drained soils in the drier expressions and moderately well-drained soils in the submesic to dry-mesic ones. The canopy closure of this system ranges from closed to somewhat open in the drier examples. Historically, these examples may have been more open under conditions of more frequent fire.

A number of different *Quercus* species may dominate stands of this system, with *Carya* species also prominent. In some drier examples on more acidic substrates, *Quercus prinus* is typical over most of the range, reflecting relations with other Appalachian systems to the east. In addition, *Quercus stellata, Quercus marilandica,* and *Quercus coccinea* will also share dominance or be prominent in many of the drier examples. *Quercus muehlenbergii* and/or *Quercus shumardii* may appear in drier examples with high base status. *Quercus alba* may also be present but not typically dominant. In the submesic to dry-mesic examples, *Quercus alba* will typically exhibit dominance, possibly with *Quercus velutina* or *Quercus falcata*. The understories are typically shrub- and small tree-dominated, with the typical species varying with aspect, soil, and moisture relations.

Classification Comments: The range of this system is consistent with the non-coastal plain portion of the "Western Mesophytic" Forest region of Braun (1950), Keever (1971), and Greller (1988). To the glaciated north, it is replaced by North-Central Interior Dry-Mesic Oak Forest and Woodland (CES202.046) or North-Central Interior Dry Oak Forest and Woodland (CES202.047).

Similar Ecological Systems:
- Allegheny-Cumberland Dry Oak Forest and Woodland (CES202.359)--is found to the east and southeast in the Cumberlands.
- East Gulf Coastal Plain Northern Dry Upland Hardwood Forest (CES203.483)--is found to the southwest in the Coastal Plain.
- North-Central Interior Dry-Mesic Oak Forest and Woodland (CES202.046)--is found to the (glaciated) north.

DESCRIPTION

Environment: This system encompasses a variety of associations ranging along a moisture gradient from submesic to drier ones. The submesic to dry-mesic expressions tend to be found on midslopes with northerly to easterly aspects, the drier ones on southerly to westerly aspects and on broad ridges. Parent material can range from calcareous to acidic with very shallow, well- to excessively well-drained soils in the drier expressions and moderately well-drained soils in the submesic to dry-mesic ones.

Vegetation: A number of different *Quercus* species may dominate stands of this system, with *Carya* species also prominent. In the drier examples, *Quercus prinus* is typical over most of the range, reflecting relations with other Appalachian systems to the east. In addition, *Quercus stellata, Quercus marilandica,* and *Quercus coccinea* will also share dominance or be prominent in many of the drier examples. *Quercus muehlenbergii* and/or *Quercus shumardii* may appear in drier examples with high base status. *Quercus alba* may also be present but not typically dominant. In the submesic to dry-mesic examples, *Quercus alba* will typically exhibit dominance, possibly with *Quercus velutina* or *Quercus falcata*. The understories are typically shrub- and small tree-dominated, with

the typical species varying with aspect, soil, and moisture relations. Some typical species include *Cornus florida, Cercis canadensis, Oxydendrum arboreum, Vaccinium pallidum, Vaccinium stamineum, Vaccinium arboreum,* other highbush *Vaccinium* species, *Kalmia latifolia, Viburnum acerifolium, Styrax americanus,* and others. Some more open and drier stands may exhibit an understory of grassland species such as *Schizachyrium scoparium, Danthonia spicata,* and others. Forbs of the Fabaceae (e.g., *Desmodium*) and Asteraceae (e.g., *Helianthus*) will be prominent in many examples.

Component Associations:
- *Pinus echinata - Quercus prinus* Interior Low Plateau Forest (CEGL004054, G2G3)
- *Quercus alba - Carya alba - (Quercus velutina) / Desmodium nudiflorum - (Carex picta)* Forest (CEGL007795, G4)
- *Quercus alba - Quercus (falcata, stellata) / Chasmanthium laxum* Forest (CEGL007746, G3G4Q)

SOUTHERN PIEDMONT DRY OAK-(PINE) FOREST (CES202.339)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Needle-Leaved Tree; Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2368; ESLF 4311; ESP 1368

CONCEPT

Summary: This system encompasses the prevailing upland forests of the southern Piedmont. High-quality and historic examples are typically dominated by combinations of upland oaks, sometimes with pines as a significant component, especially in the southern portions of the region. These forests occur in a variety of habitats and, under natural conditions, were the matrix vegetation type covering most of the landscape. Much of this system is currently composed of successional forests that have arisen after repeated cutting, clearing, and cultivation of original oak-hickory forests. Stands of these forests are dominated by combinations of upland oaks, particularly *Quercus alba*, *Quercus rubra*, *Quercus velutina*, *Quercus stellata*, *Quercus coccinea*, and *Quercus falcata*, along with *Carya glabra*, *Carya alba*, and other *Carya* spp. Other common tree species include *Pinus taeda*, *Pinus echinata*, *Pinus virginiana*, *Acer rubrum*, *Liquidambar styraciflua*, and *Liriodendron tulipifera*.
Classification Comments: Although these forests have often been called "oak-hickory" (Braun 1950) or "oak-pine-hickory" (Kuchler 1964, Greller 1989, Skeen et al. 1993), Monk et al. (1990) concluded there was insufficient abundance of hickory to justify including this genus in the name of such forests. There are fairly dramatic differences in the amount of pine present across the modern day Piedmont landscape, with it being especially prevalent in South Carolina, Georgia, and Alabama (USGS 1992). To some extent, the prevalence of pine in these southern portions of the region may represent natural conditions (Nelson 1957). It is possible that the more heavily mixed or pine-dominated forests of the southern Piedmont should be recognized as a different system, but distinguishing natural examples is difficult given a long history of land-use impacts and resulting vegetational changes in the region (Brender 1974). In addition, Skeen et al. (1993) assert that "the oak-hickory-pine designation may be reflective of past land use and disturbance history and that the steady-state typal forest of the southeastern Piedmont is in reality oak-hickory-yellow poplar."

There are fairly clear variations within this system between dry and dry-mesic forests and also between those on acidic or basic soils. These might warrant separate systems, but the similar canopy composition and similar dynamics tie them together, and those distinctions may best be made at the association level. Large areas once dominated by oak-hickory forests now have successional pine forest. This may be regarded as a distinct phase of this system for mapping purposes.

Similar Ecological Systems:
- Central Appalachian Dry Oak-Pine Forest (CES202.591)--occurs to the north and is more Appalachian in character.
- Southeastern Interior Longleaf Pine Woodland (CES202.319)
- Southern Appalachian Low-Elevation Pine Forest (CES202.332)
- Southern Appalachian Montane Pine Forest and Woodland (CES202.331)
- Southern Piedmont Mesic Forest (CES202.342)

DESCRIPTION

Environment: This system occurs on upland ridges and upper to midslopes, occupying most of the uplands where soils are not rocky or otherwise extreme. Moisture conditions, determined by topography, are dry to dry-mesic. This system may occur on any kind of rock type, with rock chemistry being an important determinant of variation. Soils include almost the full range of upland soils, with only the shallowest rocky soils and those with extreme clay hardpans excluded.

The Piedmont has mostly gently rolling topography ranging from 90 to 365 m (300-1200 feet) elevation. Several erosion-resistant metamorphic and igneous rock types have left monadnocks that stand 60 to 305 m (200-1000 feet) above the remaining landscape. Average annual precipitation is 110-122 cm (44-48 inches). The original vegetation as described by early explorers and the first settlers was a mosaic of forest and open woodland, with interspersed savannas or prairies (Lederer 1672, Logan 1859). The prairie component was located on the flat to convex and gently rolling uplands of the larger fire compartments. The largest of these in the southern part of the range was up to five miles wide without a tree or only a few blackjack oaks (Logan 1859).

This system encompasses the prevailing upland forests of the southern Piedmont. High-quality and historic examples are typically dominated by combinations of upland oaks, sometimes with pines as a significant component, especially in the southern portions of the region. These forests occur in a variety of habitats and, under natural conditions, were the matrix vegetation type covering most of the landscape.

There are fairly dramatic differences in the amount of pine present across the modern day Piedmont landscape, with it being especially prevalent in South Carolina, Georgia and Alabama (USGS 1992). To some extent, the prevalence of pine in these southern portions of the region may represent natural conditions (Nelson 1957). It is possible that the more heavily mixed or pine-dominated forests of the southern Piedmont should be recognized as a different system, but distinguishing natural examples is difficult given a long history of land-use impacts and resulting vegetational changes in the region (Brender 1974). In addition, Skeen et al. (1993) assert that "the oak-hickory-pine designation may be reflective of past land use and disturbance history and that the steady-state typal forest of the southeastern Piedmont is in reality oak-hickory-yellow poplar." Although these forests have often been called "oak-hickory" (Braun 1950) or "oak-pine-hickory" (Kuchler 1964, Greller 1989, Skeen et al. 1993), Monk et al. (1990) concluded there was insufficient abundance of hickory to justify including this genus in the name of such forests.

Vegetation: Vegetation consists of forests dominated by combinations of upland oaks, particularly *Quercus alba, Quercus rubra, Quercus velutina, Quercus stellata, Quercus coccinea*, and *Quercus falcata*, along with *Carya glabra, Carya alba*, and other *Carya* spp. Other common tree species include *Pinus taeda, Pinus echinata, Pinus virginiana, Acer rubrum, Liquidambar styraciflua*, and *Liriodendron tulipifera*. In successional forests recovering from clearcutting or cultivation, the pines dominate for a number of decades, with oaks and hickories gradually invading the understory. A well-developed understory and shrub layer is generally present, with species varying with soil chemistry. The herb layer is sparse to at most moderate in density. Before natural fires were suppressed, the forests presumably had less understory and shrub component and probably a grassy herb layer. There is some uncertainly about the composition and physiognomy of this system under presettlement conditions, in particular with some debate about the relative importance of *Quercus* spp., *Carya* spp., and *Liriodendron tulipifera*, as well as the role of *Pinus echinata* and its increasing abundance to the south.

Dynamics: Fire was probably an important natural factor in this system, affecting vegetation structure and composition of the lower strata. It may have been important in favoring oaks and pines over other trees in the canopy. Fires were likely almost always low-intensity surface fires. Native American burning was also important in the Piedmont (Cowell 1998). These forests appear to occur naturally as predominantly old-growth, with canopy dynamics dominated by gap-phase regeneration. Small to medium-sized canopy gaps created by wind are the primary natural disturbance at present, and probably were in the past as well. Fire likely created some small to medium-sized gaps in the past also, and likely caused all canopy gaps to persist longer. The dominant tree species are capable of living for several centuries.

Fire and grazing are possibly the most important natural processes affecting the floristic composition and vegetation structure of this system (Landfire 2007a). The presence of frequent (2-5 years) surface fire is important in order to support the reproduction of *Pinus echinata* and the development of diverse herbaceous understories. *Pinus echinata* is a shade-intolerant species and does not survive or grow well when fire is absent or where fire-return times are very long. Where fire occurs at an appropriate frequency, the stand may develop a relatively pure canopy of *Pinus echinata*, typified by a very open woodland structure with scattered overstory trees and an herbaceous-dominated understory (Landfire 2007a).

The frequency of fire is variable across the landscape to create a mosaic of vegetation. However, most agree that the fire-return interval was relatively short. Fire may have been as frequent as every two to three years. Brewer (2001) compared the current tree species composition to bearing tree records and found that *Pinus echinata* and more fire-tolerant species such as *Quercus velutina* and *Quercus stellata* were prevalent on the landscape, indicating a greater fire frequency. Without a short fire-return interval, community succession tends to favor upland mixed pine-xeric hardwood forests or hardwood-dominated forests. Landers (1989) inferred a fire-return interval of 10 times per century for pure stands of *Pinus echinata*.

Lightning fires occurred primarily during the spring dry season (April and May) with a second peak of Native American burning during the fall (October and November). Occasionally, during extensive droughts, mixed-severity or stand-replacement fires did occur, especially on drier pine-dominated sites. Local thunderstorms and outbreaks of southern pine beetle (*Dendroctonus frontalis*) created gaps on a small but continual basis. More extensive regional disturbances included tropical storms during the growing season, ice storms during winter, and tornadoes throughout the year (Landfire 2007a).

Component Associations:

- *Carya glabra - Fraxinus americana / Acer leucoderme / Piptochaetium avenaceum* Woodland (CEGL008489, G2G3Q)
- *Pinus echinata - (Quercus stellata, Quercus marilandica) / Schizachyrium scoparium - Salvia urticifolia* Woodland (CEGL008492, G2?)
- *Pinus echinata - Quercus marilandica / Kalmia latifolia - Symplocos tinctoria* Woodland (CEGL004446, G2?)
- *Quercus alba - Carya glabra - Fraxinus americana / Acer leucoderme / Vitis rotundifolia* Forest (CEGL004541, G2?)
- *Quercus alba - Carya glabra / Schizachyrium scoparium - Helianthus divaricatus - Salvia urticifolia - Parthenium auriculatum* Woodland (CEGL003721, G1?)
- *Quercus alba - Quercus (coccinea, velutina, prinus) / Gaylussacia baccata* Forest (CEGL008521, G5)
- *Quercus alba - Quercus rubra - Carya (ovata, carolinae-septentrionalis) / Cercis canadensis* Forest (CEGL007232, G3G4)
- *Quercus alba - Quercus rubra - Carya alba / Cornus florida / Vaccinium stamineum / Desmodium nudiflorum* Piedmont Forest (CEGL008475, G4G5)
- *Quercus alba - Quercus stellata - Carya carolinae-septentrionalis / Acer leucoderme - Cercis canadensis* Forest (CEGL007773,

G2G3)

- *Quercus prinus - Quercus marilandica* Piedmont Woodland (CEGL003708, G2G3)
- *Quercus prinus - Quercus stellata - Carya glabra / Vaccinium arboreum - Viburnum rufidulum* Forest (CEGL004416, G2G3)

SPATIAL CHARACTERISTICS

Spatial Summary: Naturally a matrix system, dominating most of the upland landscape in the Piedmont. Remnants are mostly large patch, but some large expanses remain.

Size: Once occurred as the matrix system, with contiguous patches covering many thousands of acres. Mature patches are now mostly reduced to large-patch remnants, some of hundreds of acres. A few areas have substantially forested landscapes in which oak-hickory forests in some condition cover thousands of acres in nearly contiguous patches.

Adjacent Ecological Systems:
- Piedmont Hardpan Woodland and Forest (CES202.268)
- Piedmont Seepage Wetland (CES202.298)
- Piedmont Upland Depression Swamp (CES202.336)
- Southeastern Interior Longleaf Pine Woodland (CES202.319)
- Southern Piedmont Cliff (CES202.386)
- Southern Piedmont Glade and Barrens (CES202.328)
- Southern Piedmont Granite Flatrock and Outcrop (CES202.329)
- Southern Piedmont Mesic Forest (CES202.342)

Adjacent Ecological System Comments: Most commonly associated with Southern Piedmont Mesic Forest (CES202.342). Various rock outcrops, Piedmont Hardpan Woodland and Forest (CES202.268), Piedmont Upland Depression Swamp (CES202.336), and other small-patch systems may be embedded.

DISTRIBUTION

Range: This system ranges throughout the Piedmont from Alabama to Virginia. In Virginia, it is primarily central and southern, but extends into a narrow portion of northern Virginia in the Piedmont ecoregion.

Divisions: 202:C
Nations: US
Subnations: AL, GA, NC, SC, VA
Map Zones: 54:C, 59:C, 60:C, 61:C
USFS Ecomap Regions: 231A:CC, 231I:CC

SOUTHERN PIEDMONT MESIC FOREST (CES202.342)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Very Long Disturbance Interval; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2316; ESLF 4122; ESP 1316

CONCEPT

Summary: This system encompasses mixed deciduous hardwood or occasionally hardwood-pine forests of mesic sites in the Piedmont of the southeastern United States. Most examples occur on lower or north-facing slopes where topography creates mesic moisture conditions. A mix of a small number of mesophytic trees is usually dominant, with *Fagus grandifolia* most prominent. Both acidic and basic substrates are currently included in this concept, as are certain heath bluffs, where dense shrub layers of mesophytic ericaceous shrubs may occur beneath an open tree canopy. Fire is naturally infrequent in this system, due to the slopes and moist conditions. If fire does penetrate, it is likely to be low in intensity and may not have significant ecological effects. Vegetation consists of forests dominated by combinations of trees that include a significant component of mesophytic species. *Fagus grandifolia* is almost always abundant and is often strongly dominant. *Quercus rubra, Liriodendron tulipifera,* and *Acer rubrum* may be abundant. In basic soil examples, *Fraxinus americana* and *Acer barbatum* are also abundant. A well-developed understory is usually present. Herbs range from fairly dense in basic examples to sparse in acidic examples, and may be nearly absent in a few. The composition of all lower strata varies substantially with soil acidity.
Classification Comments: This system is distinguished from Southern Piedmont Dry Oak-(Pine) Forest (CES202.339) by the significant component of mesophytic tree species, particularly *Fagus grandifolia,* as well as by occurrence on mesic topographic sites. Some oaks may also be present. It is distinguished from Southern Piedmont Small Floodplain and Riparian Forest (CES202.323) and Southern Piedmont Large Floodplain Forest (CES202.324) by the absence of characteristic alluvial or bottomland species, along with upland position. This boundary can be somewhat difficult to place, as some alluvial species will occur upslope in basic soils, and some mesic forests will extend onto higher terraces in bottomlands. This system is closely related to Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242) and in the northern part of the range may be very similar except for the geologic substrate. Farther south, there is a greater floristic difference between the two. This system is related to the cove forest systems of the southern Appalachians but lacks a number of species characteristic of those regions. These species are present in increasing numbers as one goes west in the Piedmont. The westernmost Piedmont has some examples of well-developed Southern and Central Appalachian Cove Forest (CES202.373) in the more mountainous portions. Distinct subsets of this system, which could be recognized as different systems, are the basic/circumneutral and acidic examples, and also the shrubby heath bluffs.
Similar Ecological Systems:
- Southern and Central Appalachian Cove Forest (CES202.373)
- Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242)
- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)
- Southern Piedmont Large Floodplain Forest (CES202.324)
- Southern Piedmont Small Floodplain and Riparian Forest (CES202.323)

Related Concepts:
- Basic Mesic Forest (Fleming et al. 2005) Undetermined
- Beech - Sugar Maple: 60 (Eyre 1980) Finer
- Northern Red Oak: 55 (Eyre 1980) Finer
- White Oak: 53 (Eyre 1980) Finer
- Yellow-Poplar: 57 (Eyre 1980) Finer

DESCRIPTION

Environment: Examples occur on lower slopes or on north-facing slopes, where topography creates mesic moisture conditions. This system may occur on any kind of rock type, with rock chemistry being an important determinant of variation. Most soils are acidic, but those formed on mafic rocks often are circumneutral to basic. The moist conditions and slope limit natural fire intensity and frequency.
Vegetation: Vegetation consists of forests dominated by combinations of trees that include a significant component of mesophytic species. *Fagus grandifolia* is almost always abundant and is often strongly dominant. *Quercus rubra, Liriodendron tulipifera,* and *Acer rubrum* may be abundant. In basic soil examples, *Fraxinus americana* and *Acer barbatum* are also abundant. A well-developed understory is usually present. Shrubs are generally sparse to moderate in density, except in heath bluffs. Herbs range from fairly dense in basic examples to sparse in acidic examples, and may be nearly absent in a few. The composition of all lower strata varies substantially with soil acidity. Basic examples have a fairly diverse suite, especially of herbs, which may include a number of species shared with Southern and Central Appalachian Cove Forest (CES202.373). The more common acidic examples have fewer species,

though generally they have a higher species richness than the drier systems.
Dynamics: Fire is naturally infrequent in this system, due to the slopes and moist conditions. If fire does penetrate, it is likely to be low in intensity and may not have significant ecological effects. These forests generally exist naturally as old-growth forests, with canopy dynamics dominated by gap-phase regeneration. Small to occasional medium-sized canopy gaps created by wind are likely the primary form of natural disturbance, though occasional fires might create gaps. Most of the prevailing species are shade-tolerant. Most are not very fire-tolerant. The mesophytic forest type is fire regime class III, surface fires with return intervals of 20 to 70 years (Landfire 2007a). Mixed-severity fires may occur approximately every 100 years depending on climatic conditions. This effect may also be achieved by recurrent, severe insect defoliations or droughts. Ice, straight-line winds or microbursts may cause blow-downs on a scale of 1 to 10 acres. Stand-replacement fires happen very infrequently. Low-intensity surface fires, whether natural or set by Native Americans, would have maintained the more fire-resistant American chestnut and oak species.

Component Associations:
- *Fagus grandifolia - Liriodendron tulipifera - Carya cordiformis / Lindera benzoin / Podophyllum peltatum* Forest (CEGL006055, G4?)
- *Fagus grandifolia - Liriodendron tulipifera / Euonymus americanus / Athyrium filix-femina ssp. asplenioides* Forest (CEGL007201, G4)
- *Fagus grandifolia - Quercus (alba, rubra) - Liriodendron tulipifera / (Ilex opaca var. opaca) / Polystichum acrostichoides* Forest (CEGL006075, G5)
- *Fagus grandifolia - Quercus (alba, velutina, prinus) / Kalmia latifolia* Forest (CEGL006919, G4)
- *Fagus grandifolia - Quercus alba / Kalmia latifolia - (Symplocos tinctoria, Rhododendron catawbiense) / Galax urceolata* Forest (CEGL004539, G2G3)
- *Fagus grandifolia - Quercus rubra / Acer barbatum - Aesculus sylvatica / Actaea racemosa - Adiantum pedatum* Forest (CEGL008466, G3G4)
- *Fagus grandifolia - Quercus rubra / Cornus florida / Polystichum acrostichoides - Hexastylis virginica* Forest (CEGL008465, G3G4)
- *Quercus alba - Carya alba / Euonymus americanus / Hexastylis arifolia* Forest (CEGL006227, G4G5)
- *Quercus alba - Quercus rubra - Quercus prinus - Tilia americana var. caroliniana / Ostrya virginiana* Forest (CEGL004542, G2G3)
- *Quercus alba - Quercus rubra - Quercus prinus / Collinsonia canadensis - Podophyllum peltatum - Amphicarpaea bracteata* Forest (CEGL007692, G3)
- *Quercus rubra - Quercus alba - Carya glabra / Geranium maculatum* Forest (CEGL007237, G4Q)
- *Quercus rubra / Magnolia tripetala - Cercis canadensis / Actaea racemosa - Tiarella cordifolia* Forest (CEGL003949, G3?)
- *Tilia americana var. heterophylla - Fraxinus americana - (Ulmus rubra) / Sanguinaria canadensis - (Aquilegia canadensis, Asplenium rhizophyllum)* Forest (CEGL007711, G2G3)

Spatial Characteristics

Spatial Summary: Large- to small-patch system occurring as a regular part of the landscape mosaic in most of the Piedmont.
Size: Generally occurs as large to small patches, often in convoluted bodies following slopes in the dissected lands along streams and rivers. Contiguous convoluted patches or closely associated sets of patches may once have covered thousands of acres and perhaps could have been connected along miles of river bluffs. However, the effect of past fire on the extent of this system is uncertain, and it may have been confined to a more limited range of topography and to smaller, discontinuous patches than it now appears. Most remnants at present are several tens to hundreds of acres.
Adjacent Ecological Systems:
- Southern Piedmont Cliff (CES202.386)
- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)
- Southern Piedmont Glade and Barrens (CES202.328)
- Southern Piedmont Large Floodplain Forest (CES202.324)
- Southern Piedmont Small Floodplain and Riparian Forest (CES202.323)

Adjacent Ecological System Comments: Most commonly associated with Southern Piedmont Dry Oak-(Pine) Forest (CES202.339), Southern Piedmont Small Floodplain and Riparian Forest (CES202.323), and Southern Piedmont Large Floodplain Forest (CES202.324). May contain embedded Southern Piedmont Cliff (CES202.386) or Southern Piedmont Glade and Barrens (CES202.328).

Distribution

Range: This ecological system ranges throughout the southern Piedmont, from Virginia to Alabama.
Divisions: 202:C
Nations: US

SOUTHERN RIDGE AND VALLEY / CUMBERLAND DRY CALCAREOUS FOREST (CES202.457)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Circumneutral Soil; Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2376; ESLF 4319; ESP 1376

CONCEPT

Summary: This system includes dry to dry-mesic calcareous forests of the Southern Ridge and Valley region of Alabama and Georgia, extending north into Tennessee, Kentucky, Virginia and adjacent West Virginia. It includes calcareous forests on lower escarpments of the Cumberland Plateau and other related areas. Examples occur on a variety of different landscape positions and occur on generally deeper soils than glade systems of the same regions. This system is distinguished from those farther north in the Ridge and Valley by its relatively southern location in the region, in an area which is transitional to the "Oak-Pine-Hickory" region. High-quality and historic examples are typically dominated by combinations of *Quercus* species and *Carya* species, sometimes with *Pinus* species and/or *Juniperus virginiana* as a significant component in certain landscape positions and with particular successional histories. These forests occur in a variety of habitats and are the matrix vegetation type that covers portions of the landscape under natural conditions. Examples can occur on a variety of topographic and landscape positions including valley floors, sideslopes, and lower to midslopes. Fire frequency and intensity are factors determining the relative mixture of deciduous hardwood versus evergreen trees in this system. Much of this system is currently composed of successional forests that have arisen after repeated cutting, clearing, and cultivation of the original forests. The range of this system is primarily composed of circumneutral substrates, which exert an expected influence on the composition of the vegetation.

Classification Comments: This system is defined as distinct because of its location in the portion of the Ridge and Valley region which is transitional to the "Oak-Pine-Hickory" region (Greller 1988). Most of the zone of occurrence is attributed to the "Southern Limestone/Dolomite Valleys and Low Rolling Hills" (67f) and the "Southern Shale Valleys" (67g) of Griffith et al. (2001), as well as calcareous parts of 68b and 68c (where it is more limited in extent). In addition, the system could be found in drier, more exposed portions of 66f, "Limestone Valleys and Coves" (Griffith et al. 2001), but most of this terrain is probably more mesic and concave. This ecoregion and "Southern Sedimentary Ridges" (66e) are part of the "Blue Ridge" but are clearly transitional to the Ridge and Valley region. Ecoregion 66e is more likely too acidic to support this system. It is also likely in the "Carter Hills" (EPA Ecoregion 70h of Woods et al. (2002)) of Kentucky and in limited portions of related parts of Ecoregion 70 (Western Allegheny Plateau) in Kentucky.

Similar Ecological Systems:
- Allegheny-Cumberland Dry Oak Forest and Woodland (CES202.359)--is found in some similar landscapes but on more acidic and nutrient-poor substrates, which usually correspond to different landform positions.
- Central Appalachian Alkaline Glade and Woodland (CES202.602)--of central Appalachians, mainly Virginia and north; need to clarify ranges; generally more open stands, not closed canopy.
- Central Interior Highlands Calcareous Glade and Barrens (CES202.691)--is related and overlapping in range, with more open physiognomy.
- Southern Ridge and Valley Calcareous Glade and Woodland (CES202.024)--is more open, with an overlapping range.

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Post Oak - Blackjack Oak: 40 (Eyre 1980) Finer
- Sugar Maple: 27 (Eyre 1980) Finer
- White Oak - Black Oak - Northern Red Oak: 52 (Eyre 1980) Finer
- White Oak: 53 (Eyre 1980) Finer
- Xeric Calcareous Forest (Evans 1991) Intersecting

DESCRIPTION

Environment: Examples of this forest and woodland system occur usually on dry sites, on a variety of topographic and landscape positions, including sideslopes (particularly south- and west-facing ones), ridges, and knobs, as well as valley floors, depending on where the base-rich rock is present or crops out, and where the soils are influenced by calcareous/circumneutral geology. Elevation is generally between 200 and 500 m. In some landscapes, the ridges and ridgetops will more likely be composed of sandstones and other more weather-resistant and acidic materials.

Vegetation: Natural vegetation consists of forests (or woodlands) dominated most typically by *Quercus alba, Quercus muehlenbergii, Quercus stellata,* and *Quercus shumardii,* with varying amounts of *Carya* spp., *Acer saccharum, Acer barbatum, Acer leucoderme, Acer rubrum,* and other species. This system concept also includes successional communities that have been impacted by logging or agriculture, including upland forest types dominated by *Liriodendron tulipifera, Pinus* spp., *Juniperus virginiana,* and

Robinia pseudoacacia.
Dynamics: Fire frequency and intensity are factors determining the relative mixture of deciduous hardwood versus evergreen trees in this system. Presettlement fire-return intervals are believed to have ranged from 3 to 14 years from both lightning and Native American ignitions. These frequent surface fires maintained the grassy understory and kept hardwoods and shrubs from dominating the understory and forming a midstory layer. These fires occurred in the dormant season with occasional growing-season mosaic fires (most likely occurring infrequently once or twice every 20 to 25 years) (Landfire 2007a). Occasionally, during extensive droughts, mixed-severity or stand-replacement fires could occur, especially in drier stands or those containing *Juniperus virginiana*. In addition, local thunderstorm-caused blowdowns and windthrow created gaps on a small but continual basis. More extensive regional disturbances included winter ice storms. Dense stands of middle to older aged pines (where present) were susceptible to periodic mortality from bark beetle epidemics, and younger *Juniperus virginiana* trees were killed by periodic droughts.

Component Associations:
- *Acer saccharum - Quercus muehlenbergii / Cercis canadensis* Forest (CEGL006017, G4?)
- *Quercus alba - Quercus rubra - Carya ovata / Cercis canadensis - Juniperus virginiana var. virginiana* Forest (CEGL007240, G4)
- *Quercus alba - Quercus rubra - Quercus muehlenbergii / Cercis canadensis* Forest (CEGL002070, G4G5)
- *Quercus alba - Quercus stellata / Ostrya virginiana - Acer barbatum / Chasmanthium sessiliflorum* Forest (CEGL008443, G3G4)
- *Quercus muehlenbergii - Quercus shumardii - Carya (carolinae-septentrionalis, ovata)* Forest (CEGL007808, G3)
- *Quercus shumardii - Quercus muehlenbergii - Acer (barbatum, leucoderme, saccharum) / Ostrya virginiana* Forest (CEGL008442, G2G3)
- *Quercus stellata - Juniperus virginiana var. virginiana / Ulmus alata - (Cotinus obovatus)* Woodland (CEGL004583, G3)

SPATIAL CHARACTERISTICS

Spatial Summary: This system can be large patch in some areas and matrix in others, depending on the arrangement of geological strata and relative degree of erosion of the landscape. If erosion has exposed extensive areas of calcareous materials, the extent is likely to be matrix rather than large patch.

DISTRIBUTION

Range: This system is endemic to the Southern Ridge and Valley and the Cumberland Plateau escarpment in Alabama, Georgia, Tennessee, Kentucky, Virginia and adjacent West Virginia.
Divisions: 202:C

SOUTHERN ROCKY MOUNTAIN DRY-MESIC MONTANE MIXED CONIFER FOREST AND WOODLAND (CES306.823)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: RM Montane Mesic Mixed Conifer; Moderate (100-500 yrs) Persistence; Montane [Montane]; Montane [Lower Montane]; Forest and Woodland (Treed); Aridic; Intermediate Disturbance Interval; F-Patch/Medium Intensity; F-Landscape/Medium Intensity; Needle-Leaved Tree
Non-Diagnostic Classifiers: Ridge/Summit/Upper Slope; Sideslope; Temperate [Temperate Continental]; Mesotrophic Soil; Shallow Soil; Mineral: W/ A-Horizon <10 cm
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2051; ESLF 4238; ESP 1051

CONCEPT

Summary: This is a highly variable ecological system of the montane zone of the Rocky Mountains. It occurs throughout the southern Rockies, north and west into Utah, Nevada, Wyoming and Idaho. These are mixed-conifer forests occurring on all aspects at elevations ranging from 1200 to 3300 m. Rainfall averages less than 75 cm per year (40-60 cm), with summer "monsoons" during the growing season contributing substantial moisture. The composition and structure of the overstory are dependent upon the temperature and moisture relationships of the site and the successional status of the occurrence. *Pseudotsuga menziesii* and *Abies concolor* are most frequent, but *Pinus ponderosa* may be present to codominant. *Pinus flexilis* is common in Nevada. *Pseudotsuga menziesii* forests occupy drier sites, and *Pinus ponderosa* is a common codominant. *Abies concolor*-dominated forests occupy cooler sites, such as upper slopes at higher elevations, canyon sideslopes, ridgetops, and north- and east-facing slopes which burn somewhat infrequently. *Picea pungens* is most often found in cool, moist locations, often occurring as smaller patches within a matrix of other associations. As many as seven conifers can be found growing in the same occurrence, and there are a number of cold-deciduous shrub and graminoid species common, including *Arctostaphylos uva-ursi, Mahonia repens, Paxistima myrsinites, Symphoricarpos oreophilus, Jamesia americana, Quercus gambelii*, and *Festuca arizonica*. This system was undoubtedly characterized by a mixed-severity fire regime in its "natural condition," characterized by a high degree of variability in lethality and return interval.
Classification Comments: The transition between this system and Middle Rocky Mountain Montane Douglas-fir Forest and Woodland (CES306.959) in Wyoming needs to be further clarified, both in terms of floristics and distribution details. For now, it is assumed that this system does not occur in the Bighorn Range or in the Yellowstone region, but its occurrence in isolated ranges of central and western Wyoming is possible.
Similar Ecological Systems:
- Madrean Upper Montane Conifer-Oak Forest and Woodland (CES305.798)
- Southern Rocky Mountain Mesic Montane Mixed Conifer Forest and Woodland (CES306.825)

Related Concepts:
- Blue Spruce: 216 (Eyre 1980) Finer
- Interior Douglas-fir: 210 (Eyre 1980) Intersecting
- White Fir: 211 (Eyre 1980) Intersecting

DESCRIPTION

Vegetation: This highly variable ecological system is comprised of mixed-conifer forests at montane elevations throughout the Intermountain West region. The four main alliances in this system are found on slightly different, but intermingled, biophysical environments: *Abies concolor* dominates at higher, colder locations; *Picea pungens* represents mesic conditions; and *Pseudotsuga menziesii* dominates intermediate zones. As many as seven conifers can be found growing in the same occurrence, with the successful reproduction of the diagnostic species determining the association type. Common conifers include *Pinus ponderosa, Pinus flexilis, Abies lasiocarpa var. lasiocarpa, Abies lasiocarpa var. arizonica, Juniperus scopulorum,* and *Picea engelmannii*. *Populus tremuloides* is often present as intermingled individuals in remnant aspen clones or in adjacent patches. The composition and structure of the overstory are dependent upon the temperature and moisture relationships of the site and the successional status of the occurrence (DeVelice et al. 1986, Muldavin et al. 1996).

A number of cold-deciduous shrub and graminoid species are found in many occurrences (e.g., *Arctostaphylos uva-ursi, Mahonia repens, Paxistima myrsinites, Symphoricarpos oreophilus, Jamesia americana, Quercus gambelii*, and *Festuca arizonica*). Other important species include *Acer glabrum, Acer grandidentatum, Amelanchier alnifolia, Arctostaphylos patula, Holodiscus dumosus, Jamesia americana, Juniperus communis, Physocarpus monogynus, Quercus arizonica, Quercus rugosa, Quercus X pauciloba, Quercus hypoleucoides, Robinia neomexicana, Rubus parviflorus,* and *Vaccinium myrtillus*. Where soil moisture is favorable, the herbaceous layer may be quite diverse, including graminoids *Bromus ciliatus (= Bromus canadensis), Calamagrostis rubescens, Carex geyeri, Carex rossii, Carex siccata (= Carex foenea), Festuca occidentalis, Koeleria macrantha, Muhlenbergia montana, Muhlenbergia virescens, Poa fendleriana, Pseudoroegneria spicata*, and forbs *Achillea millefolium, Arnica cordifolia, Erigeron eximius, Fragaria virginiana, Linnaea borealis, Luzula parviflora, Osmorhiza berteroi, Packera cardamine (= Senecio cardamine),*

Thalictrum occidentale, Thalictrum fendleri, Thermopsis rhombifolia, Viola adunca, and species of many other genera, including *Lathyrus, Penstemon, Lupinus, Vicia, Arenaria, Galium*, and others.

Dynamics: Forests in this ecological system represent the gamut of fire tolerance. Formerly, *Abies concolor* in the Utah High Plateaus were restricted to rather moist or less fire-prone areas by frequent ground fires. These areas experienced mixed fire severities, with patches of crowning in which all trees are killed, intermingled with patches of underburn in which larger *Abies concolor* survived (www.fs.fed.us/database/feis/). With fire suppression, *Abies concolor* has vigorously colonized many sites formerly occupied by open *Pinus ponderosa* woodlands. These invasions have dramatically changed the fuel load and potential behavior of fire in these forests. In particular, the potential for high-intensity crown fires on drier sites now codominated by *Pinus ponderosa* and *Abies concolor* has increased. Increased landscape connectivity, in terms of fuel loadings and crown closure, has also increased the potential size of crown fires.

Pseudotsuga menziesii forests are the only true 'fire-tolerant' occurrences in this ecological system. *Pseudotsuga menziesii* forests were probably subject to a moderate-severity fire regime in presettlement times, with fire-return intervals of 30-100 years. Many of the important tree species in these forests are fire-adapted (*Populus tremuloides, Pinus ponderosa, Pinus contorta*) (Pfister et al. 1977), and fire-induced reproduction of *Pinus ponderosa* can result in its continued codominance in *Pseudotsuga menziesii* forests (Steele et al. 1981). Seeds of the shrub *Ceanothus velutinus* can remain dormant in forest occurrences for 200 years (Steele et al. 1981) and germinate abundantly after fire, competitively suppressing conifer seedlings. Successional relationships in this system are complex. *Pseudotsuga menziesii* is less shade-tolerant than many northern or montane trees such as *Tsuga heterophylla, Abies concolor, Picea engelmannii*, and seedlings compete poorly in deep shade. At drier locales, seedlings may be favored by moderate shading, such as by a canopy of *Pinus ponderosa*, which helps to minimize drought stress. In some locations, much of these forests have been logged or burned during European settlement, and present-day occurrences are second-growth forests dating from fire, logging, or other occurrence-replacing disturbances (Mauk and Henderson 1984, Chappell et al. 1997).

Picea pungens is a slow-growing, long-lived tree which regenerates from seed (Burns and Honkala 1990a). Seedlings are shallow-rooted and require perennially moist soils for establishment and optimal growth. *Picea pungens* is intermediate in shade tolerance, being somewhat more tolerant than *Pinus ponderosa* or *Pseudotsuga menziesii*, and less tolerant than *Abies lasiocarpa* or *Picea engelmannii*. It forms late-seral occurrences in the subhumid regions of the Utah High Plateaus. It is common for these forests to be heavily disturbed by grazing or fire.

In general, fire suppression has lead to the encroachment of more shade-tolerant, less fire-tolerant species (e.g., climax) into occurrences and an attendant increase in landscape homogeneity and connectivity (from a fuels perspective). This has increased the lethality and potential size of fires.

DISTRIBUTION

Range: This system occurs throughout the southern Rockies, north and west into Utah, Nevada, eastern Wyoming (very southern in the Laramie Range and possibly on Sheep Mountain) and Idaho. Although not common, it does occur in southeastern Oregon but does not extend farther west into the Cascades.
Divisions: 304:C; 306:C

SOUTHERN ROCKY MOUNTAIN MESIC MONTANE MIXED CONIFER FOREST AND WOODLAND (CES306.825)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: RM Montane Dry-Mesic Mixed Conifer; Forest and Woodland (Treed); Ravine; Stream terrace (undifferentiated); Toeslope; Mesotrophic Soil; Ustic; Long Disturbance Interval; F-Patch/Low Intensity; F-Landscape/Low Intensity; Needle-Leaved Tree
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Montane [Montane]; Montane [Lower Montane]; Temperate [Temperate Continental]; Shallow Soil; Mineral: W/ A-Horizon <10 cm
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2052; ESLF 4239; ESP 1052

CONCEPT

Summary: These are mixed conifer forests of the Rocky Mountains west into the ranges of the Great Basin, occurring predominantly in cool ravines and on north-facing slopes. Elevations range from 1200 to 3300 m. Occurrences of this system are found on cooler and more mesic sites than Southern Rocky Mountain Dry-Mesic Montane Mixed Conifer Forest and Woodland (CES306.823). Such sites include lower and middle slopes of ravines, along stream terraces, moist, concave topographic positions and north- and east-facing slopes which burn somewhat infrequently. *Pseudotsuga menziesii* and *Abies concolor* are most common canopy dominants, but *Picea engelmannii, Picea pungens*, or *Pinus ponderosa* may be present. This system includes mixed conifer - *Populus tremuloides* stands. A number of cold-deciduous shrub species can occur, including *Acer glabrum, Acer grandidentatum, Alnus incana, Betula occidentalis, Cornus sericea, Jamesia americana, Physocarpus malvaceus, Robinia neomexicana, Vaccinium membranaceum,* and *Vaccinium myrtillus*. Herbaceous species include *Bromus ciliatus, Carex geyeri, Carex rossii, Carex siccata, Muhlenbergia virescens, Pseudoroegneria spicata, Erigeron eximius, Fragaria virginiana, Luzula parviflora, Osmorhiza berteroi, Packera cardamine, Thalictrum occidentale,* and *Thalictrum fendleri*. Naturally occurring fires are of variable return intervals and mostly light, erratic, and infrequent due to the cool, moist conditions.
Classification Comments: This system will need to be modeled to separate from similar dry-mesic system.
Similar Ecological Systems:

SOUTHERN ROCKY MOUNTAIN PINYON-JUNIPER WOODLAND (CES306.835)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Very Shallow Soil; Shallow Soil; Mineral: W/ A-Horizon <10 cm; Aridic; Long Disturbance Interval; Needle-Leaved Tree; Pinus edulis, Juniperus monosperma
Non-Diagnostic Classifiers: Escarpment; Foothill(s); Lowland [Foothill]; Midslope; Ridge; Temperate [Temperate Continental]; Unglaciated; F-Patch/Medium Intensity; F-Landscape/Medium Intensity; Butte
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2059; ESLF 4246; ESP 1059

CONCEPT

Summary: This southern Rocky Mountain ecological system occurs on dry mountains and foothills in southern Colorado east of the Continental Divide, in mountains and plateaus of north-central New Mexico, and extends out onto limestone breaks in the southeastern Great Plains. These woodlands occur on warm, dry sites on mountain slopes, mesas, plateaus, and ridges. Severe climatic events occurring during the growing season, such as frosts and drought, are thought to limit the distribution of pinyon-juniper woodlands to relatively narrow altitudinal belts on mountainsides. Soils supporting this system vary in texture ranging from stony, cobbly, gravelly sandy loams to clay loam or clay. *Pinus edulis* and/or *Juniperus monosperma* dominate the tree canopy. *Juniperus scopulorum* may codominate or replace *Juniperus monosperma* at higher elevations. Stands with *Juniperus osteosperma* are representative the Colorado Plateau and are not included in this system. In southern transitional areas between Madrean Pinyon-Juniper Woodland (CES305.797) and Southern Rocky Mountain Pinyon-Juniper Woodland (CES306.835) in central New Mexico, *Juniperus deppeana* becomes common. Understory layers are variable and may be dominated by shrubs, graminoids, or be absent. Associated species are more typical of southern Rocky Mountains than the Colorado Plateau and include *Artemisia bigelovii, Cercocarpus montanus, Quercus gambelii, Achnatherum scribneri, Bouteloua gracilis, Festuca arizonica,* or *Pleuraphis jamesii*.

DISTRIBUTION

Range: This system occurs on dry mountains and foothills in southern Colorado, in mountains and plateaus of northern New Mexico and Arizona, and extends out onto breaks in the Great Plains. It extends south to the Sacramento Mountains, especially the eastern side. The western side has Madrean elements (*Quercus grisea*) and may be classified as Madrean woodland.

SOUTHERN ROCKY MOUNTAIN PONDEROSA PINE WOODLAND (CES306.648)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Ridge/Summit/Upper Slope; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Sand Soil Texture; Aridic; Intermediate Disturbance Interval [Periodicity/Polycyclic Disturbance]; F-Patch/Medium Intensity; Needle-Leaved Tree; Pinus ponderosa with shrubby understory
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2054; ESLF 4241; ESP 1054

CONCEPT

Summary: This very widespread ecological system is most common throughout the cordillera of the Rocky Mountains, from the Greater Yellowstone region south. It is also found in the Colorado Plateau region, west into scattered locations of the Great Basin. Its easternmost extent in Wyoming is in the Bighorn Mountains. These woodlands occur at the lower treeline/ecotone between grassland or shrubland and more mesic coniferous forests typically in warm, dry, exposed sites. Elevations range from less than 1900 m in northern Wyoming to 2800 m in the New Mexico mountains. Occurrences are found on all slopes and aspects; however, moderately steep to very steep slopes or ridgetops are most common. This ecological system generally occurs on soils derived from igneous, metamorphic, and sedimentary material, with characteristic features of good aeration and drainage, coarse textures, circumneutral to slightly acidic pH, an abundance of mineral material, rockiness, and periods of drought during the growing season. Northern Rocky Mountain Ponderosa Pine Woodland and Savanna (CES306.030) in the eastern Cascades, Okanogan, and northern Rockies regions receives winter and spring rains, and thus has a greater spring "green-up" than the drier woodlands in the central Rockies. *Pinus ponderosa* (primarily var. *scopulorum* and var. *ponderosa* (= var. *brachyptera*)) is the predominant conifer; *Pseudotsuga menziesii, Pinus edulis, Pinus contorta, Populus tremuloides*, and *Juniperus* spp. may be present in the tree canopy. The understory is usually shrubby, with *Artemisia nova, Artemisia tridentata, Arctostaphylos patula, Arctostaphylos uva-ursi, Cercocarpus montanus, Purshia stansburiana, Purshia tridentata, Quercus gambelii, Symphoricarpos* spp., *Prunus virginiana, Amelanchier alnifolia* (less so in Montana), and *Rosa* spp. common species. *Pseudoroegneria spicata, Pascopyrum smithii*, and species of *Hesperostipa, Achnatherum, Festuca, Muhlenbergia*, and *Bouteloua* are some of the common grasses. Mixed fire regimes and ground fires of variable return intervals maintain these woodlands, depending on climate, degree of soil development, and understory density.
Classification Comments: This system intergrades with Southern Rocky Mountain Ponderosa Pine Savanna (CES306.649). They are distinguished by the high-frequency, surface-fire regime, less steep or rocky environmental setting, and more open grassy understory structure of the savanna system. Ponderosa pine woodlands, savannas, and "escarpments"' of central and eastern Montana, eastern Wyoming, the Black Hills region, western Dakotas, and Nebraska are now included in Northwestern Great Plains-Black Hills Ponderosa Pine Woodland and Savanna (CES303.650).

Because this ecological system has undergone some important changes in its concept, the original system (CES306.032) was archived, and this new system was created to account for the new concept of ponderosa pine woodlands in the Southern Rocky Mountains.
Similar Ecological Systems:

DESCRIPTION

Environment: This ecological system within the region occurs at the lower treeline/ecotone between grassland or shrubland and more mesic coniferous forests typically in warm, dry, exposed sites at elevations ranging from 1980-2800 m (6500-9200 feet). It can occur on all slopes and aspects, however, it commonly occurs on moderately steep to very steep slopes or ridgetops. This ecological system generally occurs on soils derived from igneous, metamorphic, and sedimentary material, including basalt, basaltic, andesitic flows, intrusive granitoids and porphyrites, and tuffs (Youngblood and Mauk 1985). Characteristic soil features include good aeration and drainage, coarse textures, circumneutral to slightly acidic pH, an abundance of mineral material, and periods of drought during the growing season. Some occurrences may occur as edaphic climax communities on very skeletal, infertile, and/or excessively drained soils, such as pumice, cinder or lava fields, and scree slopes. Surface textures are highly variable in this ecological system ranging from sand to loam and silt loam. Exposed rock and bare soil consistently occur to some degree in all the associations. *Pinus ponderosa / Arctostaphylos patula* represents the extreme with typically a high percentage of rock and bare soil present.

Precipitation generally contributes 25-60 cm annually to this system, mostly through winter storms and some monsoonal summer rains. Typically a seasonal drought period occurs throughout this system as well. Fire plays an important role in maintaining the characteristics of these open-canopy woodlands. However, soil infertility and drought may contribute significantly in some areas as

well.

Dynamics: *Pinus ponderosa* is a drought-resistant, shade-intolerant conifer which usually occurs at lower treeline in the major ranges of the western United States. Historically, ground fires and drought were influential in maintaining open-canopy conditions in these woodlands. With settlement and subsequent fire suppression, occurrences have become denser. Presently, many occurrences contain understories of more shade-tolerant species, such as *Pseudotsuga menziesii* and/or *Abies* spp., as well as younger cohorts of *Pinus ponderosa*. These altered structures have affected fuel loads and alter fire regimes. Presettlement fire regimes were primarily frequent (5- to 15-year return intervals), low-intensity ground fires triggered by lightning strikes or deliberately set fires by Native Americans. With fire suppression and increased fuel loads, fire regimes are now less frequent and often become intense crown fires, which can kill mature *Pinus ponderosa* (Reid et al. 1999).

Establishment is erratic and believed to be linked to periods of adequate soil moisture and good seed crops, as well as fire frequencies, which allow seedlings to reach sapling size. Longer fire-return intervals have resulted in many occurrences having dense subcanopies of overstocked and unhealthy young *Pinus ponderosa* (Reid et al. 1999). Mehl (1992) states the following: "Where fire has been present, occurrences will be climax and contain groups of large, old trees with little understory vegetation or down woody material and few occurring dead trees. The age difference of the groups of trees would be large. Where fire is less frequent, there will also be smaller size trees in the understory giving the occurrence some structure with various canopy layers. Dead, down material will be present in varying amounts along with some occurring dead trees. In both cases the large old trees will have irregular open, large branched crowns. The bark will be lighter in color, almost yellow, thick and some will like have basal fire scars."

Grace's warbler, pygmy nuthatch, and flammulated owl are indicators of a healthy ponderosa pine woodland. All of these birds prefer mature trees in an open woodland setting (Winn 1998, Jones 1998, Levad 1998 as cited in Rondeau 2001).

SOUTHWEST FLORIDA COASTAL STRAND AND MARITIME HAMMOCK (CES411.368)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Coast
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2336; ESLF 4142; ESP 1336

CONCEPT

Summary: This ecological system occurs as a narrow band of hardwood forest and strand lying just inland of the coastal dune system in southwestern Florida. It is found on stabilized, old, coastal dunes, often with substantial shell components. The vegetation is characterized by hardwood species with tropical affinities. As such, the northern extent of this type is limited by periodic freezes and cold tolerance of tropical constituent species, such as *Piscidia piscipula* and *Eugenia axillaris*. This system is closely related to both inland tropical hammocks and southeast Florida maritime hammocks, and may share some species overlap with each.
Classification Comments: This system may be distinguished from southeast Florida maritime hammocks by geographic location, presence/absence of certain indicator species, and relatively less harsh coastal exposure. It is distinguished from maritime hammocks further north which contain temperate species including *Persea borbonia, Quercus virginiana, Magnolia grandiflora*, and *Juniperus virginiana var. silicicola* (Johnson and Muller 1993a).
Similar Ecological Systems:
- Southeast Florida Coastal Strand and Maritime Hammock (CES411.369)

- Maritime Hammock (FNAI 1990) Intersecting
- Shell Mound (FNAI 1990) Intersecting
- Tropical Hardwoods: 105 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs along the coast on stabilized, old coastal dunes, often with substantial shell components. The northern extent of this type is limited by periodic freezes.
Dynamics: The northern extent of this type is limited by periodic freezes and lack of cold tolerance of tropical plants, such as *Piscidia piscipula* and *Eugenia axillaris* (Johnson and Muller 1993a). Maritime hammocks are relatively stable forest communities, as long as the canopy remains intact and the underlying landform is stable (FNAI 1990). Surface fires may help to maintain the open understory (Landfire 2007a). The shrub-dominated, coastal strand communities are considered ecotonal, and historically burned more frequently than maritime hammocks, possibly every 4-5 years (Austin and Coleman-Marois 1977). However, there is some disagreement on this point. There is little information on natural fire frequency in coastal strand (FNAI 2010a). The low stature of strand is due to the influence of storms and the ongoing salt spray pruning (FNAI 2010a). Fire is not needed to explain the shrub-dominated vegetation of coastal strands (Landfire 2007a).

WEST GULF COASTAL PLAIN CHENIER AND UPPER TEXAS COASTAL FRINGE FOREST AND WOODLAND (CES203.466)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2339; ESLF 4145; ESP 1339

CONCEPT

Summary: This system includes a range of woody vegetation typically dominated by *Quercus virginiana* present along the northern Gulf of Mexico, from Vermillion Bay in Louisiana to the upper Texas coast. Landscape position includes shell ridges along the coast and bay margins, coastal salt domes, stranded ancient barrier ridges (Ingleside barrier strandplain), and chenier ridges of the Chenier Plain. In addition to *Quercus virginiana*, other species such as *Celtis laevigata* and *Quercus nigra* may be present to codominant in the canopy which may also include *Carya illinoinensis, Diospyros virginiana, Fraxinus pennsylvanica, Liquidambar styraciflua,* and *Magnolia grandiflora*.

Related Concepts:

- Chenier Plain: Hardwood Fringe Forest (5504) [CES203.466.4] (Elliott 2011) Finer
- Chenier Plain: Live Oak Fringe Forest (5502) [CES203.466.2] (Elliott 2011) Finer
- Chenier Plain: Mixed Live Oak / Deciduous Hardwood Fringe Forest (5503) [CES203.466.3] (Elliott 2011) Finer
- Live Oak: 89 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occupies sand and shell ridges (Quaternary deposits) which resulted from ancient abandoned beach ridges associated with migrating shorelines, shell ridges, as well as salt domes near the coast. The Ingleside barrier strandplain, an ancient barrier ridge composed of deep sands and occurring well inland of the current Gulf shoreline, may support occurrences of this system. Most occurrences occupy ridges formed from sediments deposited along ancient shorelines. These ridges (cheniers), which often parallel the coast and are composed of coarse material such as sand or shell, may be up to 3 m above mean sea level. Some occurrences occupy coastal salt domes, which may rise 30 m above the surrounding landscape. The soils are typically Entisols of coarse-textured material, either sand or shell. The Ecological Site Description, which may be related to this system, is the Coastal Sand ecoclass (Elliott 2011).

Vegetation: Typically these forests and woodlands are dominated by *Quercus virginiana*; however, other species such as *Celtis laevigata* and *Quercus nigra* may be present to codominant in the canopy. Other species such as *Liquidambar styraciflua, Carya illinoinensis, Diospyros virginiana, Fraxinus pennsylvanica*, and *Magnolia grandiflora* may also be present in the canopy. The understory is often patchy but may include species such as *Ilex vomitoria, Callicarpa americana, Zanthoxylum clava-herculis, Crataegus viridis, Sabal minor, Morella cerifera*, and/or *Sideroxylon lanuginosum*. Woody vines present in this system include *Vitis mustangensis, Parthenocissus quinquefolia, Campsis radicans,* and *Toxicodendron radicans*. The two epiphytes *Tillandsia usneoides* and *Pleopeltis polypodioides* may be commonly encountered. The herbaceous layer is usually sparse, but may include species such as *Schizachyrium scoparium, Sanicula canadensis, Malvaviscus arboreus var. drummondii, Elephantopus carolinianus,* and *Oplismenus hirtellus*. *Triadica sebifera* and *Ligustrum sinense* may be important non-native invaders (Elliott 2011).

Dynamics: This ecological system is heterogeneous in physiognomy, including forests, woodlands and shrublands. The Chenier Plain was historically characterized by a prograding coastline replenished by sediments carried to the Gulf of Mexico initially by the Mississippi and subsequently the Atchafalaya and other rivers. It is void of barrier islands and sediments are reworked by waves into beach ridges, sometimes with a substantial shell component. This process has been continuing since the last glacial retreat, and as the coastline prograded, older beach ridges were left as interior ridges surrounded by marsh. These interior beach ridges are referred to as cheniers (from the French word for oak) because they were historically dominated by *Quercus virginiana*. Ridges parallel the coast and are usually 3-5 m above mean sea level. Though not confined to coastal areas, salt domes are a distinctive feature along the Gulf Coast of upper Texas and Louisiana where they often form a drastic contrast to the low-lying Coastal Plain sediments surrounding them. Formed by the rise of salt masses which push up overlying strata, salt domes may rise 30 m above the surrounding landscape. The natural vegetation of cheniers and coastal salt domes are quite similar. The Ingleside barrier strandplain is a Pleistocene barrier ridge that is exposed discontinuously along the Texas coast. One of these areas is located northeast of Galveston Bay and supports *Quercus virginiana*-dominated woodlands included within this ecological system. Shell ridges located along coast and bay margins are typically dominated by halophytic shrubs. Similar vegetation may also be found on coastal dredge spoil. Vegetation structure and composition of occurrences of this system may be influenced by salt spray (on those shell ridges, salt domes and cheniers closest to the gulf), tropical storms and hurricanes, and the distinctive climate of the immediate coast. Studies have shown that chenier forests and woodlands are very important stop-over sites for neotropical migrants during both spring and fall migration.

Component Associations:

- *Acacia farnesiana - Opuntia stricta var. dillenii - Lycium carolinianum var. quadrifidum / Spartina patens* Shrubland (CEGL003932, G3?)
- *Celtis laevigata - (Zanthoxylum clava-herculis, Acacia farnesiana) / Vitis mustangensis* Forest (CEGL007198, G3?)
- *Quercus virginiana - (Celtis laevigata) / Prunus caroliniana* Forest (CEGL002156, G2G3)
- *Quercus virginiana - Celtis laevigata / Sabal minor* Forest (CEGL007466, G2)
- *Quercus virginiana - Magnolia grandiflora - Quercus pagoda - Celtis laevigata / Sabal minor* Forest (CEGL007467, G1)

DISTRIBUTION

Range: This ecological system is found in small patches along the northern Gulf of Mexico, from Vermillion Bay in Louisiana to the upper Texas coast.

WEST GULF COASTAL PLAIN MESIC HARDWOOD FOREST (CES203.280)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Very Long Disturbance Interval; Broad-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2323; ESLF 4129; ESP 1323

CONCEPT

Summary: This ecological system is found in limited upland areas, including ravines and sideslopes, of the Gulf Coastal Plain west of the Mississippi River. These areas are topographically isolated from historically fire-prone, pine-dominated uplands in eastern Texas, western Louisiana, and southern Arkansas. Sites are often found along slopes above perennial streams in the region. These sites have moderate to high fertility and moisture retention. Soils can be quite variable, ranging from coarse to loamy in surface texture. Most are acidic in surface reactions and less commonly circumneutral. Vegetation indicators are mesic hardwoods such as *Fagus grandifolia, Quercus alba,* and *Ilex opaca,* although scattered, large-diameter pines (most often *Pinus taeda*) are also often present. Spring-blooming herbaceous species are typical in the understory of most examples.
Classification Comments: Some stands from Macon Ridge in Louisiana (a terrace ecoregion in the Mississippi River Alluvial Plain) are also included here. Some hardwood stands could occur on narrow ridgetops which are isolated from fire, but which would not be "mesic" in their composition or environment. These may be treated as a hardwood-dominated example of the widespread and variable West Gulf Coastal Plain Pine-Hardwood Forest (CES203.378). More information is needed.

DESCRIPTION

Environment: Sites are often found along slopes above perennial streams in the region. These sites have moderate to high fertility and moisture retention. Soils can be quite variable, ranging from coarse to loamy in surface texture. Most are acidic in surface reactions and less commonly circumneutral. It is found on Tertiary formations, from the Willis Formation in the south, northward through Eocene formations; it is primarily restricted to fairly rugged landscapes on ravines, steep slopes and low landscape positions, often near streams. It often occupies lower slope positions and adjacent steep slopes, where topographic position results in moisture accumulation and lower solar insolation. These sites may occur adjacent to bottomlands, but on more well-drained soils and/or slightly higher topographic positions (Elliott 2011).
Vegetation: Examples of this forested system can be diverse. Canopy trees can include *Fagus grandifolia, Magnolia grandiflora, Liquidambar styraciflua, Quercus alba, Quercus shumardii, Quercus pagoda, Quercus falcata, Quercus michauxii* (in wetter examples), *Quercus hemisphaerica* (in drier examples), *Quercus stellata* (in drier examples), *Quercus nigra, Fraxinus americana, Carya alba, Celtis laevigata, Nyssa sylvatica, Ulmus americana,* and *Pinus taeda*. *Pinus taeda,* and to a lesser extent, *Pinus echinata* may be present to codominant in the overstory. *Quercus rubra* is rare and of limited extent in the range of this ecological system but is attributed to an association which occurs in Hempstead, Howard, Little River, and Sevier counties, Arkansas. Understory trees can include *Carpinus caroliniana, Prunus caroliniana, Ostrya virginiana, Ilex opaca var. opaca, Cornus florida, Acer barbatum,* and *Acer leucoderme*. *Arundinaria gigantea* may be present in some examples. Other shrubs may include *Persea borbonia, Viburnum acerifolium,* and *Sabal minor*. *Vitis rotundifolia, Smilax* spp., and *Parthenocissus quinquefolia* are commonly encountered woody vines. Herbs can include *Solidago auriculata, Athyrium filix-femina ssp. Asplenioides, Chasmanthium sessiliflorum, Cynoglossum virginianum,* and *Trillium ludovicianum*. Some occurrences on more calcareous substrates lack *Magnolia grandiflora* and may contain species such as *Tilia americana* and *Styrax* spp., and may have a rich, more calciphilic, vernal forb flora. Such species as *Podophyllum peltatum, Arisaema dracontium, Arisaema triphyllum, Sanguinaria canadensis, Erythronium* spp., *Trillium* spp., and *Polygonatum biflorum* may dominate the ground layer of the forest in the early spring. Later in the year, these species become inconspicuous and are replaced by species such as *Chasmanthium sessiliflorum, Mitchella repens, Sanicula canadensis, Carex* spp., and *Dichanthelium* spp. Ferns, such as *Woodwardia* spp., *Osmunda cinnamomea, Athyrium filix-femina ssp. asplenioides,* and *Polystichum acrostichoides,* may be conspicuous.
Dynamics: The mesic nature of sites occupied by this system, along with the topography of the sites and the limited fine fuel

production in the system, results in reduced fire frequency.

Component Associations:
- *Fagus grandifolia - Magnolia grandiflora - Quercus alba / Carpinus caroliniana - Ostrya virginiana - Ilex opaca var. opaca* Forest (CEGL007872, G2)
- *Fagus grandifolia - Magnolia grandiflora / Ostrya virginiana / Aesculus parviflora* Forest (CEGL008554, G2?)
- *Fagus grandifolia - Quercus alba / Acer (barbatum, leucoderme) / Solidago auriculata* Forest (CEGL007207, G2G3)
- *Fagus grandifolia - Quercus alba / Ilex opaca var. opaca / Athyrium filix-femina ssp. asplenioides* Forest (CEGL007208, G3)
- *Fraxinus americana - Celtis laevigata - Nyssa sylvatica - Quercus shumardii - Ulmus americana* Forest (CEGL007897, G2G3)
- *Magnolia grandiflora / Prunus caroliniana - Carpinus caroliniana / Arundinaria gigantea* Forest (CEGL008577, G1?)
- *Quercus alba - Carya alba / Chasmanthium sessiliflorum* West Gulf Coastal Plain Forest (CEGL008413, G3G4)
- *Quercus alba - Quercus hemisphaerica / Prunus caroliniana - Persea borbonia - Viburnum acerifolium* Forest (CEGL007959, G2)
- *Quercus alba - Quercus nigra / Ostrya virginiana / Sabal minor* Forest (CEGL008581, G2G3)
- *Quercus alba - Quercus rubra / Ostrya virginiana / Arundinaria gigantea / Cynoglossum virginianum* Forest (CEGL007971, G2)
- *Quercus alba / Acer leucoderme - Ostrya virginiana / Solidago auriculata* Forest (CEGL008575, G2?)
- *Quercus falcata - Quercus stellata - (Pinus taeda)* West Gulf Coastal Plain Forest (CEGL008415, G3?)
- *Quercus shumardii - Quercus pagoda - Fraxinus americana / Ostrya virginiana - Cornus florida / Trillium ludovicianum* Forest (CEGL007272, G1)

WEST GULF COASTAL PLAIN PINE-HARDWOOD FOREST (CES203.378)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Short Disturbance Interval; Needle-Leaved Tree; Broad-Leaved Deciduous Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2371; ESLF 4314; ESP 1371

CONCEPT

Summary: This West Gulf Coastal Plain ecological system consists of forests and woodlands dominated by *Pinus taeda* and/or *Pinus echinata* in combination with a variety of dry to dry-mesic site hardwood species. This type was the historical matrix vegetation (dominant vegetation type) for large portions of the West Gulf Coastal Plain landward of the range of *Pinus palustris*, where it replaced *Pinus palustris*-dominated vegetation. In this region of southern Arkansas, northwestern Louisiana, and parts of eastern Texas, this type was historically present on nearly all uplands in the region except on the most edaphically limited sites (droughty sands, calcareous clays, and shallow soil barrens/rock outcrops). Such sites are underlain by loamy to fine-textured soils of variable depths. These are upland sites on ridgetops and adjacent sideslopes, with moderate fertility and moisture retention. This type was also present in more limited areas within the range of *Pinus palustris* (in the West Gulf Coastal Plain), where it was confined more typically to sideslopes and other locations not dominated by *Pinus palustris*. There are no known "Fidel" herbaceous species or any local endemic or globally rare plant species, and overall this system may have supported relatively low levels of vascular plant species diversity. This system has undergone major transformations since European settlement of the region.

DESCRIPTION

Environment: In southern Arkansas, northwestern Louisiana, and parts of eastern Texas, this type was historically present on nearly all uplands in the region except on the most edaphically limited sites (droughty sands, calcareous clays, and shallow soil barrens/rock outcrops). Such sites are underlain by loamy to fine-textured soils of variable depths and generally are Alfisols or Ultisols. These are upland sites on ridgetops and adjacent sideslopes, with moderate fertility and moisture retention. In Texas, this system occurs over a wide variety of landforms, with drier expressions occurring on hilltops and ridges. It occupies slopes and lower landscape positions, where conditions are more mesic, and composition of the system varies across these gradients. It is found on numerous Cenozoic sedimentary formations and some Cretaceous formations of the Mesozoic era. These formations range from sandstone, shale, alluvium, and conglomerate, to marl, with glauconitic formations (Weches) and tuffaceous formations (Catahoula) present (Elliott 2011).

Vegetation: Examples of this system are forests and woodlands dominated by *Pinus taeda* and/or *Pinus echinata* in combination with a host of dry to dry-mesic site hardwood species, such as *Quercus alba, Quercus falcata*, and *Quercus stellata*. Stands on narrow ridgetops, which can be isolated from the effects of fire, may exhibit greater dominance by hardwoods. Other species that may occur include *Quercus margarettiae, Quercus velutina, Carya alba, Carya texana, Cornus florida, Crataegus* spp., *Ostrya virginiana, Symplocos tinctoria, Morella cerifera, Vaccinium arboreum, Vaccinium elliottii, Viburnum acerifolium*, and *Viburnum dentatum*. Woody vines in this system may be conspicuous and often include *Smilax bona-nox, Vitis* spp. (often *Vitis rotundifolia* or *Vitis mustangensis* to the south), *Parthenocissus quinquefolia*, and *Toxicodendron radicans*. The herbaceous layer is generally sparse (often less than 20% cover), with *Schizachyrium scoparium, Chasmanthium laxum, Chasmanthium sessiliflorum, Dichanthelium sphaerocarpon*, and *Pteridium aquilinum* often present to dominant. The importance of *Acer barbatum, Acer leucoderme*, and *Liquidambar styraciflua* may increase with the absence of fire. In parts of southeastern Texas, the hardwood component of stands may

contain *Quercus nigra, Quercus virginiana, Quercus falcata, Liquidambar styraciflua,* and *Ulmus* spp. Shrubs include *Ilex vomitoria, Cornus florida, Morella cerifera, Callicarpa americana,* and *Vaccinium arboreum* (Elliott 2011).
Dynamics: Forests with dense tree cover (especially evergreen cover) have reduced shrub and herbaceous cover. Herbaceous cover may be additionally limited by dense litter accumulation. Few occurrences of this system can be considered old-growth.

Component Associations:
- *Pinus (echinata, taeda) / Symplocos tinctoria - Morella cerifera - Vaccinium elliottii* Forest (CEGL008410, G3?)
- *Pinus echinata - (Pinus taeda) - Quercus falcata / Dichanthelium sphaerocarpon* Forest (CEGL007947, G2G3)
- *Pinus echinata - Pinus taeda - Quercus (alba, falcata, stellata)* Forest (CEGL004713, G2G3)
- *Pinus echinata - Pinus taeda - Quercus stellata - Carya texana / Vaccinium arboreum* Woodland (CEGL007499, G3?)
- *Pinus echinata - Quercus alba / Viburnum (dentatum, acerifolium)* Forest (CEGL003855, G2G3)
- *Pinus echinata - Quercus stellata - Quercus falcata - Carya texana* Woodland (CEGL007800, G1)
- *Pinus taeda - (Pinus echinata) - Quercus alba - Carya alba / Acer barbatum - (Acer leucoderme)* Forest (CEGL007524, G2G3)
- *Pinus taeda - (Pinus echinata) - Quercus falcata - Carya texana / Vaccinium arboreum* Forest (CEGL007528, G4)
- *Pinus taeda - (Pinus echinata) / Quercus michauxii / Thaspium barbinode* Forest (CEGL008582, G1)
- *Pinus taeda* - (*Quercus* spp.) / *Ostrya virginiana - Sabal minor* Forest (CEGL007955, G2G3)
- *Pinus taeda - Quercus alba - (Fagus grandifolia) / Ilex opaca / Smilax pumila - Mitchella repens* Forest (CEGL007525, G3G4)
- *Pinus taeda - Quercus stellata / Crataegus* spp. Woodland (CEGL002112, G2G3)
- *Quercus alba - Quercus falcata - Quercus stellata - Nyssa sylvatica / Carex cherokeensis* Forest (CEGL008414, G3G4)
- *Quercus stellata - Quercus marilandica - Pinus taeda* Jackson Acidic Clay Woodland (CEGL007900, G2?Q)

WEST GULF COASTAL PLAIN SANDHILL OAK AND SHORTLEAF PINE FOREST AND WOODLAND (CES203.056)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Needle-Leaved Tree; Broad-Leaved Deciduous Tree
Non-Diagnostic Classifiers: Short Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2378; ESLF 4321; ESP 1378

CONCEPT

Summary: This ecological system occurs west of the Mississippi River primarily outside the natural range of longleaf pine (*Pinus palustris*) and less commonly within this range. Like other sandhill systems of the Gulf and Atlantic coastal plains, this type is found on uplands underlain with deep, coarse sandy soils. These sites are typified by low fertility and moisture retention, which contribute to open tree canopies with usually less than 60% canopy closure. Sparse understory vegetation and abundant patches of bare soil are indicative of this system. Vegetation indicators are species tolerant of droughty sites, especially *Quercus incana* and *Quercus arkansana*, but also *Quercus marilandica* and *Quercus stellata*. *Pinus echinata* is usually present, and *Pinus palustris* is absent (or perhaps at low frequency within its range). This system supports a large concentration of vascular plant endemics, near endemics, and a number of plant species with high fidelity to sandhills in the region. Elsewhere in the Atlantic and Gulf coastal plains, including most of the adjacent outer West Gulf Coastal Plain ecoregion, these site conditions are closely associated with longleaf pine.
Classification Comments: In Arkansas (at least), this system is most closely affiliated with the "Briley-Alaga-Bibb" Soil Association (MUID=AR039 in STATSGO).

DESCRIPTION

Environment: This system type is found on droughty uplands underlain with deep, coarse sandy soils. It is generally associated with Eocene sand formations such as Carrizo, Sparta, and Queen City sands, including the Betis, Darco, Letney, Tehran, Tonkawa, and other Grossarenic or Psammentic soil series. It is also found on sands derived from the Pliocene Willis formation (Elliott 2011). These sites are typified by low fertility and moisture retention. In particular, these are found on deep sands on generally high, convex landforms, and often display a relatively open overstory canopy.
Vegetation: Examples of this system may occur as pine dominated woodlands, with *Pinus palustris* dominating some sites within its range, and *Pinus echinata* dominating areas where *Pinus palustris* is absent. *Pinus taeda* is naturally less common, but in the current landscape, it is common and sometimes dominant. Pines may co-dominate along with deciduous species, or the canopy may be dominated by oaks and other deciduous species including *Quercus stellata, Quercus marilandica, Quercus incana, Quercus falcata, Quercus margarettiae*, and *Carya texana* (Elliott 2011). Other deciduous trees present may include *Sassafras albidum, Liquidambar styraciflua*, and *Quercus nigra*. The shrub stratum can be fairly well-developed, and includes shorter individuals of canopy species in addition to such species as *Callicarpa americana, Ilex vomitoria, Vaccinium arboreum, Rhus aromatica, Asimina parviflora, Cornus florida*, and *Smilax bona-nox*. The herbaceous layer may be quite well-developed or relatively patchy (with areas of bare sandy soil exposed). Commonly encountered species include *Schizachyrium scoparium, Pteridium aquilinum, Aristida desmantha, Ambrosia psilostachya, Cnidoscolus texanus, Rudbeckia hirta, Dichanthelium dichotomum, Pityopsis graminifolia, Croton argyranthemus, Tragia urticifolia, Froelichia floridana, Matelea cynanchoides, Opuntia humifusa, Sporobolus junceus, Triplasis purpurea, Bulbostylis ciliatifolia, Chamaecrista fasciculata, Berlandiera pumila, Commelina erecta var. angustifolia, Stylisma pickeringii, Tetragonotheca ludoviciana, Tradescantia reverchonii, Rhynchosia* spp., *Tephrosia* spp., *Yucca louisianensis*, as well as the fern ally *Selaginella arenicola ssp. riddellii* (Elliott 2011). All described community types in this system tend to support relatively open

wooded canopies (<60% closure), and one type is described as essentially treeless. A degraded expression of this type has been described [see CEGL007507], but this is treated under the semi-natural ecological system. Other types are floristically differentiated, with special importance placed on the occurrence of *Quercus arkansana*.

Dynamics: The primary natural processes controlling this system are droughty, deep sandy soils, and a natural fire regime. Fire is believed to have been a critical natural disturbance process which affected the vegetation structure and likely the species composition of communities in this system. There are several indirect pieces of evidence which suggest this: (1) *Pinus echinata* is intolerant of competition, and young stems are generally slower growing and slower to dominate sites than either *Pinus taeda* or many hardwood species (Lawson 1990); (2) *Pinus echinata* regeneration decreases dramatically with time since fire (Ferguson 1958); and (3) *Pinus echinata* has the ability to resprout. Watson (1986) postulates that most seedlings of *Pinus echinata* are killed during the periodic fires, and the mature trees are spared. This prevents the formation of thickets. This paper implies that low fuel levels accompany the sparse vegetation of these sandy areas, leading to a somewhat longer fire-return interval, which suits *Pinus echinata*. A variety of fire-return intervals have been estimated for *Pinus echinata* vegetation. Garren (1943) proposed an 8- to 10 -year return interval, Landers (1989) inferred a regime of 10 per century, and Martin and Smith (1993) estimated a 5- to 15 -year interval, however, none of these estimates were specific to *Pinus echinata* on sandhills. Many such sites in the region lack well -developed and continuous fine fuels necessary to ignite and spread fires, possibly due to site infertility and droughtiness (R. Evans pers. obs., L. Smith pers. comm.).

Component Associations:

- *(Pinus palustris) - Quercus stellata - Quercus incana / Tetragonotheca ludoviciana* Woodland (CEGL008566, G2)
- *(Quercus incana) / Schizachyrium scoparium - Bouteloua hirsuta - Dalea villosa var. grisea - Selaginella arenicola ssp. riddellii* Xeric Sand Barrens Woodland (CEGL007973, GNR)
- *Pinus echinata - (Pinus taeda) - Quercus (margarettiae, stellata, falcata) - Carya texana* Woodland (CEGL007946, G2)
- *Pinus echinata - Pinus taeda - Quercus stellata / Juniperus virginiana var. virginiana / Cornus drummondii* Woodland (CEGL007798, G1G2Q)
- *Pinus echinata - Quercus (incana, stellata, margarettiae) / Cnidoscolus texanus* Woodland (CEGL007507, G2)
- *Pinus echinata / Quercus incana / Selaginella arenicola ssp. riddellii* Woodland (CEGL003559, G2Q)
- *Pinus palustris - Pinus (echinata, taeda) - Quercus falcata - Carya texana* Woodland (CEGL008571, G2G3)
- *Quercus (incana, margarettiae, arkansana) - (Pinus echinata) / Schizachyrium scoparium* Woodland (CEGL007972, G2)

WEST GULF COASTAL PLAIN STREAM TERRACE SANDYLAND LONGLEAF PINE WOODLAND (CES203.891)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); West Gulf Coastal Plain; Very Short Disturbance Interval; Needle-Leaved Tree
National Mapping Codes: EVT 2521; ESLF 4283; ESP 1521

CONCEPT

Summary: These sandhills are dry longleaf pine-dominated woodlands or savannas found on excessively drained, xeric soils of alluvial origin in the West Gulf Coastal Plain (South Central Plains of EPA) of Texas and formerly Louisiana. They occur on areas of deep sand (ranging in texture from coarse to fine) which are present in quaternary alluvial deposits. The general habitat is on low terraces adjacent to stream floodplains, and adjacent communities may include baygalls and ponds. Precipitation rapidly dissipates via percolation due to the character of the soil. Soils include fine sands, such as fluvial terraces of Bienville-Alaga soils developed in the Deweyville Formation, and the Tonkawa fine sand, as well as other coarse sands. *Pinus palustris* historically dominated the vegetation of this region across nearly all uplands regardless of soil type or moisture. The importance of frequent fire has been well-documented for the perpetuation of this and related systems throughout the coastal plains. Stands are dominated by *Pinus palustris*, which often occurs in mixed stands with *Quercus incana, Pinus echinata*, and *Carya texana*. Some small isolated terraces (inclusions) may be dominated by oaks and hickories, with little or no *Pinus palustris*. The oaks generally become denser with fire exclusion, particularly on the small isolated areas. Mesophytic oak species are absent or extremely rare. This type, and other longleaf communities and systems of the West Gulf Coastal Plain, lie outside the range of *Aristida beyrichiana* (wiregrass). Other grasses (*Andropogon* spp., other *Aristida* spp., and *Schizachyrium* spp.) dominate understories which are rich in species diversity.
Classification Comments: This system is relatively xeric vegetation, even though it occurs on terraces adjacent to, or within, floodplains. This is the case because the soils are deep and well-drained sands (often alluvial deposits), with low moisture retention and high permeability. This system is floristically similar to other sandhill longleaf pine systems, but the landform position of the occurrences makes this system unique. This system was formerly part of West Gulf Coastal Plain Upland Longleaf Pine Forest and Woodland (CES203.293) but has been separated out due to its distinctive environment. The herbaceous cover of subtypes 2 and 3 of Bridges and Orzell (1989a) is usually sparse, with considerable exposed sand and foliose lichen cover, and is characterized by numerous West Gulf Coastal Plain endemics (Bridges and Orzell 1989a). Two taxa (*Phlox nivalis ssp. texensis* and *Gaillardia aestivalis var. winkleri*) are nearly endemic to subtype 3 and occur primarily along Village Creek in Hardin County, Texas. *Carex tenax* and *Galium hispidulum* are nearly restricted to subtype 3 and are long-distance disjuncts from the East Gulf Coastal Plain (Bridges and Orzell 1989a).
Similar Ecological Systems:
- West Gulf Coastal Plain Pine-Hardwood Forest (CES203.378)--is found on the inner (landward) side, generally north and west of the range of this type.
- West Gulf Coastal Plain Upland Longleaf Pine Forest and Woodland (CES203.293)--represents the longleaf pine system of regular uplands of varying soil textures.
- West Gulf Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.191)--is found on the outer (seaward) side, generally south and east of the range of this type, and is an upland/wetland mosaic.

DESCRIPTION

Environment: This system is relatively xeric vegetation, even though it occurs on terraces adjacent to, or within, floodplains. This is because the soils are deep and well-drained sands (often alluvial deposits), with low moisture retention and high permeability. This system usually occurs in deep, well-drained sandy soils on stream terraces, occurring above medium-sized perennial creeks that are typically clear and have sandy bottoms. These sites have very fine sands on ridgetops or slightly higher rises in the sandhill terraces. The flat areas with broad sandhills are slightly coarser and hold a little more water. A site for this system can have both fine and coarse sands. The landscape profile starts out with some bottomland hardwoods type with braided bald-cypress - tupelo, then a slight slope with a wide baygall edge against the sandhill. Sometimes there is a small ribbon of American beech slope forest just above the

baygall, then going into the upland sandhill; sometimes it is just a baygall to sandhill transition (J. Singhurst pers. comm.). It represents a distinctive subset of longleaf pine-dominated vegetation in the inner (landward) portions of the West Gulf Coastal Plain in eastern Texas (and Louisiana).

Vegetation: Stands are dominated by *Pinus palustris*, which may form a discontinuous and sparse overstory, and often occurs in mixed stands with *Quercus incana, Quercus margarettiae, Quercus marilandica, Pinus echinata,* and *Carya texana*. Some small isolated terraces (inclusions) may be dominated by oaks and hickories, with little or no *Pinus palustris*. The oaks generally become denser with fire exclusion, particularly on the small isolated areas. *Pinus elliottii* and *Pinus taeda* may be present to common in the current landscape. Other mesophytic oak species are absent or extremely rare. This type, and other longleaf communities and systems of the West Gulf Coastal Plain, lies outside the range of *Aristida beyrichiana*. Other grasses (*Andropogon* spp., other non-wiregrass *Aristida* spp., and *Schizachyrium* spp.) dominate understories rich in species diversity. Some additional small trees may include *Quercus marilandica, Quercus hemisphaerica,* and *Liquidambar styraciflua*. A sparse understory shrub component includes *Vaccinium arboreum* and *Ilex vomitoria*; however, fire suppression allows the shrubs to become more dominant in the midstory. Some other common shrubs may include *Asimina parviflora, Callicarpa americana, Crataegus* spp., *Prunus angustifolia, Prunus gracilis, Rhus aromatica, Ptelea trifoliata var. mollis, Sassafras albidum,* and *Sideroxylon lanuginosum*. Ground cover plant species are tolerant of periodic drought during the growing season, and they also exhibit adaptations to a frequent fire regime. Some characteristic herbs (which vary across environments) include *Schizachyrium scoparium, Aristida desmantha, Berlandiera pumila, Bulbostylis ciliatifolia, Cnidoscolus texanus, Croton argyranthemus, Dichanthelium acuminatum, Eriogonum longifolium, Lespedeza hirta, Liatris elegans var. elegans, Liatris pycnostachya, Opuntia humifusa var. humifusa, Paronychia drummondii, Rudbeckia grandiflora var. alismifolia, Ruellia humilis, Silphium laciniatum, Stillingia sylvatica, Stylisma pickeringii var. pattersonii, Tradescantia reverchonii, Tragia urens,* and *Yucca louisianensis*. Some other taxa that may be present include *Ambrosia trifida, Baptisia* sp., *Bulbostylis capillaris, Bulbostylis ciliatifolia, Carex tenax, Cenchrus* sp., *Chamaecrista* sp., *Commelina erecta, Croptilon divaricatum, Cyperus grayoides, Dalea* sp., *Delphinium carolinianum, Echinacea* sp., *Eragrostis secundiflora, Eriogonum multiflorum, Euphorbia corollata, Gaillardia aestivalis var. winkleri, Heterotheca subaxillaris, Hypericum drummondii, Hypericum hypericoides, Hymenopappus artemisiifolius , Lechea tenuifolia, Lechea mucronata, Nuttallanthus canadensis (= Linaria canadensis), Loeflingia squarrosa, Matelea cynanchoides, Mirabilis albida, Monarda punctata, Oenothera heterophylla, Paronychia drummondii, Polanisia erosa ssp. erosa, Polypremum procumbens, Pteridium aquilinum, Rhynchosia* sp., *Scutellaria* sp., *Solidago* spp., *Streptanthus hyacinthoides, Tephrosia* sp., *Tetragonotheca ludoviciana, Thelesperma filifolium, Toxicodendron radicans, Trichostema dichotomum,* and *Vernonia* sp. (J. Singhurst pers. comm.).

In Bridges and Orzell (1989a; table 3 - herbs), the following herbs are "differentials" (present in subtype 3 [or at much greater abundance] than in subtype 2): *Aristida desmantha, Carex tenax, Eriogonum longifolium* [which is in subtypes 1 and 3, but not 2], *Eriogonum multiflorum,* and *Polanisia erosa*. Many "indicators" are present at roughly the same frequency in subtypes 2 and 3.

Dynamics: The importance of frequent fire has been widely-accepted for the perpetuation of *Pinus palustris* systems (Stambaugh et al. 2011a), but fires may actually be less frequent, more patchy and discontinuous than in other related longleaf pine-dominated systems. The oaks generally become denser with fire exclusion, particularly in small, isolated examples. Lichens (e.g., *Cladonia* spp.) and *Selaginella arenicola ssp. riddellii* also occur along with patches of bare sand. Canopy trees are patchy in distribution, with regeneration in canopy gaps of a quarter acre or less in size, mid-successional clumps in similar sized patches, and the oldest trees occurring as isolated individuals. The reference condition classes are aggregates of numerous patches well-dispersed over the landscape. Canopy gaps are created by fire mortality, pest outbreaks, lightning, and windthrow at the scale of individual trees or several trees. Because of the irregular seed production of longleaf pine, canopy gaps may lack regeneration for several years. Uncharacteristic vegetation types include even-aged canopy stands in which age structure has been homogenized by logging or clearing. Examples include where *Pinus taeda* or *Pinus elliottii* have replaced some or all of the longleaf pine, where midstory oaks and/or low shrubs have become dense due to fire suppression, and where the grass-dominated ground cover has been lost due to soil disturbance or canopy closure.

Component Associations:

- *Pinus palustris - Pinus (echinata, taeda) - Quercus (incana, margarettiae) / Schizachyrium scoparium* Woodland (CEGL007513, G1G2)
- *Pinus palustris / Quercus incana - Quercus margarettiae / Vaccinium arboreum / Cnidoscolus texanus - Stylisma pickeringii var. pattersonii* Woodland (CEGL003602, G2G3)
- *Pinus palustris / Quercus incana / Schizachyrium scoparium - Croton argyranthemus* Woodland (CEGL008572, G2G3)
- *Pinus palustris / Quercus incana / Schizachyrium scoparium - Liatris elegans - Opuntia humifusa var. humifusa* Woodland (CEGL003580, G1?Q)
- *Pinus palustris / Quercus marilandica / Ilex vomitoria / Schizachyrium scoparium* Woodland (CEGL003579, G2)
- *Pinus palustris / Quercus marilandica / Panicum virgatum* Woodland (CEGL008580, G2)
- *Pinus palustris / Quercus marilandica / Schizachyrium scoparium - Silphium laciniatum - Ruellia humilis* Woodland (CEGL003596, G1)
- *Pinus palustris / Schizachyrium scoparium - Liatris pycnostachya* Woodland (CEGL003571, G2G3)
- *Pinus palustris / Schizachyrium scoparium - Rudbeckia grandiflora var. alismifolia* Woodland (CEGL003572, G2G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological System Comments: Adjacent communities may include baygalls and ponds.

DISTRIBUTION

Range: This upland ecological system occurs mainly in the Southern Loam Hills Subsection (232Fa) of Texas and formerly Louisiana, apparently ranging south into the Southwest Flatwoods Subsection (232Fb) (Hardin County, Texas). West Gulf Coastal Plain longleaf sandhills are distinctive from those in the East Gulf Coastal Plain because they occur beyond the limits of where wiregrass and sand post oak are dominant.

WEST GULF COASTAL PLAIN UPLAND LONGLEAF PINE FOREST AND WOODLAND (CES203.293)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); West Gulf Coastal Plain; Very Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2348; ESLF 4251; ESP 1348

CONCEPT

Summary: The common and unifying feature of this system is vegetation naturally dominated by *Pinus palustris*. This was formerly the most extensive system within its natural range in western Louisiana and eastern Texas. In most of the region, longleaf pine is (presently) a distinctive, but rarely dominant, element of existing vegetation. However, this tree historically dominated the vegetation across nearly all uplands regardless of soil type or moisture (excluding wetlands), and longleaf pine forests were among the most valuable economic resources in the region at the turn of the century. Typical sites include sandhills on well-drained to excessively drained soils, but the type is also found on loamy and clayey upland soils. The importance of frequent fire has been well documented for the perpetuation of this system. This type lies outside the ranges of *Aristida stricta* and *Aristida beyrichiana*, unlike comparable systems east of the Mississippi River, but most stands at least formerly supported open grass-dominated understories rich in species diversity.

Classification Comments: This system was part of what was once considered "the lumber region par excellence of Texas" (Bray 1906). Intensive logging began around 1880 as forests in the northern states were cut out and railroads and logging technologies were moved into the region (Collier 1964, Williams 1989). By 1917, the majority of Texas longleaf had been cut (Foster et al. 1917), and by 1934-35, loblolly had become the single most prevalent species in 17 southeastern Texas counties (Cruikshank and Eldredge 1939). Overall losses of longleaf pine in Texas have exceeded those of all other southern states (Outcalt 1997); less than 16,200 hectares of mostly second-growth stands remain (McWilliams and Lord 1988). Land-use practices continue to degrade remaining examples of longleaf pine communities (Bridges and Orzell 1989a).

DESCRIPTION

Environment: This system represents the presumed matrix vegetation type of the inner (landward) portions of the West Gulf Coastal Plain in Louisiana and eastern Texas within the range of *Pinus palustris*. In Louisiana, these are mapped as the Upper Terrace and some smaller landward units (Snead and McCulloh 1984). The system is bounded on the outer (seaward) side by West Gulf Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.191) and on the inner (landward) side primarily by West Gulf Coastal Plain Pine-Hardwood Forest (CES203.378) and other hardwood or hardwood-pine systems. Stands are found on sedimentary Pleistocene formations (particularly the Bentley Formation), to formations of the Tertiary period (particularly the Catahoula and Wilcox formations). Historically, this system was more widely distributed on older, more inland formations of the Eocene and Paleocene epochs. They occupy topography ranging from rolling uplands, to hills and ridges such as those associated with the Kisatchie Wold (or Kisatchie Cuesta) and the Sabine Uplift, and are usually associated with coarse-textured, well-drained Ultisols and Alfisols, including loams, sandy loams, loamy sands, and sands, though occurrences may also be found to a lesser extent on tighter soils such as clay loams (Elliott 2011). It is characteristically dissected by small to large streams.

Vegetation: Examples are characterized by relatively open-canopied woodlands dominated by *Pinus palustris* with an herbaceous layer often dominated by graminoids. It often occupied gently rolling uplands with coarse-textured, well-drained soils. *Pinus echinata* may be a significant component of some of the stands. *Quercus stellata, Quercus marilandica, Quercus incana, Pinus taeda, Liquidambar styraciflua,* and *Nyssa sylvatica* may also be common components of the canopy or subcanopy. Occurrences that are less frequently burned may develop a significant shrub layer with species including *Callicarpa americana, Vaccinium arboreum, Vaccinium stamineum, Morella cerifera, Ilex vomitoria, Rhus copallinum,* and *Toxicodendron radicans*. Instances with a more optimal

fire-return interval will retain a more open understory with a grassy aspect. Unlike comparable systems east of the Mississippi River, this type lies outside the ranges of *Aristida stricta* and *Aristida beyrichiana*, but most stands historically supported open grass-dominated understories rich in species diversity. The herbaceous layer is often dominated by grass species such as *Schizachyrium scoparium, Schizachyrium tenerum, Sporobolus junceus, Panicum virgatum, Nassella leucotricha, Andropogon ternarius, Dichanthelium* spp., and *Andropogon virginicus*. *Pteridium aquilinum* may be locally abundant, forming a continuous ground cover. Forbs may be diverse in the herbaceous layer, including species such as *Pityopsis graminifolia, Solidago odora, Tephrosia* spp., *Tragia urens, Euphorbia corollata, Croton argyranthemus, Vernonia texana, Alophia drummondii, Lespedeza virginica, Aristolochia reticulata, Rhynchosia reniformis, Stylosanthes biflora, Opuntia humifusa var. humifusa, Cnidoscolus texanus, Stylisma pickeringii var. pattersonii, Rudbeckia grandiflora var. alismifolia, Silphium laciniatum, Ruellia humilis, Liatris pycnostachya,* and *Liatris elegans*. With prolonged absence of fire, hardwoods and *Pinus taeda* may come to dominate the system (Elliott 2011).

In most of the region, *Pinus palustris* is (presently) a distinctive, but rarely dominant, element of existing vegetation (Harcombe et al. 1993). However, this tree historically dominated the vegetation across nearly all uplands regardless of soil type or moisture (excluding wetlands), and longleaf pine forests were among the most valuable economic resources in the region at the turn of the century (Bray 1906).

Dynamics: Frequent fire was the predominant natural disturbance in this system, which is now dependent on management with prescribed fire. The importance of frequent surface fire (every 1-5 years) has been widely accepted for the perpetuation of this system (Stambaugh et al. 2011a and others). Fires are usually low in intensity overall, consuming only shrubs and herbs, but will occasionally kill patches of young pine regeneration and rarely kill individual older trees. Historically, individual fires covered extensive areas. This high fire frequency is dependent on the presence of fine fuels in the form of grasses and pine leaf litter. This ecological system is also affected by hurricane and tornado occurrences every 200 +/- years. In mature stands, competition between pine and hardwood trees is also a factor in maintaining species composition.

Component Associations:
- *(Pinus palustris) - Quercus stellata - Quercus marilandica - Carya texana / Tragia urens* Woodland (CEGL007907, G2)
- *Pinus palustris - Pinus (echinata, taeda) - Quercus (incana, margarettiae) / Schizachyrium scoparium* Woodland (CEGL007513, G1G2)
- *Pinus palustris - Pinus (echinata, taeda)* Upper West Gulf Coastal Plain Woodland (CEGL008482, G1?)
- *Pinus palustris - Quercus marilandica* West Gulf Woodland (CEGL008579, G2G3)

WESTERN CANADIAN BOREAL [DRY] LODGEPOLE PINE FOREST (CES105.514)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Forest and Woodland (Treed)
National Mapping Codes: ESLF 4408

CONCEPT

Summary: This ecological system encompasses forests in the upper and lower foothills subregions of Alberta, extending north and west into the adjacent foothills and lower montane zone of British Columbia, and the Boreal Highlands region of Alberta. Soils are dry to very dry, and poor. These are dry forests and woodlands dominated by *Pinus contorta*. Stands are mostly even-aged with varying densities as stand sizes depending on fire history. Small *Populus tremuloides* stands are locally present. Hybrid spruce (*Picea engelmannii X glauca*) is often scattered in the understory of most stands, however, the dominance of pine is maintained by frequent fire and a slow rate of succession. The undergrowth is dominated by *Calamagrostis rubescens, Leymus innovatus, Pleurozium schreberi*, and dwarf-shrubs *Arctostaphylos uva-ursi, Juniperus communis, Linnaea borealis, Shepherdia canadensis, Rosa acicularis, Vaccinium membranaceum*, and *Vaccinium vitis-idaea*. Drier sites have less undergrowth and more lichen cover.
Classification Comments: This system includes the former North Pacific Sub-boreal Dry Lodgepole Pine Forest (CES207.344). Apparently in recent decades, *Pinus contorta* has been expanding it's range north and west, due to a warming climate in the western boreal regions.

DISTRIBUTION

Range: Western foothill and highland regions of Alberta, extending north and west into north-central British Columbia. This system is likely to occur as far north and west as the occurrence of lodgepole pine in western Canada.
Divisions: 103:C; 105:C; 207:C

WESTERN CANADIAN BOREAL MESIC BLACK SPRUCE-LODGEPOLE PINE FOREST (CES105.515)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
National Mapping Codes: ESLF 4409

CONCEPT

Summary: This ecological system encompasses forests in the upper and lower foothills subregions of Alberta, extending north and west into adjacent foothills and northern regions of British Columbia and the Boreal Highlands region of Alberta. Elevations ranges from just over 550 m to over 1700 m (1800-5570 feet). Soils are nutrient-poor, but can range from thin and rapidly drained to clayey and poorly drained. These forests are dominated by *Picea mariana* and *Pinus contorta*. In some areas, hybrids of *Pinus banksiana* and *Pinus contorta* occur in this system. Occasionally, *Picea glauca* occurs, but is not a major component of these forests. On rapidly drained sites, shrubs include *Arctostaphylos uva-ursi, Alnus viridis ssp. crispa* (which can be dominant in some areas), *Vaccinium myrtilloides*, and *Vaccinium vitis-idaea*, with lichens. *Salix bebbiana* and *Salix scouleriana* are also commonly present, especially on plateaus. More poorly drained sites have shrubs such as *Ledum groenlandicum, Vaccinium membranaceum,* and *Vaccinium vitis-idaea*. On wetter sites, species of *Equisetum* are common. Bryophytes cover much of the ground surface, including *Hylocomium splendens, Pleurozium schreberi, Ptilium crista-castrensis*, and lichens such as *Cladina mitis*.
Classification Comments: It's unclear how far north and west this system is found, but it could occur as far northwest as Yukon Territory, the furthest extension of lodgepole pine to the north.

DISTRIBUTION

Range: This system is found in the western foothill regions of Alberta, extending north and west into north-central British Columbia. It also occurs in the Boreal Highlands region of Alberta.
Divisions: 103:C; 105:C
Nations: CA

WESTERN CANADIAN BOREAL MESIC MIXED CONIFER-HARDWOOD FOREST (CES105.510)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Forest and Woodland (Treed)
National Mapping Codes: ESLF 4340

CONCEPT

Summary: This ecological system encompasses forests in the upper and lower foothills, and Boreal Highlands subregions of Alberta, extending north and west into adjacent foothills, interior plateaus, and mountains of British Columbia, and into Yukon Territory. These are mesic to moist forests and woodlands, with soil nutrient status ranging from mesotrophic to rich. *Picea glauca* is the predominant conifer tree, with varying amounts of other trees in the upper canopy, including *Picea mariana, Picea engelmannii X glauca, Pinus contorta, Pseudotsuga menziesii, Abies lasiocarpa*, and *Larix occidentalis*. Deciduous trees form an important component of these mixed forests, although in places they are absent; species include *Populus tremuloides, Populus balsamifera*, and *Betula papyrifera*. The canopy ranges from closed to open forests, usually with a shrub understory, although some stands have only a herbaceous carpet. The hybrid *Picea engelmannii X glauca* is the dominant in interior British Columbia, but *Picea mariana* is typically a minor component. *Picea glauca* associations found in Banff, Jasper, Kootenay and Yoho national parks occur on gentle to moderate slopes and are generally very mature stands. Drier to mesic sites have shrub and herbaceous taxa such as *Arctostaphylos uva-ursi, Shepherdia canadensis, Vaccinium membranaceum, Rosa acicularis*, and *Leymus innovatus*. Moist, rich sites will have higher shrub and herb cover, with such species as *Oplopanax horridus, Alnus viridis, Ledum groenlandicum, Menziesia ferruginea, Gymnocarpium dryopteris, Aralia nudicaulis*, and *Equisetum* spp. Other common shrubs and herbs include *Dasiphora fruticosa ssp. floribunda, Lonicera involucrata, Vaccinium myrtilloides, Vaccinium vitis-idaea, Cornus canadensis, Triglochin maritima*, and *Mertensia paniculata*. Feathermosses are an important component of these mesic forests, including *Abietinella abietina (= Thuidium abietinum), Hylocomium splendens* and *Pleurozium schreberi*.
Classification Comments: In the northwest of its distribution, this system transitions to Western North American Boreal White Spruce-Hardwood Forest (CES105.106), where trees such as *Pinus contorta*, and *Abies lasiocarpa* no longer occur. This is the matrix mixed forest type of the Foothills and Highlands ecoregions of Alberta, as well as the Dry Mixedwood, and is likely to be common further west into British Columbia. To the east, this system intermingles with, and transitions to, Boreal White Spruce-Fir-Hardwood Forest (CES103.021), where *Abies balsamea* and *Pinus banksiana* replace *Abies lasiocarpa* and *Pinus contorta*. This system now includes two provisionally defined types from interior British Columbia: North Pacific Sub-boreal Mesic Subalpine Fir-Hybrid White Spruce Forest (CES207.351) and North Pacific Sub-boreal Mesic Hybrid White Spruce Forest (CES207.345).
Similar Ecological Systems:
- Western North American Boreal Mesic Birch-Aspen Forest (CES105.108)

DISTRIBUTION

Range: This system is found in the western region of Alberta, extending north and west into north-central British Columbia. It is likely to occur in Yukon Territory, where it transitions to Western North American Boreal White Spruce-Hardwood (CES105.106).

WESTERN GREAT PLAINS DRY BUR OAK FOREST AND WOODLAND (CES303.667)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Lowland [Lowland]; Forest and Woodland (Treed); F-Landscape/Medium Intensity; G-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2013; ESLF 4106; ESP 1013

CONCEPT

Summary: This system is dominated by *Quercus macrocarpa* and is found in upland areas in the northern part of the Western Great Plains. It often occurs as small to large patches on buttes, escarpments, and in foothill zones, usually on northerly-facing slopes. Other species, such as *Tilia americana* (not in the Dakotas), *Populus tremuloides, Juniperus virginiana*, and *Fraxinus* spp., may be present. The herbaceous layer can vary from sparsely to moderately vegetated and is composed of prairie grasses or woodland *Carex* spp. Shrub associates can include *Prunus virginiana*, *Corylus cornuta*, *Amelanchier alnifolia*, or *Symphoricarpos* spp. Historically, higher cover of grass species occurred as these stands were more open due to more frequent fires. Few good examples of this system likely remain because of past timber harvesting and heavy grazing. Where it occurs at elevations above 915 m (3000 feet), *Pinus ponderosa* woodlands are probably adjacent.
Classification Comments: Stands of bur oak can also be included within Central Mixedgrass Prairie (CES303.659); however, that system would only include small patches or single trees protected by fire. Any stands of bur oak or more substantial woodlands should be included within this system.
Similar Ecological Systems:
- Central Mixedgrass Prairie (CES303.659)

Related Concepts:
- Aspen: 16 (Eyre 1980) Finer. Rare but possible where it might be adjacent to Aspen Parklands.
- Aspen: 217 (Eyre 1980) Finer
- Bur Oak: 236 (Eyre 1980) Broader
- Bur Oak: 42 (Eyre 1980) Finer
- Great Plains Dry Upland Bur Oak Woodland (Rolfsmeier and Steinauer 2010) Equivalent

DESCRIPTION

Environment: This system is found in upland areas throughout the northern part of the Western Great Plains. Soils are predominately dry to mesic. It usually occurs on protected eastern or northern slopes of buttes or river valleys (Rolfsmeier and Steinauer 2010).
Vegetation: This system is typified by the predominance of *Quercus macrocarpa* constituting at least 10% of the vegetation cover in any given example of this system. Other species, such as *Tilia americana, Juniperus virginiana*, and *Fraxinus* spp., may be also present. Understory vegetation can range from sparsely vegetated to more dense and usually exemplifies the surrounding prairie grassland vegetation.
Dynamics: This system is primarily driven by fire. This system occurs in a landscape where fire is common but the sites it occupies are somewhat sheltered so fire frequency is less than the surrounding prairie uplands. Fire-return intervals have been estimated at 15-25 years (Landfire 2007a). Fire reduces woody species regeneration and shrub cover and allows prairie grasses to grow under the open tree canopy.

Component Associations:
- *Quercus macrocarpa - Populus tremuloides / Aralia nudicaulis* Forest (CEGL002065, GNRQ)
- *Quercus macrocarpa - Populus tremuloides / Corylus* spp. Woodland (CEGL002139, G4?)
- *Quercus macrocarpa / Cornus drummondii / Aralia nudicaulis* Forest (CEGL002072, G4)
- *Quercus macrocarpa / Corylus americana - Amelanchier alnifolia* Woodland (CEGL000556, G3)
- *Quercus macrocarpa / Corylus cornuta* Woodland (CEGL002137, G2G3)
- *Tilia americana - (Quercus macrocarpa) / Ostrya virginiana* Forest (CEGL002012, G3)

DISTRIBUTION

Range: This system is found throughout the northern part of the Western Great Plains Division. In Wyoming, it occurs in the Bear Lodge Mountains and around Devils Tower National Monument. In North Dakota, it is found in the Killdeer Mountains, and it may occur in the Pine Ridge region of Nebraska.

WESTERN NORTH AMERICAN BOREAL MESIC BIRCH-ASPEN FOREST (CES105.108)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Ridge/Summit/Upper Slope; Sideslope; Boreal [Boreal Subcontinental]; Intermediate Disturbance Interval; Broad-Leaved Deciduous Tree; Aspen; Betula spp.
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Long Disturbance Interval; Populus tremuloides
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: EVT 2605; ESLF 4162; ESP 1605

CONCEPT

Summary: This hardwood system is common on well-drained upland terrain on south, west, and east aspects in the boreal region of interior Alaska, and extends south and east into the territories and provinces of western Canada. It is also widespread in the boreal transition region in south-central Alaska on well-drained upland terrain. *Betula papyrifera* is typically dominant in the canopy in Alaska, but other dominants or subdominants include *Populus balsamifera* and *Populus tremuloides*. In western Alberta, *Populus tremuloides* is much more abundant, often forming extensive forests across large areas. Stands are often closed-canopied with an open shrub or herbaceous understory. Canopy cover typically ranges from 25 to 90%. Common understory species include *Alnus viridis ssp. sinuata, Arctostaphylos uva-ursi, Ledum* spp., *Vaccinium vitis-idaea, Vaccinium myrtilloides, Betula nana, Betula glandulosa, Rosa acicularis, Ribes triste, Linnaea borealis, Shepherdia canadensis,* and *Viburnum edule*. This represents a persistent, often self-replacing, hardwood system and may represent a long-term seral stage of any one of several boreal systems where white spruce is important. Spruce may be present in the canopy and, in the absence of fire, could potentially occupy the site.
Classification Comments: This system now includes what was formerly Montane Boreal Aspen-Birch Forest and Woodland (CES105.851). Exactly where this system transitions to Boreal Aspen-Birch Forest (CES103.020) is unclear, but is presumed to be somewhere east of western Alberta. It may well be that these two systems should be merged into one, with the hardwood forests of Alaska considered to be a variant of the very extensive hardwood forests of western Canada. Also, North Pacific Interior Aspen Forest (CES207.360) should probably also be merged into this system, but information about its composition is inadequate to evaluate that at this time. In Alaska, this system combines those known as Boreal Transition Hardwood and Boreal Hardwood by the Alaska Natural Heritage Program. Because this system persists on the landscape for at least 50 to 100 years, it is described as a unique system, although it also occurs as a seral stage of several ecological systems in south-central Alaska, including Western North American Boreal Treeline White Spruce Woodland (CES105.137) and Western North American Boreal White Spruce Forest (CES105.104).
Similar Ecological Systems:
- Alaska Sub-boreal Mountain Hemlock-White Spruce Forest (CES105.103)
- Alaska Sub-boreal White Spruce-Hardwood Forest (CES105.136)
- Alaska Sub-boreal White-Lutz Spruce Forest and Woodland (CES105.102)
- Western Canadian Boreal Mesic Mixed Conifer-Hardwood Forest (CES105.510)
- Western North American Boreal White Spruce-Hardwood Forest (CES105.106)

- I.B.2.c - Balsam poplar (black cottonwood) (Viereck et al. 1992) Intersecting
- Paper Birch: 252 (Eyre 1980) Intersecting

DESCRIPTION

Environment: This system occurs on rolling hills and mountain sideslopes on west, east, and south aspects. In Alaska it occurs up to 750 m (2460 feet) elevation, but in western Alberta elevations where it is found range from <300 m to over 1500 m (950-5000 feet). Soils are well-drained and develop on residual material or retransported deposits including glacial till, loess, and colluvium. Permafrost is rare on most sites.
Vegetation: *Betula papyrifera* is typically dominant in the canopy, but other dominants or subdominants include *Populus balsamifera* and *Populus tremuloides*. *Salix scouleriana* is locally common. Stands are often closed-canopied with an open shrub or herbaceous understory. Canopy cover typically ranges from 25% to 90%. Common understory species include *Alnus viridis ssp. sinuata, Ledum* spp., *Vaccinium vitis-idaea, Betula nana, Rosa acicularis, Ribes triste, Linnaea borealis, Shepherdia canadensis,* and *Viburnum edule*. Common herbaceous species include *Calamagrostis canadensis, Chamerion angustifolium, Gymnocarpium dryopteris,* and *Cornus canadensis*. Feathermosses such as *Hylocomium splendens* and *Pleurozium schreberi* are common in the ground layer (Boggs and Sturdy 2005).

Dynamics: These deciduous forests originate naturally after fires and blowdowns, or after logging of conifer or mixed conifer-hardwood systems. This system is maintained by repeated disturbance within 50- to100-year return intervals and would otherwise succeed to conifer systems. This system often acts as a firebreak and has a longer fire-return interval than white and black spruce sites. On drier sites, *Populus tremuloides* or *Betula papyrifera* can persist and be self-replacing. Fire regimes prevent spruce the opportunity of reoccupying a site. Since this system represents a long-term seral stage of Alaska Sub-boreal White Spruce-Hardwood Forest (CES105.136) and Alaska Sub-boreal White-Lutz Spruce Forest and Woodland (CES105.102) (and less frequently Alaska Sub-boreal Mountain Hemlock-White Spruce Forest (CES105.103)), the disturbance regime is the same as those defined for these systems.

DISTRIBUTION

Range: This system occurs in the boreal and boreal transition regions of Alaska. It extends east and south into the western boreal regions of Canada in British Columbia and Alberta.

WESTERN NORTH AMERICAN BOREAL MESIC BLACK SPRUCE FOREST (CES105.107)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Boreal [Boreal Subcontinental]; Acidic Soil; Long Disturbance Interval; Picea mariana
Non-Diagnostic Classifiers: Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Alluvial fan; Alluvial terrace; Mineral: W/ A-Horizon >10 cm
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2604; ESLF 4287; ESP 1604

CONCEPT

Summary: This ecological system is common throughout upland slopes and inactive alluvial deposits in the boreal region of Alaska east into Yukon Territory, and east into the western provinces and territories of Canada. It is widespread in south-central Alaska on well-drained sites, including old alluvial plains, abandoned floodplains, and inactive terraces. Soils are well-drained, and permafrost may be absent. The *Picea mariana* forests in the Northern Rockies represent the southernmost extent of these expansive boreal forests. The southern limit appears to be related to July mean temperatures exceeding 65 degrees F and maximum of 75 degrees F, and where annual precipitation drops below 38-50 cm (15-20 inches). *Picea mariana* is typically the dominant species in mature stands, though *Picea glauca* may be codominant on some sites. Common understory species include *Vaccinium vitis-idaea*, *Empetrum nigrum*, and *Linnaea borealis*. Feathermosses (*Hylocomium splendens* and *Pleurozium schreberi*) are common in mature stands. Lichens may be an important component in late-seral stages. In the eastern part of its range, it intermingles with and transitions to Western Canadian Boreal Mesic Black Spruce-Lodgepole Forest (CES105.515) and Western Canadian Boreal Mesic Mixed Conifer-Hardwood Forest (CES105.510).
Classification Comments: This system combines those known as Boreal Transition Mesic Black Spruce and Boreal Mesic Black Spruce by the Alaska Natural Heritage Program. Lowland black spruce sites with peat soils are classified with wetland systems, and those with a tussock-dominated understory are classified with black spruce tussock. The full extent of upland black spruce forests into eastern Canada is uncertain. In western Alberta, pure upland black spruce forest is uncommon. In that region, black spruce is more commonly mixed with *Pinus contorta*, forming Western Canadian Boreal Mesic Black Spruce-Lodgepole Pine Forest (CES105.515).
Similar Ecological Systems:
- Montane Boreal White and Black Spruce Forest (CES105.800)

- I.A.2.g - Black spruce-white spruce (open) (Viereck et al. 1992) Finer

DESCRIPTION

Environment: This system occurs on well-drained to moderately well-drained sites in the boreal transition region, including old alluvial fans, abandoned floodplains, and inactive terraces and is widespread on uplands (all aspects) and inactive alluvial surfaces in boreal Alaska. Soils are well-drained, gravelly and feature shallow to moderately deep organic horizons. Black spruce occurs up to treeline where it may be stunted due to cold temperatures (Chapin et al. 2006). On most sites there is little to no peat development, but there may be an organic layer derived from non-sphagnum mosses. Permafrost is usually absent except on shallow soils over bedrock and coarse alluvium (Viereck et al. 1992); however, once a well-developed feathermoss layer is established, permafrost begins forming.
Vegetation: In mature stands, *Picea mariana* is the dominant overstory species, though *Picea glauca* may be codominant. Total tree cover in mature stands typically ranges from 40-70%. Early-successional stands may be dominated by *Betula papyrifera* or *Populus tremuloides*. *Populus tremuloides* replaces *Betula papyrifera* on drier sites (Foote 1983, Chapin et al. 2006). Common understory shrubs include *Betula nana*, *Ledum* spp., *Rosa acicularis*, *Vaccinium uliginosum*, *Vaccinium vitis-idaea*, and *Empetrum nigrum*. Herbaceous species include *Calamagrostis canadensis* and *Equisetum* spp. Feathermosses (*Hylocomium splendens* and *Pleurozium schreberi*) are common in mature stands (Jorgenson et al. 2003). Lichens, such as *Cladina* spp., may be an important component in late-seral stages (Klein 1982).
Dynamics: In the boreal transition region, the disturbance regime is characterized by crown fires or ground fires of enough intensity to kill overstory trees. Mean fire-return interval estimates for this system have not been defined, but estimates for similar sites from boreal Alaska range from 25 to 100 years (Rowe et al. 1974, Heinselman 1978, 1981, Viereck 1983, 1986, Yarie 1983, De Volder

1999 [Kenai Lowland including human-caused]). It is likely that the natural fire-return interval is longer than those estimated for boreal sites due to less frequent lightning strikes. A "best guess" for this system without human disturbance has been estimated at 170 years (FRCC experts pers. comm. 2004).

Post-fire succession can be self-replacement to black spruce or to hardwood before returning to black spruce. Seasonality affects burn severity. An early-season burn can kill the overstory without affecting the ground layer, but a late-season burn can reduce the duff layer and kill the understory plants. *Calamagrostis* is not a major factor in boreal transition black spruce succession.

The disturbance regime in the boreal region is characterized by large crown fires or ground fires of enough intensity to kill overstory trees. Mean fire-return interval estimates in boreal Alaska range from 25 to 130 years (Rowe et al. 1974, Heinselman 1978, 1981, Viereck 1983, 1986, Yarie 1983). The post-fire successional trajectory may be self-replacement, with black spruce following the early-seral herb-shrub stage. Alternatively, hardwood or black spruce-hardwood may follow the early-seral stage before returning to black spruce (Chapin et al. 2006).

DISTRIBUTION

Range: This system is found in the subarctic regions of Alaska and northern Yukon Territory, and the North Pacific Coast of south-central Alaska. It also occurs in northern British Columbia, and further east into Alberta and the Northwest Territories.

WESTERN NORTH AMERICAN BOREAL SPRUCE-LICHEN WOODLAND (CES105.105)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Boreal [Boreal Subcontinental]; Very Shallow Soil; Lichen
Non-Diagnostic Classifiers: Picea glauca; Picea mariana
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2602; ESLF 4288; ESP 1602

CONCEPT

Summary: This system occurs primarily in the northern and western portion of boreal Alaska (west, northeast and northwest boreal) and less commonly in the western and southwestern boreal transition (Nulato Hills and Ahklun Mountains). These are cool dry sites on well-drained to excessively well-drained substrates. Soils are thin and develop on gravels, sandy loess deposits, or bedrock and are likely free of permafrost. Forest canopy is dominated by *Picea glauca* or *Picea mariana*, and cover is generally between 10% and 25%. The shrub layer is open and typically features low and dwarf-shrubs including *Betula nana, Shepherdia canadensis, Arctostaphylos rubra, Arctostaphylos uva-ursi, Vaccinium uliginosum*, or *Empetrum nigrum*. Lichens (primarily *Cladina* spp.) are an important component of the understory in mature stands. Feathermosses are not as important as in other white spruce systems.
Classification Comments: The successional relationships of this system are poorly understood. It could be a late-successional stage of boreal white spruce (self-replacement model), or a possible late-successional stage of boreal and boreal transition white spruce woodland. The range overlaps with the area identified for self-replacement spruce (Noatak, Nulato Hills, northeast taiga: Porcupine, Chandalar, Sheenjek drainages). This system is known as Boreal Spruce Lichen Woodland by the Alaska Natural Heritage Program.

- I.A.3.e - Black spruce-white spruce (woodland) (Viereck et al. 1992) Finer. low shrub or lichen understory

DESCRIPTION

Environment: This system occurs on cool dry sites on well-drained to excessively well-drained substrates. Soils are thin and develop on gravels, sandy loess deposits, or bedrock and are likely free of permafrost.
Vegetation: Forest canopy is dominated by *Picea glauca* or *Picea mariana*, and cover is generally between 10% and 25%. The shrub layer is open and typically features low and dwarf-shrubs including *Betula nana, Shepherdia canadensis, Arctostaphylos rubra, Arctostaphylos uva-ursi, Vaccinium uliginosum*, or *Empetrum nigrum*. Lichens (primarily *Cladina* spp.) are an important component of the understory in mature stands. Feathermosses are not as important as in other white spruce systems.

DISTRIBUTION

Range: This system occurs in the boreal and, less commonly, boreal transition regions of Alaska. It is most common in the northern and western portion of the boreal region and also occurs in the western and southwestern portion of the boreal transition region (Nulato Hills and Ahklun Mountains).
Divisions: 105:C

WESTERN NORTH AMERICAN BOREAL SUBALPINE BALSAM POPLAR-ASPEN WOODLAND (CES105.110)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Slope; Boreal [Boreal Subcontinental]; Populus tremuloides; Populus balsamifera
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2607; ESLF 4163; ESP 1607

CONCEPT

Summary: Stands of *Populus balsamifera ssp. balsamifera* and *Populus tremuloides* occur along south-facing upper slopes with trees generally persisting in smaller size classes (seedling, sapling and pole). Clones often grow above the elevation limit of *Picea glauca* and into the subalpine zone. This system occurs commonly throughout the mountain ranges of south-central Alaska and also near the northern and western limit of the boreal region, and may be advancing in some areas. Small stands of *Populus balsamifera* occur on the north slope of the Brooks Range on valley bottoms and on sideslopes.
Classification Comments: *Populus balsamifera* stands in the Brooks Range are considered part of this system. This system is known as Boreal Subalpine Balsam Poplar (Aspen) by the Alaska Natural Heritage Program.
Related Concepts:
- I.B.1.c - Balsam poplar (forest) (Viereck et al. 1992) Intersecting
- I.B.2.b - Quaking aspen (open) (Viereck et al. 1992) Intersecting
- I.B.2.c - Balsam poplar (black cottonwood) (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: This system occurs on well-drained upland terrain on southerly aspects on upper slopes to treeline. In the upper elevational range of this system, it can occur in the subalpine zone above the coniferous treeline. Soils are generally well-drained, shallow, and develop on colluvial deposits, glacial till, or bedrock.
Vegetation: *Populus balsamifera ssp. balsamifera* and/or *Populus tremuloides* are dominant in the canopy. Common understory shrubs include *Viburnum edule, Rosa acicularis, Arctostaphylos* spp., and *Salix* spp. A wide variety of herbaceous species may occur, including *Calamagrostis canadensis, Pyrola* spp., and *Aconitum delphiniifolium* (Viereck 1979, Jorgenson et al. 2003).
Dynamics: The disturbance dynamics of these high-elevation forests are unclear. Stands are often small patch and can occur beyond the coniferous treeline. Wind/exposure could be a driving disturbance process.

DISTRIBUTION

Range: This system occurs beyond the coniferous treeline in western and northern Alaska (boreal and boreal transition regions).
Divisions: 104:C; 105:C; 204:C
Nations: US
Subnations: AK
Map Zones: 68:C, 69:C, 70:C, 71:C, 72:P, 73:C, 74:C, 75:C, 76:P
TNC Ecoregions: 70:C, 71:C, 76:C, 77:C, 78:C, 79:C

WESTERN NORTH AMERICAN BOREAL TREELINE WHITE SPRUCE WOODLAND (CES105.137)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Boreal [Boreal Subcontinental]; Picea glauca
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2601; ESLF 4289; ESP 1601

CONCEPT

Summary: This ecological system occurs primarily near the elevational and latitudinal limits of white spruce tree growth. Soils are cold, but peat-forming mosses are not common in the ground layer. Forest canopy is dominated by *Picea glauca* and cover is generally between 10% and 25% (40%). In some locations *Alnus viridis* is the dominant understory shrub. The shrub layer typically features *Betula nana*, but other low shrubs such as *Vaccinium uliginosum, Ledum groenlandicum*, and *Salix* spp. may be common or dominant. In the western and southwestern portions of the boreal transition region, lichens are commonly abundant in the understory.
Classification Comments: This system combines those known as Boreal White Spruce Woodland and Boreal Transition White Spruce Woodland by the Alaska Natural Heritage Program. It has some similarity and overlap with Western North American Boreal Spruce-Lichen Woodland (CES105.105); need to define differences or merge. This system occupies the elevational zone above white spruce and below subalpine shrub and tundra systems and can be seen as the transition zone between boreal white spruce forest and non-forested alpine vegetation. Depending on the topography, this system can occupy a narrow band just below non-forested subalpine or a broad expanse across gentle slopes and benches. This system also occurs at lower elevations near the western limit of white spruce.
Similar Ecological Systems:
- Western North American Boreal Spruce-Lichen Woodland (CES105.105)
- Western North American Boreal White Spruce Forest (CES105.104)

Related Concepts:
- I.A.3.c - White spruce (woodland) (Viereck et al. 1992) Intersecting. AKVC includes lichen

DESCRIPTION

Environment: This system occupies the forested transition zone between boreal white spruce forest and alpine or tundra systems. Soils are cold and permafrost may be present. The topography includes sideslopes, rolling hills, and relatively level terrain.
Vegetation: This system occurs primarily near the elevational and latitudinal limits of tree growth. Forest canopy cover is dominated by *Picea glauca* and is generally between 10% and 25%. *Picea mariana* may be codominant in the overstory on some sites. The shrub layer typically features *Betula nana*, but other shrubs such as *Vaccinium uliginosum*, *Ledum groenlandicum*, and *Salix pulchra* may be common or dominant. In some locations, *Alnus viridis* is the dominant understory shrub. Feathermosses may be common in the ground layer, but peat-forming mosses are not common. On drier or more exposed sites, *Cladina* spp. replace feathermosses as the dominant ground cover (Viereck 1979).
Dynamics: A possible scenario for post-fire succession in this system is the resprouting of low shrubs from underground propagules and *Picea glauca* then invading by seed from adjacent stands or surviving trees. *Betula papyrifera* may invade the site if a seed source is available and site conditions are favorable, but the hardwood phase only occurs in a small fraction of the landscape (may be more common in southwestern Alaska). The typical seral sequence does not generally include a hardwood sere. The rate of succession depends on severity of fire and seed source, and some sites may be shrub-dominated for long periods without spruce invasion. Spruce beetles can be a major disturbance in this system in boreal transition region.

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Western North American Boreal Mesic Scrub Birch-Willow Shrubland (CES105.113)

DISTRIBUTION

Range: This system occurs in the boreal and boreal transition regions of Alaska, although it is not common in the Kenai Mountains where *Tsuga mertensiana* dominates treeline forest systems.
Divisions: 105:C
Nations: US
Subnations: AK
Map Zones: 68:C, 69:C, 70:C, 71:C, 72:C, 73:C, 74:C, 75:C, 76:C

WESTERN NORTH AMERICAN BOREAL WHITE SPRUCE FOREST (CES105.104)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Boreal [Boreal Subcontinental]; F-Landscape/High Intensity; Picea glauca; Feathermosses
Non-Diagnostic Classifiers: Esker; Montane; Lowland [Foothill]; Lowland [Lowland]; Kame; Kame moraine; Kettle; Loess deposit (undifferentiated); Moraine; Very Long Disturbance Interval; Sphagnum spp.; Drumlin
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Evergreen closed tree canopy
National Mapping Codes: EVT 2600; ESLF 4290; ESP 1600

CONCEPT

Summary: This ecological system is common throughout interior Alaska and extends south and eastward into adjacent provinces and territories of Canada into western Alberta. The montane *Picea glauca* forests in the Northern Rockies represent the southernmost extent of these expansive boreal forests. The southern limit appears to be related to July mean temperatures exceeding 65 degrees F and maximum of 75 degrees F, and where annual precipitation drops below 38-50 cm (15-20 inches). The landscape is typically rolling hills formed by drumlins, kettle-kame, stabilized dunes, moraines, lacustrine deposits, loess deposits, eskers, and bedrock outcrops and sometimes mountain slopes. This system is composed of multi-aged stands of *Picea glauca* and the subdominants *Betula papyrifera*, *Populus tremuloides*, and *Picea mariana*. *Picea glauca* associations found in Banff, Jasper, Kootenay and Yoho national parks occur on gentle to moderate slopes and are generally very mature stands. Mature stands are often open-canopied with a well-developed shrub layer. Common understory shrubs include *Rosa acicularis, Viburnum edule, Ledum palustre ssp. decumbens, Ledum groenlandicum, Arctostaphylos uva-ursi, Vaccinium vitis-idaea, Vaccinium uliginosum, Empetrum nigrum, Betula nana*, and *Linnaea borealis*. Common herbaceous species include *Geocaulon lividum, Pyrola* spp., *Equisetum sylvaticum, Equisetum arvense*, and *Mertensia paniculata*. Feathermosses such as *Abietinella abietina, Hylocomium splendens*, and *Pleurozium schreberi* are common in the ground layer (Boggs and Sturdy 2005). The disturbance regime is characterized by large crown fires, though other disturbances, such as insect infestations and blowdown are common.
Classification Comments: It's unclear how white spruce forests in Alaska and western Canada transition to white spruce in the central Canadian boreal regions. It may be that this system is really North American boreal-wide, extending from Alaska east into eastern Canada. White spruce forests and woodlands in Alaska have been placed into Western North American Boreal White Spruce Forest (CES105.104), Western North American Boreal Treeline White Spruce Woodland (CES105.137), or Western North American Boreal Spruce-Lichen Woodland (CES105.105). In Alberta and British Columbia, where *Picea glauca* is mixed with more Rocky Mountain conifers, such as *Abies lasiocarpa, Pinus contorta, Picea engelmannii*, and *Picea engelmannii X glauca*, they are considered to belong to Western Canadian Boreal Mesic Mixed Conifer-Hardwood Forest (CES105.510).
Similar Ecological Systems:
- Alaska Sub-boreal White Spruce-Hardwood Forest (CES105.136)
- Alaska Sub-boreal White-Lutz Spruce Forest and Woodland (CES105.102)
- Montane Boreal White and Black Spruce Forest (CES105.800)
- Western North American Boreal Spruce-Lichen Woodland (CES105.105)
- Western North American Boreal Treeline White Spruce Woodland (CES105.137)
- Western North American Boreal White Spruce-Hardwood Forest (CES105.106)

Related Concepts:
- I.A.1.j - White spruce (closed) (Viereck et al. 1992) Intersecting
- I.A.2.e - White spruce (open) (Viereck et al. 1992) Intersecting
- White Spruce: 201 (Eyre 1980) Intersecting

DESCRIPTION

Environment: This system occurs on well-drained rolling hills, inactive terraces, and mountain sideslopes up to the alpine. Soils are typically derived from glacial or other depositional processes and include moraines, drumlins, eskers, kettle-kame, colluvium, and loess deposits. This system is common on all aspects except north. Permafrost is rare.
Vegetation: Canopy cover in mature stands is dominated by *Picea glauca* and typically ranges from 25% to 70% (Boggs and Sturdy 2005). Other trees such as *Picea mariana, Betula papyrifera*, and *Populus tremuloides* may be subdominant in the overstory, but *Picea glauca* contributes at least 75% of the total forest canopy. Mature stands are often open-canopied with a well-developed shrub layer. Common understory shrubs include *Rosa acicularis, Viburnum edule, Ledum palustre ssp. decumbens, Ledum groenlandicum, Arctostaphylos uva-ursi, Vaccinium vitis-idaea, Vaccinium uliginosum, Empetrum nigrum, Betula nana*, and *Linnaea borealis*. Common herbaceous species include *Geocaulon lividum, Pyrola* spp., *Equisetum sylvaticum, Equisetum arvense*, and *Mertensia paniculata*. Feathermosses such as *Hylocomium splendens* and *Pleurozium schreberi* are common in the ground layer (Boggs and Sturdy 2005).

Dynamics: The disturbance regime is characterized by large crown fires with estimates of mean fire-return intervals ranging from 50 to 238 years (Rowe 1972, Heinselman 1981, Yarie 1981, 1983, Foote 1983, Duchesne and Hawkes 2000). On light to moderate burns, pre-burn species colonize the site via rhizomes, root sprouts and trunk sprouts. A variety of herbaceous communities dominate, primarily *Chamerion angustifolium ssp. angustifolium* and *Calamagrostis canadensis*. *Betula papyrifera, Populus tremuloides*, or *Picea glauca* may individually invade and dominate sites. *Picea glauca* eventually gains dominance over broad-leaved tree species. In severe fires, the organic layer is consumed, killing the underground propagules, and revegetation of the site is by seed. At higher latitudes, *Betula papyrifera* and *Populus tremuloides* are often absent from the early-seral forests, and succession progresses from herbaceous to shrub to spruce. Successional trajectories vary regionally across the boreal region. For example, around Fairbanks, spruce stands typically go through a hardwood sere before going to spruce; in the Yukon Charley region, stands often do not go through a hardwood sere.

DISTRIBUTION

Range: This sytems is found throughout interior Alaska and extends south and eastward into adjacent provinces and territories of Canada into western Alberta.

WESTERN NORTH AMERICAN BOREAL WHITE SPRUCE-HARDWOOD FOREST (CES105.106)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Forest and Woodland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Aridic; Unconsolidated
Non-Diagnostic Classifiers: Lowland [Foothill]; Boreal [Boreal Subcontinental]; Deep Soil
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Mixed evergreen-deciduous closed tree canopy
National Mapping Codes: EVT 2603; ESLF 4335; ESP 1603

CONCEPT

Summary: This system is common on well-drained upland terrain on south, west, and east aspects. *Picea glauca* codominates with *Betula papyrifera* and/or *Populus tremuloides*, and the mixed stands are persistent for over 75 years.
Classification Comments: This system is known as Boreal White Spruce-Hardwood by the Alaska Natural Heritage Program. This system is similar to a mid-seral stage of Western North American Boreal White Spruce Forest (CES105.104).
Similar Ecological Systems:
- Alaska Sub-boreal White-Lutz Spruce Forest and Woodland (CES105.102)
- Montane Boreal White and Black Spruce Forest (CES105.800)
- Western North American Boreal Mesic Birch-Aspen Forest (CES105.108)
- Western North American Boreal White Spruce Forest (CES105.104)

Related Concepts:
- I.C.1.a - Spruce paper birch (Viereck et al. 1992) Intersecting
- I.C.1.c - Spruce-paper birch-quaking aspen (Viereck et al. 1992) Finer
- I.C.2.a - Spruce-paper birch (open) (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: This system occurs on rolling hills, inactive terraces, and mountain sideslopes up to 750 m elevation. Soils are typically well-drained and derived from glacial or other depositional processes and include moraines, drumlins, eskers, kettle-kame, colluvium, alluvial fan, floodplains, and loess deposits. This system is common on all aspects except north. Permafrost is rare on most sites; inclusions of wet mixed forest on loamy soils underlain by permafrost also occur (Jorgenson et al. 1999).
Vegetation: Canopy cover is dominated by *Picea glauca* and *Betula papyrifera* and typically ranges from 25% to 80%. *Populus tremuloides* or *Populus balsamifera* may be codominant in the hardwood component. The understory is open shrub or herbaceous. Common understory species include *Alnus* spp., *Ledum* spp., *Vaccinium vitis-idaea, Betula nana, Rosa acicularis, Shepherdia canadensis*, and *Viburnum edule*. Feathermosses such as *Hylocomium splendens* and *Pleurozium schreberi* are common in the ground layer (Boggs and Sturdy 2005). Common understory species on wet sites include *Calamagrostis canadensis* and *Equisetum* spp. (Jorgenson et al. 1999).
Dynamics: After fire, this system returns more quickly to mixed hardwood-spruce than the white spruce system.

DISTRIBUTION

Range: This system is found in the Boreal region of Alaska.
Divisions: 105:C
Nations: US
Subnations: AK

UPLAND SHRUBLAND

ACADIAN-APPALACHIAN ALPINE TUNDRA (CES201.567)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino; Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Ridge/Summit/Upper Slope
Non-Diagnostic Classifiers: Long (>500 yrs) Persistence; Glaciated; Oligotrophic Soil; Acidic Soil; Very Shallow Soil; Aquic; Udic; Consolidated; Landslide; W-Landscape/High Intensity; Dwarf-Shrub; Graminoid; Lichen
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Mixed evergreen-deciduous dwarf-shrubland
National Mapping Codes: EVT 2386; ESLF 5210; ESP 1386

CONCEPT

Summary: Restricted to the Northern Appalachians and the Gaspe Peninsula, this system encompasses vegetation above treeline on northeastern mountains. In New Hampshire, climatic treeline occurs at 1495 m (4900 feet) or greater in elevation, following the 10- to 12-degree Celsius July isotherm, but can also occur at lower elevations with high wind exposure, fire history, or shallow soils. Wind, snow, and cloud-cover fog are prominent environmental factors. Most of the cover is dwarf-shrubland, lichen, or sparse vegetation; islands of taller shrubs may occur in protected spots. The dominant plants are ericads (*Vaccinium uliginosum* is diagnostic and often dominant, with several other alpine-restricted ericads such as *Phyllodoce caerulea* and *Loiseleuria procumbens*) and cushion-plants such as *Diapensia lapponica*. *Carex bigelowii* is a characteristic and, in some places, locally dominant sedge. This system includes wetland depressions, small alpine bogs, within the surrounding upland matrix.

Related Concepts:
- Alpine Cliff (Gawler and Cutko 2010) Finer
- Bilberry - Mountain-Heath Alpine Snowbank (Gawler and Cutko 2010) Finer
- Cotton-grass - Heath Alpine Bog (Gawler and Cutko 2010) Finer
- Diapensia Alpine Ridge (Gawler and Cutko 2010) Finer
- Dwarf Heath - Graminoid Alpine Ridge (Gawler and Cutko 2010) Finer

DESCRIPTION

Environment: This system is restricted to high elevations above climatic treeline, ranging from 1460 m (4900 feet) in New Hampshire to 730 m (2400 feet) at Gros Morne National Park in Labrador.
Dynamics: Low temperature, snow accumulation, atmospheric moisture, topography, aspect, and degree of exposure to wind are the primary agents of disturbance to these systems. The degree of wind exposure and snow accumulation is directly related to topographic position. Summits and steep slopes are exposed to high winds, and receive less snow accumulation than more gentle slopes. Ravines collect abundant snowpack, which serves to protect the underlying plants from extreme weather conditions well into the spring (Sperduto and Kimball 2011). The alpine - treeline ecotone is controlled by a variety of climate variables; exposure as a result of topography and mechanical damage caused by ice and wind appear to be largely responsible for the ecotone (Kimball and Weihrauch 2000).

Component Associations:
- *Arctoparmelia centrifuga - Rhizocarpon geographicum* Nonvascular Vegetation (CEGL006420, G3G4)
- *Carex bigelowii* Herbaceous Vegetation (CEGL006081, G2)
- *Diapensia lapponica* Dwarf-shrubland (CEGL006322, G2G3)
- *Empetrum nigrum - Vaccinium uliginosum - Vaccinium oxycoccos / Rubus chamaemorus* Dwarf-shrubland (CEGL006140, GNR)
- *Kalmia angustifolia - Chamaedaphne calyculata / Rubus chamaemorus / Cladina* spp. Dwarf-shrubland (CEGL006425, GNR)
- *Trichophorum caespitosum - Calamagrostis pickeringii* Herbaceous Vegetation (CEGL006423, GNR)
- *Trichophorum caespitosum - Carex scirpoidea - Carex bigelowii* Herbaceous Vegetation (CEGL006424, GNR)
- *Trichophorum caespitosum - Saxifraga (foliolosa, paniculata, rivularis)* Herbaceous Vegetation (CEGL006428, GNR)
- *Vaccinium uliginosum - Harrimanella hypnoides - Loiseleuria procumbens* Dwarf-shrubland (CEGL006155, G2G3)
- *Vaccinium uliginosum - Rhododendron lapponicum / Juncus trifidus* Dwarf-shrubland (CEGL006298, G2G3)
- *Vaccinium uliginosum / Sibbaldiopsis tridentata* Sparse Vegetation (CEGL006533, GNR)

DISTRIBUTION

Range: This system is found at higher summits of the northern Appalachian Mountains, from northern New England and the Adirondacks into the Canadian maritimes, including Labrador, Nova Scotia and the GaspÃ© Peninsula.

ACADIAN-APPALACHIAN SUBALPINE WOODLAND AND HEATH-KRUMMHOLZ (CES201.568)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Alpine/AltiAndino; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Picea (glauca, mariana, rubens) - Abies
Non-Diagnostic Classifiers: Long (>500 yrs) Persistence; Montane; Forest and Woodland (Treed); Moss/Lichen (Nonvascular); Glaciated; Mesotrophic Soil; Oligotrophic Soil; Acidic Soil; Very Shallow Soil; Shallow Soil; Mineral: W/ A-Horizon >10 cm; Mineral: W/ A-Horizon <10 cm; Udic; Consolidated; Intermediate Disturbance Interval; Long Disturbance Interval; F-Patch/Medium Intensity; W-Landscape/High Intensity; Needle-Leaved Tree; Broad-Leaved Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2389; ESLF 5320; ESP 1389

CONCEPT

Summary: This ecological system encompasses vegetation of varying physiognomy at upper elevations, near and slightly above treeline, in the northeastern U.S. and adjacent Canada. It may be a zone between montane spruce-fir forest and alpine systems or may cover the ridgelines and summits of lower mountains. In the Appalachians it occurs mostly above 915 m (3000 feet) elevation but can be at much lower elevations near the Atlantic Coast. Trees become progressively stunted as exposure increases, with *Picea rubens* being replaced by *Picea mariana* in a stunted form. Vegetation structure ranges from woodland to shrubland to sparsely vegetated dwarf-shrubs and herbs. Woodlands may be locally extensive, and patches of open rock support areas of shrub, dwarf-shrub or sparse vegetation. In the subalpine zone, shrublands may be extensive on the upper slopes, forming krummholz or, in somewhat more protected spots, deciduous shrub thickets. Ericads, including *Kalmia angustifolia, Ledum groenlandicum,* and *Vaccinium uliginosum*, are the most characteristic shrubs; *Empetrum nigrum* and *Empetrum eamesii ssp. atropurpureum (= Empetrum atropurpureum)* are indicative of the subalpine zone. *Vaccinium boreale* occurs rarely but is diagnostic where it is present. Subalpine fens are included here: these are heath-dominated and graminoid-dominated fens, often occurring in a mosaic surrounded by other subalpine vegetation. They are on gentle slopes (usually about 10%), usually at 732 to 915 m (2400-3000 feet) elevation. *Calamagrostis pickeringii* is dominant and characteristic in the graminoid fens, with northern sedges such as *Carex michauxiana, Carex wiegandii, Carex exilis*, etc. The montane heath fens contain *Alnus viridis ssp. crispa (= Alnus crispa), Nemopanthus mucronatus*, and ericads. Peat accumulation is in the range of 10-50 cm. Occurrences are usually about 5 acres in size but range up to about 20 acres.
Classification Comments: This system is distinguished from Acadian-Appalachian Montane Spruce-Fir Forest (CES201.566) by the shift to woodland and patchy barrens from the forested character of the montane forest, including the decreased importance of *Picea rubens*. They are often contiguous on the ground. It is related to Northern Appalachian-Acadian Rocky Heath Outcrop (CES201.571) but occurs at higher elevations, lacks *Pinus* spp. (except for occasional stunted individuals) and *Quercus rubra*, and features *Vaccinium uliginosum, Empetrum* and other subalpine plant species that are lacking from the lower-elevation analog. Patches of *Picea rubens / Vaccinium angustifolium / Sibbaldiopsis tridentata* Woodland (CEGL006053) might occur in this system, but only incidentally; that association is more central to the concept of Northern Appalachian-Acadian Rocky Heath Outcrop (CES201.571). At Acadia National Park, this system could be attributed to the highest balds if *Empetrum* and/or *Vaccinium uliginosum* are present, representing a low-elevation disjunction; Northern Appalachian-Acadian Rocky Heath Outcrop (CES201.571) is the common system on Acadia's bald hills. Subalpine fens are considered a distinct system by New Hampshire Natural Heritage Program (the only state where they are currently known to occur), but because (1) there is little information currently available on them and (2) they tend to occur below treeline, they are included within this system. This could be reconsidered as more information on their landscape distribution, extent and pattern becomes available.
Similar Ecological Systems:
- Acadian-Appalachian Montane Spruce-Fir Forest (CES201.566)
- Northern Appalachian-Acadian Rocky Heath Outcrop (CES201.571)

ALASKA ARCTIC ACIDIC DRYAS DWARF-SHRUBLAND (CES104.173)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Polar [Polar Continental]; Acidic Soil; Dryas integrifolia and/or Dryas octopetala
Non-Diagnostic Classifiers: Ridge/Summit/Upper Slope; Sideslope
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2688; ESLF 5101; ESP 1688

CONCEPT

Summary: This is a common system on acidic substrates (pH typically <6) in the hills and mountains of arctic Alaska. This system does not occur in the arctic lowlands. Common slope positions include valleys, sideslopes, and summits and ridges. Sites are typically dry to mesic and are uncommon on late-lying snowbeds. Patch size is small to large. Dwarf-shrub cover is >25% and dominated by *Dryas* spp. (primarily *Dryas octopetala*). Other common shrubs include *Empetrum nigrum, Vaccinium uliginosum, Dryas integrifolia, Loiseleuria procumbens*, and *Salix phlebophylla*. Common herbaceous species include *Antennaria alpina, Hierochloe alpina, Minuartia obtusiloba, Carex scirpoidea, Carex podocarpa, Carex microchaeta*, and *Festuca altaica*. Mosses such as *Tortula ruralis* and *Polytrichum* spp. may be common. Lichens include *Cladina* spp., *Sphaerophorus globosus, Nephroma arcticum, Flavocetraria* spp., and *Alectoria ochroleuca*. In the Bering Land Bridge National Preserve and Cape Krusenstern National Monument (Jorgenson et al. 2004), this system differs from non-acidic *Dryas* by lacking the calciphilic species *Saxifraga oppositifolia, Potentilla uniflora, Hedysarum boreale ssp. mackenziei (= Hedysarum mackenziei)*, and *Oxytropis nigrescens*.
Classification Comments: This system is known as Acidic *Dryas* by the Alaska Natural Heritage Program.

ALASKA ARCTIC ACIDIC DWARF-SHRUB LICHEN TUNDRA (CES104.177)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Extreme Wind Exposure; Polar [Polar Continental]; Acidic Soil; Dwarf-Shrub; Lichen
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Sideslope; Very Long Disturbance Interval
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2691; ESLF 5102; ESP 1691

CONCEPT

Summary: This is a common system on acidic substrates in the hills and mountains of arctic Alaska. This system does not occur in arctic lowlands. Common slope positions include valleys, sideslopes, and summits and ridges. Sites are typically dry to mesic, exposed to the wind, and accumulate little winter snow. Patch size is small to large. Dwarf-shrub cover is >25%, and lichen cover is >25%. The dominant lichens are *Cladina rangiferina* and/or *Cladina stellaris*. Common dwarf-shrubs include *Dryas octopetala, Empetrum nigrum, Vaccinium uliginosum, Dryas integrifolia, Salix phlebophylla, Antennaria alpina, Hierochloe alpina, Festuca altaica*, and *Carex microchaeta*. Mosses may be present but contribute little cover.
Classification Comments: This system is known as Acidic Dwarf Shrub Lichen by the Alaska Natural Heritage Program.

DESCRIPTION

Environment: This is a common system on acidic substrates in the hills and mountains of arctic Alaska. This system does not occur in arctic lowlands. Common slope positions include valleys, sideslopes, and summits and ridges. Sites are typically dry to mesic, exposed to the wind, and accumulate little winter snow (Viereck et al. 1992). Patch size is small to large.
Vegetation: Dwarf-shrub cover is >25%, and lichen cover is >25%. The dominant lichens are *Cladina rangiferina* and/or *Cladina stellaris*. Common dwarf-shrubs include *Dryas octopetala, Empetrum nigrum, Vaccinium uliginosum, Dryas integrifolia, Salix phlebophylla, Antennaria alpina, Hierochloe alpina, Festuca altaica*, and *Carex microchaeta*. Mosses may be present but contribute little cover (Viereck et al. 1992).

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.

ALASKA ARCTIC ACIDIC SPARSE TUNDRA (CES104.171)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Extreme Wind Exposure; Polar [Polar Continental]; Acidic Soil; Very Shallow Soil
Non-Diagnostic Classifiers: Ridge/Summit/Upper Slope; Sideslope; Dwarf-Shrub; Lichen
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2685; ESLF 5103; ESP 1685

CONCEPT

Summary: This is a common system on acidic substrates (pH typically <6) in the hills and mountains of arctic Alaska. This system does not occur in the arctic lowlands. Common slope positions include valleys, sideslopes, and summits and ridges. The canopy is sparse due to extreme exposure, exposed bedrock or unstable substrates. Sites are typically dry to mesic and occur on acidic substrates. Soils are typically thin, stony, and well-drained. Patch size is small to matrix-forming. Total vascular plant cover is 10-25%, and lichen cover is <25%. Common dwarf-shrub species include *Dryas octopetala, Empetrum nigrum, Vaccinium uliginosum, Dryas integrifolia, Loiseleuria procumbens*, and *Salix phlebophylla*. Herbaceous species may include *Antennaria alpina, Hierochloe alpina (= Anthoxanthum monticola), Minuartia obtusiloba, Carex scirpoidea, Carex podocarpa, Carex microchaeta*, and *Festuca altaica*. Lichens include *Cladina* spp., *Sphaerophorus globosus, Nephroma arcticum, Flavocetraria* spp., and *Alectoria ochroleuca*.
Classification Comments: This system is known as Acidic Sparse Vegetation by the Alaska Natural Heritage Program.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US

ALASKA ARCTIC DWARF-SHRUBLAND (CES104.175)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane; Shrubland (Shrub-dominated); Polar [Polar Oceanic]; Dwarf-Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2690; ESLF 5104; ESP 1690

CONCEPT

Summary: This is a common system on acidic and non-acidic substrates in the hills and mountains of arctic Alaska. This system does not occur in arctic lowlands. Common slope positions include valleys, sideslopes (especially north-facing), late-lying snowbeds, and summits and ridges. Sites are typically dry to mesic. Patch size is small to large. Dwarf-shrub cover is >25%, dominated by dwarf-shrubs other than *Dryas* spp., and lichen cover is <25%. Dwarf-shrubs that dominate or codominate the system are *Cassiope tetragona, Empetrum nigrum, Vaccinium uliginosum, Salix reticulata, Salix arctica, Salix rotundifolia,* and *Arctostaphylos alpina*. *Cassiope tetragona* is more common on non-acidic sites. Other shrubs include *Betula nana, Dryas octopetala, Dryas integrifolia, Ledum palustre ssp. decumbens, Loiseleuria procumbens, Vaccinium vitis-idaea*, and *Salix phlebophylla*. Common herbaceous species include *Hierochloe alpina, Boykinia richardsonii, Carex microchaeta, Carex scirpoidea, Geum glaciale, Pedicularis lanata, Eriophorum angustifolium ssp. triste*, and *Equisetum* spp. Mosses such as *Rhytidium rugosum, Aulacomnium turgidum, Distichium capillaceum, Racomitrium lanuginosum, Dicranum elongatum*, and *Polytrichum* sp. may be common.
Classification Comments: This system is known as Dwarf Shrub by the Alaska Natural Heritage Program.

ALASKA ARCTIC MESIC ALDER SHRUBLAND (CES104.168)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Mountainside; Shrubland (Shrub-dominated); Sideslope; Polar [Polar Oceanic]; Broad-Leaved Deciduous Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2638; ESLF 5328; ESP 1638

CONCEPT

Summary: The alder system is widespread but uncommon on mountain slopes, hillslopes and small steep streams throughout arctic Alaska. Patch size is typically small. Soils are mesic but sometimes wet if found adjacent to a small stream. Total shrub cover is >25% and dominated by alders. *Alnus viridis ssp. crispa* is the dominant shrub species but may codominate with *Salix glauca* and *Salix pulchra*. Additional species include *Vaccinium uliginosum, Vaccinium vitis-idaea, Betula nana, Ledum palustre ssp. decumbens, Empetrum nigrum, Equisetum* spp., *Spiraea stevenii (= Spiraea beauverdiana), Dryas* spp., and *Cassiope tetragona*. Mosses include *Hylocomium splendens* and *Dicranum* spp. Low-shrub tundra and dwarf-shrubs are common in the gaps between alder patches.
Classification Comments: This system is known as Alder by the Alaska Natural Heritage Program.
Related Concepts:
- II.B.1.b - Alder (closed) (Viereck et al. 1992) Intersecting
- II.B.1.d - Alder-willow (closed) (Viereck et al. 1992) Intersecting
- II.B.2.b - Alder (open) (Viereck et al. 1992) Intersecting
- II.B.2.d - Alder-willow (open) (Viereck et al. 1992) Intersecting
- II.C.1.e - Low alder-willow (closed) (Viereck et al. 1992) Intersecting
- II.C.2.k - Low alder-willow (open) (Viereck et al. 1992) Intersecting
- II.C.2.l - Low alder (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: This system may or may not be controlled by avalanche activity and unstable slopes. Alder will resprout following fire, but no studies exist on fire effects in this type. The fire-return interval is likely long. Burns are more common on the Seward Peninsula and other parts of western Alaska near the spruce forest boundary. Early-season fire prior to green-up would be more likely to carry than late-season fire. Insect defoliators and canker also affect alder. Alder invades disturbed sites but also spreads into undisturbed sites adjacent to existing patches. After establishing in the uplands, it may be stable for long periods. Alder appears to be increasing in cover in the Arctic.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK
Map Zones: 67:C, 68:C, 69:C, 72:C, 76:C
TNC Ecoregions: 73:C, 74:C, 75:C, 79:C

ALASKA ARCTIC MESIC-WET WILLOW SHRUBLAND (CES104.169)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Saturated Soil; Shrubland (Shrub-dominated); Polar [Polar Oceanic]; Salix alaxensis, Salix pulchra, and Salix glauca
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2639; ESLF 5276; ESP 1639

CONCEPT

Summary: The low-tall willow system is widespread and common on mesic to wet mountain slopes, hillslopes, flats, and adjacent to streams throughout arctic Alaska. Patch size is small to large and often linear along small streams. Soils are mesic to wet, including wet sites with subsurface waterflow, water tracks, adjacent to narrow constrained streams, and on snow accumulation areas with late snowmelt. Total low- and tall-shrub (>0.2 m tall) cover is >25% and dominated by willows. This system does not include floodplain or tussock-dominated (>35% tussocks) sites. *Salix alaxensis*, *Salix pulchra*, and *Salix glauca* are the dominant species. Other shrubs may codominate, such as *Salix niphoclada*, *Salix chamissonis*, *Salix bebbiana*, *Salix planifolia*, *Salix richardsonii*, *Alnus viridis ssp. crispa*, *Betula nana*, *Vaccinium uliginosum*, and *Ledum palustre ssp. decumbens*. Dwarf-shrubs such as *Empetrum nigrum* and *Vaccinium vitis-idaea* may be common under the low-shrub layer. Herbaceous species are sparse but sedges are sometimes common. Feathermosses (*Hylocomium splendens* and *Pleurozium schreberi*) and lichens may be common.
Classification Comments: This system is known as Low-Tall Willow by the Alaska Natural Heritage Program.
Related Concepts:
- II.B.1.a - Willow (closed) (Viereck et al. 1992) Intersecting
- II.B.2.a - Willow (open) (Viereck et al. 1992) Intersecting
- II.C.1.b - Low willow (Viereck et al. 1992) Intersecting
- II.C.2.g - Willow low (open) (Viereck et al. 1992) Intersecting
- II.D.3.a - Willow tundra (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: Expert review indicates that this system is not controlled by avalanche activity, although avalanches may occur. The fire-return interval is likely long. The willow canopy shades the understory vegetation, possibly making the fine-fuel layer moist and less able to carry fire. Insects and diseases also affect willows. Shrub stringers that occur next to small streams or water tracks appear to be stable. Seasonal overbank flooding may occur, but generally it does not result in shifting channels or gravel bar formation. Subsurface flow may be common, and the soils are often stony.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK

ALASKA ARCTIC NON-ACIDIC DRYAS DWARF-SHRUBLAND (CES104.174)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Montane]; Shrubland (Shrub-dominated); Polar [Polar Oceanic]; Circumneutral Soil; Dwarf-Shrub; Dryas integrifolia and/or Dryas octopetala
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2689; ESLF 5105; ESP 1689

CONCEPT

Summary: This is a common system on non-acidic substrates (pH typically >6) in the hills and mountains of arctic Alaska. This system also occurs as small patches on river bluffs on the Beaufort Coastal Plain, but otherwise does not occur in the arctic lowlands. Common slope positions include valleys, sideslopes, and summits and ridges. Sites are typically dry to mesic and are rare on late-lying snowbeds. Non-acidic sites are more common near floodplains, on carbonate substrates, and loess deposition areas. Patch size is small to large. Dwarf-shrub cover is >25% and dominated by *Dryas* spp. *Dryas octopetala* and/or *Dryas integrifolia* codominate with *Saxifraga oppositifolia* and *Rhododendron lapponicum*. Other common dwarf-shrubs include *Salix arctica, Salix reticulata, Cassiope tetragona,* and *Arctostaphylos rubra*. Herbaceous species include *Lupinus arcticus, Carex scirpoidea, Carex rupestris, Oxytropis nigrescens, Potentilla uniflora, Artemisia senjavinensis, Artemisia globularia, Artemisia furcata, Hedysarum boreale ssp. mackenziei (= Hedysarum mackenziei), Saxifraga oppositifolia,* and *Equisetum* spp. Lichens such as *Thamnolia* spp. and *Cetraria islandica* also occur.
Classification Comments: This system is known as Non-Acidic *Dryas* by the Alaska Natural Heritage Program.
Related Concepts:
- II.D.1.a - Dryas tundra (Viereck et al. 1992) Broader

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.

ALASKA ARCTIC NON-ACIDIC DWARF-SHRUB LICHEN TUNDRA (CES104.176)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Montane]; Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Circumneutral Soil; Dwarf-Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2692; ESLF 5106; ESP 1692

CONCEPT

Summary: This is a common system on non-acidic substrates (pH typically >6) in the hills and mountains of arctic Alaska. This system does not occur in arctic lowlands. Common slope positions include valleys, sideslopes, and summits and ridges. Sites are typically dry to mesic, exposed to the wind, and do not accumulate much winter snow. Non-acidic sites are more common near floodplains, on carbonate substrates, and loess deposition areas. Patch size is small to large. Dwarf-shrub cover is >25%, and lichen cover is >25%. Common lichens include *Flavocetraria cucullata (= Cetraria cucullata), Flavocetraria* spp., *Stereocaulon* spp., *Alectoria nigricans*, and *Thamnolia vermicularis*. *Cladonia* and *Cladina* species are uncommon. Dwarf-shrubs include *Dryas octopetala, Dryas integrifolia, Saxifraga oppositifolia, Rhododendron lapponicum, Salix arctica, Salix reticulata*, *Cassiope tetragona*, and *Arctostaphylos rubra*. Mosses contribute little cover.
Classification Comments: This system is known as Non-Acidic Dwarf Shrub Lichen by the Alaska Natural Heritage Program.

DESCRIPTION

Environment: This is a common system on non-acidic substrates (pH typically >6) in the hills and mountains of arctic Alaska. This system does not occur in arctic lowlands. Common slope positions include valleys, sideslopes, and summits and ridges. Sites are typically dry to mesic, exposed to the wind, and do not accumulate much winter snow (Viereck et al. 1992). Non-acidic sites are more common near floodplains, on carbonate substrates, and loess deposition areas. Patch size is small to large.
Vegetation: Dwarf-shrub cover is >25%, and lichen cover is >25%. Common lichens include *Flavocetraria cucullata (= Cetraria cucullata), Flavocetraria* spp., *Stereocaulon* spp., *Alectoria nigricans*, and *Thamnolia vermicularis*. *Cladonia* and *Cladina* species are uncommon. Dwarf-shrubs include *Dryas octopetala, Dryas integrifolia, Saxifraga oppositifolia, Rhododendron lapponicum, Salix arctica, Salix reticulata*, *Cassiope tetragona*, and *Arctostaphylos rubra*. Mosses contribute little cover (Viereck et al. 1992).

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK
Map Zones: 67:C, 68:C, 69:C, 72:C, 76:C
TNC Ecoregions: 73:C, 74:C, 75:C, 79:C

ALASKA ARCTIC NON-ACIDIC SPARSE TUNDRA (CES104.172)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Extreme Wind Exposure; Polar [Polar Oceanic]; Circumneutral Soil; Very Shallow Soil; Dwarf-Shrub
Non-Diagnostic Classifiers: Ridge/Summit/Upper Slope; Calcareous
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2686; ESLF 5107; ESP 1686

CONCEPT

Summary: This is a common system on non-acidic substrates (pH typically >6) in the hills and mountains of arctic Alaska. This system does not occur in arctic lowlands. Common slope positions include valleys, sideslopes, and summits and ridges. The canopy is sparse due to extreme exposure, exposed bedrock or unstable substrates. Sites are typically dry to mesic and occur on non-acidic substrates. Soils are typically thin, stony, and well-drained. Non-acidic sites are more common near floodplains, on carbonate substrates, and loess deposition areas. Patch size is small to large. Total vascular plant cover is 10-25%, and lichen cover is <25%. Common dwarf-shrubs include *Dryas octopetala, Dryas integrifolia, Saxifraga oppositifolia, Rhododendron lapponicum, Salix arctica, Salix reticulata, Cassiope tetragona,* and *Arctostaphylos rubra*. Herbaceous species may include *Lupinus arcticus, Hedysarum boreale ssp. mackenziei (= Hedysarum mackenziei), Carex scirpoidea, Carex rupestris, Oxytropis nigrescens, Potentilla uniflora, Artemisia senjavinensis, Artemisia globularia, Artemisia furcata, Saxifraga oppositifolia,* and *Equisetum* spp. Lichens such as *Thamnolia* spp. and *Cetraria islandica* also occur.
Classification Comments: This system is known as Non-Acidic Sparse Vegetation by the Alaska Natural Heritage Program.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK
Map Zones: 67:C, 68:C, 69:C, 72:C, 76:C

ALASKA ARCTIC SCRUB BIRCH-ERICACEOUS SHRUBLAND (CES104.170)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Arctic (104)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Polar [Polar Oceanic]; Dwarf-Shrub; Betula nana, Vaccinium uliginosum, Ledum palustre ssp. decumbens
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2682; ESLF 5277; ESP 1682

CONCEPT

Summary: This system is common throughout arctic Alaska on mesic mountain slopes, hillslopes and flats. Patch size is small to matrix-forming. Soils are mesic. The total low- and tall-shrub cover is >25%, and *Betula nana, Vaccinium uliginosum*, or *Ledum palustre ssp. decumbens* typically dominate or codominate. *Salix* spp. (such as *Salix pulchra*) do not dominate but may codominate. This system does not include tussock-dominated (>35% tussocks) sites. Dwarf-shrubs such as *Empetrum nigrum* and *Vaccinium vitis-idaea* may be common under the low-shrub layer. Herbaceous species are sparse, and feathermosses (*Hylocomium splendens* and *Pleurozium schreberi*) and lichens may be common.
Classification Comments: This system is known as Birch Ericaceous Low Shrub by the Alaska Natural Heritage Program.
Related Concepts:

- II.C.2.f - Shrub birch-willow (open) low (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: Expert review suggests that the fire-return interval may be 200 years in fire-prone regions of western Alaska, but may be 1000 years on the Beaufort Coastal Plain. After a fire, mesic herbaceous species may dominate initially, and self-replacement may occur within 5 to 25 years.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK
Map Zones: 67:C, 68:C, 69:C, 72:C, 76:C
TNC Ecoregions: 73:C, 74:C, 75:C, 79:C

ALASKA SUB-BOREAL AVALANCHE SLOPE SHRUBLAND (CES105.111)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Montane]; Shrubland (Shrub-dominated); Avalanche chute; Boreal [Boreal Subcontinental]; Avalanche; Broad-Leaved Deciduous Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2608; ESLF 5329; ESP 1608

CONCEPT

Summary: This system occurs commonly throughout the boreal transition region and infrequently in boreal Alaska on mountain slopes where slopes are steep enough to produce frequent snow slides thus preventing forest development. Slopes that produce regular avalanches typically have an upper slope angle of at least 70%, but the lower slopes and run-out zones may be much less steep. The dominant shrub species is typically *Alnus viridis ssp. sinuata*, but other shrubs, including *Sambucus racemosa, Salix* spp., and *Spiraea stevenii*, may be common. Herbaceous patches are often dominated by *Calamagrostis canadensis* and *Chamerion angustifolium*; other common herbs include *Athyrium filix-femina*, *Dryopteris expansa*, and *Veratrum viride*. Tree seedlings and saplings may be common on some slopes but do not emerge as an overstory due to frequent snow avalanche.
Classification Comments: This system is known as Boreal Transition Avalanche Slope Shrubland by the Alaska Natural Heritage Program. It is similar in species composition to Alaska Sub-boreal Mesic Subalpine Alder Shrubland (CES105.112), but it occurs below the subalpine zone, and tree growth is limited by avalanche frequency not elevation as in the subalpine system. Avalanche slopes occur from alpine to lower slopes; however, we do not plan to map or model the alpine avalanche slopes. Alaska Sub-boreal Avalanche Slope Shrubland (CES105.111) can be differentiated from Alaskan Pacific Maritime Avalanche Slope Shrubland (CES204.162) by geographic region and by the lack of species common to the Pacific Northwest coast such as *Rubus spectabilis*.
Similar Ecological Systems:
- Alaska Sub-boreal Mesic Subalpine Alder Shrubland (CES105.112)
- Alaskan Pacific Maritime Avalanche Slope Shrubland (CES204.162)

Related Concepts:
- II.B.1.b - Alder (closed) (Viereck et al. 1992) Intersecting
- II.B.1.d - Alder-willow (closed) (Viereck et al. 1992) Intersecting
- II.B.2.b - Alder (open) (Viereck et al. 1992) Intersecting
- II.B.2.d - Alder-willow (open) (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: Avalanche slopes occur where mountain slopes are steep enough to produce frequent snow slides thus preventing forest development. Upper avalanche slopes typically have a slope angle of at least 70%, but the lower slopes and run-out zones may be much less steep. Soils are shallow and stony, underlain by colluvium, glacial till, and residuum.
Vegetation: The dominant shrub species is typically *Alnus viridis ssp. sinuata*, but other shrubs, including *Sambucus racemosa, Salix* spp., and *Spiraea stevenii (= Spiraea beauverdiana)*, may be common. Herbaceous patches are often dominated by *Calamagrostis canadensis* and *Chamerion angustifolium*; other common herbs include *Athyrium filix-femina*, *Dryopteris expansa*, and *Veratrum viride* (Viereck et al. 1992). Tree seedlings and saplings may be common on some slopes but do not emerge as an overstory due to frequent snow avalanche.
Dynamics: This system represents a topoedaphic climax (Viereck et al. 1992). *Alnus viridis ssp. sinuata* has a growth form that tolerates avalanche disturbance and can maintain dominance on the site. Frequent snow slides prevent tree seedlings and saplings from reaching the upper canopy. On sites with a less frequent avalanche cycle, trees may temporarily dominate the overstory.

DISTRIBUTION

Range: Boreal transition is the dominant region, but this system also occurs infrequently in boreal Alaska.
Divisions: 105:C; 204:C
Nations: US
Subnations: AK
Map Zones: 69:C, 70:C, 71:C, 72:C, 73:C, 74:C, 75:C, 76:C

ALASKA SUB-BOREAL MESIC SUBALPINE ALDER SHRUBLAND (CES105.112)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Montane]; Shrubland (Shrub-dominated); Boreal [Boreal Subcontinental]; Broad-Leaved Deciduous Shrub
Non-Diagnostic Classifiers: Montane [Upper Montane]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2609; ESLF 5330; ESP 1609

CONCEPT

Summary: This system is widespread on upper mountain slopes above treeline throughout south-central and southwestern Alaska. It occurs less commonly throughout the northern boreal region to the southern slopes of the Brooks Range. This system often appears as a band of alder above treeline and below alpine systems. Low shrub replaces this system as the dominant subalpine shrub type in the northern boreal region of the state. *Alnus viridis ssp. sinuata* is the dominant shrub species, but other shrubs including *Salix* spp. (sometimes the dominant shrub), *Sambucus racemosa*, and *Spiraea stevenii (= Spiraea beauverdiana)* may be common. In the boreal transition region, the alder zone is intermixed with mesic herbaceous meadows (*Calamagrostis canadensis* and *Chamerion angustifolium*); in boreal Alaska, low-shrub tundra is more common in the gaps between alder patches.
Classification Comments: This system is known as Boreal Transition Tall Shrub by the Alaska Natural Heritage Program. It is similar in species composition to Alaska Sub-boreal Avalanche Slope Shrubland (CES105.111), but it occurs in the subalpine zone and tree growth is limited by elevation not avalanche frequency. Alaskan Pacific Maritime Subalpine Alder-Salmonberry Shrubland (CES204.152) occupies a similar landscape position along the Gulf Coast of Alaska, but this system may be dominated by *Rubus spectabilis*, which does not occur in boreal regions.
Similar Ecological Systems:
- Alaska Sub-boreal Avalanche Slope Shrubland (CES105.111)
- Alaskan Pacific Maritime Subalpine Alder-Salmonberry Shrubland (CES204.152)

Related Concepts:
- II.B.1.b - Alder (closed) (Viereck et al. 1992) Intersecting. also occurs on avalanche slopes
- II.B.1.d - Alder-willow (closed) (Viereck et al. 1992) Intersecting. also occurs on avalanche slopes
- II.B.2.b - Alder (open) (Viereck et al. 1992) Intersecting. also occurs on avalanche slopes
- II.B.2.d - Alder-willow (open) (Viereck et al. 1992) Intersecting. also occurs on avalanche slopes

DESCRIPTION

Environment: This system is widespread on upper mountain slopes above treeline throughout south-central and southwestern Alaska (Viereck 1979). It occurs less commonly throughout the northern boreal region to the southern slopes of the Brooks Range. This system occurs on well-drained mesic sites. Soils are shallow and stony, underlain by colluvium, glacial till, and residuum.
Vegetation: *Alnus viridis ssp. sinuata* is the dominant shrub species, but other shrubs including *Salix* spp. (sometimes the dominant shrub), *Sambucus racemosa*, and *Spiraea stevenii* may be common. Herbaceous patches often occur within the shrub zone and may be dominated by *Calamagrostis canadensis* and *Chamerion angustifolium*; other common herbs include *Athyrium filix-femina, Dryopteris expansa, Veratrum viride, Valeriana sitchensis, Lupinus nootkatensis*, and *Sanguisorba canadensis (= Sanguisorba sitchensis)* (Viereck et al. 1992).
Dynamics: This system represents a topoedaphic climax (Viereck et al. 1992). It occurs above treeline and is not controlled by avalanche activity, although avalanches may occur. This system may be extending further into the alpine in recent decades. Alder will resprout following fire, but no studies exist on fire effects in this type. The fire-return interval is likely long, possibly 500 to 1000 years. Early-season fire prior to green-up would be more likely to carry than late-season fire. Alder is also affected by insects and diseases.

DISTRIBUTION

Range: This system occurs at mid-elevation through subalpine in the boreal transition and, less commonly, boreal regions of Alaska.
Divisions: 105:C; 204:C
Nations: US
Subnations: AK
Map Zones: 68:C, 69:?, 70:C, 71:C, 72:C, 73:C, 74:C, 75:C

ALASKAN PACIFIC MARITIME ALPINE SPARSE SHRUB AND FELL-FIELD (CES204.318)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Alpine Mosaic; Shrubland (Shrub-dominated); Temperate [Temperate Oceanic]; W-Landscape/High Intensity; Dwarf-Shrub
Non-Diagnostic Classifiers: Fell-field; Ridge/Summit/Upper Slope; Sideslope
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2674; ESLF 5109; ESP 1674

CONCEPT

Summary: This sparsely vegetated ecological system occurs on exposed summits, windswept ridges, and fell-fields. These sites are characterized by harsh environmental conditions. Slopes vary from moderately sloped to flat. Dominant species include *Empetrum nigrum, Vaccinium uliginosum, Loiseleuria procumbens, Phyllodoce aleutica, Harrimanella stelleriana*, and *Luetkea pectinata*. Lichens may be common. Total vegetation cover ranges from 10 to 25%.
Classification Comments: This system is known as Maritime Alpine Sparse Dwarf-Shrub by the Alaska Natural Heritage Program.
Similar Ecological Systems:
- Western North American Boreal Alpine Dwarf-Shrub Summit (CES105.129)

ALASKAN PACIFIC MARITIME AVALANCHE SLOPE SHRUBLAND (CES204.162)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Montane [Montane]; Shrubland (Shrub-dominated); Rockfall avalanche; Soil creep slope; Avalanche chute; Temperate [Temperate Oceanic]; Avalanche; Broad-Leaved Deciduous Shrub; Rubus spectabilis
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2680; ESLF 5331; ESP 1680

CONCEPT

Summary: This system occurs on mountain sideslopes from sea level to treeline where slopes are steep enough to produce frequent snowslides preventing forest development. Mass wasting, including rockfall and soil creep, also contributes to the disturbance cycle. This system is similar in species composition to Alaskan Pacific Maritime Subalpine Alder-Salmonberry Shrubland (CES204.152), but it occurs below the subalpine zone, and tree growth is limited by disturbance frequency, not elevation and temperature as in the subalpine system. Sites are usually dominated by *Alnus viridis ssp. sinuata* and *Rubus spectabilis*. Other shrubs may include *Sambucus racemosa, Salix alaxensis, Salix barclayi*, and *Oplopanax horridus*. Herbaceous patches are common and are dominated by *Calamagrostis canadensis* and *Chamerion angustifolium*. Other common herbs include *Athyrium filix-femina, Veratrum viride, Heracleum maximum, Streptopus amplexifolius*, and *Aruncus dioicus*. Near treeline, forb-sedge meadows replace *Calamagrostis* meadows. Tree seedlings and saplings may be abundant on some slopes but do not emerge as an overstory due to frequent disturbance.
Classification Comments: This system is known as Tall Shrub Avalanche Slopes by the Alaska Natural Heritage Program. Avalanche slopes in the Cascades and mountains of southern British Columbia are probably drier than these found farther north in Alaska, where the precipitation regime does not have a seasonal component to it. Hence, these have been split into two different systems. Exactly where they transition from one to another is yet to be determined.
Similar Ecological Systems:
- Alaska Sub-boreal Avalanche Slope Shrubland (CES105.111)
- Alaskan Pacific Maritime Subalpine Alder-Salmonberry Shrubland (CES204.152)
- North Pacific Avalanche Chute Shrubland (CES204.854)

Related Concepts:
- II.B.1.b - Alder (closed) (Viereck et al. 1992) Intersecting
- II.B.1.d - Alder-willow (closed) (Viereck et al. 1992) Intersecting
- II.B.2.b - Alder (open) (Viereck et al. 1992) Intersecting
- II.B.2.d - Alder-willow (open) (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: Avalanche slopes occur from sea level to treeline where mountain slopes are steep enough to produce frequent snow slides preventing forest development. Upper avalanche slopes typically have a slope angle of at least 70% but the lower slopes and run-out zones may be much less steep. Soils are shallow and stony, underlain by colluvium, glacial till, and residuum.
Vegetation: Sites are usually dominated by *Alnus viridis ssp. sinuata* and *Rubus spectabilis*. Other shrubs may include *Sambucus racemosa, Salix alaxensis, Salix barclayi*, and *Oplopanax horridus*. Herbaceous patches are common and are dominated by *Calamagrostis canadensis* and *Chamerion angustifolium*. Other common herbs include *Athyrium filix-femina, Veratrum viride, Heracleum maximum, Streptopus amplexifolius*, and *Aruncus dioicus* (Viereck et al. 1992, DeVelice et al. 1999). Near treeline, forb-sedge meadows replace *Calamagrostis* meadows. Tree seedlings and saplings may be abundant on some slopes but do not emerge as an overstory due to frequent disturbance.
Dynamics: This shrubland system is maintained by frequent disturbance and represents a topoedaphic climax (Viereck et al. 1992). Severe slides often with a debris component may break branches, bury, or kill shrubs, but recolonization through resprouting is usually rapid. On sites with a less frequent avalanche cycle, trees may temporarily dominate the overstory. Herbaceous seres may be present on sites with very frequent avalanche cycles. On older landscapes *Rubus spectabilis* may be dominant or codominant.

DISTRIBUTION

Range: This system occurs from Kodiak Island through southeastern Alaska into British Columbia, but the southern boundary needs to be determined.
Divisions: 204:C
Nations: CA, US
Subnations: AK, BC
Map Zones: 77:C, 78:C

ALASKAN PACIFIC MARITIME SUBALPINE ALDER-SALMONBERRY SHRUBLAND (CES204.152)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Temperate [Temperate Oceanic]; Broad-Leaved Deciduous Shrub
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2652; ESLF 5332; ESP 1652

CONCEPT

Summary: This ecological system typically occurs just above treeline and below the alpine throughout the maritime region of Alaska. Soils are typically mesic, well-drained, shallow, and stony, and underlain by colluvium, glacial till or residuum. *Alnus viridis ssp. sinuata* is often the dominant species, but *Rubus spectabilis* may be codominant. Other common species include *Sambucus racemosa, Oplopanax horridus*, and *Elliottia pyroliflorus*. The tall shrub system is often mosaiced with the mesic herbaceous meadow system. Common herbaceous species include *Calamagrostis canadensis, Chamerion angustifolium, Veratrum viride, Heracleum maximum, Athyrium filix-femina, Dryopteris expansa, Phegopteris connectilis, Equisetum arvense, Streptopus amplexifolius, Lupinus nootkatensis, Valeriana sitchensis, Geranium erianthum, Aconitum delphiniifolium, Castilleja unalaschcensis, Sanguisorba canadensis*, and *Carex macrochaeta*.

This system also includes partially vegetated bedrock ridges and cliffs in the alpine and subalpine, where it is found primarily on or near ridgetops and is exposed to extremely harsh growing conditions. More exposed sites subject the vegetation to a very short growing season, freeze-thaw pattern, and desiccating winds. Exposed bedrock or talus is usually a major component of the sites. In the more extreme locations, the vegetation cover is often fragmented or sparse and includes a complex of sparse tall or low shrubs, dwarf-shrubs, and herbaceous species.

This system appears to be relatively stable, although there may be an upward trend in the elevation of this system. Treeline conifers appear to be invading from below in some areas, and the elevational limit of low and tall shrub establishment appears to be rising.
Classification Comments: This system combines those known as Maritime Tall Shrub and Maritime Sparse Alder by the Alaska Natural Heritage Program. P. Krosse (USFS ecologist, pers. comm.) comments regarding the alpine sparse alder: "We have this type mapped in our soil survey with bedrock and talus ranging from 25 to 40%. We also have map units that are predominantly rock outcrop (85%) with no more than 15% shrub and herbaceous vegetation contained within this map unit." On Kodiak Island, alder shrublands are placed into Aleutian Mesic Alder-Salmonberry Shrubland (CES105.147).
Similar Ecological Systems:
- Alaska Sub-boreal Mesic Subalpine Alder Shrubland (CES105.112)
- Alaskan Pacific Maritime Avalanche Slope Shrubland (CES204.162)
- Aleutian Mesic Alder-Salmonberry Shrubland (CES105.147)

Related Concepts:
- II.B.1.b - Alder (closed) (Viereck et al. 1992) Intersecting
- II.B.2.b - Alder (open) (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: This system appears to be relatively stable (Mitchell 1968, Viereck et al. 1992). It is hypothesized that infrequent soil disturbance can lead to a short-lived herbaceous sere. The climate is likely too cold to allow fires to burn in this system.

DISTRIBUTION

Range: This system occurs from Prince William Sound through southeastern Alaska.
Divisions: 204:C
Nations: US
Subnations: AK
Map Zones: 77:C, 78:C
TNC Ecoregions: 69:C, 70:C

ALASKAN PACIFIC MARITIME SUBALPINE COPPERBUSH SHRUBLAND (CES204.316)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Temperate [Temperate Oceanic]; Broad-Leaved Deciduous Shrub
Non-Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Montane [Upper Montane]; Montane [Montane]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2672; ESLF 5280; ESP 1672

CONCEPT

Summary: This ecological system occurs in the lower alpine and subalpine. *Elliottia pyroliflorus* dominates the overstory (10 to 80% cover) and ranges in height from 0.6-1.5 m (2-5 feet). Other species include *Phyllodoce aleutica, Nephrophyllidium crista-galli, Cornus suecica, Luetkea pectinata, Athyrium filix-femina, Cassiope mertensiana, Dryopteris expansa, Gymnocarpium dryopteris, Viola glabella*, and *Rubus spectabilis*. Krummholz *Tsuga mertensiana* occur in some sites. Adjacent to this system at higher elevations are alpine herbaceous meadows or dwarf-shrublands; at lower elevations *Tsuga mertensiana* forests or woodlands are common.
Classification Comments: This system is poorly documented and not well-understood. It is included in the systems classification for Alaska because it is somewhat different floristically from the other shrubland systems in the maritime. With further information, it is possible it will be merged with another ecological system. This system is known as Maritime Alpine Low Shrub (Copperbush) by the Alaska Natural Heritage Program.
Related Concepts:
- *Elliottia pyroliflora* (Boggs et al. 2008b) Undetermined

ALEUTIAN MESIC ALDER-SALMONBERRY SHRUBLAND (CES105.147)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Boreal [Boreal Oceanic]; Rubus spectabilis
Non-Diagnostic Classifiers: Flat; Slope; Colluvial slope
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2718; ESLF 5333; ESP 1718

CONCEPT

Summary: The alder-salmonberry system is matrix-forming on the Alaska Peninsula and Kodiak Island, diminishes moving west, and is absent by Dutch Harbor. It occurs on flat to steep slopes (0-50 degrees) at low to mid elevations (1-1000 m) in valleys, hills and mountains. The slopes are typically ash-covered, colluvium, or glacial drift. Total low- and tall-shrub cover is >25%, and *Alnus viridis* or *Rubus spectabilis* contribute greater than 50% of the total shrub cover. *Rubus spectabilis* is dominant primarily on the oldest stabilized talus slopes and stable colluvial slopes (older substrates), while *Alnus viridis* may be the dominant shrub on recently disturbed sites, wind-sheltered sites or recent ash deposits. Common codominants include *Sambucus racemosa, Oplopanax horridus, Spiraea stevenii*, and tall willows such as *Salix barclayi* or *Salix glauca*. *Alnus viridis ssp. sinuata* is the most common alder species, however, *Alnus viridis ssp. fruticosa* dominates some sites. Alder height ranges from 0.5 m at higher elevations to 8 m downslope. In closed-canopy sites, *Sambucus racemosa* and *Rubus spectabilis* shrubs are usually woven in among and around the edges of the alder thickets, and the understory is sparse, often with *Athyrium filix-femina*, graminoids and sparse *Rubus spectabilis*. Litter cover is high. Sites codominated by tall willows typically occur along streams and at the upper limits of alder growth. Some *Rubus spectabilis* sites are mixed with herbaceous species of equal height, including *Athyrium filix-femina, Aconitum maximum, Calamagrostis canadensis, Chamerion angustifolium ssp. angustifolium, Deschampsia caespitosa, Dryopteris expansa, Heracleum maximum*, and *Veratrum viride*. In sites where patches of alder are mosaiced with mesic herbaceous meadows, common species include *Athyrium filix-femina, Aconitum maximum, Calamagrostis canadensis, Chamerion angustifolium ssp. angustifolium, Deschampsia caespitosa, Dryopteris expansa, Heracleum maximum, Lupinus nootkatensis, Solidago* spp., and *Veratrum viride.*
Classification Comments: This system combines those known as Alder and *Rubus spectabilis* by the Alaska Natural Heritage Program.
Similar Ecological Systems:
- Alaskan Pacific Maritime Subalpine Alder-Salmonberry Shrubland (CES204.152)

DESCRIPTION

Environment: The alder-salmonberry system is matrix-forming on the Alaska Peninsula and Kodiak Island, diminishes moving west, and is absent by Dutch Harbor. It occurs on flat to steep slopes (0-50 degrees) at low to mid elevations (1-1000 m) in valleys, hills and mountains. The slopes are typically ash-covered, colluvium, or glacial drift.
Vegetation: Total low- and tall-shrub cover is >25%, and *Alnus viridis* or *Rubus spectabilis* contribute greater than 50% of the total shrub cover. *Rubus spectabilis* is dominant primarily on the oldest stabilized talus slopes and stable colluvial slopes (older substrates), while *Alnus viridis* may be the dominant shrub on recently disturbed sites, wind-sheltered sites or recent ash deposits. Common codominants include *Sambucus racemosa, Oplopanax horridus, Spiraea stevenii*, and tall willows such as *Salix barclayi* or *Salix*

glauca. *Alnus viridis ssp. sinuata* is the most common alder species, however, *Alnus viridis ssp. fruticosa* dominates some sites. Alder height ranges from 0.5 m at higher elevations to 8 m downslope. In closed-canopy sites, *Sambucus racemosa* and *Rubus spectabilis* shrubs are usually woven in among and around the edges of the alder thickets, and the understory is sparse, often with *Athyrium filix-femina*, graminoids and sparse *Rubus spectabilis*. Litter cover is high. Sites codominated by tall willows typically occur along streams and at the upper limits of alder growth. Some *Rubus spectabilis* sites are mixed with herbaceous species of equal height, including *Athyrium filix-femina, Aconitum maximum, Calamagrostis canadensis, Chamerion angustifolium ssp. angustifolium, Deschampsia caespitosa, Dryopteris expansa, Heracleum maximum*, and *Veratrum viride*. In sites where patches of alder are mosaiced with mesic herbaceous meadows, common species include *Athyrium filix-femina*, *Aconitum maximum, Calamagrostis canadensis, Chamerion angustifolium ssp. angustifolium, Deschampsia caespitosa*, *Dryopteris expansa, Heracleum maximum, Lupinus nootkatensis, Solidago* spp., and *Veratrum viride*.

Dynamics: Alder's response to fire in this system is unknown. Alder can often dominate new ash deposits on the Alaska Peninsula. It is also affected by insects and diseases.

ALEUTIAN MESIC-WET WILLOW SHRUBLAND (CES105.148)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Saturated Soil; Lake terrace; Shrubland (Shrub-dominated); Stream terrace (undifferentiated); Boreal [Boreal Oceanic]
Non-Diagnostic Classifiers: Slope; Valley
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2640; ESLF 5278; ESP 1640

CONCEPT

Summary: This willow shrubland system is relatively uncommon yet widespread on the eastern Alaska Peninsula and Kodiak Island at low to mid elevations (range of 3-657 m in Katmai National Park and Preserve) and diminishes moving west. It typically occurs as small patches in broad valleys, on mountain sideslopes with slopes ranging from 0 to 30 degrees. It is also frequently found on wet sites in lowlands, along streams, terraces, lakeshores and the edge of small streams, as well as adjacent to peatlands and wet meadows. Some sites are not wet and support predominantly tall willows, but this is probably <10% of sites. The soil substrates range from mineral to peat. Total tall- and low-shrub cover (>20 cm height) is >25%, and *Salix* spp. contribute greater than 25% of the total shrub cover. The dominant willow species is *Salix barclayi*, although *Salix alaxensis, Salix commutata, Salix glauca*, and *Salix pulchra* are also important. *Alnus viridis ssp. sinuata* may codominate. Understory shrub species include *Betula nana, Empetrum nigrum, Vaccinium vitis-idaea*, and *Vaccinium uliginosum*. Understory herbaceous species include *Achillea millefolium var. borealis, Angelica lucida, Calamagrostis canadensis, Chamerion angustifolium ssp. angustifolium, Equisetum arvense, Geranium erianthum, Heracleum maximum, Rubus arcticus*, and *Sanguisorba canadensis*. Wetter sites support *Carex lenticularis var. lipocarpa, Carex aquatilis var. aquatilis, Carex utriculata*, and *Equisetum pratense*.
Classification Comments: This system combines those known as Tall Willow and Low Willow by the Alaska Natural Heritage Program.

APACHERIAN-CHIHUAHUAN MESQUITE UPLAND SCRUB (CES302.733)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Thorn Shrub; Prosopis spp.-dominated
Non-Diagnostic Classifiers: Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Aridic; Intermediate Disturbance Interval; F-Patch/High Intensity [Seasonality/Winter Fire]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2095; ESLF 5301; ESP 1095

CONCEPT

Summary: This ecological system often occurs as invasive upland shrublands that are concentrated in the extensive desert grassland in foothills and piedmonts of the Chihuahuan Desert, extending into the Sky Island region to the west. Substrates are typically derived from alluvium, often gravelly without a well-developed argillic or calcic soil horizon that would limit infiltration and storage of winter precipitation in deeper soil layers. *Prosopis* spp. and other deep-rooted shrubs exploit this deep-soil moisture that is unavailable to grasses and cacti. Vegetation is typically dominated by *Prosopis glandulosa* or *Prosopis velutina* and succulents. Other desert scrub species that may codominate include *Acacia neovernicosa, Acacia constricta, Juniperus monosperma,* or *Juniperus coahuilensis*. *Larrea tridentata* is typically absent or has low cover. Grass cover is typically low and composed of desert grasses such as *Dasyochloa pulchella (= Erioneuron pulchellum), Muhlenbergia porteri, Muhlenbergia setifolia,* and *Pleuraphis mutica*. During the last century, the area occupied by this system has increased through conversion of desert grasslands as a result of drought, overgrazing by livestock, and/or decreases in fire frequency. It is similar to Chihuahuan Mixed Desert and Thornscrub (CES302.734) but is generally found at higher elevations where *Larrea tridentata* and other desert scrub are not codominant. It is also similar to Chihuahuan Stabilized Coppice Dune and Sand Flat Scrub (CES302.737) but does not occur on eolian-deposited substrates (sandsheets), although some stands may have evidence of wind erosion and deposition.
Classification Comments: This system is similar to Chihuahuan Mixed Desert and Thornscrub (CES302.734) but is generally found at higher elevations where *Larrea tridentata* and other desert scrub are not codominant. It is also similar to Chihuahuan Stabilized Coppice Dune and Sand Flat Scrub (CES302.737) but does not occur on eolian-deposited substrates. This system includes mesquite-dominated types resulting from conversion of desert grasslands to shrublands. Landfire mapzone 25 modeling workshops limited BpS to naturally occurring mesquite shrublands found on rocky outcrop and foothills. During the last century, the area occupied by the uncharacteristic portion of this system has increased through conversion of desert grasslands as a result of drought, overgrazing and seed dispersion by livestock, and/or decreases in fire frequency. The boundary between Apacherian-Chihuahuan Mesquite Upland Scrub (CES302.733) and Tamaulipan Mesquite Upland Scrub (CES301.984) needs to be defined.
Similar Ecological Systems:
- Apacherian-Chihuahuan Semi-Desert Grassland and Steppe (CES302.735)
- Chihuahuan Mixed Desert and Thornscrub (CES302.734)
- Chihuahuan Stabilized Coppice Dune and Sand Flat Scrub (CES302.737)
- Tamaulipan Mesquite Upland Scrub (CES301.984)

DESCRIPTION

Environment: This desert scrub occurs on substrates that are typically derived from alluvium, often gravelly without a well-developed argillic or calcic soil horizon that would limit infiltration and storage of winter precipitation in deeper soil layers. *Prosopis* spp. and other deep-rooted shrubs exploit this deep-soil moisture that is unavailable to grasses and cacti (Burgess 1995).
Vegetation: Vegetation is typically dominated by *Prosopis glandulosa* or *Prosopis velutina* and succulents. Other desert scrub species that may codominate include *Acacia neovernicosa, Acacia constricta, Juniperus monosperma,* or *Juniperus coahuilensis*. Grass cover is variable and ranges from sparse to moderately dense. Common species may include *Aristida purpurea, Bothriochloa barbinodis, Bouteloua curtipendula, Dasyochloa pulchella (= Erioneuron pulchellum), Muhlenbergia porteri, Muhlenbergia setifolia, Pleuraphis mutica,* and *Setaria leucopila*. The deeper soils help support good grass cover beneath the shrub canopy. Areas of higher annual rainfall and deeper soils allow for a more diverse plant community.
Dynamics: During the last century, the area occupied by this system has increased through conversion of desert grasslands as a result of drought, overgrazing and *Prosopis glandulosa* seed dispersion by livestock, and/or decreases in fire frequency (Buffington and Herbel 1965, Brown and Archer 1987). It is believed that this system formerly occurred in relatively minor amounts and was largely confined to drainages until cattle distributed seed upland from the bosques into desert grasslands (Brown and Archer 1987, 1989).

Shrublands dominated by *Prosopis* spp. have replaced large areas of desert grasslands, especially those formerly dominated by *Bouteloua eriopoda*, in Trans Pecos Texas, southern New Mexico and southeastern Arizona (York and Dick-Peddie 1969, Hennessy et al. 1983). Studies on the Jornada Experimental Range suggest that combinations of drought, overgrazing by livestock, wind and water erosion, seed dispersal by livestock, fire suppression, shifting dunes, and changes in the seasonal distribution of precipitation have caused this recent, dramatic shift in vegetation physiognomy (Buffington and Herbel 1965, Herbel et al. 1972, Humphrey 1974, McLaughlin and Bowers 1982, Gibbens et al. 1983, Hennessy et al. 1983, Schlesinger et al. 1990, McPherson 1995).

Historical natural-ignition fires were relatively small, probably 10-15 acres in size. Repeated fire is thought to help maintain a general mosaic pattern between open grassland and shrub-dominated areas (Johnston 1963). Wright et al. (1976) found that *Prosopis glandulosa* is very fire-tolerant when only 3 years old. Most plants resprout after being top-killed by fire. Thus, prior to livestock grazing reducing fire frequency, repeated grassland fires probably maintained lower stature of shrubs and prevented new establishment by killing seedlings.

Drought is a relatively common occurrence in this desert scrub, generally occurring every 10-15 years and lasting 2-3 years with occasional long-term drought periods (10-15 years duration). *Prosopis* spp. and other shrubs have extensive root systems that allow them to exploit deep-soil water that is unavailable to shallower rooted grasses and cacti (Burgess 1995). This strategy works well, especially during drought. However, on sites that have well-developed argillic or calcic soil horizons that limit infiltration and storage of winter moisture in the deeper soil layers, *Prosopis* spp. invasion can be limited to a few, small individuals (McAuliffe 1995). This has implications in plant geography and desert grassland restoration work in the southwestern United States.

Component Associations:
- *Fouquieria splendens* Shrubland (CEGL004452, GNR)
- *Prosopis glandulosa / Bouteloua gracilis* Shrubland (CEGL001383, G5)
- *Prosopis glandulosa / Muhlenbergia porteri* Shrubland (CEGL001511, G5)
- *Prosopis glandulosa / Sporobolus airoides* Shrubland (CEGL001385, G5)
- *Prosopis glandulosa var. torreyana* Shrubland (CEGL001381, G3)
- *Prosopis velutina - Acacia greggii* Shrubland (CEGL001388, GUQ)
- *Prosopis velutina / Celtis laevigata var. reticulata* Shrubland (CEGL001390, GNR)
- *Prosopis velutina / Muhlenbergia porteri* Shrubland (CEGL001391, G3Q)

DISTRIBUTION

Range: This system is found on foothills and piedmont in the Chihuahuan Desert, extending into the Sky Island region and into the lower Mogollon Rim to the west.

BAJA SEMI-DESERT COASTAL SUCCULENT SCRUB (CES206.934)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Mediterranean [Mediterranean Desertic-Oceanic]; Xeric
Non-Diagnostic Classifiers: Headland; Shrubland (Shrub-dominated); Sideslope; Salt Spray; Bluff; Coast
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2073; ESLF 5250; ESP 1073

CONCEPT

Summary: This ecological system includes succulent-rich shrublands along maritime coastal bluffs and terraces that are restricted to isolated locations from Baja Norte, Mexico, north to Orange County and Catalina Island, California. This system is very localized and patchy from San Diego County south into Baja California and on the Channel Islands. These areas are frost-free and receive the least annual precipitation of the California coastal shrublands, a significant proportion of which falls in summer from rare summer thunderstorms or is augmented by summer fog drip. Characteristic plant species include *Lycium californicum, Rhus integrifolia, Opuntia californica var. parkeri (= Opuntia parryi), Opuntia prolifera, Opuntia littoralis, Yucca schidigera, Ferocactus viridescens, Agave shawii, Euphorbia misera, Bergerocactus emoryi*, and *Simmondsia chinensis*.

Component Associations:
- *Opuntia littoralis* Shrubland (CEGL003066, G3G4)

DISTRIBUTION

Range: This system occurs from Baja Norte, Mexico, north to Orange County and Catalina Island, California. This system is very localized and patchy from San Diego County south into Baja California and on the Channel Islands.

BOREAL DRY SCRUB BIRCH SHRUBLAND (CES105.322)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Boreal
National Mapping Codes: ESLF 5287

CONCEPT

Summary: This ecological system encompasses open, dry, lichen-covered scrublands dominated by *Betula glandulosa* with an occasional stunted *Picea glauca*.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).
Related Concepts:

BOREAL DRY SHRUB-STEPPE (CES105.325)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Boreal
National Mapping Codes: ESLF 5471

CONCEPT

Summary: This ecological system encompasses open dry to mesic shrublands, typically found on well-drained soils and south-facing (warm) slopes or river bluffs. Shrub cover ranges up to about 30%, dominated by *Juniperus communis, Juniperus horizontalis, Arctostaphylos uva-ursi, Shepherdia canadensis, Dasiphora fruticosa ssp. floribunda (= Pentaphylloides floribunda), Vaccinium vitis-idaea*, or *Rosa acicularis*. More mesic dips or swales might have *Symphoricarpos occidentalis, Amelanchier alnifolia, Prunus* spp., or *Elaeagnus commutata*. The herbaceous component will typically include both graminoids and forbs, including *Leymus innovatus, Koeleria macrantha, Festuca altaica (= Festuca scabrella)*, and dry sedges such as *Carex concinnoides* (in British Columbia). Forbs include *Hedysarum boreale, Zigadenus elegans*, and *Solidago multiradiata*. Trees such as *Picea glauca* or *Pinus contorta* may be present with <5% cover. Sites are on warm aspects of coarse colluvial soils.
Classification Comments: This system should possibly be combined with Western Canadian Boreal Dry Grassland and Bluff (CES103.864), and the concept include dry grasslands, bluffs and dry shrubby grasslands throughout western Canada. This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

CALIFORNIA MARITIME CHAPARRAL (CES206.929)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Mediterranean [Mediterranean Xeric-Oceanic]; Udic; Evergreen Sclerophyllous Shrub
Non-Diagnostic Classifiers: Lowland [Lowland]; Herbaceous; Sideslope; Sand Soil Texture
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2096; ESLF 5302; ESP 1096

CONCEPT

Summary: This ecological system includes chaparral in patches restricted by edaphic conditions (sands, sandstones, other marine sediments, and stabilized sand dunes) within the fog belt throughout the central and northern California coast. This system is characterized by a combination of locally endemic species of *Arctostaphylos* and *Ceanothus*, species that primarily reproduce by seed rather than resprouting. Shrubs vary in height (up to 3 m tall) and occur in variable densities. More open patches support herbaceous vegetation, while occurrences of high shrub density have no understory. Characteristic species include *Arctostaphylos tomentosa, Arctostaphylos nummularia (= Arctostaphylos sensitiva), Arctostaphylos tomentosa ssp. crustacea (= Arctostaphylos crustacea), Arctostaphylos hookeri, Arctostaphylos pajaroensis, Arctostaphylos montaraensis* (and others), *Ceanothus masonii, Ceanothus griseus,* and *Ceanothus verrucosus*. In occurrences in southern Oregon, *Arctostaphylos hispidula* is the predominant chaparral shrub. Southernmost stands (San Diego County) can include *Cneoridium* spp. and *Comarostaphylis diversifolia*. Other common widespread woody taxa can include *Adenostoma fasciculatum, Eriogonum fasciculatum, Salvia mellifera, Frangula californica (= Rhamnus californica), Rhamnus crocea,* and *Quercus agrifolia*. Controlled burns have resulted in poor survivorship of the *Arctostaphylos* spp., and current theories are that they need long fire-free intervals to develop a viable seedbank that can reproduce following fire. This system often co-occurs with California Coastal Closed-Cone Conifer Forest and Woodland (CES206.922).
Related Concepts:
- Ceanothus Mixed Chaparral (208) (Shiflet 1994) Intersecting
- Chamise Chaparral (206) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This system is restricted by edaphic conditions (sands, sandstones, other marine sediments, and stabilized sand dunes) within the summer coastal fog belt throughout the central and northern California coast, usually below 300 m (1000 feet) in elevation (Keeley and Davis 2007, Sawyer et al. 2009). The climate is distinctly Mediterranean, with warm, dry summers and cool, moist winters. Rainfall is rather variable due to the large latitudinal range. Sandy soils with low nutrient levels tend to be the norm, usually within just a few kilometers of the ocean.
Dynamics: These shrublands are characterized by species that primarily reproduce by seed rather than resprouting, and are fire-dependent. Infrequent fire results in encroachment of trees and a decline in shrub vigor and seedbank quality. Frequent fire tends to convert the stands to coastal scrub or grassland. Recent studies of many sites that have been fire-free for decades suggest that at least some of the species of *Ceanothus* may be able to germinate without fire and thus sustain populations for long fire-free intervals. Controlled burns have resulted in poor survivorship of the *Arctostaphylos* spp., and current theories are that they need long fire-free intervals to develop a viable seedbank that can reproduce following fire (Keeley and Davis 2007). Most of the dominant shrubs are nitrogen fixers.

Landfire (2007a) model: Chaparral burns in high-intensity, stand-replacing crown fires that burn large acreages in a single event. However, there is a considerable range in the flammability of shrub species (e.g., chamise is "flashier" than manzanita). Large, stand-replacement events can interact with seed availability and, hence, influence post-fire successional pathways differently than for smaller, less severe fires. Mean fire-return intervals are variable and longer than intervals of other chaparral types. Fire intervals can exceed 100 years, and the specimens can grow to large size. Season of burning plays a large part in species composition. Occasionally, frost affects mortality and increases fuel buildup.

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- California Coastal Closed-Cone Conifer Forest and Woodland (CES206.922)

Adjacent Ecological System Comments: This system often co-occurs with California Coastal Closed-Cone Conifer Forest and Woodland (CES206.922).

DISTRIBUTION

Range: This systems occurs within the fog belt from southern California to the Mendocino coast of northern California. It extends north into coastal Oregon in very small patches.

CALIFORNIA MESIC CHAPARRAL (CES206.926)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Shrubland (Shrub-dominated); Mediterranean [Mediterranean Xeric-Oceanic]; Udic; Quercus berberidifolia
Non-Diagnostic Classifiers: Sideslope; Ustic; Intermediate Disturbance Interval; F-Landscape/High Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2097; ESLF 5303; ESP 1097

CONCEPT

Summary: This ecological system occurs in mesic site conditions, such as north-facing slopes, concavities, or toeslopes, with well-drained soils throughout Mediterranean California away from the coastal fog belt. It occurs most commonly on north-facing slopes up to 1500 m (4550 feet) in elevation and up to 1830 m (6000 feet) in southern California. This system tends to be dominated by a variety of mixed or single-species, evergreen, sclerophyllous shrubs that resprout from lignotubers following fire. Common species include *Quercus berberidifolia, Quercus wislizeni var. frutescens, Cercocarpus montanus var. glaber (= Cercocarpus betuloides), Fraxinus dipetala, Garrya flavescens, Garrya elliptica, Heteromeles arbutifolia, Lonicera* spp., *Prunus ilicifolia, Rhamnus crocea, Rhamnus ilicifolia, Toxicodendron diversilobum, Ribes* spp., and *Sambucus* spp. Weakly re-sprouting or obligate seeders that also commonly occur in this system include arborescent *Ceanothus* spp., such as *Ceanothus spinosus, Ceanothus oliganthus, Ceanothus tomentosus*, and *Ceanothus leucodermis*. *Umbellularia californica* and *Aesculus californica* can also occur as shrubs and, lacking disturbance, can grow to tree size, as do some of the other chaparral shrubs (some old-growth stands can reach 10.6 m [35 feet] in height!). Most chaparral species are fire-adapted, resprouting vigorously after burning or producing fire-resistant seeds. This is not a system that requires frequent fire for perpetuation.
Related Concepts:
- Montane Shrubland (209) (Shiflet 1994) Broader. Some portions of SRM type 209 are ncluded in the Mesic Chaparral system.
- Scrub Oak Mixed Chaparral (207) (Shiflet 1994) Equivalent. These are basically equivalent.

DESCRIPTION

Dynamics: TNC fire model information: Chaparral burns in high-intensity stand-replacing crown fires that burn thousands of acres in a single event. However, there is a considerable range in the flammability of shrub species (e.g., chamise is "flashier" than manzanita). Large, stand-replacement events can interact with seed availability and, hence, influence post-fire successional pathways differently than for smaller, less severe fires. Mean fire-return intervals are highly variable across the state depending on species composition and other factors. Sediment cores taken from the Santa Barbara Channel in central California dating from the 16th and 17th centuries indicate that large fires burned the Santa Ynez and Santa Lucia mountains every 40-60 years. Season of burning plays a large part in species composition. Occasionally, frost affects mortality and increases fuel buildup. In the last century, the high frequency of human ignitions has reduced the mean fire-return interval to 30-35 years in southern California.

Component Associations:
- *Cercocarpus montanus var. glaber* Sierran Chaparral Shrubland (CEGL008638, G4?)
- *Prunus ilicifolia / Sanicula crassicaulis* Shrubland (CEGL003342, G2)

DISTRIBUTION

Range: This system occurs throughout Mediterranean California away from the coastal fog belt. It may occur as very small patches in southwestern Oregon, but it isn't clearly documented from there.
Divisions: 206:C
Nations: US
Subnations: CA
Map Zones: 3:C, 4:C, 5:C, 6:C

CALIFORNIA MONTANE WOODLAND AND CHAPARRAL (CES206.925)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Short (50-100 yrs) Persistence; Shrubland (Shrub-dominated); Mediterranean [Mediterranean Xeric-Oceanic]; Shallow Soil
Non-Diagnostic Classifiers: Montane [Montane]; Sideslope; Xeric; F-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2098; ESLF 5304; ESP 1098

CONCEPT

Summary: This ecological system includes chaparral or open shrubby woodlands found among montane forests above 1500 m (4550 feet) elevation from the southern Cascades of Oregon to the Peninsular Ranges of California into Baja California, Mexico, where much annual precipitation occurs as snow. These are often locations with steep, exposed slopes with rocky and/or shallow soils, often glaciated. Stands are not found in the foothills but rather occur commonly above 1524 m (5000 feet) in elevation. These are mosaics of woodlands with chaparral understories, shrub-dominated chaparral, or short-lived chaparral with conifer species invading, if good seed source is available. Shrubs will often have higher densities than the trees, which are more limited due to the rocky/thin soils. These can also be short-duration chaparrals in previously forested areas that have experienced crown fires. Trees tend to have a scattered open canopy or can be clustered, over a usually continuous dense shrub layer. Trees can include *Pinus jeffreyi, Abies concolor, Abies magnifica, Pinus monticola, Pinus lambertiana, Pinus coulteri, Pinus attenuata, Cupressus forbesii, Cupressus arizonica ssp. stephensonii*, and *Cupressus arizonica ssp. nevadensis (= Cupressus nevadensis)*. Typical sclerophyllous chaparral shrubs include *Arctostaphylos nevadensis, Arctostaphylos patula, Arctostaphylos glandulosa, Ceanothus cordulatus, Ceanothus diversifolius, Ceanothus pinetorum, Ceanothus velutinus*, and *Chrysolepis sempervirens (= Castanopsis sempervirens)*. Some stands can be dominated by winter deciduous shrubs, such as *Prunus emarginata, Prunus subcordata* and *Ceanothus sanguineus* (in Oregon), *Prunus virginiana, Ceanothus integerrimus, Holodiscus discolor (= Holodiscus microphyllus)*, and *Quercus garryana var. breweri*. Most chaparral species are fire-adapted, resprouting vigorously after burning or producing fire-resistant seeds. Occurrences of this system likely shift across montane forested landscapes with catastrophic fire events.
Classification Comments: Two phases are recognized: first, early-seral and post-fire shrub fields with conifers, and second, edaphically controlled sites, with soils that are too dry or shallow-soiled for trees, hence sites where shrubs stay dominant (such as *Quercus vacciniifolia, Arctostaphylos patula, Chrysolepis sempervirens*). This treatment combines "interior closed-cone conifer" woodlands (obligate fire-reproducing species) with montane chaparral and may need to be revisited.
Related Concepts:
- Bittercherry (419) (Shiflet 1994) Intersecting. Sierran chaparral on east-side includes *Prunus emarginata* shrublands.
- Montane Shrubland (209) (Shiflet 1994) Broader. This ecological system includes early-seral and post-fire shrub fields with conifers, and secondly edaphically-controlled sites, with soils that are too dry or shallow-soiled for trees, hence sites where shrubs stay dominant. Nearly equivalent to 209.

CALIFORNIA XERIC SERPENTINE CHAPARRAL (CES206.927)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Mediterranean [Mediterranean Xeric-Oceanic]; Ultramafic with low Ca:Mg ratio; Very Shallow Soil; Xeric; Broad-Leaved Evergreen Shrub; Cupressus macnabiana
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Shrubland (Shrub-dominated); Serpentine; Consolidated
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2099; ESLF 5305; ESP 1099

CONCEPT

Summary: This ecological system occurs throughout Mediterranean California (excluding far southern California) on thin, rocky, ultramafic (gabbro, peridotite, serpentinite) soils and in areas below winter snow accumulations that typically experience hot and dry summers. Not all ultramafic outcrops support distinct vegetation; only those with very low Ca:Mg ratios impact biotic composition. This system is highly variable and spotty in distribution. Characteristic plant species include *Cupressus macnabiana, Quercus durata, Arctostaphylos viscida, Arctostaphylos pungens*, and *Arctostaphylos glauca*. Common associates include *Adenostoma fasciculatum, Ceanothus cuneatus, Fremontodendron californicum, Quercus sadleriana, Quercus vacciniifolia, Garrya* spp., *Umbellularia californica, Ceanothus pumilus, Frangula californica (= Rhamnus californica)*, and *Arctostaphylos nevadensis*. California endemics such as *Ceanothus jepsonii* also occur. *Pinus sabiniana* can occur at varying cover from trace to more abundant. Many locally endemic and often rare forbs can occur, such as *Streptanthus* spp., *Hesperolinon* spp., *Eriogonum* spp., *Madia* spp., *Mimulus* spp., *Allium* spp., and *Asclepias solanoana*. This chaparral type tends to have fewer trees than mesic chaparral.
Classification Comments: Xeric serpentine chaparral shrublands occurring in the Klamath-Siskiyou region of northwestern California are placed into the similar Klamath-Siskiyou Xeromorphic Serpentine Savanna and Chaparral (CES206.150). However, the distribution of these two systems, as currently described, overlaps somewhat. Further review and clarification of their differences and differing distributions are desirable.
Related Concepts:
- Chamise Chaparral (206) (Shiflet 1994) Intersecting. Includes sepentine chaparral

DESCRIPTION

Environment: This system occurs on thin, rocky, ultramafic (gabbro, peridotite, serpentinite) soils and in areas below winter snow accumulations that typically experience hot and dry summers. Not all ultramafic outcrops support distinct vegetation; only those with very low Ca:Mg ratios impact biotic composition. Soils on ultramafics are usually shallow and skeletal, with little profile development. Ultramafic soils impose the following stresses on plants: imbalance of calcium and magnesium, magnesium toxicity, low availability of molybdenum, toxic levels of heavy metals, sometime high alkalinity, low concentrations of some essential nutrients, and low soil water storage capacity (Sanchez-Mata 2007). In some cases, the steepness of the slopes and general sparseness of the vegetation result in continual erosion.
Dynamics: Landfire (2007a) model: Due to the poor soil nutrient levels, biomass accumulation tends to be significantly lower in these serpentine systems than in neighboring patches of sandstone chaparral. As a result, fire frequency and fire severity are reduced. A study at the McLaughlin Reserve (Safford and Harrison 2008) found that time since last fire was nearly four times longer than on non-serpentine sites, and severity was also significantly reduced. The effects of fire on diversity in these systems are less pronounced than in non-serpentine systems, though they may be longer lasting (Safford and Harrison 2004); these authors found that few species on serpentine depended on fire for germination.

DISTRIBUTION

Range: This system occurs throughout Mediterranean California (excluding far southern California) into Oregon, on thin, rocky, ultramafic soils.
Divisions: 206:C
Nations: US
Subnations: CA, OR

CHIHUAHUAN CREOSOTEBUSH DESERT SCRUB (CES302.731)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Xeromorphic Shrub
Non-Diagnostic Classifiers: Lowland [Lowland]; Toeslope/Valley Bottom; Alkaline Soil; Aridic
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2074; ESLF 5251; ESP 1074

CONCEPT

Summary: This ecological system is the common lower elevation desert scrub that occurs throughout much of the Chihuahuan Desert and has recently expanded into former desert grasslands in the northern portion of its range. Stands typically occur in flat to gently sloping desert basins and on alluvial plains, extending up into lower to mid positions of piedmont slopes (bajada). Substrates range from coarse-textured loams on gravelly plains to finer-textured silty and clayey soils in basins. Soils are alluvial, typically loamy and non-saline, and frequently calcareous as they are often derived from limestone, and to a lesser degree igneous rocks. The vegetation is characterized by a moderate to sparse shrub layer (<10% cover on extremely xeric sites) that is typically strongly dominated by *Larrea tridentata* with *Flourensia cernua* often present to codominant. A few scattered shrubs or succulents may also be present, such as *Agave lechuguilla, Parthenium incanum, Jatropha dioica, Koeberlinia spinosa, Lycium* spp., and *Yucca* spp. Additionally, *Flourensia cernua* will often strongly dominate in silty basins that are included in this ecological system. In general, shrub diversity is low as this ecological system lacks codominant thornscrub and other mixed desert scrub species that are common on the gravelly mid to upper piedmont slopes. However, shrub diversity and cover may increase locally where soils are deeper and along minor drainages with occasional *Atriplex canescens, Gutierrezia sarothrae*, or *Prosopis glandulosa*. Herbaceous cover is usually low and composed of grasses. Common species may include *Bouteloua eriopoda, Dasyochloa pulchella (= Erioneuron pulchellum), Muhlenbergia porteri, Pleuraphis mutica, Scleropogon brevifolius*, and *Sporobolus airoides*. Included in this ecological system are *Larrea tridentata*-dominated shrublands with a sparse understory that occur on gravelly to silty, upper basin floors and alluvial plains. A pebbly desert pavement may be present on the soil surface.
Classification Comments: NRCS Ecological Site Description MLRA 42 SD-2 Loamy Ecological Site descriptions describe this system on the Jornada Experimental Range with State-and-Transition Model showing shifts in species composition with land use. Historic stands are thought to have been *Pleuraphis mutica*- and *Bouteloua eriopoda*-dominated desert grassland with few scrubs present. During Landfire mapzone 25 BpS modeling workshops, experts considered this type to be non-reference condition, shrub-invaded Chihuahuan Tobosa Flats and Loamy Plains Desert Grassland (BpS) at the Jornada.

DESCRIPTION

Environment: This ecological system is the common lower elevation desert scrub that occurs throughout much of the Chihuahuan Desert and has recently expanded into former desert grasslands in the northern portion of its range. Stands typically occur in flat to gently sloping, desert basins and on alluvial plains, extending up into the lower to mid positions of piedmont slopes (bajada). Substrates range from coarse-textured loams on gravelly plains to finer-textured silty and clayey soils in basins. Soils are alluvial, typically loamy and non-saline, and frequently calcareous as they are often derived from limestone, and to a lesser degree igneous rocks (Brown 1982, MacMahon and Wagner 1985, Henrickson and Johnston 1986, MacMahon 1988, Dick-Peddie 1993).
Vegetation: This alluvial plains desert scrub is characterized by a moderate to sparse shrub layer (<10% cover on extremely xeric sites) that is typically strongly dominated by *Larrea tridentata* with *Flourensia cernua* often present to codominant (Brown 1982, MacMahon and Wagner 1985, Henrickson and Johnston 1986, MacMahon 1988, Dick-Peddie 1993). A few scattered shrubs or succulents may also be present such as *Agave lechuguilla, Parthenium incanum, Jatropha dioica, Koeberlinia spinosa, Lycium* spp., and *Yucca torreyi*. Additionally, *Flourensia cernua* will often strongly dominate in silty basins that are included in this ecological system. In general, shrub diversity is low as this ecological system lacks codominant thornscrub and other mixed desert scrub species that are common on the gravelly mid to upper piedmont slopes. However, shrub diversity and cover may increase locally where soils are deeper and along minor drainages with occasional *Atriplex canescens, Gutierrezia sarothrae*, or *Prosopis glandulosa*. In the southern Chihuahuan Desert, stands are dominated by *Larrea tridentata* with *Agave parryi (= Agave scabra), Opuntia kleiniae, Opuntia imbricata*, and *Yucca filifera* (Huerta-Martinez et al. 2004). Herbaceous cover is usually low and composed of grasses.

Common species may include *Bouteloua eriopoda, Dasyochloa pulchella, Muhlenbergia porteri, Pleuraphis mutica, Scleropogon brevifolius*, and *Sporobolus airoides*. Included in this ecological system are *Larrea tridentata*-dominated shrublands with a sparse understory that occur on gravelly to silty, upper basin floors and alluvial plains. A pebbly desert pavement may be present on the soil surface.

Dynamics: In the U.S., much of this scrubland is thought to be a result of recent expansion of *Larrea tridentata* into former desert grasslands in the last 150 years as a result of drought, overgrazing by livestock, and/or decreases in fire over the last 70-250 years (Buffington and Herbel 1965, Ahlstrand 1979, Donart 1984, Dick-Peddie 1993, Gibbens et al. 2005). This system includes vast areas of loamy plains that have been converted from *Pleuraphis mutica* and *Bouteloua eriopoda* desert grasslands to *Larrea tridentata* scrub. This system also includes invasive *Flourensia cernua* shrublands that occur in former (degraded) tobosa (*Pleuraphis mutica*) flats and loamy plains. Presence of *Scleropogon brevifolius* is common in these invasive stands. Dick-Peddie (1993) suggested that absence of *Flourensia cernua* as codominant and presence of *Dasyochloa pulchella, Acourtia nana (= Perezia nana)*, and *Yucca elata* may be indicators of recent conversion of desert grasslands into desert scrub, but more research is needed. Conversely, shrublands with a sparse understory of *Larrea tridentata* on remnant early Holocene erosional surfaces often with desert pavement may indicate historic distributions of *Larrea tridentata* desert scrub in the Chihuahuan Desert (Muldavin et al. 2000b).

Component Associations:
- *Larrea tridentata - Parthenium incanum* Shrubland (CEGL001274, G5)
- *Larrea tridentata / Bouteloua eriopoda* Shrubland (CEGL001265, G4)
- *Larrea tridentata / Dasyochloa pulchella* Shrubland (CEGL001269, G5)
- *Larrea tridentata / Muhlenbergia porteri* Shrubland (CEGL001272, GNR)
- *Larrea tridentata* / Sparse Understory Shrubland (CEGL001276, GNR)
- *Larrea tridentata / Sporobolus airoides* Shrubland (CEGL001277, GNR)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Chihuahuan Mixed Desert and Thornscrub (CES302.734)
- North American Warm Desert Playa (CES302.751)

Adjacent Ecological System Comments: This ecological system occurs on loamy substrates typically below Chihuahuan Mixed Desert and Thornscrub (CES302.734) that is characteristic of gravelly mid to upper piedmont slopes.

DISTRIBUTION

Range: This extensive, lower elevation desert scrub ecological system occurs in the Chihuahuan Desert in broad desert basins and alluvial plains extending up into the lower bajada.
Divisions: 302:C
Nations: MX, US

Non-Diagnostic Classifiers: Toeslope/Valley Bottom; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Aridic; Xeromorphic Shrub; Thorn Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2100; ESLF 5306; ESP 1100

CONCEPT

Summary: This ecological system is the widespread desert scrub that occurs on gravelly mid to upper bajadas, foothills and dissected gravelly alluvial fans in the Chihuahuan Desert and has recently expanded into former desert grasslands in the northern portion of its range. It generally occurs on mid to upper piedmonts above the desert plains Chihuahuan Creosotebush Desert Scrub (CES302.731) and extends up to the chaparral zone. Soils are typically well-drained, non-saline, gravelly loams often with a petrocalic layer. Substrates are frequently derived from limestone although igneous rocks are common in some areas. Vegetation is characterized by the presence of *Larrea tridentata*, typically mixed with thornscrub or other desert scrub such as *Agave lechuguilla, Aloysia wrightii, Baccharis pteronioides, Dasylirion leiophyllum, Flourensia cernua* (not bottomland), *Fouquieria splendens, Koeberlinia spinosa, Krameria erecta, Leucophyllum minus, Mimosa aculeaticarpa var. biuncifera, Mortonia scabrella (= Mortonia sempervirens ssp. scabrella), Opuntia engelmannii, Parthenium incanum, Prosopis glandulosa*, and *Rhus microphylla* (in drainages). Stands of *Acacia constricta-, Acacia neovernicosa-* or *Acacia greggii*-dominated thornscrub are included in this system, and limestone substrates appear important for at least these species. If present, *Prosopis glandulosa* has relatively low cover and does not dominate the shrub layer. This system also includes upper piedmont stands of desert scrub that are strongly dominated by *Larrea tridentata*. Grasses are common but generally have lower cover than shrubs. Common species may include *Bouteloua curtipendula, Bouteloua eriopoda, Bouteloua gracilis, Bouteloua hirsuta, Bouteloua ramosa, Dasyochloa pulchella*, and *Muhlenbergia porteri*. Also included in this ecological system are shrublands with a sparse understory of *Larrea tridentata* that occur on gravelly piedmont slopes that may extend down gravelly upper basins. A pebbly desert pavement may be present on the soil surface. This may indicate remnant erosional surfaces from the early Holocene that are thought to be some of the historic distribution of *Larrea tridentata* desert scrub in the Chihuahuan Desert. Historically, much of this desert scrub was thought to be a steppe characterized by perennial desert grasses (typically *Bouteloua eriopoda)* with an open creosotebush - mixed desert shrub layer.

DESCRIPTION

Environment: This ecological system is the widespread desert scrub that occurs on gravelly mid to upper bajadas, foothills and dissected gravelly alluvial fans in the Chihuahuan Desert and has recently expanded into former desert grasslands in the northern portion of its range. It generally occurs on mid to upper piedmonts above the desert plains Chihuahuan Creosotebush Desert Scrub (CES302.731) and extends up to the chaparral zone. Soils are typically well-drained, non-saline, gravelly loams often with a petrocalic layer. Substrates are frequently derived from limestone, although igneous rocks are common in some areas (Brown 1982, MacMahon and Wagner 1985, Henrickson and Johnston 1986, MacMahon 1988, Dick-Peddie 1993).

Vegetation: This mid to upper piedmont ecological system is characterized by the presence of *Larrea tridentata* typically mixed with thornscrub or other desertscrub such as *Agave lechuguilla, Aloysia wrightii, Baccharis pteronioides, Dasylirion leiophyllum, Flourensia cernua* (not bottomland), *Fouquieria splendens, Koeberlinia spinosa, Krameria erecta, Leucophyllum minus, Mimosa aculeaticarpa var. biuncifera, Mortonia scabrella (= Mortonia sempervirens ssp. scabrella), Opuntia engelmannii, Parthenium incanum, Prosopis glandulosa*, and *Rhus microphylla* (in drainages). Stands of *Acacia constricta-, Acacia neovernicosa-* or *Acacia greggii*-dominated thornscrub are included in this system, and limestone substrates appear important for at least these species. If present, *Prosopis glandulosa* has lower cover than other shrubs and does not dominate the shrub layer. This system also includes upper piedmont stands of desert scrub that are strongly dominated by *Larrea tridentata*. Grasses are common but generally have lower

cover than shrubs. Common species may include *Bouteloua curtipendula, Bouteloua eriopoda, Bouteloua gracilis, Bouteloua hirsuta, Bouteloua ramosa, Dasyochloa pulchella,* and *Muhlenbergia porteri*. Also included in this ecological system are shrublands with a sparse understory of *Larrea tridentata* that occur on gravelly piedmont slopes that may extend down gravelly upper basins. A pebbly desert pavement may be present on the soil surface. This may indicate remnant erosional surfaces from the early Holocene that are thought to be some of the historic distribution of *Larrea tridentata* desert scrub in the Chihuahuan Desert (Muldavin et al. 2000b). Historically, much of this desert scrub was thought to be a steppe characterized by perennial desert grasses such as *Bouteloua eriopoda, Bouteloua ramosa, Muhlenbergia porteri, Bothriochloa barbinodis*, or *Digitaria californica* with an open creosotebush - mixed desert shrub layer.

Dynamics: In the U.S., much of this scrubland is thought to be a result of recent expansion of *Larrea tridentata* into former desert grasslands and steppe in the last 150 years as a result of drought, overgrazing by livestock, and/or decreases in fire over the last 70-250 years (Buffington and Herbel 1965, Ahlstrand 1979, Donart 1984, Dick-Peddie 1993, Gibbens et al. 2005). Dick-Peddie (1993) suggested that absence of *Flourensia cernua* as codominant and presence of *Dasyochloa pulchella, Acourtia nana,* and *Yucca elata* may be indicators of recent conversion of desert grasslands into desert scrub, but more research is needed. Conversely, sparse understory *Larrea tridentata* shrublands on remnant early Holocene erosional surfaces often with shallow calcareous soils and desert pavement may indicate historic distributions of *Larrea tridentata* desert scrub in the Chihuahuan Desert (Stein and Ludwig 1979, Muldavin et al. 2000b).

In the northern Chihuahuan Desert, this creosotebush mixed desert and thornscrub shrubland ecological system is thought to occur in presettlement conditions largely as mixed desert shrub-steppe on upper bajada gravelly soils and dissected gravelly alluvial fans (S. Yanoff pers. comm. 2006). This grama grass steppe with an open canopy of desert scrub species is a mostly historical grama grass steppe BpS that was described during Landfire MZ25 BpS modeling workshops as Chihuahuan Grama Grass Creosote Steppe. It is distinct from creosotebush mixed shrublands on similar sites because it has an open shrub layer characterized by dense perennial grasses (typically black grama).

CHIHUAHUAN MIXED SALT DESERT SCRUB (CES302.017)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Atriplex spp.
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2075; ESLF 5252; ESP 1075

CONCEPT

Summary: This ecological system includes extensive open-canopied shrublands of typically saline basins in the Chihuahuan Desert. Stands often occur on alluvial flats and around playas, as well as in floodplains along the Rio Grande and Pecos rivers, possibly also extending into the San Simon of Southeastern Arizona. Substrates are generally fine-textured, saline soils. Vegetation is typically composed of one or more *Atriplex* species such as *Atriplex canescens, Atriplex obovata,* or *Atriplex polycarpa* along with species of *Allenrolfea, Flourensia, Salicornia, Suaeda*, or other halophytic plants. Graminoid species may include *Sporobolus airoides, Pleuraphis mutica*, or *Distichlis spicata* at varying densities.

DESCRIPTION

Environment: This system includes extensive open-canopied shrublands of typically saline basins in the Chihuahuan Desert. Stands often occur on alluvial flats, around playas and floodplains of the Rio Grande and Pecos rivers, possibly also extending into the San Simon of southeastern Arizona. Sites are flat to gently sloping with slopes up to 3%. Elevation ranges from 1000-1300 m (3300-4300 feet). Substrates are generally fine-textured, saline soils but may include moderately coarse-textured alluvium in the floodplains. Water tables are generally shallow but fluctuate within reach of deep-rooted plants, and in most places are high enough that salts accumulate on the surface of the soil.
Vegetation: Vegetation is typically composed of one or more *Atriplex* species, such as *Atriplex canescens, Atriplex obovata*, or *Atriplex polycarpa*, along with species of *Allenrolfea, Flourensia, Salicornia, Suaeda*, or other halophytic plants. Graminoid species may include *Sporobolus airoides, Sporobolus wrightii, Pleuraphis mutica*, or *Distichlis spicata* at varying densities. Occasional riparian species may be present near watercourses, such as *Prosopis pubescens* or *Populus deltoides ssp. wislizeni*.

Component Associations:
- *Atriplex canescens / Parthenium confertum* Shrubland (CEGL001290, GNRQ)
- *Atriplex canescens / Sporobolus airoides* Shrubland (CEGL001291, G5?)
- *Atriplex canescens / Sporobolus wrightii* Shrubland (CEGL001292, GNRQ)
- *Atriplex obovata / Tidestromia carnosa* Dwarf-shrubland (CEGL004575, G2?)
- *Atriplex polycarpa / Pleuraphis mutica* Shrubland (CEGL001319, GU)
- *Distichlis spicata* Herbaceous Vegetation (CEGL001770, G5)
- *Flourensia cernua / Achnatherum eminens* Shrubland (CEGL001338, GNRQ)
- *Flourensia cernua / Bouteloua curtipendula* Shrubland (CEGL001336, GNRQ)
- *Flourensia cernua / Pleuraphis mutica* Shrubland (CEGL001541, G4)
- *Flourensia cernua / Sporobolus airoides* Shrubland (CEGL001337, GNRQ)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:

CHIHUAHUAN STABILIZED COPPICE DUNE AND SAND FLAT SCRUB (CES302.737)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Plain; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Sand Soil Texture; Aridic; Very Short Disturbance Interval; W-Landscape/High Intensity; Thorn Shrub; Prosopis spp.-dominated
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2076; ESLF 5253; ESP 1076

CONCEPT

Summary: This ecological system includes the open desert scrub of vegetated coppice dunes and sandsheets found in the Chihuahuan Desert. Stands are usually dominated by *Prosopis glandulosa* or *Artemisia filifolia* but also include *Atriplex canescens, Ephedra torreyana, Ephedra trifurca, Poliomintha incana*, and *Rhus microphylla* coppice and sand flat scrub usually with 10-30% total vegetation cover. *Yucca elata, Gutierrezia sarothrae, Bouteloua eriopoda*, and *Sporobolus flexuosus* are commonly present. In northern stands, *Artemisia filifolia* dominates and *Prosopis glandulosa* becomes less common or absent. This system includes degraded sandy desert plains grasslands now dominated by *Artemisia filifolia*.
Classification Comments: Heavy grazing in late 1800s and early 1900s may have caused mesquite to increase. Naturally occurring coppice dunes may have been limited to areas peripheral to active dunes. Coppice dunes in the Tularosa Basin and elsewhere are currently more extensive, resulting from sand movement due to degradation of desert grasslands and steppe. For Landfire mapzone 25 BpS modeling, this system is considered to be historically uncharacteristic of most sites where it occurs. Much of the current extent of this system is thought to have been formerly Chihuahuan Sandy Plains Semi-Desert Grassland (CES302.736).
Similar Ecological Systems:
- Apacherian-Chihuahuan Mesquite Upland Scrub (CES302.733)

Related Concepts:

CHIHUAHUAN SUCCULENT DESERT SCRUB (CES302.738)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Temperate [Temperate Xeric]; Succulent Shrub; Cacti-dominated
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Aridic
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2077; ESLF 5254; ESP 1077

CONCEPT

Summary: This ecological system is found in the Chihuahuan Desert on colluvial slopes, upper bajadas, sideslopes, ridges, canyons, hills and mesas. Sites are hot and dry, typically with southerly aspects. Gravel and rock are often abundant on the ground surface. The vegetation is characterized by the relatively high cover of succulent species such as *Agave lechuguilla, Euphorbia antisyphilitica, Fouquieria splendens, Ferocactus* spp., *Opuntia engelmannii, Opuntia imbricata, Opuntia spinosior, Yucca baccata*, and many others. Perennial grass cover is generally low. The abundance of succulents is diagnostic of this desert scrub system, but desert shrubs are usually present. Stands in rolling topography may form a mosaic with more mesic desert scrub or desert grassland ecological systems that would occur on less xeric northerly slopes. *Agave lechuguilla* is more abundant in stands in the southern part of the mapzone. This system does not include loamy plains desert grasslands or shrub-steppe with a strong cacti component such as cholla grasslands.

COLORADO PLATEAU BLACKBRUSH-MORMON-TEA SHRUBLAND (CES304.763)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Shrubland (Shrub-dominated); Temperate [Temperate Xeric]; Aridic
Non-Diagnostic Classifiers: Ridge/Summit/Upper Slope; Sideslope; Alkaline Soil; Sand Soil Texture; Very Long Disturbance Interval; F-Patch/High Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2078; ESLF 5255; ESP 1078

CONCEPT

Summary: This ecological system occurs in the Colorado Plateau on benchlands, colluvial slopes, pediments or bajadas. Elevation ranges from 560-1650 m. Substrates are shallow, typically calcareous, non-saline and gravelly or sandy soils over sandstone or limestone bedrock, caliche or limestone alluvium. It also occurs in deeper soils on sandy plains where it may have invaded desert grasslands. The vegetation is characterized by extensive open shrublands dominated by *Coleogyne ramosissima* often with *Ephedra viridis, Ephedra torreyana*, or *Grayia spinosa*. Sandy portions may include *Artemisia filifolia* as codominant. The herbaceous layer is sparse and composed of graminoids such as *Achnatherum hymenoides, Pleuraphis jamesii*, or *Sporobolus cryptandrus*.
Related Concepts:
- Blackbush (212) (Shiflet 1994) Broader

DESCRIPTION

Environment: This ecological system typically occurs on gentle to steep, bouldery or rocky slopes of mountains, canyons, and mesas with varying aspects. This system is an evergreen, microphyllous desert scrub with succulents, half-shrubs, and scattered deciduous shrubs typically found at elevations ranging from 580 to 1650 m. (1903-5413 feet). This shrubland system occurs in an arid to semi-arid climate with annual precipitation in the form of summer monsoons and winter storms averaging approximately 20 cm. Soils are highly variable and parent materials may include shale, sandstone, limestone, quartzites, and igneous rocks. Soils are generally coarse-textured, often rocky, shallow and well-drained. Effective soil moisture appears to be primarily controlled by regolith depth and position in relation to the water table. This brushland system occupies most sites where regolith is uniformly shallow. In association with blackbrush (*Coleogyne ramosissima*) sites, the soil moisture is concentrated on top of impermeable bedrock at a shallow depth. This perching effect allows for gradual uptake of moisture by the plants roots (Loope and West 1979). This permits growth of plants with more mesic habitat requirements (Warren et al. 1982). On sites with deep soil, blackbrush may occur in almost pure occurrences with only a few associated species (Warren et al. 1982). Dark-colored cryptogamic soil crusts, composed of lichens, mosses, fungi, and algae, are often present in this system in fairly undisturbed areas. Sandy soils may have more cryptogamic crusts than clayish or silty soil surfaces.
Vegetation: This ecological system is dominated by sparse to moderately dense shrubs. Dominant shrubs include *Coleogyne ramosissima, Ephedra nevadensis*, and *Ephedra viridis* (which may codominate with *Grayia spinosa, Salvia dorrii*, and *Lycium andersonii*). There is usually a sparse herbaceous layer with some perennial grasses and forbs. Annual grasses and forbs are present seasonally. Some characteristic species associated with this system include the shrubs *Gutierrezia sarothrae, Chrysothamnus viscidiflorus, Yucca baccata*, and *Krameria grayi*, succulents such as *Ferocactus cylindraceus (= Ferocactus acanthodes), Opuntia* spp., *Echinocereus* spp., *Echinocactus* spp., and *Agave* spp., the graminoid *Pleuraphis rigida*, and perennial forbs such as *Machaeranthera pinnatifida* and *Sphaeralcea ambigua*.
Dynamics: Fire does not appear to play a role in maintenance of shrublands within this system. Topographic breaks dissect the landscape, and isolated pockets of vegetation are separated by rock walls or steep canyons. Blackbrush is fire-intolerant (Loope and West 1979). Following fires, these communities are often colonized by non-native grasses, which serve to encourage recurrent fires and delay shrub regeneration (IVC 1999). In shallow regolith situations, secondary succession, in the sense of site preparation by seral plants, may not occur at all (Loope and West 1979).

Component Associations:
- *Artemisia filifolia / Bouteloua eriopoda* Shrubland (CEGL001077, G4)

COLORADO PLATEAU MIXED LOW SAGEBRUSH SHRUBLAND (CES304.762)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Temperate [Temperate Xeric]; Aridic
Non-Diagnostic Classifiers: Alkaline Soil
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Evergreen dwarf-shrubland
National Mapping Codes: EVT 2064; ESLF 5201; ESP 1064

CONCEPT

Summary: This ecological system occurs in the Colorado Plateau, Tavaputs Plateau and Uinta Basin in canyons, gravelly draws, hilltops, and dry flats at elevations generally below 1800 m. Soils are often rocky, shallow, and alkaline. This type extends across northern New Mexico into the southern Great Plains on limestone hills. It includes open shrublands and steppe dominated by *Artemisia nova* or *Artemisia bigelovii* sometimes with *Artemisia tridentata ssp. wyomingensis* codominant. Semi-arid grasses such as *Achnatherum hymenoides, Aristida purpurea, Bouteloua gracilis, Hesperostipa comata, Pleuraphis jamesii*, or *Poa fendleriana* are often present and may form a graminoid layer with over 25% cover.

Related Concepts:
- Black Sagebrush (405) (Shiflet 1994) Intersecting
- Other Sagebrush Types (408) (Shiflet 1994) Intersecting. *Artemisia bigelovii* shrublands are included in this ecological system.

Component Associations:
- *Artemisia arbuscula ssp. longiloba / Elymus lanceolatus* Shrubland (CEGL002585, GNR)
- *Artemisia bigelovii - Ephedra (viridis, torreyana)* Talus Shrubland (CEGL003755, GNR)

COLORADO PLATEAU PINYON-JUNIPER SHRUBLAND (CES304.766)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Mesa; Ridge/Summit/Upper Slope; Sedimentary Rock; Temperate [Temperate Xeric]; Aridic; Pinus edulis, Juniperus osteosperma
Non-Diagnostic Classifiers: Foothill(s); Shrubland (Shrub-dominated); Sideslope; Alkaline Soil; Long Disturbance Interval; F-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2102; ESLF 5308; ESP 1102

CONCEPT

Summary: This ecological system is characteristic of the rocky mesatops and slopes on the Colorado Plateau and western slope of Colorado, but these stunted tree shrublands may extend further upslope along the low-elevation margins of taller pinyon-juniper woodlands. Sites are drier than Colorado Plateau Pinyon-Juniper Woodland (CES304.767). Substrates are shallow/rocky and shaly soils at lower elevations (1200-2000 m). Sparse examples of the system grade into Colorado Plateau Mixed Bedrock Canyon and Tableland (CES304.765). The vegetation is dominated by dwarfed (usually <3 m tall) *Pinus edulis* and/or *Juniperus osteosperma* trees forming extensive tall shrublands in the region along low-elevation margins of pinyon-juniper woodlands. Other shrubs, if present, may include *Artemisia nova, Artemisia tridentata ssp. wyomingensis, Chrysothamnus viscidiflorus,* or *Coleogyne ramosissima*. Herbaceous layers are sparse to moderately dense and typically composed of xeric graminoids.

COLUMBIA PLATEAU SCABLAND SHRUBLAND (CES304.770)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Basalt; Shallow Soil
Non-Diagnostic Classifiers: Plain; Plateau; Toeslope/Valley Bottom; Temperate [Temperate Continental]; Aridic
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Evergreen dwarf-shrubland
National Mapping Codes: EVT 2065; ESLF 5202; ESP 1065

CONCEPT

Summary: This ecological system is found in the Columbia Plateau region and forms extensive low shrublands. These xeric shrublands occur under relatively extreme soil-moisture conditions. Substrates are typically shallow lithic soils with limited water-holding capacity over fractured basalt. Because of poor drainage through basalt, these soils are often saturated from fall to spring by winter precipitation but typically dry out completely to bedrock by midsummer. Total vegetation cover is typically low, generally less than 50% and often much less than that. Vegetation is characterized by an open dwarf-shrub canopy dominated by *Artemisia rigida* along with other shrub and dwarf-shrub species, particularly *Eriogonum* spp. Other shrubs are uncommon in this system; mixes of *Artemisia rigida* and other *Artemisia* species typically belong to different ecological systems than this. Low cover of perennial bunch grasses, such as *Danthonia unispicata, Elymus elymoides, Festuca idahoensis*, or primarily *Poa secunda*, as well as scattered forbs, including species of *Allium, Antennaria, Balsamorhiza, Lomatium, Phlox*, and *Sedum*, characterize these sites. Individual sites can be dominated by grasses and semi-woody forbs, such as *Stenotus stenophyllus*. Annuals may be seasonally abundant, and cover of moss and lichen is often high in undisturbed areas (1-60% cover).

EDWARDS PLATEAU LIMESTONE SHRUBLAND (CES303.041)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Plain; Plateau; Shrubland (Shrub-dominated); Alkaline Soil; Very Shallow Soil; Xeric
Non-Diagnostic Classifiers: Lowland [Foothill]; Calcareous
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2393; ESLF 5324; ESP 1393

CONCEPT

Summary: This ecological system occurs as a matrix on relatively thin-soiled surfaces of plateaus of the massive limestones such as the Edwards limestone. These short to tall shrublands are variable in density depending on the relative amount of, and depth to, bedrock. *Quercus sinuata var. breviloba* is an important component of the system, with some areas dominated by *Quercus fusiformis*. *Juniperus ashei* is often an important component of this system. Important components in western examples may include *Pinus remota, Quercus mohriana, Quercus vaseyana*, and *Juniperus pinchotii*. Herbaceous cover may be patchy and is generally graminoid with species including *Schizachyrium scoparium, Bouteloua curtipendula, Bouteloua rigidiseta, Bouteloua trifida, Hilaria belangeri, Bothriochloa laguroides ssp. torreyana, Nassella leucotricha, Erioneuron pilosum, Aristida* spp., and others. Disturbances such as fire may be important processes maintaining this system. However, it appears to persist on thin-soiled sites. In the western portions of the Edwards Plateau, more xeric conditions lead to the slow succession of sites to woodlands, resulting in long-persisting shrublands.
Classification Comments: This system represents naturally occurring shrublands that are maintained over long periods (greater than 50 years) as shrublands. It tends to occur on shallow soils over massive hard-bedded limestone formations and/or in the western and drier portions of the Edwards Plateau of Texas. Early-successional vegetation of Edwards Plateau Limestone Savanna and Woodland (CES303.660) may exhibit a composition and structure similar to the vegetation described and classified here, but the temporal dynamics are different. This system was modeled for mapzone 26, however, Edwards Plateau Limestone Savanna and Woodland (CES303.660) was not. Both systems occur on the far eastern edge of the mapzone on the Stockton Plateau.
Similar Ecological Systems:

- Edwards Plateau: Shin Oak Slope Shrubland (1226) [CES303.041.18] (Elliott 2011) Finer

DESCRIPTION

Environment: This system occurs on thin soils over massive limestone such as Edwards or related formations in the Edwards Plateau of Texas. It may occur on plateaus or slopes and may often form a discontinuous band around a plateau edge as it breaks into the adjacent slope. Soils are characterized by Shallow or Very Shallow Ecological Sites, but may also be found on Low Stony Hill Ecological Sites (Elliott 2011).
Vegetation: This system may be represented by extensive continuous shrub cover, or occur as a discontinuous shrubland, often with scattered emergent overstory trees. *Quercus sinuata var. breviloba*, *Quercus fusiformis*, and/or *Juniperus ashei* may be important components of the system. In the interior of the Edwards Plateau ecoregion, *Quercus sinuata var. breviloba* is an important component, with some areas dominated by a shinnery of *Quercus fusiformis*, although monotypic stands of *Quercus fusiformis* occupying the shrub layer are uncommon. In the west, *Pinus remota* may also contribute to a scattered emergent overstory. Shrub cover may be dominated by these species, or may be represented as an assemblage of a rather diverse array of species including *Rhus virens, Rhus lanceolata, Cercis canadensis var. texensis, Forestiera pubescens, Forestiera reticulata, Ungnadia speciosa, Sophora secundiflora, Diospyros texana, Salvia ballotiflora, Mimosa borealis, Condalia hookeri, Rhus trilobata, Opuntia engelmannii var. lindheimeri*, and *Mahonia trifoliolata*. In the northwest corner of the ecoregion, this system may occur as a *Quercus mohriana*-dominated shrubland (a type more common in the Southern Shortgrass Prairie ecoregion), often sharing dominance with *Juniperus pinchotii*. Towards the southwest, *Quercus vaseyana (= Quercus pungens var. vaseyana)* becomes an important component of the system, and areas dominated by *Sophora secundiflora, Diospyros texana*, and other shrub species become more common. In the southwest corner of the ecoregion, on the Stockton Plateau, this system may be represented by *Acacia berlandieri* shrublands. Where shrub cover is distributed in a patchy mosaic, such sites may be used by black-capped vireos (*Vireo atricapilla*). Herbaceous cover may be patchy and is generally graminoid-dominated with species including *Schizachyrium scoparium, Bouteloua curtipendula,*

Bouteloua rigidiseta, Bouteloua trifida, Hilaria belangeri, Bothriochloa laguroides ssp. torreyana, Nassella leucotricha, Erioneuron pilosum, Aristida spp., and others (Elliott 2011).

Dynamics: This system occurs in a steady state on thin-soiled xeric sites. Shrub cover can be 100% in patches, but overall cover may be 40-50%. Patches of dense shrubs may be interspersed with bare rock and grasslands over shallow soil. Farther west this system grades into other shallow-soiled shrubland systems. Disturbances such as fire may be important processes maintaining this system. However, it appears to persist on thin-soiled sites. In the western portions of the Edwards Plateau, more xeric conditions lead to the slow succession of sites to woodlands resulting in long-persisting shrublands.

Component Associations:
- *Quercus mohriana - Juniperus pinchotii / Bouteloua curtipendula* Scrub (CEGL002173, G4)
- *Quercus sinuata var. breviloba* Scrub (CEGL004453, G2G3)

FLORIDA PENINSULA INLAND SCRUB (CES203.057)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Forest and Woodland (Treed); Xeric; F-Patch/High Intensity; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2387; ESLF 5318; ESP 1387

CONCEPT

Summary: This system appears in many forms, but generally consists of xeromorphic shrub vegetation (mostly evergreen oak species) with or without an emergent overstory of *Pinus clausa*. The shrubs can be very thick in places, but usually there are open patches. Ground cover is always sparse, and bare soil patches are typically evident. It is found on a sequence of sand ridges and ancient dune fields which are oriented essentially north-south in the Florida Peninsula. The appearance, floristics, and boundary of Florida scrub may contrast dramatically with the "high pine" or sandhill vegetation which is often adjacent, although lack of fire can blur these boundaries.

Related Concepts:

- Sand Pine: 69 (Eyre 1980) Intersecting
- Scrub (FNAI 1990) Finer
- Scrub (FNAI 2010a) Broader
- Southern Scrub Oak: 72 (Eyre 1980) Finer

DESCRIPTION

Environment: This system is restricted to a sequence of north/south-trending sand ridges, ancient dune fields, and former shorelines in the Florida peninsula. The largest inland scrub is found in two primary areas, essentially isolated from one another. The so called "Big Scrub" of the Ocala National Forest is the largest expanse of this system, with a somewhat smaller, more southerly area associated with the Lake Wales Ridge. According to Myers (1990), inland scrub occurs on Quartzipsamments which are excessively well-drained, nearly pure siliceous sands low in nutrients. Although all scrub soils are Entisols, there is considerable variation in soil color. This color variation appears to be related to the amount of leaching which has taken place, and appears to be related to the amount of time a site has been occupied by scrub vegetation. Excessive leaching, due to inferred long occupation by scrub vegetation, is believed to bleach upper soil horizons and develop pure white soils (such as the St. Lucie series), while moderate leaching, due to shorter occupation by scrub, contributes to less bleaching and consequently more yellow-colored soils (Paola and Orsino series).
Vegetation: This system is dominated by xeromorphic, evergreen shrub species with or without an emergent layer of *Pinus clausa*. The shrub layer composition is relatively constant, as is the abundance of individual species. *Quercus myrtifolia, Quercus inopina, Serenoa repens, Quercus geminata, Quercus chapmanii, Lyonia ferruginea,* and *Ceratiola ericoides* are the most important species. Myers (1990) indicates that much of the variability in Florida scrub is due to variation in fire-return interval, ranging from once every 10 to 100 years. Ground cover is always sparse but typically includes *Licania michauxii, Rhynchospora megalocarpa, Andropogon floridanus,* and a variety of lichens (*Cladonia* and *Cladina* species). There are a number of endemic plant species which may occur in inland Florida scrubs, including at least 13 federally listed species; many of the rarest scrub species are found only in the Lake Wales region.

This system has long been noted for its unique and interesting vegetation by authors such as Vignoles (1823), Harper (1914), Mulvania (1931), Kurz (1942), and Laessle (1958, 1968). More recent treatments by Myers (1990) and Menges (1999) have provided the most comprehensive summaries of scrub available. According to Harper (1927), "the nearly pure white sand of the ground surface, when viewed from a short distance, gives the impression of a thin rift of wind-driven snow. The vegetation is mostly dwarfed, gnarled and crooked, and presents a tangled, scraggly aspect." The appearance, floristics, and boundary of Florida scrub contrast dramatically with the "high pine" or sandhill vegetation which is often adjacent (Laessle 1968), although lack of fire can blur these boundaries. Scrub generally consists of xeromorphic shrub vegetation, such as evergreen *Ceratiola ericoides, Lyonia* spp., *Quercus* spp., *Sabal etonia, Sabal palmetto*, and *Serenoa repens*, with or without an emergent overstory of *Pinus clausa*.
Dynamics: Florida scrub is a pyrogenic system with floral and faunal components adapted to fire. Unlike most ecological systems of the Gulf and Atlantic coastal plains, this system is maintained by high-intensity, infrequent fires. Litter-fall rates are high, while turnover rates are low, contributing to fuel buildup (Lugo and Zucca 1983, Schmalzer and Hinkle 1996). However, scrub typically lacks fine-textured fuels necessary to ignite fires; most scrub fires ignite in other adjacent ecological systems. If fire spreads into scrub it is often under severe conditions of high wind, low humidity, and low fuel moisture. When fires occur in scrub they can be stand-replacing events. *Pinus clausa*, if present, is killed outright but may regenerate from seed released from serotinous cones. In parts of fires that burn completely, the shrub layer is typically killed back to ground layer but rapidly resprouts and returns to prefire levels of cover (Abrahamson 1984, Schmalzer and Hinkle 1992b). Other species such as *Ceratiola ericoides* may regenerate from seeds stored in soil (Johnson 1982). *Eryngium cuneifolium* and *Dicerandra christmanii* are narrowly endemic herb species which exhibit peaks in survival, recruitment, and density after fire (Menges 1999, Menges et al. 1999, Menges and Quintana-Ascencio 2004).

Many scrub fires burn heterogeneously with resulting patches of unburned fuels. This gap dynamics can be significant (Weekley and Menges 2003), especially in the most xeric types like rosemary scrub (Menges 1994). In the sustained absence of fire, smaller shrubs and herbs may be lost as a consequence of increasing dominance of oak stems (Menges et al. 1993).

This system has likely persisted on fossil dunes since the Pleistocene (Laessle 1968), but remaining examples are merely remnants of an ecosystem once expansive in the late Pleistocene (Myers 1990). The stature and appearance of Florida scrub may be due primarily to nutrient-poor soils, to which many of the scrub species have adapted evergreen habits (Monk 1966). Drought stress is most likely during winter and early spring, but frequent fog during these periods may ameliorate such conditions (Menges 1994). Surprisingly, given the excessively well-drained soils, drought stress may not be an important ecological factor except to limit seedling establishment (Myers 1987, 1990).

Component Associations:
- *Carya floridana - Quercus myrtifolia - Quercus geminata* Shrubland (CEGL007997, G1)
- *Ceratiola ericoides - Quercus geminata - (Quercus inopina) - Serenoa repens / Cladonia* spp. - *Cladina* spp. Shrubland (CEGL003863, G2G3)

- Florida Longleaf Pine Sandhill (CES203.284)

DISTRIBUTION

Range: This system is endemic to the Florida Peninsula. It is most common in two discrete islands or patches, the Big Scrub of Ocala and the Lake Wales Ridge, which is now highly fragmented and mostly lost to agriculture and development (Weekley et al. 2008).
Divisions: 203:C
Nations: US
Subnations: FL
Map Zones: 55:C, 56:C
USFS Ecomap Regions: 232D:CC, 232G:CC, 232K:CC
TNC Ecoregions: 55:C

GREAT BASIN SEMI-DESERT CHAPARRAL (CES304.001)

CLASSIFIERS

Classification Status: Standard

Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Shrubland (Shrub-dominated); Temperate [Temperate Continental]; Broad-Leaved Evergreen Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2103; ESLF 5309; ESP 1103

CONCEPT

Summary: This system includes chaparral on sideslopes transitioning from low-elevation desert landscapes up into pinyon-juniper woodlands of the western and central Great Basin. There are limited occurrences extending as far west as the inner Coast Ranges in central California. These are typically fairly open-canopy shrublands with open spaces either bare or supporting patchy grasses and forbs. Characteristic species may include *Arctostaphylos patula, Arctostaphylos pungens, Ceanothus greggii, Ceanothus velutinus, Cercocarpus montanus var. glaber, Cercocarpus intricatus, Eriogonum fasciculatum, Garrya flavescens, Quercus turbinella, Purshia stansburiana*, and *Rhus trilobata*. *Cercocarpus ledifolius* is generally absent. Typical fire regime in these systems varies with the amount of organic accumulation.

Related Concepts:
- Bittercherry (419) (Shiflet 1994) Intersecting
- Chokecherry - Serviceberry - Rose (421) (Shiflet 1994) Intersecting. Moister inclusions of this system can be dominated by chokecherry, serviceberry and rose.
- Littleleaf Mountain-Mahogany (417) (Shiflet 1994) Intersecting
- Snowbush (420) (Shiflet 1994) Intersecting

Component Associations:
- *Arctostaphylos patula - Artemisia tridentata (ssp. vaseyana, ssp. wyomingensis)* Shrubland (CEGL002694, GNR)
- *Arctostaphylos patula - Quercus gambelii - (Amelanchier utahensis)* Shrubland (CEGL002695, GNR)
- *Arctostaphylos patula / Ceanothus velutinus - Ceanothus prostratus* Shrubland (CEGL000957, G3)
- *Arctostaphylos patula* Shrubland (CEGL002696, GNR)
- *Arctostaphylos pungens* Shrubland (CEGL000958, G4)
- *Purshia stansburiana / Pseudoroegneria spicata* Shrubland (CEGL001053, G2G4)
- *Purshia stansburiana* Shrubland (CEGL002957, GNR)
- *Quercus turbinella - (Amelanchier utahensis)* Colluvial Shrubland (CEGL002950, GNR)

GREAT BASIN XERIC MIXED SAGEBRUSH SHRUBLAND (CES304.774)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Aridic; Low Artemisia spp.
Non-Diagnostic Classifiers: Montane [Montane]; Montane [Lower Montane]; Foothill(s); Hill(s); Piedmont; Plain; Plateau; Alluvial fan; Sideslope; Alluvial plain; Temperate [Temperate Continental]; Alkaline Soil; Shallow Soil
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2079; ESLF 5256; ESP 1079

CONCEPT

Summary: This ecological system occurs in the Great Basin on dry flats and plains, alluvial fans, rolling hills, rocky hillslopes, saddles and ridges at elevations between 1000 and 2600 m. Sites are dry, often exposed to desiccating winds, with typically shallow, rocky, non-saline soils. Shrublands are dominated by *Artemisia nova* (mid and low elevations), *Artemisia arbuscula ssp. longicaulis*, or *Artemisia arbuscula ssp. longiloba* (higher elevation) and may be codominated by *Artemisia tridentata ssp. wyomingensis* or *Chrysothamnus viscidiflorus*. Other shrubs that may be present include *Atriplex confertifolia, Ephedra* spp., *Ericameria* spp., *Grayia spinosa, Lycium shockleyi, Picrothamnus desertorum, Sarcobatus vermiculatus*, and *Tetradymia* spp. The herbaceous layer is likely sparse and composed of perennial bunch grasses, such as *Achnatherum hymenoides, Achnatherum speciosum, Achnatherum thurberianum, Elymus elymoides*, or *Poa secunda*.

Related Concepts:
- Black Sagebrush (405) (Shiflet 1994) Intersecting
- Low Sagebrush (406) (Shiflet 1994) Intersecting. Drier portions of this SRM type overlap with this system.
- Wyoming Big Sagebrush (403) (Shiflet 1994) Intersecting. Drier portions of this SRM type overlap with this ecological system in the Great Basin region.

DESCRIPTION

Environment: This ecological system is widely distributed in the western United States. Climate is generally arid with 20 to 30 cm of annual precipitation and warm summers and cold winters. This shrubland system occurs at elevations from 1000 to 2600 m in the southwestern United States. It occupies flat to steeply sloping upland sites, on a wide variety of landform positions. These include toeslopes, lower and middle slopes, badly eroded badland slopes, and foothills. Sites with little slope tend to have deep soils, while those with steeper slopes have shallow to moderately deep soils that are well-drained. Sloping sites tend to have southerly aspects. Soil texture is loam, sandy loam, or clay loam (Hansen and Hoffman 1988), and there is often a significant amount of coarse fragments in the soil profile. Hironaka et al. (1983) reported that most of the habitat occurred on calcareous soils, often with a cemented duripan or silica hardpan at about 1 m in depth.
Dynamics: This shrubland system is associated with shallow, rocky soils which experience extreme drought in summer. The plants are low and widely spaced, which tends to decrease the risk of fire (Chappell et al. 1997). Barbour and Major (1988) report that *Artemisia nova* is utilized by livestock to a much greater degree than other species of *Artemisia*, resulting in low, pruned plants. *Artemisia nova* dwarf-shrublands grow in more xeric sites than other *Artemisia* shrublands. Blackburn and Tueller (1970) noted rapid invasion of these communities by *Juniperus osteosperma* and *Pinus monophylla* in Nevada, citing overgrazing coupled with fire suppression, and possibly climate change as causative variables.

Component Associations:
- *Artemisia arbuscula ssp. longicaulis - Grayia spinosa* Shrubland (CEGL002984, G4)
- *Artemisia arbuscula ssp. longicaulis / Elymus elymoides* Shrubland (CEGL002986, G3)
- *Artemisia arbuscula ssp. longiloba / Festuca idahoensis* Shrub Herbaceous Vegetation (CEGL001522, G2)

HAWAI'I ALPINE DWARF-SHRUBLAND (CES412.401)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Lava; Cinder; Tropical/Subtropical [Tropical Xeric]; Dwarf-Shrub
Non-Diagnostic Classifiers: Long (>500 yrs) Persistence; Mountain(s); Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Basalt
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Evergreen dwarf-shrubland
National Mapping Codes: EVT 2824; ESLF 5211; ESP 1824

CONCEPT

Summary: This ecological system occurs on dry alpine slopes of Maui and Hawai'i from near 3000 to 3400 m (9835-11,150 feet) elevation sometime extending down into the subalpine 2600 m (8525 feet) in arid zones. The wet trade winds frequently do not rise above 1900 m, being suppressed by the tropical inversion layer, leaving upper slopes too dry to support wet vegetation. Annual rainfall is generally 750-1250 mm and falls from October to March. Sites are wind-exposed. Frost is frequent, even during summer months. Substrates are well-drained and gravelly and derived from cinder and ash, but they can include glacial moraine. Vegetation is characterized by scattered dwarf-shrubs (10-20%) of *Argyroxiphium* spp., *Dubautia menziesii, Silene struthioloides*, and sometimes scattered *Coprosma ernodeoides, Geranium* spp., *Styphelia tameiameiae, Tetramolopium humile*, or *Vaccinium* spp. Also present may be scattered grasses (*Agrostis sandwicensis, Deschampsia nubigena, Trisetum glomeratum*), forbs (*Pseudognaphalium sandwicensium (= Gnaphalium sandwicensium)*), ferns (*Pellaea ternifolia, Asplenium adiantum-nigrum, Asplenium trichomanes*), lichens (*Lecanora melaena*), and mosses (*Grimmia haleakalae, Racomitrium* spp.).
Classification Comments: Dwarf-shrub refers to short shrubs (usually less than a half meter tall), not necessarily shrubs dwarfed by adverse environmental conditions.
Similar Ecological Systems:
- Hawai'i Alpine Bedrock and Scree (CES412.400)

Related Concepts:
- 'Ahinahina/Na'ena'e (*Argyroxiphium/Dubautia*) Shrubland (Gagne and Cuddihy 1990) Finer

DESCRIPTION

Environment: This alpine ecological system is restricted to the arid zone (Zone 1) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This ecological system occurs on dry alpine slopes of Maui and Hawai'i from near 3000 to 3400 m (9835-11,150 feet) elevation extending down into the subalpine (Gagne and Cuddihy 1990). The wet trade winds frequently do not rise above 1900 m, being suppressed by the tropical inversion layer, leaving upper slopes too dry to support wet vegetation (Mueller-Dombois and Fosberg 1998). Annual rainfall is generally 750-1250 mm and falls from October to March. Sites are wind exposed. Frost is frequent even during summer months. Substrates are well-drained and gravelly derived from cinder and ash, but can include glacial moraine.
Vegetation: Vegetation is characterized by scattered dwarf-shrubs (10-20%) of *Argyroxiphium* spp., *Dubautia menziesii, Silene struthioloides*, and sometimes scattered *Coprosma ernodeoides, Geranium* spp., *Styphelia tameiameiae, Tetramolopium humile*, or *Vaccinium* spp. (Gagne and Cuddihy 1990). Also present may be scattered grasses (*Agrostis sandwicensis, Deschampsia nubigena, Trisetum glomeratum*), forbs (*Pseudognaphalium sandwicensium (= Gnaphalium sandwicensium)*), ferns (*Pellaea ternifolia, Asplenium adiantum-nigrum, Asplenium trichomanes*), lichens (*Lecanora melaena*), and mosses (*Grimmia haleakalae, Racomitrium* spp.). *Coprosma ernodeoides* is a diagnostic species.

Component Associations:
- *Argyroxiphium sandwicense - Dubautia menziesii* Dry Dwarf-shrubland (CEGL008082, G1)

SPATIAL CHARACTERISTICS

HAWAI'I DRY CLIFF (CES412.414)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Tropical/Subtropical [Tropical Xeric]; Cliff (Landform)
Non-Diagnostic Classifiers: Montane; Lowland; Shrubland (Shrub-dominated); Very Shallow Soil; W-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2825; ESLF 5282; ESP 1825

CONCEPT

Summary: This ecological system occurs on dry cliffs away from the direct influence of the shoreline (surf, wind and salt spray) on the larger islands, extending up to montane and subalpine slopes on Maui and Hawai'i, from 15 to 3000 m (50-9835 feet) elevation. Stands occur on the leeward sides of islands in the rainshadows. Annual rainfall is generally low (500-1500 mm). Substrates include sandy loam soils derived from cinder, volcanic ash, and weathered basaltic lava with little soil development. Many sites are wind-exposed. Vegetation is variable but is generally sparse, composed of an open shrub or herbaceous layer, and restricted to ledges or less steep slopes. Common grass and fern species include *Deschampsia nubigena*, *Heteropogon contortus*, *Peperomia tetraphylla*, *Plectranthus parviflorus*, and *Trisetum glomeratum*, and shrubs such as *Artemisia mauiensis*, *Chamaesyce celastroides*, and *Psydrax odorata*. Stands are often weedy, being invaded by several introduced species such as *Melinis repens*, *Lantana camara*, *Leucaena leucocephala*, *Acacia farnesiana*, and *Prosopis pallida*.
Classification Comments: This system is based on a Hawaiian Mixed Shrub Lowland Dry Cliff (Gon and HNHP 2006). It should include higher elevation examples, up to subalpine on Maui, with notes on some different species present in higher vs. lower examples.
Related Concepts:
- Hawaiian Mixed Shrub Lowland Dry Cliff (Gon and HNHP 2006) Finer
- Vegetation on Dry Cliffs (Mueller-Dombois and Fosberg 1998) Equivalent

DESCRIPTION

Environment: This lowland to montane dry cliff ecological system occurs over a broad moisture range within the arid, very dry, and moderately dry zones (Zones 1, 2 and 3) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This ecological system occurs on dry cliffs away from the direct influence of the shoreline (surf, wind and salt spray) on the larger islands, extending up to montane and subalpine slopes on Maui and Hawai'i, from 15 to 3000 m (50-9835 feet) elevation. Stands occur on the leeward sides of islands in the rainshadows. Annual rainfall is generally low (500-1500 mm). Substrates include sandy loam soils derived from cinder, volcanic ash, and weathered basaltic lava with little soil development. Many sites are wind-exposed.
Vegetation: Vegetation is variable but is generally sparse, composed of an open shrub or herbaceous layer, and restricted to ledges or less steep slopes. Common grass and fern species include *Deschampsia nubigena*, *Heteropogon contortus*, *Peperomia tetraphylla*, *Plectranthus parviflorus*, and *Trisetum glomeratum*, and shrubs include *Artemisia mauiensis*, *Chamaesyce celastroides*, and *Psydrax odorata*. Stands are often weedy, being invaded by several introduced species such as *Melinis repens*, *Lantana camara*, *Leucaena leucocephala*, *Acacia farnesiana*, and *Prosopis pallida*.
Dynamics: Goats have destroyed the vegetation in many dry cliff areas to where the original vegetation is unknown (Mueller-Dombois and Fosberg 1998). Landslides are the only common natural disturbance. Fire could possibly burn because of pili grass presence, but does not really affect vegetation structure and composition.

DISTRIBUTION

Range: This ecological system occurs on the larger Hawai'ian islands on dry cliffs away from the direct influence of the shoreline.

HAWAI'I DRY COASTAL STRAND (CES412.418)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shoreline; Grassland, Savanna, Steppe (graminoid-dominated); Tropical/Subtropical [Tropical Xeric]; Salt Spray; Coast
Non-Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Woody-Herbaceous; Herbaceous; Beach (Substrate); Lava; Basalt
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Evergreen dwarf-shrubland
National Mapping Codes: EVT 2826; ESLF 5212; ESP 1826

CONCEPT

Summary: This coastal ecological system occurs on the drier leeward side of the larger Hawaiian Islands and on all sides of the smaller, arid islands and atolls that are widespread in the northwestern Hawaiian Islands. Annual precipitation is usually less than 1200 mm. Stands are restricted to the shoreline and the zone immediately back of it where sites are strongly influenced by surf, wind and salt spray. Substrates are variable, ranging from gentle to steep rocky, cobbly shores, derived from tuff or disintegrating lava or raised coral beds (limestone), and lava flows (basalt) to flat surf-pounded sandy beaches, some with adjacent dunes or low alkaline flats above the saturated zone and behind the high-tide mark. Vegetation varies largely with substrate but tends to be sparse and patchy. Stands include succulent herbs, low wind-sheared shrubs, grasslands, a mix of shrub and grass or taller shrublands. Native species that may be dominant locally include graminoids *Fimbristylis cymosa, Eragrostis variabilis*, or *Sporobolus virginicus*, or forbs *Boerhavia acutifolia, Boerhavia repens, Nama sandwicense*, and *Sesuvium portulacastrum*, or *Sida fallax* mats with *Jacquemontia ovalifolia ssp. sandwicensis* or *Scaevola sericea* shrubs. Other shrubs, such as *Chamaesyce celastroides, Chenopodium oahuense, Gossypium tomentosum, Heliotropium anomalum, Lipochaeta* spp., *Myoporum sandwicense, Scaevola coriacea, Tetramolopium rockii, Tribulus cistoides*, and *Vitex rotundifolia*, may also dominate stands.
Classification Comments: Wet salt marshes belong to Northern Polynesia Tidal Salt Marsh (CES412.224) which includes barren beaches to thick dry grasses on the back sides of sand dunes.
Similar Ecological Systems:
- Hawai'i Lowland Dry Grassland (CES412.410)
- Hawai'i Lowland Dry Shrubland (CES412.409)
- Hawai'i Mesic Coastal Forest (CES412.417)

DESCRIPTION

Environment: This coastal ecological system occurs on the drier leeward side of the larger Hawaiian Islands and on all sides of the smaller, arid islands and atolls that are widespread in the Northwest Hawaiian Islands. Annual precipitation is usually less than 1200 mm. This arid to moderately dry coastal strand ecological system occurs within the arid, very dry, and moderately dry zones (Zones 1, 2 and 3) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). Stands are restricted to the shoreline and the zone immediately back of it where sites are strongly influenced by surf, wind and salt spray. Substrates are variable, ranging from gentle to steep rocky, cobbly shores, derived from tuff or disintegrating lava or raised coral beds (limestone), and lava flows (basalt) to flat surf-pounded sandy beaches, some with adjacent dunes or low alkaline flats above the saturated zone and behind the high-tide mark. This habitat is driven by its proximity to the sea, with wind and salt spray and dry climate.
Vegetation: The dry strand vegetation varies largely with substrate but tends to be sparse and patchy. Stands include succulent herbs, low wind-sheared shrubs, grasslands, a mix of shrub and grass or taller shrublands. Native species that may be dominant locally include graminoids *Fimbristylis cymosa, Eragrostis variabilis*, or *Sporobolus virginicus*, or forbs *Boerhavia acutifolia, Boerhavia repens, Nama sandwicense*, and *Sesuvium portulacastrum*, or *Sida fallax* mats with *Jacquemontia ovalifolia ssp. sandwicensis* or *Scaevola sericea* shrub. Other shrubs, such as *Chamaesyce celastroides, Chenopodium oahuense, Gossypium tomentosum, Heliotropium anomalum, Lipochaeta* spp., *Myoporum sandwicense, Scaevola coriacea, Tetramolopium rockii, Tribulus cistoides*, and *Vitex rotundifolia*, may also dominate stands. Other common native dry strand species are *Capparis sandwichiana, Chamaesyce degeneri, Chamaesyce skottsbergii, Cocos nucifera, Cordia subcordata, Cyperus javanicus, Lycium sandwicense, Heliotropium curassavicum, Heteropogon contortus, Ipomoea pes-caprae, Nama sandwicense, Pandanus tectorius, Panicum fauriei, Panicum torridum, Pseudognaphalium sandwicensium, Sesbania tomentosa, Solanum nelsonii, Tetramolopium rockii, Vigna marina*, and *Waltheria indica* (Warshauer et al. 2008). Many species occur in both dry strand and wet-mesic strand, including *Chenopodium oahuense, Nama sandwicense, Panicum fauriei, Panicum torridum, Sesbania tomentosa, Tetramolopium rockii*, and Waltheria indica (Warshauer et al. 2008). Disturbed stands are often weedy, being invaded by several introduced species such as *Melinis repens, Lantana camara, Leucaena leucocephala, Acacia farnesiana*, and *Prosopis pallida*.

Component Associations:
- *Chamaesyce celastroides* Coastal Dry Dwarf-shrubland (CEGL008075, G1)
- *Chenopodium oahuense* Coastal Dry Dwarf-shrubland (CEGL008083, G2)

- *Eragrostis variabilis* Coastal Dry Herbaceous Vegetation (CEGL008087, G3)
- *Gossypium tomentosum* Coastal Dry Shrubland (CEGL008064, G1)
- *Heliotropium anomalum* Coastal Dry Dwarf-shrubland (CEGL008084, G3)
- *Ipomoea* spp. Herbaceous Vegetation (CEGL008096, G3)
- *Lipochaeta* spp. Coastal Dry Dwarf-shrubland (CEGL008076, G3)
- *Myoporum sandwicense* Coastal Dry Shrubland (CEGL008050, G1)
- *Scaevola coriacea* Coastal Dry Dwarf-shrubland (CEGL008072, G1)
- *Scaevola sericea* Coastal Dry Shrubland (CEGL008054, G4)
- *Sida fallax* Coastal Dry Dwarf-shrubland (CEGL008078, G3)
- *Sida fallax* Coastal Dry Shrubland (CEGL008055, G3)
- *Sporobolus virginicus* Coastal Dry Shrub Herbaceous Vegetation (CEGL008094, G4)
- *Tetramolopium rockii* Coastal Dry Dwarf-shrubland (CEGL008099, G1)
- *Tribulus cistoides* Coastal Dry Dwarf-shrubland (CEGL008079, G2)
- *Vitex rotundifolia* Coastal Dry Dwarf-shrubland (CEGL008073, G3)

HAWAI'I LOWLAND DRY SHRUBLAND (CES412.409)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2817; ESLF 5283; ESP 1817

CONCEPT

Summary: Dry lowland shrublands occur mostly on the leeward side of all the main islands except Ni'ihau and Kaho'olawe, and are found between 10 and 1000 m in elevation. These shrublands are generally less than 2 m in height. These shrublands occur on open gentle slopes to steep ridges of dissected slopes. Rainfall is 500-1500 mm, mostly restricted to the winter months, with summers hot and dry. Soils vary from silty loams to relatively unweathered pÃ¢hoehoe lava. Vegetation consists of a low shrubland dominated by *Dodonaea viscosa, Bidens* spp., *Sesbania tomentosa*, or *Wikstroemia* spp. Indicators species of this system include *Abutilon* spp., *Achyranthes* spp., *Capparis sandwichiana, Gossypium* spp., *Hibiscus brackenridgei, Plectranthus parviflorus (= Plectranthus australis), Portulaca* spp., and *Waltheria* spp. Stands often have other native shrubs such as *Argemone glauca, Canthium odoratum, Canavalia* spp., *Chamaesyce* spp., *Cassytha filiformis, Ipomoea* spp., *Lipochaeta* spp., *Nototrichium* spp., *Osteomeles anthyllidifolia, Peperomia tetraphylla, Peperomia leptostachya, Santalum ellipticum, Senna gaudichaudii, Sicyos* spp., *Myoporum sandwicense, Sida fallax*, and *Styphelia tameiameiae*; fern species of *Doryopteris* and *Pellaea*; and grass species of *Panicum* and also alien grasses such as *Pennisetum setaceum*. The density and height of shrubs may be reduced by recent fire or increased with increased moisture, for example when near riparian areas. Lowland dry shrublands are relatively intolerant to grazing pressure and fire and are replaced by alien-dominated communities when subject to these disturbances.
Classification Comments: This dry shrubland system grades into the dry coastal strand system near the leeward coasts. Coastal dry shrublands that are affected by immediate sea coast processes (salt spray and salinity) are classified in the dry coastal strand ecological system.
Similar Ecological Systems:
- Hawai'i Dry Coastal Strand (CES412.418)
- Hawai'i Lowland Dry Grassland (CES412.410)

Related Concepts:
- Nehe (*Lipochaeta*) Shrubland (Gagne and Cuddihy 1990) Finer

DESCRIPTION

Environment: This lowland ecological system occurs over a broad moisture range within the arid, very dry, moderately dry, and seasonally mesic zones (Zones 1, 2, 3 and 4) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). Dry lowland shrublands occur mostly on the leeward side of all the main islands except Ni'ihau and Kaho'olawe, and are found between 10 and 1000 m in elevation. These shrublands are generally less than 2 m in height. These shrublands occur on open gentle slopes to steep ridges of dissected slopes. Rainfall is 500-1500 mm, mostly restricted to the winter months, with summers hot and dry. Soils vary from silty loams to relatively unweathered pÃ¢hoehoe lava.
Vegetation: Vegetation consists of a low shrubland dominated by *Dodonaea viscosa, Bidens* spp., *Sesbania tomentosa*, or *Wikstroemia* spp. Indicators species of this system include *Abutilon* spp., *Achyranthes* spp., *Capparis sandwichiana, Gossypium* spp., *Hibiscus brackenridgei, Plectranthus parviflorus (= Plectranthus australis), Portulaca* spp., and *Waltheria* spp. Stands often have other native shrubs such as *Argemone glauca, Canthium odoratum, Canavalia* spp., *Chamaesyce* spp., *Cassytha filiformis, Ipomoea* spp., *Lipochaeta* spp., *Nototrichium* spp., *Osteomeles anthyllidifolia, Peperomia tetraphylla, Peperomia leptostachya, Santalum ellipticum, Senna gaudichaudii, Sicyos* spp., *Myoporum sandwicense, Sida fallax*, and *Styphelia tameiameiae*; fern species of *Doryopteris* and *Pellaea*; and grass species of *Panicum* and as well as alien grasses such as *Pennisetum setaceum*.
Dynamics: The density and height of shrubs may be reduced by recent fire or increased with increased moisture, for example when near riparian areas. Lowland dry shrublands are relatively intolerant to grazing pressure and fire and are replaced by alien-dominated communities when subject to these disturbances. Severe drought can favor grasses. Burning by early Hawaiians to encourage *Heteropogon contortus* may have suppressed shrubs in favor of grasses.

Component Associations:
- *Artemisia australis - Dodonaea viscosa* Lowland Dry Dwarf-shrubland (CEGL008065, G3)
- *Bidens* spp. Lowland Dry Dwarf-shrubland (CEGL008067, G3)
- *Canthium odoratum* Lowland Dry Shrubland (CEGL008056, G2)
- *Dodonaea viscosa* Lowland Dry Shrubland (CEGL008059, G4)
- *Sesbania tomentosa* Lowland Dry Dwarf-shrubland (CEGL008077, G1)
- *Wikstroemia* spp. / *Dodonaea* spp. / *Osteomeles anthyllidifolia* Lowland Dry Dwarf-shrubland (CEGL008074, G3)

HAWAI'I LOWLAND MESIC SHRUBLAND (CES412.412)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Pluviseasonal]; Very Shallow Soil
Non-Diagnostic Classifiers: Ridge/Summit/Upper Slope
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2818; ESLF 5334; ESP 1818

CONCEPT

Summary: Communities in this ecological system occur between 30 and 850 m (262-2800 feet) elevation on all of the main islands except Kaho'olawe; they are well-developed on leeward Moloka'i and leeward western Maui. The climate is seasonal, with hot dry summers and primarily winter rainfall (up to 2000 mm annually). These shrublands develop where forests cannot be supported, such as ridgetops subject to seasonal drought. Soils are often thin and easily dried out. Vegetation has an open to closed canopy, up to 3 m (10 feet) in height, with varying herbaceous undergrowth. Common species include shrubby *Metrosideros polymorpha, Chamaesyce* spp., *Cladonia* (lichen), *Cocculus* spp., *Dicranopteris* spp., *Dodonaea viscosa, Korthalsella* spp., *Lobelia yuccoides, Osteomeles anthyllidifolia, Pittosporum* spp., *Sadleria* spp., *Scaevola gaudichaudiana, Scaevola gaudichaudii, Odontosoria (= Sphenomeris), Styphelia tameiameiae, Vaccinium* spp., and *Wikstroemia* spp. Grass cover is relatively sparse, usually less than 10% in historic times. Common graminoids are *Carex* spp., *Dianella* spp., *Eragrostis variabilis, Gahnia* spp., and *Luzula* spp.

DESCRIPTION

Environment: This lowland ecological system occurs mostly within the seasonally mesic and moist mesic zones (Zones 4 and 5) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007), but may extend into the moderately dry (Zone 3) at lower elevation (<300 m). Communities in this ecological system occur between 30 and 850 m (262-2800 feet) elevation on all of the main islands except Kaho'olawe; they are well-developed on leeward Moloka'i and leeward western Maui. The climate is seasonal, with hot dry summers and primarily winter rainfall (up to 2000 mm annually). These shrublands develop where forests cannot be supported, such as ridgetops subject to seasonal drought. They occupy large bands below mesic forest and above lowland dry systems. Soils are often thin and easily dried out.
Vegetation: Vegetation has an open to closed canopy, up to 3 m (10 feet) in height, with varying herbaceous undergrowth. Common species include shrubby *Metrosideros polymorpha, Chamaesyce* spp., *Cladonia* (lichen), *Cocculus* spp., *Dicranopteris* spp., *Dodonaea viscosa, Korthalsella* spp., *Lobelia yuccoides, Osteomeles anthyllidifolia, Pittosporum* spp., *Sadleria* spp., *Scaevola gaudichaudiana, Scaevola gaudichaudii, Odontosoria (= Sphenomeris), Styphelia tameiameiae, Vaccinium* spp., and *Wikstroemia* spp. Grass cover is relatively sparse, usually less than 10% in historic times. Common graminoids are *Carex* spp., *Dianella* spp., *Eragrostis variabilis, Gahnia* spp., and *Luzula* spp.

Component Associations:
- *Dodonaea viscosa - Styphelia tameiameiae* Lowland Mesic Shrubland (CEGL008058, G3)
- *Metrosideros polymorpha* Lowland Mesic Shrubland (CEGL008062, G3)
- *Osteomeles anthyllidifolia* Lowland Mesic Dwarf-shrubland (CEGL008070, G3)

HAWAI'I MONTANE-SUBALPINE DRY SHRUBLAND (CES412.403)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Broad-Leaved Evergreen Shrub
Non-Diagnostic Classifiers: Mountainside
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2821; ESLF 5284; ESP 1821

CONCEPT

Summary: This ecological system occurs on dry slopes of higher mountains of Maui and Hawai'i, from near 900 to 3000 m (2950-9835 feet) elevation. An inversion layer of warmer air forms 50-70% of the time between 1600 and 3000 m that dramatically reduces precipitation at higher elevations. This is because the wet trade winds generally do not rise above 1900 m (6230 feet) and are deflected around the mountains, leaving upper slopes too dry to support rain forests. Stands also occur at lower elevations on leeward sides of islands where there is a strong rainshadow effect. Annual rainfall is generally 400-1500 mm. Many sites are wind-exposed. Substrates include cinder, well-drained, sandy loam soils derived from volcanic ash, and weathered 'a'Ã¢ or pÃ¢hoehoe basaltic lava with little soil development. Vegetation is often dominated by an open to dense shrub layer dominated by one or more of *Dodonaea viscosa, Styphelia tameiameiae, Chenopodium oahuense*, shrubby *Metrosideros*, and *Vaccinium* spp. *Dubautia linearis* is a diagnostic species. Other shrubs may include *Argyroxiphium* spp., *Bidens menziesii, Chamaesyce* spp., *Dubautia ciliolata, Dianella* spp., *Exocarpos* spp., *Geranium cuneatum, Lipochaeta* spp., *Osteomeles anthyllidifolia, Sida fallax, Silene* spp., and *Tetramolopium* spp. Scattered *Metrosideros polymorpha, Sophora chrysophylla*, or *Myoporum sandwicense* trees may be present in some stands. Shrubs extend up to 3 m on relatively mesic, protected sites. Native bunch grasses and forbs (especially rosettes) and ferns are present (e.g., *Sadleria cyatheoides, Pellaea ternifolia, Asplenium* spp.), but contribute low cover at higher elevation. Grasses can be more abundant at montane elevations but are generally sparse. Native graminoids include *Eragrostis atropioides, Deschampsia nubigena (= Deschampsia australis), Eragrostis deflexa, Gahnia* spp., and *Luzula* spp. Fire-adapted exotic grasses such as *Pennisetum setaceum* are invasive and threaten these dry shrublands by increasing fire intensity, frequency and size. The exotic rosette forb *Verbascum thapsus* is a common in many stands.

DESCRIPTION

Environment: This montane to subalpine ecological system occurs within the very dry and moderately dry zones (Zones 2 and 3) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This ecological system occurs on dry slopes of higher mountains of Maui and Hawai'i, from near 900 to 3000 m (2950-9835 feet) elevation. An inversion layer of warmer air forms 50-70% of the time between 1600 and 3000 m that dramatically reduces precipitation at higher elevations (Gagne and Cuddihy 1990). This is because the wet trade winds generally do not rise above 1900 m (6230 feet) and are deflected around the mountains, leaving upper slopes too dry to support rain forests (Mueller-Dombois and Fosberg 1998). Stands also occur at lower elevations on leeward sides of islands where there is a strong rainshadow effect. Annual rainfall is generally 400-1500 mm. Many sites are wind-exposed. Substrates include cinder, well-drained, sandy loam soils derived from volcanic ash, and weathered 'a'Ã¢ or pÃ¢hoehoe basaltic lava with little soil development.

Vegetation: Vegetation is often dominated by an open to dense shrub layer dominated by one or more of *Dodonaea viscosa, Styphelia tameiameiae, Chenopodium oahuense*, shrubby *Metrosideros*, and *Vaccinium* spp. *Dubautia linearis* is a diagnostic species. Other shrubs may include *Bidens menziesii, Chamaesyce* spp., *Dubautia ciliolata, Dianella* spp., *Exocarpos* spp., *Geranium*

cuneatum, Osteomeles anthyllidifolia, Silene spp., *Argyroxiphium* spp., *Lipochaeta* spp., *Sida fallax,* and *Tetramolopium* spp. Scattered *Metrosideros polymorpha, Sophora chrysophylla,* or *Myoporum sandwicense* trees may be present in some stands. Shrubs extend up to 3 m on relatively mesic, protected sites. Native bunch grasses and forbs (especially rosettes) and ferns are present (e.g., *Sadleria cyatheoides, Pellaea ternifolia, Asplenium* spp.), but contribute low cover at higher elevation. Grasses can be more abundant at montane elevations but are generally sparse. Native graminoids include *Eragrostis atropioides, Deschampsia nubigena (= Deschampsia australis), Eragrostis deflexa, Gahnia* spp., and *Luzula* spp. Fire-adapted exotic grasses such as *Pennisetum setaceum* are invasive and threaten these dry shrublands by increasing fire intensity, frequency and size (Castillo 1997). The exotic rosette forb *Verbascum thapsus* is a common in many stands.

Dynamics: These dry shrublands have broad transition zones with dry woodlands dominated by *Metrosideros polymorpha, Sophora chrysophylla,* or *Myoporum sandwicense* trees. In areas below upper treeline, these shrublands may exist as a persistent seral stage maintained by disturbance such as periodic fire. More frequent burning because of presence of fire-adapted exotic grasses such as *Pennisetum setaceum* has converted stands of this dry shrubland to introduced grassland (Castillo 1997).

Component Associations:

- *Chenopodium oahuense* Subalpine Dry Shrubland (CEGL008053, G1)
- *Dodonaea viscosa* Subalpine Dry Shrubland (CEGL008060, G3)
- *Metrosideros polymorpha / Dodonaea viscosa* Montane Dry Shrubland (CEGL008061, G3)
- *Styphelia tameiameiae* Subalpine Dry Shrubland (CEGL008063, G3)

SPATIAL CHARACTERISTICS

HAWAI'I SUBALPINE MESIC SHRUBLAND (CES412.404)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Pluviseasonal]
Non-Diagnostic Classifiers: Mountainside
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2828; ESLF 5285; ESP 1828

CONCEPT

Summary: This ecological system occurs on mesic, windward slopes of eastern Maui and outer north slopes of Haleakala Crater, from 1950 to 2300 m elevation and the upper Kaupo Gap area east-southeast of Haleakala Crater. Sites include ridges and upper slopes that are dissected. Annual precipitation is 1300-1900 mm with rain distributed fairly evenly throughout the year. The thin cinder-derived soil has many rock outcrops. Vegetation is a closed shrubland dominated by *Sadleria cyatheoides* and *Vaccinium calycinum*. At higher elevations and on ridges, there is a single shrub layer 1-1.2 m tall; at lower elevation, stands often have two shrub layers: a tall *Vaccinium*-dominated shrub layer (2 m tall) emergent over a 1-m tall dense shrub layer dominated by other shrubs. Other characteristic shrubs include *Coprosma ernodeoides, Geranium multiflorum, Rubus hawaiensis, Rubus macraei,* and *Vaccinium reticulatum*. *Lycopodium venustulum* is important in the Kipahulu Valley stands. *Dodonaea viscosa* and *Styphelia tameiameiae* are important shrubs in the upper Kaupo Gap area east-southeast of Haleakala Crater. Herbaceous species are generally sparse, e.g., *Deschampsia nubigena* and *Fragaria chiloensis ssp. sandwicensis*. Ferns include *Dryopteris wallichiana* and *Pteridium aquilinum*.
Similar Ecological Systems:
- Hawai'i Montane-Subalpine Mesic Forest (CES412.406)

Related Concepts:
- Subalpine Mesic Shrubland (Gagne and Cuddihy 1990) Equivalent

DESCRIPTION

Environment: This montane to subalpine ecological system occurs within the seasonal mesic zone (Zone 4) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This ecological system occurs on mesic, windward slopes of eastern Maui and outer north slopes of Haleakala Crater, from 1950 to 2300 m elevation. It extends to the upper Kaupo Gap area east-southeast of Haleakala Crater Sites include ridges and upper slopes that are dissected. Annual precipitation is 1300-1900 mm with rain distributed fairly evenly throughout the year. The thin cinder-derived soil has many rock outcrops (Gagne and Cuddihy 1990, J. Jacobi pers. comm.).

Vegetation: Vegetation is a closed shrubland dominated by *Sadleria cyatheoides* and *Vaccinium calycinum*. At higher elevations and on ridges, there is a single shrub layer 1-1.2 m tall; at lower elevation, stands often have two shrub layers: a tall *Vaccinium*-dominated shrub layer (2 m tall) emergent over a 1-m tall dense shrub layer dominated by other shrubs. Other characteristic shrubs include *Coprosma ernodeoides, Geranium multiflorum, Rubus hawaiensis, Rubus macraei,* and *Vaccinium reticulatum*. *Lycopodium venustulum* is important in the Kipahulu Valley stands. *Dodonaea viscosa* and *Styphelia tameiameiae* are important shrubs in the upper Kaupo Gap area east-southeast of Haleakala Crater. Herbaceous species are generally sparse, e.g., *Deschampsia nubigena* and *Fragaria chiloensis ssp. sandwicensis*. Ferns include *Dryopteris wallichiana* and *Pteridium aquilinum*. Diagnostic species for this system are *Vaccinium calycinum, Geranium multiflorum, Rubus hawaiensis,* and *Rubus macraei*.

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Hawai'i Montane Rainforest (CES412.215)
- Hawai'i Montane-Subalpine Mesic Forest (CES412.406)

Adjacent Ecological System Comments: There is a narrow band of mesic forest below that transitions quickly to the rainforest. Above is the dry shrubland

DISTRIBUTION

Range: These mesic shrublands have a narrow range and are only found in a relative narrow subalpine band on the windward side of Haleakala on eastern Maui, Hawai'i.

HAWAI'I WET CLIFF AND RIDGE CREST SHRUBLAND (CES412.218)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Ridge; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Tropical/Subtropical [Tropical Pluvial]; Tropical/Subtropical [Tropical Pluviseasonal]; Landslide; Cliff (Landform)
Non-Diagnostic Classifiers: Montane; Lowland
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2811; ESLF 5274; ESP 1811

CONCEPT

Summary: This ecological system occupies crests of steep ridges and cliff faces throughout the main Hawaiian Islands. These environments are characterized by regularly windy and usually foggy and wet conditions. Soils are generally thin over soft, highly weathered rock and thin mucky clays. Vegetation is windswept and variable, ranging from dense dwarf-shrublands to dominant sedges with few scattered shrubs to sparse rock with very little plant life. Wind-stunted trees and shrubs are 1-3 m in height, are clothed with masses of epiphytic cryptogams, and have a diverse array of native shrubs, vines, herbs and ferns. Woody plants become so stunted in some sites that sedges and ferns form a continuous canopy with them. Dominant species vary according to island and abiotic factors but generally include wind-stunted species of *Metrosideros, Cibotium, Melicope, Myrsine*, and *Vaccinium*. Other species include *Asplenium* spp., *Astelia menziesiana, Bidens* spp., *Broussaisia arguta, Cyrtandra* spp., *Diplopterygium pinnatum, Dicranopteris linearis, Dubautia* spp., *Eurya sandwicensis, Freycinetia arborea, Hedyotis terminalis, Lycopodiella cernua, Lobelia* spp., *Machaerina angustifolia, Peperomia* spp., *Phyllostegia* spp., *Scaevola* spp., *Sadleria pallida, Tetraplasandra* spp., *Trematolobelia* spp., and several rare endemic species including the orchid *Anoectochilus sandvicensis*.

DESCRIPTION

Environment: This system occupies crests of steep ridges and cliff faces throughout the main Hawaiian Islands. Climate is moderately wet to very wet (Zones 6 and 7) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). These environments are characterized by regularly windy and usually foggy and wet conditions. Soils are generally thin over soft, highly weathered rock and thin mucky clays.
Vegetation: Vegetation is windswept and variable, ranging from dense dwarf-shrublands to dominant sedges with few scattered shrubs to sparse rock with very little plant life. Wind-stunted trees and shrubs are 1-3 m in height, are clothed with masses of epiphytic cryptogams, and have a diverse array of native shrubs, vines, herbs and ferns. Woody plants become so stunted in some sites that sedges and ferns form a continuous canopy with them. Dominant species vary according to island and abiotic factors but may include wind-stunted *Metrosideros, Cibotium, Melicope, Myrsine*, and *Vaccinium*. Other species include *Asplenium* spp., *Astelia menziesiana, Bidens* spp., *Broussaisia arguta, Cyrtandra* spp., *Diplopterygium pinnatum, Dicranopteris linearis, Dubautia* spp., *Eurya sandwicensis, Freycinetia arborea, Hedyotis terminalis, Lycopodiella cernua, Lobelia* spp., *Machaerina angustifolia, Peperomia* spp., *Phyllostegia* spp., *Scaevola* spp., *Sadleria pallida, Tetraplasandra* spp., *Trematolobelia* spp., and several rare endemic species.
Dynamics: Landslides occur occasionally in this system, uncovering bare mineral soils, which are colonized by pioneer species such as *Metrosideros, Dicranopteris*, and other ruderal natives.

Component Associations:
- *Metrosideros polymorpha* Montane Wet Dwarf-shrubland (CEGL008069, G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological System Comments: This system is found adjacent to montane cloud forest, montane rainforest, and lowland rainforest.

DISTRIBUTION

Range: This system occurs between 200 and 900 m (650-2950 feet) elevation on Kaua'i, O'ahu, Moloka'i, LÃ¢na'i, Maui, and Hawai'i.

HAWAI'I WET-MESIC COASTAL STRAND (CES412.419)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shoreline; Grassland, Savanna, Steppe (graminoid-dominated); Tropical/Subtropical [Tropical Pluvial]; Tropical/Subtropical [Tropical Pluviseasonal]; Salt Spray; Coast
Non-Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Woody-Herbaceous; Herbaceous
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2827; ESLF 5286; ESP 1827

CONCEPT

Summary: This mesic to wet coastline ecosystem is found on the windward sides of the larger Hawaiian Islands except Kaho'olawe and Lanai. Stands are restricted to seasonally mesic to wet shoreline and the zone immediately back of it. Substrates are variable and include a mix of sand, cobble and/or bedrock. Elevation is generally below 30 m. Annual precipitation ranges from over 3500 mm down to 1200 mm on seasonally mesic sites. Vegetation is variable depending largely on substrate and may include shrublands, grasslands or may be sparse. Scattered trees may be present but generally do not form a canopy, except on disturbed sites invaded by introduced trees such as *Casuarina* spp. Species characteristic of the wet strand are *Cyclosorus interruptus, Deschampsia nubigena, Machaerina angustifolia, Pilea peploides, Scleria testacea, Selaginella arbuscula*, and *Wikstroemia oahuensis*. Characteristic species of mesic or seasonally moist strand are *Artemisia australis, Bacopa monnieri, Bidens hillebrandiana, Bidens molokaiensis, Chenopodium oahuense, Cyperus javanicus, Cyperus phleoides, Diospyros sandwicensis, Eragrostis variabilis, Ischaemum byrone, Lipochaeta succulenta, Lysimachia mauritiana, Osteomeles anthyllidifolia, Pandanus tectorius, Plectranthus parviflorus, Sadleria cyatheoides, Schiedea globosa*, and *Solanum americanum*.
Classification Comments: Strand with native tree canopy is classified a Hawai'i Mesic Coastal Forest (CES412.417).
Similar Ecological Systems:
- Hawai'i Mesic Coastal Forest (CES412.417)

DESCRIPTION

Environment: This mesic to wet coastal ecological system is found on the windward sides of the larger Hawaiian Islands except Kaho'olawe and Lanai. Stands are restricted to seasonally mesic to wet shoreline and the zone immediately back of it. Elevation is generally below 30 m. Annual precipitation ranges from over 3500 mm down to 1200 mm on seasonally mesic sites. This wet to mesic strand occurs within the seasonally mesic, moist mesic, and moderately wet zones (Zones 4, 5 and 6) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). Substrates are variable and include a mix of sand, cobble and/or bedrock.
Vegetation: Vegetation is variable depending largely on substrate and includes shrublands, grasslands or may be sparse. Scattered trees may be present but generally do not form a canopy, except on disturbed sites invaded by introduced trees such as *Casuarina* spp. Species characteristic of the wet strand are *Thelypteris interrupta (= Cyclosorus interruptus), Deschampsia nubigena, Machaerina angustifolia, Pilea peploides, Scleria testacea, Selaginella arbuscula*, and *Wikstroemia oahuensis*. Characteristic species of mesic or seasonally moist strand are *Artemisia australis, Bacopa monnieri, Bidens hillebrandiana, Bidens molokaiensis, Chenopodium oahuense, Cyperus javanicus, Cyperus phleoides, Diospyros sandwicensis, Eragrostis variabilis, Ischaemum byrone, Lipochaeta succulenta, Lysimachia mauritiana, Osteomeles anthyllidifolia, Pandanus tectorius, Plectranthus parviflorus, Sadleria cyatheoides, Schiedea globosa*, and *Solanum americanum*. Other common native mesic to wet strand species are *Capparis sandwichiana, Cocos nucifera, Cordia subcordata, Cyperus polystachyos, Fimbristylis cymosa, Fimbristylis dichotoma, Hedyotis st.-johnii, Ipomoea pes-caprae, Jacquemontia ovalifolia, Lycium sandwicense, Scaevola sericea, Scaevola sericea var. taccada (= Scaevola taccada), Sida fallax, Vigna marina, Vitex rotundifolia*, and *Waltheria indica* (Warshauer et al. 2008). Many species occur in both dry strand and wet-mesic strand such as *Chenopodium oahuense, Nama sandwicense, Panicum fauriei, Panicum torridum, Sesbania tomentosa, Tetramolopium rockii*, and *Waltheria indica* (Warshauer et al. 2008).
Dynamics: Coastal processes such as surf, wind and salt spray define this system. Wave action from occasional strong storms maintains seral vegetation on many sites.

INTER-MOUNTAIN BASINS BIG SAGEBRUSH SHRUBLAND (CES304.777)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Toeslope/Valley Bottom; Deep Soil; Aridic; Artemisia tridentata ssp. tridentata
Non-Diagnostic Classifiers: Plain; Alluvial plain; Temperate [Temperate Continental]; Alkaline Soil; Xeromorphic Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2080; ESLF 5257; ESP 1080

CONCEPT

Summary: This ecological system occurs throughout much of the western U.S., typically in broad basins between mountain ranges, plains and foothills between 800 and 2500 m elevation. Soils are typically deep, well-drained and non-saline. These shrublands are dominated by *Artemisia tridentata ssp. tridentata* (not as common in Wyoming or Montana but possibly on stabilized part of Killpecker Dunes in Wyoming) and/or *Artemisia tridentata ssp. wyomingensis* (predominant in Wyoming and Montana). Scattered *Juniperus* spp., *Sarcobatus vermiculatus*, and *Atriplex* spp. may be present in some stands. *Ericameria nauseosa, Chrysothamnus viscidiflorus, Purshia tridentata* (not commonly in Montana or Wyoming), or *Symphoricarpos oreophilus* may codominate disturbed stands (e.g., in burned stands, these may become more predominant). Perennial herbaceous components typically contribute less than 25% vegetative cover. Common graminoid species can include *Achnatherum hymenoides, Bouteloua gracilis, Elymus lanceolatus, Festuca idahoensis* (not in Montana or Wyoming), *Hesperostipa comata, Leymus cinereus, Pleuraphis jamesii* (not present in northeastern portions of the range), *Pascopyrum smithii, Poa secunda*, or *Pseudoroegneria spicata* (not in Wyoming). Some semi-natural communities are included that often originate on abandoned agricultural land/or on other disturbed sites. In these locations, *Bromus tectorum* or other annual bromes and invasive weeds can be abundant. Most *Artemisia tridentata ssp. wyomingensis* communities in Wyoming are placed in Inter-Mountain Basins Big Sagebrush Steppe (CES304.778); the shrubland system is more restricted in environmental setting than the steppe. Dunes in the Red Desert have areas of large basin big sage with very dense canopies. In Wyoming, this system is likely to only contain *Artemisia tridentata ssp. tridentata*.

- Threetip Sagebrush - Idaho Fescue (324) (Shiflet 1994) Broader. *Artemisia tripartita ssp. tripartita* communities are included in this ecological system.
- Wyoming Big Sagebrush (403) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This widespread interior western U.S. shrubland occurs in broad basins between mountain ranges, plains and foothills with its core distribution in the Great Basin region. Elevations range from 800 to 2500 m depending on latitude. The climate is semi-arid with annual precipitation ranging from 15-40 cm and high inter-annual variation. Much of the precipitation falls as snow, and growing-season drought is characteristic. Temperatures are continental with large annual and diurnal variation. In drier regions, these shrublands are usually associated with perennial or ephemeral stream drainages with water tables less than 3 m from the soil surface. Sites supporting this system include sloping fans, footslopes, rolling hills, swales, draws, and deep, well-drained alluvial bottomlands. Substrates are typically deep, well-drained and non-saline, fine- to medium-textured alluvial soils with some source of subirrigation during the summer season, but moderately deep upland soils with ample moisture storage also support these shrublands. Some stands occur on deep, sandy soils, or soils that are highly calcareous (Hironaka et al. 1983). Although this system may grade into sites with alkaline soils at the edge of internally drained basins, *Artemisia tridentata* is a non-halophyte and requires low salinity for optimum growth. The importance of perennial bunch grasses, the most typical herbaceous associates, is favored with greater spring and summer rain, which increases northward and eastward. Open shrublands occur on sand deposits/stabilized dunes in the Red Desert of Wyoming.

Dynamics: Complex ecological interactions of fire regimes, grazing history, and climate patterns result in equally complex patterns of species structure and composition in *Artemisia tridentata* stands. Prolonged drought on the more xeric sites may reduce shrub cover or cause plant mortality. Flooding may also cause mortality if the soil remains saturated for an extended period of time. The Aroga moth is capable of defoliating large acreages (i.e., >1000 acres, but usually 10-100 acres). Heavy grazing by wildlife can remove the

fine fuels that support mixed-severity fires and result in woody fuel buildup that leads to severe, stand-replacement fires (Landfire BpS 1210800) (Landfire 2007a). Big sagebrush stands are reduced by fire as *Artemisia tridentata* does not sprout after burning (Tirmenstein 1999c). Excessive grazing may decrease fire frequency due to consumption of herbaceous forage (fine fuels) resulting in increased shrub density. However, vast areas with depleted understory sagebrush shrublands have burned because of recent extreme fire/weather conditions. Change in fire frequency will lead to altered species composition (West 1983a). Increasing fire frequency significantly can eliminate the shrubs from the stands (Daubenmire 1970, Tirmenstein 1999c). Locally, in areas with a high fire frequency (every 2-5 years) or high-severity fire, perennial grasses and shrubs may be eliminated and non-native annual grasses such as *Bromus tectorum* can dominate. At fire-return intervals of 10-30 years, short-lived resprouting shrubs such as *Chrysothamnus* or *Tetradymia* spp. dominate. At fire-return intervals of 30-70 years, a mixture of perennial bunch grasses and non-sprouting shrubs is maintained (Johnson 2000b). Finally, in the complete absence of fire, deep-rooted shrubs such as *Artemisia tridentata* become dominant. At higher-elevation sites with absence of fire (>100 years), *Pinus monophylla* and *Juniperus osteosperma* trees may invade and eventually dominate sites (Tirmenstein 1999c).

Insects are an important component of many shrub-steppe and grassland systems. Mormon crickets and grasshoppers are natural components of many rangeland systems (USDA-APHIS 2003, 2010). There are almost 400 species of grasshoppers that inhabit the western United States with 15-45 species occurring in a given rangeland system (USDA-APHIS 2003). Mormon crickets are also present in many western rangelands and, although flightless, are highly mobile and can migrate large distances consuming much of the forage while travelling in wide bands (USDA-APHIS 2010). Following a high population year for grasshoppers or Mormon crickets and under relatively warm dry spring environmental conditions that favor egg hatching and grasshopper and Mormon cricket survival, there may be large population outbreaks that can utilize 80% or more of the forage in areas as large as 2000 square mile (USDA-APHIS 2010). Conversely, relatively cool and wet spring weather can limit the potential for outbreaks. These outbreaks are naturally occurring cycles and, especially during drought, can denude an area of vegetation leaving it exposed to increased erosion rates from wind and water (USDA-APHIS 2003).

DISTRIBUTION

Range: This system occurs throughout much of the western U.S., typically in broad basins between mountain ranges, plains and foothills. Its core distribution is in the Great Basin, but it extends north into the Columbia Basin and west into the foothills of the Sierra Nevada and Cascades, and east into the Colorado Plateau, Wyoming Basins and central and eastern Montana, although much of the sagebrush in this region is more steppe in physiognomy.

INTER-MOUNTAIN BASINS MAT SALTBUSH SHRUBLAND (CES304.783)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Plain; Shrubland (Shrub-dominated); Alluvial flat; Alluvial plain; Alkaline Soil; Saline Substrate Chemistry; Calcareous; Silt Soil Texture; Clay Soil Texture; Dwarf-Shrub; Atriplex spp.
Non-Diagnostic Classifiers: Temperate [Temperate Continental]; Oligotrophic Soil; Basin floor
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Evergreen dwarf-shrubland
National Mapping Codes: EVT 2066; ESLF 5203; ESP 1066

CONCEPT

Summary: This ecological system occurs on gentle slopes and rolling plains in the northern Colorado Plateau and Uinta Basin on Mancos shale and arid, windswept basins and plains across parts of Wyoming. It is also found in eastern Wyoming in Great Plains areas, and may extend north into Montana and Canada. Substrates are shallow, typically saline, alkaline, fine-textured soils developed from shale or alluvium and may be associated with shale badlands. Infiltration rate is typically low. These landscapes typically support dwarf-shrublands composed of relatively pure stands of *Atriplex* spp., such as *Atriplex corrugata* (in Colorado and Utah) or *Atriplex gardneri* (Wyoming and Montana into Canada). Other dominant or codominant dwarf-shrubs may include *Artemisia longifolia, Artemisia pedatifida* (very important in Wyoming, rare in Colorado stands), or *Picrothamnus desertorum*, sometimes with a mix of other low shrubs, such as *Krascheninnikovia lanata* or *Tetradymia spinosa*. *Atriplex confertifolia* or *Atriplex canescens* may be present but do not codominate. *Artemisia tridentata ssp. wyomingensis* can occur in patches within this system. The herbaceous layer is typically sparse. Scattered perennial forbs occur, such as *Xylorhiza glabriuscula* and *Sphaeralcea grossulariifolia*; perennial grasses *Achnatherum hymenoides, Bouteloua gracilis* (not in Wyoming), *Elymus elymoides, Elymus lanceolatus ssp. lanceolatus, Pascopyrum smithii, Poa secunda,* or *Sporobolus airoides* may dominate the herbaceous layer. In less saline areas, there may be inclusions of grasslands dominated by *Hesperostipa comata, Leymus salinus, Pascopyrum smithii*, or *Pseudoroegneria spicata*. In Wyoming and possibly elsewhere, inclusions of non-saline, gravelly barrens or rock outcrops dominated by cushion plants such as *Arenaria hookeri* and *Phlox hoodii* without dwarf-shrubs may be present (these are not restricted to this system). Annuals are seasonally present and may include *Eriogonum inflatum, Plantago tweedyi, Monolepis nuttalliana*, and the introduced annual grass *Bromus tectorum*. In Montana, *Atriplex gardneri* also occurs associated with badlands, and determining which system it falls into may be difficult.
Classification Comments: Reviewers have proposed renaming this system to be more "broad" than just mat saltbush (*Atriplex corrugata*), but an alternative name has not yet been identified.

INTER-MOUNTAIN BASINS MIXED SALT DESERT SCRUB (CES304.784)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Plain; Shrubland (Shrub-dominated); Alluvial flat; Alluvial plain; Alkaline Soil; Saline Substrate Chemistry; Calcareous; Silt Soil Texture; Clay Soil Texture; Xeromorphic Shrub; Dwarf-Shrub; Atriplex spp.
Non-Diagnostic Classifiers: Temperate [Temperate Continental]; Oligotrophic Soil; Basin floor
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2081; ESLF 5258; ESP 1081

CONCEPT

Summary: This extensive ecological system includes open-canopied shrublands of typically saline basins, alluvial slopes and plains across the Intermountain western U.S. This type also extends in limited distribution into the southern Great Plains. Substrates are often saline and calcareous, medium- to fine-textured, alkaline soils, but include some coarser-textured soils. The vegetation is characterized by a typically open to moderately dense shrubland composed of one or more *Atriplex* species, such as *Atriplex confertifolia, Atriplex canescens, Atriplex polycarpa*, or *Atriplex spinifera*. *Grayia spinosa* tends to occur on coppice dunes that may have a silty component to them. Northern occurrences lack *Atriplex* species and are typically dominated by *Grayia spinosa, Krascheninnikovia lanata*, and/or *Artemisia tridentata*. Other shrubs present to codominant may include *Artemisia tridentata ssp. wyomingensis, Chrysothamnus viscidiflorus, Ericameria nauseosa, Ephedra nevadensis, Grayia spinosa, Krascheninnikovia lanata, Lycium* spp., *Picrothamnus desertorum*, or *Tetradymia* spp. In Wyoming, occurrences are typically a mix of *Atriplex confertifolia, Grayia spinosa, Artemisia tridentata ssp. wyomingensis, Sarcobatus vermiculatus, Krascheninnikovia lanata*, and various *Ericameria* or *Chrysothamnus* species. Some places are a mix of *Atriplex confertifolia* and *Artemisia tridentata ssp. wyomingensis*. In the Great Basin, *Sarcobatus vermiculatus* is generally absent but, if present, does not codominate. The herbaceous layer varies from sparse to moderately dense and is dominated by perennial graminoids such as *Achnatherum hymenoides, Bouteloua gracilis, Elymus lanceolatus ssp. lanceolatus, Pascopyrum smithii, Pleuraphis jamesii, Pleuraphis rigida, Poa secunda*, or *Sporobolus airoides*. Various forbs are also present
Similar Ecological Systems:

- Saltbush - Greasewood (501) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This salt-desert shrubland system is a matrix system in the Intermountain West. This system is comprised of arid to semi-arid shrublands on lowland and upland sites usually at elevations between 1520 and 2200 m (4987-7218 feet). Sites can be found on all aspects and include valley bottoms, alluvial and alkaline flats, mesas and plateaus, playas, drainage terraces, washes and interdune basins, bluffs, and gentle to moderately steep sandy or rocky slopes. Slopes are typically gentle to moderately steep but are sometimes unstable and prone to surface movement. Many areas within this system are degraded due to erosion and may resemble "badlands." Soil surface is often very barren in occurrences of this system. The interspaces between the characteristic plant clusters are commonly covered by a microphytic crust (West 1982).

This is typically a system of extreme climatic conditions, with warm to hot summers and freezing winters. Annual precipitation ranges from approximately 13-33 cm. In much of the ecological system, the period of greatest moisture will be mid- to late summer, although in the more northern areas a moist period is to be expected in the cold part of the year. However, plotted seasonality of occurrence is probably of less importance on this desert system than in other ecosystems because desert precipitation comes with an extreme irregularity that does not appear in graphs of long-term seasonal or monthly averages (Blaisdell and Holmgren 1984). Soils are shallow to moderately deep, poorly developed, and a product of an arid climate and little precipitation. Soils are often alkaline or saline. Vegetation within this system is tolerant of these soil conditions but not restricted to it. The shallow soils of much of the area are poorly developed Entisols. Vegetation within this system can occur on level pediment remnants where coarse-textured and well-developed soil profiles have been derived from sandstone gravel and are alkaline, or on Mancos shale badlands, where soil profiles are typically fine-textured and non-alkaline throughout (West and Ibrahim 1968). They can also occur in alluvial basins where parent materials from the other habitats have been deposited over Mancos shale and the soils are heavy-textured and saline-alkaline throughout the profile (West and Ibrahim 1968).

Vegetation: Occurrences of this ecological system vary from almost pure occurrences of single species to fairly complex mixtures. The characteristic mix of low shrubs and grasses is sparse, with large open spaces between the plants (Blaisdell and Holmgren 1984). Occurrences have a sparse to moderately dense cover of woody species that is dominated by *Atriplex canescens* (may codominate with *Artemisia tridentata*), *Atriplex confertifolia* (may codominate with *Lycium andersonii*), *Atriplex obovata, Picrothamnus desertorum*, or *Krascheninnikovia lanata*. Other shrubs that may occur within these occurrences include *Purshia stansburiana, Psorothamnus polydenius, Ephedra* spp., *Acacia greggii, Encelia frutescens, Tiquilia latior, Parthenium confertum, Atriplex polycarpa, Atriplex*

lentiformis, Atriplex spinifera, Picrothamnus desertorum (= Artemisia spinescens), Frankenia salina, Artemisia frigida, Chrysothamnus spp., *Lycium* ssp., *Suaeda* spp., *Yucca glauca,* and *Tetradymia spinosa*. Dwarf-shrubs include *Gutierrezia sarothrae* and *Eriogonum* spp. Warm-season medium-tall and short perennial grasses dominate in the sparse to moderately dense graminoid layer. The species present depend on the geographic range of the grasses, alkalinity/salinity and past land use. Species may include *Pleuraphis jamesii, Bouteloua gracilis, Sporobolus airoides, Sporobolus cryptandrus, Achnatherum hymenoides, Elymus elymoides, Distichlis spicata, Leymus salinus, Pascopyrum smithii, Hesperostipa comata, Pseudoroegneria spicata, Poa secunda, Leymus ambiguus,* and *Muhlenbergia torreyi*. A number of annual species may also grow in association with the shrubs and grasses of this system, although they are usually rare and confined to areas of recent disturbance (Blaisdell and Holmgren 1984). Forb cover is generally sparse. Perennial forbs that might occur include *Sphaeralcea coccinea, Chaetopappa ericoides, Xylorhiza venusta, Descurainia sophia,* and *Mentzelia* species. Annual natives include *Plantago* spp., *Vulpia octoflora,* or *Monolepis nuttalliana*. Associated halophytic annuals include *Salicornia rubra, Salicornia bigelovii,* and *Suaeda* species. Exotic annuals that may occur include *Salsola kali, Bromus rubens,* and *Bromus tectorum*. Cacti like *Opuntia* spp. and *Echinocereus* spp. may be present in some occurrences. Trees are not usually present but some scattered *Juniperus* spp. may be found.

Dynamics: West (1982) stated that "salt desert shrub vegetation occurs mostly in two kinds of situations that promote soil salinity, alkalinity, or both. These are either at the bottom of drainages in enclosed basins or where marine shales outcrop." However, salt-desert shrub vegetation may be an indication of climatically dry as well as physiologically dry soils (Blaisdell and Holmgren 1984). Not all salt-desert shrub soils are salty, and their hydrologic characteristics may often be responsible for the associated vegetation (Naphan 1966). Species of the salt-desert shrub complex have different degrees of tolerance to salinity and aridity, and they tend to sort themselves out along a moisture/salinity gradient (West 1982). Species and communities are apparently sorted out along physical, chemical, moisture, and topographic gradients through complex relations that are not understood and are in need of further study (Blaisdell and Holmgren 1984).

The winter months within this system are a good time for soil moisture accumulation and storage. There is generally at least one good snow storm per season that will provide sufficient moisture to the vegetation. The winter moisture accumulation amounts will affect spring plant growth. Plants may grow as little as a few inches to 1 m. Unless more rains come in the spring, the soil moisture will be depleted in a few weeks, growth will slow and ultimately cease, and the perennial plants will assume their various forms of dormancy (Blaisdell and Holmgren 1984). If effective rain comes later in the warm season, some of the species will renew their growth from the stage at which it had stopped. Others, having died back, will start over as if emerging from winter dormancy (Blaisdell and Holmgren 1984). *Atriplex confertifolia* shrubs often develop large leaves in the spring, which increase the rate of photosynthesis. As soil moisture decreases, the leaves are lost, and the plant takes on a dead appearance. During late fall, very small overwintering leaves appear which provide some photosynthetic capability through the remainder of the year (IVC 1999). Other communities are maintained by intra- or inter-annual cycles of flooding followed by extended drought, which favor accumulation of transported salts. The moisture supporting these intermittently flooded wetlands is usually derived off-site, and they are dependent upon natural watershed function for persistence (Reid et al. 1999).

In summary, desert communities of perennial plants are dynamic and changing. The composition within this system may change dramatically and may be both cyclic and unidirectional. Superimposed on the compositional change is great variation from year to year in growth of all the vegetation, the sum of varying growth responses of individual species to specific conditions of different years (Blaisdell and Holmgren 1984). Desert plants grow when temperature is satisfactory, but only if soil moisture is available at the same time. Because amount of moisture is variable from year to year and because different species flourish under different seasons of soil moisture, seldom do all components of the vegetation thrive in the same year (Blaisdell and Holmgren 1984).

Component Associations:

- *Artemisia tridentata - Atriplex canescens - Sarcobatus vermiculatus / (Achnatherum hymenoides)* Shrubland (CEGL001355, G1)
- *Artemisia tridentata ssp. wyomingensis - Atriplex confertifolia* Shrubland (CEGL001040, G3G5)
- *Atriplex canescens - Artemisia tridentata* Shrubland (CEGL001282, G4)
- *Atriplex canescens - Ephedra viridis* Talus Shrubland (CEGL001287, G4)
- *Atriplex canescens - Krascheninnikovia lanata* Shrubland (CEGL001285, G5)
- *Atriplex canescens / Achnatherum hymenoides* Shrubland (CEGL001289, G3G5)
- *Atriplex canescens / Bouteloua gracilis* Shrubland (CEGL001283, G3)

MADREAN ORIENTAL CHAPARRAL (CES302.031)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Shrubland (Shrub-dominated); Shallow Soil; Xeric; F-Patch/High Intensity
Non-Diagnostic Classifiers: Temperate [Temperate Xeric]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2101; ESLF 5307; ESP 1101

CONCEPT

Summary: This ecological system occurs in mountains across southeastern New Mexico (Guadalupe Mountains), Trans-Pecos Texas (Chisos and Davis mountains) and Madrean Oriental in northern Mexico. It often dominates along the mid-elevation transition from the Chihuahuan Desert into mountains (1700-2500 m). It occurs on foothills, mountain slopes and canyons in drier habitats below the encinal and pine woodlands, and is often associated with more xeric and coarse-textured substrates such as limestone, basalt or alluvium, especially in transition areas with more mesic woodlands. The moderate to dense shrub canopy includes many shrub oak species, such as *Quercus emoryi, Quercus grisea, Quercus intricata, Quercus invaginata, Quercus laceyi, Quercus mohriana, Quercus pringlei, Quercus pungens*, and *Quercus vaseyana*, and several widespread chaparral species, such as *Arctostaphylos pungens, Ceanothus greggii, Cercocarpus montanus, Fallugia paradoxa*, and *Garrya wrightii*; other species characteristic of this system include *Arbutus xalapensis (= Arbutus texana), Fraxinus greggii, Fendlera rigida (= Fendlera linearis), Garrya ovata, Purshia mexicana, Rhus virens var. choriophylla (= Rhus choriophylla), Salvia lycioides (= Salvia ramosissima), Salvia roemeriana*, and *Salvia regla*. In the Trans-Pecos of Texas, disjunct *Quercus gambelii* may occur as a significant component of this shrubland. Most chaparral species are fire-adapted, resprouting vigorously after burning or producing fire-resistant seeds. Stands occurring within montane woodlands are seral and a result of recent fires. Grass cover may be significant. Dominant grasses often include *Bouteloua curtipendula, Bouteloua hirsuta*, and *Muhlenbergia emersleyi*.
Classification Comments: The similar Mogollon chaparral system has floristics mostly derived from the Sierra Madre Occidentale, whereas floristics of this system are derived from the Sierra Madre Oriental. However, this system is not mattoral (thornscrub) as it is typically dominated by shrubby evergreen oaks and chaparral species, not thornscrub species. More survey is needed to determine if *Quercus turbinella*, common in the Mogollon Chaparral system, also occurs in the Madrean Oriental Chaparral.
Related Concepts:
- Sideoats Grama - Sumac - Juniper (735) (Shiflet 1994) Undetermined

DESCRIPTION

Vegetation: The moderate to dense shrub canopy includes many shrub oak species, such as *Quercus emoryi, Quercus grisea, Quercus intricata, Quercus invaginata, Quercus laceyi, Quercus mohriana, Quercus pringlei, Quercus pungens*, and *Quercus vaseyana*, and several widespread chaparral species, such as *Arctostaphylos pungens, Ceanothus greggii, Cercocarpus montanus, Fallugia paradoxa*, and *Garrya wrightii*; other species characteristic of this system include *Arbutus xalapensis (= Arbutus texana), Fraxinus greggii, Fendlera rigida (= Fendlera linearis), Garrya ovata, Purshia mexicana, Rhus virens var. choriophylla (= Rhus choriophylla), Salvia lycioides (= Salvia ramosissima), Salvia roemeriana*, and *Salvia regla*. In the Trans-Pecos of Texas, disjunct *Quercus gambelii* may occur as a significant component of this shrubland. Most chaparral species are fire-adapted, resprouting vigorously after burning or producing fire-resistant seeds. Stands occurring within montane woodlands are seral and a result of recent fires. Grass cover may be significant. Dominant grasses often include *Bouteloua curtipendula, Bouteloua hirsuta*, and *Muhlenbergia emersleyi*.

Component Associations:
- *Cercocarpus montanus / Muhlenbergia pauciflora* Shrubland (CEGL001089, GNR)
- *Quercus intricata - Dasylirion leiophyllum* Shrubland (CEGL004530, GNR)
- *Quercus pungens - Cercocarpus montanus* Shrubland (CEGL003832, G3?)
- *Rhus virens var. choriophylla / Cercocarpus montanus var. paucidentatus* Shrubland (CEGL001123, G3)

DISTRIBUTION

Range: This system is found on mountains across southeastern New Mexico, Trans-Pecos Texas and northern Mexico. It often dominants along the mid-elevation transition from the Chihuahuan Desert into mountains (1700-2500 m elevation).

MEDITERRANEAN CALIFORNIA ALPINE FELL-FIELD (CES206.900)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Alpine Mosaic; Ridge/Summit/Upper Slope; Temperate [Temperate Oceanic]; Very Shallow Soil; Cushion plants
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); Herbaceous; Moss/Lichen (Nonvascular); Talus (Landform); Sideslope; Talus (Substrate); Avalanche chute; Glaciated; W-Landscape/High Intensity; Dwarf-Shrub; Nonvascular; Cirque; Colluvial slope
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Mixed evergreen-deciduous dwarf-shrubland
National Mapping Codes: EVT 2067; ESLF 5204; ESP 1067

CONCEPT

Summary: This ecological system occurs in limited alpine environments mostly concentrated in the Sierra Nevada but also on Mount Shasta and as far south as the Peninsular Ranges and White Mountains. Alpine elevations begin around 3500 m (10,600 feet) in the southern mountain ranges and 2700 m (8200 feet) in the southern Cascades. Wind scours fell-fields free of snow in the winter, exposing the plants to severe environmental stress. These systems typically have immature soils. Most fell-field plants are cushioned or matted, frequently succulent, flat to the ground in rosettes, and often densely hairy and thickly cutinized. Common species include *Ribes cereum, Leptodactylon pungens, Ericameria discoidea, Castilleja nana, Minuartia nuttallii (= Arenaria nuttallii), Phlox condensata, Draba densifolia, Oxyria digyna*, and *Aquilegia pubescens*. Plants cover 15-50%, while exposed rock makes up the rest. Fell-fields are usually nested within or adjacent to alpine tundra dry meadows.
Related Concepts:
- Alpine Grassland (213) (Shiflet 1994) Broader. SRM type 213 includes all alpine communities in Sierra, Klamath and California Cascades, both herbaceous and shrub dominated, and wet meadows.

DESCRIPTION

Environment: These are wind-scoured fell-fields that are free of snow in the winter, such as ridgetops and exposed saddles, exposing the plants to severe environmental stress. Soils on these windy unproductive sites are shallow, stony, low in organic matter, and poorly developed; wind deflation often results in a gravelly pavement. Fell is Gaelic for stone, and these are stone fields. Sites are stable for 100s to 1000s of years as soils develop. Alpine elevations begin around 3500 m (10,600 feet) in the southern Sierra Nevada and 2700 m (8200 feet) in the southern Cascades.
Dynamics: TNC model information: Avalanches on steeper slopes where soil accumulates can cause infrequent soil-slips, which expose bare ground.

Very small burns of a few square meters (replacement fire) caused by lightning strikes are a rare disturbance, although lighting storms are frequent in those elevations. The calculation of lightning strike frequency was not based on fire-return intervals but on the number of strikes (in this case, five) per 1000 possible locations per year, thus 0.005.

Alpine rodents (pikas, marmots, etc.) cause common but generally small-scale disturbances in this system. Native herbivores (Rocky Mountain bighorn sheep, mule deer, and elk) were common in the alpine but probably did not greatly affect vegetation cover because animals move frequently as they reduce vegetation cover.

SPATIAL CHARACTERISTICS

Spatial Summary: This ecological system can occupy large areas of the alpine. Patch size varies from a few acres to 1000 acres on mountain ridges and tops. Stand-replacement fires may be caused by lightning strikes that do not spread due to the sparse cover of fine fuels and extensive barren areas acting as firebreaks.

DISTRIBUTION

Range: This system occurs in limited alpine environments mostly concentrated in the Sierra Nevada but also on Mount Shasta and as far south as the Peninsular Ranges and White Mountains.

MOGOLLON CHAPARRAL (CES302.741)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Intermediate Disturbance Interval; F-Patch/High Intensity; Evergreen Sclerophyllous Shrub
Non-Diagnostic Classifiers: Montane [Montane]; Shrubland (Shrub-dominated); Temperate [Temperate Continental]; Temperate [Temperate Xeric]; Xeric; Aridic; Broad-Leaved Evergreen Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2104; ESLF 5310; ESP 1104

CONCEPT

Summary: This ecological system occurs across central Arizona (Mogollon Rim), western New Mexico, and southern Utah and Nevada. It often dominates along the mid-elevation transition from the Mojave, Sonoran, and northern Chihuahuan deserts into mountains (1000-2200 m). It occurs on foothills, mountain slopes and canyons in hotter and drier habitats below the encinal and *Pinus ponderosa* woodlands. Stands are often associated with more xeric and coarse-textured substrates such as limestone, basalt or alluvium, especially in transition areas with more mesic woodlands. The moderate to dense shrub canopy includes species such as *Quercus turbinella, Quercus toumeyi, Cercocarpus montanus var. paucidentatus, Canotia holacantha, Ceanothus greggii, Garrya wrightii, Purshia stansburiana, Rhus ovata, Rhus trilobata,* and *Arctostaphylos pungens* and *Arctostaphylos pringlei* at higher elevations. Scattered remnant pinyon and juniper trees may be present. Most chaparral species are fire-adapted, resprouting vigorously after burning or producing fire-resistant seeds. Stands occurring within montane woodlands are seral and a result of recent fires.

MOJAVE MID-ELEVATION MIXED DESERT SCRUB (CES302.742)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Shrubland (Shrub-dominated); Evergreen Sclerophyllous Tree
Non-Diagnostic Classifiers: Sideslope; Temperate [Temperate Xeric]; Aridic; Xeromorphic Shrub; Succulent Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2082; ESLF 5259; ESP 1082

CONCEPT

Summary: This ecological system represents the extensive desert scrub in the transition zone above *Larrea tridentata - Ambrosia dumosa* desert scrub and below the lower montane woodlands (700-1800 m elevations) that occur in the eastern and central Mojave Desert. It is also common on lower piedmont slopes in the transition zone into the southern Great Basin. The vegetation in this ecological system is quite variable. Codominants and diagnostic species include *Coleogyne ramosissima, Eriogonum fasciculatum, Ephedra nevadensis, Grayia spinosa, Lycium* spp., *Menodora spinescens, Nolina* spp., *Opuntia acanthocarpa, Salazaria mexicana, Viguiera parishii, Yucca brevifolia,* or *Yucca schidigera*. Less common are stands with scattered Joshua trees and a saltbush short-shrub layer dominated by *Atriplex canescens, Atriplex confertifolia,* or *Atriplex polycarpa,* or occasionally *Hymenoclea salsola*. In some areas in the western Mojave, *Juniperus californica* is common with the yuccas. Desert grasses, including *Achnatherum hymenoides, Achnatherum speciosum, Muhlenbergia porteri, Pleuraphis jamesii, Pleuraphis rigida,* or *Poa secunda,* may form an herbaceous layer. Scattered *Juniperus osteosperma* or desert scrub species may also be present.

NORTH PACIFIC AVALANCHE CHUTE SHRUBLAND (CES204.854)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Montane]; Shrubland (Shrub-dominated); Avalanche
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Lower Montane]; Temperate [Temperate Continental]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2083; ESLF 5260; ESP 1083

CONCEPT

Summary: This tall shrubland system occurs throughout mountainous regions of the Pacific Northwest, from the southern Cascades and Coast Ranges north into the mountains of British Columbia. This system occurs on sideslopes of mountains on glacial till or colluvium. These habitats range from moderately xeric to wet and occur on snow avalanche chutes at montane elevations. In the mountains of Washington, talus sites and snow avalanche chutes very often coincide spatially. On the west side of the Cascades, the major dominant species are *Acer circinatum, Alnus viridis ssp. sinuata, Rubus parviflorus*, and small trees, especially *Chamaecyparis nootkatensis*. Forbs, grasses, or other shrubs can also be locally dominant. *Prunus virginiana, Amelanchier alnifolia, Vaccinium membranaceum* or *Vaccinium scoparium*, and *Fragaria* spp. are common species on drier avalanche tracks on the east side of the Cascades. The main feature of this system is that it occurs on steep, frequently disturbed (snow avalanches) slopes. Avalanche chutes can be quite long, extending from the subalpine into the montane and foothill toeslopes.
Classification Comments: Avalanche slopes in the Cascades and mountains of southern British Columbia are probably drier than those found further north in Alaska, where the precipitation regime does not have a seasonal component to it. Hence, these have been split into two different systems. Exactly where they transition from one to another is yet to be determined.
Similar Ecological Systems:

NORTH PACIFIC DRY AND MESIC ALPINE DWARF-SHRUBLAND, FELL-FIELD AND MEADOW (CES204.862)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Shrubland (Shrub-dominated)
Non-Diagnostic Classifiers: Long (>500 yrs) Persistence; Temperate [Temperate Oceanic]; W-Landscape/High Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Mixed evergreen-deciduous dwarf-shrubland
National Mapping Codes: EVT 2068; ESLF 5205; ESP 1068

CONCEPT

Summary: This system occurs above the environmental limit of trees, at the highest elevations of the mountain regions of the Pacific Northwest Coast. It is confined to the coldest, wind-blown areas above treeline and above the subalpine parkland. This system is found at elevations above 2350 m (7200 feet) in the Klamath Mountains and Cascades north into the Cascade and Coastal mountains of British Columbia. It is commonly comprised of a mosaic of plant communities with characteristic species including *Cassiope mertensiana, Phyllodoce empetriformis, Phyllodoce glanduliflora, Luetkea pectinata, Saxifraga tolmiei,* and *Carex* spp. It occurs on slopes and depressions where snow lingers, the soil has become relatively stabilized, and the water supply is more or less constant. Vegetation in these areas is controlled by snow retention, wind desiccation, permafrost, and a short growing season. This system includes all vegetated areas in the alpine zone of the North Pacific. Typically it is a mosaic of dwarf-shrublands, fell-fields, tundra (sedge turfs), and sparsely vegetated snowbed communities. Small patches of krummholz (shrub-form trees) are also part of this system and occur at the lower elevations. Communities are dominated by graminoids, foliose lichens, dwarf-shrubs, and/or forbs. Vegetation cover ranges from about 5 or 10% (snowbeds) to nearly 100%. The alpine tundra of the northern Cascades has floristic affinities with many mountain regions in western North America. The strongest relationships are with the Arctic and Cordilleran regions to the north and east.
Classification Comments: Alpine systems in Alaska are placed into different types than this.

DESCRIPTION

Dynamics: Landfire VDDT models: #RALME includes this and Rocky Mountain alpine systems.

Component Associations:
- *Antennaria lanata* Herbaceous Vegetation (CEGL001949, G4)
- *Arctostaphylos uva-ursi* Dwarf-shrubland (CEGL001392, G3G4)
- *Calamagrostis purpurascens* Herbaceous Vegetation (CEGL001850, G2)
- *Carex breweri* Herbaceous Vegetation (CEGL001805, G3?)
- *Carex capitata* Herbaceous Vegetation (CEGL001807, G3?)
- *Carex nardina* Scree Herbaceous Vegetation (CEGL001812, GNR)
- *Carex pellita* Herbaceous Vegetation (CEGL001809, G3)
- *Carex proposita* Herbaceous Vegetation (CEGL001859, G3?)
- *Carex scirpoidea ssp. pseudoscirpoidea* Herbaceous Vegetation (CEGL001865, G3?)
- *Cassiope mertensiana - Phyllodoce empetriformis* Dwarf-shrubland (CEGL001398, G5)
- *Cassiope mertensiana / Luetkea pectinata* Dwarf-shrubland (CEGL001397, G3G4)
- *Cassiope mertensiana* Dwarf-shrubland (CEGL001395, G3G4)
- *Dryas octopetala* Dwarf-shrub Herbaceous Vegetation (CEGL001891, G3?)
- *Empetrum nigrum / Lupinus sellulus var. lobbii* Dwarf-shrubland (CEGL001400, G3G4)
- *Empetrum nigrum* Dwarf-shrubland (CEGL001399, G3G4)
- *Erigeron aureus - Lupinus sellulus var. lobbii* Herbaceous Vegetation (CEGL001961, G3G4)
- *Eriogonum pyrolifolium - Luzula piperi* Herbaceous Vegetation (CEGL001963, G4)
- *Festuca roemeri - Delphinium glareosum* Herbaceous Vegetation (CEGL001613, G2)
- *Festuca roemeri - Phlox diffusa ssp. longistylis* Herbaceous Vegetation (CEGL001622, G2)
- *Pedicularis contorta - Carex spectabilis* Herbaceous Vegetation (CEGL001977, G3?)
- *Phlox diffusa ssp. longistylis - Arenaria capillaris* Herbaceous Vegetation (CEGL001978, G3?)
- *Phlox diffusa ssp. longistylis - Carex spectabilis* Herbaceous Vegetation (CEGL001979, GNR)
- *Phyllodoce glanduliflora / Oreostemma alpigenum* Dwarf-shrubland (CEGL001408, G3G4)

- *Salix cascadensis / Festuca brachyphylla* Dwarf-shrubland (CEGL001433, G3G4)
- *Salix nivalis / Festuca brachyphylla* Dwarf-shrubland (CEGL001434, G3G4)
- *Saxifraga tolmiei - Luzula piperi* Herbaceous Vegetation (CEGL001986, G4)

DISTRIBUTION

Range: This system occurs above the environmental limit of trees, at the highest elevations of the mountain regions of the Pacific Northwest Coast. Alpine systems in Alaska are placed into different types than this.
Divisions: 204:C
Nations: CA, US

NORTH PACIFIC MONTANE SHRUBLAND (CES204.087)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated)
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2084; ESLF 5261; ESP 1084

CONCEPT

Summary: This system occurs as small to large patches scattered throughout the North Pacific region, but it is largely absent from the windward sides of the coastal mountains where fires are rare due to very wet climates. It is defined as long-lived seral shrublands that persist for several decades or more after major wildfires, or smaller patches of shrubland on dry sites that are marginal for tree growth and that have typically also experienced fire. This system occurs on ridgetops and upper to middle mountain slopes and is more common on sunny southern aspects. It occurs from about 152 m (500 feet) elevation up to the lower limits of subalpine parkland. Vegetation is mostly deciduous broadleaf shrubs, sometimes mixed with shrub-statured trees or sparse evergreen needleleaf trees. It can also be dominated by evergreen shrubs, especially *Xerophyllum tenax* (usually considered a forb). Species composition is highly variable; some of most common species include *Acer circinatum, Arctostaphylos nevadensis, Acer glabrum, Vaccinium membranaceum, Ceanothus velutinus, Holodiscus discolor, Shepherdia canadensis, Sorbus* spp., and *Rubus parviflorus*. On the west side of the Cascades, *Gaultheria shallon* is an important dominant.

Related Concepts:

- Snowbush (420) (Shiflet 1994) Intersecting. *Ceanothus velutinus* shrublands in the southern Cascades are included in this ecological system.

Component Associations:

- *Acer circinatum / Athyrium filix-femina - Tolmiea menziesii* Shrubland (CEGL003291, G5)
- *Amelanchier alnifolia / Xerophyllum tenax* Herbaceous Vegetation (CEGL001066, GNRQ)
- *Rubus parviflorus / Chamerion angustifolium - Heracleum maximum* Shrubland (CEGL001127, G4)
- *Vaccinium membranaceum / Xerophyllum tenax* Shrubland (CEGL005891, G3?)
- *Xerophyllum tenax - Sanguisorba officinalis* Herbaceous Vegetation (CEGL003439, G1)

DISTRIBUTION

Range: This system occurs as small to large patches scattered throughout mountainous regions of the Pacific Northwest, from the southern Cascade and Coast ranges north to southern British Columbia. Its northernmost distribution is not clear, but it does not appear to occur in Alaska.
Divisions: 204:C
Nations: CA, US
Subnations: BC, OR, WA

NORTHERN AND CENTRAL CALIFORNIA DRY-MESIC CHAPARRAL (CES206.931)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Mediterranean [Mediterranean Xeric-Oceanic]; Sand Soil Texture; Ustic; Intermediate Disturbance Interval; F-Landscape/High Intensity; Ceanothus cuneatus, Adenostoma fasciculatum
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Sideslope; Xeric
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2105; ESLF 5311; ESP 1105

CONCEPT

Summary: This ecological system includes chaparral typically located inland from maritime chaparral up to 1500 m (4550 feet) elevation in central and northern California through the northern end of the Central Valley and north into Oregon. This system includes extensive areas on coarse-grained soils with annual precipitation up to 75 cm (winter rain but not snow). Adjacent fine-textured soils support savanna under similar climatic regimes. These areas have supported extensive stand-replacing wildfires. This system is made up of a mixture of mostly obligate seeders. Characteristic species include *Adenostoma fasciculatum, Ceanothus cuneatus, Arctostaphylos viscida, Arctostaphylos manzanita, Arctostaphylos glauca, Arctostaphylos glandulosa, Arctostaphylos stanfordiana, Fremontodendron californicum, Malacothamnus fasciculatus, Dendromecon rigida,* and *Pickeringia montana*. Common shrubs in Oregon include *Arctostaphylos viscida, Cercocarpus montanus var. glaber,* and *Ceanothus cordulatus*. Fire regimes are intense, stand-replacing crown fires. Scattered and young trees may occur, such as *Pinus ponderosa, Pinus sabiniana, Pseudotsuga menziesii,* and *Quercus wislizeni*.

Related Concepts:
- Ceanothus Mixed Chaparral (208) (Shiflet 1994) Broader
- Chamise Chaparral (206) (Shiflet 1994) Broader. SRM groups all *Adenostoma*-dominated communities into one range type; several ecological systems can have *Adenostoma fasciculatum* as a dominant.

Component Associations:
- *Adenostoma fasciculatum - Arctostaphylos glandulosa - Ceanothus jepsonii / Calamagrostis ophitidis* Shrubland (CEGL003176, G2)
- *Adenostoma fasciculatum - Arctostaphylos glandulosa - Quercus wislizeni* Shrubland (CEGL003177, G3)
- *Adenostoma fasciculatum - Ceanothus cuneatus* Sierran Chaparral Shrubland (CEGL003468, G4?)
- *Adenostoma fasciculatum - Diplacus aurantiacus* Shrubland (CEGL003178, G3)
- *Adenostoma fasciculatum* Sierran Chaparral Shrubland (CEGL005816, G5?)
- *Arctostaphylos glandulosa - Quercus wislizeni* Shrubland (CEGL003180, G3)
- *Arctostaphylos glauca* Shrubland (CEGL003008, G3G4)
- *Arctostaphylos viscida* Sierran Chaparral Shrubland (CEGL005817, G5?)
- *Ceanothus cuneatus* / Poaceae Shrubland (CEGL003158, GNR)
- *Ceanothus cuneatus* Shrubland (CEGL003025, G4?)

DISTRIBUTION

Range: This system is located inland from maritime chaparral up to 1500 m (4550 feet) elevation in central and northern California, and southwestern Oregon, through the north end of the California Central Valley.
Divisions: 206:C
Nations: US
Subnations: CA, OR
Map Zones: 2:C, 3:C, 4:C, 5:C, 6:C, 7:C

NORTHERN ATLANTIC COASTAL PLAIN HEATHLAND AND GRASSLAND (CES203.895)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Glaciated plains; Shrubland (Shrub-dominated); Grassland, Savanna, Steppe (graminoid-dominated); North Atlantic Coastal Plain; Sandplains/Glacial Outwash or Flats; Temperate; Sand Soil Texture; Very Short Disturbance Interval; Coastal plain
Non-Diagnostic Classifiers: Salt Spray
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2522; ESLF 5275; ESP 1522

CONCEPT

Summary: Sandplain grasslands and heathlands of the southern New England / New York coast are areas of graminoid- and shrub-dominated vegetation maintained by periodic fire or other disturbance, as well as exposure to maritime influences. Developing on acidic, nutrient-poor, and very well-drained soils within a few kilometers of the ocean, they may occur as heathlands, grasslands, or support a patchwork of grass and shrub vegetation. Characteristic species include *Gaylussacia baccata, Arctostaphylos uva-ursi, Corema conradii, Amelanchier nantucketensis, Hudsonia ericoides, Hudsonia tomentosa, Vaccinium angustifolium, Deschampsia flexuosa, Schizachyrium scoparium,* and *Carex pensylvanica*. They provide habitat for several rare or uncommon forbs including *Liatris scariosa var. novae-angliae* and *Agalinis acuta*. They are important habitat for several bird and other animal species including the short-eared owl and regal fritillary, and (along with brushy plains and woodlands) provided habitat for the extinct heath hen.
Classification Comments: This system includes both the very distinctive Hempstead Plains grasslands of Long Island, New York (which occur a bit further inland than other sites), as well as the maritime heathlands/grasslands of Cape Cod and nearby islands. Grass-dominated and shrub-dominated expressions are separated at the association level; they can occur together and intergrade at some sites. This system is related to dune grasslands but occurs on sandplains, not dunes, and lacks significant amounts of *Ammophila breviligulata*. In the absence of disturbance (fire, grazing, mowing), coverage by *Pinus rigida* and *Quercus ilicifolia* can increase, creating vegetation similar to a pitch pine - scrub oak barren (hence the inclusion of CEGL006315 in the associations list); or in some cases, a tall-shrub community can develop in the absence of fire (CEGL006379). Neither of these associations is core to the concept of this system. Its landscape position and dynamics are sufficiently distinct that it is segregated rather than being treated as a phase or a patch of the coastal pine barrens system.
Similar Ecological Systems:
- Northern Atlantic Coastal Plain Dune and Swale (CES203.264)
- Northern Atlantic Coastal Plain Pitch Pine Barrens (CES203.269)

- Sandplain Grassland and Sandplain Heathland (Lundgren et al. 2000) Equivalent

DESCRIPTION

Environment: Sandplain grasslands and heathlands of the southern New England / New York coast are areas of graminoid- and shrub-dominated vegetation maintained by extreme conditions and periodic fire or other disturbance. Developing on acidic, nutrient-poor, and very well-drained soils, they may occur as heathlands, grasslands, or support a patchwork of grass and shrub vegetation.
Vegetation: Characteristic species include *Gaylussacia baccata, Arctostaphylos uva-ursi, Corema conradii, Amelanchier nantucketensis, Hudsonia ericoides, Hudsonia tomentosa, Vaccinium angustifolium, Deschampsia flexuosa, Schizachyrium scoparium,* and *Carex pensylvanica*. They provide habitat for several rare or uncommon forbs including *Liatris scariosa var. novae-angliae* and *Agalinis acuta*.
Dynamics: The largely exposed locations experience extreme variations in temperature and moisture, and the sandy, nutrient-poor soils contribute to prevention of establishment of woody vegetation. Coastal occurrences maintain their open nature with the stress and killing of woody plant tissue caused by high winds, desiccation, and salt spray. Examples that developed in slight depressions are also maintained by frost that persists longer into the growing season (MNHESP 2010a, 2010b). Prior to European settlement, this system is believed to have occurred as small patches in limited areas near the coast (Motzkin and Foster 2002); there may also have been patches in the vicinity of Native American settlements, based on the prevalence of charcoal in some palynological cores (Dunwiddie

1989). Presettlement grasslands appear to have been more likely on portions of Long Island (Hempstead Plains and Montauk) and Martha's Vineyard than on Nantucket, Block Island, or Cape Cod (Motzkin and Foster 2002). This native vegetation is often confused with similar semi-natural grasslands and heathlands characterized by a mixture of native and exotic species developed as a result of agriculture; some natural occurrences may have resulted as expansions of original native vegetation. They have increased in extent and largely post-date land clearing following European settlement (Foster et al. 2002). In addition, some heathlands may have developed on severely disturbed soils following the abandonment of agriculture and grazing (Motzkin and Foster 2002). Efforts to reverse the conversion of these heathlands and grasslands to tall shrublands or woodlands have generally used a mixture of prescribed fire and mowing, and less commonly grazing.

Component Associations:
- *Amelanchier canadensis - Viburnum* spp. - *Morella pensylvanica* Scrub Forest (CEGL006379, GNR)
- *Gaylussacia baccata - Vaccinium angustifolium - Arctostaphylos uva-ursi / Schizachyrium littorale* Dwarf-shrubland (CEGL006066, G3)
- *Morella pensylvanica / Schizachyrium littorale - Danthonia spicata* Shrub Herbaceous Vegetation (CEGL006067, G2)
- *Pinus rigida / Quercus ilicifolia / Morella pensylvanica* Woodland (CEGL006315, G3)
- *Quercus stellata - Sassafras albidum / Smilax glauca* Woodland (CEGL006372, GNR)
- *Schizachyrium scoparium - Sorghastrum nutans - Hypoxis hirsuta - Baptisia tinctoria* Herbaceous Vegetation (CEGL006187, G1Q)

SPATIAL CHARACTERISTICS

Spatial Summary: Occurs as a large-patch system, some presently reduced to small-patch.
Size: Historically occurred in small to large patches (100 ha plus, with the Hempstead Plains upward of 14,000 ha), but most have been reduced by land-use changes or conversion. Some of the remnants are naturally small, occurring on islands.
Adjacent Ecological Systems:
- Northern Atlantic Coastal Plain Dune and Swale (CES203.264)

DISTRIBUTION

Range: This system is endemic to a small area ranging from the southern New York coastline north to Cape Cod, Massachusetts.
Divisions: 203:C
Nations: US
Subnations: CT?, MA, NY, RI
Map Zones: 65:C
USFS Ecomap Regions: 221Ab:CCC, 221Ac:CCC, 221Ad:CCP, 221An:CCC

NORTHERN CALIFORNIA COASTAL SCRUB (CES206.932)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Marine Sedimentary; Mediterranean [Mediterranean Xeric-Oceanic]; Bluff; Baccharis pilularis
Non-Diagnostic Classifiers: Dune (Landform); Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Herbaceous; Terrace; Sideslope; Intermediate Disturbance Interval; F-Landscape/High Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2128; ESLF 5457; ESP 1128

CONCEPT

Summary: This ecological system includes a variety of mixed and single-species-dominated shrublands along a narrow coastal strip with maritime and summer fog influences, on marine sediments, coastal bluffs, terraces, stabilized dunes, and hills below 500 m (1500 feet) elevation from southern Oregon south through central California. It is restricted to coastal plateaus and lower slopes of the Coast Ranges where precipitation ranges from 50-200 cm annually. These are dominated by evergreen, microphyllous-leaved or hemi-sclerophyllous shrub taxa; drought-deciduous species are unimportant or absent in this system. Dense shrublands typically include a well-developed woody and herbaceous understory. Characteristic species include *Baccharis pilularis, Lupinus arboreus, Ceanothus thyrsiflorus, Eriophyllum stoechadifolium, Diplacus aurantiacus (= Mimulus aurantiacus), Toxicodendron diversilobum, Rubus ursinus, Rubus parviflorus, Rubus spectabilis, Frangula californica (= Rhamnus californica), Holodiscus discolor, Gaultheria shallon, Heracleum maximum (= Heracleum lanatum),* and *Polystichum munitum*. These areas have supported extensive stand-replacing wildfires. This system has direct seral relationships with California Northern Coastal Grassland (CES206.941) as, in the absence of fire and grazing, the grassland will usually succeed to this system. In the absence of fire in this system, conifers (*Abies grandis, Pseudotsuga menziesii*) can invade and become prominent.
Classification Comments: Transitions to Southern California Coastal Scrub (CES206.933) begin in the northern San Francisco Bay area where *Artemisia californica* begins to mix with *Baccharis* and others. Further south in the Santa Lucia Range (Big Sur area of Monterey County), *Baccharis pilularis* and *Artemisia californica* tend to codominate, and other southern coastal sage species such as *Salvia leucophylla* and *Eriogonum fasciculatum* become more prominent. South of Monterey County most of the northern California coastal scrub influence is gone, and coastal shrublands shift to Southern California Coastal Scrub (CES206.933). The combination of <30% relative cover of *Artemisia californica* or *Salvia* spp. and high cover *Baccharis* and *Rhamnus*, or having *Polystichum munitum, Gaultheria shallon*, and *Heracleum maximum* makes it Northern California Coastal Scrub (CES206.932).
Similar Ecological Systems:
- Southern California Coastal Scrub (CES206.933)

Related Concepts:
- North Coastal Shrub (204) (Shiflet 1994) Broader. Nearly equivalent, but SRM type includes coastal salal shrublands which are in a different ecological system.

Component Associations:
- *Baccharis pilularis - Artemisia californica* Shrubland (CEGL003184, G5)
- *Baccharis pilularis - Ceanothus thyrsiflorus* Shrubland (CEGL003186, G3)
- *Baccharis pilularis - Eriophyllum stoechadifolium* Shrubland (CEGL003190, G3)
- *Baccharis pilularis - Frangula californica - Rubus parviflorus* Shrubland (CEGL003191, G2)
- *Baccharis pilularis - Holodiscus discolor* Shrubland (CEGL003192, G3)
- *Baccharis pilularis - Lupinus (arboreus, chamissonis)* Shrubland (CEGL003193, G3)
- *Baccharis pilularis - Rubus ursinus* / Weedy Herbs Shrubland (CEGL003196, G5)
- *Baccharis pilularis - Toxicodendron diversilobum* Shrubland (CEGL003197, G5)
- *Baccharis pilularis* / Annual Grass - Herb Shrubland (CEGL003183, G5)
- *Baccharis pilularis / Carex obnupta - Juncus patens* Shrubland (CEGL003185, G3)
- *Baccharis pilularis / Danthonia californica* Shrubland (CEGL003187, G2)
- *Baccharis pilularis / Deschampsia caespitosa* Shrubland (CEGL003188, G2)
- *Baccharis pilularis / Dudleya farinosa* Shrubland (CEGL003189, G3)
- *Baccharis pilularis / Nassella pulchra* Shrubland (CEGL003194, G3)
- *Baccharis pilularis / Polystichum munitum* Shrubland (CEGL003195, G3)
- *Ceanothus thyrsiflorus - Baccharis pilularis - Toxicodendron diversilobum* Shrubland (CEGL003198, G4?)
- *Frangula californica ssp. californica - Baccharis pilularis / Scrophularia californica* Shrubland (CEGL003316, G4)
- *Rubus spectabilis* Wet Shrubland (CEGL003472, G4)
- *Toxicodendron diversilobum - Baccharis pilularis - Rubus parviflorus* Shrubland (CEGL003473, G3)

DISTRIBUTION

Range: This system occurs along a narrow coastal strip below 500 m (1500 feet) elevation from southern Oregon south through central California.

NORTHERN ROCKY MOUNTAIN MONTANE-FOOTHILL DECIDUOUS SHRUBLAND (CES306.994)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Montane [Lower Montane]; Lowland [Foothill]; Shrubland (Shrub-dominated); Very Shallow Soil; Broad-Leaved Deciduous Shrub
Non-Diagnostic Classifiers: Sideslope; Toeslope/Valley Bottom; Temperate [Temperate Continental]; Ustic
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2106; ESLF 5312; ESP 1106

CONCEPT

Summary: This shrubland ecological system is found in the lower montane and foothill regions around the Columbia Basin, and north and east into the northern Rockies, including Alberta and British Columbia. These shrublands typically occur below treeline, within the matrix of surrounding low-elevation grasslands and sagebrush shrublands. They also occur in the ponderosa pine and Douglas-fir zones, but rarely up into the subalpine zone (on dry sites). The shrublands are usually found on steep slopes of canyons and in areas with some soil development, either loess deposits or volcanic clays; they occur on all aspects. Fire, flooding and erosion all impact these shrublands, but they typically will persist on sites for long periods. These communities develop near talus slopes as garlands, at the heads of dry drainages, and toeslopes in the moist shrub-steppe and steppe zones. *Physocarpus malvaceus, Prunus emarginata, Prunus virginiana, Rosa* spp., *Rhus glabra, Acer glabrum, Amelanchier alnifolia, Symphoricarpos albus, Symphoricarpos oreophilus,* and *Holodiscus discolor* are the most common dominant shrubs, occurring alone or any combination. In the Alberta's Upper and Lower Foothills subregions, common shrubs include *Arctostaphylos uva-ursi, Juniperus communis, Symphoricarpos* spp., *Amelanchier alnifolia,* and *Rosa* spp. *Rubus parviflorus* and *Ceanothus velutinus* are other important shrubs in this system, being more common in montane occurrences than in subalpine situations. Occurrences in central and eastern Wyoming can include *Artemisia tridentata ssp. vaseyana* and *Cercocarpus montanus,* but neither of these are dominant, and where they occur, the stands are truly mixes of shrubs, often with *Amelanchier alnifolia, Prunus virginiana,* and others being the predominant taxa. In moist areas, *Crataegus douglasii* can be common. *Shepherdia canadensis* and *Spiraea betulifolia* can be abundant in some cases but also occur in Northern Rocky Mountain Subalpine Deciduous Shrubland (CES306.961). *Festuca idahoensis, Festuca campestris, Calamagrostis rubescens, Carex geyeri, Koeleria macrantha, Pseudoroegneria spicata,* and *Poa secunda* are the most important grasses. *Achnatherum thurberianum* and *Leymus cinereus* can be locally important. *Poa pratensis* and *Phleum pratense* are common introduced grasses. *Geum triflorum, Potentilla gracilis, Lomatium triternatum, Balsamorhiza sagittata,* and species of *Eriogonum, Phlox,* and *Erigeron* are important forbs.
Classification Comments: Seral shrub fields of comparable composition that typically will develop into a seral stage with trees (within 50 years) are excluded from this shrub system and are included in their appropriate forest system.

DISTRIBUTION

Range: This system is found in the lower montane and foothill regions around the Columbia Basin, and north and east into the northern Rockies, including east into central Montana around the "Sky Island" ranges. It also occurs farther south into central and eastern Wyoming, where it forms compositionally diverse shrublands.

NORTHERN ROCKY MOUNTAIN SUBALPINE DECIDUOUS SHRUBLAND (CES306.961)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Montane [Upper Montane]; Shrubland (Shrub-dominated); Very Shallow Soil; Broad-Leaved Deciduous Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2169; ESLF 5326; ESP 1169

CONCEPT

Summary: This shrubland ecological system is found within the zone of continuous forest in the upper montane and lower subalpine zones of the northern Rocky Mountains. Soils tend to be moist to wet. Stands are typically initiated by fires and will persist on sites for long periods because of repeated burns and changes in the presence of volatile oils in the soil which impedes tree regeneration. *Menziesia ferruginea, Rhamnus alnifolia, Ribes lacustre, Rubus parviflorus, Alnus viridis, Rhododendron albiflorum, Sorbus scopulina, Sorbus sitchensis, Vaccinium myrtillus, Vaccinium scoparium*, and *Vaccinium membranaceum* are the most common dominant shrubs, occurring alone or in any combination. Other shrubs can include *Shepherdia canadensis* and *Ceanothus velutinus*, but these also commonly occur in Northern Rocky Mountain Montane-Foothill Deciduous Shrubland (CES306.994). *Rubus parviflorus* and *Ceanothus velutinus* are occasionally present, being more common in montane shrublands than in this subalpine system. Important forbs include *Xerophyllum tenax, Chamerion angustifolium*, and *Pteridium aquilinum*, reflecting the mesic nature of many of these shrublands.
Classification Comments: This system is floristically somewhat similar to Northern Rocky Mountain Avalanche Chute Shrubland (CES306.801), but the avalanche chutes originate from very different processes, tend to be more diverse within stands, and are wetter, being driven ecologically by snow-loading and concomitant snowmelt. Seral shrub fields of comparable composition that typically will develop into a seral stage with trees (within 50 years) are excluded from this shrub system and are included in their appropriate forest system.

Component Associations:
- *Menziesia ferruginea / Xerophyllum tenax* Shrubland (CEGL005888, G3G4)
- *Rhamnus alnifolia* Shrubland (CEGL001132, G3)
- *Vaccinium membranaceum / Xerophyllum tenax* Shrubland (CEGL005891, G3?)

DISTRIBUTION

Range: This system is found in the subalpine and upper montane zones in the northern Rockies, south and west around the Columbia Basin.

NORTHWESTERN GREAT PLAINS SHRUBLAND (CES303.662)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); Temperate [Temperate Continental]; Ustic; G-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2085; ESLF 5262; ESP 1085

CONCEPT

Summary: This ecological system ranges from South Dakota into southern Canada on moderately shallow to deep, fine to sandy loam soils. These sites are typically more mesic than most of the surrounding area. This system may be located along upper terraces of rivers and streams, gently inclined slopes near breaklands, and upland sandy loam areas throughout its range. This system is dominated by shrub species such as *Amelanchier alnifolia, Rhus trilobata, Symphoricarpos* spp., *Shepherdia argentea, Crataegus douglasii, Elaeagnus commutata, Dasiphora fruticosa ssp. floribunda*, and dwarf-shrubs such as *Juniperus horizontalis*. Midgrasses such as *Festuca* spp., *Koeleria macrantha*, and *Pseudoroegneria spicata* and species such as *Carex filifolia* can co-occur. This system differs from Northwestern Great Plains Mixedgrass Prairie (CES303.674) in that it contains greater than 10% cover in conjunction with topographic relief (breaks) of natural shrub species. Fire and grazing constitute the primary dynamics affecting this system; drought can also impact this system. This system may include areas of Northwestern Great Plains Mixedgrass Prairie (CES303.674) where fire suppression has allowed for a greater cover of shrub species. This system is similar to Northern Rocky Mountain Montane-Foothill Deciduous Shrubland (CES306.994) but occurs in the grassland matrix of the Great Plains, whereas the Rocky Mountain system occurs adjacent to the lower treeline of generally forested mountains and highlands. Floristically their shrub composition is similar, but associated grasses and forbs will differ somewhat given their respective adjacent vegetation types.
Classification Comments: This may not be a separate system from the prairie matrix. Those areas that have increased shrub cover due to fire suppression should be considered part of Northwestern Great Plains Mixedgrass Prairie (CES303.674). More information from Canada is probably needed to fully define this system.
Similar Ecological Systems:
- Northwestern Great Plains Mixedgrass Prairie (CES303.674)
- Southwestern Great Plains Canyon (CES303.664)

Related Concepts:
- Sagebrush - Grass (612) (Shiflet 1994) Intersecting. Some *Artemisia cana ssp. cana* shrublands occur in this ecological system if they are not associated with stream terraces.

DESCRIPTION

Environment: Climate and growing season length for the region this system occurs are intermediate to the shortgrass regions to the west and the tallgrass regions to the east with a shorter growing season with semi-arid moisture conditions. This system occurs on sites more mesic than most of the surrounding area such as upper river terraces, gently inclined slopes, and upland sandy areas. Soils range from shallow to deep and fine to sandy loams.
Vegetation: This system is dominated by shrub and dwarf-shrub species such as *Amelanchier alnifolia, Rhus trilobata, Symphoricarpos* spp., *Dasiphora fruticosa ssp. floribunda*, and *Juniperus horizontalis*. Mid grasses such as *Festuca* spp., *Koeleria macrantha*, and *Pseudoroegneria spicata* can also occur. This system differs from Northwestern Great Plains Mixedgrass Prairie (CES303.674) in that it contains greater than 60% cover of natural shrub species.
Dynamics: Fire and grazing constitute the primary dynamics affecting this system. Drought can also impact this system. Conversion to agriculture can impact this system, and its range has probably been decreased by human activities.

Component Associations:
- *Amelanchier alnifolia / Pseudoroegneria spicata* - Bunchgrass Shrubland (CEGL001065, G3G4Q)
- *Amelanchier alnifolia* Shrubland (CEGL002183, GNR)
- *Dasiphora fruticosa ssp. floribunda / Festuca campestris* Shrub Herbaceous Vegetation (CEGL001503, G4)
- *Dasiphora fruticosa ssp. floribunda / Festuca idahoensis* Shrub Herbaceous Vegetation (CEGL001502, G4)
- *Dasiphora fruticosa ssp. floribunda / Schizachyrium scoparium* Shrub Herbaceous Vegetation (CEGL002198, G3G4)
- *Elaeagnus commutata / Pascopyrum smithii* Shrubland (CEGL001099, G3?)
- *Juniperus horizontalis / Schizachyrium scoparium* Dwarf-shrubland (CEGL001394, G4)
- *Rhus trilobata / Calamovilfa longifolia* Shrub Herbaceous Vegetation (CEGL001457, G3Q)
- *Rhus trilobata / Carex filifolia* Shrub Herbaceous Vegetation (CEGL001504, G3)
- *Rhus trilobata / Festuca idahoensis* Shrub Herbaceous Vegetation (CEGL001505, G2?)
- *Rhus trilobata / Pseudoroegneria spicata* Shrub Herbaceous Vegetation (CEGL001120, G4)
- *Rhus trilobata / Schizachyrium scoparium* Shrub Herbaceous Vegetation (CEGL001506, G3)
- *Sarcobatus vermiculatus / Artemisia tridentata* Shrubland (CEGL001359, G4)

Spatial Characteristics

Adjacent Ecological Systems:
- Northwestern Great Plains Canyon (CES303.658)
- Northwestern Great Plains Mixedgrass Prairie (CES303.674)

Adjacent Ecological System Comments: This system may include areas of Northwestern Great Plains Mixedgrass Prairie (CES303.674) where fire suppression has allowed for a greater cover of shrub species.

Distribution

Range: This system extends from South Dakota into southern Canada, west into the foothills of north-central Montana. The U.S. range corresponds to Bailey et al. (1994) sections Northeast Glaciated Plains (332A), Western Glaciated Plains (332B), North Central Glaciated Plains - extreme western part (251B), and in Canada to the Moist Mixed Grassland and Fescue Grassland.

ROCKY MOUNTAIN ALPINE DWARF-SHRUBLAND (CES306.810)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine Slopes; Alpine/AltiAndino [Alpine/AltiAndino]; Patterned ground (undifferentiated); Glaciated; Acidic Soil; Udic; Very Long Disturbance Interval; Dwarf-Shrub
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); Temperate [Temperate Continental]; Mineral: W/ A-Horizon >10 cm; Bryophyte
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Evergreen dwarf-shrubland
National Mapping Codes: EVT 2070; ESLF 5207; ESP 1070

CONCEPT

Summary: This widespread ecological system occurs above upper timberline throughout the Rocky Mountain cordillera, including alpine areas of ranges in Utah and Nevada, and north into Canada. Elevations are above 3360 m in the Colorado Rockies but drop to less than 2100 m in northwestern Montana and in the mountains of Alberta. This system occurs in areas of level or concave glacial topography, with late-lying snow and subirrigation from surrounding slopes. Soils have become relatively stabilized in these sites, are moist but well-drained, strongly acidic, and often with substantial peat layers. Vegetation in these areas is controlled by snow retention, wind desiccation, permafrost, and a short growing season. This ecological system is characterized by a semi-continuous layer of ericaceous dwarf-shrubs or dwarf willows which form a heath type ground cover less than 0.5 m in height. Dense tuffs of graminoids and scattered forbs occur. *Dryas octopetala* or *Dryas integrifolia* communities are not included here, except for one very moist association, because they occur on more windswept and drier sites than the heath communities. Within these communities. *Cassiope mertensiana, Salix arctica, Salix reticulata, Salix vestita*, or *Phyllodoce empetriformis* can be dominant shrubs. *Vaccinium* spp., *Ledum glandulosum, Phyllodoce glanduliflora*, and *Kalmia microphylla* may also be shrub associates. The herbaceous layer is a mixture of forbs and graminoids, especially sedges, including, *Erigeron* spp., *Luetkea pectinata, Antennaria lanata, Oreostemma alpigenum (= Aster alpigenus), Pedicularis* spp., *Castilleja* spp., *Deschampsia caespitosa, Caltha leptosepala, Erythronium* spp., *Juncus parryi, Luzula piperi, Carex spectabilis, Carex nigricans*, and *Polygonum bistortoides*. Fellfields often intermingle with the alpine dwarf-shrubland.

ROCKY MOUNTAIN GAMBEL OAK-MIXED MONTANE SHRUBLAND (CES306.818)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Shallow Soil; Mineral: W/ A-Horizon <10 cm; Loam Soil Texture; Sand Soil Texture; Ustic; Unconsolidated; Intermediate Disturbance Interval [Periodicity/Polycyclic Disturbance]; Broad-Leaved Deciduous Shrub
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Ridge/Summit/Upper Slope; Sideslope; Temperate [Temperate Continental]; F-Patch/Medium Intensity; F-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2107; ESLF 5313; ESP 1107

CONCEPT

Summary: This ecological system occurs in the mountains, plateaus and foothills of the southern Rocky Mountains and Colorado Plateau, including the Uinta and Wasatch ranges and the Mogollon Rim. These shrublands are most commonly found along dry foothills, lower mountain slopes, and at the edge of the western Great Plains from approximately 2000 to 2900 m in elevation, and are often situated above pinyon-juniper woodlands. Substrates are variable and include soil types ranging from calcareous, heavy, fine-grained loams to sandy loams, gravelly loams, clay loams, deep alluvial sand, or coarse gravel. The vegetation is typically dominated by *Quercus gambelii* alone or codominant with *Amelanchier alnifolia, Amelanchier utahensis, Artemisia tridentata, Cercocarpus montanus, Prunus virginiana, Purshia stansburiana, Purshia tridentata, Robinia neomexicana, Symphoricarpos oreophilus*, or *Symphoricarpos rotundifolius*. There may be inclusions of other mesic montane shrublands with *Quercus gambelii* absent or as a relatively minor component. This ecological system intergrades with the lower montane-foothills shrubland system and shares many of the same site characteristics. Density and cover of *Quercus gambelii* and *Amelanchier* spp. often increase after fire.
Classification Comments: Disjunct *Quercus gambelii*-dominated shrublands found in the Davis Mountains and probably the Guadalupe Range in the Trans-Pecos of Texas are included in the concept of Madrean Oriental Chaparral (CES302.031).

Landfire modeled this BpS with Coahuilan Chaparral (Madrean Oriental Chaparral (CES302.031)). *Quercus gambelii* apparently occurs as a significant component of a shrubland of the Trans-Pecos of Texas, however, most of the other species that codominate in this system do not occur in the Trans-Pecos. This system is not currently attributed to Texas, and it seems more appropriate to modify the description of CES302.031 to allow for the presence of *Quercus gambelii* as a significant component of some occurrences. However, *Quercus gambelii / Symphoricarpos oreophilus* Shrubland (CEGL001117) is an association found in the Trans-Pecos. Also, there is a need to clarify the relationship with Rocky Mountain Lower Montane-Foothill Shrubland (CES306.822).
Similar Ecological Systems:
- Rocky Mountain Lower Montane-Foothill Shrubland (CES306.822)

Related Concepts:
- Gambel Oak (413) (Shiflet 1994) Equivalent

DESCRIPTION

Environment: This ecological system typically occupies the lower slope positions of the foothill and lower montane zones. They may occur on level to steep slopes, cliffs, escarpments, rimrock slopes, rocky outcrops, and scree slopes. Climate is semi-arid and characterized by mostly hot-dry summers with mild to cold winters and annual precipitation of 25 to 70 cm. Precipitation mostly occurs as winter snows but may also consist of some late-summer rains. Soils are typically poorly developed, rocky to very rocky, and well-drained. Parent materials include alluvium, colluvium, and residuum derived from igneous, metamorphic, or sedimentary rocks such as granite, gneiss, limestone, quartz, monzonite, rhyolite, sandstone, schist, and shale. Although this is a shrub-dominated system, some trees may be present. In older occurrences, or occurrences on mesic sites, some of the shrubs may acquire tree-like sizes. Adjacent communities often include woodlands or forests of *Abies concolor, Pinus ponderosa, Pseudotsuga menziesii*, or *Populus tremuloides* at higher elevations, and *Pinus edulis* and *Juniperus osteosperma* on the lower and adjacent elevations. Shrublands of *Artemisia tridentata* or grasslands of *Festuca* sp., *Stipa* sp., or *Pseudoroegneria* sp. may also be present at the lower elevations.
Vegetation: Vegetation types in this system may occur as sparse to dense shrublands composed of moderate to tall shrubs. Occurrences may be multi-layered, with some short shrubby species occurring in the understory of the dominant overstory species. In many occurrences of this system, the canopy is dominated by the broad-leaved deciduous shrub *Quercus gambelii*, which occasionally reaches small tree size. Occurrences can range from dense thickets with little understory to relatively mesic mixed-shrublands with a rich understory of shrubs, grasses and forbs. These shrubs often have a patchy distribution with grass growing in between. Scattered trees are occasionally present in stands and typically include species of *Pinus* or *Juniperus*. Characteristic shrubs that may co-occur, or be singularly dominant, include *Amelanchier alnifolia, Amelanchier utahensis, Arctostaphylos patula, Artemisia tridentata, Cercocarpus montanus, Ptelea trifoliata, Prunus virginiana, Purshia stansburiana, Robinia neomexicana, Rosa* spp., *Symphoricarpos oreophilus*, and *Symphoricarpos rotundifolius*. The herbaceous layer is sparse to moderately dense, ranging from 1-40% cover.

Perennial graminoids are the most abundant species, particularly *Bouteloua curtipendula, Bouteloua eriopoda, Bouteloua gracilis, Aristida* spp., *Carex inops, Carex geyeri, Elymus arizonicus, Eragrostis* spp., *Festuca* spp., *Koeleria macrantha, Muhlenbergia* spp., and *Stipa* spp. Many forb and fern species can occur, but none have much cover. Commonly present forbs include *Achillea millefolium, Artemisia* spp., *Geranium* spp., *Maianthemum stellatum, Thalictrum fendleri*, and *Vicia americana*. Ferns include species of *Cheilanthes* and *Woodsia*. Annual grasses and forbs are seasonally present, and weedy annuals are often present, at least seasonally.
Dynamics: Fire typically plays an important role in this system, causing die-back of the dominant shrub species in some areas, promoting stump sprouting of the dominant shrubs in other areas, and controlling the invasion of trees into the shrubland system. Natural fires typically result in a system with a mosaic of dense shrub clusters and openings dominated by herbaceous species. In some instances these associations may be seral to the adjacent *Pinus ponderosa, Abies concolor*, and *Pseudotsuga menziesii* woodlands and forests. Ream (1964) noted that on many sites in Utah, Gambel oak may be successional and replaced by bigtooth maple (*Acer grandidentatum)*.

Component Associations:
- *Amelanchier alnifolia* / (Mixed Grass, Forb) Shrubland (CEGL005885, GNR)
- *Amelanchier alnifolia / Artemisia tridentata / Festuca idahoensis* Shrubland (CEGL001064, G4Q)

ROCKY MOUNTAIN LOWER MONTANE-FOOTHILL SHRUBLAND (CES306.822)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Shrubland (Shrub-dominated); Very Shallow Soil; Aridic; Intermediate Disturbance Interval [Periodicity/Polycyclic Disturbance]
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Foothill(s); Gulch; Midslope; Ridge; Temperate [Temperate Continental]; Mineral: W/ A-Horizon <10 cm; Canyon; Colluvial slope
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2086; ESLF 5263; ESP 1086

CONCEPT

Summary: This ecological system is found in the foothills, canyon slopes and lower mountains of the Rocky Mountains and on outcrops and canyon slopes in the western Great Plains. It ranges from southern New Mexico, extending north into Wyoming, and west into the Intermountain West region. These shrublands occur between 1500 and 2900 m elevation and are usually associated with exposed sites, rocky substrates, and dry conditions, which limit tree growth. It is common where *Quercus gambelii* is absent, such as the northern Colorado Front Range and in drier foothills and prairie hills. This system is generally drier than Rocky Mountain Gambel Oak-Mixed Montane Shrubland (CES306.818) but may include mesic montane shrublands where *Quercus gambelii* does not occur. *Cercocarpus montanus* dominates pure stands in parts of Wyoming and Colorado. Scattered trees or inclusions of grassland patches or steppe may be present, but the vegetation is typically dominated by a variety of shrubs, including *Amelanchier utahensis, Cercocarpus montanus, Purshia tridentata, Rhus trilobata, Ribes cereum, Symphoricarpos oreophilus*, or *Yucca glauca*. Grasses are represented as species of *Muhlenbergia, Bouteloua, Hesperostipa,* and *Pseudoroegneria spicata*. Fires play an important role in this system as the dominant shrubs usually have a severe die-back, although some plants will stump sprout. *Cercocarpus montanus* requires a disturbance such as fire to reproduce, either by seed sprout or root-crown sprouting. Fire suppression may have allowed an invasion of trees into some of these shrublands, but in many cases sites are too xeric for tree growth. In Wyoming, stands where *Cercocarpus montanus* is a component of mixed shrublands are placed in Northern Rocky Mountain Montane-Foothill Deciduous Shrubland (CES306.994).
Classification Comments: Some reviewers have requested that this system be renamed in such a way as to more strongly indicate that it is dominated primarily by *Cercocarpus montanus*. However, while *Cercocarpus montanus* is an important shrub in this system, it is not the only dominant, and in many occurrences is not found at all.

SIERRA NEVADA ALPINE DWARF-SHRUBLAND (CES206.924)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Alpine Mosaic; Shrubland (Shrub-dominated); Dwarf-Shrub
Non-Diagnostic Classifiers: Herbaceous; Ridge/Summit/Upper Slope; Temperate [Temperate Oceanic]; Shallow Soil; W-Patch/High Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Evergreen dwarf-shrubland
National Mapping Codes: EVT 2071; ESLF 5208; ESP 1071

CONCEPT

Summary: This ecological system is found only at the highest elevations, usually above 2800 m (8500 feet), throughout the Sierra Nevada and surrounding high mountain ranges. The system is commonly comprised of a mosaic of plant communities that include *Arenaria kingii, Cassiope mertensiana, Ericameria discoidea, Artemisia arbuscula, Phlox covillei, Eriogonum incanum, Eriogonum ovalifolium, Eriogonum roseum, Kalmia microphylla, Polygonum shastense, Leptodactylon pungens, Phyllodoce breweri, Salix arctica, Salix nivalis, Salix reticulata*, and *Vaccinium caespitosum*. Floristically, communities within this system have desert affinities, rather than cordilleran affinities. Vegetation in these areas is controlled by the absence of persistent snow, wind desiccation, permafrost, and a short growing season.

Related Concepts:
- Alpine Grassland (213) (Shiflet 1994) Broader. SRM type 213 includes all alpine communities in Sierra, Klamath and California Cascades, both herbaceous and shrub dominated, and wet meadows.

DESCRIPTION

Environment: Elevations are above 2800 m. This system occurs in areas of level or concave glacial topography, with late-lying snow, and subirrigation from surrounding slopes. Soils have become relatively stabilized in these sites, are moist, but well-drained, strongly acidic, and often with substantial peat layers.

Component Associations:
- *Phlox covillei - Elymus elymoides - Podistera nevadensis* Herbaceous Vegetation (CEGL003488, G3?)

SPATIAL CHARACTERISTICS

Spatial Summary: This ecological system occurs sporadically in variably sized patches of the alpine. Patch size varies from a few to 100 acres in mountain basins. Stand-replacement fires may be caused by lightning strikes that do not spread due to the sparse cover of fine fuels and extensive barren areas acting as firebreaks.

DISTRIBUTION

Range: This system is found only at the highest elevations, usually above 2800 m (8500 feet), throughout the Sierra Nevada and surrounding high mountain ranges.
Divisions: 204:C; 206:C
Nations: US

SONORA-MOJAVE CREOSOTEBUSH-WHITE BURSAGE DESERT SCRUB (CES302.756)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Aridic; Xeromorphic Shrub
Non-Diagnostic Classifiers: Toeslope/Valley Bottom; Alkaline Soil; W-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2087; ESLF 5264; ESP 1087

CONCEPT

Summary: This ecological system forms the vegetation matrix in broad valleys, lower bajadas, plains and low hills in the Mojave and lower Sonoran deserts. This desert scrub is characterized by a sparse to moderately dense layer (2-50% cover) of xeromorphic microphyllous and broad-leaved shrubs. *Larrea tridentata* and *Ambrosia dumosa* are typically dominants, but many different shrubs, dwarf-shrubs, and cacti may codominate or form typically sparse understories. Associated species may include *Atriplex canescens, Atriplex hymenelytra, Encelia farinosa, Ephedra nevadensis, Fouquieria splendens, Lycium andersonii*, and *Opuntia basilaris*. The herbaceous layer is typically sparse, but may be seasonally abundant with ephemerals. Herbaceous species such as *Chamaesyce* spp., *Eriogonum inflatum, Dasyochloa pulchella, Aristida* spp., *Cryptantha* spp., *Nama* spp., and *Phacelia* spp. are common. This system can often appear as very open sparse vegetation, with the mostly barren ground surface being the predominant feature.

SONORA-MOJAVE MIXED SALT DESERT SCRUB (CES302.749)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Toeslope/Valley Bottom; Temperate [Temperate Xeric]; Alkaline Soil; Basin floor; Atriplex spp.
Non-Diagnostic Classifiers: Tropical/Subtropical [Tropical Xeric]; Saline Substrate Chemistry; Aridic
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2088; ESLF 5265; ESP 1088

CONCEPT

Summary: This ecological system includes extensive open-canopied shrublands of typically saline basins in the Mojave and Sonoran deserts. Stands most often occur around playas and in valley bottoms or basins where evapotranspiration results in saline soils. Substrates are generally fine-textured, saline soils. Vegetation is typically composed of one or more *Atriplex* species, such as *Atriplex canescens* or *Atriplex polycarpa*, along with other species of *Atriplex*. Species of *Allenrolfea, Salicornia, Suaeda, Krascheninnikovia lanata*, or other halophytic plants are often present to codominant. In some locations, scattered *Yucca brevifolia* may occur, but other Mojavean taxa are typically not present. Graminoid species may include *Sporobolus airoides* or *Distichlis spicata* at varying densities.
Related Concepts:

SONORA-MOJAVE SEMI-DESERT CHAPARRAL (CES302.757)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Intermediate Disturbance Interval; F-Patch/High Intensity; Evergreen Sclerophyllous Shrub
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Ridge/Summit/Upper Slope; Sideslope; Aridic; Broad-Leaved Deciduous Shrub; Broad-Leaved Evergreen Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2108; ESLF 5314; ESP 1108

CONCEPT

Summary: This ecological system is composed of evergreen shrublands or dwarf-woodlands on sideslopes transitioning from low-elevation desert landscapes up into woodlands of the western Mojave and Sonoran deserts. It extends from northeast Kern County, California, into Baja Norte, Mexico. Associated species include *Quercus john-tuckeri, Quercus cornelius-mulleri, Quercus berberidifolia, Arctostaphylos patula, Arctostaphylos pungens, Arctostaphylos glauca, Rhus ovata, Cercocarpus montanus var. glaber (= Cercocarpus betuloides), Ceanothus greggii, Garrya flavescens, Juniperus californica,* and *Nolina parryi*. Sometimes *Juniperus californica* forms an open, shrubby tree layer over the evergreen oaks and other shrubs.
Related Concepts:
- Snowbush (420) (Shiflet 1994) Undetermined. uncertain if these are related in concept.

Component Associations:
- *Arctostaphylos pungens* Shrubland (CEGL000958, G4)
- *Mortonia utahensis* Shrubland (CEGL005153, GNR)
- *Quercus turbinella - (Rhus trilobata, Artemisia tridentata)* Shrubland (CEGL005168, GNR)
- *Quercus turbinella - Coleogyne ramosissima* Shrubland (CEGL000982, G4)
- *Quercus turbinella - Garrya flavescens - Arctostaphylos pungens* Shrubland (CEGL000977, G4)
- *Quercus turbinella - Juniperus osteosperma* Shrubland (CEGL000981, G4?)
- *Quercus turbinella - Ptelea trifoliata - Fraxinus anomala* Mesic Shrubland (CEGL005160, GNR)

DISTRIBUTION

SONORAN BRITTLEBUSH-IRONWOOD DESERT SCRUB (CES302.758)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]
Non-Diagnostic Classifiers: Lowland [Lowland]; Aridic
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2089; ESLF 5266; ESP 1089

CONCEPT

Summary: This Sonoran Desert scrub ecological system is common in plains of Sonora, Mexico, between 100-800 m elevation, but may not occur in the U.S. Vegetation is a sparse to moderately dense layer of short trees and xeromorphic microphyllous and broad-leaved evergreen shrubs that is dominated by *Olneya tesota* and *Encelia farinosa*. *Parkinsonia microphylla* and *Prosopis* spp. can also be common in the short-tree canopy. The understory is typically sparse but may also include desert grasses and ephemerals.

Component Associations:
- *Encelia farinosa* Shrubland (CEGL001251, G5)

DISTRIBUTION

Range: Plains of Sonora, Mexico, between 100-800 m elevation, but may not occur in the U.S.

SONORAN GRANITE OUTCROP DESERT SCRUB (CES302.760)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Granitic Rock; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Aridic
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Ridge; Woody-Herbaceous; Ridge/Summit/Upper Slope; Sideslope; Sand Soil Texture; Canyon; Cliff (Landform)
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2090; ESLF 5267; ESP 1090

CONCEPT

Summary: This ecological system occurs in foothills and mountains of Sonora, Mexico, and extends north across the border into southern Arizona. It is found on low- to mid-elevation granitic outcrops. Tropical genera of *Jatropha* and *Bursera* become codominants in dense to sparse vegetation transitioning upslope from Sonoran Paloverde-Mixed Cacti Desert Scrub (CES302.761). Diagnostic species are *Bursera microphylla, Jatropha cuneata, Nolina bigelovii, Parkinsonia microphylla,* or *Rhus kearneyi*.
Classification Comments: This ecological system is likely to be a northern expression of a more widely distributed desert scrub system of Sonora, Mexico, where it may not be restricted to rock outcrops or sites, such as in Arizona.

Component Associations:
- *Nolina bigelovii* Shrubland (CEGL003064, G3?)
- *Parkinsonia microphylla - Larrea tridentata* Shrubland (CEGL001375, G4)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:

SONORAN MID-ELEVATION DESERT SCRUB (CES302.035)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Shrubland (Shrub-dominated); Alkaline Soil
Non-Diagnostic Classifiers: Alluvial fan; Sideslope; Temperate [Temperate Xeric]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2091; ESLF 5268; ESP 1091

CONCEPT

Summary: This transitional desert scrub system occurs along the northern edge of the Sonoran Desert in an elevational band along the lower slopes of the Mogollon Rim/Central Highlands region between 750 and 1300 m. Stands occur in the Bradshaw, Hualapai, and Superstition mountains, among other desert ranges, and are found above Sonoran Paloverde-Mixed Cacti Desert Scrub (CES302.761) and below Mogollon Chaparral (CES302.741). Sites range from a narrow strip on steep slopes to very broad areas such as the Verde Valley. Climate is too dry for chaparral species to be abundant, and freezing temperatures during winter are too frequent and prolonged for many of the frost-sensitive species that are characteristic of Sonoran Paloverde-Mixed Cacti Desert Scrub (CES302.761), such as *Carnegiea gigantea*, *Parkinsonia microphylla*, *Prosopis* spp., *Olneya tesota*, *Ferocactus* sp., and *Opuntia bigelovii*. Substrates are generally rocky soils derived from parent materials such as limestone, granitic rocks or rhyolite. The vegetation is typically composed of an open shrub layer of *Larrea tridentata*, *Ericameria linearifolia*, or *Eriogonum fasciculatum* with taller shrub such as *Canotia holacantha* (limestone or granite) or *Simmondsia chinensis* (rhyolite). The herbaceous layer is generally sparse.
Classification Comments: Includes Brown's (1982) Jojoba-Mixed Scrub and Creosotebush-Crucifixion-thorn Series.

Component Associations:
- *Ambrosia deltoidea / Simmondsia chinensis* Shrubland (CEGL000953, G4)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Mogollon Chaparral (CES302.741)
- Sonoran Paloverde-Mixed Cacti Desert Scrub (CES302.761)

Adjacent Ecological System Comments: It is found above Sonoran Paloverde-Mixed Cacti Desert Scrub (CES302.761) and below Mogollon Chaparral (CES302.741).

SONORAN PALOVERDE-MIXED CACTI DESERT SCRUB (CES302.761)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Aridic; Xeromorphic Shrub; Succulent Shrub; Cacti-dominated
Non-Diagnostic Classifiers: Sideslope; Toeslope/Valley Bottom; Alkaline Soil; Sand Soil Texture; Broad-Leaved Deciduous Shrub; Succulent Forb
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2109; ESLF 5315; ESP 1109

CONCEPT

Summary: This ecological system occurs on hillsides, mesas and upper bajadas in southern Arizona and extreme southeastern California. The vegetation is characterized by a diagnostic sparse, emergent tree layer of *Carnegiea gigantea* (3-16 m tall) and/or a sparse to moderately dense canopy codominated by xeromorphic deciduous and evergreen tall shrubs *Parkinsonia microphylla* and *Larrea tridentata*, with *Prosopis* sp., *Olneya tesota*, and *Fouquieria splendens* less prominent. Other common shrubs and dwarf-shrubs include *Acacia greggii, Ambrosia deltoidea, Ambrosia dumosa* (in drier sites), *Calliandra eriophylla, Jatropha cardiophylla, Krameria erecta, Lycium* spp., *Menodora scabra, Simmondsia chinensis*, and many cacti, including *Ferocactus* spp., *Echinocereus* spp., and *Opuntia* spp. (both cholla and prickly-pear). The sparse herbaceous layer is composed of perennial grasses and forbs with annuals seasonally present and occasionally abundant. On slopes, plants are often distributed in patches around rock outcrops where suitable habitat is present. Outliers of this succulent-dominated ecological system occur as "Cholla Gardens" in transitional areas in the southern and eastern Mojave Desert ecoregion. In this area, the system is characterized by *Opuntia bigelovii, Senna armata*, and other succulents, but it lacks the *Carnegiea gigantea* and *Parkinsonia microphylla* which are typical farther east. *Fouquieria splendens* is present in increasingly diminishing amounts in as the system occurs further west and north
Related Concepts:
- Palo Verde - Cactus (507) (Shiflet 1994) Equivalent

DESCRIPTION

Environment: This succulent desert scrub system is typically found below 1200 m elevation, with rare occurrences up to 1400 m. Climate is arid to semi-arid, continental with mild winters and hot summers (Niering and Lowe 1984). Precipitation has a bimodal distribution generally occurring during in the winter (December-February) and a summer monsoon (July-September). Landforms range from steep, rocky slopes of desert mountains to upper and lower bajadas extending out on to alluvial flats. With decreasing elevation, the system typically occurs in xeroriparian habitats and on rock outcrops. In uplands, the system is found on coarse soils that may be associated with poorly developed geomorphic surfaces; at lower elevations, it is found on very stable geomorphic surfaces. The soils are often underlain by an impervious caliche layer.

Extended periods of drought or episodes of extreme cold limit this type. Specifically, establishment of dominant species is constrained by decadal or longer periods of below-average precipitation (Turner et al. 1995). Twenty-four hours of below-freezing temperature causes nearly total mortality of the dominant plants. At the southern end of the system's range, competition from more mesic species may constrain distribution of this system (Turner et al. 1995).
Dynamics: This system is not thought to have supported fuel loads to sustain large fires prior to European habitation of the region. Natural fires are associated with dry lightning coincident with monsoonal storms following years when previous winter precipitation was sufficient to create a thick fine-fuel bed of annual plants to carry fire. These fires tend to be patchy due to heavier fuel in microsites, or linear when high winds were associated with convection storms (Landfire 2007a). Replacement fires were very rare or absent (average FRI of 100-1000 years, and perhaps longer) (Landfire 2007b). If they occurred, they did so only during conditions of extreme fire behavior after consecutive years of above-average winter precipitation when necessary fine fuels accumulate. These rare fires - which may or may not have occurred - had tremendous influence on community structure because the dominant overstory plants are extremely susceptible to fires, even those of low intensity (McLaughlin and Bowers 1982, Esque et al. 2004).

Prolonged weather-related stress (drought or frost) thinned dominant overstory plants and, in rare cases, led to stand replacement. It is speculated that these events occurred with similar frequency as stand-replacing fires (Landfire 2007b). Cold stress is more common in stands at the northern extent and at higher elevations on desert mountain ranges. Large (presumably old) saguaro plants are also susceptible to windthrow, particularly after rainstorms saturate the soil (Landfire 2007b).

Component Associations:
- *Acacia greggii - Parkinsonia microphylla* Shrubland (CEGL001340, G4G5)
- *Ambrosia deltoidea / Simmondsia chinensis* Shrubland (CEGL000953, G4)
- *Carnegiea gigantea / Prosopis velutina* Wooded Shrubland (CEGL001389, GNR)
- *Fouquieria splendens / Bouteloua curtipendula* Shrubland (CEGL001376, GNR)

- *Fouquieria splendens / Bouteloua hirsuta* Shrubland (CEGL001377, G3?)
- *Opuntia bigelovii* Shrubland (CEGL003065, G4?)
- *Parkinsonia microphylla - Larrea tridentata* Shrubland (CEGL001375, G4)

SOUTHERN CALIFORNIA COASTAL SCRUB (CES206.933)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Sideslope; Mediterranean [Mediterranean Xeric-Oceanic]; Xeric; Intermediate Disturbance Interval; F-Landscape/High Intensity; Evergreen Sclerophyllous Shrub; Semi-Shrub; Artemisia californica, Salvia mellifera
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2092; ESLF 5269; ESP 1092

CONCEPT

Summary: This ecological system includes mixed coastal shrublands from Monterey, California, south into Baja Norte, Mexico. It is dominated by drought-deciduous shrubs but at times can have characteristic (constant but not dominant) resprouting, deep-rooted sclerophyllous shrubs. It occurs below 1000 m (3000 feet) elevation and may extend inland from the maritime zone in hotter, drier conditions than northern (less fog-drenched) shrublands (e.g., areas with 10-60 cm of annual precipitation). Soils vary from coarse gravels to clays but typically only support plant-available moisture with winter and spring rain. Most predominant shrubs include *Artemisia californica, Salvia mellifera, Salvia apiana, Salvia leucophylla, Encelia californica, Eriogonum fasciculatum, Eriogonum cinereum, Opuntia littoralis, Diplacus aurantiacus (= Mimulus aurantiacus), Lotus scoparius* (early seral after fire), and *Baccharis pilularis* (in moister, disturbed sites). Characteristic (constant but not dominant) resprouting, deep-rooted sclerophyllous shrubs include *Malosma laurina, Rhus integrifolia*, and *Rhamnus crocea*. Fire frequency was historically low, but in recent years with adjacency to urban and suburban areas, the fire frequency has increased (a result of arson or cigarette ignition) resulting in type conversion to non-native and ruderal annual grasslands. *Malosma laurina* and *Rhus integrifolia* are also increasing in abundance because they can continually resprout after repeated fires. In places, *Opuntia littoralis* may proliferate and cover entire slopes in dry rocky areas with repeated fires that have killed the scrub taxa, while *Opuntia littoralis* can resprout and spread to cover large patches.
Similar Ecological Systems:
- Northern California Coastal Scrub (CES206.932)

Related Concepts:
- Coastal Sage Shrub (205) (Shiflet 1994) Equivalent

DESCRIPTION

Environment: The most important environmental factors are cool-season precipitation and minimum winter temperature (Rundel 2007, Sawyer et al. 2009). Mean minimum winter temperature is substantially more predictive of southern sage scrub distribution patterns than is mean maximum summer temperature. Southern scrub prefers warm winters and relatively low total precipitation. This means that this system is restricted to low-elevation areas that receive some marine climatic influence; generally it occurs below 1000 m (3000 feet) elevation and receives about 10-60 cm of annual precipitation. The coastal region where it occurs has a longer dry season than further north in California. Southern coastal scrub often responds sensitively to aspect on a local scale (for example, in San Diego County sometimes occurring on south-facing slopes where north-facing slopes are occupied by chaparral types), but occurs on all aspects when viewed at a regional scale (Sawyer et al. 2009). Species composition of stands varies both with distance from the coast and with latitude. Soils vary from coarse gravels to clays but typically only support plant-available moisture with winter and spring rain. Stands often form complex mosaics interdigitated with stands of chaparral and grassland types on scales of 10s-100s of meters.
Dynamics: This is not an ecosystem type that requires fire for regeneration of the major shrubs (Landfire 2007a, Rundel 2007). Coastal scrub often occupies sites denuded by landslides, slumps, debris flows, and other mass-wasting events. It sometimes occupies chaparral sites for a number of years after a burn, before the larger, woodier chaparral shrubs reestablish their dominance. The main sage scrub species have seeds that are wind-dispersed, and recovery of sage scrub communities post-disturbance may involve dispersal and germination from plants outside the disturbed area (Rundel 2007). Although *Lotus scoparius* can temporarily occupy chaparral sites, *Artemisia californica* could not have the seedbank necessary to be abundant in post-fire chaparral, except in a case where there were repeated burns over several to many years that opened up the chaparral. Southern coastal scrub can clearly persist on favorable sites for at least a hundred years and probably much longer in the absence of any fire (Rundel 2007).

Component Associations:
- *Opuntia littoralis* Shrubland (CEGL003066, G3G4)
- *Salvia mellifera - Artemisia californica* Shrubland (CEGL003012, G4)

DISTRIBUTION

Range: This system is found from Monterey, California, south into Baja Norte, Mexico. It occurs below 1000 m (3000 feet) elevation and may extend inland from the maritime zone.
Divisions: 206:C

Nations: MX, US
Subnations: CA, MXBC(MX)
Map Zones: 4:C, 5:?, 6:?

SOUTHERN CALIFORNIA DRY-MESIC CHAPARRAL (CES206.930)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Sideslope; Mediterranean [Mediterranean Desertic-Oceanic]; Ustic; F-Landscape/High Intensity; Broad-Leaved Shrub
Non-Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Deep Soil; Intermediate Disturbance Interval; Evergreen Sclerophyllous Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2110; ESLF 5316; ESP 1110

CONCEPT

Summary: This ecological system includes chaparral from sea level up to 1500 m (4550 feet) elevation throughout central and southern California and inland portions of Baja Norte, Mexico. It is found in dry-mesic to mesic site conditions analogous to mesic chaparral. Santa Ana winds drive late-summer, stand-replacing fires in these systems. Characteristic species include *Ceanothus megacarpus, Ceanothus crassifolius, Ceanothus leucodermis, Ceanothus greggii, Adenostoma fasciculatum, Adenostoma sparsifolium, Arctostaphylos glauca, Cercocarpus montanus var. glaber (= Cercocarpus betuloides), Cercocarpus montanus var. minutiflorus (= Cercocarpus minutiflorus), Rhus ovata,* and *Xylococcus bicolor*.
Related Concepts:
- Ceanothus Mixed Chaparral (208) (Shiflet 1994) Broader
- Chamise Chaparral (206) (Shiflet 1994) Broader. SRM groups all Adenostoma-dominated communities into one range type; several ecological systems can have Adenostoma fasciculatum as a dominant.

Component Associations:
- *Ceanothus megacarpus - Cercocarpus montanus var. glaber* Shrubland (CEGL003029, G3?)

DISTRIBUTION

SOUTHERN COLORADO PLATEAU SAND SHRUBLAND (CES304.793)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Woody-Herbaceous; Temperate [Temperate Xeric]; Alkaline Soil; Aridic; Very Short Disturbance Interval; G-Landscape/High Intensity
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Mechanical Disturbance; Xeromorphic Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2093; ESLF 5270; ESP 1093

CONCEPT

Summary: This large-patch ecological system is found on the south-central Colorado Plateau in northeastern Arizona extending into southern and central Utah. It occurs on windswept mesas, broad basins and plains at low to moderate elevations (1300-1800 m). Substrates are stabilized sandsheets or shallow to moderately deep sandy soils that may form small hummocks or small coppice dunes. This semi-arid, open shrubland is typically dominated by short shrubs (10-30 % cover) with a sparse graminoid layer. The woody layer is often a mixture of shrubs and dwarf-shrubs. Characteristic species include *Ephedra cutleri, Ephedra torreyana, Ephedra viridis,* and *Artemisia filifolia*. *Coleogyne ramosissima* is typically not present. *Poliomintha incana, Parryella filifolia, Quercus havardii var. tuckeri*, or *Ericameria nauseosa* may be present to dominant locally. *Ephedra cutleri* and *Ephedra viridis* often assume a distinctive matty growth form. Characteristic grasses include *Achnatherum hymenoides*, *Bouteloua gracilis*, *Hesperostipa comata*, and *Pleuraphis jamesii*. The general aspect of occurrences is an open low shrubland but may include small blowouts and dunes. Occasionally grasses may be moderately abundant locally and form a distinct layer. Disturbance may be important in maintaining the woody component. Eolian processes are evident, such as pediceled plants, occasional blowouts or small dunes, but the generally higher vegetative cover and less prominent geomorphic features distinguish this system from Inter-Mountain Basins Active and Stabilized Dune (CES304.775).
Similar Ecological Systems:
- Inter-Mountain Basins Active and Stabilized Dune (CES304.775)

Component Associations:
- *Artemisia filifolia - Ephedra (torreyana, viridis)* Shrubland (CEGL002786, GNR)
- *Artemisia filifolia / Bouteloua eriopoda* Shrubland (CEGL001077, G4)
- *Ephedra torreyana - Achnatherum hymenoides* Hummock Shrubland (CEGL005802, GNR)
- *Ephedra torreyana / Bouteloua eriopoda* Shrub Herbaceous Vegetation (CEGL001731, G2)
- *Ephedra viridis / Achnatherum hymenoides - Bouteloua gracilis* Shrub Herbaceous Vegetation (CEGL001648, G2G4)
- *Ephedra viridis / Achnatherum hymenoides - Sporobolus cryptandrus* Shrub Herbaceous Vegetation (CEGL001649, G2G4)
- *Ephedra viridis / Pleuraphis rigida* Shrubland (CEGL001257, G3)
- *Ericameria nauseosa* Sand Deposit Sparse Shrubland (CEGL002980, GNR)
- *Poliomintha incana / (Pleuraphis jamesii)* Shrubland (CEGL002930, GNR)

TAMAULIPAN CALCAREOUS THORNSCRUB (CES301.986)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Caliche Layer; Lowland [Lowland]; Ridge; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Tropical/Subtropical [Tropical Xeric]; Calcareous; Very Shallow Soil
Non-Diagnostic Classifiers: Oligotrophic Soil; Alkaline Soil
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2392; ESLF 5323; ESP 1392

CONCEPT

Summary: This xeric thornscrub ecological system is restricted to limestone and calcareous sandstone hills and caliche substrates such as along the Bordas Scarp in southern Texas and northeastern Mexico. Soils are shallow, alkaline, strongly calcareous and underlain by bedrock or a caliche layer. It has a shorter, more open shrub canopy (usually less than 2 m) when compared to more typical thornscrub growing on more favorable sites. However, shrub cover is generally greater than 70% and often greater than 85%. Dominant species include *Leucophyllum frutescens*, *Acacia berlandieri*, and *Acacia farnesiana* with many other shrub species that may be locally dominant . The sparse to moderately dense herbaceous layer is dominated by perennial graminoids.

Similar Ecological Systems:
- Edwards Plateau Limestone Shrubland (CES303.041)
- Tamaulipan Mesquite Upland Scrub (CES301.984)
- Tamaulipan Mixed Deciduous Thornscrub (CES301.983)
- Tamaulipan Saline Thornscrub (CES301.711)

- South Texas: Calcareous Sparse Shrubland (7207) [CES301.986.7] (Elliott 2011) Finer
- Upland Thornscrub (Jahrsdoerfer and Leslie 1988) Broader

DESCRIPTION

Environment: This system is restricted to xeric, rocky hills, rolling or level plateaus, and ridges composed of limestone and calcareous sandstone, as well as caliche substrates such as of the Goliad Formation or Uvalde gravel along the Bordas Scarp in southern Texas and northeastern Mexico. Soils are thin, alkaline, strongly calcareous and underlain by bedrock or a caliche layer. These are Shallow, Shallow Ridge or Gravelly Ridge Ecological Sites.

Vegetation: Sites are most frequently dominated by shrubs between 0.5 and 2 m in height. Shrub canopy can be dense (to about 90% cover), or sparser where rocky exposures reduce substrate for rooting. A sparse overstory, usually <4 m in height, may be present and composed of species such as *Prosopis glandulosa* and, in the south, *Ebenopsis ebano, Cordia boissieri*, and/or *Helietta parvifolia*. *Quercus fusiformis* may form a relatively open canopy in areas in the northeastern part of the South Texas Plains. The shrub layer may be heavily dominated by *Leucophyllum frutescens, Acacia berlandieri*, and/or *Acacia rigidula*. More commonly, a diverse array of shrubs is present, including these three in addition to several of the following species: *Acacia schaffneri, Aloysia macrostachya, Amyris madrensis, Amyris texana, Bernardia myricifolia, Castela erecta ssp. texana, Celtis pallida (= Celtis ehrenbergiana), Condalia spathulata, Croton incanus, Diospyros texana, Ephedra antisyphilitica, Eysenhardtia texana, Forestiera angustifolia, Guajacum angustifolium, Helietta parvifolia, Jatropha dioica, Karwinskia humboldtiana, Koeberlinia spinosa, Krameria ramosissima, Mahonia trifoliolata, Opuntia leptocaulis (= Cylindropuntia leptocaulis), Parkinsonia texana var. macra, Salvia ballotiflora, Sideroxylon celastrinum, Sophora secundiflora, Yucca treculeana*, and others. More southerly occurrences may also contain *Lippia graveolens, Helietta parvifolia, Gochnatia hypoleuca, Croton humilis, Ebenopsis ebano*, and/or *Mortonia greggii*. The herbaceous layer may be somewhat well-developed, but often bare rock is easily visible through the layer. Many sites are now dominated by non-native grasses, particularly *Bothriochloa ischaemum var. songarica* and/or *Pennisetum ciliare*. Other grasses are often short grasses, with species such as *Bouteloua rigidiseta, Bouteloua hirsuta, Buchloe dactyloides (= Bouteloua dactyloides), Hilaria belangeri, Aristida purpurea, Bouteloua curtipendula*, and *Setaria leucopila* present. Forbs and subshrubs are conspicuous in the herbaceous layer and include species such as *Tiquilia canescens, Thamnosma texana, Galphimia angustifolia, Polygala alba, Cordia podocephala, Acourtia runcinata, Dalea aurea, Calliandra conferta, Chamaecrista greggii, Heliotropium torreyi, Melampodium cinereum, Hymenopappus scabiosaeus, Desmanthus velutinus, Calylophus hartwegii, Simsia calva, Hermannia texana, Macrosiphonia lanuginosa var. macrosiphon, Viguiera stenoloba, Hedyotis nigricans (= Stenaria nigricans), Thymophylla pentachaeta, Wedelia texana (= Wedelia hispida)*, and *Meximalva filipes* (Elliott 2011). Downslope from these sites, soil development increases, soils tend to be tight, a more well-developed overstory of *Prosopis glandulosa* becomes prominent, and species such as

Castela erecta and *Ziziphus obtusifolia* increase in cover relative to other species.
Dynamics: Erosion occurs on these sites, creating gullies, but not causing a shift in the community. Fire played little to no role in this system, though may have spread into the margins of stands during drought and high wind conditions (Landfire 2007a).

This system was modeled by Landfire (2007a) using a single class. Dense shrubland, generally 40-90% cover with sparse cover from emergent overstory species. Little natural disturbance affects this shrubland. Low fine fuel loadings make fire spread minimal except under extreme windy and dry conditions when fire may spread into it from surrounding sites. Species are drought-resistant. However, this system occurs in large patch to matrix scale and marginal fires likely spread little into the interior portions of occurrences.

Component Associations:
- *Acacia rigidula - Leucophyllum frutescens - Hechtia glomerata* Shrubland (CEGL007760, G2G3Q)
- *Helietta parvifolia - Acacia rigidula - Ebenopsis ebano - Leucophyllum frutescens* Shrubland (CEGL004923, G3)
- *Leucophyllum frutescens - Salvia ballotiflora - Lippia graveolens* Shrubland (CEGL007789, G2?)
- *Leucophyllum frutescens* Shrubland (CEGL002168, G4)

DISTRIBUTION

TAMAULIPAN LOMAS (CES301.462)

CLASSIFIERS

Classification Status: Standard

Primary Division: Madrean Semidesert (301)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Herbaceous
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2439; ESLF 7152; ESP 1439

CONCEPT

Summary: This system occurs on well-drained portions of clay dunes (lomas) rising above surrounding coastal tidal flats. It is a xeric, subtropical shrubland dominated by thorny evergreen shrubs, generally 2-4 m tall. Composition of this system is extremely variable, and there is usually no clear dominant, except locally. Local dominants may include *Citharexylum berlandieri, Leucophyllum frutescens, Havardia pallens (= Pithecellobium pallens),* and *Ebenopsis ebano*. While there is often no clear dominant, *Yucca treculeana* is a constant and conspicuous emergent in many occurrences. Some lomas may be flooded by the sea during severe storm events. Vegetation in this system is sometimes influenced by salt spray, high winds, limited rooting depth, saline water table, and extreme xeric conditions.

Related Concepts:
- Clay Lomas/Wind Tidal Flats (Jahrsdoerfer and Leslie 1988) Broader
- South Texas: Loma Deciduous Shrubland (7306) [CES301.462.6] (Elliott 2011) Finer
- South Texas: Loma Evergreen Shrubland (7305) [CES301.462.5] (Elliott 2011) Finer
- South Texas: Loma Grassland (7307) [CES301.462.7] (Elliott 2011) Finer

DESCRIPTION

Environment: This system occupies well-drained portions of clay dunes (lomas) along the lower Texas coast (and somewhat inland) and adjacent Mexico. These rise above surrounding coastal tidal flats and often develop from deposition of windblown fine sediments, resulting in elevated landforms within a matrix of tidal flats (Elliott 2011). At the time of formation, lomas were located on the leeward side of irregularly flooded lagoons and tidal flats that when dry provided the source for the windblown clayey sediments. The geology consists of Quaternary windblown deposits identified as clay dunes (Qcd). Landforms are round, elliptic, or crescent-shaped topographic highs, often within a matrix of low flats influenced by wind-driven tides. Soils include Point Isabel clay loam and Lalinda fine sandy loam, which are often associated with the Coastal Ridge Ecological Site. Lomas are characterized as wind-formed clay dunes on or near the coast, often surrounded by flats containing halophytic vegetation, coastal grasslands, or unvegetated wind-tidal flats. They usually occur as topographic highs in the surrounding level landscape, sometimes to 10 m above the surrounding plain and are a small-patch occurrence.

Vegetation: These are typically fairly dense to extremely dense shrublands, often 2-4 m in height. While there is often no clear dominant, *Yucca treculeana* is a constant and conspicuous emergent in many occurrences (Johnston 1952). Other dominants may include *Acacia rigidula, Castela erecta, Celtis pallida (= Celtis ehrenbergiana), Citharexylum berlandieri, Ebenopsis ebano, Forestiera angustifolia, Guajacum angustifolium, Jatropha dioica, Karwinskia humboldtiana, Leucophyllum frutescens, Opuntia engelmannii var. lindheimeri, Phaulothamnus spinescens, Prosopis glandulosa, Sideroxylon celastrinum, Zanthoxylum fagara,* and *Ziziphus obtusifolia*. There may be scattered emergent trees of *Ebenopsis ebano* and *Prosopis glandulosa* forming a sparse woodland. Within these shrublands, the herbaceous layer is typically not well-developed, however, the non-native *Urochloa maxima* may be conspicuous. A grassland, often dominated by *Sporobolus wrightii* occupies the margins of these clay dunes, as they grade downslope into the surrounding salty flats. These margins may also contain *Sporobolus coromandelianus (= Sporobolus pyramidatus), Monanthochloe littoralis,* and *Spartina spartinae*. Other somewhat halophytic species, such as *Maytenus phyllanthoides* and *Prosopis reptans,* may also occupy these dunes. The proximity of many of these dunes to active tidal fluctuations and salt spray also influences species composition at these sites.

Dynamics: From Landfire (2007a): Hurricanes and tropical storms can affect these sites through tidal surge causing influx of saline waters. Saltwater inundation would be restricted temporally to the period during storm surge and would not likely significantly affect shrub mortality. Also, high-intensity storms may completely eliminate these sites through erosion. Erosional processes would tend to completely eliminate sites rather than causing changes in the system structure. Fire is not a process important to this system and does not or rarely occurs. Tidal flat islands are important for wildlife such as migratory birds, mollusks and fish (USACE 2013).

This system occurs as small-patch sites ranging from 10s to a few 100 acres. Disturbances tend to have local effects or completely eliminate a site. This BpS occurs as a stable system.

Component Associations:
- *Citharexylum berlandieri - Yucca treculeana - Ebenopsis ebano - Phaulothamnus spinescens* Shrubland (CEGL002170, G1)
- *Maytenus phyllanthoides - Prosopis reptans / Spartina patens* Herbaceous Vegetation (CEGL007764, G2?)
- *Sporobolus wrightii* Herbaceous Vegetation (CEGL002232, G2?)

DISTRIBUTION

Range: This coastal system is known from Aransas County, Texas, south into Mexico.
Divisions: 301:C
Nations: US
Subnations: TX

TAMAULIPAN MIXED DECIDUOUS THORNSCRUB (CES301.983)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2390; ESLF 5321; ESP 1390

CONCEPT

Summary: This thornscrub ecological system occurs throughout much of northeastern Mexico and southern Texas. It occurs on a variety of substrates and landforms. Dominant species include *Acacia roemeriana, Leucophyllum frutescens,* and *Prosopis glandulosa*. Other species present to codominant include *Acacia berlandieri, Acacia farnesiana, Amyris madrensis, Amyris texana, Celtis pallida, Parkinsonia texana,* and cacti such as *Opuntia engelmannii var. lindheimeri*. The herbaceous layer is not well-developed but *Chloris pluriflora (= Trichloris pluriflora), Setaria* spp. and *Malpighia glabra* are present. This system generally occurs as a closed shrubland or low woodland, usually lacking a purely open herbaceous component. Soils are clays, clay loams, and clay flats and are often calcareous or alkaline to varying degrees. Some sites are highly saline, and these sites are occupied by Tamaulipan Saline Thornscrub (CES301.711), but transitions between the systems may be subtle.
Classification Comments: This shrubland is differentiated from Tamaulipan Savanna Grassland (CES301.985) as it occupies tighter soils, as opposed to the sandier soils of the savanna grassland. The sites are often lower in the landscape compared to nearby savanna grassland or Tamaulipan Calcareous Thornscrub (CES301.986), but would be considered uplands as they are distant from bottomland soils and drainages, and are not well-developed woodlands typical of the lowest landscape positions. To a large degree, all of these systems share numerous shrub species, but show subtle differences in relative dominance. However, this system generally occurs as a closed shrubland or low woodland, usually lacking a purely open herbaceous component.
Similar Ecological Systems:
- Tamaulipan Calcareous Thornscrub (CES301.986)
- Tamaulipan Mesquite Upland Scrub (CES301.984)
- Tamaulipan Saline Thornscrub (CES301.711)
- Tamaulipan Savanna Grassland (CES301.985)--occupies sandier soils.

Related Concepts:
- Chihuahuan Thorn Forest (Jahrsdoerfer and Leslie 1988) Intersecting
- South Texas: Clayey Blackbrush Mixed Shrubland (7005) [CES301.983.5] (Elliott 2011) Finer
- South Texas: Clayey Live Oak Motte and Woodland (7002) [CES301.983.2] (Elliott 2011) Finer
- South Texas: Clayey Mesquite Mixed Shrubland (7004) [CES301.983.4] (Elliott 2011) Finer
- Upland Thornscrub (Jahrsdoerfer and Leslie 1988) Broader

DESCRIPTION

Environment: This system is well-represented on the Eocene Claiborne and Jackson groups and the Pleistocene Beaumont Formation, but is also found on various other formations. Its landforms are gently rolling to nearly level sites, sometimes interdigitated with calcareous ridges and low-lying drainages and bottomlands. Found on upland sites on tight soils deposited through alluvial processes associated with the Rio Grande, also occurs on uplands away from the delta on deeper soils. Clay, Clay Flat, and Clay Loam Ecological Sites are the typical soils for this system.
Vegetation: *Prosopis glandulosa* is very often a conspicuous component of the canopy in stands of this system, sometimes reaching to 6 m in height. This canopy may be dense, but given the open nature of the canopy of individual *Prosopis glandulosa*, significant solar radiation reaches the lower strata. *Acacia farnesiana, Celtis pallida (= Celtis ehrenbergiana), Ebenopsis ebano*, and *Celtis laevigata* may also be components of the canopy, but *Prosopis glandulosa* usually dominates. The overstory canopy may be open with only scattered emergent trees over a dense shrub layer at 1 to 3 m in height. Depending on land-use history, the shrub understory may be limited to a few species such as *Opuntia engelmannii var. lindheimeri, Ziziphus obtusifolia*, or *Celtis pallida* on relatively recently cleared sites. On more mature sites, a diverse assemblage of species, such as *Acacia rigidula, Castela erecta, Malpighia glabra, Opuntia engelmannii var. lindheimeri, Opuntia leptocaulis (= Cylindropuntia leptocaulis), Ziziphus obtusifolia, Celtis pallida, Lycium berlandieri, Forestiera angustifolia, Guajacum angustifolium, Diospyros texana, Amyris texana, Karwinskia humboldtiana, Havardia pallens, Phaulothamnus spinescens, Schaefferia cuneifolia, Condalia hookeri*, and *Zanthoxylum fagara*, may occur. *Leucophyllum frutescens* and *Acacia berlandieri* may be present, but occur as scattered individuals as opposed to dominating the aspect of the community as they sometimes do on some shallow-soiled calcareous sites. However, like some shallow-soiled calcareous sites, *Acacia rigidula* is the aspect dominant of the shrub layer. The herbaceous layer is usually fairly sparse. Currently, the herbaceous layer may actually be dense with the non-native grass *Urochloa maxima*. Other non-native species, such as *Pennisetum ciliare, Cynodon dactylon, Bothriochloa ischaemum var. songarica*, and *Dichanthium annulatum*, may also be present to dominant. Native grasses, such as *Bothriochloa laguroides ssp. torreyana, Chloris* spp. (= *Trichloris* spp.), and *Pappophorum bicolor*, may be present.

Dynamics: Fire plays a role in this system, occurring in situations adjacent to grasslands during dry conditions when fire would jump to the canopy and carry during wind events. Drought would influence fire occurring in the woodland and shrubland classes (Landfire 2007a).

This system was modeled by Landfire (2007a) using three classes: early-, mid- and late-seral. The early-seral (0-5 years) class is dominated by perennial grasses. This class was maintained on higher topographic positions somewhat longer because of slower shrub growth in more xeric situations. Frequent replacement fire (MFRI = 7 years) is the dominant disturbance type in this class (Landfire 2007a). Mid-seral class is dominated by shrubs (40-70% cover). In this class, mesquite is a component of the shrub layer along with the other shrubs. Drought is incorporated into the MFRI in that dry conditions would be required for fire to be carried in the canopy. Replacement fire (MFRI = 20 years) is the dominant disturbance type in this class (Landfire 2007a). The late-seral class has a shrub layer at a height of 2-4 m and 70-100% cover. Mesquite canopy is well-developed in this class. Shrub layer development is extensive forming an almost continuous layer. Replacement fire (MFRI = 30 years) is the dominant disturbance type in this class (Landfire 2007a).

Component Associations:

TAMAULIPAN SALINE THORNSCRUB (CES301.711)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Tropical/Subtropical [Tropical Xeric]; Saline Substrate Chemistry
National Mapping Codes: ESLF 9393

CONCEPT

Summary: This system is an open shrubland on gently rolling to level sites where soil salinity is particularly high on saline clays. It occurs in the Tamaulipan region of southern Texas and possibly ranges into Mexico. Scattered *Prosopis glandulosa* usually form an emergent canopy less than 5 m in height, creating an overstory canopy cover of around 10%. A variety of shrubs and subshrubs form the dominant layer with a cover of 20-70% interspersed in a mosaic with patchy grasses.

Similar Ecological Systems:
- Tamaulipan Calcareous Thornscrub (CES301.986)
- Tamaulipan Mesquite Upland Scrub (CES301.984)
- Tamaulipan Mixed Deciduous Thornscrub (CES301.983)--occurs on soils mapped as saline clay or saline clay loam, but where soil salinity is not extreme and is often found upslope of Tamaulipan Saline Thornscrub.
- Tamaulipan Savanna Grassland (CES301.985)--occupies sandier soils.

Related Concepts:
- South Texas: Salty Thornscrub (6806) (Elliott 2011) Equivalent

DESCRIPTION

Environment: This ecological system occurs on gently rolling to low flats, sometimes dissected by minor drainages. It is frequently associated with the Yegua Formation or the Jackson Group and within the Saline Clay and Saline Clay Loam Ecological Sites. Soils are typically saline clays such as Montell, Maverick, and Catarina soils and may have a veneer of gravel over the clay.
Vegetation: *Prosopis glandulosa* usually forms a scattered emergent canopy less than 5 m in height, creating an overstory canopy cover of around 10%. Shrubs and subshrubs, such as *Varilla texana, Castela erecta, Acacia rigidula, Atriplex canescens, Isocoma coronopifolia, Condalia spathulata, Jatropha dioica, Suaeda* spp., *Opuntia engelmannii var. lindheimeri, Opuntia leptocaulis (= Cylindropuntia leptocaulis), Xylothamia palmeri, Tiquilia canescens*, and *Prosopis reptans*, are conspicuous elements of the relatively open shrubland (20-70% canopy cover). Patchy grasses typify the herbaceous layer, with such species as *Hilaria belangeri, Sporobolus coromandelianus (= Sporobolus pyramidatus), Pappophorum bicolor, Buchloe dactyloides (= Bouteloua dactyloides), Bouteloua trifida*, and occasionally *Monanthochloe littoralis*. Forbs such as *Billieturnera helleri, Chamaesyce albomarginata, Heliotropium curassavicum*, and *Thymophylla pentachaeta* may be present and conspicuous. Cacti are sometimes well-represented in the ground layer, including species such as *Echinocereus reichenbachii var. fitchii, Escobaria emskoetteriana, Mammillaria heyderi, Sclerocactus scheeri, Echinocactus texensis*, and *Thelocactus setispinus*.
Dynamics: Regular fire plays a limited role in this system because of the relatively low cover of fine fuel. During dry conditions it may burn when fire would jump to the shrub layer and canopy and carry during wind events spreading from adjacent grasslands that have more frequent fires. Saline substrates are the driving environmental variable that limits plant growth and species diversity. Substrates are highly erodible saline clay and saline clay loam soils.

Component Associations:
- *Varilla texana - Castela erecta ssp. texana - Isocoma coronopifolia / Hilaria belangeri* Shrubland (CEGL007763, G1?)

WESTERN GREAT PLAINS MESQUITE WOODLAND AND SHRUBLAND (CES303.668)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); F-Patch/Medium Intensity; G-Patch/Medium Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2111; ESLF 5317; ESP 1111

CONCEPT

Summary: This system is found primarily in the southern portion of the Western Great Plains Division, primarily in Texas, Oklahoma and eastern New Mexico. It is dominated by *Prosopis glandulosa* with shortgrass species in the understory. *Ziziphus obtusifolia* and *Atriplex canescens* can codominate in some examples, as can *Opuntia* species in heavily grazed areas. Shortgrass species *Bouteloua gracilis* or *Buchloe dactyloides* are typically present. Other grasses may include *Aristida purpurea, Bouteloua curtipendula, Bouteloua eriopoda, Bouteloua hirsuta, Muhlenbergia torreyi, Pleuraphis jamesii, Sporobolus airoides*, and *Sporobolus cryptandrus*. Historically this system probably occurred as a natural component on more fertile soils and along drainages, but it has expanded its range into prairie uplands in recent decades.
Classification Comments: With fire suppression and grazing, *Prosopis glandulosa* has been able to extend its range and become dense in examples of Western Great Plains Shortgrass Prairie (CES303.672) or Central Mixedgrass Prairie (CES303.659). Those areas should still be considered part of the prairie system. In Landfire mapzone 26 BpS modeling workshops, this was modeled in its limited extent along drainages rather than as the pervasive EVT.
Similar Ecological Systems:
- Central Mixedgrass Prairie (CES303.659)
- Tamaulipan Mesquite Upland Scrub (CES301.984)
- Western Great Plains Shortgrass Prairie (CES303.672)

Related Concepts:
- Mesquite (729) (Shiflet 1994) Broader
- Mesquite (southern type): 68 (Eyre 1980) Finer
- Mesquite (western type): 242 (Eyre 1980) Broader
- Mesquite - Buffalograss (727) (Shiflet 1994) Finer
- Mesquite - Grama (718) (Shiflet 1994) Equivalent

DESCRIPTION

Environment: This system occurs naturally on deeper or more fertile soils and along drainages.
Vegetation: This system is dominated by *Prosopis glandulosa* with *Ziziphus obtusifolia*, and *Atriplex canescens* can codominate. *Opuntia* spp. can be prevalent in areas in heavily grazed examples of this system. The understory of this system is often dominated by shortgrass species.
Dynamics: Historically, fire controlled this system and limited the development of woody cover. Likewise, edaphic conditions and topographic factors limited this system to deep alluvial soils in relatively low topographic positions along broad valley floors.

Component Associations:
- *Acacia farnesiana - (Prosopis glandulosa)* Woodland (CEGL002131, G5)
- *Prosopis glandulosa - Ziziphus obtusifolia* Shrubland (CEGL004939, G2G3)
- *Prosopis glandulosa / Bouteloua curtipendula - Nassella leucotricha* Woodland (CEGL002133, G3?)
- *Prosopis glandulosa / Bouteloua curtipendula* Shrubland (CEGL002194, GNR)
- *Prosopis glandulosa var. glandulosa / Bouteloua gracilis - Buchloe dactyloides* Shrubland (CEGL003877, GNR)
- *Schizachyrium scoparium - (Sorghastrum nutans) - Sporobolus compositus var. compositus - Liatris mucronata* Herbaceous Vegetation (CEGL004211, GNR)
- *Schizachyrium scoparium - Bouteloua curtipendula - Nassella leucotricha* Herbaceous Vegetation (CEGL004070, GNR)

DISTRIBUTION

Range: This system is primarily found in the southern portion of the Western Great Plains division, particularly in Texas, Oklahoma and eastern New Mexico.
Divisions: 303:C
Nations: US
Subnations: NM, OK, TX

WESTERN GREAT PLAINS SANDHILL STEPPE (CES303.671)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); Sand Soil Texture; Ustic; F-Landscape/Medium Intensity; G-Landscape/Medium Intensity
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2094; ESLF 5271; ESP 1094

CONCEPT

Summary: This system is found mostly in south-central areas of the Western Great Plains Division ranging from southwestern Wyoming and southwestern Nebraska up into the Nebraska Sandhill region, south though eastern Colorado, and New Mexico to central Texas, although some examples may reach as far north as the Badlands of South Dakota. The climate is semi-arid to arid for much of the region in which this system occurs. This system is found on somewhat excessively to excessively well-drained, deep sandy soils that are often associated with dune systems and ancient floodplains. In some areas, this system may actually occur as a result of overgrazing in Western Great Plains Tallgrass Prairie (CES303.673) or Western Great Plains Sand Prairie (CES303.670). Typically, this system is characterized by a sparse to moderately dense woody layer dominated or codominated by *Artemisia filifolia*, but other characteristic species may be present, including *Amorpha canescens, Prosopis glandulosa* (southern stands), *Prunus angustifolia, Prunus pumila var. besseyi* (northern stands), *Rhus trilobata*, and *Yucca glauca*. Associated herbaceous species can vary with geography, amount and season of precipitation, disturbance, and soil texture. The herbaceous layer typically has a moderate to dense canopy but may include stands with sparse understory. Several mid- to tallgrass species characteristic of sand substrates are usually present to dominant, such as *Andropogon hallii, Calamovilfa gigantea, Calamovilfa longifolia, Schizachyrium scoparium, Sporobolus cryptandrus, Sporobolus giganteus*, or *Hesperostipa comata*.
Classification Comments: This system is minor in the sandhills region of western Nebraska which is dominated by sand prairie. It may overlap in concept with East-Central Texas Plains Xeric Sandyland (CES205.897). This system was modeled Monahans and Mescalero Sands of Texas and New Mexico during Landfire workshops, but probably needs significant review because of the complexity of the relationship among tallgrass, shin oak, and sandsage types. This type is probably best represented in mapzone 34.
Similar Ecological Systems:
- East-Central Texas Plains Xeric Sandyland (CES205.897)
- Western Great Plains Sand Prairie (CES303.670)
- Western Great Plains Tallgrass Prairie (CES303.673)

- Sandsage Prairie (605) (Shiflet 1994) Broader

DESCRIPTION

Environment: This system is found primarily in semi-arid to arid areas of the Western Great Plains Division. It occurs on somewhat excessively to excessively well-drained and deep sandy soils. This system is often found associated with dune systems and/or ancient floodplains but may occur in soils derived from sandstone residuum. In parts of Texas, this system is apparently restricted to thick sandy deposits in the Seymour Formation (a Pleistocene formation formed from ancient channel deposits of the Clear Fork of the Brazos River), and is found on rolling to level uplands. In these areas, it is restricted to Deep Sand, Sand Hills or Sandy Ecological Sites (Elliott 2011).
Vegetation: This system is distinguished by a sparse to moderately dense shrub layer (15-90% canopy cover in Texas) dominated or codominated by *Artemisia filifolia* with *Quercus havardii* and *Prosopis glandulosa* to the south. In addition, *Rhus trilobata, Yucca glauca, Prunus angustifolia*, or *Prunus pumila var. besseyi* (northern stands) may also be conspicuous. Shrub cover may sometimes be sufficient to greatly reduce the cover of herbaceous species in the understory. At some sites, shrub cover may be low, and the herbaceous cover is typically dominated by grass species such as *Schizachyrium scoparium* and *Sporobolus cryptandrus*. Several mid- to tallgrass species characteristic of sand substrates are usually present to dominant within this system, including *Andropogon hallii, Calamovilfa gigantea, Calamovilfa longifolia, Sporobolus giganteus*, and/or *Hesperostipa comata*.

Dynamics: Fire and grazing constitute the most important processes impacting this system. Burning shrublands reduces cover of *Artemisia filifolia* for several years resulting in grassland patches that form a mosaic pattern with shrublands. Composition of grasslands depends on precipitation and management. Drought stress can also influence this system in some areas. In the southern range of this system, *Quercus havardii* may also be present to dominant and represents one succession pathway that develops over time following a disturbance. *Quercus havardii* is able to resprout following a fire and thus may persist for long periods of time once established, forming extensive clones. Edaphic and climatic factors are the most important dynamic processes for this type, with drought and extreme winds impacting this system significantly in some areas. Because *Quercus havardii* is able to resprout rapidly following fire, fire tends to cause structural changes in the vegetation, and compositional shifts are less significant in most cases. Overgrazing can lead to decreasing dominance of some of the grass species such as *Andropogon hallii*, *Calamovilfa gigantea*, and *Schizachyrium scoparium*. In the western extent of this system in the shortgrass prairie, more xeric mid- and shortgrass species such as *Hesperostipa comata*, *Sporobolus cryptandrus* and *Bouteloua gracilis* often dominate the herbaceous layer.

Component Associations:
- *Artemisia filifolia / Andropogon hallii* Shrubland (CEGL001459, G3?)
- *Artemisia filifolia / Bouteloua (curtipendula, gracilis)* Shrubland (CEGL002176, GNR)
- *Artemisia filifolia / Calamovilfa longifolia* Shrubland (CEGL002177, G2G3)
- *Artemisia filifolia / Schizachyrium scoparium - Andropogon hallii* Shrubland (CEGL002178, GNR)
- *Artemisia filifolia / Sporobolus cryptandrus* Shrubland (CEGL002179, GNR)
- *Quercus havardii / Sporobolus cryptandrus - Schizachyrium scoparium* Shrubland (CEGL002171, G3)

DISTRIBUTION

Range: This system is found primarily within the south-central areas of the Western Great Plains Division ranging from the Nebraska Sandhills south into central Texas. However, examples of this system can be found as far north as the Badlands in South Dakota.

WESTERN NORTH AMERICAN BOREAL ALPINE DRYAS DWARF-SHRUBLAND (CES105.132)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Boreal [Boreal Subcontinental]; Dwarf-Shrub; Dryas integrifolia and/or Dryas octopetala
Non-Diagnostic Classifiers: Sideslope
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2634; ESLF 5110; ESP 1634

CONCEPT

Summary: This alpine and subalpine system occurs commonly on mountain sideslopes, low summits and ridges, and in alpine valleys, throughout the boreal region and northern Alaska; it is uncommon throughout the boreal transition. Sites are well-drained and mesic to somewhat dry. *Dryas integrifolia* and/or *Dryas octopetala* dominate the shrub layer with at least 20% cover. Lichen cover is less than 25% and may include species of the genera *Cladina, Cetraria*, and *Stereocaulon*. Other dwarf-shrubs that may be common include *Cassiope tetragona, Salix arctica, Salix reticulata, Vaccinium uliginosum, Empetrum nigrum, Ledum palustre ssp. decumbens, Diapensia lapponica*, and *Oxytropis nigrescens*. Common herbaceous species include *Carex microchaeta, Senecio lugens, Minuartia arctica, Anemone parviflora, Podistera macounii (= Ligusticum mutellinoides ssp. alpinum), Castilleja elegans, Poa arctica, Trisetum spicatum, Silene acaulis, Saxifraga* spp., *Campanula lasiocarpa*, and *Polygonum bistorta*. Common mosses include *Hylocomium splendens, Polytrichum* spp., and *Racomitrium* spp. Lichen cover is less than 25% and may include species of the genera *Cladina, Cetraria*, and *Stereocaulon*.
Classification Comments: This system is known as Alpine Dryas Dwarf Shrub by the Alaska Natural Heritage Program.
Related Concepts:
- II.D.1.a - Dryas tundra (Viereck et al. 1992) Intersecting
- II.D.1.b - Dryas-sedge tundra (Viereck et al. 1992) Intersecting

DESCRIPTION

WESTERN NORTH AMERICAN BOREAL ALPINE DWARF-SHRUB SUMMIT (CES105.129)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Extreme Wind Exposure; Alpine/AltiAndino; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Boreal [Boreal Subcontinental]; W-Landscape/High Intensity; Dwarf-Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2631; ESLF 5111; ESP 1631

CONCEPT

Summary: This system occurs on windswept summits and ridges on alpine sites in the boreal and boreal transition regions of Alaska. Soils are thin, stony, and well-drained to excessively well-drained. Canopy cover is sparse, generally less than 25%, due to extreme exposure. Common species include *Dryas* spp., *Vaccinium uliginosum, Empetrum nigrum, Vaccinium vitis-idaea, Diapensia lapponica, Loiseleuria procumbens,* and dwarf *Salix* spp. Exposed rock and lichens are abundant.
Classification Comments: This system is known as Alpine Sparse Dwarf Shrub Summits by the Alaska Natural Heritage Program.
Similar Ecological Systems:
- Alaskan Pacific Maritime Alpine Sparse Shrub and Fell-Field (CES204.318)

WESTERN NORTH AMERICAN BOREAL ALPINE DWARF-SHRUB-LICHEN SHRUBLAND (CES105.134)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino; Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Dwarf-Shrub; Dryas integrifolia and/or Dryas octopetala
Non-Diagnostic Classifiers: Ridge/Summit/Upper Slope; Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2636; ESLF 5112; ESP 1636

CONCEPT

Summary: This ecological system is common on summits and ridges throughout boreal, northern, and western Alaska. The shrub component is often mixed, with ericaceous shrubs, *Dryas*, and willows contributing to the layer. Lichen cover is at least 25%. Sites are generally exposed to the wind and do not accumulate much winter snow. Common shrub species include *Vaccinium uliginosum, Vaccinium vitis-idaea, Empetrum nigrum, Arctostaphylos rubra, Arctostaphylos alpina, Dryas integrifolia, Salix arctica, Salix rotundifolia*, and *Salix reticulata*. Fruticose lichens often codominate with the shrubs. Common lichens include *Cladina rangiferina, Cladina stellaris, Flavocetraria cucullata (= Cetraria cucullata), Stereocaulon* spp., *Alectoria nigricans*, and *Thamnolia vermicularis*. Herbaceous species include *Hierochloe alpina (= Anthoxanthum monticola ssp. alpinum), Polygonum bistorta, Anemone* spp., *Festuca* spp., and *Luzula* spp. Mosses may be present but do not contribute much cover.
Classification Comments: This system is known as Alpine Dwarf Shrub Lichen by the Alaska Natural Heritage Program.
Related Concepts:

WESTERN NORTH AMERICAN BOREAL ALPINE ERICACEOUS DWARF-SHRUBLAND (CES105.133)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Boreal [Boreal Subcontinental]; Dwarf-Shrub; Ericaceous dwarf-shrubs
Non-Diagnostic Classifiers: Sideslope
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Deciduous dwarf-shrubland
National Mapping Codes: EVT 2635; ESLF 5113; ESP 1635

CONCEPT

Summary: This is a common alpine system throughout the boreal and boreal transition regions and in northern Alaska. Common slope positions include alpine valleys, sideslopes, and low summits and ridges. Ericaceous dwarf-shrubs typically dominate, but a wide range of species and plant communities are encompassed in this system. Total lichen cover is less than 25% and may include species of *Cetraria, Cladina*, and *Cladonia*. Common dwarf-shrub dominants include *Cassiope tetragona* (more common north of the Alaska Range), *Empetrum nigrum, Vaccinium uliginosum, Harrimanella stelleriana* (more common south of the Alaska Range), and *Arctostaphylos* spp. Other shrubs that may be common include *Betula nana, Diapensia lapponica, Dryas octopetala, Ledum palustre ssp. decumbens, Vaccinium vitis-idaea, Salix reticulata, Salix phlebophylla*, and *Salix rotundifolia*. Common herbaceous species include *Hierochloe alpina (= Anthoxanthum monticola ssp. alpinum), Arnica lessingii, Carex bigelowii*, and *Carex microchaeta*. Mosses such as *Aulacomnium palustre, Hylocomium splendens, Pleurozium schreberi*, and *Polytrichum* may be common. Sites are typically mesic. *Cassiope* and *Harrimanella* tundra sites occur on terrain that is well-protected by snow in the winter, and often remains snow-covered until the middle of the growing season.
Classification Comments: This system is known as Alpine Ericaceous Dwarf Shrub by the Alaska Natural Heritage Program.
Related Concepts:

WESTERN NORTH AMERICAN BOREAL MESIC SCRUB BIRCH-WILLOW SHRUBLAND (CES105.113)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Montane [Upper Montane]; Shrubland (Shrub-dominated); Boreal [Boreal Subcontinental]; Feathermosses
Non-Diagnostic Classifiers: Lowland [Lowland]; Ridge/Summit/Upper Slope; Sideslope; Mineral: W/ A-Horizon >10 cm; Broad-Leaved Deciduous Shrub; Dwarf-Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2610; ESLF 5281; ESP 1610

CONCEPT

Summary: This ecological system occurs throughout the boreal and boreal transition regions of Alaska on mesic sites on mid- to upper slopes, above treeline and on flats and sideslopes. *Betula nana* usually dominates the shrub layer, but *Vaccinium uliginosum, Ledum palustre ssp. decumbens, Salix pulchra, Salix barclayi*, or other *Salix* spp. may also be common. *Salix* spp. may occasionally be dominant. Dwarf-shrubs such as *Empetrum nigrum* and *Vaccinium vitis-idaea* may be common under the low-shrub layer. Herbaceous species are sparse, but feathermosses (*Hylocomium splendens* and *Pleurozium schreberi*) and lichens may be common. Sites with organic soils are not included in this type.
Classification Comments: This system is known as Boreal Shrub Birch by the Alaska Natural Heritage Program. Low-shrub types on peat deposits are included in wetland types. This type (formerly North Pacific Mesic Low Shrubland (CES204.855)) was originally defined for the south-central and southeast Alaska region, into Oregon and Washington. Review clarified this is not found in the lower 48 states. Nor is it found in the Pacific maritime regions of Alaska, except on the north of the Alaska Range. It is highly likely to occur in British Columbia.

- II.C.2.g - Willow low (open) (Viereck et al. 1992) Intersecting
- Low Scrub Shrub Birch - Ericaceous (912) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This system occurs on well-drained slopes and terraces often in the subalpine. Soils are mineral with a well-decomposed organic layer 5-30 cm thick (Viereck et al. 1992).
Vegetation: *Betula nana* usually dominates the shrub layer, but *Vaccinium uliginosum, Ledum palustre ssp. decumbens, Salix pulchra, Salix barclayi*, or other *Salix* spp. may also be common (Viereck 1979, Viereck et al. 1992). *Salix* spp. are occasionally dominant. Dwarf-shrubs such as *Empetrum nigrum* and *Vaccinium vitis-idaea* may be common under the low-shrub layer. Herbaceous species are sparse but may include *Festuca altaica* and *Hierochloe alpina (= Anthoxanthum monticola ssp. alpinum)*. Feathermosses (*Hylocomium splendens* and *Pleurozium schreberi*) and lichens are common, but peat-forming mosses and sedges are not (Viereck et al. 1992). *Betula nana* and *Betula glandulosa* are described as low-shrub species (Viereck and Little 1972); however, shrub height is variable, and sites with shrubs greater than 1.5 m are reported.
Dynamics: This system represents a topoedaphic climax in some areas; in other cases it may be seral to shrub-tussock over long time periods (Viereck et al. 1992). At treeline, this system occurs above Western North American Boreal Treeline White Spruce Woodland (CES105.137).

There is little information available about the fire history of shrub communities in Alaska. Birch and ericaceous shrub tundra tends to produce more severe burns than sedge-shrub tussock tundra (Racine 1979). After fire, shrubs resprout readily from underground propagules if they have not been burned, and a shrub community re-establishes on the site within 5 years. After severe fires that remove the organic layer and burn the propagules, herbaceous species that establish by seed may dominate the site for more than 5 years. Burned-over spruce woodlands near treeline may be converted to low shrub after fire (Pegau 1972) and may slowly regenerate a spruce overstory. The fire-return interval is longer in the boreal transition region than in boreal Alaska. Adjacent vegetation influences the fire frequency. If the adjacent vegetation is flammable, then this low-shrub type will have a more frequent fire return. Without adjacent flammable vegetation, fire-return intervals are probably more than 100+ years. Trees may also invade these shrublands but over long time frames.

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:

- Western North American Boreal Treeline White Spruce Woodland (CES105.137)

DISTRIBUTION

Range: This system occurs in the boreal and, less commonly, boreal transition regions of Alaska at low elevation through subalpine.

WYOMING BASINS DWARF SAGEBRUSH SHRUBLAND AND STEPPE (CES304.794)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Shrubland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Hill(s); Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Sideslope; Shallow Soil; Silt Soil Texture; Clay Soil Texture; Aridic; W-Landscape/High Intensity; Low Artemisia spp.
Non-Diagnostic Classifiers: Temperate [Temperate Continental]; Alkaline Soil; Dwarf-Shrub
FGDC Crosswalk: Vegetated, Shrub-dominated, Dwarf-shrubland, Evergreen dwarf-shrubland
National Mapping Codes: EVT 2072; ESLF 5209; ESP 1072

CONCEPT

Summary: This windswept ecological system is composed of dwarf sagebrush shrubland and shrub-steppe that forms matrix vegetation and large patches on the margins of high-elevation basins in central and southern Wyoming. Typical sites are gently rolling hills and long, gently sloping pediments and fans. These sites are very windy and have shallow, often rocky soils. The distinguishing feature of this system is a short-shrub stratum in which dwarf-shrubs (≤30 cm tall) contribute at least two-thirds of the woody canopy. Four sagebrush taxa may dominate the shrub stratum: *Artemisia tripartita ssp. rupicola*, *Artemisia nova*, *Artemisia arbuscula ssp. longiloba*, and wind-dwarfed *Artemisia tridentata ssp. wyomingensis*. Two or more of these sagebrushes often codominate, but any of them may occur alone. Where graminoids are common and tall, the vegetation often has the appearance of grassland without shrubs; the shrubs are obvious only when the vegetation is viewed from up close. Where graminoids contribute less cover, the vegetation is a compact shrubland. The herbaceous component of the vegetation includes both rhizomatous and bunch-form graminoids, cushion plants, and other low-growing forbs. *Bouteloua gracilis*, a common species of Inter-Mountain Basins Big Sagebrush Steppe (CES304.778) in Wyoming, is absent.

SAVANNA AND SHRUB-STEPPE

ALABAMA KETONA GLADE AND WOODLAND (CES202.338)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Rock Outcrops/Barrens/Glades
FGDC Crosswalk: Vegetated, Tree-dominated, Sparse tree canopy, Mixed evergreen-deciduous sparse tree canopy
National Mapping Codes: EVT 2408; ESLF 5424; ESP 1408

CONCEPT

Summary: This system consists of open glades and related vegetation on Ketona dolomite slopes found in Bibb County, Alabama, in the vicinity of the Little Cahaba River. The vegetation includes herbaceous, shrubland, and open woodlands, which occur on thin soils or outcrops of Ketona dolomite. *Juniperus virginiana, Quercus muehlenbergii, Pinus palustris, Croton alabamensis, Sabal minor*, and *Leptopus phyllanthoides* are the dominant woody plants of the woodlands. The system supports eight endemic and numerous disjunct plant taxa and has very high conservation value based on rare plants.
Classification Comments: As TNC ecoregions are officially defined, examples of this system are found in the Cumberlands and Southern Ridge and Valley (Ecoregion 50), as well as in the Upper East Gulf Coastal Plain (Ecoregion 43). However, the occurrence in the latter ecoregion may be due to inaccurate boundaries; the system is fundamentally associated with the Cumberlands and Southern Ridge and Valley due to its fidelity to ancient dolomites not more recent sediments. It appears to be restricted to EPA level III Ecoregion 67 (Ridge and Valley) not 65 ("Southeastern Plains") (EPA 2004) and the corresponding MRLC mapzones (i.e., 48 not 46), and the attributions reflect this determination.
Similar Ecological Systems:
- Central Interior Highlands Calcareous Glade and Barrens (CES202.691)

Related Concepts:
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Longleaf Pine: 70 (Eyre 1980) Finer

DESCRIPTION

Environment: This system consists of open glades and related vegetation on Ketona dolomite slopes found in Bibb County, Alabama, in the vicinity of the Little Cahaba River (Allison and Stevens 2001).
Vegetation: The vegetation of the system includes a mixture of herbaceous, shrubland, and open woodlands, which occur on thin soils surrounding outcrops of Ketona dolomite. *Juniperus virginiana, Quercus muehlenbergii, Pinus palustris, Croton alabamensis, Sabal minor*, and *Leptopus phyllanthoides* are the dominant woody plants of the woodlands. *Schizachyrium scoparium* is a frequent grass in this system and is commonly associated with *Andropogon gerardii* and other calcium-loving, drought-tolerant plant species. Stunted woodlands are primarily dominated by *Quercus muehlenbergii* interspersed with *Juniperus virginiana* and occur on variable-depth-to-bedrock soils. The trees may occur as islands in a wider herbaceous or rocky area. The islands are found in microenvironments where the soil depth and available water are sufficient to support trees (e.g., depressions or fissures in the bedrock). Small-scale stands of annual *Sporobolus* spp. may be prominent in some examples. More than 60 plant taxa of conservation concern occur on or near these glades, marking them as one of the most significant reservoirs of botanical diversity in the eastern United States. Eight endemic taxa were recently found and newly described: *Castilleja kraliana, Coreopsis grandiflora var. inclinata, Dalea cahaba, Erigeron strigosus var. dolomiticola, Liatris oligocephala, Onosmodium decipiens, Silphium glutinosum*, and *Spigelia gentianoides var. alabamensis*. Seven Alabama state records were discovered: *Solanum carolinense var. hirsutum (= Solanum pumilum)*, last collected in 1837 and presumed extinct; *Astrolepis integerrima*, disjunct from Texas; *Paronychia virginica*, bridging a gap between Arkansas and Virginia; *Baptisia australis var. australis, Rhynchospora capillacea, Rhynchospora thornei*, and *Spiranthes lucida*.
Dynamics: Fire and periodic drought both play a role in the natural dynamics of this system. Fires help manage this system by restricting woody growth and maintaining the more open glade structure. Historically, grazing by wild and domestic ungulate species represented a significant disturbance regime. Regionally significant drought cycles affect severity of other disturbance regimes. Some portions of sites for this system are so droughty and rocky that woody succession is severely retarded, and fuels are either sparse of composed of low annual grasses and scattered forbs (Landfire 2007a). Severe droughts kill tree saplings growing in cracks and potholes, helping to retain the open character of the glades (Quarterman et al. 1993).

Component Associations:
- *Juniperus virginiana var. virginiana - Croton alabamensis - Leptopus phyllanthoides / Carex eburnea* Shrubland (CEGL003937, G1)
- *Quercus muehlenbergii - Carya carolinae-septentrionalis / Acer (barbatum, leucoderme) - Juniperus virginiana var. virginiana /*

Croton alabamensis Woodland (CEGL003758, G1)

- *Schizachyrium scoparium - Sporobolus junceus - Rudbeckia triloba var. pinnatiloba - Onosmodium decipiens* Wooded Herbaceous Vegetation (CEGL004080, G1)

DISTRIBUTION

Range: This small-patch system is restricted to Ketona dolomite slopes found in Bibb County, Alabama, in the vicinity of the Little Cahaba River.

ALASKA ARCTIC MESIC SEDGE-DRYAS TUNDRA (CES102.199)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Polar [Polar Oceanic]; Dwarf-Shrub; Dryas integrifolia and/or Dryas octopetala
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2684; ESLF 5466; ESP 1684

CONCEPT

Summary: This mesic sedge-*Dryas* tundra system is common on mountain slopes, hillslopes, drained lake basins, stabilized dunes, and snowbeds throughout arctic Alaska. Patch size is small to matrix-forming. pH ranges from circumneutral to non-acidic. Permafrost is present, and the soil surface is mesic but may be saturated below 15 cm. This system is codominated by sedges and dwarf- or low shrubs. *Dryas* spp. cover is >10%, and total low-shrub cover is <25%. *Dryas integrifolia* typically dominates or codominates with *Salix richardsonii (= Salix lanata ssp. richardsonii), Salix pulchra, Salix reticulata,* and *Rhododendron lapponicum*. The dominant sedges are *Carex bigelowii, Carex aquatilis,* and *Eriophorum angustifolium*. Other common species are *Eriophorum vaginatum* and *Equisetum arvense*. Nonvascular species include *Oncophorus wahlenbergii, Hylocomium splendens, Tomentypnum nitens,* and *Thamnolia vermicularis*.
Classification Comments: This system is known as Mesic Sedge-*Dryas* Tundra by the Alaska Natural Heritage Program.
Related Concepts:
- II.D.1.b - Dryas-sedge tundra (Viereck et al. 1992) Intersecting
- III.A.2.j - Sedge-dryas tundra (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: This system's disturbance processes and succession have not been described.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.
Divisions: 102:C; 104:C
Nations: CA, US
Subnations: AK
Map Zones: 67:C, 68:C, 69:C, 72:C, 76:C
TNC Ecoregions: 73:C, 74:C, 75:C, 79:C

ALASKA ARCTIC MESIC SEDGE-WILLOW TUNDRA (CES102.187)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Sideslope; Polar [Polar Oceanic]; Salix pulchra, Salix richardsonii (= Salix lanata ssp. richardsonii)
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2683; ESLF 5467; ESP 1683

CONCEPT

Summary: This ecological system is common on mountain slopes, hillslopes, drained lake basins, stabilized dunes, and snowbeds throughout arctic Alaska. Permafrost is present. Patch size is small to large. The mesic sedge-willow tundra system is codominated by sedges and dwarf- and low shrubs, although low-shrub cover is <25%; *Salix* cover is >20%. The dominant shrubs are *Betula nana, Salix pulchra, Salix richardsonii (= Salix lanata ssp. richardsonii),* and *Vaccinium uliginosum*. Other willows that may occur include *Salix bebbiana, Salix glauca,* and *Salix planifolia*. The dominant sedges are *Carex aquatilis, Eriophorum angustifolium*, and *Carex microchaeta*. Other species include *Petasites frigidus, Polemonium acutiflorum*, and *Sphagnum* spp.
Classification Comments: This system is known as Mesic Sedge-Willow Tundra by the Alaska Natural Heritage Program.
Related Concepts:

ALASKAN PACIFIC MARITIME ALPINE DWARF-SHRUBLAND (CES204.310)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Alpine Mosaic; Shrubland (Shrub-dominated); Temperate [Temperate Oceanic]; Dwarf-Shrub
Non-Diagnostic Classifiers: Ridge/Summit/Upper Slope; Sideslope; Forb; Graminoid
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2643; ESLF 5468; ESP 1643

CONCEPT

Summary: This system occurs primarily on alpine and subalpine sites of southeastern, maritime Alaska, but it can also be found at lower elevations (e.g., Kenai Fjords and Prince William Sound). It occurs on sideslopes, shoulder slopes, and low summits, and the terrain varies from gently sloping to steep. The vegetation can be a mosaic of herbaceous meadow and alpine heath (dwarf-shrublands) or herbaceous meadow with a heath understory; however, in some areas dwarf-shrub cover is continuous. Dominant dwarf-shrub species include *Empetrum nigrum, Phyllodoce aleutica, Phyllodoce glanduliflora, Cassiope mertensiana, Cassiope tetragona, Harrimanella stelleriana*, and *Luetkea pectinata*. Other common species may include *Vaccinium uliginosum, Vaccinium vitis-idaea*, and *Loiseleuria procumbens*. Ericaceous species typically dominate this type, but sites dominated by *Salix arctica* and *Salix reticulata* are included in this system. Scattered tall shrubs and dwarf trees may be present. Common herbaceous species include *Carex macrochaeta, Lupinus nootkatensis, Valeriana sitchensis, Geranium erianthum, Aconitum delphiniifolium, Castilleja unalaschcensis, Sanguisorba canadensis, Anemone narcissiflora, Artemisia arctica*, and *Viola* spp. On slopes on the outer coast and also in Kenai Fjords and Prince William Sound *Nephrophyllidium crista-galli* is common in this system.
Classification Comments: This system includes the types known as Maritime Dwarf Shrubland and Herbaceous-Dwarf-Shrub by the Alaska Natural Heritage Program. If herbaceous cover is greater than 75%, then it will be mapped as herbaceous (shrub understory will not be mappable).

ALEUTIAN CROWBERRY-HERBACEOUS HEATH (CES105.230)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch, Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Dune (Landform); Boreal [Boreal Oceanic]; Seabird Colony Nutrient Input; Empetrum nigrum
Non-Diagnostic Classifiers: Moraine; Slope; Terrace; Valley bottom
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2719; ESLF 5469; ESP 1719

CONCEPT

Summary: This system is common in valley bottoms, sideslopes, stabilized dunes, terraces, moraines and fans. Patch size is small to matrix forming. It typically occupies lower elevation sites than Aleutian Mixed Dwarf-Shrub-Herbaceous Shrubland (CES105.231). Dwarf-shrub cover is >25% and dominated by *Empetrum nigrum*; herbaceous cover is variable, ranging from none to well over 50%. Other dwarf-shrub species include dwarf willows, *Harrimanella stelleriana, Phyllodoce aleutica, Vaccinium vitis-idaea,* and *Arctostaphylos alpina*. Herbaceous species include *Lupinus nootkatensis, Polemonium acutiflorum, Chamerion angustifolium, Solidago* spp., and grasses. A more abundant herbaceous component, particularly graminoids, may be due to nutrient inputs from seabird colonies; where seabirds have been impacted by introduced predators, the cover of herbaceous species appears to be lower (Croll et al. 2005). Fruticose lichens and *Racomitrium lanuginosum* may also be common. Heath hummocks may occur.
Classification Comments: This system combines those known as *Empetrum nigrum* Heaths and *Empetrum nigrum*-Herbaceous by the Alaska Natural Heritage Program.
Related Concepts:
- *Empetrum nigrum* (Boggs et al. 2003) Finer
- II.D.2.c - Crowberry tundra (Viereck et al. 1992) Broader

DESCRIPTION

Environment: This system is common in valley bottoms, sideslopes, stabilized dunes, terraces, moraines and fans. Patch size is small to matrix forming. It typically occupies lower elevation sites than Aleutian Mixed Dwarf-Shrub-Herbaceous Shrubland (CES105.231).
Vegetation: Dwarf-shrub cover is >25% and dominated by *Empetrum nigrum*; herbaceous cover is variable, ranging from none to well over 50%. Other dwarf-shrub species include dwarf willows, *Harrimanella stelleriana, Phyllodoce aleutica, Vaccinium vitis-idaea,* and *Arctostaphylos alpina*. Herbaceous species include *Lupinus nootkatensis, Polemonium acutiflorum, Chamerion angustifolium, Solidago* spp., and grasses. A more abundant herbaceous component, particularly graminoids, may be due to nutrient inputs from seabird colonies; where seabirds have been impacted by introduced predators, the cover of herbaceous species appears to be lower (Croll et al. 2005). Fruticose lichens and *Racomitrium lanuginosum* may also be common. Heath hummocks may occur.

ALEUTIAN MIXED DWARF-SHRUB-HERBACEOUS SHRUBLAND (CES105.231)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Steppe/Savanna
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); W-Patch/High Intensity; Dwarf-Shrub
Non-Diagnostic Classifiers: Ridge; Slope; Terrace; Valley
FGDC Crosswalk: Vegetated, Shrub-dominated, Herbaceous - shrub-steppe, Perennial graminoid steppe
National Mapping Codes: EVT 2720; ESLF 5470; ESP 1720

CONCEPT

Summary: This is a common system throughout the Alaska Peninsula and Aleutian Islands from low to high elevations. It occurs in valleys, terraces, sideslopes, and ridges. In the mountains, this system often grades upslope into the Aleutian sparse heath and fell-field system. The continuous dwarf-shrub heaths often fragment into strips that alternate with almost bare ground, possibly due to wind erosion and frost action. In this system, dwarf-shrub cover is >25%, not dominated by *Empetrum nigrum*, and herbaceous cover varies from none to 75%. Various dwarf-shrub species dominate or codominate, including *Harrimanella stelleriana, Phyllodoce aleutica, Salix arctica, Salix rotundifolia, Cassiope lycopodioides, Loiseleuria procumbens, Vaccinium vitis-idaea, Vaccinium uliginosum*, and *Arctostaphylos alpina*. While *Empetrum nigrum* may codominate, it is mixed with other dwarf-shrubs. Common herbaceous species include *Carex macrochaeta, Chamerion angustifolium, Deschampsia caespitosa, Lupinus nootkatensis, Leymus mollis, Geum calthifolium, Carex circinata, Polygonum viviparum*, and *Festuca rubra*. Bryophyte cover is often high.
Classification Comments: This system combines those known as Mixed Dwarf-Shrub and Mixed Dwarf-Shrub-Herbaceous by the Alaska Natural Heritage Program.
