Classification Comments: The solution ponds of the Eldorado Plateau are superficially similar to the playa lakes of the Llano Estacado, but the underlying geology of the Edwards Plateau (Cretaceous limestone) occurrences is different from the Llano Estacado (Pliocene and late Tertiary) conglomerates and caliche of the Ogallala Formation and is mantled by a thick layer of wind-deposited Pleistocene sands and silty sands. Further field investigation is needed to better develop the association-level information for this system.

Related Concepts:
- Edwards Plateau: Playa (1507) [CES303.654.9] (Elliott 2011) Equivalent

DESCRIPTION

Environment: This system occurs in shallow depressions over massive Cretaceous limestones, such as the Edwards Formation in the Edwards Plateau of Texas. These are internally draining depressions of karstic origin on level plateau surfaces. Soils are loams and clay loams, often mapped as Lakebed ecoclass (Elliott 2011). This system includes shallow wetlands formed over limestone on the Edwards Plateau of Texas. Variable in size and duration of inundation, these wetlands are typically found on level uplands. Formation of these occurrences is apparently from solution of the underlying limestone.

Vegetation: Dominant vegetation includes both graminoids and forbs tolerant of wet periods but not necessarily wetland-dependent. Dominant species may include *Pleuraphis mutica, Buchloe dactyloides, Tridens albescens, Sedum pulchellum, Sedum nuttallianum, Sporobolus vaginiflorus, Chaetopappa bellidifolia, Ambrosia psilostachya, Paronychia* spp., and the alga *Nostoc commune*. *Panicum obtusum, Bothriochloa barbinodis, Pascopyrum smithii, Bouteloua gracilis, Chenopodium album, Helianthus ciliaris*, and *Solanum elaeagnifolium* may also be present (Elliott 2011).

Component Associations:
- *Pleuraphis mutica - Buchloe dactyloides* Herbaceous Vegetation (CEGL002272, G4?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Edwards Plateau Cliff (CES303.653)
- Edwards Plateau Dry-Mesic Slope Forest and Woodland (CES303.656)
- Edwards Plateau Floodplain Terrace (CES303.651)
- Edwards Plateau Limestone Savanna and Woodland (CES303.660)
- Edwards Plateau Limestone Shrubland (CES303.041)
- Edwards Plateau Mesic Canyon (CES303.038)
- Edwards Plateau Riparian (CES303.652)

DISTRIBUTION

Range: This system is found throughout the Edwards Plateau of Texas. Some larger occurrences of this wetland system are found in Crockett, Reagan, Schleicher, Irion and Sterling counties in the northwest Edwards Plateau (the Eldorado Plateau). In TPWD Phase 1, they are found primarily in Runnels, Concho, and Sutton counties (Elliott 2011).

FLORIDA BIG BEND FRESH AND OLIGOHALINE TIDAL MARSH (CES203.507)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Freshwater]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9290

CONCEPT

Summary: This ecological system includes tidal freshwater and oligohaline marshes of the northern Gulf of Mexico along the Florida Big Bend area (roughly from Wakulla County to the Pasco/Hernando county line on Florida's west coast). The tidal range in this region is higher than in the western Panhandle, and wave energy is low; lunar, wind and seasonal tides make flooding irregular. In comparison to the matrix-forming salt and brackish marshes of the same region, this system is confined to small patches that are generally restricted to areas near the mouths of rivers where freshwater is abundant. This system is dominated by herbaceous graminoids tolerant of tidal flooding, but not tolerant of saltwater and with only a limited tolerance of true brackish conditions.
Related Concepts:
- Tidal Marsh (FNAI 1990) Broader

DESCRIPTION

Environment: The flooding regime is tidal (irregular) but influenced by the freshwater flows of rivers. This system occurs where there is adequate river flow and discharge to maintain fresh to oligohaline conditions, while still within tidal range. These marshes occur near the mouths and upstream, well inside the mouths of tidal creeks and rivers.
Vegetation: This system is dominated by herbaceous graminoids tolerant of tidal flooding, but not tolerant of saltwater and with only a limited tolerance of true brackish conditions. It does not include the abundant salt marshes of *Spartina alterniflora* and *Juncus roemerianus* (brackish).
Dynamics: The tidal range in this region is higher than in the western Panhandle, and wave energy is low; lunar, wind and seasonal tides make flooding irregular (Montague and Wiegert 1990). In times of drought and low freshwater flows, brackish water will reach upstream further, into areas which would normally be freshwater. This can be a disturbance which alters community structure, decreasing populations or fecundity of those species intolerant of brackish water.

Component Associations:
- *Eleocharis rostellata - Rhynchospora colorata - Rhynchospora microcarpa* Herbaceous Vegetation (CEGL004951, G2?Q)
- *Sagittaria lancifolia - Glottidium vesicarium - Solidago sempervirens - Lythrum lineare* Herbaceous Vegetation (CEGL008447, G3G4)
- *Schoenoplectus californicus* Tidal Herbaceous Vegetation (CEGL003985, G4G5)
- *Typha domingensis* Tidal Herbaceous Vegetation (CEGL008456, GNR)
- *Zizaniopsis miliacea* Tidal Herbaceous Vegetation (CEGL004705, G3G5)

DISTRIBUTION

Range: Endemic to Florida from Wakulla County (Apalachicola Bay) to Pasco/Hernando county line, north of Tampa Bay.

FLORIDA BIG BEND SALT AND BRACKISH TIDAL MARSH (CES203.508)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9289

CONCEPT

Summary: This ecological system represents salt and brackish marshes of the northern Gulf of Mexico along the Florida Big Bend (roughly from Wakulla County [Apalachicola Bay] to the Pasco/Hernando county line [more or less to Tampa Bay] on Florida's west coast). The tidal range here is higher than in the western Panhandle, and wave energy is low; lunar, wind and seasonal tides make flooding irregular. The bulk of these marshes are comprised of monospecific stands of *Juncus roemerianus* that often exhibit tall- and short-growth zones. Patches of *Spartina alterniflora* are less common, and may be confined to the edges of creeks or in other pockets of low elevation. Small patches of *Distichlis spicata* may also be present near berms or levees.
Related Concepts:
- Tidal Marsh (FNAI 1990) Broader

DESCRIPTION

Environment: Irregularly tidal; wind, lunar, and seasonal influences are important.
Vegetation: This system consists of salt marshes characterized by *Spartina alterniflora, Juncus roemerianus,* and *Distichlis spicata* and brackish marshes dominated by *Juncus roemerianus*. The bulk of these marshes are comprised of monospecific stands of *Juncus roemerianus* that often exhibit tall- and short-growth zones. Patches of *Spartina alterniflora* are less common, and may be confined to the edges of creeks or in other pockets of low elevation. Small patches of *Distichlis spicata* may also be present near berms or levees (Montague and Wiegert 1990). The brackish marshes are in areas slightly higher than the salt marshes, where flooding is greater.
Dynamics: The tidal range here is higher than in the western Panhandle, and wave energy is low; lunar, wind and seasonal tides make flooding irregular (Montague and Wiegert 1990).

Component Associations:
- *Batis maritima - Sarcocornia pacifica* Dwarf-shrubland (CEGL003956, G5)
- *Juncus roemerianus* Herbaceous Vegetation (CEGL004186, G5)
- *Spartina alterniflora - Juncus roemerianus - Distichlis spicata* Louisianian Zone Salt Tidal Herbaceous Vegetation (CEGL004190, G5)

DISTRIBUTION

Range: This system is endemic to Florida from Wakulla County (Apalachicola Bay) to the Pasco/Hernando county line, north of Tampa Bay. (To the west of Apalachicola Bay, where the tides are diurnal instead of semi-diurnal, Mississippi Sound Salt and Brackish Tidal Marsh (CES203.303) replaces this system.)

FLORIDA KEYS SEAGRASS BED (CES411.285)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Aquatic Herb
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9270

CONCEPT

Summary: This system encompasses seagrass beds of Florida Bay and the Florida Keys. *Thalassia testudinum, Cymodocea filiformis (= Syringodium filiforme),* and *Halodule beaudettei* are the primary potential species. All three species may co-occur in mixed beds, or stands may be heavily dominated by *Thalassia testudinum* only. Some stands may be further characterized by high density and abundance of calcareous green algae.

Similar Ecological Systems:
- Atlantic Coastal Plain Indian River Lagoon Seagrass Bed (CES203.256)
- East Gulf Coastal Plain Florida Big Bend Seagrass Bed (CES203.244)
- Southwest Florida Seagrass Bed (CES203.274)

Related Concepts:
- Seagrass Bed (FNAI 1990) Broader

DESCRIPTION

Environment: The Florida Bay region is characterized by a peculiar depositional environment (Tanner 1960) with low wave energy, shallow waters, and prevalence of calcareous material. The extensive seagrass beds may form marine peats.
Vegetation: *Thalassia testudinum, Cymodocea filiformis,* and *Halodule* are the primary potential species. All three species may co-occur in mixed beds, while other areas may be heavily dominated by *Thalassia testudinum* only, such as Bob Allen Key and Duck Key (http://serc.fiu.edu/seagrass/!CDreport/DataHome.htm). Some stands may be further characterized by high density and abundance of calcareous green algae.

Component Associations:
- *Thalassia testudinum - Cymodocea filiformis* Herbaceous Vegetation (CEGL008384, GNR)
- *Thalassia testudinum* Herbaceous Vegetation (CEGL004319, G4?)

DISTRIBUTION

Range: Endemic to south Florida.

FLORIDA RIVER FLOODPLAIN MARSH (CES203.055)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9246

CONCEPT

Summary: This system occupies generally narrow, but widely fluctuating, zones of herbaceous vegetation along rivers of northeastern, central and southern Florida. *Cladium mariscus ssp. jamaicense* or *Panicum hemitomon* and *Polygonum punctatum* were apparently the historical dominant plant species, but a variety of other species may also be present. Plant species composition (including dominants) may vary seasonally or annually depending on inundation and fire history.
Classification Comments: Placing all component associations is difficult due to a number of factors; the current list (8-03) is incomplete.
Similar Ecological Systems:
- Floridian Highlands Freshwater Marsh (CES203.077)--is found on lakes and former lakes (i.e., Paynes Prairie) not on rivers.
- South Florida Slough, Gator Hole and Willow Head (CES411.485)

Related Concepts:
- Floodplain Marsh (FNAI 1990) Broader
- Floodplain Marsh (FNAI 2010a) Broader

DESCRIPTION

Environment: This system occupies non-tidal, generally narrow, but widely fluctuating, zones of freshwater herbaceous marsh vegetation along rivers of northeastern, central and southern Florida. These include the Myakka, St. Johns, Kissimmee, and perhaps Caloosahatchee rivers.
Vegetation: A relatively diverse assemblage of vegetation is present, ranging from open-water communities to emergent and graminoid marshes and scattered shrublands. See floristic list provided by Huffman and Judd (1998). In the absence of fire, portions of stands will become dominated by *Salix caroliniana*. If fire continues to be absent, these areas may succeed to *Acer rubrum* until a replacement fire or mechanical activity restores the marsh.
Dynamics: This system is subject to river flooding. In the absence of fire, portions of stands will become dominated by *Salix caroliniana*. If fire continues to be absent, these areas may succeed to *Acer rubrum* until a replacement fire or mechanical activity restores the marsh.

Component Associations:
- *Cephalanthus occidentalis / Limnobium spongia - Salvinia minima* Shrubland (CEGL004457, G3?)
- *Cladium mariscus ssp. jamaicense* Herbaceous Vegetation (CEGL003940, GNR)
- *Nelumbo lutea - Pontederia cordata - Schoenoplectus tabernaemontani* Herbaceous Vegetation (CEGL004470, G2G3)
- *Osmunda regalis var. spectabilis - Peltandra virginica - Sagittaria lancifolia* Herbaceous Vegetation (CEGL004471, G2?)
- *Panicum hemitomon - Pontederia cordata* Herbaceous Vegetation (CEGL004461, G3G4)
- *Salix caroliniana / Decodon verticillatus / Typha latifolia* Forest (CEGL004423, G2G3)
- *Salix caroliniana* Temporarily Flooded Coastal Plain Shrubland (CEGL007052, G4?)
- *Typha latifolia - Pontederia cordata* Herbaceous Vegetation (CEGL004462, G3?)

DISTRIBUTION

Range: This system is endemic to rivers of northeastern, central and southern Florida.
Divisions: 203:C; 411:C

FLORIDIAN HIGHLANDS FRESHWATER MARSH (CES203.077)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Depressional [Sinkhole]; Graminoid
Non-Diagnostic Classifiers: Herbaceous; Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2489; ESLF 9214; ESP 1489

CONCEPT

Summary: This system represents non-tidal marsh vegetation in the peninsula of Florida and in the Tallahassee area. These highland marshes occupy different types of depressions such as former lake basins, shallow peat-filled valleys, and zones around existing natural lakes. The marshes and the basins they occur within are unstable over time due to subsurface subsidence and drainage pattern changes. In some examples, surface waterflow is generally lacking due to the presence of limestone near the surface, but water levels have fluctuated greatly over time. Soils range from mucky surfaces to sandy loams or sands, but slowly permeable subsoils contribute to the presence of standing water for much of the year. The vegetation mosaic includes a range of mostly herbaceous plant communities that may be referred to as marshes, meadows, and prairies, collectively comprising a relatively diverse number of associations. Permanent water bodies support a range of submerged and floating aquatic species. Areas with approximately a meter of standing water tend to support dense stands of emergent herbaceous perennials, often in monospecific stands; species include *Typha latifolia, Pontederia cordata, Nelumbo lutea*, and others. Where there is less water (usually present only during wet season), more graminoid vegetation is present, with species such as *Panicum hemitomon, Leersia hexandra*, and other species. With historic water level fluctuations, the vegetation mosaic has also changed, sometimes quite rapidly.
Classification Comments: This system was originally intended to cover Paynes Prairie only, but the concept was greatly expanded to include other non-tidal marsh vegetation of Florida, including that around natural lakes, as well as the large Kissimmee and St. Johns River marshes. The Kissimmee and St. Johns River marshes also occur within floodplains but are influenced by somewhat different processes than typical highland marshes. These were formerly considered part of Florida River Floodplain Marsh (CES203.055).
Similar Ecological Systems:
- Florida River Floodplain Marsh (CES203.055)
- South Florida Slough, Gator Hole and Willow Head (CES411.485)

Related Concepts:
- Basin Marsh (FNAI 2010a) Broader
- Basin Marsh (FNAI 1990) Broader

DESCRIPTION

Environment: These highland marshes occupy different types of depressions such as former lake basins, shallow peat-filled valleys, and zones around existing natural lakes (Kushlan 1990). The marshes and the basins they occur within are unstable over time due to subsurface subsidence and drainage pattern changes. Soils range from mucky surfaces to sandy loams or sands, but slowly permeable subsoils contribute to the presence of standing water for much of the year.
Vegetation: A relatively diverse assemblage of vegetation is present, ranging from open water communities to emergent and graminoid marshes, and scattered shrublands. Placing all component associations is difficult due to a number of factors; the current list (12-02) is incomplete. In the absence of fire, portions of stands will become dominated by *Salix caroliniana.* If fire continues to be absent, these areas may succeed to *Acer rubrum* until a replacement fire or mechanical activity restores the marsh.
Dynamics: In some examples, surface waterflow is generally lacking due to the presence of limestone near the surface, but water levels have fluctuated greatly over time (Patton and Judd 1986). In the absence of fire, portions of stands will become dominated by *Salix caroliniana*. If fire continues to be absent, these areas may succeed to *Acer rubrum* until a replacement fire or mechanical activity restores the marsh. Paynes Prairie is a large permanently protected example of highland marsh. Water-control structures allow the manipulation of water levels in Paynes Prairie to achieve ecosystem management goals (Kushlan 1990).

Component Associations:
- *Andropogon (capillipes, glaucopsis) - Rhynchospora fascicularis var. fascicularis - Rhexia mariana* Herbaceous Vegetation (CEGL004460, G2?)
- *Cephalanthus occidentalis / Limnobium spongia - Salvinia minima* Shrubland (CEGL004457, G3?)
- *Cladium mariscus ssp. jamaicense* Herbaceous Vegetation (CEGL003940, GNR)
- *Nelumbo lutea - Pontederia cordata - Schoenoplectus tabernaemontani* Herbaceous Vegetation (CEGL004470, G2G3)
- *Osmunda regalis var. spectabilis - Peltandra virginica - Sagittaria lancifolia* Herbaceous Vegetation (CEGL004471, G2?)
- *Panicum hemitomon - Pontederia cordata* Herbaceous Vegetation (CEGL004461, G3G4)
- *Pontederia cordata* Seasonally Flooded Herbaceous Vegetation (CEGL004474, G3?)
- *Salix caroliniana / Decodon verticillatus / Typha latifolia* Forest (CEGL004423, G2G3)

- *Salix caroliniana* Temporarily Flooded Coastal Plain Shrubland (CEGL007052, G4?)
- *Spartina bakeri - Muhlenbergia filipes - Andropogon glomeratus - Rhynchospora colorata* Herbaceous Vegetation (CEGL004511, G3?)
- *Typha latifolia - Pontederia cordata* Herbaceous Vegetation (CEGL004462, G3?)

DISTRIBUTION

Range: This system is found in the Florida Peninsula and in the Tallahassee Hills/Valdosta Limesink area, possibly ranging into adjacent Georgia.

GREAT LAKES FRESHWATER ESTUARY AND DELTA (CES202.033)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Riverine / Alluvial; Tidal / Estuarine
Non-Diagnostic Classifiers: >180-day hydroperiod; Lowland [Lowland]; Temperate [Temperate Continental]
National Mapping Codes: ESLF 9268

CONCEPT

Summary: This system is found throughout the southern Great Lakes Basin in the United States and Canada. It can include many associated wetlands occurring along portions of tributary rivers and streams that are directly affected by Great Lakes water regimes. It also forms much of the St. Clair River delta. Species distributions and community patterns are determined by multiple abiotic factors, including the type of aquatic system (major river channels, smaller tributary rivers, major deltas, or estuarine), Great Lakes water-level fluctuations, surficial bedrock, glacial landform, climate, and land use. Although wetland species are generally widely distributed, those of more temperate prairie regions are found in the southern parts of the basin. Vegetation types found across this diverse set of abiotic factors can be placed into a number of zones, though not all are present at a given site. The first four zones are typically inundated directly by lake waters: (a) submergent marsh; (b) emergent marsh; (c) shore fen; and (d) shoreline or strand. The next set of zones are inland from the water's edge and include: (e) herbaceous and shrubby wet meadows and (f) shrub or wooded swamps.

This system can be divided into a number of geographical variants, based on the various community types found across the range of the system: (1) Lake Michigan Lacustrine Estuary; (2) Lake Erie-St. Clair Lakeplain Marsh; (3) Lake Ontario Lagoon Marsh; and (4) St Lawrence River Estuary.

Similar Ecological Systems:

- Northern Great Lakes Coastal Marsh (CES201.722)

DESCRIPTION

Environment: Species distributions and community patterns are determined by multiple abiotic factors. Great Lakes water-level fluctuations, surficial bedrock, glacial landform, climate, and land use. Great Lakes water level fluctuate over at least three temporal time scales: first, short-term fluctuations caused by winds or barometric pressures; second, seasonal fluctuations reflecting the annual hydrologic cycle in the basin; and third, interannual fluctuations in lake level as a result of variable precipitation and evaporation within the drainage basin. Interannual fluctuations can be as much as 1.3-2.5 m, with apparently little or no periodicity. These fluctuations, which also alter turbidity, nutrient availability, ice scour zones, etc., cause locational shifts in vegetation zones, but also in the composition of these zones, as species have individual tolerance limits.

The major bedrock distinction in the Great Lakes Basin is between igneous and metamorphic bedrock of the Precambrian period and younger (Paleozoic) sedimentary bedrock. The igneous and metamorphic bedrock form the rugged north shore of Lake Superior and Georgian Bay, and line much of the St. Lawrence River; they are locally present on the south shore of western Lake Superior. They lack the shallow protected waters and fine-textured substrates that support broad coastal wetlands. Where such bedrock is at or near the surface, it forms soils that are nutrient-poor and acidic. The rest of the basin is dominated by softer, sedimentary bedrock, which, with its broad, horizontal depositions, favors broad zones of shallow waters. The sedimentary rocks are typically more alkaline (calcareous), forming soils that are nutrient- and moisture-rich loams and clays. Bedrock patterns are overlaid by glacial landforms that, in combination with recent long-shore transport processes, create the prevalent physiographic features of the shorelines. In the lakes themselves, sand lakeplains, clay lakeplains, and moraines are shaped by currents, and the long-shore transportation of sediments has created sand-spit embayments and swales, dune-swale complexes, and tombolos. Channels and rivers contain channel-side wetlands, embayments, and deltas, and estuaries form as either open or barred river mouths. It is this diversity of landforms that has given rise to a diverse set of vegetation types.

Finally, regional patterns of climate affect the basin. The strong latitudinal gradient from southern Lake Erie to northern Lake Superior creates marked differences in length of growing season and solar radiation. Although wetland species are generally widely distributed, those of more temperate and prairie regions are found in the southern parts.

Vegetation: Vegetation types found across this diverse set of abiotic factors vary in any number of ways, but they can be placed into a number of zones, though not all are present at a given site. The first four zones are typically inundated directly by lake waters: (a) submergent marsh - containing submergent and/or floating vegetation; (b) emergent marsh - characterized by shallow water or semipermanently flooded soils, and typically dominated by bulrushes, cattails, and other emergent species, but also containing submergent and/or floating vegetation; (c) shore fen - saturated vegetation mats characterized by groundwater influence from shoreline habitats but affected by lake level fluctuations, and dominated by herbaceous or shrubby species; and (d) shoreline or strand - a narrow zone at or just above the water level where seasonal water-level fluctuations and waves cause erosion, and which is dominated by annual or pioneer herbaceous species. The next set of zones are inland from the water's edge and include: (e) herbaceous and shrubby wet meadows - characterized by saturated or seasonally flooded soils, and typically dominated by sedges, grasses, and

other herbs, but occasionally dominated by shrubs; and (f) shrub or wooded swamps - characterized by seasonal flooding and dominated by woody species. Species assemblages in these zones change depending on the interaction of factors across the Great Lakes Basin.

Component Associations:
- *Calamagrostis canadensis - Carex viridula - Cladium mariscoides - Lobelia kalmii* Herbaceous Vegetation (CEGL005115, G1G2)
- *Carex* spp. - *(Carex pellita, Carex vulpinoidea)* Herbaceous Vegetation (CEGL005272, GNR)
- *Nelumbo lutea* Herbaceous Vegetation (CEGL004323, G4?)
- *Nuphar advena - Nymphaea odorata* Herbaceous Vegetation (CEGL002386, G4G5)
- *Potamogeton zosteriformis - Ceratophyllum demersum - Elodea canadensis* Southern Great Lakes Shore Herbaceous Vegetation (CEGL005152, G3G4)
- *Typha* spp. - *Schoenoplectus tabernaemontani* - Mixed Herbs Southern Great Lakes Shore Herbaceous Vegetation (CEGL005112, G3G4)

DISTRIBUTION

Range: Throughout the southern Great Lakes Basin in the United States and Canada.
Divisions: 201:?; 202:C
Nations: CA, US

GULF COAST CHENIER PLAIN FRESH AND OLIGOHALINE TIDAL MARSH (CES203.467)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Freshwater]; Aquatic Herb; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9237

CONCEPT

Summary: This system includes large expanses of tidal marshes, strongly influenced by freshwater, along the Chenier Plain of Louisiana and Texas. Fresh to oligohaline marsh is the most common marsh type of the Chenier Plain because of the unique geomorphology of the area. The Chenier Plain is characterized by a prograding coastline replenished by sediments carried to the Gulf of Mexico by the Atchafalaya and other rivers. It is void of barrier islands, and shoreline sediments are reworked by waves into beach ridges. This process has been continuing since the last glacial retreat, and as the coastline progrades, older beach ridges are left as interior ridges surrounded by marsh. Historically, there were very few natural connections between the marshes and the ocean, resulting in a predominance of fresh to oligohaline salinity. This is a highly threatened system in coastal Louisiana.
Classification Comments: This system also includes some flotant marshes formerly recognized as a distinct ecological group.
Similar Ecological Systems:
- Mississippi Delta Fresh and Oligohaline Tidal Marsh (CES203.470)
- Texas Coast Fresh and Oligohaline Tidal Marsh (CES203.472)

Related Concepts:
- Chenier Plain: Fresh and Intermediate Tidal Marsh (5807) [CES203.541.7] (Elliott 2011) Finer
- Chenier Plain: Fresh and Intermediate Tidal Shrub Wetland (5806) [CES203.541.6] (Elliott 2011) Finer

DESCRIPTION

Environment: This system occupies coastal sites with mucky soils and salinities generally less than 4 ppt. Soils are recent alluvial deposits. It occurs along bay margins and outlets of coastal rivers where freshwater inflow is sufficient to drive marsh composition. Sites may be interspersed with areas of open water. Soils are saturated, very deep, mineral soils, often with high organic content, at least at the surface. Ecoclasses (from Ecological Site Descriptions) include various fresh and intermediate marsh types (Elliott 2011). Coastal Louisiana contains about "37% of the estuarine herbaceous marshes in the conterminous U.S." (Glick et al. 2013).
Vegetation: Dominant plant species are graminoids, including *Panicum hemitomon, Paspalum vaginatum, Zizaniopsis miliacea, Typha latifolia, Spartina patens, Schoenoplectus* spp., and *Phragmites australis*. Other wetland species such as *Sagittaria* spp., *Ludwigia* spp., and *Vigna luteola* may also be present. Some occurrences may have some woody cover with species such as *Iva frutescens* or *Baccharis halimifolia* (Elliott 2011).
Dynamics: Historically, the deltaic processes of the Mississippi River helped to build and maintain this system. Sediments brought to the coast by the Mississippi River and its distributaries were carried west along the coast by longshore currents. The shifting over time of the location of the Mississippi River deltas resulted in variations in sediment availability which, along with other coastal processes, caused an alternating prograding and retreating chenier plain coastline. Sediments were reworked into beach ridges that trapped freshwater flowing coastward off the mainland resulting in a chenier plain of beach ridges (cheniers) alternating with large expanses of fresh to oligohaline marshes. Today, sediments from the Atchafalaya River are again forming mudflats in the chenier plain but not to the extent that was associated with Mississippi River deltaic processes (Gosselink et al. 1998). One of the few areas of coastal accretion in Louisiana is located in the eastern Chenier Plain, a process fed by sediments from the Atchafalaya. Given the predominance of coastal loss and subsidence in Louisiana, the accretion of the eastern Chenier Plain is unusual (Gosselink et al. 1998, Draut et al. 2005). In addition to local rainfall, freshwater entering the chenier plain marshes comes from rivers and streams, and is dependent on functioning hydrological processes in those systems. This marsh system is dependent upon freshwater input, sediment input and organic matter build-up. Species richness is typically higher in oligohaline marshes than in brackish marshes. In addition to these natural barriers limiting waterflow, many human-made impoundments exist in the Chenier Plain. These impoundments tend to support fresh marsh because water loss through evapotranspiration is less than local rainfall (Gosselink et al. 1979).

Component Associations:
- *Panicum hemitomon* Semipermanently Flooded Herbaceous Vegetation (CEGL004665, G3G4)
- *Paspalum vaginatum - Spartina patens* Oligohaline Herbaceous Vegetation (CEGL007885, G2?)
- *Phragmites australis - (Sagittaria platyphylla, Vigna luteola)* Tidal Herbaceous Vegetation (CEGL007891, G4?)
- *Sagittaria lancifolia - Typha* spp. - *Ludwigia* spp. Herbaceous Vegetation (CEGL007894, G3G4)
- *Schoenoplectus americanus - (Spartina patens) - Typha* spp. Herbaceous Vegetation (CEGL008476, G3?)
- *Schoenoplectus californicus* Tidal Herbaceous Vegetation (CEGL003985, G4G5)
- *Spartina patens - Typha* spp. Chenier Plain Oligohaline Herbaceous Vegetation (CEGL007887, G3?)
- *Zizaniopsis miliacea - Panicum hemitomon* Herbaceous Vegetation (CEGL007895, G3G4)

SPATIAL CHARACTERISTICS

Spatial Summary: Typically in large patches but may also occur in small patches.

DISTRIBUTION

Range: This system extends from Vermillion Bay, Louisiana, through Jefferson County, Texas. It does not extend into Galveston Bay. Approximately 3000 square km of marshes were present in the Chenier Plain of Louisiana in 1997 and the majority of these were fresh to oligohaline marshes (Visser et al. 2000).

GULF COAST CHENIER PLAIN SALT AND BRACKISH TIDAL MARSH (CES203.468)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saltwater (Polyhaline); Brackish (Mesohaline); Tidal / Estuarine [Haline]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9240

CONCEPT

Summary: This system includes brackish to salt intertidal marshes in the Chenier Plain of Louisiana and Texas. This area was characterized historically by a prograding coastline replenished by sediments carried to the Gulf of Mexico by the Mississippi, Atchafalaya and other rivers. It is void of barrier islands. Shoreline sediments are deposited by longshore currents and reworked by waves into alternating beach ridges and mudflats depending on the amount of sediment input. This process started after the last glacial retreat and, as the coastline prograded over time, older beach ridges were left as interior ridges surrounded by marsh. Historically, natural connections between the marshes and the ocean were limited by these beach ridges, resulting in an abundance of fresh to oligohaline (intermediate) marsh, not as much brackish marsh, and even less salt marsh. In more recent times, with the increase of dredged canals connecting the marsh system to the gulf, an increase in salinity has occurred, to the detriment of plants adapted to freshwater environments. Significant fresh marsh loss has occurred in this area. Increases in salinity levels may be caused by saltwater intrusion and/or freshwater diversion. Both water level and salinity influence species composition. Salt marshes (about 16 ppt) receive regular daily tides and are typically dominated by *Spartina alterniflora*. Brackish marshes (about 8 ppt), under slightly less tidal influence and moderately influenced by freshwater, are typically dominated by *Spartina patens*, and degraded by saltwater intrusion. Brackish occurrences may be found along tidal creeks, smaller ponds and at the upper reaches of daily tides or in areas more influenced by wind tides. Inclusions of *Juncus roemerianus* and other brackish species are found in small to large patches. Through the control of the Mississippi River, historic chenier processes have been lost. Historically a progradational shoreline, today the Chenier Plain shoreline is dominated by erosion. However, coastal processes of progradation are still present in limited areas fed by sediments from the Atchafalaya River.

Similar Ecological Systems:
- Mississippi Delta Salt and Brackish Tidal Marsh (CES203.471)
- Texas Coast Salt and Brackish Tidal Marsh (CES203.473)

Related Concepts:
- Chenier Plain: Salt and Brackish High Tidal Marsh (5717) [CES203.468.17] (Elliott 2011) Finer
- Chenier Plain: Salt and Brackish High Tidal Shrub Wetland (5716) [CES203.468.16] (Elliott 2011) Finer
- Chenier Plain: Salt and Brackish Low Shrub Tidal Wetland (5706) [CES203.468.6] (Elliott 2011) Finer
- Chenier Plain: Salt and Brackish Low Tidal Marsh (5707) [CES203.468.7] (Elliott 2011) Finer

DESCRIPTION

Environment: Salt marshes on the Gulf Coast receive regular daily microtides. Brackish marshes, under slightly less tidal influence and moderately influenced by freshwater, are degraded by saltwater intrusion. This ecological system is found flanking large bays, along tidal creeks, between saltwater and fresh to oligohaline marshes, and in areas more influenced by wind tides. Examples are found on recent alluvial deposits of coastlines, bay margins, bay inlets, along dredged canals, creeks, and river inlets where tidal influence is adequate to maintain mesohaline to polyhaline conditions. Soils are fine-textured, sometimes with high organic content at the surface. Ecoclasses (from Ecological Site Descriptions) include brackish and salt marsh types in Texas (Elliott 2011). Though progradation has been reduced from the loss of sediment as a result of the control of the Mississippi River, the Chenier Plain is prograding in some places, most notably west of the mouth of the Atchafalaya River. Historically a progradational shoreline, the Chenier Plain shoreline is now dominated by erosion.

Vegetation: This typically herbaceous-dominated system has a species composition that varies depending on the salinity of the environment and the depth of frequent tidal flooding. Marshes that are frequently flooded by tides (low marshes) tend to be strongly dominated by *Spartina alterniflora*. Occasionally these sites may have significant cover of *Avicennia germinans*, though freezes tend to reduce the cover of mangrove. Some patches of *Juncus roemerianus* may be interspersed. Higher marshes of saline to brackish sites tend to be somewhat more diverse, with *Spartina patens* a common dominant. *Spartina alterniflora* may be present but is typically not strongly dominant. Other species that may be present or sometimes dominant include *Spartina spartinae, Distichlis spicata, Batis maritima, Salicornia* spp., *Schoenoplectus robustus, Schoenoplectus americanus, Paspalum vaginatum, Sporobolus virginicus*, and *Borrichia frutescens*. *Iva frutescens* and *Baccharis halimifolia* are commonly encountered woody species (Elliott 2011).

Dynamics: Historic natural processes of the Chenier Plain were tied to the deltaic processes of the Mississippi River and the natural hydrological processes of other rivers along the western coast of Louisiana and eastern coast of Texas. These natural processes have all been altered, but processes of freshwater and sediment input still persist even though in an altered state. Sediment input is critical to marsh persistence and becomes even more important under accelerated sea-level rise scenarios. Marsh vegetation plays an equally

important role in maintaining marsh elevation (Baustian et al. 2012). The Chenier Plain of Louisiana has unusually high relative sea-level rise (Draut et al. 2005). This is a microtidal environment. Salt and brackish marshes are important habitats for many animal species.

Component Associations:
- *Borrichia frutescens / (Spartina patens, Juncus roemerianus)* Shrubland (CEGL003924, G4)
- *Iva frutescens ssp. frutescens - Baccharis halimifolia / Spartina spartinae* Shrubland (CEGL004616, G4?)
- *Juncus roemerianus* Herbaceous Vegetation (CEGL004186, G5)
- *Sarcocornia pacifica* - (*Batis maritima, Distichlis spicata*) Dwarf-shrubland (CEGL002278, G4)
- *Spartina alterniflora - Distichlis spicata - Spartina patens* Mesohaline Tidal Herbaceous Vegetation (CEGL002230, G4?)
- *Spartina alterniflora - Juncus roemerianus - Distichlis spicata* Louisianian Zone Salt Tidal Herbaceous Vegetation (CEGL004190, G5)
- *Spartina patens - Schoenoplectus (americanus, pungens) - (Distichlis spicata)* Herbaceous Vegetation (CEGL004755, G4?)
- *Spartina spartinae - Sporobolus virginicus* Tidal Herbaceous Vegetation (CEGL004199, G4G5)
- *Typha domingensis* Tidal Herbaceous Vegetation (CEGL008456, GNR)

DISTRIBUTION

Range: This system extends from Vermillion Bay, Louisiana, to East Bay, Texas. Salt marsh is limited to areas fringing saltwater shorelines. Brackish marshes are found landward of the salt marshes (typically between fresh to oligohaline marshes and salt marshes) and are more prominent around coastal lakes.

HAWAI'I ANCHIALINE POOL (CES412.420)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Brackish (Mesohaline); Shrubland (Shrub-dominated); Shoreline; Sinkhole; Grassland, Savanna, Steppe (graminoid-dominated); Lava; Depressional
Non-Diagnostic Classifiers: Lowland [Lowland]; Herbaceous; Basalt; Tropical/Subtropical [Tropical Pluvial]; Tropical/Subtropical [Tropical Pluviseasonal]; Tropical/Subtropical [Tropical Xeric]; Tidal / Estuarine [Freshwater]; Tidal / Estuarine [Haline]; Salt Spray; Coast
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2801; ESLF 9438; ESP 1801

CONCEPT

Summary: This ecological system is composed of rare, land-locked, often brackish pools with indirect subterranean connections to the ocean. They occur on the coasts of Hawai'i, Maui, Moloka'i, O'ahu, and Kaho'olawe with most of the pools occurring on the Big Island. The pools are found on relatively recent lava flows or on uplifted corral beds (limestone). Fresh surface water and groundwater mix with seawater to create different salinity levels with and among pools. Water levels in pools may fluctuate with tidal changes, although delayed depending on the hydraulic conductivity of the substrates. Vegetation is limited and includes a variety of algae (green, blue-green, red) and emergent vegetation including *Carex* spp., *Sesuvium portulacastrum*, and *Thespesia populnea*. The fauna is most distinctive and includes many endemic and native crustaceans (shrimps (*Halocaridina rubra*), prawns, amphipods, and isopods), small fish, and invertebrates such as the orange-black damselfly (*Megalagrion xanthomelas*), which is a rare, anchialine pool endemic.

DESCRIPTION

Environment: This ecological system is composed of rare, land-locked, often brackish pools with indirect subterranean connections to the ocean. They occur on the coasts of Hawai'i, Maui, Moloka'i, O'ahu, and Kaho'olawe with most of the pools occurring on the Big Island. Climate is variable depending on which coast the pools occur and ranges from arid to moderately wet (Zones 1-6) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). The pools are found on relatively recent lava flows or on uplifted corral beds (limestone). Fresh surface water and groundwater mix with seawater to create different salinity levels with and among pools. Water levels in pools may fluctuate with tidal changes, although delayed depending on the hydraulic conductivity of the substrates.
Vegetation: The vegetation of this ecological system is very limited and includes a variety of algae (green, blue-green, red) and emergent vegetation including *Carex* spp., *Sesuvium portulacastrum*, and *Thespesia populnea*. The fauna is most distinctive and includes many endemic and native crustaceans (shrimps (*Halocaridina rubra*), prawns, amphipods, and isopods), small fish, and invertebrates such as the orange-black damselfly (*Megalagrion xanthomelas*), which is a rare, anchialine pool endemic.

HAWAI'I BOG (CES412.216)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Impermeable Layer; Saturated Soil; Peat and mud; Tropical/Subtropical [Tropical Pluvial]; Depressional; Isolated Wetland [Strictly Isolated]; Organic Peat (>40 cm); Muck; Bog
Non-Diagnostic Classifiers: Montane; Lowland; Herbaceous; Seepage-Fed Sloping; Extensive Wet Flat
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2806; ESLF 9286; ESP 1806

CONCEPT

Summary: Hawai'i Bog occurs primarily between 1067 and 1670 m (3500-5500 feet) elevation as isolated small patches on flat or gently sloping topography in high rainfall areas in cloud forests and other wet forests on all of the high islands. This bog system also occurs in the subalpine zone at 2270 m (7446 feet) elevation on Maui, and as a low-elevation bog at 646 m (2120 feet) on Kaua'i. Soils remain saturated on a shallow to deep layer of peat (0.01-5 m), underlain by an impervious basal clay layer that impedes drainage. A few sloping bogs occur on steeper terrain were precipitation is extremely high, such as in North Bog in the Wai'ale'ale summit region of Kaua'i, where soils remain saturated despite adequate drainage. Two bogs are believed to have formed in former small lakes, one along the Wailuku River, Hawai'i (Treeless bog), the other the subalpine bog on East Maui (Flat Top bog). The low-elevation bog on Kaua'i occurs on shallow, poorly drained acidic peat. Bogs are characterized by an uneven hummocky matrix of sedges and grasses (*Oreobolus furcatus, Carex* spp., *Rhynchospora* spp., *Dichanthelium* spp.) and stunted woody plants including *Metrosideros* spp. (ohi'a), *Coprosma ochracea* (pilo), and (*Dubautia* spp. (na'ena'e). Dwarfed or stunted woody plants can occur as scattered individuals, in clumps, or as a continuous layer. Associated ferns and herbs include *Dicranopteris linearis, Sadleria* spp., *Polypodium* spp., *Hymenophyllum* spp., *Elaphoglossum* spp., *Athyrium* spp., *Schizaea robusta, Selaginella deflexa, Plantago* spp., *Astelia* spp., *Viola* spp., *Machaerina* spp., *Lysimachia* spp., and on Kaua'i, the boreal catchfly *Drosera anglica*.

DESCRIPTION

Environment: Clay formation in Hawaiian bogs is typically a result of basaltic weathering under cool, wet conditions that permits an accumulation of humus. Climate is generally very wet (Zones 7) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). Annual precipitation typically is over 4500 mm. On flat and gently sloping terrain, the clay formation impedes drainage resulting in perched water on top of the clay. In addition, it has now been established that eolian clay mineral deposits accumulated on broad summits and ridges within high rainfall and cloud areas over a 200,000- to 500,000-year time span have also contributed to the formation of clay substrates that support Hawaiian bogs.
Vegetation: Bogs are characterized by an uneven hummocky matrix of sedges and grasses (*Oreobolus furcatus, Carex* spp., *Rhynchospora* spp., *Dichanthelium* spp.) and stunted woody plants including *Metrosideros* spp., *Coprosma ochracea*, and *Dubautia* spp. Dwarfed or stunted woody plants can occur as scattered individuals, in clumps, or as a continuous layer. Associated ferns and herbs include *Sadleria* spp., *Polypodium* spp., *Hymenophyllum* spp., *Elaphoglossum* spp., *Athyrium* spp., *Schizaea robusta, Selaginella deflexa, Plantago* spp., *Astelia* spp., *Viola* spp., *Machaerina* spp., *Lysimachia* spp., and on Kaua'i, the boreal catchfly *Drosera anglica*.
Dynamics: All bogs are threatened by feral pig rooting followed by invasion of exotic sedges (*Cyperus* spp.) and colonization by grasses (*Andropogon virginicus, Schizachyrium condensatum*). Fencing at a few bogs has been shown to arrest damage, by keeping pigs away.

Component Associations:
- *Metrosideros polymorpha / Rhynchospora* spp. / *Dicranopteris linearis* Mixed Lowland Bog Dwarf-shrubland (CEGL008080, G1)
- *Metrosideros polymorpha* Mixed Montane Bog Dwarf-shrubland (CEGL008081, G2)

DISTRIBUTION

Range: This system is found near mountain summits on Kaua'i, O'ahu, Moloka'i, and West Maui (Selling 1948, Carlquist 1980), on high-rainfall windward slopes of East Maui, and on windward slopes of the Kohala Mountains, Mauna Kea, and Mauna Loa on Hawai'i Island.

HAWAI'I FRESHWATER AQUATIC BED (CES412.225)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Pond; Depressional [Pond]; Aquatic Herb
Non-Diagnostic Classifiers: Montane; Lowland; Herbaceous; Tropical/Subtropical
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Hydromorphic-rooted grassland
National Mapping Codes: EVT 2803; ESLF 9245; ESP 1803

CONCEPT

Summary: This freshwater aquatic bed system is permanently flooded and characterized by submerged, partially submerged or floating vegetation lacking structural support. This system is found in reservoirs, ponds, pools, slow-moving streams, irrigation ditches, canals, and open bodies of water surrounded by freshwater marshes. Mean water depths of these habitats are too great for rooted emergent plants. Habitats may be subject to water level fluctuations greater than 1 m (3 feet) and to regular or intermittent exposure at extreme low tides. Vegetation consists entirely of floating and submerged aquatics. Many of the dominant species may remain dormant/dry part of the year and complete their reproductive cycle during the wet part of the year. *Potamogeton foliosus* and *Potamogeton nodosus* are characteristic of this system.

DESCRIPTION

Dynamics: Aquatic bed plants serve as important food sources for waterfowl and are bird-dispersed. This system is threatened by alien and naturalized species, including *Ceratophyllum demersum, Eichhornia crassipes, Hydrocotyle verticillata, Lemna perpusilla, Ludwigia palustris, Monochoria vaginalis, Myriophyllum aquaticum, Pistia stratiotes*, and *Spirodela polyrrhiza*.

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Hawai'i Floodplain Forest (CES412.221)
- Hawai'i Riparian Forest and Shrubland (CES412.220)

DISTRIBUTION

Range: This system occurs in coastal areas to 1220 m (4000 feet) elevation on Kaua'i, O'ahu, Maui, and Hawai'i.

HAWAI'I FRESHWATER MARSH (CES412.222)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Marsh; Tropical/Subtropical; Seepage-Fed Sloping; Depressional [Pond]; Riverine / Alluvial; Tidal / Estuarine
Non-Diagnostic Classifiers: Floodplain; Lowland [Lowland]; Herbaceous; Riverine / Alluvial [Brownwater]; Tidal / Estuarine [Oligohaline]; Basin
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2804; ESLF 9299; ESP 1804

CONCEPT

Summary: Freshwater marshes occur on the northwestern Hawaiian Islands and throughout the main islands as a mostly small-patch system confined to limited areas in floodplain or basin topography. This system occupies estuaries, surrounds open bodies of water, occurs in former ponds, and sometimes along streams and springs. Water levels in freshwater marshes fluctuate seasonally, but they usually retain standing water most of the year. Soils range from silty clays to deep gley mucks to loams and sand over less permeable subsoils. Vegetation is dominated by emergent herbaceous bulrushes, sedges and grasses, including *Schoenoplectus maritimus (= Bolboschoenus maritimus), Cyperus* spp., *Schoenoplectus* spp., and *Urochloa mutica (= Brachiaria mutica)*. Forbs include *Bacopa monnieri* and *Ludwigia octovalvis*. Introduced species include *Typha latifolia* and the subshrub *Pluchea indica*. In a few locations known to formerly support bodies of water on Hawai'i (Waimanu Valley) and O'ahu (Kawai Nui marsh and at Ka'au Crater), marsh vegetation is dominated by *Cladium mariscus ssp. jamaicense (= Cladium jamaicense)*. This system interfaces with saline tidal marsh in windward estuaries, where species from both freshwater and saltwater marshes coexist. This system serves as important habitat for endemic and migratory waterbirds.
Classification Comments: This system does not include bogs where sphagnum moss develop as the substrate. This type may be historic. Known stands are largely converted to introduced wetland. Invasive species are a serious threat to all wetlands in Hawai'i.

DESCRIPTION

Environment: Freshwater marshes occur as a mostly small-patch system confined to limited areas in floodplain or basin topography. This system occupies estuaries, surrounds open bodies of water, occurs in former ponds, and sometimes along streams and springs. Water levels in freshwater marshes fluctuate seasonally, but they usually retain standing water most of the year. Climate is variable depending on where the stand occurs, ranging from arid to very wet (Zones 1-7) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). Soils range from silty clays to deep gley mucks to loams and sand over less permeable subsoils.
Vegetation: Vegetation is dominated by emergent herbaceous bulrushes, sedges and grasses, including *Schoenoplectus maritimus (= Bolboschoenus maritimus), Cyperus* spp., *Schoenoplectus* spp., and *Urochloa mutica (= Brachiaria mutica)*. Forbs include *Bacopa monnieri* and *Ludwigia octovalvis*. Introduced species include *Typha latifolia* and the subshrub *Pluchea indica*. In a few locations known to formerly support bodies of water on Hawai'i (Waimanu Valley) and O'ahu (Kawai Nui marsh and at Ka'au Crater), marsh vegetation is dominated by *Cladium mariscus ssp. jamaicense (= Cladium jamaicense)*.
Dynamics: Nearly all occurrences have been cultivated in the past. Agricultural and alien-species pressures continue to degrade this system and diminish its ability to provide suitable habitat for wildlife.

Component Associations:
- *Bolboschoenus* spp. - *Schoenoplectus* spp. - *Cyperus laevigatus* Coastal Wet Herbaceous Vegetation (CEGL008093, G4)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Northern Polynesia Tidal Salt Marsh (CES412.224)

Adjacent Ecological System Comments: This system interfaces with saline tidal marsh in windward estuaries, where species from both freshwater and saltwater marshes coexist.

DISTRIBUTION

Range: This system occurs from sea level up to 500 m (1640 feet) elevation on Laysan, Kaua'i, O'ahu, Moloka'i, LÃ¢na'i, Maui, and Hawai'i.
Divisions: 412:C
Nations: US

INTER-MOUNTAIN BASINS ALKALINE CLOSED DEPRESSION (CES304.998)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Saline Water Chemistry; Herbaceous; Depressional [Mineral]; Isolated Wetland [Partially Isolated]; Depression
National Mapping Codes: ESLF 9297

CONCEPT

Summary: This ecological system occurs on in playas that are seasonally to semipermanently flooded, usually retaining water into the growing season and drying completely only in drought years. Many are associated with hot and cold springs, located in basins with internal drainage. Soils are alkaline to saline clays with hardpans. Seasonal drying exposes mudflats colonized by both annual and perennial wetland vegetation. Salt encrustations can occur on the surface in some examples of this system, and the soils are severely affected and have poor structure. Species that typify this system are salt-tolerant and halophytic species such as *Distichlis spicata, Puccinellia lemmonii, Poa secunda, Muhlenbergia* spp., *Leymus triticoides (= Elymus triticoides), Schoenoplectus maritimus, Schoenoplectus americanus, Triglochin maritima,* and *Salicornia* spp. During exceptionally wet years, an increase in precipitation can dilute the salt concentration in the soils of some examples of this system which may allow for less salt-tolerant species to occur. Communities found within this system may also occur in floodplains (i.e., more open depressions), but probably should not be considered a separate system unless they transition to areas outside the immediate floodplain. Types often occur along the margins of perennial lakes, in alkaline closed basins, with extremely low-gradient shorelines. This system is very similar to Western Great Plains Closed Depression Wetland (CES303.666).

Similar Ecological Systems:
- Western Great Plains Closed Depression Wetland (CES303.666)

Related Concepts:
- Other Sagebrush Types (408) (Shiflet 1994) Intersecting. *Artemisia cana ssp. bolanderi* shrublands are included in this ecological system.

DESCRIPTION

Environment: This system occurs in cooler context than the playas found further south in the southern Great Basin and Mojave/Sonoran deserts. This ecological system occurs on sites that are seasonally to semipermanently flooded, usually retaining water into the growing season and drying completely only in drought years. Many are associated with hot and cold springs, located in basins with internal drainage. Soils are alkaline to saline clays with hardpans. Seasonal drying exposes mudflats colonized by annual wetland vegetation. The soils are severely affected by salts and have poor structure. This system is distinct from the freshwater depression systems by its brackish nature caused by strongly saline soils. Salt encrustations could occur near the surface in some examples of this system.

Vegetation: Species that typify this system are salt-tolerant and halophytic species such as *Distichlis spicata, Puccinellia lemmonii, Poa secunda, Muhlenbergia* spp., *Leymus triticoides (= Elymus triticoides), Schoenoplectus maritimus, Schoenoplectus americanus, Triglochin maritima,* and *Salicornia* spp. It also supports many Federally-listed plant species.

Dynamics: This ecological system is primarily driven by hydrological processes. It occurs on sites that are seasonally to semipermanently flooded, usually retaining water into the growing season, drying completely only in drought years. Increases in precipitation and/or runoff can dilute the salt concentration and allow for less salt-tolerant species to occur.

Component Associations:
- *Artemisia tridentata ssp. tridentata / Leymus cinereus* Shrubland (CEGL001016, G2)
- *Distichlis spicata* Herbaceous Vegetation (CEGL001770, G5)
- *Eleocharis palustris - Distichlis spicata* Herbaceous Vegetation (CEGL001834, G2G4)
- *Eleocharis palustris - Juncus balticus* Herbaceous Vegetation (CEGL001835, G2G4)
- *Leymus triticoides - Poa secunda* Herbaceous Vegetation (CEGL001572, G2)
- *Leymus triticoides* Herbaceous Vegetation (CEGL001571, G4?)
- *Poa secunda - Muhlenbergia richardsonis* Herbaceous Vegetation (CEGL002755, GNR)
- *Puccinellia lemmonii - Poa secunda* Seasonally Flooded Herbaceous Vegetation (CEGL001658, G1)
- *Schoenoplectus americanus - Eleocharis palustris* Herbaceous Vegetation (CEGL001585, G4)

DISTRIBUTION

Range: This system can occur throughout the Columbia Plateau and the northern Great Basin but is most common in eastern Oregon and northern Nevada. It occurs in the Wyoming basins (central Wyoming) where it is surrounded by sage steppe systems.

INTER-MOUNTAIN BASINS INTERDUNAL SWALE WETLAND (CES304.059)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Dune (Landform); Dune field; Dune (Substrate); Temperate [Temperate Xeric]; Depressional; Isolated Wetland [Partially Isolated]; Sand Soil Texture; W-Landscape/High Intensity; Graminoid
Non-Diagnostic Classifiers: Dune (undifferentiated); Lowland [Lowland]; Shrubland (Shrub-dominated); Herbaceous; Temperate [Temperate Continental]; Aridic
National Mapping Codes: ESLF 9235

CONCEPT

Summary: This ecological system occurs within dune fields in the Intermountain western U.S. as small (usually less than 0.1 ha) interdunal wetlands that occur in wind deflation areas, where sands are scoured down to the water table. Small ponds may be associated. The water table may be perched over an impermeable layer of caliche or clay or, in the case of the Great Sand Dunes of Colorado, a geologic dike that creates a closed basin that traps water. These wetland areas are typically dominated by common emergent herbaceous vegetation such as species of *Eleocharis, Juncus*, and *Schoenoplectus*. Dune field ecological processes distinguish these emergent wetlands from similar non-dune wetlands.
Classification Comments: This system was originally included within Inter-Mountain Basins Active and Stabilized Dune (CES304.775). These small-scale wetlands were pulled out into their own system because they are isolated wetlands and support completely different biota than the surrounding dry dunes. Many dune fields in the Great Basin are associated with playas and playa lakes such as Washoe Lake, Great Salt Lake, and Mono Lake. At Great Sand Dunes National Monument, Colorado, isolated interdunal swale wetlands occur where winds scour sand to expose wet sand at the water table, largely on the west side (windward) of the main dune field. The same groundwater source also feeds springs that form intermittent creeks that are not part of this interdunal swale system.

DESCRIPTION

Environment: Occurs in wet interdunal swales.
Vegetation: A variety of emergent herbaceous vegetation may occur including, *Juncus balticus, Schoenoplectus pungens, Typha* spp., *Cyperus* spp., *Eleocharis* spp., and *Salix exigua*.
Dynamics: The dunes are shaped by the wind and continue to change. The size and exact location of the wet swales may change as the sand dunes shift, due to active dune migration. Dune "blowouts" and subsequent stabilization through succession are characteristic processes of the active dunes which surround the interdunal swales.

Component Associations:
- *Carex nebrascensis* Herbaceous Vegetation (CEGL001813, G4)
- *Carex utriculata* Herbaceous Vegetation (CEGL001562, G5)
- *Juncus balticus* Herbaceous Vegetation (CEGL001838, G5)
- *Salicornia rubra* Herbaceous Vegetation (CEGL001999, G2G3)
- *Schoenoplectus acutus* Herbaceous Vegetation (CEGL001840, G5)
- *Schoenoplectus americanus - Carex* spp. Herbaceous Vegetation (CEGL004144, GNR)
- *Schoenoplectus americanus - Eleocharis palustris* Herbaceous Vegetation (CEGL001585, G4)
- *Schoenoplectus americanus - Eleocharis* spp. Herbaceous Vegetation (CEGL001586, GNR)
- *Schoenoplectus americanus* Western Herbaceous Vegetation (CEGL001841, G3Q)
- *Schoenoplectus maritimus* Herbaceous Vegetation (CEGL001843, G4)
- *Schoenoplectus pungens* Herbaceous Vegetation (CEGL001587, G3G4)
- *Typha (latifolia, angustifolia)* Western Herbaceous Vegetation (CEGL002010, G5)
- *Typha domingensis* Western Herbaceous Vegetation (CEGL001845, G5?)

SPATIAL CHARACTERISTICS

Spatial Summary: Small patch.
Adjacent Ecological Systems:
- Inter-Mountain Basins Active and Stabilized Dune (CES304.775)

Adjacent Ecological System Comments: This wetland system occurs in wet swales within Inter-Mountain Basins Active and Stabilized Dune (CES304.775).

DISTRIBUTION

Range: The system occurs in some dune fields across the Intermountain western U.S., including the Great Sand Dunes in southern Colorado and the Pink Coral Dunes in Utah. Interdunal wetlands may also occur in dune fields in northeastern Arizona and the Great Basin, as well as in southwestern Wyoming in the Killpecker Dunes and Ferris Dunes, and southern Idaho.

INTERIOR LOW PLATEAU SEEPAGE FEN (CES202.346)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Seepage-Fed Sloping
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated)
National Mapping Codes: ESLF 9409

CONCEPT

Summary: This system accommodates small-scale, herbaceous-dominated seepage areas found in limited areas of the Interior Low Plateau of Tennessee, Kentucky and possibly Ohio. It is most frequent in the Western Highland Rim of Tennessee (Lewis, Cheatham, and Williamson counties). There are also rare occurrences of this system in the Eastern Highland Rim of Tennessee and related limited areas of Kentucky and possibly Ohio (D. Minney pers. comm. 2006). These features have been generally known as "seepage fens" and are fed by mineral-rich groundwater. Examples are associated with stream drainages but are generally not affected by stream-related hydrology. Soils contain a thin organic layer over limestone gravel, over a less permeable layer of more solid rock. The vegetation is dominated by herbaceous plants. Characteristic species include *Carex atlantica, Carex lurida, Carex leptalea ssp. harperi, Parnassia grandifolia, Juncus brachycephalus, Rudbeckia fulgida var. umbrosa, Cardamine bulbosa, Impatiens capensis, Juncus coriaceus, Juncus effusus, Lobelia puberula, Lobelia cardinalis, Oxypolis rigidior, Phlox glaberrima, Rhynchospora capitellata, Scirpus atrovirens, Scirpus cyperinus, Solidago patula var. patula,* and *Thelypteris palustris var. pubescens*. Woody species include *Alnus serrulata, Salix humilis, Salix caroliniana, Cornus amomum,* and *Acer rubrum,* which may invade the herbaceous seep. *Xyris tennesseensis* is endemic to this system and occurs in 50% or more of its occurrences.
Classification Comments: This system is a small-patch system, originally described from a small region. Its range has been expanded to include a greater geographic scope.
Similar Ecological Systems:
- North-Central Appalachian Seepage Fen (CES202.607)
- Ozark-Ouachita Fen (CES202.052)
- Southern Ridge and Valley Seepage Fen (CES202.458)

Related Concepts:
- *Carex lurida (hystericina?) - Carex leptalea - Rhynchospora capillacea* Alkaline Seep (Minney 2000) Undetermined
- Calcareous Seep (Evans 1991) Finer

DESCRIPTION

Environment: These features are fed by mineral-rich groundwater. Stands occur on the sideslopes of hills in narrow valleys, bases of bluffs, rock ledges, and terraces of streams and rivers, where the soil or substrate is saturated by calcareous groundwater seepage. Examples are associated with stream drainages but are generally not affected by stream-related hydrology. The parent material is a mixture of gravel and dolomite with fragments of deeply weathered bedrock present or colluvium over bedrock. Soils contain a thin organic layer over limestone gravel, over a less permeable layer of more solid rock.
Vegetation: The vegetation is dominated by herbaceous plants. Characteristic species include *Carex atlantica, Carex lurida, Carex leptalea ssp. harperi, Parnassia grandifolia, Juncus brachycephalus, Rudbeckia fulgida var. umbrosa, Cardamine bulbosa, Impatiens capensis, Juncus coriaceus, Juncus effusus, Lobelia puberula, Lobelia cardinalis, Oxypolis rigidior, Phlox glaberrima, Rhynchospora capitellata, Scirpus atrovirens, Scirpus cyperinus, Solidago patula var. patula,* and *Thelypteris palustris var. pubescens*. Woody species include *Alnus serrulata, Salix humilis, Salix caroliniana, Cornus amomum,* and *Acer rubrum*. Some stands in southern Ohio may lack *Parnassia* (D. Minney pers. comm. 2006).

Component Associations:
- *Alnus serrulata* Saturated Southern Interior Shrubland (CEGL007059, G3)
- *Carex lurida - Carex leptalea - Parnassia grandifolia - Juncus brachycephalus - (Xyris tennesseensis)* Herbaceous Vegetation (CEGL004161, G1)

DISTRIBUTION

Range: This system is found in limited areas of the Interior Low Plateau of Tennessee, Kentucky and possibly Ohio, including primarily the Western Highland Rim region of Tennessee (Ecoregion 71f of Griffith et al. (1998), EPA (2004); Subsection 222Eg of Keys et al. (1995)).

LAURENTIAN-ACADIAN FRESHWATER MARSH (CES201.594)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shallow (<15 cm) Water; >180-day hydroperiod; Depressional [Lakeshore]; Riverine / Alluvial; Graminoid
Non-Diagnostic Classifiers: Circumneutral Water; Acidic Water; Moderate (100-500 yrs) Persistence; Herbaceous; Extensive Wet Flat; Depressional [Pond]; Muck; Aquatic Herb
National Mapping Codes: ESLF 9405

CONCEPT

Summary: These freshwater emergent and/or submergent marshes are dominated by herbaceous vegetation. They are common throughout the northeastern United States and adjacent Canadian provinces. Freshwater marshes occur in closed or open basins that are generally flat and shallow. They are associated with lakes, ponds, slow-moving streams, and/or impoundments or ditches. The herbaceous vegetation does not persist through the winter. Scattered shrubs are often present and usually total less than 25% cover. Trees are generally absent and, if present, are scattered. The substrate is typically muck over mineral soil. Examples of vegetation in the Delaware Estuary freshwater marsh communities include *Typha latifolia, Typha angustifolia, Phragmites australis, Schoenoplectus americanus, Thelypteris palustris, Impatiens capensis, Carex* spp., *Vallisneria americana, Potamogeton perfoliatus, Nuphar advena (= Nuphar lutea ssp. advena),* and *Nymphaea odorata*.

LAURENTIAN-ACADIAN WET MEADOW-SHRUB SWAMP (CES201.582)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shallow (<15 cm) Water; Depressional [Lakeshore]; Riverine / Alluvial; Broad-Leaved Shrub; Graminoid
Non-Diagnostic Classifiers: Circumneutral Water; Acidic Water; Moderate (100-500 yrs) Persistence; Herbaceous; Extensive Wet Flat; Depressional [Pond]; Muck
National Mapping Codes: ESLF 9406

CONCEPT

Summary: This system encompasses shrub swamps and wet meadows on mineral soils of the Northeast and upper Midwest. They are often associated with lakes and ponds, but are also found along streams, where the water level does not fluctuate greatly. They are commonly flooded for part of the growing season but often do not have standing water throughout the season. The size of occurrences ranges from small pockets to extensive acreages. The system can have a patchwork of shrub and graminoid dominance; typical species include *Salix* spp., *Cornus amomum*, *Alnus incana*, *Spiraea alba*, *Calamagrostis canadensis*, tall *Carex* spp., and *Juncus effusus*. Trees are generally absent and, if present, are scattered.
Classification Comments: Compared to North-Central Interior Wet Meadow-Shrub Swamp (CES202.701), this system is more often dominated by *Alnus* spp. rather than the *Cornus* spp. dominance of the latter.
Similar Ecological Systems:
- Laurentian-Acadian Freshwater Marsh (CES201.594)
- North-Central Interior Wet Meadow-Shrub Swamp (CES202.701)

MEDITERRANEAN CALIFORNIA COASTAL INTERDUNAL WETLAND (CES206.951)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shallow (<15 cm) Water; Sand Subsoil Texture; Coastal Dune Mosaic; Herbaceous; Mediterranean [Mediterranean Xeric-Oceanic]; Depressional [Pond]; Mineral: W/ A-Horizon <10 cm; Graminoid
Non-Diagnostic Classifiers: Dune field; Saturated Soil; Very Short Flooding Interval; 1-29-day hydroperiod; Short (50-100 yrs) Persistence; Lowland [Lowland]; Slough; Swale; Isolated Wetland [Partially Isolated]; Barrier flat; Forb; Aquatic Herb
National Mapping Codes: ESLF 9262

CONCEPT

Summary: Coastal interdunal wetlands are common components of larger active and stabilized coastal dune fields, ranging from Coos Bay, Oregon, south to San Luis Obispo County, California. They can be referred to as "slack dune ponds" when associated with larger and deeper water or "coastal dune swales" when water is shallow, and typically occur behind active foredunes, especially where the base of the dunes are at or near groundwater levels. They may result from active dune movement, sometimes when dunes interrupt surface waterflow, or where extensive dune "blowouts" remove sand down to the water table. Seasonal rise in the water table from winter rains are one source of pond formation and wet swale formation. Water tends to be fresh but may grade to brackish as ponds dry up. This ecosystem is defined as herbaceous, emergent vegetation. Common plant species include *Argentina anserina (= Potentilla anserina), Hydrocotyle umbellata, Eleocharis palustris, Eleocharis acicularis, Euthamia occidentalis, Juncus* spp., *Carex obnupta*, and *Sparganium* spp.
Related Concepts:
- Wetlands (217) (Shiflet 1994) Broader

DESCRIPTION

Environment: Interdunal ponds occur where water is shallow, and typically occur behind active foredunes, especially where the base of the dunes are at or near groundwater levels. They may result from active dune movement, sometimes when dunes interrupt surface waterflow, or where extensive dune "blowouts" remove sand down to the water table. Lakes within dune sheets occur in deflated areas where the water table is intercepted, typically shallow and subject to seasonal changes in water levels (Christy et al. 1998).
Dynamics: Dune sands have poor moisture-holding capacity. They are underlain by groundwater aquifers that maintain a high water table (Christy et al. 1998). Winter precipitation elevates the water table and inundates some deflation plains to a depth of 1 m (3 feet). The seasonal rises in water table also cause interdunal swale ponds to form (Christy et al. 1998). Some ponds dry up seasonally, others are permanent features of the dune sheet. But all ponds have seasonal fluctuations in the water depth and consequently pond size (Christy et al. 1998, Pickart and Barbour 2007). These coastal freshwater marshes are unique in that they are also subject to salt spray, and therefore have more salt-tolerant species than freshwater marshes not associated with coastal sand dunes (Christy et al. 1998, Pickart 2006, Pickart and Barbour 2007).

DISTRIBUTION

Range: This system is found in Coos Bay, Oregon, south to San Luis Obispo County, California. In California dune swales are present at Tomales Bay, Point Reyes, Bodega Bay and Tolowa Dunes (Pickart and Barbour 2007).

MEDITERRANEAN CALIFORNIA EELGRASS BED (CES206.999)

CLASSIFIERS

Classification Status: Standard

Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saline Water Chemistry; Mediterranean [Mediterranean Pluviseasonal-Oceanic]; Mediterranean [Mediterranean Xeric-Oceanic]; Mediterranean [Mediterranean Desertic-Oceanic]; Aquatic Herb; Marine Algae
Non-Diagnostic Classifiers: >180-day hydroperiod; Short (50-100 yrs) Persistence; Lowland [Lowland]; Herbaceous
National Mapping Codes: ESLF 9266

CONCEPT

Summary: Intertidal zones are found with clear water in bays, inlets and lagoons, typically dominated by macrophytic algae and marine aquatic angiosperms along the temperate Pacific Coast. Subtidal portions are never exposed, while intertidal areas support species that can tolerate exposure to the air. Common substrates include marine silts, but may also include exposed bedrock and cobble, where many algal species become attached with holdfasts. Intertidal systems are dominated by *Zostera marina (= Zostera pacifica), Phyllospadix scouleri, Fucus distichus, Postelsia palmiformis*, and a host of green and brown algae. Adjacent subtidal zones, where rocky substrates are common, support undersea kelp "forest."

DISTRIBUTION

Range: This system is found along the temperate Pacific Coast.

MEDITERRANEAN CALIFORNIA SERPENTINE FEN (CES206.953)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Ultramafic; Bog and Fen Mosaic; Moss/Lichen (Nonvascular); Mediterranean [Mediterranean Pluviseasonal-Oceanic]; Seepage-Fed Sloping; Organic Peat (>40 cm); Bryophyte; Darlingtonia californica
Non-Diagnostic Classifiers: Acidic Water; Montane; Lowland; Shrubland (Shrub-dominated); Herbaceous; Forb; Graminoid
National Mapping Codes: ESLF 9255

CONCEPT

Summary: This ecological system is found uncommonly throughout coastal lowlands and high mountains of the Klamath Mountains and surrounding landscapes where serpentine soils are common in cool and moist environments. This system includes unique assemblages of wetlands species restricted to serpentine and ultramafic substrates. These sites remain moist or wet throughout the year and may have substantial *Sphagnum* accumulation. Some may be bogs in the sense of nutrients and moisture primarily coming from rainfall, or more commonly they are seeps or fens maintained by groundwater discharge. Soils are acidic and often derived from ultramafic parent materials. The acidic (6.5-6.7 pH) and nutrient-poor substrates produce severe nitrogen deficiency which favors insectivorous plants. Characteristic plant species include *Darlingtonia californica*, *Drosera rotundifolia*, *Eleocharis quinqueflora*, *Eriophorum crinigerum*, *Carex californica*, and *Deschampsia caespitosa*. Around the edges of these fens *Chamaecyparis lawsoniana* can occur and form part of the fen. Burning is essential to maintain healthy stands. *Darlingtonia* fens are important habitat for rare species that respond positively to burning. Burning at least eliminates some of the tree invaders (*Pinus jeffreyi*, *Pseudotsuga menziesii*, *Chamaecyparis lawsoniana*) and maintains a high water table, essential for the fen-dependent plants.

DESCRIPTION

Environment: This system comprises wetlands located on serpentine soils, where a layer of sphagnum moss overlays serpentine soils and parent material. Soils are acidic and often derived from ultramafic parent materials. The acidic (6.5-6.7 pH) and nutrient-poor substrates produce severe nitrogen deficiency.
Dynamics: Consistently high water table and spring flows to maintain wet soils, water quantity and quality are very important, and stable groundwater, surface water, or precipitation inputs are crucial for continual integrity of these organic soils.

Component Associations:
- *Chamaecyparis lawsoniana / Rhododendron occidentale / Carex* spp. Temporarily Flooded Forest (CEGL000047, G2)

DISTRIBUTION

Range: This system is found uncommonly throughout coastal lowlands and high mountains of the Klamath Mountains of California and Oregon and surrounding landscapes where serpentine soils are common in cool and moist environments.

MEDITERRANEAN CALIFORNIA SUBALPINE-MONTANE FEN (CES206.952)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Circumneutral Water; Extreme (Mineral) Rich and Iron-Rich; Bog and Fen Mosaic; Temperate [Temperate Oceanic]; Seepage-Fed Sloping; Muck
Non-Diagnostic Classifiers: Saturated Soil; Long (>500 yrs) Persistence; Montane [Upper Montane]; Montane [Montane]; Herbaceous; Moss/Lichen (Nonvascular); Organic Peat (>40 cm); Forb; Graminoid; Bryophyte
National Mapping Codes: ESLF 9248

CONCEPT

Summary: This system is found in montane to subalpine elevations confined to specific environments defined by groundwater discharge, soil chemistry, and peat accumulation. This system includes extreme rich fens which are quite rare. Fens form at low points in the landscape or near slopes where groundwater intercepts the soil surface. Groundwater inflows maintain a fairly constant water level year-round, with water at or near the surface most of the time. Constant high water levels lead to accumulation of organic material. In addition to peat accumulation and perennially saturated soils, the extreme rich fens have distinct soil and water chemistry, with high levels of one or more minerals such as calcium and/or magnesium. They usually occur as a mosaic of several plant associations dominated by species of *Carex*, *Betula*, *Kobresia*, or *Schoenoplectus*. The surrounding landscape may be ringed with other wetland systems, e.g., riparian shrublands, or a variety of upland systems from grasslands to forests.
Related Concepts:
- Wetlands (217) (Shiflet 1994) Broader

DISTRIBUTION

Range: These fens are found in montane to subalpine elevations of California mountains, in the Sierra Nevada, northwestern California coastal mountains, and possibly the Klamath - Siskiyou mountains.

MISSISSIPPI DELTA FRESH AND OLIGOHALINE TIDAL MARSH (CES203.470)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Freshwater]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9241

CONCEPT

Summary: This system includes tidal marshes strongly influenced by freshwater producing a fresh to oligohaline chemistry. These areas can occupy small to large patches of the Mississippi Delta. A unique type of floating fresh marsh (flotant) is also included in this system. This system has a heterogeneous physiognomy including shrublands, grasslands, and aquatic herbs. Significant fresh marsh loss has occurred in the deltaic plain of the Mississippi River. These losses are related to natural and anthropogenic causes. Subsidence and loss of wetlands are a natural part of the deltaic process, but they have been exacerbated by the reduction in sediment load and freshwater input into coastal areas caused by the impoundment and channelization of streams and rivers. In addition dredged channels in the marsh facilitate saltwater intrusion, and spoil banks prevent marshes from draining. Increases in salinity cause shifts in composition to species more tolerant of salinity, ultimately resulting in loss of species diversity and open saline waters.

Similar Ecological Systems:
- Gulf Coast Chenier Plain Fresh and Oligohaline Tidal Marsh (CES203.467)

DESCRIPTION

Environment: This system occurs in the Mississippi River deltaic plain where freshwater inflow is greatest - near the mouths of distributary channels for the Mississippi River and near the mainland where freshwater flow from upland runoff and smaller creeks and rivers enters the marshes.

Vegetation: Species found in examples of this system include *Colocasia esculenta, Eleocharis baldwinii, Eleocharis rostellata, Hydrocotyle ranunculoides, Hydrocotyle umbellata, Ludwigia* spp., *Morella cerifera, Panicum hemitomon, Paspalum vaginatum, Phragmites australis, Sagittaria lancifolia, Sagittaria latifolia, Sagittaria platyphylla, Schoenoplectus californicus, Spartina patens, Vigna luteola, Typha domingensis*, and *Zizaniopsis miliacea*.

Dynamics: Historically, the deltaic processes of the Mississippi River helped to build and maintain this system. Today, in addition to the large fresh to oligohaline marshes that hug the mainland, two active deltas, the Atchafalaya and the Mississippi Balize deltas, support fresh to oligohaline marshes areas. However, these areas of sediment accumulation and accretion are an anomaly compared to the predominance of coastal loss and subsidence in the Mississippi River deltaic plain (Gosselink et al. 1998, Draut et al. 2005). The natural sediment load and freshwater entering the deltaic marshes are dependent on functioning hydrological processes in the Mississippi River. This marsh system is dependent upon freshwater input, sediment input and organic matter build-up. Species richness is typically higher in oligohaline marshes than in brackish marshes. Much of this system is characterized by floating mats of vegetation (Visser et al. 1998). Some studies suggest that marshes may convert to floating mats as a result of rapid subsidence.

Component Associations:
- *Eleocharis baldwinii - Hydrocotyle (ranunculoides, umbellata)* Herbaceous Vegetation (CEGL007893, G3G4Q)
- *Eleocharis rostellata - Sagittaria lancifolia* Oligohaline Herbaceous Vegetation (CEGL007886, G3G4)
- *Morella cerifera - Panicum hemitomon* Flotant Marsh Herbaceous Vegetation (CEGL007834, G2G3)
- *Panicum hemitomon* Semipermanently Flooded Herbaceous Vegetation (CEGL004665, G3G4)
- *Paspalum vaginatum - Spartina patens* Oligohaline Herbaceous Vegetation (CEGL007885, G2?)
- *Phragmites australis - (Sagittaria platyphylla, Vigna luteola)* Tidal Herbaceous Vegetation (CEGL007891, G4?)
- *Sagittaria lancifolia - Typha* spp. - *Ludwigia* spp. Herbaceous Vegetation (CEGL007894, G3G4)
- *Sagittaria lancifolia* Mississippi River Deltaic Plain Herbaceous Vegetation (CEGL007889, G3G4)
- *Sagittaria latifolia - Sagittaria platyphylla - (Colocasia esculenta)* Deltaic Herbaceous Vegetation (CEGL007890, G3G4)
- *Schoenoplectus californicus* Tidal Herbaceous Vegetation (CEGL003985, G4G5)
- *Spartina patens - Vigna luteola* Mississippi River Deltaic Plain Herbaceous Vegetation (CEGL007888, G3G4)
- *Typha domingensis* Tidal Herbaceous Vegetation (CEGL008456, GNR)
- *Zizaniopsis miliacea - Panicum hemitomon* Herbaceous Vegetation (CEGL007895, G3G4)
- *Zizaniopsis miliacea* Tidal Herbaceous Vegetation (CEGL004705, G3G5)

DISTRIBUTION

Range: This system occurs in the Mississippi River deltaic plain. Marshes in the Mississippi River deltaic plain encompass 22% of the marshes in the conterminous U.S. and about half of these are fresh to oligohaline marshes (Gosselink 1984, Visser et al. 1998).

MISSISSIPPI DELTA SALT AND BRACKISH TIDAL MARSH (CES203.471)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saltwater (Polyhaline); Brackish (Mesohaline); Tidal / Estuarine [Haline]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9242

CONCEPT

Summary: This system includes brackish to saline intertidal marshes in the Mississippi Delta area of Louisiana. Both water level and salinity influence species composition. The salt marsh component of this system receives regular daily tides; these areas are typically dominated by large to extensive expanses of *Spartina alterniflora*. Brackish marshes, under slightly less tidal influence and moderate freshwater influence, are typically dominated or codominated by *Spartina patens* and may cover larger expanses than salt marshes in this system. Inclusions of *Juncus roemerianus* and other brackish species are found in small to large patches. Significant brackish marsh loss has occurred in the deltaic plain of the Mississippi River. These losses are related to natural and anthropogenic causes. Subsidence and loss of wetlands are a natural part of the deltaic process, but they have been exacerbated by the reduction in sediment load into coastal areas caused by the impoundment and channelization of the Mississippi River. In addition dredged channels in the marsh facilitate saltwater intrusion, and spoil banks prevent marshes from draining. Increases in salinity cause shifts in composition to species more tolerant of salinity, ultimately resulting in loss of species diversity and potentially open saline waters when marsh accretion is outpaced by a rising sea level.

Similar Ecological Systems:
- Gulf Coast Chenier Plain Salt and Brackish Tidal Marsh (CES203.468)

DESCRIPTION

Environment: This system occurs in the Mississippi River deltaic plain. Salt marshes in this system receive regular daily microtides. Brackish marshes, under slightly less tidal influence and moderately influenced by freshwater, are degraded by saltwater intrusion. This ecological system is found flanking large bays, along tidal creeks, between saline waters and fresh to oligohaline marshes, and in areas more influenced by wind tides. Examples are found on recent alluvial deposits of coastlines, bay margins, bay inlets, along dredged canals, creeks, and river inlets where tidal influence is adequate to maintain high salinities. Soils are fine-textured, sometimes with high organic content at the surface. Historically, these marshes have been protected from the Gulf of Mexico by a series of barrier islands associated with different delta lobes. With the alteration of the Mississippi River deltaic processes, these islands are undergoing increasing deterioration with potential negative effects on the marshes they protect.

Dynamics: Historically, the deltaic processes of the Mississippi River helped to build and maintain this system. However, today there is a predominance of coastal loss and subsidence in the Mississippi River deltaic plain (Gosselink et al. 1998, Draut et al. 2005). The natural sediment load and freshwater entering the deltaic marshes are dependent on functioning hydrological processes in the Mississippi River. This marsh system is dependent upon freshwater input, sediment input and organic matter build-up. Historically, these marshes have been protected from the Gulf of Mexico by a series of barrier islands associated with different delta lobes. With the alteration of the Mississippi River deltaic processes, these islands are undergoing increasing deterioration with potential negative effects on the marshes they protect. Sediment input is critical to marsh persistence and becomes even more important under accelerated sea-level rise scenarios. Salt and brackish marshes are important habitats for many animal species.

Component Associations:
- *Avicennia germinans / Spartina alterniflora* Shrubland (CEGL003801, G2?)
- *Juncus roemerianus* Herbaceous Vegetation (CEGL004186, G5)
- *Sarcocornia pacifica* - (*Batis maritima, Distichlis spicata*) Dwarf-shrubland (CEGL002278, G4)
- *Spartina alterniflora - Distichlis spicata - Spartina patens* Mesohaline Tidal Herbaceous Vegetation (CEGL002230, G4?)
- *Spartina alterniflora - Juncus roemerianus - Distichlis spicata* Louisianian Zone Salt Tidal Herbaceous Vegetation (CEGL004190, G5)
- *Spartina patens - Schoenoplectus (americanus, pungens) - (Distichlis spicata)* Herbaceous Vegetation (CEGL004755, G4?)

DISTRIBUTION

Range: This system is confined to the deltaic plain of Louisiana. Marshes in the Mississippi River deltaic plain encompass approximately 20% of the marshes in the conterminous U.S. and about half of these are salt and brackish marshes (Gosselink 1984, Field et al. 1991, Visser et al. 1998, Hester et al. 2005).

MISSISSIPPI SOUND FRESH AND OLIGOHALINE TIDAL MARSH (CES203.067)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Freshwater]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9271

CONCEPT

Summary: This system includes fresh and oligohaline tidal marshes of the northern Gulf of Mexico region of northwestern Florida, southern Alabama, and southeastern Mississippi. These marshes are typically associated with mud-bottomed bays behind barrier islands. Wind-dominated tides and low tidal amplitudes (<1 meter) characterize this region. Diverse freshwater marshes dominate this system. Some typical and dominant graminoids include *Eleocharis rostellata, Rhynchospora colorata, Rhynchospora microcarpa, Schoenoplectus californicus*, and *Zizaniopsis miliacea*. Stands of *Typha domingensis* may also be present in some stands. More information is needed.

Similar Ecological Systems:
- North-Central Gulf of Mexico Salt and Brackish Tidal Marsh (CES203.303)

Related Concepts:
- Floodplain Marsh - Tidal Freshwater Marsh (FNAI 2010a) Broader
- Tidal Freshwater Marsh (Wieland 2000b) Equivalent

DESCRIPTION

Environment: This marsh system occurs in a region characterized by diurnal tides, with waves usually less than 0.5 m in amplitude. Inundation is irregular and depends upon wind speed and direction and the flow of water from nearby rivers; generally more flooding occurs in the summer than winter (Hackney and de la Cruz 1982). The climate is mixed, with subtropical conditions prevailing during years with mild winters and temperate conditions when strong arctic cold fronts extend to the gulf.

Vegetation: Diverse freshwater marshes dominate this system. Some typical and dominant graminoids include *Eleocharis rostellata, Rhynchospora colorata, Rhynchospora microcarpa, Schoenoplectus californicus*, and *Zizaniopsis miliacea*. Some other herbs include *Sagittaria lancifolia, Glottidium vesicarium, Solidago sempervirens*, and *Lythrum lineare*. *Typha domingensis* may also be present in some stands.

Component Associations:
- *Eleocharis rostellata - Rhynchospora colorata - Rhynchospora microcarpa* Herbaceous Vegetation (CEGL004951, G2?Q)
- *Panicum virgatum - (Cladium mariscus ssp. jamaicense, Juncus roemerianus)* Herbaceous Vegetation (CEGL004962, G3?)
- *Sagittaria lancifolia - Glottidium vesicarium - Solidago sempervirens - Lythrum lineare* Herbaceous Vegetation (CEGL008447, G3G4)
- *Schoenoplectus californicus* Tidal Herbaceous Vegetation (CEGL003985, G4G5)
- *Typha domingensis* Tidal Herbaceous Vegetation (CEGL008456, GNR)
- *Zizania aquatica* Gulf Coast Herbaceous Vegetation (CEGL003887, G4?)
- *Zizaniopsis miliacea* Tidal Herbaceous Vegetation (CEGL004705, G3G5)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- North-Central Gulf of Mexico Salt and Brackish Tidal Marsh (CES203.303)

DISTRIBUTION

Range: This system is found along the northern Gulf of Mexico in northwestern Florida, southern Alabama, and southeastern Mississippi, from Bourne Lake on the west to Cape San Blas on the east. The eastern extent of this system coincides with the range of diurnal tides in the northern Gulf of Mexico. East of Apalachicola Bay, the tides are semi-diurnal (Stout 1984), and Florida Big Bend Fresh and Oligohaline Tidal Marsh (CES203.507) replaces this system. To the west, Mississippi Delta Fresh and Oligohaline Tidal Marsh (CES203.470) replaces this system in the Mississippi Delta.

MODOC BASALT FLOW VERNAL POOL (CES204.996)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Impermeable Layer; 1-29-day hydroperiod; Vernal Pool Mosaic; Depressional
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Montane [Montane]; Montane [Lower Montane]; Herbaceous; Mediterranean [Mediterranean Xeric-Oceanic]; Temperate [Temperate Oceanic]; Isolated Wetland [Strictly Isolated]; Consolidated
National Mapping Codes: ESLF 9264

CONCEPT

Summary: This system includes shallow ephemeral waterbodies found in very small depressions (typically no larger than 50 square meters) throughout the Lassen, Klamath, and upper Pit river drainages, as well as the Devils Garden area of northern California, and along the eastern flanks of the Columbia River Gorge along the Oregon-Washington border. These vernal pools are located on top of massive basalt flows where soils are very thin over solid bedrock. Where soils are better developed, they trend towards Vertisols (freeze-thaw characteristics). Characteristic species include *Blennosperma nanum, Epilobium densiflorum (= Boisduvalia densiflora), Callitriche marginata, Cicendia quadrangularis, Eryngium vaseyi, Psilocarphus brevissimus*, and *Sedella pumila (= Parvisedum pumilum). Artemisia cana ssp. bolanderi* can occur on better developed soils. Endemic plant species *Eryngium mathiasiae*, as well as several species of *Mimulus* and *Pogogyne*, may occur.
Related Concepts:
- Wetlands (217) (Shiflet 1994) Broader

DESCRIPTION

Environment: These vernal pools are located on top of massive basalt flows where soils are very thin over solid bedrock. Where soils are better developed, they trend towards Vertisols (with freeze-thaw characteristics).
Dynamics: Vernal pools are precipitation-filled seasonal wetlands inundated during the growing season, allowing for plant growth, followed by a brief water-logged terrestrial stage and culminating in complete drying of surface and subsurface soils. Inundation during the growing season eliminates establishment of upland species in the pool basins and the dry period prevents the establishment of many typical wetland taxa (Keeley and Zedler 1998). Pool filling is a combination of direct precipitation (Solomeshch et al. 2007). Soils are shallow over basalt that prevents drainage. What is unique about vernal pools is the seasonality of the wetting period followed by the desiccation period, which generally is supported by a Mediterranean climate (Keeley and Zedler 1998). Natural fire regimes for vernal pools are generally unknown, but are assumed to be similar to their surrounding upland grassland fire regimes (Wills 2006). Fire can have a positive effect on vernal pool vegetation as it can results in robust response by native grasses and can reduce non-native invasive woody and non-native herbaceous species (Pollak and Kan 1998).

DISTRIBUTION

Range: Throughout the Lassen, Klamath, and upper Pit river drainages, as well as the Devils Garden area of northern California, and along the eastern flanks of the Columbia River Gorge along the Oregon-Washington border.

NORTH AMERICAN ARID WEST EMERGENT MARSH (CES300.729)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Deep (>15 cm) Water; Saturated Soil; Herbaceous; Depressional [Lakeshore]; Depressional [Pond]; Mineral: W/ A-Horizon >10 cm; Aquatic Herb; Graminoid
Non-Diagnostic Classifiers: Clay Subsoil Texture; Floodplain; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Marsh; Oxbow; Pond; Backwater; Temperate [Temperate Continental]; Forb; Alga; Drainage bottom (undifferentiated)
National Mapping Codes: ESLF 9222

CONCEPT

Summary: This widespread ecological system occurs throughout much of the arid and semi-arid regions of western North America, typically surrounded by savanna, shrub-steppe, steppe, or desert vegetation. Natural marshes may occur in depressions in the landscape (ponds, kettle ponds), as fringes around lakes, and along slow-flowing streams and rivers (such riparian marshes are also referred to as sloughs). Marshes are frequently or continually inundated, with water depths up to 2 m. Water levels may be stable, or may fluctuate 1 m or more over the course of the growing season. Water chemistry may include some alkaline or semi-alkaline situations, but the alkalinity is highly variable even within the same complex of wetlands. Marshes have distinctive soils that are typically mineral, but can also accumulate organic material. Soils have characteristics that result from long periods of anaerobic conditions in the soils (e.g., gleyed soils, high organic content, redoximorphic features). The vegetation is characterized by herbaceous plants that are adapted to saturated soil conditions. Common emergent and floating vegetation includes species of *Scirpus* and/or *Schoenoplectus, Typha, Juncus, Potamogeton, Polygonum, Nuphar*, and *Phalaris*. This system may also include areas of relatively deep water with floating-leaved plants (*Lemna, Potamogeton*, and *Brasenia*) and submerged and floating plants (*Myriophyllum, Ceratophyllum*, and *Elodea*).
Classification Comments: This ecological system occurs in the arid and semi-arid regions of western North America, where semipermanently flooded habitats are found as small patches in the matrix of a relatively dry landscape. Except for stands in the semi-arid portions of the western Great Plains, emergent marsh found in the Great Plains should be classified into one of the Western Great Plains depressional wetland systems.
Similar Ecological Systems:
- Western Great Plains Closed Depression Wetland (CES303.666)
- Western Great Plains Open Freshwater Depression Wetland (CES303.675)
- Western Great Plains Saline Depression Wetland (CES303.669)

Related Concepts:
- Wooded Potholes and Basins (Jahrsdoerfer and Leslie 1988) Finer

DESCRIPTION

Environment: Natural marshes may occur in depressions in the landscape (ponds, kettle ponds), as fringes around lakes, and along slow-flowing streams and rivers (such riparian marshes are also referred to as sloughs). Marshes are frequently or continually inundated, with water depths up to 2 m. Water chemistry may include some alkaline or semi-alkaline situations, but the alkalinity is highly variable even within the same complex of wetlands. Marshes have distinctive soils that are typically mineral, but can also accumulate organic material. Soils have characteristics that result from long periods of anaerobic conditions in the soils (e.g., gleyed soils, high organic content, redoximorphic features).
Dynamics: Water levels may be stable, or may fluctuate 1 m or more over the course of the growing season. Some marshes draw down completely on an annual or semi-annual cycle, or longer 5-20 year cycle. During the "dry" period, different plant species may become established, encouraging seedlings and discouraging others, in fact, allowing for natural changes in water levels leads to higher diversity of structure and composition of the marsh ecosystems (Mitsch and Gosselink 2000). Fire also has profound effects on marsh vegetation (Kirby et al. 1988). Literature on the specifics of natural fire frequency and effects in western U.S. non-tidal wetlands is very limited (Kirby et al. 1988, Clark and Wilson 2001).

NORTH AMERICAN BOREAL FRESHWATER AQUATIC BED (CES103.125)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Boreal (103)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Aquatic Herb
Non-Diagnostic Classifiers: Lake; Pond; Herbaceous; Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Hydromorphic-rooted grassland
National Mapping Codes: EVT 2627; ESLF 9433; ESP 1627

CONCEPT

Summary: Freshwater aquatic beds are found at all elevations below timberline throughout boreal Alaska, the montane boreal of western Canada, and the boreal plains into eastern Canada. This system is small patch in size and confined to lakes, ponds, and slow-moving portions of rivers and streams. In large bodies of water, it is usually restricted to the littoral region where penetration of light is the limiting factor for growth. Bodies of water may be deep or shallow. A variety of rooted or floating-aquatic herbaceous species may dominate, including *Nuphar polysepala (= Nuphar lutea ssp. polysepala)*, *Nuphar variegata*, *Nymphaea tetragona*, *Potamogeton* spp., *Lemna minor*, *Lemna trisulca*, *Spirodela polyrrhiza*, *Sparganium* spp., *Ranunculus* spp., *Myriophyllum* spp., *Hippuris vulgaris*, *Brasenia schreberi*, and *Callitriche* spp.
Classification Comments: This system is known as Boreal Freshwater Aquatic Bed by the Alaska Natural Heritage Program. All aquatic beds throughout the boreal region of North America are combined into this one ecological system. Floristics, environmental settings and successional trajectories are the same across this huge area, so there is no reason to keep boreal Alaska as a separate system from boreal Canada. In addition, freshwater aquatic beds found in the arctic might be included in this, but that remains to be worked out.
Similar Ecological Systems:
- Alaska Arctic Freshwater Aquatic Bed (CES102.182)
- Aleutian Freshwater Aquatic Bed (CES105.234)
- Western North American Boreal Freshwater Emergent Marsh (CES105.123)

- III.D.1.h - Cryptogam (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: Freshwater aquatic beds occur in permanently flooded depressions, shallow ponds, and the littoral zone of lakes. Soils are mineral or muck (National Wetlands Working Group 1997).
Vegetation: A variety of rooted or floating aquatic herbaceous species may dominate, including *Nuphar polysepala (= Nuphar lutea ssp. polysepala)*, *Potamogeton* spp., *Lemna minor*, *Sparganium* spp., and *Ranunculus* spp. Other common species include *Myriophyllum* spp., *Hippuris vulgaris*, *Isoetes tenella (= Isoetes muricata)*, and *Callitriche* spp. (Ritchie et al. 1981, Hogan and Tande 1983, Tande 1983, Talbot et al. 1984, Rosenburg 1986, Jorgenson et al. 1999, 2001a, 2001b, 2003, Gracz et al. 2005). Deep ponds (>3 m) often feature *Nuphar polysepala*, while species such as *Hippuris vulgaris* and *Sparganium* spp. often grow in shallower water (5-50 cm). Several of the shallow-water species are facultative aquatics and can survive in wet muck soils during periods of low water (Viereck et al. 1992).
Dynamics: Freshwater aquatic beds are early-successional wetlands and will likely be replaced by marshes, wet meadows, fens, or floating bog mats (Viereck et al. 1992). Aquatic beds form in shallow water in ponds and lake margins including kettles, oxbow lakes, and thaw ponds (Racine et al. 1998, Jorgenson et al. 2001a, 2001b, 2003).

NORTH AMERICAN WARM DESERT CIENEGA (CES302.747)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Alkaline Water; Lowland [Lowland]; Seep; Seepage-Fed Sloping [Mineral]
Non-Diagnostic Classifiers: Herbaceous; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Aquatic Herb; Graminoid
National Mapping Codes: ESLF 9284

CONCEPT

Summary: This ecological system occurs at low elevations (<2000 m) across the warm deserts of western North America. "CiÃ©negas" are freshwater spring-fed wetlands, characterized by non-fluctuating shallow surface water; the term ciÃ©nega was applied to riparian marshlands by Spanish explorers. CiÃ©negas are characterized by permanently saturated, highly organic, reducing soils and a relatively simple flora dominated by low-statured herbaceous hydrophytes (water-loving plants), with only occasional patches of trees. Evaporation often creates saline conditions especially on the margins as evidenced by salt-tolerant species such as *Distichlis spicata* and *Sporobolus airoides*. Typically, low-elevation examples are too warm to accumulate a deep organic layer. The type of vegetation depends on depth of water. In shallow margins, emergent plants typical of riparian vegetation are present including species of *Carex*, *Juncus*, and *Schoenoplectus*. In adjacent deeper waters, emergent marsh can be characteristic. The hydrology is controlled by permanently saturated hydrosols, with reducing conditions limiting the type of plant life that may grow there. The dense vegetation can slow surface waterflow, reducing the erosive power of flood waters and increase sedimentation within the ciÃ©nega. Soils can have many meters of organic deposition. Plant life is limited to low shallow-rooted semi-aquatic sedges such as *Eleocharis* spp., Juncus spp., *Carex* spp., a few grasses, and more rarely, *Typha* spp. Forbs include *Hydrocotyle verticillata* and *Ludwigia repens (= Ludwigia natans)*, which can be rooted in patches of gravel below organic root zone in pool bottoms. Few trees and shrubs may be present but may include *Salix gooddingii*, *Populus fremontii*, *Fraxinus velutina*, and *Cephalanthus occidentalis*.

DESCRIPTION

Environment: This spring-fed marsh ecosystem occurs at mid to low elevations (<2000 m [6562 feet]) across the warm deserts of western North America. "CiÃ©negas" are freshwater spring-fed wetlands, characterized by non-fluctuating shallow surface water (PAG 2001, Stromberg et al. 2009). CiÃ©negas are characterized by permanently saturated, highly organic, reducing soils (Hendrickson and Minckley 1984, Stromberg et al. 2009, Stevens et al. 2012).

Vegetation: CiÃ©negas are characterized by permanently saturated, highly organic, reducing soils and a relatively simple flora dominated by low-statured herbaceous hydrophytes (water-loving plants), with only occasional patches of trees (Hendrickson and Minckley 1984, Stromberg et al. 2009, Stevens et al. 2012). Evaporation often creates saline conditions especially on the margins as evidenced by salt-tolerant species such as *Distichlis spicata* and *Sporobolus airoides*. Typically, low-elevation examples are too warm to accumulate a deep organic layer. The type of vegetation depends on depth of water. In shallow margins, emergent plants typical of riparian vegetation are present including species of *Carex*, *Juncus*, and *Schoenoplectus*. In adjacent deeper waters, emergent marsh can be characteristic. The hydrology is controlled by permanently saturated hydrosols, with reducing conditions limiting the type of plant life that may grow there. The dense vegetation can slow surface waterflow, reducing the erosive power of flood waters and increase sedimentation within the ciÃ©nega. Soils can have many meters of organic deposition (Stromberg et al. 1996). Plant life is limited to low shallow-rooted semi-aquatic sedges such as *Eleocharis* spp., Juncus spp., *Carex* spp., a few grasses, and more rarely, *Typha* spp. (Stromberg et al. 2009, Stevens et al. 2012). Forbs include *Hydrocotyle verticillata* and *Ludwigia repens (= Ludwigia natans)*, which can be rooted in patches of gravel below organic root zone in pool bottoms (Stromberg et al. 2009, Stevens et al. 2012). Few trees and shrubs may be present but may include *Salix gooddingii*, *Populus fremontii*, *Fraxinus velutina*,and *Cephalanthus occidentalis* (Stromberg et al. 2009, Stevens et al. 2012).

Dynamics: CiÃ©negas described here are isolated spring-fed wetlands found at the outer edge of floodplains and valley floors. Therefore, they have very stable surface hydrologic dynamics. As such they are entirely dependent on groundwater flow to their source spring, and are sensitive to changes in groundwater levels (Hendrickson and Minckley 1984, Stromberg et al. 1996, 1997, 2009, Bagstad et al. 2005, Noonan 2013). Overland surface flow from intense monsoon rains in the summer may deliver sediments into the ciÃ©nega, depending on the amount of vegetation and exposed soils on hillslopes above. Winter storms are less intense and are more likely to result in soil moisture absorption, groundwater recharge, and less surface runoff. Groundwater level stability is key to maintaining ciÃ©negas (Hendrickson and Minckley 1984, Stromberg et al. 1996, 1997, 2009, Bagstad et al. 2005, Noonan 2013)

Component Associations:
- *Eleocharis palustris - Carex praegracilis - Berula erecta* Herbaceous Vegetation (CEGL002634, G2)
- *Schoenoplectus americanus - Eleocharis* spp. Herbaceous Vegetation (CEGL001586, GNR)
- *Schoenoplectus americanus - Flaveria chlorifolia - (Helianthus paradoxus)* Herbaceous Vegetation (CEGL004592, G1)

DISTRIBUTION

Range: Occurs at low elevations (<1000 m) across the warm deserts of western North America, including the Mojave, Sonoran, and Chihuahuan.

NORTH AMERICAN WARM DESERT INTERDUNAL SWALE WETLAND (CES302.039)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Dune (Landform); Dune field; Dune (Substrate); Temperate [Temperate Xeric]; Isolated Wetland [Partially Isolated]; Sand Soil Texture; W-Landscape/High Intensity; Graminoid
Non-Diagnostic Classifiers: Dune (undifferentiated); Lowland [Lowland]; Shrubland (Shrub-dominated); Herbaceous; Tropical/Subtropical [Tropical Xeric]; Depressional; Aridic
National Mapping Codes: ESLF 9238

CONCEPT

Summary: This interdunal wetland ecological system occurs in dune fields in the Chihuahuan Desert and likely in the Sonoran and Mojave deserts. This isolated or partially isolated wetland system is an occasional component of the more extensive active and stabilized desert dune system. Stands are typically small (usually less than 0.1 ha) interdunal swales that occur in wind deflation areas, where sands are scoured down to the water table. Water table may be perched over an impermeable layer of caliche or clay layer. These wetland areas are typically dominated by common emergent herbaceous vegetation, such as species of *Eleocharis, Juncus*, and *Schoenoplectus*, but may include endemic plants or animals. Occasionally wetlands are dominated by trees and shrubs, such as *Populus fremontii* and *Baccharis salicifolia*, which survive both being buried as dunes advance and having their root system exposed when deflation of the dune occurs. The specific dune field ecological processes distinguish these wetlands from non-dune emergent wetlands with similar species composition.
Classification Comments: Additional interdunal wetland surveys and classification work are needed at dune systems in the Chihuahuan Desert at Cuatro Cienegas, Guadalupe Mountains, and Samalayuca dunes as well as dune systems in the Sonoran or Mojave deserts, such as Algondones, Death Valley, Ereka, Gran Desierto, Kelso, Mohawk, and Salton Sea dunes, to clarify the extent of this small-patch ecological system. It may be necessary to restrict the system to the Chihuahuan Desert if that is the extent. Gypsum dunes have species unique to that substrate and may need to be treated differently.

DESCRIPTION

Environment: This interdunal wetland ecological system occurs in some dune fields in the Chihuahuan and likely the Sonoran and Mojave deserts. This isolated or partially isolated wetland system is an occasional component of the more extensive active and stabilized desert dune system. Stands are typically small (usually less than 0.1 ha) interdunal swales that occur in wind deflation areas, where sands are scoured down to the water table. Water table may be perched over an impermeable layer of caliche or clay. Dune sands may be quartz or gypsum. Gypsum dunes have species unique to that substrate and may need to be treated differently. The specific dune field ecological processes distinguish these wetlands from similar emergent wetlands. In west Texas, these wetlands occur in interdunal swales in Monahan and Kermit quartz sand dunes. These dunes occur northeast of the Pecos River where the prevailing southwest winds have blown the sands to the east where they are trapped by the escarpment of the High Plains (Southern Shortgrass Prairie Ecoregion). The ponds are on a perched water table underlain by impermeable caliche layers. The interdunal ponds are dynamic and change location as active dunes migrate. The White Sands dunes of the Tularosa Basin in southern New Mexico are a gypsum interdunal/dune system that is moving/semi-stable; during the rainy season, many of the interdunes become ephemeral lakes with wetland indicators.
Vegetation: These wetland areas are typically dominated by common emergent herbaceous vegetation, such as species of *Eleocharis, Juncus*, and *Schoenoplectus*, but may include endemic plants or animals, especially on gypsum dunes. Occasionally wetlands are dominated by trees and shrubs, such as *Populus fremontii*, *Baccharis salicifolia*, or *Salix* spp., which must survive both being buried as dunes advance and having their root system exposed when deflation of the dune occurs. On occasion, dunes move over a site, leaving only the tops of cottonwood trees as remnants of the buried community (Muldavin et al. 1994b). The specific dune field ecological processes distinguish these wetlands from non-dune emergent wetlands with similar species composition.

In west Texas, stands in the Monahan and Kermit sandsheets wet interdunal swales, ponds and fringing wetlands are vegetated by herbaceous graminoids (generally >10% plant cover) between active dunes in sandsheets derived from quartz sands. Common vegetation is characterized by herbaceous graminoids and *Salix* spp. These interdunal valleys over impermeable substrata (as with the Monahans Sandsheet) may contain seasonal swales or ephemeral ponds supporting *Achnatherum hymenoides* and other grasses, *Schoenoplectus tabernaemontani, Juncus* spp., *Cyperus* spp., *Baccharis* spp., *Prosopis glandulosa, Salix interior, Pluchea odorata (= Pluchea purpurascens), Xanthium strumarium*, and other weeds (TPWD 1989d). The fringing wetland plants of the more permanent ponds include *Salix* spp., *Scirpus* and/or *Schoenoplectus* spp., *Typha* spp., *Cyperus* spp., *Juncus* spp., *Eleocharis* spp., and others. *Cyperus onerosus* is a rare plant, endemic to this region, also associated with these unusual wetlands (El-Hage and Moulton 1998).
Dynamics: This system is created by iteration of two key processes: hydrological processes and eolian processes. Wind scours out deflation areas between dunes and exposes the water table creating an interdunal wetland. These wetlands exist because a perched water table is underlain by impermeable layers such as a caliche layer. These wetlands receive groundwater flow from the surrounding dune system where precipitation quickly infiltrates and percolates down to the impermeable layer. These interdunal wetlands are

dynamic and change location as active dunes are shaped by the wind (10-100 year timeframe). The size and exact location of the wet swales may change as the sand dunes shift, due to active dune migration. Dune "blowouts" and subsequent stabilization through succession are characteristic processes of the active dunes which surround this system. Drought and mechanical disturbance such as ORVs are linked to periods of active dune migration, whereas periods of above average precipitation are linked to dune stabilization.

Component Associations:
- *Baccharis salicifolia - Baccharis neglecta / Eustoma exaltatum* Shrubland (CEGL004590, G2?)
- *Eleocharis palustris - Carex praegracilis - Berula erecta* Herbaceous Vegetation (CEGL002634, G2)
- *Salix exigua / Baccharis salicifolia - Baccharis neglecta / Schoenoplectus* spp. Woodland (CEGL004587, G2?)
- *Schoenoplectus americanus - Eleocharis* spp. Herbaceous Vegetation (CEGL001586, GNR)
- *Schoenoplectus americanus - Flaveria chlorifolia - (Helianthus paradoxus)* Herbaceous Vegetation (CEGL004592, G1)

SPATIAL CHARACTERISTICS

Spatial Summary: Small patch.
Adjacent Ecological Systems:
- North American Warm Desert Active and Stabilized Dune (CES302.744)

Adjacent Ecological System Comments: This wetland system occurs in wet swales in North American Warm Desert Active and Stabilized Dune (CES302.744).

DISTRIBUTION

Range: This interdunal wetland ecological system occurs in some dune fields in the Chihuahuan Desert and likely occurs in dune fields of the Sonoran and Mojave deserts, but more research in needed to learn the exact extent.

NORTH PACIFIC COASTAL INTERDUNAL WETLAND (CES204.062)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shallow (<15 cm) Water; Sand Subsoil Texture; Coastal Dune Mosaic; Herbaceous; Depressional [Pond]; Isolated Wetland [Partially Isolated]; Mineral: W/ A-Horizon <10 cm; Graminoid
National Mapping Codes: ESLF 9229

CONCEPT

Summary: Coastal interdunal wetlands are common components of larger active and stabilized coastal barrier islands, spits, and coastal dunes, ranging from southern Oregon through the Aleutian Islands. Distinct landform and vegetation patterns are common to these dune systems. Landforms on the ocean side include low-gradient beaches, sparse to unvegetated dunes, slacks dominated by low herbaceous vegetation, and back dunes dominated by tall herbaceous, shrub, or forested communities. Foredunes in Oregon and Washington are usually densely covered by *Ammophila arenaria* that was introduced for dune stabilization projects and has spread throughout the region. This has largely replaced native *Leymus mollis* that is a less effective sand-binder. *Ammophila* is much less abundant behind the foredunes, and dunes in these areas range from unvegetated and actively moving to completely stabilized with mostly native vegetation.

In Alaska, slacks between dunes are colonized by *Equisetum variegatum* and other herbaceous species. The sites are elevated by the deposition of wind-blown sand, tectonic uplift and isostatic rebound. This further removes the sites from tidal water and allows shrubs, such as *Salix commutata, Salix sitchensis*, and *Myrica gale* to invade. Organic mats also develop. Some slacks may develop into forested sites or peatlands, whereas other slacks may not persist to late succession because of dune encroachment. Depending on moisture and salinity gradients, dune slacks in Oregon and Washington are colonized by *Carex obnupta, Argentina egedii, Juncus lesueurii, Juncus nevadensis, Salix hookeriana*, and various other emergent species. The higher portions of dunes are dry and nutritionally poor because of leaching, moving the moisture and nutrients into the dune bases and slacks.
Classification Comments: Oregon and Washington interdunal wetlands had previously been included in other freshwater wetland ecosystems. The truly interdunal wetlands are included here. While interdunal wetlands undoubtedly occur in Alaska, recent systems classification work did not split them out into a separate system. In the future, it may be appropriate to include interdunal wetlands in Alaska in this system. Currently included in Alaskan Pacific Maritime Coastal Dune, Beach and Beach Meadow (CES204.166) in that state.

DESCRIPTION

Environment: In Oregon and Washington, habitat ranges from small interdunal depressions to extensive deflation plains behind stabilized foredunes. Winter precipitation elevates the water table and inundates some communities to a depth of 1 m (3 feet). The seasonal rise in water table also causes vernal pools to form in forested sites on old deflation plains. These pools are teeming with invertebrates and are temporary sources of food and breeding grounds for amphibians and waterfowl. Some wetlands are perched on an iron-cemented duripan, and groundwater may be charged with iron. pH ranges from 5.0-6.3 (6.9), with low conductivity.

Component Associations:
- *Carex exsiccata* Herbaceous Vegetation (CEGL003312, G2G3)
- *Carex lyngbyei - Argentina egedii* Herbaceous Vegetation (CEGL003289, G4)
- *Carex obnupta - Argentina egedii ssp. egedii* Herbaceous Vegetation (CEGL001820, G4)
- *Carex obnupta* Herbaceous Vegetation (CEGL003313, G4)
- *Juncus falcatus - Trifolium wormskioldii* Herbaceous Vegetation (CEGL001570, G4)
- *Picea sitchensis / Carex obnupta - Lysichiton americanus* Forest (CEGL000400, G2G3)
- *Pinus contorta var. contorta / Carex obnupta* Forest (CEGL000142, G2)
- *Pinus contorta var. contorta / Gaultheria shallon - Rhododendron macrophyllum - Vaccinium ovatum* Forest (CEGL000152, G1)
- *Salix hookeriana - (Malus fusca) / Carex obnupta - Lysichiton americanus* Shrubland (CEGL003432, G3)
- *Salix hookeriana - Morella californica* Shrubland (CEGL001138, G4)
- *Schoenoplectus acutus* Herbaceous Vegetation (CEGL001840, G5)

SPATIAL CHARACTERISTICS

Size: In Oregon and Washington, size ranges from 0.25 to 50 acres or more.
Adjacent Ecological Systems:
- North Pacific Maritime Coastal Sand Dune and Strand (CES200.881)

DISTRIBUTION

Range: This system ranges from southern Oregon into British Columbia. In Alaska, they are treated as part of the dune and beach system.

Divisions: 204:C
Nations: US
Subnations: AK?, OR, WA

NORTH PACIFIC HARDPAN VERNAL POOL (CES204.859)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Depressional [Vernal Pool]
Non-Diagnostic Classifiers: Lowland [Lowland]; Temperate [Temperate Oceanic]; Isolated Wetland [Strictly Isolated]
National Mapping Codes: ESLF 9225

CONCEPT

Summary: This system includes shallow ephemeral waterbodies found in depressions (up to several hectares in size) among grasslands and open woodlands throughout intermountain valleys of California, Oregon and the Gulf and San Juan islands of Washington and British Columbia. Northern hardpan vernal pools include an indurated clay or cemented (Si or Fe) hardpan that retains water inputs throughout some portion of the spring, but typically the depression dries down entirely into early summer months. In the Sand Juan and Gulf islands, they are created in small depressions in bedrock. This system typically occurs with a hummocky micro-relief. They tend to be acidic wetlands with characteristic plant species including *Downingia elegans, Isoetes orcuttii, Pilularia americana, Triteleia hyacinthina, Eleocharis* spp., *Eryngium petiolatum, Plagiobothrys figuratus, Plagiobothrys scouleri, Grindelia nana, Veronica peregrina, Deschampsia danthonioides*, and *Callitriche* spp. Due to draw-down characteristics, vernal pools typically form concentric rings of similar vegetation. Given their relative isolation in upland-dominated landscapes, many endemic and Federally-listed plant species are common in California vernal pools.
Classification Comments: This system includes both duripan/hardpan and bedrock types, which are segregated in the California systems. Decided to lump them for this system because both occur intermixed in the geographic area defined.

DESCRIPTION

Environment: Northern hardpan vernal pools include an indurated clay or cemented (Si or Fe) hardpan that retains water inputs throughout some portion of the spring, but typically the depression dries down entirely into early summer months. In the Sand Juan and Gulf islands, they are created in small depressions in bedrock. This system typically occurs with a hummocky micro-relief.
Dynamics: Vernal pools are precipitation-filled seasonal wetlands inundated during the growing season, allowing for plant growth, followed by a brief water-logged terrestrial stage and culminating in complete drying of surface and subsurface soils. Inundation during the growing season eliminates establishment of upland species in the pool basins and the dry period prevents the establishment of many typical wetland taxa (Keeley and Zedler 1998). Pool filling is a combination of direct precipitation (Solomeshch et al. 2007). Soils are shallow over basalt bedrock that prevents drainage. What is unique about vernal pools is the seasonality of the wetting period followed by the desiccation period, which generally is supported by a Mediterranean climate (Keeley and Zedler 1998). Natural fire regimes for vernal pools are generally unknown, but are assumed to be similar to their surrounding upland grassland fire regimes (Wills 2006). Fire can have a positive effect on vernal pool vegetation as it can results in robust response by native grasses and can reduce non-native invasive woody and non-native herbaceous species (Pollak and Kan 1998).

Component Associations:
- *Eryngium petiolatum - Grindelia nana* Herbaceous Vegetation (CEGL003345, G1G2)
- *Eryngium petiolatum - Lasthenia glaberrima* Herbaceous Vegetation (CEGL003458, G1G2)
- *Plagiobothrys figuratus* Vernal Pool Herbaceous Vegetation (CEGL003346, G1G2)
- *Plagiobothrys scouleri - Plantago bigelovii* Herbaceous Vegetation (CEGL003459, G2)

DISTRIBUTION

Range: Found in depressions among grasslands and open woodlands throughout intermountain valleys of California, Oregon and the Gulf and San Juan islands of Washington.

NORTH PACIFIC INTERIOR SUBALPINE FEN (CES207.395)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Fen
National Mapping Codes: ESLF 9446

CONCEPT

Summary: This ecological system encompasses peatlands with 30 to >300 cm depth of peat. These fens occur at high, subalpine elevations (>1200 m) or where cold-air drainage pools. Fens are found on a wide variety of landscape positions but most commonly on palustrine basins. They occupy wetter zones in large peatland complexes but also form extensive pure "meadows." By and large, these fens are dominated by herbaceous species such as *Carex, Eleocharis, Eriophorum angustifolium, Trichophorum* spp., and others.
Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH PACIFIC INTERTIDAL FRESHWATER WETLAND (CES204.875)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9220

CONCEPT

Summary: This ecological system occurs throughout the coastal margin and intertidal zone of the Pacific Northwest Coast of Oregon, Washington and north into British Columbia. It may occur in Alaska, but has not been described from there. Intertidal freshwater wetlands occur as narrow strips to more extensive patches along tidally influenced portions of rivers. There has been little vegetation data collection of this type in this region; a few studies indicate dominant species include *Picea sitchensis, Alnus rubra, Cornus sericea, Myriophyllum hippuroides, Typha angustifolia, Athyrium filix-femina,* and *Carex lyngbyei*. This system is driven by daily tidal flooding of freshwater and associated soil saturation. Vegetation structure and composition are varied and depend on substrate characteristics and the tidal flooding regime of particular sites. Where small areas of mudflat occur in tidally influenced freshwater areas, they are included in this intertidal freshwater wetland and not in Temperate Pacific Freshwater Mudflat (CES200.878).
Classification Comments: It's unclear if this system occurs in Alaska; it was not identified in recent systems classification work.

Component Associations:
- *Alnus rubra / Rubus spectabilis / Carex obnupta - Lysichiton americanus* Forest (CEGL003389, G3G4)
- *Carex lyngbyei* Herbaceous Vegetation (CEGL003369, G4)
- *Cornus sericea - Salix (hookeriana, sitchensis)* Shrubland (CEGL003292, G3)
- *Picea sitchensis / Carex obnupta - Lysichiton americanus* Forest (CEGL000400, G2G3)
- *Picea sitchensis / Cornus sericea / Lysichiton americanus* Forest (CEGL000055, G2)
- *Populus balsamifera ssp. trichocarpa - Acer macrophyllum / Equisetum hyemale* Forest (CEGL003406, G3)
- *Populus balsamifera ssp. trichocarpa / Cornus sericea / Impatiens capensis* Forest (CEGL003408, G1)

NORTH PACIFIC MARITIME EELGRASS BED (CES200.882)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Temperate [Temperate Oceanic]; Aquatic Herb
Non-Diagnostic Classifiers: Lowland [Lowland]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2670; ESLF 9230; ESP 1670

CONCEPT

Summary: Eelgrass beds are found throughout the coastal areas of the North Pacific Coast, from southern Oregon (Coos Bay) north into the Gulf of Alaska, Cook Inlet, and Bristol Bay coasts. Intertidal zones are found with clear water in bays, inlets and lagoons, typically dominated by macrophytic algae and marine aquatic angiosperms along the temperate Pacific Coast. Subtidal portions are never exposed while intertidal areas support species that can tolerate exposure to the air. Common substrates include marine silts, but may also include exposed bedrock and cobble, where many algal species become attached with holdfasts. Subtidal/lower intertidal in clear water. Substrate is usually marine silts, but may be cobble. Beds are dominated by *Zostera marina*.

NORTH PACIFIC SUB-BOREAL LOWER MONTANE FEN (CES207.396)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Warm Continental (207)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Fen
National Mapping Codes: ESLF 9447

CONCEPT

Summary: This ecological system encompasses peatlands with 30 to >300 cm depth of peat. These fens occur at lower elevations (<1400 m) and are dominated by lower-elevation Carices such as *Carex aquatilis, Carex lasiocarpa*, and *Carex limosa*. Scatted shrubs may be present such as *Betula glandulosa* and *Salix barclayi*. These fens occur throughout the central and sub-boreal interior of British Columbia, at middle elevations but below 1400 m. Most sites are hummocked or ribbed with elevated sites and permanent shallow-water hollows. These fens cover much of the acidity-alkalinity gradient with little change in the vascular flora but with a marked difference in bryophyte compositions.

Classification Comments: This ecological system was developed for the purpose of capturing the coarse filter of terrestrial biodiversity in the interior of British Columbia Ecoregional Assessment, conducted by The Nature Conservancy of Canada, with NatureServe's assistance. This system was designed to be equivalent to those developed for neighboring ecoregions: Canadian Rocky Mountains (7), Okanagan (68), Alaska Coastal Forest and Mountains (69), and the North Cascades (3).

NORTH-CENTRAL AND NORTHEASTERN SEEP (CES202.456)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland

CONCEPT

Summary: This ecological system contains primarily herbaceous seep vegetation of the north-central and northeastern United States from Maryland and Pennsylvania north to Maine, Vermont, Wisconsin, and into adjacent Canada. Vegetation of this group is primarily dominated by tall and short forbs, as well as by graminoids and *Sphagnum* mosses in some associations. These are seepage-fed wetlands of temperate northeastern North America found on gentle slopes. Examples are linear, non-peaty, non-sphagnous, often rocky, groundwater slope wetlands that are embedded in an upland forest setting. Some smaller examples may be nearly or fully shaded by overhanging trees rooted in the adjacent forest, but others are open. Stands of this group are dominated by a wetland flora, but with a lack of species characteristic of floodplains or acidic peatlands. Trees may be present on the edges of stands, or often overhanging, but are not characteristic. Shrub species are typically sparse and most typically mesophytic, rather than obligate wetland species. They may form dense zones around the edge but are not characteristic. The herb layer is generally well-developed, and is usually dominated either by characteristic forbs such as *Impatiens capensis, Impatiens pallida, Symplocarpus foetidus, Chelone* spp., and *Rudbeckia laciniata*, or with presence of *Carex* spp. and other graminoids, e.g., *Glyceria striata* and *Eriophorum virginicum*. In addition, *Sphagnum* spp. may occur in a minority of examples, but it is more characteristic of vegetation in the other groups within this macrogroup.
Classification Comments: The memberships of the clearly related Southern Appalachian Seepage Wetland (CES202.317) and this system have been resolved along (more-or-less) clear biogeographic lines. CES202.317 is "Central and Southern Appalachian" in its affinity and membership, and the range of this system is "North-Central and Northeastern." Clay Seeps Sparse Vegetation (CEGL005163) is an outlier both in geography and environmental setting, but does not appear to fit well in any other existing systems. This is a small-patch system and, as with other forested seeps, could be treated as a component of the larger upland forest system within which it is embedded.
Similar Ecological Systems:
- Southern Appalachian Seepage Wetland (CES202.317)

DESCRIPTION

Environment: This vegetation occurs in small patches where seepage creates permanent or seasonal saturated soil conditions. Wetness may vary substantially over short distances in response to amounts of seepage, flow, and pooling by topography or the presence of an impermeable substrate. Stands of the group occur over a wide elevational range, from low and moderate elevations northward nearly to the highest peaks of the Southern Appalachians. Landforms are usually concave slopes but may be convex slopes or even (rarely) ridgetop gaps. This vegetation is almost never found on flat valley bottoms, though it may be found on the edge of them. Soils are usually saturated mineral soils, rather than peats or mucks, and may be residual or colluvial, and deep or shallow.

Climate: A cool temperate climate, where cool temperatures and high rainfall make more water available, making seepage flow more reliable. *Soil/substrate/hydrology:* This vegetation occurs in small patches where seepage creates permanent or seasonal saturated soil conditions. Soils are usually saturated mineral soils, rather than peats or mucks. Soil wetness may limit recruitment of most tree and shrub seedlings to drier microsites, making canopy gaps persist longer than in adjacent forests and creating and sustaining the openings where this vegetation is found. Wetness may vary substantially over short distances in response to amounts of seepage, flow, and pooling by topography or impermeable substrate.
Vegetation: Stands of this system are typically dominated by tall and short wetland forbs or by graminoids, and normally with a lack of species characteristic of floodplains and acidic peatlands. Trees may be present on the edges of stands, often overhanging, but are not characteristic. Shrub species are typically sparse and most typically mesophytic, rather than obligate wetland species. They may form dense zones around the edge but are not characteristic. The herb layer is generally well-developed, and is usually dominated either by characteristic forbs such as *Impatiens capensis, Impatiens pallida, Chelone* spp., *Symplocarpus foetidus*, and *Rudbeckia laciniata*, or with presence of *Carex* spp. and other graminoids such as *Glyceria striata* and *Eriophorum virginicum*.
Dynamics: The presence of seepage is the primary environmental characteristic of stands of this system. Long-term droughts that would affect seepage flow are presumed to have an effect, but this has not been documented. Soil wetness may limit recruitment of most tree and shrub seedlings to drier microsites, making canopy gaps persist longer than in adjacent forests and creating and sustaining the openings where this vegetation is found. Fire may penetrate from adjacent forests, but only in the driest conditions are they likely to be intense enough to have much effect within. Seeps are fairly permanent features of the landscape, but may potentially be created, destroyed, or changed in extent because of changes in groundwater flow, stream entrenchment or headward erosion, mass movement on slopes, or long-term climatic cycles. Examples are often left undisturbed when surrounding forests are logged. Effects of logging on water infiltration or surface flow may have significant indirect effects.

Component Associations:
- *Carex echinata - Solidago uliginosa / Sphagnum* spp. Herbaceous Vegetation (CEGL008534, G2?)

NORTH-CENTRAL APPALACHIAN SEEPAGE FEN (CES202.607)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Seepage-Fed Sloping
Non-Diagnostic Classifiers: Circumneutral Water; 1-29-day hydroperiod; Short (50-100 yrs) Persistence; Lowland; Shrubland (Shrub-dominated); Temperate; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9232

CONCEPT

Summary: This system is found in scattered locations in the Central Appalachians and eastern Great Lakes regions. Mostly non-forested, these open fens develop on shallow to deep peat over a sloping substrate, where seepage waters provide nutrients. Conditions are often circumneutral to alkaline. Sedges are the major dominants. *Packera aurea, Symplocarpus foetidus*, and *Lobelia kalmii* are among the characteristic forbs. Some of these areas are kept open by grazing, and succession to shrublands may occur in the absence of disturbance.

Similar Ecological Systems:

NORTH-CENTRAL GULF OF MEXICO SALT AND BRACKISH TIDAL MARSH (CES203.303)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saltwater (Polyhaline); Brackish (Mesohaline); Tidal / Estuarine [Haline]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9263

CONCEPT

Summary: This ecological system includes salt and brackish tidal marshes of the north-central Gulf of Mexico, ranging from the Pearl River to northwestern Florida. These marshes are typically found bordering protected bays, sounds, lagoons and other low-energy shorelines. Wind-dominated tides and low tidal amplitudes (less than 1 m) characterize this region. This system includes predominately brackish marshes and supports what is probably the largest zone of *Juncus roemerianus* in the Atlantic and Gulf coastal plains outside of the North Carolina/Virginia Embayed Region estuarine marshes.

Similar Ecological Systems:
- Mississippi Sound Fresh and Oligohaline Tidal Marsh (CES203.067)

Related Concepts:
- Live Oak: 89 (Eyre 1980) Finer

DESCRIPTION

Environment: This marsh system occurs along low-energy shorelines in a region characterized by diurnal tides usually less than 0.5 m in amplitude. Inundation is irregular and depends upon wind speed and direction, and the flow of water from nearby rivers; generally more flooding occurs in the summer than winter (Hackney and de la Cruz 1982). The climate is mixed, with subtropical conditions prevailing during years with mild winters and temperate conditions when strong arctic cold fronts extend to the Gulf of Mexico.

Vegetation: Brackish needlerush marshes dominate this system. Communities distinguished by tall and short *Juncus roemerianus* may both be present. A *Spartina* zone occurs in narrow bands only; small-scale hypersaline tidal flats are frequently present. Other herbaceous species that may be found in stands include *Cladium mariscus ssp. jamaicense*, *Distichlis spicata*, *Panicum virgatum*, *Schoenoplectus americanus*, *Schoenoplectus pungens*, *Spartina alterniflora*, *Spartina patens*, *Spartina spartinae*, and *Sporobolus virginicus*. Examples of this system may also support inclusions of shrublands containing *Ilex vomitoria* and stunted *Quercus virginiana*.

Dynamics: Important processes and interactions in this system include the natural hydrological processes of rivers bringing freshwater and sediments to the coast, diurnal tides, and protection from high-energy wave actions (Morton et al. 2004). These natural processes have generally all been altered to some degree, but processes of freshwater and sediment input still persist even though in an altered state. Sediment input is critical to marsh persistence and becomes even more important under accelerated sea-level rise scenarios. Marsh vegetation plays an equally important role in maintaining marsh elevation (Baustian et al. 2012). Salt and brackish marshes are important habitats for many animal species.

Component Associations:
- *Cladium mariscus ssp. jamaicense* Tidal Herbaceous Vegetation (CEGL004178, G4?)
- *Ilex vomitoria - Quercus (geminata, virginiana) - Morella cerifera - Serenoa repens* Shrubland (CEGL003813, G2G3)
- *Juncus roemerianus* Herbaceous Vegetation (CEGL004186, G5)
- *Panicum virgatum - (Cladium mariscus ssp. jamaicense, Juncus roemerianus)* Herbaceous Vegetation (CEGL004962, G3?)
- *Spartina alterniflora - Juncus roemerianus - Distichlis spicata* Louisianian Zone Salt Tidal Herbaceous Vegetation (CEGL004190, G5)
- *Spartina patens - Schoenoplectus (americanus, pungens) - (Distichlis spicata)* Herbaceous Vegetation (CEGL004755, G4?)
- *Spartina spartinae - Sporobolus virginicus* Tidal Herbaceous Vegetation (CEGL004199, G4G5)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Mississippi Sound Fresh and Oligohaline Tidal Marsh (CES203.067)

DISTRIBUTION

Range: This system is found along the northern Gulf of Mexico in northwestern Florida, southern Alabama, and southern Mississippi. The eastern extent of this system coincides with the range of diurnal tides in the northeastern Gulf of Mexico. (East of Apalachicola Bay, where the tides are semi-diurnal (Stout 1984), Florida Big Bend Salt and Brackish Tidal Marsh (CES203.508) replaces this system.) To the west, Mississippi Delta Salt and Brackish Tidal Marsh (CES203.471) replaces this system in the Mississippi Delta.

NORTH-CENTRAL INTERIOR FRESHWATER MARSH (CES202.899)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shallow (<15 cm) Water; >180-day hydroperiod; Depressional [Lakeshore]; Graminoid
Non-Diagnostic Classifiers: Circumneutral Water; Acidic Water; Moderate (100-500 yrs) Persistence; Herbaceous; Depressional [Pond]; Isolated Wetland [Partially Isolated]; Muck; Aquatic Herb
National Mapping Codes: ESLF 9294

CONCEPT

Summary: This system is found throughout the northern Midwest ranging into southern Canada. It is typically found on glacial potholes, along small streams, ponds, channels in glacial outwash and on lakeplains. This system contains a deep to shallow area of freshwater marsh dominated by emergent and submergent species. Stands may be open ponds with floating or rooted aquatics, or deep marsh with bulrush or cattails, and range from fairly small to several acres. It contains hydric soils flooded by water ranging from several centimeters to over 1 meter for most of the growing season. Emergent marsh species such as *Typha* spp. and *Schoenoplectus* spp. dominate this system with an occasional scattering of tall *Carex* spp. and forbs that can vary from dense to open cover. Trees are generally absent and, if present, are scattered. Submergent wetlands include a variety of macrophytes.
Classification Comments: Some of the specific communities will also be found in the floodplain system and should not be considered a separate system in that case [see North-Central Interior Floodplain (CES202.694)]. Many of these marshes also may have a border of shrubby wet-meadow species similar to North-Central Interior Wet Meadow-Shrub Swamp (CES202.701), but only those areas with a relatively narrow border (<5-10 m) should included with this system.
Similar Ecological Systems:
- Boreal Freshwater Emergent Marsh (CES103.525)

NORTHERN ATLANTIC COASTAL PLAIN BRACKISH TIDAL MARSH (CES203.894)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Brackish (Mesohaline); Herbaceous; Tidal / Estuarine [Haline]; Graminoid
National Mapping Codes: ESLF 9272

CONCEPT

Summary: This system ranges from Massachusetts south to the Chesapeake drainage and is comprised of brackish marshes occurring on the portion of large tidal rivers and their tributaries where saltwater is mixed with freshwater. Vegetation typically exhibits zonation, with associations distributed by flooding frequency. Typical species include *Spartina alterniflora, Typha angustifolia, Agrostis stolonifera, Spartina cynosuroides*, and *Schoenoplectus americanus*.
Classification Comments: In contrast to Northern Atlantic Coastal Plain Tidal Salt Marsh (CES203.519), which this type grades into, brackish marshes are distinguished by being confined within a tidal river and by reduced cover of *Spartina patens* and increased cover of associated brackish marsh species such as *Schoenoplectus americanus, Typha angustifolia, Amaranthus cannabinus*, and *Polygonum* spp. Flats with low forbs will be dominated by plants such as *Sagittaria subulata* and *Limosella australis* rather than by the halophytes (*Salicornia* and *Sarcocornia* spp., for example) seen in salt marsh flats.
Similar Ecological Systems:
- Acadian Estuary Marsh (CES201.579)

DESCRIPTION

Environment: This vegetation develops on tidal reaches of large rivers where freshwater from inland alluvial inputs mixes with marine saltwater incursion. Salinity levels are variable but generally range from 0.5 to 18 ppt. These marshes most commonly form on freely drained river levees. The substrate is moderately consolidated peat (Barrett 1989).
Dynamics: Tidal flooding by mesohaline waters; alluvial deposition of sediments forms levees where this vegetation develops.

Component Associations:
- *Amaranthus cannabinus* Tidal Herbaceous Vegetation (CEGL006080, G3G5)
- *Sagittaria subulata - Limosella australis* Tidal Herbaceous Vegetation (CEGL004473, G2G4)
- *Schoenoplectus americanus - Spartina patens* Herbaceous Vegetation (CEGL006612, GNR)
- *Schoenoplectus pungens* Tidal Herbaceous Vegetation (CEGL004188, GNR)
- *Schoenoplectus robustus - Spartina alterniflora* Herbaceous Vegetation (CEGL006416, GNR)
- *Spartina alterniflora - Lilaeopsis chinensis* Herbaceous Vegetation (CEGL004193, G3G4)
- *Spartina alterniflora - Polygonum punctatum - Amaranthus cannabinus* Herbaceous Vegetation (CEGL006418, GNR)
- *Spartina cynosuroides* Herbaceous Vegetation (CEGL004195, G4)
- *Spartina patens - Agrostis stolonifera* Herbaceous Vegetation (CEGL006365, GNR)
- *Typha angustifolia - Hibiscus moscheutos* Herbaceous Vegetation (CEGL004201, G4G5)

DISTRIBUTION

Range: This system ranges from Massachusetts south to the Chesapeake drainage and the James River, Virginia.
Divisions: 203:C

NORTHERN ATLANTIC COASTAL PLAIN FRESH AND OLIGOHALINE TIDAL MARSH (CES203.516)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9293

CONCEPT

Summary: This system includes freshwater tidal vegetation occurring on the upper reaches of large rivers influenced by tidal flooding, but beyond the reach of the salt or brackish waters. The system is well-developed on the Chesapeake and Delaware Bay drainages, including the rivers of southern New Jersey, then extends northeast and includes inland portions of the Hudson, Connecticut, Merrimack, Kennebec, and Penobscot rivers and their tributaries. The vegetation includes tall marshes dominated by tall grasses such as *Zizania aquatica*, marshes of lower stature dominated by forbs such as *Amaranthus cannabinus, Hibiscus moscheutos* and others, and vegetation characterized by short-statured and rosette-forming forbs such as *Eriocaulon parkeri* and *Isoetes riparia*. Associations are distributed by proximity to tidal waters and thus duration and force of flooding. Sediments of more protected and isolated vegetation is comprised of finer-grained materials that are poorly drained, or of well-consolidated peat deposits. Vegetation exposed to greater flooding force and scouring action is supported by mineral substrates such as sand and gravel.

Similar Ecological Systems:
- Acadian Estuary Marsh (CES201.579)

Related Concepts:
- Freshwater Tidal Marsh (Gawler and Cutko 2010) Finer

DESCRIPTION

Environment: This system forms on the upper reaches of large rivers regularly inundated by tidal flooding but beyond the effects of saline waters.

Dynamics: This system is characterized by a mosaic of patches controlled by a combination of substrate particle size, amount of organic matter deposition, and the degree of stress (persistent natural processes) versus disturbance (episodic and disruptive processes) (Barrett 1994). Tidal amplitude in the Delaware Estuary supporting this system is approximately 2m.

Component Associations:
- *Acorus calamus* Tidal Herbaceous Vegetation (CEGL006833, GNR)
- *Alnus (incana ssp. rugosa, serrulata) - Cornus amomum* Shrubland (CEGL006337, GNR)
- *Alnus maritima ssp. maritima / Acorus calamus* Shrubland (CEGL006841, GNR)
- *Alnus serrulata - Salix nigra / Pilea (fontana, pumila)* Tidal Shrubland (CEGL006843, GNR)

NORTHERN ATLANTIC COASTAL PLAIN POND (CES203.518)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Herbaceous; Depressional; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9283

CONCEPT

Summary: This system includes vegetation of groundwater-flooded depressions characterized by a flora generally characteristic of the northeastern and mid-Atlantic Coastal Plain, with peripheral occurrences to southern Maine and southern Vermont. Also included in this system are ponds supporting coastal plain flora in southern Canada, and in scattered locations in the Great Lakes region. Ponds may contain permanent water, such as the deep glacial kettleholes of Cape Cod and Long Island, New York, or may be shallow basins where groundwater drops below the surface late in the growing season. This system occurs on porous deposits such as outwash plains of the glaciated region, and on sandy and silty sediments of the mid-Atlantic and Great Lakes region. Vegetation within this system varies from nearly forested to entirely herbaceous, largely dependent on the depth and duration of seasonal inundation. Overall the floristics are characterized by species that are well-adapted to long periods of submersion or inundation. The vegetation of steeper-sided basins (generally those containing permanent water) are characterized by strong zonation, with a border of tall shrubs, such as *Vaccinium corymbosum*, and several essentially concentric bands or zones dominated by different associations, depending on geography. Characteristic species in Massachusetts and Long Island include *Carex striata, Cyperus dentatus, Drosera filiformis, Euthamia caroliniana (= Euthamia tenuifolia), Fimbristylis autumnalis, Gratiola aurea, Juncus militaris, Juncus pelocarpus, Panicum verrucosum, Rhexia virginica, Rhynchospora capillacea, Rhynchospora macrostachya, Sabatia kennedyana, Scleria reticularis, Xyris difformis*, and many others. In very steep-sided ponds, zonation is compressed or nonexistent.

Ponds of the New Jersey Pine Barrens share many of these species, with others including *Juncus repens, Muhlenbergia torreyi, Rhynchospora cephalantha, Rhynchospora chalarocephala, Rhynchospora oligantha*, and many others. In shallow basins, such strong zonation is generally lacking but still remains evident in some cases. On Cape Cod, Long Island, and New Jersey, this system most often occurs within the pitch pine barrens. From Cape May and south, the system occurs within an upland matrix of mixed hardwood forests and generally supports a seasonally flooded swamp forest characterized by *Liquidambar styraciflua, Acer rubrum*, wetland oaks such as *Quercus palustris* and *Quercus phellos*, and in Virginia and scattered locations on the Inner Coastal Plain of Maryland *Nyssa biflora*. Shrub zones are characterized by *Cephalanthus occidentalis*, *Diospyros virginiana*, and *Leucothoe racemosa*. The vegetation includes many of the species from New England, New York and New Jersey and also *Boltonia asteroides*, *Carex joorii, Coelorachis rugosa, Dichanthelium spretum, Eleocharis quadrangulata, Fimbristylis perpusilla, Juncus repens, Rhynchospora corniculata, Saccharum baldwinii*, *Saccharum giganteum, Torreyochloa pallida*, and others. This system provides important habitat for the state-rare chicken turtle (*Deirochelys reticularia*) and three state-listed amphibians: Mabee's salamander (*Ambystoma mabeei*), tiger salamander (*Ambystoma tigrinum*), and barking tree frog (*Hyla gratiosa*). In addition, the globally rare plants *Fimbristylis perpusilla* and *Litsea aestivalis* are confined to these habitats in Virginia.
Classification Comments: In some cases, these are locally known as "Delmarva bays."
Similar Ecological Systems:
- Atlantic Coastal Plain Clay-Based Carolina Bay Wetland (CES203.245)
- Northern Atlantic Coastal Plain Pitch Pine Lowland (CES203.374)
- Southern Atlantic Coastal Plain Depression Pond (CES203.262)

Related Concepts:
- Three-way Sedge - Goldenrod Outwash Plain Pondshore (Gawler and Cutko 2010) Finer

DESCRIPTION

Environment: This system formed in shallow depressions on sand plains of the glaciated Northeast and mid-Atlantic Coastal Plain. Many examples are likely to be underlain with clay soil lens or dense organic material that limit drainage seasonally. In the Chesapeake Bay region, these wetlands are seasonally flooded and are believed to be sinkhole features that formed through dissolution of underlying carbonate-rich, shell marl deposits. The marl deposits are too deep to influence soil or water chemistry of the depressions, which are strongly acidic in most examples (Fleming et al. 2013).
Dynamics: The primary driver of this system is annual fluctuation of water levels, causing winter and spring flooding that prevent incursion of woody species, and late-season exposure when seed-banking annuals and perennial forbs and grasses emerge (Schneider 1994, NYNHP 2013g). Dry-season fires in adjacent uplands may spread into ponds and may be another factor limiting the invasion of woody species, although fire frequencies throughout the region have been much reduced in recent decades. Use of ponds as reservoirs for cranberry bogs causes contamination by returning water carrying nutrients and pesticides.

Component Associations:
- *Calamagrostis canadensis - Dichanthelium meridionale* - (Mixed Shrub) Herbaceous Vegetation (CEGL006243, GNR)
- *Carex striata var. brevis* Herbaceous Vegetation (CEGL004120, G3G4)

- *Cephalanthus occidentalis / Polygonum hydropiperoides - Panicum verrucosum* Shrubland (CEGL006242, G3?)
- *Cladium mariscoides - Coelorachis rugosa* Herbaceous Vegetation (CEGL006332, G1)
- *Cladium mariscoides - Eleocharis equisetoides* Herbaceous Vegetation (CEGL006016, GNR)
- *Decodon verticillatus / Triadenum virginicum* Shrubland (CEGL006087, GNR)
- *Decodon verticillatus* Semipermanently Flooded Shrubland (CEGL005089, GNR)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Northern Atlantic Coastal Plain Pitch Pine Barrens (CES203.269)

DISTRIBUTION

Range: This system ranges from the southern portion of the Delmarva peninsula to Cape Cod, Massachusetts, with scattered Coastal Plain occurrences north to southern Maine; also in limited, highly disjunct occurrences on sand lakeplain in Nova Scotia, near southern Lake Michigan and in southeastern Vermont. Outwash sandplains in the Connecticut River Valley of southern Massachusetts support a few degraded occurrences.

NORTHERN ATLANTIC COASTAL PLAIN SEAGRASS BED (CES203.246)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saltwater (Polyhaline); Tidal / Estuarine; Aquatic Herb
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9273

CONCEPT

Summary: This ecological system represents submerged aquatic vegetation found in marine environments from Chesapeake Bay northward to the Maine coast. In contrast to Atlantic Coastal Plain Embayed Region Seagrass Bed (CES203.243) to the south, which can be generally characterized as *Zostera* - *Halodule*, this system is more typically characterized as *Zostera* - *Ruppia* (Thayer et al. 1984). A host of marine algae is also an important component of this system.

Similar Ecological Systems:

- Atlantic Coastal Plain Embayed Region Seagrass Bed (CES203.243)
- North Atlantic Tidal Sand Flat (CES201.049)

DESCRIPTION

Environment: Found in quiet, polyhaline waters of tidal embayments where saline fluctuations are relatively minor (Edinger et al. 2002).

Vegetation: The vegetation dominants are *Zostera* and *Ruppia* (Thayer et al. 1984) with some segregation along salinity gradients. *Zostera marina* is dominant in the most saline areas, while *Ruppia* tends to be most common in somewhat less saline water (Edinger et al. 2002) of the bay where salinity is highest. However, mixed beds of the two species do occur. Thayer et al. (1984) point out that these mixed beds of *Zostera* and *Ruppia* vary in seasonal dominance, with *Ruppia* largely replacing *Zostera* during the midsummer. A diverse array of algae are also present (Edinger et al. 2002).

Dynamics: The dynamics of tidal, aquatic communities dominated by vascular plants are complex and poorly understood. The distribution and abundance of vascular plants in these habitats are probably controlled by responses to water chemistry, water clarity and light penetration, the impact of currents and boat wakes, and herbivory by aquatic animals (Fleming et al. 2001).

Component Associations:

- *Ruppia maritima* Acadian/Virginian Zone Temperate Herbaceous Vegetation (CEGL006167, GNR)
- *Zostera marina* Herbaceous Vegetation (CEGL004336, G4G5)

DISTRIBUTION

Range: The southern boundary may need clarification. The conceptual boundary occurs where *Halodule* beds become important; it is presumed that this transition occurs at or around Cape Hatteras, North Carolina.

NORTHERN ATLANTIC COASTAL PLAIN TIDAL SALT MARSH (CES203.519)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: North Atlantic Coastal Plain; Tidal / Estuarine; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9282

CONCEPT

Summary: This system encompasses the mesohaline to saline intertidal marshes of the North Atlantic Coastal Plain, ranging from Chesapeake Bay north to Cape Cod, Massachusetts, and sporadically to the southern Maine coast. It includes a number of different broad vegetation types including salt pannes, salt marshes, and salt shrublands. This system occurs on the bay side of barrier beaches and the outer mouth of tidal rivers where salinity is not much diluted by freshwater input. The typical salt marsh profile, from sea to land, can be summarized as follows: a low regularly flooded marsh strongly dominated by *Spartina alterniflora*; a higher irregularly flooded marsh dominated by *Spartina patens* and *Distichlis spicata*; low hypersaline pannes characterized by *Salicornia* spp.; and a salt scrub ecotone characterized by *Iva frutescens, Baccharis halimifolia*, and *Panicum virgatum*. Salt marsh "islands" of slightly higher elevation also support *Juniperus virginiana*. This system also includes the rare sea-level fen vegetation, which occurs at the upper reaches of the salt marsh where groundwater seepage creates a freshwater fen that differs from other poor fens in its generally higher species richness, absence of *Chamaedaphne calyculata*, and presence of *Eleocharis rostellata* and *Cladium mariscoides*.
Classification Comments: A continuous gradation in salinity presents challenges in separating salt from brackish marsh systems. This system is defined by its landscape position in saltwater bays and outer river mouths as well as actual salinity ranges. Moving up a tidal river, brackish marshes have less cover of *Spartina patens* and increased cover of associated species including tall graminoids such as *Schoenoplectus americanus* and *Typha angustifolia*. Further southward along the East Coast, salt and brackish marshes fall within the same system because the differences in hydrodynamics and landforms in that region produce less distinct habitats.
Similar Ecological Systems:
- Acadian Coastal Salt Marsh (CES201.578)

Related Concepts:
- Loblolly Pine: 81 (Eyre 1980) Finer
- Mixed Graminoid - Forb Saltmarsh (Gawler and Cutko 2010) Finer
- Spartina Saltmarsh (Gawler and Cutko 2010) Finer

DESCRIPTION

Environment: Forms behind barrier beaches or at the outer mouths of tidal rivers where freshwater input is minimal and where vegetation is protected from high-energy wave action. Substrate is organic peat, which can reach 1-2 m in depth in low marsh.
Dynamics: Tidal flooding regulated by elevation; flooding is diurnal in low marshes, decreasing to more irregular flooding in high marsh and fringing salt shrublands. Ponded water remains in depressions, causing hypersaline conditions and panne formation.

Component Associations:
- *Baccharis halimifolia - Iva frutescens / Panicum virgatum* Shrubland (CEGL003921, G5)
- *Cladium mariscoides - Drosera intermedia - Eleocharis rostellata* Herbaceous Vegetation (CEGL006310, G1)
- *Eleocharis rostellata - Spartina patens* Herbaceous Vegetation (CEGL006611, GNR)
- *Iva frutescens / Spartina patens* Shrubland (CEGL006848, G5)
- *Juncus roemerianus* Herbaceous Vegetation (CEGL004186, G5)
- *Morella cerifera / Spartina patens* Shrubland (CEGL003839, G3G4)
- *Panicum virgatum - Spartina patens - Carex silicea* Herbaceous Vegetation (CEGL006150, GNR)
- *Pinus taeda / Morella cerifera / Spartina patens* Tidal Woodland (CEGL006849, GNR)
- *Ruppia maritima - Stuckenia pectinata* Herbaceous Vegetation (CEGL006370, GNR)
- *Salicornia (virginica, bigelovii, maritima) - Spartina alterniflora* Herbaceous Vegetation (CEGL004308, G5)
- *Schoenoplectus pungens - Eleocharis parvula* Herbaceous Vegetation (CEGL006398, GNR)
- *Spartina alterniflora - Distichlis spicata* Tidal Herbaceous Vegetation (CEGL006586, GNR)
- *Spartina alterniflora / (Ascophyllum nodosum)* Acadian/Virginian Zone Herbaceous Vegetation (CEGL004192, G5)
- *Spartina patens - Distichlis spicata - (Juncus gerardii)* Herbaceous Vegetation (CEGL006006, G5)
- *Spartina patens - Distichlis spicata - (Juncus roemerianus)* Herbaceous Vegetation (CEGL004197, G4G5)
- *Spartina patens - Festuca rubra - (Spartina pectinata)* Herbaceous Vegetation (CEGL006368, GNR)
- *Spartina patens - Thinopyrum pycnanthum* Herbaceous Vegetation (CEGL006149, GNR)

DISTRIBUTION

Range: This system is found from the southern Maine coast south to the Chesapeake Bay.

NORTHERN CALIFORNIA CLAYPAN VERNAL POOL (CES206.948)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Circumneutral Water; Saline Water Chemistry; Impermeable Layer; Vernal Pool Mosaic; Depressional; Forb
Non-Diagnostic Classifiers: Shallow (<15 cm) Water; Intermittent Flooding; Lowland [Foothill]; Lowland [Lowland]; Herbaceous; Mediterranean [Mediterranean Xeric-Oceanic]; Isolated Wetland [Strictly Isolated]; Depression
National Mapping Codes: ESLF 9251

CONCEPT

Summary: These systems are shallow ephemeral waterbodies found in depressions (up to several hectares in size) among grasslands and open woodlands throughout the northern Central Valley of California. Northern claypan vernal pools include a clay hardpan that retains water inputs throughout some portion of the spring, but typically the depression dries down entirely into early summer months. They tend to be circumneutral to alkaline and slightly saline wetlands with characteristic plant species including *Downingia bella, Downingia insignis, Cressa truxillensis, Plagiobothrys leptocladus (= Allocarya leptoclada), Pogogyne douglasii, Eryngium aristulatum, Veronica peregrina, Lasthenia ferrisiae, Lasthenia glaberrima*, and *Spergularia salina (= Spergularia marina)*. Due to draw-down characteristics, vernal pools typically form concentric rings of similar forb-rich vegetation. Given their relative isolation in upland-dominated landscapes, many endemic and Federally-listed plant species are common in California vernal pools.
Related Concepts:
- Valley Grassland (215) (Shiflet 1994) Intersecting. The SRM valley grassland includes vernal pools and serpentine seeps occurring in Central Valley grassland areas.

DESCRIPTION

Environment: These systems are shallow ephemeral waterbodies found in depressions (up to several hectares in size) among grasslands and open woodlands throughout the northern Central Valley of California. Northern claypan vernal pools include a clay hardpan that retains water inputs throughout some portion of the spring, but typically the depression dries down entirely into early summer months. They tend to be circumneutral to alkaline and slightly saline wetlands. Pool depth rarely exceeds 50 cm (Solomeshch et al. 2007).
Dynamics: Vernal pools are precipitation-filled seasonal wetlands inundated during the growing season, allowing for plant growth, followed by a brief water-logged terrestrial stage and culminating in complete drying of surface and subsurface soils. Inundation during the growing season eliminates establishment of upland species in the pool basins and the dry period prevents the establishment of many typical wetland taxa (Keeley and Zedler 1998). Pool filling is a combination of direct precipitation and lateral flow among pools within a complex of pools and subsurface flow from uplands which buffers pool volume, keeping them filled into the dry season (Hanes and Stromberg 1998). Subsurface soils have a hard pan of clay that prevents drainage. What is unique about vernal pools is the seasonality of the wetting period followed by the desiccation period, which generally is supported by a Mediterranean climate (Keeley and Zedler 1998) and resulted in development of diverse and highly endemic vegetation (Barbour et al. 2003, 2005, Solomeshch et al. 2007). Natural fire regimes for vernal pools are generally unknown, but are assumed to be similar to their surrounding upland grassland fire regimes (Wills 2006). Fire can have a positive effect on vernal pool vegetation as it can results in robust response by native grasses and can reduce non-native invasive woody and non-native herbaceous species (Pollak and Kan 1998).

DISTRIBUTION

Range: Found in depressions among grasslands and open woodlands throughout the northern Central Valley of California.

NORTHERN CALIFORNIA VOLCANIC VERNAL POOL (CES206.949)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Shallow (<15 cm) Water; Impermeable Layer; Intermittent Flooding; Vernal Pool Mosaic; Mediterranean [Mediterranean Xeric-Oceanic]; Depressional; Forb
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Herbaceous; Isolated Wetland [Strictly Isolated]; Depression
National Mapping Codes: ESLF 9250

CONCEPT

Summary: These systems are shallow ephemeral waterbodies found in very small depressions (typically no larger than 50 square meters) throughout foothills of the southern Cascades and Sierra Nevada. Where short inundation periods are characteristic, *Lasthenia californica, Downingia bicornuta, Psathyrotes* spp., and *Sedella* spp. (= *Parvisedum* spp.) are often present. Where longer inundation periods are characteristic, *Eryngium constancei* and *Eleocharis acicularis* may be found. They are often on solid volcanic bedrock, but also can be found on volcanic ash flows (lahars) over bedrock.

DESCRIPTION

Environment: These pools are often on solid volcanic bedrock, but also can be found on volcanic ash flows (lahars) over bedrock. Hydrologically, they vary from flashy to more persistent hydrological regimes, typically due to the amount and periodicity of precipitation received. Where hydrology is flashy, they fill and evaporate rapidly several times during the wet season. Typically these vernal pools do not support species requiring long inundation periods. Those on volcanic ash flows are less flashy and have pools that are larger and deeper.
Dynamics: Vernal pools are precipitation-filled seasonal wetlands inundated during the growing season, allowing for plant growth, followed by a brief water-logged terrestrial stage and culminating in complete drying of surface and subsurface soils. Inundation during the growing season eliminates establishment of upland species in the pool basins and the dry period prevents the establishment of many typical wetland taxa (Keeley and Zedler 1998). Pool filling is a combination of direct precipitation (Hanes and Stromberg 1998). Soils are shallow with underlain by volcanic substrates that prevents drainage. What is unique about vernal pools is the seasonality of the wetting period followed by the desiccation period, which generally is supported by a Mediterranean climate (Keeley and Zedler 1998) and resulted in development of diverse and highly endemic vegetation (Barbour et al. 2003, 2005, Solomeshch et al. 2007). Natural fire regimes for vernal pools are generally unknown, but are assumed to be similar to their surrounding upland grassland fire regimes (Wills 2006). Fire can have a positive effect on vernal pool vegetation as it can results in robust response by native grasses and can reduce non-native invasive woody and non-native herbaceous species (Pollak and Kan 1998).

DISTRIBUTION

Range: Throughout foothills of the southern Cascades and Sierra Nevada.
Divisions: 204:?; 206:C
Nations: US

NORTHERN COLUMBIA PLATEAU BASALT POTHOLE POND (CES304.058)

CLASSIFIERS

Conf.: 3 - Weak
Classification Status: Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Impermeable Layer; Depressional
Non-Diagnostic Classifiers: Short (50-100 yrs) Persistence; Herbaceous; Mediterranean [Mediterranean Xeric-Oceanic]; Temperate [Temperate Oceanic]; Isolated Wetland [Strictly Isolated]; Consolidated
National Mapping Codes: ESLF 9233

CONCEPT

Summary: This system includes shallow freshwater water bodies found in small depressions gouged into basalt by Pleistocene floods. These are found throughout channeled scablands of the Columbia Plateau in Washington's eastern Columbia River Gorge. They typically occupy the bottom of a basalt cliff (1-20+ m tall) lined circular or linear depression. Characteristic shoreline vegetation lining the aquatic environment is an emergent marsh that includes species of *Scirpus* and/or *Schoenoplectus, Typha, Juncus, Potamogeton, Polygonum, Nuphar*, and *Phalaris*. This system may also include areas of relatively deep water with floating-leaved plants (*Lemna, Potamogeton*, and *Brasenia*). Woody plants, including *Populus tremuloides, Salix exigua, Crataegus douglasii*, or *Rosa woodsii*, are present adjacent to more northerly potholes. Ponds are within *Artemisia* shrub-steppe and *Pinus ponderosa* savanna or woodland. The wetland vegetation occupies a narrow zone (0.5-10 m) between open water and upland vegetation.
Classification Comments: This may be a subset of North American Arid West Emergent Marsh (CES300.729), or it could be a freshwater aquatic system with primarily zoological species composition (amphibians and invertebrates).

Component Associations:
- *Carex utriculata* Herbaceous Vegetation (CEGL001562, G5)
- *Carex vesicaria* Herbaceous Vegetation (CEGL002661, G4Q)
- *Juncus balticus* Herbaceous Vegetation (CEGL001838, G5)
- *Lemna* spp. Western North American Aquatic Vegetation (CEGL005450, G5)
- *Nuphar polysepala* Herbaceous Vegetation (CEGL002001, G5)
- *Phalaris arundinacea* Western Herbaceous Vegetation (CEGL001474, G5)
- *Phragmites australis* Western North America Temperate Semi-natural Herbaceous Vegetation (CEGL001475, G5)
- *Schoenoplectus acutus* Herbaceous Vegetation (CEGL001840, G5)
- *Schoenoplectus americanus* Western Herbaceous Vegetation (CEGL001841, G3Q)
- *Schoenoplectus maritimus* Herbaceous Vegetation (CEGL001843, G4)
- *Schoenoplectus tabernaemontani* Temperate Herbaceous Vegetation (CEGL002623, G5)
- *Typha (latifolia, angustifolia)* Western Herbaceous Vegetation (CEGL002010, G5)

SPATIAL CHARACTERISTICS

Size: Depressions (50-10,000 sq m)
Adjacent Ecological System Comments: Primarily Inter-Mountain Basins Big Sagebrush Steppe (CES304.778) and Columbia Plateau Scabland Shrubland (CES304.770).

DISTRIBUTION

Range: Restricted to the northern Columbia Plateau ecoregion commonly called the Columbia Basin.
Divisions: 304:C
Nations: US
Subnations: OR, WA
Map Zones: 7:C, 8:C, 9:P

NORTHERN GREAT LAKES COASTAL MARSH (CES201.722)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Laurentian-Acadian (201)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9296

CONCEPT

Summary: This system is found throughout the northern Great Lakes Basin in the United States and Canada. This system, which can include many associated wetlands, occurs along the Great Lakes shoreline directly affected by Great Lakes water regimes. Species distributions and community patterns are determined by multiple abiotic factors, including Great Lakes water-level fluctuations, surficial bedrock, glacial landform, climate, and land use. Although wetland species are generally widely distributed, those of more boreal and subarctic regions are found in the northern parts of the basin.

Vegetation types found across this diverse set of abiotic factors vary in any number of ways, but they can be placed into a number of zones, though not all are present at a given site. The first four zones are typically inundated directly by lake waters: (a) submergent marsh; (b) emergent marsh; (c) shore fen; and (d) shoreline or strand. The next set of zones are inland from the water's edge and include: (e) herbaceous and shrubby wet meadows and (f) shrub or wooded swamps.

This system can be divided into a number of geographical variants, based on the various community types found across the range of the system: (1) Lake Superior Poor Fen; (2) Northern Rich Fen; (3) Northern Great Lakes Marsh; (4) Green Bay Disturbed Marsh; (5) Lake Michigan Lacustrine Estuary; (6) Saginaw Bay Lakeplain Marsh; (7) Lake Erie-St. Clair Lakeplain Marsh; (8) Lake Ontario Lagoon Marsh; and (9) St Lawrence River Estuary.
Classification Comments: Differs from Great Lakes Freshwater Estuary and Delta (CES202.033) based on its lakeshore setting; the estuary system occurs along rivers, where there is typically more nutrient (e.g., from silts).
Similar Ecological Systems:
- Great Lakes Freshwater Estuary and Delta (CES202.033)

DESCRIPTION

Environment: Species distributions and community patterns are determined by multiple abiotic factors. Great Lakes water-level fluctuations, surficial bedrock, glacial landform, climate, and land use. Great Lakes water level fluctuate over at least three temporal time scales: first, short-term fluctuations caused by winds or barometric pressures; second, seasonal fluctuations reflecting the annual hydrologic cycle in the basin; and third, interannual fluctuations in lake level as a result of variable precipitation and evaporation within the drainage basin. Interannual fluctuations can be as much as 1.3-2.5 m, with apparently little or no periodicity. These fluctuations, which also alter turbidity, nutrient availability, ice scour zones, etc., cause locational shifts in vegetation zones, but also in the composition of these zones, as species have individual tolerance limits.

The major bedrock distinction in the Great Lakes Basin is between igneous and metamorphic bedrock of the Precambrian period and younger (Paleozoic) sedimentary bedrock. The igneous and metamorphic bedrock form the rugged north shore of Lake Superior and Georgian Bay, and line much of the St. Lawrence River; they are locally present on the south shore of western Lake Superior. They lack the shallow protected waters and fine-textured substrates that support broad coastal wetlands. Where such bedrock is at or near the surface, it forms soils that are nutrient-poor and acidic. The rest of the basin is dominated by softer, sedimentary bedrock, which, with its broad, horizontal depositions, favors broad zones of shallow waters. The sedimentary rocks are typically more alkaline (calcareous), forming soils that are nutrient- and moisture-rich loams and clays. Bedrock patterns are overlaid by glacial landforms that, in combination with recent long-shore transport processes, create the prevalent physiographic features of the shorelines. In the lakes themselves, sand lakeplains, clay lakeplains, and moraines are shaped by currents, and the long-shore transportation of sediments has created sand-spit embayments and swales, dune-swale complexes, and tombolos. Channels and rivers contain channel-side wetlands, embayments, and deltas, and estuaries form as either open or barred river mouths. It is this diversity of landforms that has given rise to a diverse set of vegetation types.

Finally, regional patterns of climate affect the basin. The strong latitudinal gradient from southern Lake Erie to northern Lake Superior creates marked differences in length of growing season and solar radiation. Although wetland species are generally widely distributed, those of more boreal and subarctic regions are found in the northern parts of the basin, whereas those of more temperate and prairie regions are found in the southern parts.
Vegetation: Vegetation types found across this diverse set of abiotic factors vary in any number of ways, but they can be placed into a number of zones, though not all are present at a given site. The first four zones are typically inundated directly by lake waters: (a) submergent marsh - containing submergent and/or floating vegetation; (b) emergent marsh - characterized by shallow water or semipermanently flooded soils, and typically dominated by bulrushes, cattails, and other emergent species, but also containing submergent and/or floating vegetation; (c) shore fen - saturated vegetation mats characterized by groundwater influence from shoreline habitats but affected by lake level fluctuations, and dominated by herbaceous or shrubby species; and (d) shoreline or strand

- a narrow zone at or just above the water level where seasonal water-level fluctuations and waves cause erosion, and which is dominated by annual or pioneer herbaceous species. The next set of zones are inland from the water's edge and include: (e) herbaceous and shrubby wet meadows - characterized by saturated or seasonally flooded soils, and typically dominated by sedges, grasses, and other herbs, but occasionally dominated by shrubs; and (f) shrub or wooded swamps - characterized by seasonal flooding and dominated by woody species. Species assemblages in these zones change depending on the interaction of factors across the Great Lakes Basin.

Component Associations:
- *Calamagrostis canadensis - Carex viridula - Cladium mariscoides - Lobelia kalmii* Herbaceous Vegetation (CEGL005115, G1G2)
- *Carex utriculata - Carex lacustris - (Carex vesicaria, Carex stricta)* Herbaceous Vegetation (CEGL002257, G4G5)
- *Dasiphora fruticosa ssp. floribunda - Myrica gale* Rich Shore Fen Shrubland (CEGL005275, G1G2)
- *Nuphar advena - Nymphaea odorata* Herbaceous Vegetation (CEGL002386, G4G5)
- *Potamogeton gramineus - Potamogeton natans* Northern Great Lakes Shore Herbaceous Vegetation (CEGL005273, G3?)
- *Potamogeton zosteriformis - Ceratophyllum demersum - Elodea canadensis* Southern Great Lakes Shore Herbaceous Vegetation (CEGL005152, G3G4)
- *Schoenoplectus acutus - Schoenoplectus subterminalis - Eleocharis palustris - (Schoenoplectus americanus)* Northern Great Lakes Shore Herbaceous Vegetation (CEGL005274, G3?)

DISTRIBUTION

Range: This system is found throughout the northern Great Lakes Basin in the United States and Canada.

NORTHERN GREAT LAKES INTERDUNAL WETLAND (CES201.034)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Intermittent Flooding; Coastal Dune Mosaic; Mineral: W/ A-Horizon <10 cm
Non-Diagnostic Classifiers: Herbaceous; Depressional [Lakeshore]; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9269

CONCEPT

Summary: This system occurs in scattered location along the northern Great Lakes shoreline with scattered occurrences along southern Lake Michigan where coastal dunes are low and support swales close to lake water levels. The swale immediately behind the foredune is influenced by short-term variation in lake levels and can be partially or occasionally completely filled by dune sands following major storm events. Species common to this first swale include *Juncus balticus, Juncus pelocarpus, Juncus nodosus, Eleocharis acicularis*, species of *Solidago* such as *Oligoneuron houghtonii (= Solidago houghtonii)*, and *Schoenoplectus americanus (= Scirpus americanus)*. Often, such swales contain lake-influenced, calcareous sands, and the shallow swale may contain moderately alkaline indicators, such as *Argentina anserina (= Potentilla anserina), Cladium mariscoides, Dasiphora fruticosa ssp. floribunda (= Pentaphylloides floribunda), Euthamia graminifolia, Hypericum kalmianum, Lobelia kalmii, Myrica gale, Rhynchospora capillacea, Thuja occidentalis*, and *Utricularia cornuta*, and others.
Classification Comments: While this type is most commonly described from the northern Great Lakes region, there are likely more occurrences across the southern half of the Great Lakes that may vary in floristic composition from the type described here. Interdunal wetlands are treated as a separate type from dune and swale because in more active wave environments there are single swales immediately adjacent to the shore, with no series of swales/ridges further inlands (D. Albert pers. comm.). The flora is typically herb-dominated and the dynamics are extreme due to water-level fluctuations (D. Albert pers. comm.).
Similar Ecological Systems:
- Great Lakes Wooded Dune and Swale (CES201.726)

DESCRIPTION

Environment: This system is found on the Great Lakes shoreline where coastal dunes are low and support swales close to lake water levels. This occurs mostly on the northern Great Lakes but there are examples around southern Lake Michigan. Soils are usually sands but some sites occur on loams or clays (Kost et al. 2007). The swale immediately behind the foredune is influenced by short-term variation in lake levels. Interdunal wetlands can be partially or occasionally completely filled by dune sands following major storm events. Some sites receive groundwater seepage or are formed adjacent to rivers flowing into the Great Lakes.
Dynamics: This system is affected by short-term variation in Great Lake levels, storm events that may partially or completely fill in stands. Sites draw-down and dry out in response to Great Lakes water level variation or, in smaller, shallower ponds, during the summer. Many stands are small and shallow enough that they do not show pronounced zonation in species composition, but deeper and large stands can have "rings" of vegetation around them (Herbert et al. 1986, Kost et al. 2007). Individual examples can move as the dunes are moved by wind. This dynamic system recovers from disturbance quickly if the underlying habitat variables are still present.

Component Associations:
- *Dasiphora fruticosa ssp. floribunda / Cladium mariscoides - Juncus balticus - (Rhynchospora capillacea)* Herbaceous Vegetation (CEGL005105, G3?)

SPATIAL CHARACTERISTICS

NORTHERN GULF OF MEXICO SEAGRASS BED (CES203.263)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Aquatic Herb
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9267

CONCEPT

Summary: Northern Gulf of Mexico seagrass beds are found behind protective barrier islands and in near-shore areas ranging about 560 km (350 miles) from the panhandle of Florida (approximately St. Marks National Wildlife Refuge, Lighthouse Point) westward to Mississippi. Within this area, the drowned alluvial plain and barriers protect the seagrass beds from normal storm surges; such protection is absent in the region immediately to the east. However, such protection alone is insufficient to allow for development of expansive beds. The total acreage of submerged vegetation in this region is relatively small, and individual patches rarely exceed several thousand acres. Beds are locally abundant in St. Joseph Bay, St. Andrews Bay, Santa Rosa Sound, Perdido Bay, Mississippi Sound, and the Chandeleur Islands of Louisiana. Of the true seagrasses, *Ruppia maritima* displays the most tolerance to freshwater and consequently is an important component of this system. *Vallisneria americana*, which is not often considered a true seagrass, is a component of this system due to the prevalence of oligohaline waters. The other species, *Halodule, Thalassia,* and *Cymodocea,* are also present, usually in monospecific, typically small beds.

Similar Ecological Systems:
- East Gulf Coastal Plain Florida Big Bend Seagrass Bed (CES203.244)
- Southwest Florida Seagrass Bed (CES203.274)

Related Concepts:
- Seagrass Bed (FNAI 1990) Broader

DESCRIPTION

Environment: The largely temperate climate of the region tests the limits of many of the seagrass species which attain their best development in tropical climes. Further, the prevalence of sandy substrates is not optimal for rooting of most species which prefer softer, even mucky sediments. Finally, salinity in this region is dramatically affected by freshwater inputs from the Apalachicola, Mobile, and the Mississippi rivers, in the vicinity of which seagrasses are generally absent. Although most seagrasses are able to tolerate fluctuations in salinity, optimum salt concentrations vary by species. Long periods of exposure to freshwater kill seagrass leaves, rhizomes, and eventually decimate the entire plant (Wieland 1994a). Due to the large freshwater inputs in this system, Vallisneria americana, which is not often considered a true seagrass, is a component of this system, found in oligohaline waters.
Dynamics: *Thalassia* and *Cymodocea* do not grow in areas with low salinity levels (less than 17 ppt); significant leaf loss can occur at these levels. *Thalassia* does not photosynthesize well in less than full strength sea water (Zieman and Zieman 1989). Both species may be more damaged by the effects of freshwater runoff resulting from hurricanes than from high winds and tidal surges (Thomas et al. 1961a).

Component Associations:
- *Cymodocea filiformis - (Thalassia testudinum)* Herbaceous Vegetation (CEGL004317, G4?)
- *Halodule wrightii* Herbaceous Vegetation (CEGL004318, G4?)
- *Ruppia maritima* Louisianian Zone Herbaceous Vegetation (CEGL004450, G4G5)
- *Thalassia testudinum* Herbaceous Vegetation (CEGL004319, G4?)
- *Vallisneria americana* Estuarine Bayou Herbaceous Vegetation (CEGL004634, G3G5)

DISTRIBUTION

Range: Northern Gulf of Mexico seagrass beds range from the panhandle of Florida (approximately St. Marks National Wildlife Refuge, Lighthouse Point) westward to Mississippi and the Chandeleur Islands of Louisiana.

NORTHERN POLYNESIA TIDAL SALT MARSH (CES412.224)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saltwater (Polyhaline); Estuary; Marsh; Herbaceous; Tidal / Estuarine [Haline]
Non-Diagnostic Classifiers: Lowland [Lowland]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2807; ESLF 9247; ESP 1807

CONCEPT

Summary: Intertidal salt marshes are found throughout the coastal areas of the main Hawaiian Islands. This system is defined by salinity and tidal inundation regime and is influenced by tides daily. Salt marshes occur on silt, sand, or coralline substrates, and on the main islands in depressions and on mudflats adjacent to ponds, lagoons, and anchialine pools. Relative salinity of the system is dictated in part by inflows of freshwater streams and groundwater toward coastal areas. Leeward marshes are typically of higher salinity due to less freshwater influence. They occur as small patches at mouths of annual streambeds and in depressions behind beaches and rocky shorelines. At sites along drier leeward coasts, the vegetation is dominated by a succulent dwarf scrub, the non-native *Batis maritima* sometimes forming monotypic coverage, up to 0.75 m tall. The indigenous *Sesuvium portulacastrum* sometimes shares dominance with non-native *Batis maritima* and *Pluchea indica* which occur both in the marsh and with *Atriplex semibaccata* along margins. The vegetation in windward marshes is generally less than 0.25 m tall and dominated by indigenous plants, including *Paspalum vaginatum, Sesuvium portulacastrum, Ipomoea pes-caprae, Vigna marina, Cyperus* spp., *Eleocharis* spp., and *Fimbristylis cymosa*. Under slightly brackish conditions at mouths of large windward river valleys, it merges into Hawai'i Freshwater Marsh (CES412.222), where dominance becomes shared with *Schoenoplectus* spp., *Schoenoplectus maritimus (= Bolboschoenus maritimus), Cyperus laevigatus*, and *Urochloa mutica (= Brachiaria mutica)*.
Classification Comments: It is suggested that this is not just Northern Polynesia in distribution but Pacific Oceania. This type is likely historic in the main Hawaiian Islands. Known stands are disturbed or converted to introduced coastal wetlands.

DESCRIPTION

Dynamics: *Batis* and *Pluchea* have and continue to displace native *Sesuvium* herbland. In addition, mangrove swamps (*Bruguiera gymnorrhiza* and *Rhizophora mangle)* are displacing this system in fishponds, harbors and canals. Mangrove swamps are considered to be a degraded condition of the tidal salt marsh.

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Hawai'i Freshwater Marsh (CES412.222)

Adjacent Ecological System Comments: Under slightly brackish conditions at mouths of large windward river valleys, it merges into Hawai'i Freshwater Marsh (CES412.222).

DISTRIBUTION

Range: This system occurs in the northwestern Hawaiian Islands and throughout the coastal areas of the main islands, generally in leeward coastal areas.

OZARK-OUACHITA FEN (CES202.052)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Ozark/Ouachita; Seepage-Fed Sloping; Circumneutral Soil; Aquic
Non-Diagnostic Classifiers: Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9227

CONCEPT

Summary: This fen system is found in the Ozarks region of the United States. Stands occur on the sideslopes of hills in narrow valleys, bases of bluffs, rock ledges, and terraces of streams and rivers, where the soil or substrate is saturated by calcareous groundwater seepage. Soils are moist to wet, mucky peat or mineral, with pH above 6.5, and vary from shallow (0-40 cm) to moderately deep (40-100 cm), depending on natural disturbance and slope. The parent material is a mixture of gravel and dolomite with fragments of deeply weathered bedrock present, or colluvium over bedrock. The bedrock strata are exposed, especially in hanging fens where the slope is greater than 35 degrees. Hydrophytic plants dominate the fen, which varies from mixed grass or sedge fen with complex zonation to more tallgrass prairie species mixed with calciphiles. Fires are possible in some of the larger prairie fens.
Classification Comments: Some fens are typically associated with riparian vegetation. Seeps in the Ozarks are typically acidic to circumneutral and differ substantially in floristics and groundwater chemistry from these alkaline fens.
Similar Ecological Systems:
- Interior Low Plateau Seepage Fen (CES202.346)
- Southern Ridge and Valley Seepage Fen (CES202.458)

Related Concepts:
- Sedge-Shrub Fen (Orzell et al. 1985) Finer
- Streamside Seep-Fen (Orzell et al. 1985) Finer

DESCRIPTION

Vegetation: Stands of this small-scale system are typically dominated by primarily wetland obligate species of sedges (*Carex* spp.), ferns (*Osmunda* spp.), and other herbaceous species such as *Impatiens capensis* and *Parnassia grandifolia*.

Component Associations:
- *(Carex interior, Carex lurida) - Carex leptalea - Parnassia grandifolia - Rhynchospora capillacea* Herbaceous Vegetation (CEGL002404, G2G3)
- *Carex interior - Carex lurida - Andropogon gerardii - Parnassia grandifolia* Herbaceous Vegetation (CEGL002416, G1G2)

DISTRIBUTION

Range: This fen community type is found in the Ozarks region of the United States.

Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Montane [Upper Montane]; Herbaceous; Seepage-Fed Sloping [Mineral]; Depressional [Lakeshore]; Depressional [Pond]; Graminoid
Non-Diagnostic Classifiers: Mesotrophic Water; Saturated Soil; Montane [Montane]; Temperate [Temperate Continental]; Mineral: W/ A-Horizon >10 cm; Mineral: W/ A-Horizon <10 cm; Forb
National Mapping Codes: ESLF 9217

CONCEPT

Summary: These are high-elevation communities found throughout the Rocky Mountains and Intermountain regions, dominated by herbaceous species found on wetter sites with very low-velocity surface and subsurface flows. They range in elevation from montane to alpine (1000-3600 m). These types occur as large meadows in montane or subalpine valleys, as narrow strips bordering ponds, lakes, and streams, and along toeslope seeps. They are typically found on flat areas or gentle slopes, but may also occur on sub-irrigated sites with slopes up to 10%. In alpine regions, sites typically are small depressions located below late-melting snow patches or on snowbeds. Soils of this system may be mineral or organic. In either case, soils show typical hydric soil characteristics, including high organic content and/or low chroma and redoximorphic features. This system often occurs as a mosaic of several plant associations, often dominated by graminoids, including *Calamagrostis stricta, Caltha leptosepala, Cardamine cordifolia, Carex illota, Carex microptera, Carex nigricans, Carex scopulorum, Carex utriculata, Carex vernacula, Deschampsia caespitosa, Eleocharis quinqueflora, Juncus drummondii, Phippsia algida, Rorippa alpina, Senecio triangularis, Trifolium parryi*, and *Trollius laxus*. Often alpine dwarf-shrublands, especially those dominated by *Salix*, are immediately adjacent to the wet meadows. Wet meadows are tightly associated with snowmelt and typically not subjected to high disturbance events such as flooding.
Classification Comments: Similar systems to this one include Temperate Pacific Subalpine-Montane Wet Meadow (CES200.998) and Boreal Wet Meadow (CES103.873). Rocky Mountain Alpine-Montane Wet Meadow (CES306.812) occurs to the east of the coastal and Sierran mountains, in the semi-arid interior regions of western North America. Boreal wet meadow systems occur farther north and east in boreal regions where the climatic regime is generally colder than that of the Rockies or Pacific Northwest regions. Floristics of these three systems are somewhat similar, but there are differences related to biogeographic affinities of the species composing the vegetation.
Similar Ecological Systems:
- Rocky Mountain Subalpine-Montane Mesic Meadow (CES306.829)
- Western North American Boreal Wet Meadow (CES105.124)

Related Concepts:
- Alpine Rangeland (410) (Shiflet 1994) Intersecting. Alpine wet meadows are included in this SRM type.
- Tall Forb (409) (Shiflet 1994) Intersecting. Forb-dominated wet meadows are included in this ecological system.
- Tufted Hairgrass - Sedge (313) (Shiflet 1994) Intersecting. Wetter portions of this SRM type overlap with this system.

DESCRIPTION

Environment: Moisture for these wet meadow community types is acquired from groundwater, stream discharge, overland flow, overbank flow, and on-site precipitation. Salinity and alkalinity are generally low due to the frequent flushing of moisture through the meadow. Depending on the slope, topography, hydrology, soils and substrate, intermittent, ephemeral, or permanent pools may be present. These areas may support species more representative of purely aquatic environments. Standing water may be present during some or all of the growing season, with water tables typically remaining at or near the soil surface. Fluctuations of the water table throughout the growing season are not uncommon, however. On drier sites supporting the less mesic types, the late-season water table may be one meter or more below the surface.

Soils typically possess a high proportion of organic matter, but this may vary considerably depending on the frequency and magnitude of alluvial deposition (Kittel et. al. 1999b). Organic composition of the soil may include a thin layer near the soil surface or accumulations of highly sapric material of up to 120 cm thick. Soils may exhibit gleying and/or mottling throughout the profile. Wet meadow ecological systems provide important water filtration, flow attenuation, and wildlife habitat functions.
Dynamics: Associations in this ecological system are adapted to soils that may be flooded or saturated throughout the growing season. They may also occur on areas with soils that are only saturated early in the growing season, or intermittently. Typically these associations are tolerant of moderate-intensity ground fires and late-season livestock grazing (Kovalchik 1987). Most appear to be relatively stable types, although in some areas these may be impacted by intensive livestock grazing.

ROCKY MOUNTAIN SUBALPINE-MONTANE FEN (CES306.831)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Extreme (Mineral) Rich and Iron-Rich; Saturated Soil; Moss/Lichen (Nonvascular); Seepage-Fed Sloping [Peaty]; Organic Peat (>40 cm); Graminoid; Bryophyte
Non-Diagnostic Classifiers: Shallow (<15 cm) Water; Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Temperate [Temperate Continental]; Depressional [Pond]
National Mapping Codes: ESLF 9234

CONCEPT

Summary: This system occurs infrequently throughout the Rocky Mountains from Colorado north into Canada. It is confined to specific environments defined by groundwater discharge, soil chemistry, and peat accumulation of at least 40 cm. This system includes extreme rich fens and iron fens, both being quite rare. Fens form at low points in the landscape or near slopes where groundwater intercepts the soil surface. Groundwater inflows maintain a fairly constant water level year-round, with water at or near the surface most of the time. Constant high water levels lead to accumulation of organic material. In addition to peat accumulation and perennially saturated soils, the extreme rich and iron fens have distinct soil and water chemistry, with high levels of one or more minerals such as calcium, magnesium, or iron. These fens usually occur as a mosaic of several plant associations dominated by *Carex aquatilis*, *Carex limosa*, *Carex lasiocarpa*, *Betula glandulosa*, *Kobresia myosuroides*, *Kobresia simpliciuscula*, and *Trichophorum pumilum (= Scirpus pumilus)*. *Sphagnum* spp. (peatmoss) is indicative of iron fens. The surrounding landscape may be ringed with other wetland systems, e.g., riparian shrublands, or a variety of upland systems from grasslands to forests.
Classification Comments: Need to clarify this system in relation to Boreal Fen system. In Montana, small fens are found in scattered locations in the plains and the small isolated mountain ranges of the central part of the state; these are included here.
Related Concepts:
- Tufted clubrush - Star moss (ESSFdc2/Wf11) (Steen and Coupe 1997) Intersecting

DESCRIPTION

Environment: The montane fen ecological system is a small-patch system comprised of mountain wetlands that support a unique ecology of rare plants not found in other types of wetlands. These fens are confined to specific environments defined by groundwater discharge, soil chemistry, and peat accumulation of at least 40 cm. Fens form at low points in the landscape or near slopes where groundwater intercepts the soil surface (CNHP 2010b). Groundwater inflows maintain a fairly constant water level year-round, with water at or near the surface most of the time. Constant high water levels lead to accumulations of organic material (CNHP 2010b).Within the region this system occurs at montane elevations ranging from 2440-3500 m (8000-11,480 feet) and is characterized by mosaics of plant communities. These communities typically occur in seeps and wet sub-irrigated meadows in narrow to broad valley bottoms. Surface topography is typically smooth to concave with slopes ranging from 0-10%. The soils within this system are organic Histosols with 40 cm or more of organic material. These Histosols range in texture from clayey-skeletal to loamy-skeletal and fine-loams. They may occur on a variety of parent materials including alluvial and colluvial deposits of granitic and gneiss origins. The pH of wetlands within this system in generally between 4.8 and 6.0-7.0.
Dynamics: Groundwater inflows maintain a fairly constant water level year-round, with water at or near the surface most of the time. Constant high water levels lead to accumulations of organic material. Peatlands in the southern Rocky Mountains are fens that remain saturated primarily as a result of discharging groundwater, seasonal and/or perennial surface water input, or due to their location on the fringes of lakes and ponds (Cooper 1990). Thus, peatlands only occur in confining basins, near persistent groundwater-discharge sites, or near permanent waterbodies such as lakes, ponds, and streams. Due to the limited amount of precipitation and low humidity in the southern Rocky Mountains, true bogs do not occur in the region (Cooper 1990).

Snowmelt maintains high water tables through June in many wetland types (wet meadows, fens, riparian areas, etc.); however, only those areas with soil saturation or a water table within 30 cm of the soil surface through July and August accumulate peat (Cooper 1990, Chimner and Cooper 2003). Thus, a distinguishing characteristic between wet meadows and fens is the depth of the water table in these months. Even in fens, the water table begins to drop in late-July and August. However, late-summer precipitation often replenishes local aquifers thereby raising water tables, suggesting summer precipitation may be important to maintaining high water tables in Southern Rocky Mountain fens (Cooper 1990). In the Northern Rocky Mountains that lack late-summer rains, continuous groundwater discharge is important (Chadde et al. 1998).

Mountain fens function as natural filters cleaning ground and surface water. Fens also act as sponges by absorbing heavy precipitation, slowly releasing it downstream, minimizing erosion and recharging groundwater systems (Windell et al. 1986). The persistent groundwater and cold temperatures allow organic matter to accumulate (forming peat) which allows classification of wetlands within this system as fens. Fens in the Southern Rockies produce peat that accumulates at the rate of 20 to 28 cm (8-11 inches) per 1000 years, making peatlands a repository of 10,000 years of post-glacial history (Windell et al. 1986).

Component Associations:
- *Alnus incana / Scirpus microcarpus* Shrubland (CEGL000481, G2G3)
- *Betula glandulosa / Carex* spp. Shrubland (CEGL005887, GNR)
- *Betula glandulosa / Sphagnum* spp. Shrubland (CEGL002899, GU)
- *Carex aquatilis - Sphagnum* spp. Herbaceous Vegetation (CEGL002898, G2G3)
- *Carex buxbaumii* Herbaceous Vegetation (CEGL001806, G3)
- *Carex lasiocarpa* Herbaceous Vegetation (CEGL001810, G4?)
- *Carex limosa* Herbaceous Vegetation (CEGL001811, G2)
- *Carex simulata* Herbaceous Vegetation (CEGL001825, G4)
- *Carex utriculata* Herbaceous Vegetation (CEGL001562, G5)
- *Carex utriculata* Perched Wetland Herbaceous Vegetation (CEGL002922, G3?)
- *Dulichium arundinaceum* Seasonally Flooded Herbaceous Vegetation (CEGL001831, G3)
- *Kobresia myosuroides - Thalictrum alpinum* Herbaceous Vegetation (CEGL002900, G2)
- *Kobresia simpliciuscula - Trichophorum pumilum* Saturated Herbaceous Vegetation (CEGL002901, G2)
- *Ledum glandulosum* Shrubland (CEGL002739, G4)
- *Salix farriae / Eleocharis quinqueflora* Saturated Shrubland (CEGL000229, G2)

DISTRIBUTION

Range: This system occurs infrequently throughout the Rocky Mountains from Colorado north into Canada. In Montana, small fens included here are found in scattered locations in the plains and the small isolated mountain ranges of the central part of the state. Similarly, recent inventory in Wyoming has revealed the occurrence of small fens throughout the mountain ranges of that state.

SOUTH COASTAL CALIFORNIA VERNAL POOL (CES206.950)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Impermeable Layer; 1-29-day hydroperiod; Vernal Pool Mosaic; Herbaceous; Mediterranean [Mediterranean Xeric-Oceanic]; Forb
Non-Diagnostic Classifiers: Shallow (<15 cm) Water; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Depressional; Isolated Wetland [Strictly Isolated]
National Mapping Codes: ESLF 9249

CONCEPT

Summary: These systems are shallow ephemeral waterbodies found in small depressions that range from Baja Norte, Mexico, north through Santa Barbara County, California. They are found from sea level to 2600 m (7800 feet), and concomitant temperature and moisture ranges, but floristically distinct from more northerly distributed vernal pool types. These vernal pool systems are found on flat-topped marine terraces with Si-Fe cemented hardpans, volcanic bedrock, and acidic intrusive rock underlying thin soils. Characteristic plant species include *Trichostema austromontanum, Pogogyne abramsii, Eryngium aristulatum, Orcuttia californica, Pogogyne nudiuscula, Navarretia fossalis, Hemizonia parryi ssp. australis,* and *Lasthenia glabrata ssp. coulteri*.
Related Concepts:
- Wetlands (217) (Shiflet 1994) Broader

DESCRIPTION

Environment: These systems are shallow ephemeral waterbodies found in depressions (up to several hectares in size) among grasslands and open woodlands throughout the northern Central Valley of California. Northern claypan vernal pools include a clay hardpan that retains water inputs throughout some portion of the spring, but typically the depression dries down entirely into early summer months. They tend to be circumneutral to alkaline and slightly saline wetlands. Pool depth rarely exceeds 50 cm (Solomeshch et al. 2007).
Dynamics: Vernal pools are precipitation-filled seasonal wetlands inundated during the growing season, allowing for plant growth, followed by a brief water-logged terrestrial stage and culminating in complete drying of surface and subsurface soils. Inundation during the growing season eliminates establishment of upland species in the pool basins and the dry period prevents the establishment of many typical wetland taxa (Keeley and Zedler 1998). Pool filling is a combination of direct precipitation and lateral flow among pools within a complex of pools and subsurface flow from uplands which buffers pool volume, keeping them filled into the dry season (Hanes and Stromberg 1998). Subsurface soils have a hard pan of clay that prevents drainage. What is unique about vernal pools is the seasonality of the wetting period followed by the desiccation period, which generally is supported by a Mediterranean climate (Keeley and Zedler 1998) and resulted in development of diverse and highly endemic vegetation (Barbour et al. 2003, 2005, Solomeshch et al. 2007). Natural fire regimes for vernal pools are generally unknown, but are assumed to be similar to their surrounding upland grassland fire regimes (Wills 2006). Fire can have a positive effect on vernal pool vegetation as it can results in robust response by native grasses and can reduce non-native invasive woody and non-native herbaceous species (Pollak and Kan 1998).

DISTRIBUTION

SOUTH FLORIDA DEPRESSION PONDSHORE (CES411.054)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Herbaceous; Depressional; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9228

CONCEPT

Summary: This system occupies shallow depressional wetlands in southern and south-central Florida. As currently defined, this system includes a variety of wetlands occupying somewhat different environments. Included for now in this concept are isolated drainages or seasonal ponds as well as solution holes (may have only subsurface or historic water presence), and possibly the shores of large natural lakes. Examples found in these different environments tend to have obviously different landscape contexts, and often different floristics. For instance, examples embedded in Florida Dry Prairie (CES203.380) and/or South Florida Pine Flatwoods (CES411.381) tend to display distinct vegetation zones (Winchester et al. 1985, Huffman and Judd 1998). In contrast, solution holes embedded in South Florida Pine Rockland (CES411.367) and/or South Florida Hardwood Hammock (CES411.287) are small (may be less than 1 to 15 m across and less than 1 to 3+ m deep) and therefore tend to lack zonal vegetation (M. Fellows pers. comm.). More detailed information is needed on the range of vegetation present across this system. Huffman and Judd (1998) provide information on some examples of this system in southwestern Florida.
Classification Comments: Examples of South Florida Slough, Gator Hole and Willow Head (CES411.485) are generally larger and deeper water wetlands, usually connected with distinct drainageways.
Similar Ecological Systems:
- South Florida Slough, Gator Hole and Willow Head (CES411.485)

Related Concepts:
- Depression Marsh (FNAI 1990) Broader

DESCRIPTION

Vegetation: According to Huffman and Judd (1998), some examples of this system tend to display distinct vegetation zones [see also Winchester et al. (1985)]. In these cases, *Aristida palustris* is characteristic and possibly *Hypericum fasciculatum*, depending upon fire history. A large number of other wetland species may be present, such as *Xyris jupicai*, *Rhexia cubensis*, *Rhynchospora filifolia*, and others. Deeper zones dominated by *Pontederia cordata*, as well as "heads" of woody species (*Cephalanthus occidentalis*, *Salix caroliniana*, *Persea palustris*), also may be present. More floristic information is needed from examples of this system found in other parts of south Florida.

Component Associations:
- *Eleocharis cellulosa* Herbaceous Vegetation (CEGL003972, G3?)
- *Eleocharis interstincta - Pontederia cordata - Crinum americanum* Herbaceous Vegetation (CEGL003975, G2G3)
- *Hypericum fasciculatum / Rhynchospora (chapmanii, harperi)* Shrubland (CEGL003869, G2G3)
- *Panicum hemitomon* Tropical Herbaceous Vegetation (CEGL003980, G3?)
- *Schoenoplectus tabernaemontani* Tropical Herbaceous Vegetation (CEGL003986, G3G5)
- *Typha domingensis - Pontederia cordata* Herbaceous Vegetation (CEGL003988, G3?)
- *Zizaniopsis miliacea* Subtropical Herbaceous Vegetation (CEGL003989, G2G4Q)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Florida Dry Prairie (CES203.380)
- South Florida Hardwood Hammock (CES411.287)
- South Florida Pine Flatwoods (CES411.381)
- South Florida Pine Rockland (CES411.367)

Adjacent Ecological System Comments: May be embedded in Florida Dry Prairie (CES203.380), South Florida Pine Flatwoods (CES411.381), South Florida Pine Rockland (CES411.367) and/or South Florida Hardwood Hammock (CES411.287).

SOUTH FLORIDA EVERGLADES SAWGRASS MARSH (CES411.286)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Extensive Wet Flat; Graminoid
Non-Diagnostic Classifiers: Herbaceous
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2483; ESLF 9204; ESP 1483

CONCEPT

Summary: This marsh system was a dominant type throughout much of the Everglades region of southeastern Florida. It consists largely of herbaceous marsh vegetation across a range of soil and hydrologic conditions, but generally falls within conditions outlined by Duever et al. (1986), i.e., hydroperiod of 225-275 days per year, maximum wet-season water level of 40 cm., and occurrence on peat soils. Several individual marsh community associations have been recognized based on species composition, structure, and aspect. Variations are largely due to the interrelated effects of fire, soils, and hydroperiod. Sawgrass beds or "glades" may have been the single most extensive component of this system (Hilsenbeck et al. 1979), and large areas may have the appearance of nearly monotypic stands of *Cladium mariscus ssp. jamaicense*. However, local variation in composition and stature are also often apparent. For example, two broad aspect types of *Cladium* marsh are often recognized based on density and/or height (Kushlan 1990, Gunderson and Loftus 1993) with denser and taller stands typically occurring on higher topographic positions and deeper organic soils, while sparser, shorter stands occur in lower topography on shallower soils. In addition, other marsh types are also interfingered in the sawgrass matrix where wetter depressions are found and/or where fires have burned away peat soils.
Classification Comments: The term "wet prairie" has often been used to describe a variety of marsh types which are included in the concept of this system. We follow the definition of Duever et al. (1986) in which prairies occupy mineral soils and marshes occupy peats. The community components of these systems are largely based on Davis (1943) and Hilsenbeck et al. (1979). Open and emergent marshes of the region are generally covered by South Florida Slough, Gator Hole and Willow Head (CES411.485); these are generally small patches included in the sawgrass matrix.
Similar Ecological Systems:
- South Florida Slough, Gator Hole and Willow Head (CES411.485)
- South Florida Wet Marl Prairie (CES411.370)

Related Concepts:
- Swale (FNAI 1990) Equivalent

DESCRIPTION

Environment: A range of conditions are present. Soils vary from shallow marl to relatively deep peat. Hydroperiod ranges from 5-12 months. The effect of fire is influenced by both factors and affects them in turn. For example, peat accumulates in the absence of fire, but under certain conditions, fires may burn away accumulated sawgrass peat resulting in a thin, residual, marly soil and relative increase of effective water depth (resulting in community change).
Vegetation: Marsh communities present in this system include tall and short-statured *Cladium mariscus ssp. jamaicense*, spikerush - beaksedge flats, and maidencane flats. In the absence of fire, portions of stands will become dominated by *Salix caroliniana.* If fire continues to be absent, these areas may succeed to *Acer rubrum* until a replacement fire or mechanical activity restores the marsh.
Dynamics: In the absence of fire, portions of stands will become dominated by *Salix caroliniana.* If fire continues to be absent, these areas may succeed to *Acer rubrum* until a replacement fire or mechanical activity restores the marsh.

Component Associations:
- Algal Periphyton Nonvascular Vegetation (CEGL004390, G3?)
- *Cladium mariscus ssp. jamaicense - Bacopa caroliniana* Herbaceous Vegetation (CEGL003969, G3)
- *Cladium mariscus ssp. jamaicense* / Algal Periphyton Herbaceous Vegetation (CEGL003970, G2?)
- *Eleocharis cellulosa - Rhynchospora tracyi* / (Algal Periphyton) Herbaceous Vegetation (CEGL003973, G2G3)
- *Panicum hemitomon* Tropical Herbaceous Vegetation (CEGL003980, G3?)
- *Salix caroliniana / Bacopa caroliniana - Blechnum serrulatum* Forest (CEGL007409, G2?)

SOUTH FLORIDA SLOUGH, GATOR HOLE AND WILLOW HEAD (CES411.485)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: >180-day hydroperiod; Woody-Herbaceous; Herbaceous; Depressional [Peaty]
National Mapping Codes: ESLF 9407

CONCEPT

Summary: This ecological system includes a series of wetlands of southern Florida, ranging in physiognomy from open and herbaceous-dominated to tree-dominated patches, including nearly monospecific stands of *Salix caroliniana*. These wetlands hold water for much of the year and have some of the longest hydroperiods (8-12 months) in a region characterized by wetlands. Most are maintained, at least historically, by American alligators. Alligators were such a dominant disturbance force in many plant communities of southern Florida that their role has been compared with that of bison in the prairies. Through constant movement, they create numerous small pools and ponds (analogous to buffalo wallows), as well as trails to and from these pools through sawgrass marshes. These paths eventually widen and deepen into creeks. Many of these small freshwater creeks have been invaded by mangroves and hardwoods, including *Salix caroliniana*, in the absence of fire and with decreases in alligator populations. Some emergent wetlands included within the concept of this system may also have originated from soil and topographic changes in former sawgrass marshes following severe fires that consume organic substrate and decrease soil elevation. One component of this system ("heads") may originate as circular or oval-shaped solution holes or basins, being maintained and possibly enhanced by the alligator activity. Without this activity, there would be a tendency for the hole or basin to fill with organic material and succeed to other systems. Soils are mucky peats. In addition, *Salix caroliniana* seeds are readily dispersed by wind and may rapidly colonize wet depressions and disturbed areas. In the absence of fire and disturbance, these areas may remain in a forested condition. Otherwise, they would cycle between different physiognomic states, including sawgrass marsh.

Similar Ecological Systems:
- Florida River Floodplain Marsh (CES203.055)
- Floridian Highlands Freshwater Marsh (CES203.077)
- South Florida Depression Pondshore (CES411.054)
- South Florida Everglades Sawgrass Marsh (CES411.286)
- South Florida Pond-apple/Popash Slough (CES411.486)

Related Concepts:
- Cabbage Palmetto: 74 (Eyre 1980) Finer
- Slough (FNAI 1990) Broader

DESCRIPTION

Environment: Examples of this system may originate as solution holes in sawgrass marsh, with a longer hydroperiod, but expand and contract in size and extent with disturbance, including fire and American alligator activity. Some examples are directly caused by alligator activity and/or the effect of severe fire in sawgrass marshes, South Florida Everglades Sawgrass Marsh (CES411.286) (Craighead 1971, Hilsenbeck et al. 1979). At least some examples attributed to this system occupy "marshes" with long hydroperiods (8-12 months) and deep organic soils (Hilsenbeck et al. 1979).

Vegetation: A number of discrete communities may be recognized as part of this system. Two of the most common types can be considered cattail marshes and flag - pickerelweed communities (Hilsenbeck et al. 1979). Also included are nearly monospecific stands of *Salix caroliniana* (Davis 1943, Loveless 1959, Craighead 1971) called "willow heads." Aquatic and wetland plants that may be present include *Bacopa caroliniana, Ceratophyllum demersum, Najas guadalupensis, Utricularia inflata, Nuphar advena, Nymphaea odorata, Chara* sp., *Pistia stratiotes, Pontederia cordata, Sagittaria lancifolia*, and *Thalia geniculata*. Ferns include *Acrostichum danaeifolium, Nephrolepis exaltata*, and *Blechnum serrulatum*. Grasses and graminoids may include *Schoenoplectus tabernaemontani, Typha domingensis*, and *Zizaniopsis miliacea*. Trees include *Sabal palmetto, Quercus virginiana, Ulmus americana, Ficus aurea*, and *Salix caroliniana*.

Dynamics: The American alligators was a dominant force that helped maintain this system, at least historically. Their role has been compared with that of bison in the prairies (Craighead 1971). Through constant movement they create numerous small pools and ponds (analogous to buffalo wallows) as well as trails to and from these pools through sawgrass marshes. These paths eventually widen and deepen into creeks. Many of these small freshwater creeks have been invaded by mangroves and hardwoods in the absence of fire and decrease in alligator populations (Craighead 1971). Some emergent wetlands included within the concept of this system may also have originated from soil and topographic changes in former sawgrass marshes following severe fires that consume organic substrate and decrease soil elevation (Gunderson and Loope 1982b).

Component Associations:
- *Najas guadalupensis - Ceratophyllum demersum - Utricularia inflata* Herbaceous Vegetation (CEGL004313, G2G4)
- *Nuphar advena / Chara* sp. Tropical Herbaceous Vegetation (CEGL004315, G2G3)

- *Nymphaea odorata* Tropical Herbaceous Vegetation (CEGL004316, G4?)
- *Pistia stratiotes* Herbaceous Vegetation (CEGL004902, G4?)
- *Pontederia cordata* Tropical Herbaceous Vegetation (CEGL004261, G3G4)
- *Sabal palmetto - Quercus virginiana - Ulmus americana - Ficus aurea / Acrostichum danaeifolium - Nephrolepis exaltata* Forest (CEGL004409, G2?)
- *Sagittaria lancifolia* Herbaceous Vegetation (CEGL004262, G3?Q)
- *Salix caroliniana / Bacopa caroliniana - Blechnum serrulatum* Forest (CEGL007409, G2?)
- *Schoenoplectus tabernaemontani* Tropical Herbaceous Vegetation (CEGL003986, G3G5)
- *Thalia geniculata - Pontederia cordata* Herbaceous Vegetation (CEGL004264, G2)
- *Typha domingensis - Pontederia cordata* Herbaceous Vegetation (CEGL003988, G3?)
- *Zizaniopsis miliacea* Subtropical Herbaceous Vegetation (CEGL003989, G2G4Q)

SPATIAL CHARACTERISTICS

SOUTH FLORIDA WET MARL PRAIRIE (CES411.370)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Graminoid
Non-Diagnostic Classifiers: Herbaceous; Extensive Wet Flat
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2484; ESLF 9205; ESP 1484

CONCEPT

Summary: This system includes marl prairies of the southern Florida Everglades region and related vegetation of the Florida Keys. This system occurs only on shallower soils with bedrock close to the surface. Composition and variability in this system is heavily influenced by hydrology. Especially unusual are small-patch communities found on elevated areas of oolitic rocks referred to as pinnacle rock or table rock. This system also includes embedded solution holes (depressions formed from limestone collapse).
Classification Comments: Plant community components have been variously and often confusingly described. For example, the term wet prairie has often been used to describe a variety of marsh types which are NOT included in the concept of this system [see South Florida Everglades Sawgrass Marsh (CES411.286)]. We follow the definition of Duever et al. (1986) in which prairies occupy mineral soils and marshes occupy peats.
Similar Ecological Systems:
- South Florida Everglades Sawgrass Marsh (CES411.286)

Related Concepts:
- Marl Prairie (FNAI 1990) Broader

DESCRIPTION

Environment: This system occurs only on shallower soils with bedrock close to the surface (Gunderson and Loftus 1993). Composition and variability in this system are heavily influenced by hydrology, with the predominant community types occurring on marl substrates which are seasonally inundated (2-4 months per year). With diminished hydroperiod, species composition changes (Hilsenbeck et al. 1979). Examples of this ecological system can include elevated areas of oolitic rocks referred to as pinnacle rock (Gunderson and Loftus 1993) or table rock (Hilsenbeck et al. 1979), and also include embedded solution holes (depressions formed from limestone collapse).
Dynamics: Composition and variability in this system are heavily influenced by hydrology; with shortened hydroperiod, species composition changes (Hilsenbeck et al. 1979). Marl prairie depends on a hydroperiod of two to four months. Longer hydroperiods favor the development of peat and the dominance of *Cladium mariscus ssp. jamaicense*; shorter hydroperiods permit the invasion of woody species (FNAI 2010a). Marl prairie normally dries out during the winter and is subject to fires at the end of the dry season, in late spring. These late-spring fires promote flowering of the dominant grasses (FNAI 2010a). Biomass recovers to pre-fire levels after two years. The natural fire frequency may be once every two to six years, or up to ten years for marl prairies with sparse herbaceous vegetation, such as is found on shallow soils (FNAI 2010a).

Component Associations:
- *Croton linearis - Morinda umbellata / Sporobolus* spp. - *Panicum* spp. Shrub Herbaceous Vegetation (CEGL003999, G1)
- *Muhlenbergia filipes - Rhynchospora microcarpa - Centella erecta* Herbaceous Vegetation (CEGL003978, G2)
- *Schizachyrium rhizomatum - Aristida purpurascens var. tenuispica - Eragrostis spectabilis* Herbaceous Vegetation (CEGL003962, G1)
- *Schoenus nigricans* Herbaceous Vegetation (CEGL003984, G2?)

DISTRIBUTION

Range: Southern Florida Everglades region and related vegetation of the Florida Keys. Marl prairies with scattered dwarf cypress cover large areas of Big Cypress National Preserve in Collier and Monroe counties. In the Everglades region, marl prairie forms the border between the Miami Rock Ridge and the lower slough and glades marsh and occurs in the narrow finger glades on Long Pine Key (FNAI 2010a).

SOUTHEASTERN COASTAL PLAIN INTERDUNAL WETLAND (CES203.258)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Depressional; Coast
Non-Diagnostic Classifiers: Herbaceous; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9257

CONCEPT

Summary: This system encompasses the wettest dune swales and basins on barrier islands and coastal areas, supporting pond or marsh-like vegetation, from the Coastal Plain of Texas to southern Virginia. Most examples are permanently or semipermanently flooded with freshwater but are affected by salt spray or overwash during periodic storm events. It is broadly defined in terms of floristic composition and is wide-ranging along the Atlantic and Gulf coasts of the United States. These are graminoid-dominated sites, with species such as *Andropogon glomeratus, Cladium mariscus ssp. jamaicense, Distichlis spicata, Eleocharis* spp., *Fimbristylis castanea, Panicum virgatum, Paspalum monostachyum, Rhynchospora colorata, Rhynchospora* spp., *Schoenoplectus pungens*, and *Typha domingensis*.
Classification Comments: This system is currently defined with a much broader geographic range than most other coastal systems in the Southeast. The extreme variability within even a limited geographic range limits the ability to find broader vegetational patterns. Examples may vary regionally with regard to the amount of wind or salt spray and the texture of the sand. The northern end of the range is not clearly defined.
Similar Ecological Systems:
- Northern Atlantic Coastal Plain Dune and Swale (CES203.264)--(the primary range of which is north of this system) may have small interdunal swales embedded within it.
- Southern Atlantic Coastal Plain Dune and Maritime Grassland (CES203.273)

Related Concepts:
- Coastal and Sandsheet: Deep Sand Grasslands Swale Marsh (6507) [CES203.258] (Elliott 2011) Equivalent
- Coastal Interdunal Swale (FNAI 1990) Intersecting

DESCRIPTION

Environment: These wetlands occur on topographic lows, including dune swales or other basins, in nearly level to steeply rolling landscapes on sands and deep sands on barrier islands along the coast and inland on the South Texas Sand Sheet. These ponds have standing water well into the growing season, and most are permanently flooded. The water is from rainfall or the local water table and is fresh, except perhaps during storm events that produce overwash. Soils are sand, sometimes with a thin layer of muck accumulated in the pond. The geology includes coastal eolian sands, extending inland on the South Texas Sand Sheet, as well as Pleistocene barrier island and beach deposits of the Beaumont Formation, such as on the Ingleside Barrier. Examples occupy topographic lows of interdunal swales and potholes. Soils are deep sands and coastal sands (Elliott 2011).
Vegetation: Vegetation is characterized by emergent or drawdown wetland plants, often tall graminoids. Vegetation varies substantially from one example to the next. These sites are alternately wet and dry (due to seasonal rainfall events) and generally lack tidal influence, but may contain halophytic species due to the influence of salt spray and repeated inundation and evaporation. They are graminoid-dominated sites, with species such as *Spartina patens, Andropogon glomeratus, Panicum virgatum, Paspalum monostachyum, Distichlis spicata, Fimbristylis castanea, Rhynchospora colorata, Eleocharis* spp., *Rhynchospora* spp., *Typha* spp., and *Schoenoplectus pungens*. Forbs such as *Hydrocotyle bonariensis, Centella erecta, Phyla nodiflora, Samolus ebracteatus, Bacopa monnieri*, and *Pluchea foetida* may be conspicuous. Woody species such as *Batis maritima, Sesbania* spp., *Prosopis glandulosa*, and *Baccharis* spp. may be present but do not typically constitute significant cover (Elliott 2011).
Dynamics: This system occurs in a geologically dynamic environment, where wind and waves may change landforms and hydrology quickly (Feagin et al. 2010). However, ponds usually occur in stable portions of islands, where they may last for decades. Salt spray, salt overwash, and heavy rainfall from storms may affect component communities, sometimes limiting vegetation to species that are somewhat salt-tolerant. Severe storms may bring about major changes in the landforms and hydrology (Feagin et al. 2010).

Component Associations:
- (*Morella cerifera*) / *Panicum virgatum - Spartina patens* Herbaceous Vegetation (CEGL004129, G2G4)
- *(Stillingia aquatica) / Panicum tenerum - Dichanthelium erectifolium* Herbaceous Vegetation (CEGL004954, G2?)
- *Carex hyalinolepis* Seasonally Flooded Herbaceous Vegetation (CEGL004724, G1G3)
- *Cladium mariscus ssp. jamaicense - Woodwardia virginica* Herbaceous Vegetation (CEGL004949, G2?)
- *Eleocharis elongata - Panicum tenerum - Nymphaea odorata* Herbaceous Vegetation (CEGL004961, G2?)
- *Fimbristylis castanea - Paspalum distichum* Herbaceous Vegetation (CEGL004110, G3)
- *Fimbristylis castanea - Schoenoplectus pungens* Seasonally Flooded Herbaceous Vegetation (CEGL003790, GNR)
- *Fuirena scirpoidea - Fuirena longa - Rhynchospora microcarpa - Rhynchospora divergens* Herbaceous Vegetation (CEGL004952,

G2)
- *Hypericum reductum - Licania michauxii / Andropogon capillipes - Polygonella gracilis - Xyris caroliniana* Dwarf-shrubland (CEGL003953, G2)
- *Leptochloa fusca ssp. fascicularis - Sesuvium maritimum* Herbaceous Vegetation (CEGL004125, G1Q)
- *Panicum hemitomon - (Cladium mariscus ssp. jamaicense, Muhlenbergia filipes)* Herbaceous Vegetation (CEGL007716, G2G3)
- *Paspalum vaginatum* Herbaceous Vegetation (CEGL004114, G3G4)
- *Spartina bakeri - Muhlenbergia filipes - Andropogon glomeratus - Rhynchospora colorata* Herbaceous Vegetation (CEGL004511, G3?)
- *Spartina patens - Fimbristylis (caroliniana, castanea) - (Panicum virgatum)* Herbaceous Vegetation (CEGL007836, G2G3)
- *Typha domingensis - Setaria magna* Herbaceous Vegetation (CEGL004138, G2G3)
- *Typha domingensis* Seasonally Flooded Gulf Coastal Plain Herbaceous Vegetation (CEGL004137, G3?)

SPATIAL CHARACTERISTICS

Spatial Summary: Small patch.
Size: Occurs as small patches, with most individual ponds an acre or less in size. Often ponds will occur in complexes of up to a dozen.
Adjacent Ecological Systems:
- Central Atlantic Coastal Plain Maritime Forest (CES203.261)

Adjacent Ecological System Comments: Surrounded by maritime forest or maritime grassland systems.

DISTRIBUTION

SOUTHERN APPALACHIAN SEEPAGE WETLAND (CES202.317)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Seepage-Fed Sloping
Non-Diagnostic Classifiers: Herbaceous; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9259

CONCEPT

Summary: This system consists of seepage-fed wetlands in the Southern Appalachians on gentle slopes, with substantial seepage flow. Vegetation is variable, both within and among examples, but lacks vegetation characteristic of bogs or floodplains. This is a small-patch system occurring over a wide elevational range, nearly to the highest peaks, but is generally lacking from flat valley bottoms.

Classification Comments: This system is fairly heterogeneous, covering a broad range of environments and vegetation, but without apparent breaks. At one extreme, the system contains rich, low-elevation, forb-dominated seeps closely related floristically to cove forests; at the other extreme, it contains acidic, sedge- and moss-dominated, bog-like, high-elevation seeps. This system is distinguished from Southern and Central Appalachian Bog and Fen (CES202.300) by occurrence in sloping settings rather than flat valley bottoms, with more rapid flow of water, and by lack of dominance by the characteristic bog or fen flora (though some of it may be present). The only other systems with wetland systems within its range, floodplains and upland pools, are more distinct floristically as well as associated with very different landforms.

Similar Ecological Systems:

- High Allegheny Wetland (CES202.069)
- North-Central and Northeastern Seep (CES202.456)
- North-Central Appalachian Seepage Fen (CES202.607)
- Piedmont Seepage Wetland (CES202.298)
- Southern and Central Appalachian Bog and Fen (CES202.300)

DESCRIPTION

Environment: This system occurs in small patches where seepage creates saturated soil conditions permanently or seasonally. Wetness may vary substantially over short distances in response to amounts of seepage, flow, and pooling by topography or impermeable substrate. The system occurs over a wide elevational range, nearly to the highest peaks. Landforms are usually concave slopes but may be convex slopes or even ridgetop gaps. This system is almost never found on flat valley bottoms, though it may be found on the edge of them. Soils may be muck or coarse boulders but are usually saturated mineral soils. They may be residual or colluvial and deep or shallow. The most extensive and wettest examples occur at elevations above 1525 m (5000 feet), where cool temperatures and high rainfall make more water available. In Kentucky, this system consists of streamhead seepages on Pine and Cumberland mountains.

Vegetation: Vegetation consists of a series of forested and open associations united by the presence of a wetland flora but lack of floodplain species and most bog species. Some tree cover by mesophytic species is usually present, but often only by trees rooted on the edge of adjacent systems. Shrubs, including *Alnus serrulata, Rosa palustris, Lindera benzoin,* and *Physocarpus opulifolius*, may be sparse or may form dense zones around the edge. Shrub species are mostly mesophytic rather than obligate wetland species. The herb layer is generally well-developed and is usually dominated either by characteristic forbs such as *Impatiens capensis, Impatiens pallida, Monarda didyma, Chelone* spp., and *Rudbeckia triloba*, or by *Carex* spp. *Sphagnum* may occur in a minority of examples.

Dynamics: The presence of seepage is the primary determinant of this system. Long-term droughts that affect seepage flow presumably have an effect, but this has not been documented. Canopy dynamics are not well known and potentially may vary substantially over short distances in response to wetness. Wetness may limit recruitment of most tree and shrub seedlings to drier microsites, making canopy gaps persist longer than in adjacent forests and creating a more open canopy. Fire may penetrate from the adjacent forest systems, but only in the driest conditions are they likely to be intense enough to have much effect within this system. Seeps are fairly permanent features of the landscape, but may potentially be created, destroyed, or changed in extent because of changes in groundwater flow, stream entrenchment or headward erosion, mass movement on slopes, or long-term climatic cycles. Examples are often left undisturbed when surrounding forests are logged. Effects of logging on water infiltration or surface flow may have significant indirect effects.

Component Associations:

- *Acer rubrum / Viburnum nudum - Photinia pyrifolia / Smilax laurifolia / Carex debilis var. pubera* Seepage Forest (CEGL007041, G2)
- *Acer rubrum var. trilobum - Nyssa sylvatica / Osmunda cinnamomea - Chasmanthium laxum - Carex intumescens / Sphagnum lescurii* Forest (CEGL007443, G3?)

- *Oxypolis rigidior - Drosera rotundifolia - Platanthera clavellata - Rhexia mariana var. mariana* Seep Herbaceous Vegetation (CEGL007043, G1)
- *Pinus strobus - Acer rubrum / Spiraea alba var. latifolia / Sanguisorba canadensis* Woodland (CEGL004994, G1)
- *Schoenoplectus robustus - Juncus gerardii - Hordeum jubatum - Atriplex patula* Herbaceous Vegetation (CEGL006234, G1)
- *Trichophorum caespitosum - Osmunda cinnamomea - Carex barrattii - Carex buxbaumii* Herbaceous Vegetation (CEGL007723, G1Q)

SPATIAL CHARACTERISTICS

Spatial Summary: Small-patch system, from less than one to no more than several acres in size, potentially surrounded by a number of different systems.

Size: Occurs as small patches, most less than one acre in size. The largest patches at high elevations are several acres. Patches occasionally occur in complexes but more often occur singly.

Adjacent Ecological Systems:
- Southern and Central Appalachian Cove Forest (CES202.373)
- Southern Appalachian Grass and Shrub Bald (CES202.294)
- Southern Appalachian Northern Hardwood Forest (CES202.029)

Adjacent Ecological System Comments: This system may be embedded in a variety of other systems. Most common are Southern Appalachian Northern Hardwood Forest (CES202.029) and Southern and Central Appalachian Cove Forest (CES202.373).

DISTRIBUTION

Range: This system ranges throughout the Southern Appalachians, from northern Georgia and South Carolina north through Virginia, and westward into eastern Tennessee and Kentucky.

Divisions: 202:C

Nations: US

Subnations: GA, KY, NC, SC, TN, VA

Map Zones: 57:C, 61:C

SOUTHERN ATLANTIC COASTAL PLAIN DEPRESSION POND (CES203.262)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Woody-Herbaceous; Depressional [Pond]; Coastal plain
Non-Diagnostic Classifiers: Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9305

CONCEPT

Summary: This ecological system consists of wetlands in small basins formed in unconsolidated sediments of the Atlantic Coastal Plain, from southeastern Virginia to Florida. Many basins are formed by subsidence of surface sediments caused by solution in underlying limestone. Others may be formed as swales in mainland eolian sands, natural blockage of small drainages by sediment movement, and more obscure causes. Soils are generally sandy, with mucky surfaces in the wettest areas. Vegetation is often zonal in response to variation in duration of flooding in different parts of the depression pond. Vegetation usually ranges from open water or floating-leaved aquatic plants in the center of the deepest basins, to emergent marsh zones in semipermanent water, to drawdown zones with diverse small graminoid and forb vegetation, to dense shrub or woodland edges. A smaller number of basins may have emergent trees throughout their extent. Hydroperiod can vary substantially from year to year, and vegetation can similarly vary significantly in aspect and dominants. In addition to flooding, fire is an important natural disturbance to vegetation in the outer, drier portions of the pond.

Classification Comments: The boundary of this system with adjacent upland or wetland systems occurs where vegetation begins to reflect the influence of regular flooding and basin hydrology. This system shares much of its character with Atlantic Coastal Plain Clay-Based Carolina Bay Wetland (CES203.245) but generally accommodates all "limesink depressions" as opposed to mineral soil Carolina bay wetlands. Other basins, especially broad, gently sloped basins on the Outer Coastal Plain and steep-sided depressions farther inland, will need to be placed based on the preponderance of evidence. The northern and southern range limits of this system are not well known. It is tentatively placed at the mouth of Chesapeake Bay and in south Georgia. Northern Atlantic Coastal Plain Pond (CES203.518) of Virginia and Maryland and the wet prairies of north-central Florida are closely related systems.

Similar Ecological Systems:
- Atlantic Coastal Plain Clay-Based Carolina Bay Wetland (CES203.245)
- East Gulf Coastal Plain Depression Pond (CES203.558)
- Northern Atlantic Coastal Plain Pond (CES203.518)
- Southeastern Coastal Plain Natural Lakeshore (CES203.044)

DESCRIPTION

Environment: This system occurs in small basins, primarily in sandy terrain of the Atlantic Coastal Plain, from southeastern Virginia to Florida. Most basins are formed by subsidence of surface sediments caused by solution in underlying limestone. Others may be formed as dune swales in mainland eolian sands, natural blockage of small drainages by sediment movement, and more obscure causes. Basins often occur in complexes of a few to dozens, which vary in size, depth, and steepness of sides. Most of these basins are considered groundwater windows, with water levels matching the level of the local water table. Rainfall is probably also a substantial contributor. The water is acidic and is apparently not influenced by the underlying limestone or deeper groundwater. Hydroperiods vary substantially, with the deepest ponds having permanent water in the center, and the shallowest normally holding water only in the winter and spring. However, water levels can fluctuate substantially over the course of a year and from year to year in response to rainfall and longer term droughts. Soils have a mucky surface layer in the centers of basins that hold water most or all of the year and are generally sandy in smaller basins and in the outer drawdown zones that are more frequently exposed. Fire is potentially an important, if infrequent, influence in the system, penetrating the portions of the basin that are dry when adjacent communities burn. The northern range limit of this system is generally consistent with the northern limit of *Pinus palustris*, although this species is not a component.

Vegetation: This system consists of wetland vegetation that is often strongly zoned within single basins and may vary substantially among basins even in close proximity. Most of the associations are herbaceous, but woody associations may be present. The center of the deepest basins generally is open water or floating-leaved aquatics. Semipermanently flooded zones may have marsh vegetation of medium to large emergents. Outer, mineral soil drawdown zones often have a species-rich flora of small to medium graminoids and

forbs. These include a number of specialized species that are rare in states, some that are globally rare, and some that are widespread but nowhere common. The aspect of this vegetation may vary substantially from year to year depending on when water level drops. Some basins have a dense shrubby edge zone. Some trees or shrubs tolerant of standing water, especially bald-cypress (*Taxodium distichum*), pond-cypress (*Taxodium ascendens*) or swamp blackgum (*Nyssa biflora*), may grow within the basins, either as scattered individuals, as a distinct zone, or forming an open canopy over the whole basin. Because the basins are isolated from larger water bodies and most dry out at least occasionally, their aquatic fauna does not include fish unless fish have been artificially introduced. These systems are well known as important breeding sites for amphibians, and may support important aquatic invertebrate communities as well.

Dynamics: Flooding hydrology is the most important dynamic process. Standing water excludes plants not characteristic of the system. Variation in hydroperiod and amount of drawdown drive vegetation changes from year to year. Because ponds are connected to the local water table, hydroperiods respond to seasonal and long-term cycles in rainfall as much as, perhaps more than, single rainfall events. They may also be affected by regional drainage and groundwater extraction which lowers the water table. Fire is also an important dynamic process in the drier portions of this system. Fire may be important for preventing invasion of trees such as *Pinus taeda* during long-running droughts, as well as for driving variation in herbaceous species.

Component Associations:

- *Amphicarpum muehlenbergianum - (Panicum hemitomon)* Herbaceous Vegetation (CEGL008588, G2G3)
- *Carex hyalinolepis* Seasonally Flooded Herbaceous Vegetation (CEGL004724, G1G3)

- *Taxodium ascendens / Ilex myrtifolia* Depression Forest (CEGL007418, G3?)
- *Vaccinium formosum - Vaccinium fuscatum / Sphagnum cuspidatum* Shrubland (CEGL003907, G3?)
- *Woodwardia virginica / Sphagnum cuspidatum* Herbaceous Vegetation (CEGL004475, G2?)

Spatial Characteristics

Size: Depressions often occur in complexes, in a matrix of upland or saturated wetland systems. Individual depressions range from about 100 square meters to a hectare or two. Complexes may occupy several hectares within the space of several square kilometers.

Adjacent Ecological Systems:

- Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281)
- Central Atlantic Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.265)

Adjacent Ecological System Comments: Most often associated with Atlantic Coastal Plain Upland Longleaf Pine Woodland (CES203.281), but any upland or saturated wetland system can potentially surround them.

Distribution

Range: This system is found from southeastern Virginia to Florida, primarily in the Outer Coastal Plain, but occasional depressions in the Inner Coastal Plain and Sandhills could be included.

SOUTHERN ATLANTIC COASTAL PLAIN FRESH AND OLIGOHALINE TIDAL MARSH (CES203.376)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Freshwater]; Tidal / Estuarine [Oligohaline]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9413

CONCEPT

Summary: This ecological system represents tidally-influenced freshwater herbaceous marshes and tidal shrublands ranging from the vicinity of Morehead City, Carteret County, North Carolina (south of the Embayed Region), south to the vicinity of Marineland or Daytona Beach (Flagler/Volusia counties) in northern Florida. This system occurs where there is adequate riverflow and discharge to maintain fresh to oligohaline conditions, while still within tidal range. These marshes most often occur well inside the mouths of tidal creeks and rivers. Different vegetation types occupy areas of slightly different elevations within the marsh.
Classification Comments: Montague and Wiegert (1990) state that "Northeast Florida salt marshes" occur "south to Marineland," which is in northern Flagler County, Florida. These "Northeast Florida salt marshes" are assumed to be the Florida part of Southern Atlantic Coastal Plain Salt and Brackish Tidal Marsh (CES203.270) which ranges north to southern North Carolina. It is further assumed that the range of CES203.270 and Southern Atlantic Coastal Plain Fresh and Oligohaline Tidal Marsh (CES203.376) are basically identical. Some other sources refer to Daytona Beach (Volusia County) as the southern limit. Atlantic Coastal Plain Indian River Lagoon Tidal Marsh (CES203.257) is found to the south.
Related Concepts:
- Tidal Marsh (FNAI 1990) Broader

DESCRIPTION

Environment: This system occurs where there is adequate riverflow and discharge to maintain fresh to oligohaline conditions, while still within tidal range. These marshes most often occur upstream, well inside the mouths of tidal creeks and rivers. Most of the region where this system occurs consists of marshy shores and sea islands.
Vegetation: Shrubs may include *Alnus serrulata, Baccharis halimifolia, Iva frutescens, Morella cerifera,* and *Ilex vomitoria*. Dominant grasses and graminoids may include *Juncus roemerianus, Carex stricta, Schoenoplectus pungens, Spartina cynosuroides, Spartina patens, Zizania aquatica,* and *Zizaniopsis miliacea*. Forbs may include *Borrichia frutescens, Peltandra virginica, Sagittaria lancifolia ssp. media, Sagittaria latifolia,* and the fern *Osmunda regalis var. spectabilis*.
Dynamics: Tidal flooding is the ecological factor that distinguishes this system from others. Tides bring nutrients, making the regularly-flooded marshes fertile. Rising sea level will affect this system strongly, drowning some marsh areas, promoting shoreline erosion, and causing salt or brackish marshes to spread inland upstream into areas that have been freshwater marsh areas. Some limited natural shifting between this system and tidal swamps may occur, as trees are killed by storm-driven salt water intrusion and later trees may gradually regenerate. Fire may also have affected this boundary in the past - flammable marsh vegetation and non-flammable swamp vegetation may both have affected fire regimes in ways that helped maintain them, for instance when dry, herbaceous marsh vegetation may promote the spread of fires, which kill trees. Tidal swamps which have a shaded understory rarely have adequate dry fine fuels to carry fire.

Component Associations:
- *Alnus serrulata / (Zizania aquatica, Zizaniopsis miliacea)* Shrubland (CEGL004627, G3?)
- *Baccharis halimifolia - Iva frutescens - Morella cerifera - (Ilex vomitoria)* Shrubland (CEGL003920, G4?)
- *Borrichia frutescens / (Spartina patens, Juncus roemerianus)* Shrubland (CEGL003924, G4)
- *Carex stricta - Peltandra virginica - Sagittaria (lancifolia ssp. media, latifolia)* Tidal Herbaceous Vegetation (CEGL004314, G2?)
- *Schoenoplectus pungens - (Osmunda regalis var. spectabilis)* Herbaceous Vegetation (CEGL004189, G2G3)
- *Spartina cynosuroides* Herbaceous Vegetation (CEGL004195, G4)
- *Zizania aquatica* Tidal Herbaceous Vegetation (CEGL004202, G4?)
- *Zizaniopsis miliacea* Tidal Herbaceous Vegetation (CEGL004705, G3G5)

SOUTHERN ATLANTIC COASTAL PLAIN SALT AND BRACKISH TIDAL MARSH (CES203.270)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Haline]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9236

CONCEPT

Summary: This system encompasses the brackish to saline intertidal marshes of the Atlantic Coast ranging from the vicinity of Morehead City, Carteret County, North Carolina (south of the Embayed Region), south to the vicinity of Marineland or Daytona Beach (Flagler/Volusia counties) in northern Florida. It is dominated by medium to extensive expanses of *Spartina alterniflora*, flooded twice daily by lunar tides. *Juncus roemerianus* and other brackish marshes occur upstream in tidal creeks, and a variety of small-patch associations occur near the inland edges. Examples of this system may also support inclusions of shrublands dominated by either *Baccharis halimifolia* and/or *Borrichia frutescens*, as well as forests or woodlands with *Juniperus virginiana var. silicicola* in the overstory.

Classification Comments: This system is distinguished from Atlantic Coastal Plain Embayed Region Tidal Salt and Brackish Marsh (CES203.260) because of the characteristic hydrology of the Embayed Region and what it implies about ecosystem dynamics. This system is dominated by salt marshes regularly flooded by lunar tides, while the Embayed Region is dominated by brackish marshes irregularly flooded by wind tides. This system is distinguished from salt marsh systems of the Gulf Coast because of the differences in tidal dynamics and energy.

The range of this system is somewhat larger than the "Embayed Region" tidal marshes (which range southward only to Cape Lookout). This is due to the fact that submerged aquatic vegetation occurs throughout the region without discernable patterns of change, whereas the tidal marshes do vary across this range.

Montague and Wiegert (1990) state that "Northeast Florida salt marshes" occur "south to Marineland," which is in northern Flagler County, Florida. These "Northeast Florida salt marshes" are assumed to be the Florida part of Southern Atlantic Coastal Plain Salt and Brackish Tidal Marsh (CES203.270) which ranges north to southern North Carolina. It is further assumed that the range of CES203.270 and Southern Atlantic Coastal Plain Fresh and Oligohaline Tidal Marsh (CES203.376) are basically identical. Some other sources refer to Daytona Beach (Volusia County) as the southern limit. Atlantic Coastal Plain Indian River Lagoon Tidal Marsh (CES203.257) is found to the south.

Similar Ecological Systems:
- Atlantic Coastal Plain Embayed Region Tidal Salt and Brackish Marsh (CES203.260)
- Atlantic Coastal Plain Indian River Lagoon Tidal Marsh (CES203.257)

DESCRIPTION

Environment: This system occurs on intertidal flats that are tidally-flooded with salt to brackish water along the Atlantic Coast south of the Embayed Region of North Carolina, extending to northern Florida (south to the vicinity of Flagler and Volusia counties). Regular tidal flooding occurs over most of the system, with irregular flooding in unusually high tides occurring in the upper zones. Tidal ranges vary but are two feet or more. The water is salty over most of the expanse of this system, grading to brackish upstream in tidal rivers and creeks. Upper zones tend to have vegetation suggestive of brackish water as well, but this is apparently the result of a combination of irregular saltwater flooding with freshwater input. Local depressions in upper zones may be hypersaline due to concentration of salt by evaporation. Flooding depth and salinity are the primary determinants of the boundary of this system and of the variation in associations within it. Soils are either sandy or clayey and often are sulfidic and high in organic matter. The input of cations in sea water prevents them from being strongly acidic, but they may rapidly become extremely acidic if drained.

Vegetation: Vegetation is primarily marsh. *Spartina alterniflora* is the predominant vegetation. *Juncus roemerianus* may dominate fairly large expanses along brackish portions of tidal creeks and rivers. Upper zones include a few herbaceous and shrubland associations with plants tolerant of occasional to frequent saltwater, and a few herbaceous to sparse vegetation associations in hypersaline depressions. All associations are low in plant species richness. Salt marsh communities are known for their high primary productivity, much of which is exported to estuarine systems with tidal flushing. Examples of this system may also support inclusions of shrublands dominated by either *Baccharis halimifolia* and/or *Borrichia frutescens*, as well as forests or woodlands with *Juniperus virginiana var. silicicola* in the overstory. Some shrub stands containing *Ilex vomitoria* and stunted *Quercus virginiana* may also be

included.
Dynamics: Tidal flooding is the ecological factor that distinguishes this system from others. Tides bring nutrients, making the regularly flooded marshes fertile. Storms may push saltwater into brackish areas and higher zones, acting as a disturbance to vegetation. In salt marshes, storms locally concentrate debris into piles or bands (wrack) that smother vegetation. For marshes on the back of barrier islands, storm overwash may deposit sand in the marsh. Marshes usually recover from this, but if sufficient sand is deposited, a different system may develop on the site. Fire may be a natural force in some patches that are connected to the mainland. Most salt marshes are probably too wet to burn. Rising sea level will affect this system strongly, drowning some marsh areas, promoting shoreline erosion, and causing salt or brackish marshes to spread inland into freshwater marsh areas. However, elevated atmospheric CO2 increases the productivity of marsh grasses, which can lead to marsh elevation gain (Langley et al. 2009). The marsh snail (*Littoraria irrorata*) is a native and characteristic part of the marsh ecosystem, and is eaten by blue crabs. The disruption of marsh snail predation by blue crabs can lead to a trophic cascade (Silliman and Bertness 2002, Bertness et al. 2004).

Component Associations:
- *Baccharis halimifolia - Iva frutescens / Panicum virgatum* Shrubland (CEGL003921, G5)

- *Spartina alterniflora* Carolinian Zone Herbaceous Vegetation (CEGL004191, G5)
- *Spartina patens - Distichlis spicata - (Juncus roemerianus)* Herbaceous Vegetation (CEGL004197, G4G5)

SPATIAL CHARACTERISTICS

Spatial Summary: Large-patch system.
Size: Occurs in small to large patches, with a few ranging up to 1000 acres or more.
Adjacent Ecological Systems:
- Central Atlantic Coastal Plain Maritime Forest (CES203.261)
- Southern Atlantic Coastal Plain Fresh and Oligohaline Tidal Marsh (CES203.376)

Adjacent Ecological System Comments: Grades to Southern Atlantic Coastal Plain Fresh and Oligohaline Tidal Marsh (CES203.376) upstream on tidal rivers. Grades to a variety of systems on adjacent higher area dune and coastal grassland types, Central Atlantic Coastal Plain Maritime Forest (CES203.261), and various mainland upland systems.

DISTRIBUTION

Range: This systems ranges from central North Carolina (Carteret County) south to the vicinity of Flagler and Volusia counties, Florida. The northern boundary is roughly the eastern end of Carteret County, North Carolina.
Divisions: 203:C
Nations: US
Subnations: FL, GA, NC, SC
Map Zones: 55:C, 58:C

SOUTHERN COASTAL PLAIN HERBACEOUS SEEP AND BOG (CES203.078)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Seepage-Fed Sloping; Graminoid
Non-Diagnostic Classifiers: Herbaceous
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2515; ESLF 9404; ESP 1515

CONCEPT

Summary: This small-patch ecological system includes wet, fire-maintained, seepage communities in the outermost portions of the East Gulf Coastal Plain, east of the Mississippi River in Louisiana, Mississippi, Alabama, and extending across northern Florida. These wetlands are generally found on gentle, almost imperceptible slopes maintained by constant seepage zones and/or perched water tables. Examples are typically grass and sedge dominated, and are often species-rich. *Sarracenia* spp. are notable indicators of many community types in this system. Shrubs frequently encroach in the absence of fire; due to greater topographic isolation, the most interior examples are often naturally shrubbier.
Classification Comments: Known from Clay County (Jennings State Forest) and Nassau County (Ralph E. Simmons State Forest), Florida, based on EORs reported from Florida (A. Johnson pers. comm.).
Similar Ecological Systems:
- East Gulf Coastal Plain Interior Shrub Bog (CES203.385)

- Slash Pine: 84 (Eyre 1980) Intersecting
- Wet Flatwoods (FNAI 2010a) Intersecting
- Wet Prairie (FNAI 2010a) Intersecting

DESCRIPTION

Environment: Kindell et al. (1997) document examples for the Leefield, Albany, Pactolus, Pamlico, Rutledge, and Pansey soil series. Clewell (1981) describes these bogs as commonly occurring between bay swamps and pine flatwoods. These habitats occur on gentle slopes, where seepage water maintains saturated conditions most of the time.
Vegetation: Examples are typically grass- and sedge dominated, and are often species-rich. Pitcher plants (*Sarracenia* spp.) are notable indicators of many community types in this system. *Rhynchospora* spp. are dominant or codominant in many examples. Shrubs (e.g., *Lyonia lucida, Ilex glabra, Cyrilla racemiflora*) frequently encroach in the absence of fire. Scattered *Pinus elliottii var. elliottii, Pinus palustris,* and/or *Pinus serotina* may be present.
Dynamics: Frequent fires are necessary to maintain this system. In the absence of fire, shrubs encroach, eventually shading out understory plants. Fires may have occurred every 1-4 years (FNAI 2010a).

Component Associations:
- *Andropogon arctatus - Rhynchospora chapmanii* Herbaceous Vegetation (CEGL008596, G1G2)
- *Aristida beyrichiana - Rhynchospora oligantha - Panicum nudicaule - (Eurybia eryngiifolia)* Herbaceous Vegetation (CEGL004155, G2)
- *Arundinaria gigantea ssp. tecta* Shrubland (CEGL003843, G1)
- *Hypericum fasciculatum - Hypericum chapmanii / Aristida palustris - Sarracenia (flava, psittacina)* Shrubland (CEGL008594, G1)
- *Pinus elliottii var. elliottii - (Pinus serotina) / Aristida beyrichiana - Rhynchospora oligantha - Sarracenia (flava, minor, psittacina)* Woodland (CEGL003673, G2?)
- *Pinus palustris - Pinus serotina / Ilex glabra - Lyonia lucida / Ctenium aromaticum* Woodland (CEGL003860, G3)
- *Pinus serotina / Lyonia lucida - Ilex glabra - (Cyrilla racemiflora)* Shrubland (CEGL003846, G3)
- *Rhynchospora macra - Rhynchospora stenophylla - Panicum nudicaule - Xyris chapmanii - Carex exilis* Herbaceous Vegetation (CEGL004667, G1)
- *Rhynchospora oligantha - Sarracenia (alata, psittacina) - Carphephorus pseudoliatris* Herbaceous Vegetation (CEGL004687, G2)
- *Rhynchospora stenophylla - Rhynchospora macra - Panicum nudicaule - Eriocaulon nigrobracteatum - Pleea tenuifolia* Herbaceous Vegetation (CEGL004177, G1)

DISTRIBUTION

SOUTHERN COASTAL PLAIN SPRING-RUN STREAM AQUATIC VEGETATION (CES203.275)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Riverine / Alluvial [Whitewater]
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9258

CONCEPT

Summary: Spring-run streams are perennial watercourses fed with artesian waters originating in karstic or limestone topography in the outer portions of the southeastern Coastal Plain of the United States. Such areas are rare in the Gulf and Atlantic coastal plains and apparently confined to Florida and small areas of Georgia. Waters are mineral-rich and circumneutral to alkaline with pH of 7.0-8.2. Water temperatures are relatively cool; clarity is often high. These factors contribute to sometimes lush growth of submerged aquatic vegetation which may include *Vallisneria americana, Sagittaria kurziana, Potamogeton* spp., and *Myriophyllum* spp. Emergent marshes dominated by *Cladium* and/or *Zizania* may occur along the edges. Floodplain development is not usually advanced, but many of these streams are bordered by forests in which *Taxodium distichum* is present.

Similar Ecological Systems:
- Atlantic Coastal Plain Blackwater Stream Floodplain Forest (CES203.247)
- Southern Coastal Plain Hydric Hammock (CES203.501)

Related Concepts:
- Spring-Run Stream (FNAI 1990) Equivalent

DESCRIPTION

Environment: Channels may have sandy bottoms or exposed limestone. Spring "boils" and "blue holes" are encountered with some frequency (Wharton 1978, FNAI 1990).
Dynamics: Consistent flow from groundwater springs are characteristic of these streams.

Component Associations:
- *Cladium mariscus ssp. jamaicense - Typha domingensis - Fimbristylis caroliniana - Bacopa monnieri* Herbaceous Vegetation (CEGL008591, G3?)
- *Nuphar ulvacea* Herbaceous Vegetation (CEGL004329, G2)
- *Sagittaria kurziana - Potamogeton illinoensis - Vallisneria americana* Herbaceous Vegetation (CEGL004332, G2)
- *Stuckenia pectinata - Vallisneria americana* Herbaceous Vegetation (CEGL008590, G2G3)
- *Zizania aquatica - Cicuta maculata - Hydrocotyle umbellata* Herbaceous Vegetation (CEGL004716, G2?)

DISTRIBUTION

Range: This system is endemic to Florida and Georgia.

SOUTHERN RIDGE AND VALLEY SEEPAGE FEN (CES202.458)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Seepage-Fed Sloping
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated)
National Mapping Codes: ESLF 9440

CONCEPT

Summary: This ecological system accommodates small-scale, herbaceous-dominated seepage areas found in limited areas of the southern part of the Ridge and Valley in Alabama and Georgia. These features have been generally known as "seepage fens" and are fed by mineral-rich groundwater. Examples are associated with stream drainages but are generally not affected by stream-related hydrology. Soils contain a thin organic layer over limestone gravel, over a less permeable layer of more solid rock. The vegetation is dominated by herbaceous plants. Characteristic species include *Carex atlantica, Carex lurida, Carex leptalea ssp. harperi, Parnassia grandifolia, Juncus brachycephalus, Rudbeckia fulgida var. umbrosa, Cardamine bulbosa, Impatiens capensis, Juncus coriaceus, Juncus effusus, Lobelia puberula, Lobelia cardinalis, Oxypolis rigidior, Phlox glaberrima, Rhynchospora capitellata, Scirpus atrovirens, Scirpus cyperinus, Solidago patula var. patula*, and *Thelypteris palustris var. pubescens*. Woody species include *Alnus serrulata, Salix humilis, Salix caroliniana, Cornus amomum*, and *Acer rubrum*, which may invade the herbaceous seep. The Federally-listed *Xyris tennesseensis* may be a component of this system and occurs in many of its occurrences.
Classification Comments: This system is a small-patch system, originally described from a small region.
Similar Ecological Systems:
- Interior Low Plateau Seepage Fen (CES202.346)
- North-Central Appalachian Seepage Fen (CES202.607)
- Ozark-Ouachita Fen (CES202.052)

DESCRIPTION

Environment: Examples of this system are typically a complex of seeps, springs and small streams whose hydrology is variable (and perhaps locally ambiguous), but the supply of moisture is reliable, at least during most of the year. Soils are typically circumneutral, organic sandy loams, intermixed with or overlying gravel or chert, and containing elevated levels of calcium and magnesium. These edaphic and hydrologic conditions promote a graminoid- and herbaceous-dominated community, although woody plant succession will occur without periodic disturbance (M. Moffett, GDNR, pers. comm. 2009). Seepage fens of the Southern Ridge and Valley ecoregion (including both Georgia and Alabama) reflect the influence of unique physiographic, geologic, and edaphic features. They are found primarily in the "valley" areas (Great Valley) of the ecoregion, corresponding to the Southern Limestone/Dolomite Valleys and Low Rolling Hills (67f) and the Southern Shale Valleys (67g) Level IV ecoregions of Griffith et al. (2001). These valley areas are broad, relatively deep-soiled, and offer little to moderate topographic relief. Softer and weaker sedimentary rock (i.e., limestone, dolostone, and shale) forms the valley floor, with harder and more resistant sedimentary rock (e.g., sandstone, metamorphosed sandstone [quartzite], conglomerate, and/or chert) forming the ridges. The underlying geology of these sites is principally that of the Conasauga and Rome formations (Szabo et al. 1988); shale and sandstone bedrocks, respectively, frequently interbedded with limestone and dolostone units (Butts and Gildersbee 1948). Hydrologic regimes vary by site along an ephemeral-intermittent-perennial flow gradient. Fens that developed around ephemeral (i.e., unreliable) isolated seeps, whose flow is mostly dependent upon local recharge by precipitation, may experience either low flow conditions from the late summer through mid fall, or even complete "seep-failure" during extended periods of drought. At the other extreme are sites supported by the nearby presence of a high-volume perennial spring or stream that are wet year-round and experience substrate drying only along the ecotonal margins of the fen. Slopes are relatively gentle (mostly in the range of 1-3%) and do not appear to substantially affect the moisture retention, overall structure, or floral composition among the various fens (Moffett 2008).
Vegetation: he vegetation is dominated by herbaceous plants. Characteristic species include *Carex atlantica, Carex lurida, Carex leptalea ssp. harperi, Parnassia grandifolia, Juncus brachycephalus, Rudbeckia fulgida var. umbrosa, Cardamine bulbosa, Impatiens capensis, Juncus coriaceus, Juncus effusus, Lobelia puberula, Lobelia cardinalis, Oxypolis rigidior, Phlox glaberrima, Rhynchospora capitellata, Scirpus atrovirens, Scirpus cyperinus, Solidago patula var. patula*, and *Thelypteris palustris var. pubescens*. Woody species include *Alnus serrulata, Salix humilis, Salix caroliniana, Cornus amomum*, and *Acer rubrum*, which may invade the herbaceous seep. The Federally-listed *Xyris tennesseensis* may be a component of this system and occurs in many of its occurrences. Fens with a history or presence of beaver and cattle tend to include "weedier/nutrient-loving species" among their flora, including *Typha latifolia, Leersia virginica, Ludwigia* spp., *Schoenoplectus* spp., and *Pontederia cordata*, as well as increased levels of the non-native invasive species *Murdannia keisak, Microstegium vimineum*, and *Arthraxon hispidus*.
Dynamics: Since most known fens are located in areas where the use of prescribed fire is impractical, competition from woody trees and shrubs must be controlled using mechanical/manual methods. Two invasive non-native plant species, *Microstegium vimineum* and *Arthraxon hispidus*, are present in most fens. In some instances, they form thick "lawnlike" patches and exclude native herbs and

graminoids. Control of these monocots is normally best approached chemically, but presents a difficult management challenge here. The Federally endangered *Xyris tennesseensis* inhabits more than one-half of the known fen locations, making the use of herbicides problematic and potentially ill-advised (M. Moffett pers. comm.). Disturbances that historically maintained fens in an open state likely included beaver activity, ungulate herbivory, and occasional fire. Scouring from flash floods was less likely given the gentle topography and the fen's primary association with groundwater sources. However, fens that may have once existed in Georgia along second- and third-order streams would have experienced flooding disturbance (similar to those in Alabama). Without disturbance, shrubs and trees will likely invade the fen and promote succession. Some fens, however, appear able to resist invasion and succession, due perhaps to unstable soil conditions or unfavorable hydrologic fluctuations.

Component Associations:
- *Hypericum densiflorum - Alnus serrulata / Jamesianthus alabamensis - Xyris tennesseensis* Shrubland (CEGL008494, G1G2)
- *Hypericum densiflorum - Alnus serrulata / Tripsacum dactyloides* Shrubland (CEGL008495, G1G2)

DISTRIBUTION

Range: This system is restricted to the southern end of the Ridge and Valley in Alabama and Georgia.
Divisions: 202:C

SOUTHWEST FLORIDA SEAGRASS BED (CES203.274)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Aquatic Herb
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9224

CONCEPT

Summary: This system is found along Florida's west coast ranging from Anclote Key (Tarpon Springs) south to Charlotte Harbor. Estuarine grassbeds of this region have been among the most extensively studied in Florida [see references in Zieman and Zieman (1989)] and at least 5 types of seagrass meadows are known to be present. Some types are comprised of mixed species while others are essentially pure stands of individual species. In general, these meadows are found along the fringes of Tampa Bay and Boca Ciega Bay landward of unvegetated sandbars. Composition varies according to water depth and position relative to shoals and shorelines. Mixed beds of *Halodule, Cymodocea*, and *Thalassia* are found in mid-bay shoals. Fringing beds support *Ruppia* nearest the shore in shallowest waters, followed by almost pure stands of *Halodule, Thalassia*, and *Cymodocea*.

Similar Ecological Systems:
- Atlantic Coastal Plain Indian River Lagoon Seagrass Bed (CES203.256)
- East Gulf Coastal Plain Florida Big Bend Seagrass Bed (CES203.244)
- Florida Keys Seagrass Bed (CES411.285)
- Northern Gulf of Mexico Seagrass Bed (CES203.263)

Related Concepts:
- Seagrass Bed (FNAI 1990) Broader

DESCRIPTION

Environment: This system is found along Florida's west coast ranging from Anclote Key (Tarpon Springs) south to Charlotte Harbor. Beds in this region are found behind barrier islands and within sounds and bays, protected from normal storm surges. Within this region, by far the largest acreages of submerged vegetation are found in the Pine Island Sound and Charlotte Harbor. Other large bays with abundant submerged vegetation include Tampa Bay, Boca Ciega Bay, and Sarasota Bay (Zieman and Zieman 1989). The seagrasses are rooted primarily in soft muddy sands and are essentially absent from sandier substrates. Beds occur generally landward of unvegetated sandbars which when destabilized may lead to the disappearance of the beds.
Vegetation: Seagrasses are monocots which carry out their entire life cycle completely submerged in the marine environment.
Dynamics: Colonization of seagrasses often follows a generalized successional sequence. Non-vegetated areas may first be colonized by rhizophytic macroalgae which have some sediment-binding capacity. Possibly more importantly they contribute sedimentary particles as they die and decompose (Zieman and Zieman 1989). *Halodule beaudettei (= Halodule wrightii)* is the local pioneering species which colonizes areas from seed or vegetative reproduction. *Cymodocea* often appears next and may mix with *Halodule*. *Thalassia* occupies beds as succession advances. This pattern marks a progressive increase of biomass in the system with increased leaf areas, increased sediment-trapping capacity, and increased microbial cycling.

Component Associations:
- *Halodule wrightii* Herbaceous Vegetation (CEGL004318, G4?)
- *Halophila engelmannii* Herbaceous Vegetation (CEGL004688, G3?)
- *Ruppia maritima* Tropical Herbaceous Vegetation (CEGL004906, G4G5)
- *Thalassia testudinum - Cymodocea filiformis* Herbaceous Vegetation (CEGL008384, GNR)
- *Thalassia testudinum* Herbaceous Vegetation (CEGL004319, G4?)

DISTRIBUTION

Range: This system is found along Florida's west coast ranging from Anclote Key south to Charlotte Harbor to the outlet of the Caloosahatche River.

TAMAULIPAN SALINE LAKE (CES301.717)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Isolated Wetland; Saline Substrate Chemistry; Graminoid
National Mapping Codes: ESLF 9442

CONCEPT

Summary: This ecological system includes small to medium-sized, highly saline, interior drainage basins in the Tamaulipan region of south Texas. The edges of these basins may be sparsely to moderately vegetated by halophytic grasses and subshrubs.
Related Concepts:

- Tamaulipan Saline Lake Flats (7700) (Elliott 2011) Finer. Unvegetated or very sparsely vegetated lake margin.
- Tamaulipan Saline Lake Grassland (7707) (Elliott 2011) Finer. Sites along the margin of saline lakes where grasses, forbs, and subshrubs have sufficient cover to be mapped as vegetated.

DESCRIPTION

Environment: This system occupies broad, gently sloping, interior draining basins receiving runoff from the surrounding landscape. Solution of salts from parent material, deposition from runoff, and subsequent evaporation has lead to a highly saline situation. These areas occur over the Goliad Formation on the edge of the Texas Sandsheet on highly saline sands or sandy loams in south Texas and may be related to the formation of Quaternary-aged clay dunes that sometimes occur nearby.
Vegetation: Sites may be unvegetated or have sparse vegetation. Some areas at very slightly higher landscape positions in the basin are dominated by halophytic grasses such as *Sporobolus airoides, Distichlis spicata, Sporobolus coromandelianus (= Sporobolus pyramidatus)*, and *Monanthochloe littoralis*. Other halophytic forbs and subshrubs may also be present, including *Borrichia frutescens, Batis maritima, Salicornia* spp., *Atriplex matamorensis, Sesuvium portulacastrum*, and *Suaeda linearis*.

DISTRIBUTION

Range: This system occurs in the Tamaulipan region of south Texas and possibly Mexico.

TEMPERATE PACIFIC FRESHWATER AQUATIC BED (CES200.876)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Depressional [Pond]; Aquatic Herb
Non-Diagnostic Classifiers: Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Lake; Pond; Temperate [Temperate Continental]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Hydromorphic-rooted grassland
National Mapping Codes: EVT 2664; ESLF 9219; ESP 1664

CONCEPT

Summary: Freshwater aquatic beds are found throughout the humid temperate regions of the Pacific Coast of North America. They are small patch in size, confined to lakes, ponds, oxbows, and slow-moving portions of rivers and streams. In large bodies of water, they are usually restricted to the littoral region where penetration of light is the limiting factor for growth. A variety of rooted or floating aquatic herbaceous species may dominate, including *Azolla* spp., *Nuphar polysepala, Polygonum* spp., *Potamogeton* spp., *Ranunculus* spp., and *Wolffia* spp. Submerged vegetation, such as *Myriophyllum* spp., *Ceratophyllum* spp., and *Elodea* spp., is often present. These communities occur in water too deep for emergent vegetation.
Classification Comments: The aquatic beds in the Alaska systems classification for the maritime region are included here. However, aquatic beds on Kodiak Island, Alaska, are placed into Aleutian Freshwater Aquatic Bed (CES105.234).
Similar Ecological Systems:
- Aleutian Freshwater Aquatic Bed (CES105.234)

TEMPERATE PACIFIC FRESHWATER EMERGENT MARSH (CES200.877)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Temperate [Temperate Continental]; Depressional [Pond]
Non-Diagnostic Classifiers: 30-180-day hydroperiod; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Depressional [Lakeshore]; Depressional [Sinkhole]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2662; ESLF 9260; ESP 1662

CONCEPT

Summary: Freshwater marshes are found at all elevations below timberline throughout the temperate Pacific Coast and mountains of western North America. In the Pacific Northwest, they are mostly small-patch, confined to limited areas in suitable floodplain or basin topography. They are mostly semipermanently flooded, but some marshes have seasonal hydrologic flooding. Water is at or above the surface for most of the growing season. Soils are muck or mineral (in Alaska typically muck over a mineral soil), and water is high-nutrient. Occurrences of this system typically are found in a mosaic with other wetland systems. It is often found along the borders of ponds, lakes or reservoirs that have more open basins and a permanent water source throughout all or most of the year. Some of the specific communities will also be found in floodplain systems where more extensive bottomlands remain. By definition, freshwater marshes are dominated by emergent herbaceous species, mostly graminoids (*Carex, Scirpus* and/or *Schoenoplectus, Eleocharis, Juncus, Typha latifolia*) but also some forbs. Common emergent and floating vegetation includes species of *Scirpus* and/or *Schoenoplectus, Typha, Eleocharis, Sparganium, Sagittaria, Bidens, Cicuta, Rorippa, Mimulus*, and *Phalaris*. Maritime Alaska freshwater marshes are described as having *Carex rostrata, Equisetum fluviatile* (often pure stands), *Carex aquatilis var. dives (= Carex sitchensis), Menyanthes trifoliata, Comarum palustre, Eleocharis palustris*, and *Schoenoplectus tabernaemontani*. In relatively deep water, there may be occurrences of the freshwater aquatic bed system, where there are floating-leaved genera such as *Lemna, Potamogeton, Polygonum, Nuphar, Hydrocotyle*, and *Brasenia*. A consistent source of freshwater is essential to the function of these systems.

Classification Comments: In Alaska, freshwater marshes found in floodplain wetland mosaics are not included in this system. Also, freshwater marshes on Kodiak Island, Alaska, are placed into Aleutian Freshwater Marsh (CES105.235). This system encompasses a very large geographic range. We may want to split it into two types, on a north-south gradient. However, the species composition and environmental settings of freshwater marshes throughout the temperate Pacific region are markedly similar. Where to make a split that would make sense biogeographically is hard to determine. For now, they are maintained as one ecological system.

TEMPERATE PACIFIC SUBALPINE-MONTANE WET MEADOW (CES200.998)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: 30-180-day hydroperiod; Herbaceous; Muck; Graminoid
Non-Diagnostic Classifiers: Circumneutral Water; Montane; Temperate [Temperate Oceanic]; Depressional; Riverine / Alluvial
National Mapping Codes: ESLF 9265

CONCEPT

Summary: Montane and subalpine wet meadows occur in open wet depressions, basins and flats among montane and subalpine forests from California's Transverse and Peninsular ranges north to British Columbian coastal forests at varying elevations depending on latitude. Sites are usually seasonally wet, often drying by late summer, and many occur in a tension zone between perennial wetlands and uplands, where water tables fluctuate in response to long-term climatic cycles. They may have surface water for part of the year, but depths rarely exceed a few centimeters. Soils are mostly mineral and may show typical hydric soil characteristics, and shallow organic soils may occur as inclusions. This system often occurs as a mosaic of several plant associations with varying dominant herbaceous species that may include *Camassia quamash, Carex bolanderi, Carex utriculata, Carex exsiccata, Dodecatheon jeffreyi, Glyceria striata (= Glyceria elata), Carex nigricans, Calamagrostis canadensis, Juncus nevadensis, Caltha leptosepala ssp. howellii, Veratrum californicum*, and *Scirpus* and/or *Schoenoplectus* spp. Trees occur peripherally or on elevated microsites and include *Picea engelmannii, Abies lasiocarpa, Abies amabilis, Tsuga mertensiana*, and *Chamaecyparis nootkatensis*. Common shrubs may include *Salix* spp., *Vaccinium uliginosum, Betula glandulosa*, and *Vaccinium macrocarpon*. Wet meadows are tightly associated with snowmelt and typically are not subjected to high disturbance events such as flooding.
Classification Comments: Rocky Mountain Alpine-Montane Wet Meadow (CES306.812) occurs to the east of the coastal and Sierran mountains, in the semi-arid interior regions of western North America. Boreal wet meadow systems occur further north and east in boreal regions where the climatic regime is generally colder than that of the Rockies or Pacific Northwest regions. Floristics of these three systems are somewhat similar, but there are differences related to biogeographic affinities of the species composing the vegetation. Wet meadows in southeastern Alaska have been placed into a new system (2008), Alaskan Pacific Maritime Fen and Wet Meadow (CES204.158).
Similar Ecological Systems:
- Alaskan Pacific Maritime Fen and Wet Meadow (CES204.158)

Related Concepts:

TEMPERATE PACIFIC TIDAL SALT AND BRACKISH MARSH (CES200.091)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saline Water Chemistry; 30-180-day hydroperiod; Temperate [Temperate Hyperoceanic]; Temperate [Temperate Oceanic]; Tidal / Estuarine [Haline]; Tidal / Estuarine [Oligohaline]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2668; ESLF 9281; ESP 1668

CONCEPT

Summary: Intertidal salt and brackish marshes are found throughout the Pacific Coast, from Kodiak Island and south-central Alaska to the central California coast. They are primarily associated with estuaries or coastal lagoons. Salt marshes are limited to bays and behind sand spits or other locations protected from wave action. Typically these areas form with a mixture of inputs from freshwater sources into coastal saltwater, so they commonly co-occur with brackish marshes. This is a small-patch system, confined to specific environments defined by ranges of salinity, tidal inundation regime, and soil texture. Patches usually occur as zonal mosaics of multiple communities. They vary in location and abundance with daily and seasonal dynamics of freshwater input from inland balanced against evaporation and tidal flooding of saltwater. Summer-dry periods result in decreased freshwater inputs from inland. Hypersaline environments within salt marshes occur in "salt pans" where tidal water collects and evaporates. Characteristic plant species include *Distichlis spicata, Limonium californicum, Jaumea carnosa, Salicornia* spp., *Suaeda* spp., and *Triglochin* spp. Low marshes are located in areas that flood every day and are dominated by a variety of low-growing forbs and low to medium-height graminoids, especially *Salicornia virginica, Distichlis spicata, Schoenoplectus maritimus (= Scirpus maritimus), Schoenoplectus americanus (= Scirpus americanus), Carex lyngbyei*, and *Triglochin maritima*. In Alaska, tidal marshes are often dominated by near-monotypic stands of *Carex lyngbyei*, while the frequently inundated lower salt marshes are often dominated by *Eleocharis palustris* or *Puccinellia* spp. Other common species in Alaska include *Hippuris tetraphylla, Plantago maritima, Cochlearia groenlandica (= Cochlearia officinalis), Spergularia canadensis, Honckenya peploides*, or *Glaux maritima*. In the Cook Inlet and Alaska Peninsula, *Carex ramenskii* may be an associated species. High marshes are located in areas that flood infrequently and are dominated by medium-tall graminoids and low forbs, especially *Deschampsia caespitosa, Argentina egedii, Juncus balticus*, and *Symphyotrichum subspicatum (= Aster subspicatus)*, and in Alaska *Poa eminens, Argentina egedii, Festuca rubra*, and *Deschampsia caespitosa*. Transition zone (slightly brackish) marshes are often dominated by *Typha* spp. or *Schoenoplectus acutus*. *Atriplex prostrata (= Atriplex triangularis), Juncus mexicanus, Phragmites* spp., *Cordylanthus* spp., and *Lilaeopsis masonii* are important species in California. The invasive weed *Lepidium latifolium* is a problem in many of these marshes. Rare plant species include *Cordylanthus maritimus ssp. maritimus*.
Classification Comments: Discussions with John Christy and Todd Keeler-Wolf led to lumping all West Coast salt and brackish marshes into one system because they co-occur so intimately and frequently, are not readily distinguished without detailed on-the-ground surveys, and are totally intergraded (seemingly continuous variation) in terms of degree of salinity and resulting vegetation. This system encompasses a very large geographic range. We may want to split it into two types, on a north-south gradient. However, the species composition and environmental settings of tidal marshes throughout the temperate Pacific region are markedly similar. Where to make a split that would make sense biogeographically is hard to determine. For now, they are maintained as one ecological system.

- III.D.2.a - Four-leaf marestail (Viereck et al. 1992) Intersecting
- Wetlands (217) (Shiflet 1994) Broader

DESCRIPTION

Environment: The frequency of tidal flooding and salinity vary widely. Soils are usually fine-textured and saturated. Tidal marshes have a limited distribution along the Gulf of Alaska and British Columbia coastline due to the topography and geomorphology of the coast, which features steep slopes and deep fjords and offers limited protection from wave action (National Wetlands Working Group 1988).
Dynamics: Tidal marsh zonal mosaics of multiple communities vary in location and abundance with daily and seasonal dynamics of freshwater input from inland balanced against evaporation and tidal flooding of saltwater. Summer-dry periods result in decreased freshwater inputs from inland. Hypersaline environments within salt marshes occur in "salt pans" where tidal water collects and evaporates. High marshes flood infrequently, mid marshes flood usually at higher tides and are usually brackish waters, while low marshes are inundated with saltwater daily.

TEXAS COAST FRESH AND OLIGOHALINE TIDAL MARSH (CES203.472)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Freshwater]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9243

CONCEPT

Summary: This ecological system includes tidal marshes strongly influenced by freshwater producing a fresh to oligohaline chemistry, where salinity is maintained sufficiently low through freshwater inflows to produce fresh to oligohaline water chemistry. These marshes typically occur as small patches along bay margins and river or bayou mouths of inflowing rivers from Galveston Bay in Chambers County, Texas, south to approximately Corpus Christi Bay. Some characteristic plant species include *Paspalum vaginatum, Spartina patens, Schoenoplectus americanus, Phragmites australis, Sagittaria platyphylla, Vigna luteola,* and *Typha* spp.
Similar Ecological Systems:
- Gulf Coast Chenier Plain Fresh and Oligohaline Tidal Marsh (CES203.467)

Related Concepts:
- Coastal: Fresh and Intermediate Tidal Marsh (5907) [CES203.472] (Elliott 2011) Equivalent

DESCRIPTION

Environment: The typical geology is young Quaternary alluvium. Characteristic landforms include the mouths of rivers and bayous emptying into bays of the Galveston Bay system. The soils on which this system is found are the typical soils of the Tidal Flats and Salt Marsh Ecological Sites where they occur in areas of sufficient freshwater inflow (Elliott 2011).
Vegetation: Some characteristic plant species include *Paspalum vaginatum, Spartina patens, Schoenoplectus americanus, Phragmites australis, Sagittaria platyphylla, Vigna luteola,* and *Typha* spp.
Dynamics: This marsh system is dependent upon freshwater input, sediment input and organic matter build-up. Species richness is higher in oligohaline marshes than in mesohaline and polyhaline marshes.

Component Associations:
- *Paspalum vaginatum - Spartina patens* Oligohaline Herbaceous Vegetation (CEGL007885, G2?)
- *Phragmites australis - (Sagittaria platyphylla, Vigna luteola)* Tidal Herbaceous Vegetation (CEGL007891, G4?)
- *Schoenoplectus americanus - (Spartina patens) - Typha* spp. Herbaceous Vegetation (CEGL008476, G3?)

DISTRIBUTION

Range: This fresh and oligohaline marsh system ranges along the Texas coast south of the Chenier Plain. It is best developed along the central and upper coast of Texas from Galveston Bay in Chambers County, Texas, south to approximately Corpus Christi Bay.
Divisions: 203:C
Nations: US

TEXAS COAST SALT AND BRACKISH TIDAL MARSH (CES203.473)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Haline]; Graminoid
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9244

CONCEPT

Summary: This ecological system encompasses all of the brackish to salt intertidal marshes of the Texas coast south of the Chenier Plain. It ranges from Galveston Bay in Chambers County, Texas, south. These marshes typically occur on the bay side of barrier islands. Representative examples are dominated by *Spartina alterniflora, Juncus roemerianus,* or *Avicennia germinans*. Significant areas of *Avicennia germinans* become more frequent towards the south, while extensive areas of *Spartina alterniflora* become rare south of Corpus Christi Bay. The system also includes extensive irregularly-flooded tidal flats and salt pannes, some vegetated by succulent herbs such as *Sarcocornia, Salicornia,* and *Batis*; some are nonvegetated.

- Coastal: Tidal Flat (5600) [CES203.473.1] (Elliott 2011) Finer

DESCRIPTION

Environment: These marshes occupy relatively low-lying, coastal situations on level landforms influenced by microtidal fluctuations. Some sites are only influenced by storm tides or tides resulting from extreme wind events. These marshes typically occur on the bay side of barrier islands. This system also includes extensive irregularly-flooded tidal flats and salt pannes. The geology consists of recent marine, alluvial and eolian deposits along the coast. Landforms are nearly level to very gentle slopes and flats influenced by tides, including wind tides. Soils are coastal sands, and the system occupies various Salt Marsh Ecological Sites.

Vegetation: Representative examples are dominated by *Spartina alterniflora, Juncus roemerianus,* or *Avicennia germinans*. These marshes may be dominated by species such as *Spartina patens, Distichlis spicata, Schoenoplectus robustus, Schoenoplectus americanus, Sporobolus virginicus, Monanthochloe littoralis,* and *Spartina spartinae*. Shrubs, subshrubs and forbs, such as *Batis maritima, Borrichia frutescens, Sesuvium portulacastrum, Salicornia* spp., *Suaeda linearis, Limonium* spp., and *Lycium carolinianum*, are commonly encountered in these marshes. Some irregularly-flooded sites may become shrub-dominated with species such as *Iva frutescens* or *Baccharis halimifolia*. In the south, extensive areas are dominated by *Borrichia frutescens*, and these often occur at very slightly lower elevations and higher salinities than nearby *Spartina spartinae* salty prairie. These *Borrichia* flats may be very infrequently flooded, perhaps only under extreme storm tide conditions. Other species that may be encountered in these situations include *Maytenus phyllanthoides, Prosopis reptans, Monanthochloe littoralis, Distichlis spicata,* and *Batis maritima*. The aspect dominant on these sites is clearly *Borrichia frutescens*. Some examples may have unvegetated patches. Other plants that may be found in examples of this system include *Andropogon hallii, Artemisia filifolia, Iva frutescens ssp. frutescens, Schoenoplectus californicus, Schoenoplectus pungens*, and the exotic shrubs *Tamarix* spp (Elliott 2011).

Dynamics: Important processes and interactions in this system include the natural hydrological processes of rivers bringing freshwater and sediments to the coast, diurnal microtides, and protection from high-energy wave actions (Morton et al. 2004). The composition of these marshes is primarily influenced by the frequency and duration of tidal inundation. Salinity on some marshes, particularly in the south, is maintained by salt spray from prevailing southeasterly winds. Low marshes are regularly flooded. Areas of decreased frequency and/or duration of tidal inundation are often referred to as high, or irregularly flooded, marsh (Elliott 2011). Freshwater and sediment input are scarce in the southern part of this system's range. Sediment input is critical to marsh persistence and becomes even more important under accelerated sea-level rise scenarios. Marsh vegetation plays an equally important role in maintaining marsh elevation (Baustian et al. 2012). Salt and brackish marshes are important habitats for many animal species.

Component Associations:
- *Avicennia germinans / Spartina alterniflora* Shrubland (CEGL003801, G2?)
- *Batis maritima - Sarcocornia pacifica* Dwarf-shrubland (CEGL003956, G5)
- *Borrichia frutescens / (Spartina patens, Juncus roemerianus)* Shrubland (CEGL003924, G4)
- *Distichlis spicata - (Sporobolus virginicus)* Herbaceous Vegetation (CEGL007694, G3G5)
- *Iva frutescens ssp. frutescens - Baccharis halimifolia / Spartina spartinae* Shrubland (CEGL004616, G4?)

- *Juncus roemerianus* Herbaceous Vegetation (CEGL004186, G5)
- *Monanthochloe littoralis* Herbaceous Vegetation (CEGL003991, G2G3)
- *Sarcocornia pacifica* - (*Batis maritima, Distichlis spicata*) Dwarf-shrubland (CEGL002278, G4)
- *Spartina alterniflora - Distichlis spicata - Spartina patens* Mesohaline Tidal Herbaceous Vegetation (CEGL002230, G4?)
- *Spartina alterniflora - Juncus roemerianus - Distichlis spicata* Louisianian Zone Salt Tidal Herbaceous Vegetation (CEGL004190, G5)
- *Spartina patens - Schoenoplectus (americanus, pungens) - (Distichlis spicata)* Herbaceous Vegetation (CEGL004755, G4?)
- *Spartina spartinae - Sporobolus virginicus* Tidal Herbaceous Vegetation (CEGL004199, G4G5)

DISTRIBUTION

TEXAS COASTAL BEND SEAGRASS BED (CES203.474)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Aquatic Herb
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9287

CONCEPT

Summary: This system includes seagrass beds occurring along the Texas Coast south of San Antonio Bay. Dominants may include, individually or in admixtures with other seagrasses, *Cymodocea filiformis*, which is restricted in Texas to this ecological system, *Halophila engelmannii* or *Halodule wrightii (= Halodule beaudettei)*, which occupy thousands of acres of the Laguna Madre, and *Thalassia testudinum*. This system includes Texas' largest occurrences of *Thalassia testudinum* and *Halophila engelmannii*. Other dominants may include *Ruppia maritima*.

DESCRIPTION

Environment: This system occurs in clear shallow marine waters on muddy or sandy substrates.
Vegetation: As a result of natural climatic perturbations, such as tropical storms and hurricanes and human-induced disturbances, seagrass beds are often dynamic in their composition and size. As seagrasses are periodically uprooted by sea currents, turbulent waters, and exceptionally high tides, they are usually deposited in great masses on the beaches. *Thalassia testudinum*, along with *Cymodocea filiformis* are considered competitively superior to *Halodule wrightii (= Halodule beaudettei)* and may succeed this species in bays with optimum environments. Dramatic conversion of shoal-grass beds to beds dominated by these other two species, especially *Thalassia testudinum*, has occurred in the Laguna Madre of Texas (Onuf 1995). *Halophila engelmannii* often occurs in deeper waters than other seagrasses.

Component Associations:
- *Cymodocea filiformis - (Thalassia testudinum)* Herbaceous Vegetation (CEGL004317, G4?)
- *Halodule wrightii* Herbaceous Vegetation (CEGL004318, G4?)
- *Halophila engelmannii* Herbaceous Vegetation (CEGL004688, G3?)
- *Ruppia maritima* Louisianian Zone Herbaceous Vegetation (CEGL004450, G4G5)
- *Thalassia testudinum* Herbaceous Vegetation (CEGL004319, G4?)

TEXAS SALINE COASTAL PRAIRIE (CES203.543)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Herbaceous; West Gulf Coastal Plain; Extensive Wet Flat; Saline Substrate Chemistry
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2486; ESLF 9207; ESP 1486

CONCEPT

Summary: This system encompasses grassland vegetation occurring along the Gulf Coast of Texas on saline and nonsaline soils on level topography of the Beaumont Formation and in brackish marshes. These areas are often saturated by local rainfall and periodically flooded by saline waters during major storm events. Outliers also occur as scattered patches in salt flats. It is characteristically dominated by *Spartina spartinae*, a tall (1.5 m) warm-season perennial bunchgrass; other dominants may include *Schizachyrium littorale* and *Muhlenbergia capillaris*. This system also includes depressions often dominated by *Spartina patens*. Saline prairie continues to occupy extensive areas, though quality of the system is often degraded by the invasion of woody shrubs due to the absence of regular fire. Fire is an important ecological process needed to maintain this system, though periodic submersion with saltwater during storm events also helps to control the invasion of woody species.

Similar Ecological Systems:
- Texas Saline Inland Prairie (CES301.720)

Related Concepts:
- Gulf Coast: Salty Prairie (2207) [CES203.543.7] (Elliott 2011) Finer
- Gulf Coast: Salty Shrubland (2206) [CES203.543.6] (Elliott 2011) Finer

DESCRIPTION

Environment: This system occurs on saline and nonsaline soils of the Pleistocene Beaumont Formation that are often saturated by local rainfall and periodically flooded by saline waters during major storm events. Landforms are mostly level or very gently undulating, and typically found near the coast. These sites may be inundated by saltwater during storm surges. Pimple mounds may lend some local topographic variation to the otherwise level surface. Soils are very deep, somewhat poorly to poorly drained, often with high salinity and/or sodicity, at least at some depth. These may be loams or clays. These soils may be saturated from local rainfall or occasionally from storm surges (Elliott 2011). This system often forms a band between coastal salt marshes and coastal nonsaline prairie.

Vegetation: This system is characteristically dominated by *Spartina spartinae*, which may occur in nearly monotypic stands; other dominants may include *Schizachyrium littorale* and *Muhlenbergia capillaris*. This system includes depressions often dominated by *Spartina patens*. Other graminoids that may be present to abundant include *Schizachyrium scoparium, Andropogon glomeratus, Panicum virgatum*, or *Sporobolus indicus*. On lower, somewhat wetter sites, *Aristida oligantha, Paspalum hartwegianum, Sporobolus virginicus, Paspalum vaginatum*, and *Distichlis spicata* may be common. Forbs are generally uncommon but may include species such as *Borrichia frutescens, Solidago sempervirens, Iva angustifolia, Euthamia* spp., or other species more common to the non-saline soils nearby or the salt marsh that may also be nearby. Microtopographic highs in the form of pimple mounds often have species more characteristic of less saline adjacent habitats. Shrubby species may invade the prairie, commonly including species such as *Iva frutescens, Prosopis glandulosa, Acacia farnesiana, Lycium carolinianum, Tamarix* sp., and *Baccharis halimifolia* (Elliott 2011).

Dynamics: Fire is an important ecological process needed to maintain this system. Periodic submersion with saltwater during storm events also helps to control the invasion of woody species and contributes to higher soil salinity levels.

Component Associations:
- *Muhlenbergia capillaris* Herbaceous Vegetation (CEGL004607, G1G2)
- *Spartina spartinae - Schizachyrium scoparium* Herbaceous Vegetation (CEGL002231, G3)
- *Spartina spartinae* Herbaceous Vegetation (CEGL004608, G4)

DISTRIBUTION

Range: This system is restricted to the Gulf Coast of Texas.

TEXAS-LOUISIANA COASTAL PRAIRIE PONDSHORE (CES203.541)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: West Gulf Coastal Plain; Hardpan; Depressional; Graminoid
Non-Diagnostic Classifiers: Herbaceous; Isolated Wetland [Partially Isolated]; Palustrine
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2487; ESLF 9208; ESP 1487

CONCEPT

Summary: This ecological system includes small to moderately large ponds and swales in the coastal prairie of southeastern Texas and adjacent Louisiana. These wetlands contain surface water during much of the year, desiccating only in the driest summer months. They are often fed by water runoff but may result from percolation from adjacent sandy areas. Soils in the basins are finer-textured than surrounding areas and may be underlain by pans that enhance perched water tables in the winter. These wetlands occur within the coastal prairie matrix of southeastern Texas and Louisiana and are wetter than wet prairie dominated by *Tripsacum dactyloides* and *Panicum virgatum*. These wetlands may be dominated by *Eleocharis quadrangulata*. Other species that may be present include *Sagittaria papillosa, Sagittaria longiloba, Steinchisma hians, Panicum virgatum, Cyperus haspan, Cyperus virens, Ludwigia glandulosa, Ludwigia linearis, Fuirena squarrosa, Xyris jupicai, Leersia hexandra, Centella erecta, Symphyotrichum subulatum (= Aster subulatus), Sesbania* spp., and *Rhynchospora* spp. Open areas in the ponds may contain floating and submersed aquatic vegetation, including *Utricularia gibba, Stuckenia pectinata, Ceratophyllum demersum, Brasenia schreberi, Nymphoides aquatica, Nuphar advena,* and *Nelumbo lutea*.

Similar Ecological Systems:
- Texas-Louisiana Coastal Prairie (CES203.550)

Related Concepts:
- Gulf Coast: Coastal Prairie Pondshore (5307) [CES203.541] (Elliott 2011) Equivalent

DESCRIPTION

Environment: This small-patch system occurs in shallow depressions (microtopographic lows) on coastal Pleistocene terraces, including the Beaumont and Lissie formations, within the matrix of the generally level landscape of the Texas-Louisiana Coastal Prairie (CES203.550). Soils tend to be fine-textured, or are characterized by a relatively impermeable subsurface horizon (Elliott 2011). Examples of this system are often fed by water runoff but may result from groundwater percolation from adjacent sandy areas. Studies have shown that coastal prairie ponds may collectively occupy a large percentage of the land area within the coastal prairie (Enwright et al. 2011).

Vegetation: This system occurs as ponds or swales within the coastal prairie matrix. These wetlands are primarily herbaceous, sometimes with sparse woody cover, and are composed of various species, including *Eleocharis quadrangulata* (which may dominate some stands), *Fuirena squarrosa, Cyperus haspan, Cyperus virens, Rhynchospora* spp., *Leersia hexandra, Steinchisma hians, Panicum virgatum, Andropogon glomeratus, Xyris jupicai, Centella erecta, Sagittaria papillosa, Sagittaria longiloba, Ludwigia glandulosa, Ludwigia linearis, Bacopa* spp., *Hydrocotyle* spp., *Symphyotrichum subulatum (= Aster subulatus),* and *Sesbania* spp. Large areas of some of the occurrences may be relatively homogeneous, dominated by one or a few species. Areas of open water within the ponds may contain floating and submerged aquatic species, including *Stuckenia pectinata, Ceratophyllum demersum, Brasenia schreberi, Nymphoides aquatica,* and *Nelumbo lutea*. Occurrences are wetter than *Tripsacum dactyloides*- or *Panicum virgatum*-dominated prairie sites of Texas-Louisiana Coastal Prairie (CES203.550).

Dynamics: These wetlands are part of the larger hydrologic cycle of the coastal prairie ecosystem. They store surface water and in some cases groundwater during much of the year, desiccating only in the driest summer months. Soils in the basins are finer-textured than surrounding areas and may be underlain by pans that enhance perched water tables in the winter. They have been shown to play a role in landscape-level water quality regulation (Forbes et al. 2012). The herbaceous wetlands are maintained by fire.

Component Associations:
- *Brasenia schreberi* Eastern Herbaceous Vegetation (CEGL004527, G4?)
- *Eleocharis quadrangulata - Sagittaria* spp. Herbaceous Vegetation (CEGL007929, G3?)
- *Nelumbo lutea* Herbaceous Vegetation (CEGL004323, G4?)
- *Nuphar advena - Nymphaea odorata* Herbaceous Vegetation (CEGL002386, G4G5)
- *Potamogeton nodosus* Herbaceous Vegetation (CEGL004529, GNR)
- *Stuckenia pectinata - Ceratophyllum demersum* Texas Coastal Herbaceous Vegetation (CEGL004147, G3G4)

DISTRIBUTION

Range: This system is restricted to the coastal prairie of southeastern Texas and Louisiana.
Divisions: 203:C

Nations: US
Subnations: LA, TX

TEXAS-LOUISIANA FRESH-OLIGOHALINE SUBTIDAL AQUATIC VEGETATION (CES203.511)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine; Aquatic Herb
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9277

CONCEPT

Summary: This system includes subtidal beds of aquatic vegetation in fresh to oligohaline tidal waters of the Gulf of Mexico in Louisiana and Texas. Species composition may include *Stuckenia pectinata (= Potamogeton perfoliatus), Zannichellia palustris, Vallisneria americana, Najas guadalupensis,* and *Ruppia maritima*. It is found in the Trinity Bay portion of the Galveston Bay complex along the upper coast of Texas. Although the substrate of most Texas bays is sand, this system occurs on mud-dominated substrates (Adair et al. 1994). This system is also distinguished by the prevalence of oligohaline waters, whereas other Texas bays are considerably more saline. As a consequence, the predominant species, *Najas guadalupensis* and *Vallisneria americana*, which are salt intolerant, are able to attain dominance here. Both species are largely restricted to the northeastern portions of the bay where they are protected by a sand bar system which restricts wave action and turbidity. The extent and quality of this system have been heavily reduced by shoreline development and associated draining and filling, bulkheading, and channelization. Seagrass communities are declining in many bays along the Texas coast.

Component Associations:
- *Potamogeton perfoliatus - (Stuckenia pectinata, Zannichellia palustris)* Permanently Flooded - Tidal Herbaceous Vegetation (CEGL007689, GNR)
- *Vallisneria americana* Estuarine Bayou Herbaceous Vegetation (CEGL004634, G3G5)

DISTRIBUTION

Range: This system occurs primarily from Trinity Bay in Texas north along the Gulf of Mexico into Louisiana.
Divisions: 203:C
Nations: US

UPPER TEXAS COAST SEAGRASS BED (CES203.545)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saltwater (Polyhaline)
Non-Diagnostic Classifiers: Herbaceous
National Mapping Codes: ESLF 9401

CONCEPT

Summary: This system includes seagrass communities occurring in bays along the upper Texas coast north of and including San Antonio Bay. It includes vegetation dominated by *Thalassia testudinum*, *Halophila engelmannii*, *Ruppia maritima*, or *Halodule wrightii (= Halodule beaudettei)*. Many of these occurrences have declined in extent. Seagrass communities are declining in many bays along the Texas coast.

DESCRIPTION

Environment: See Adair et al. (1994). Examples are found in Christmas Bay, San Antonio Bay, and Copano Bay.
Vegetation: Some of the seagrass species found in examples of this system include *Halodule wrightii (= Halodule beaudettei)*, *Halophila engelmannii*, *Ruppia maritima*, and *Thalassia testudinum*.

Component Associations:
- *Halodule wrightii* Herbaceous Vegetation (CEGL004318, G4?)
- *Halophila engelmannii* Herbaceous Vegetation (CEGL004688, G3?)
- *Ruppia maritima* Louisianian Zone Herbaceous Vegetation (CEGL004450, G4G5)
- *Thalassia testudinum* Herbaceous Vegetation (CEGL004319, G4?)

DISTRIBUTION

WEST GULF COASTAL PLAIN FLATWOODS POND (CES203.547)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: West Gulf Coastal Plain; Depressional; Graminoid
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9349

CONCEPT

Summary: This system represents predominantly graminoid-dominated flatwoods ponds of the West Gulf Coastal Plain of eastern Texas and western Louisiana. These ponds are generally circular or elliptical, flat-bottomed depressions on flat terraces in the Outer Coastal Plain. The slowly permeable soils trap local runoff and precipitation resulting in higher water tables than surrounding areas. Water depth may be 3-5 feet in the winter and even deeper toward the center of some examples. Examples range from shallow to several meters in depth; the large and deeper examples may exhibit distinct vegetation zonation. Most examples have a layer of tall wetland grasses and sedges above a layer of semi-aquatic herbs. Many lack a significant woody layer due in part to periodic fires originating in the pine savanna matrix. However, scattered, often stunted *Nyssa biflora* and stems of *Cephalanthus occidentalis* may be present. The following species are characteristic of this type: *Eriocaulon compressum, Xyris fimbriata, Eleocharis equisetoides, Eleocharis quadrangulata*, as well as two additional species, *Carex verrucosa* and *Rhynchospora cephalantha*, which are more frequent in other pond types. Some other species frequently found in this type include *Eriocaulon compressum, Rhynchospora corniculata, Panicum hemitomon, Ludwigia sphaerocarpa, Xyris laxifolia var. iridifolia (= Xyris iridifolia)*, and *Sagittaria graminea*. Other herbaceous species may include *Gratiola brevifolia, Hydrolea ovata, Proserpinaca pectinata, Pluchea rosea, Ludwigia pilosa, Bacopa caroliniana, Xyris* sp., and *Rhynchospora capitellata*.

Similar Ecological Systems:
- West Gulf Coastal Plain Nonriverine Wet Hardwood Flatwoods (CES203.548)

Related Concepts:
- Pineywoods: Herbaceous Flatwoods Pond (3507) [CES203.547] (Elliott 2011) Equivalent
- Sweetbay - Swamp Tupelo - Redbay: 104 (Eyre 1980) Finer
- Water Tupelo - Swamp Tupelo: 103 (Eyre 1980) Finer

DESCRIPTION

Environment: This system tends to occur as inclusions within wetland pine savannas in depression ponds or ancient stream channels and sloughs. Occurrences range in size from less than an acre to 30-40 acres. Local runoff and rainfall collect in these depressions with slowly permeable soils. Resulting water tables persist for long periods after rain, at higher levels than surrounding parts of the landscape. Water depth in this pond type ranges from a few inches to several feet and is often 3-5 feet deep in winter, and even deeper areas (with floating aquatic vegetation) may occur in the center of some sites (Bridges 1988, Bridges and Orzell 1989a, LDWF 2005). They tend to occur as inclusions within wetland pine savannas, but may also be bordered by upland depression swamps. The depressions are typically closed, with no surface outlet. Water collects from local rainfall and runoff from small watersheds. There is typically no input from streamflow and little or no outflow (Bridges and Orzell 1989a). The geological setting is the Pleistocene terraces, including the upper Beaumont Formation, but also mapped on the high Pleistocene terraces in the northern part of Texas. These are estimated to occur on Quaternary Fluviatile Terrace (Tile) Deposits along the Red, Sulphur, and Sabine rivers. Stands occupy local topographic lows within the flatwoods. Soils are relatively fine-textured, with an impermeable subsoil horizon, giving rise to a perched water table and saturated conditions during extended periods of the year (Elliott 2011).

Vegetation: Plant species dominance varies greatly depending upon water depth and the spread of colonial, rhizomatous species, and may also be related to geographic isolation of individual ponds and variations in local fire regimes. Most examples have a layer of tall wetland grasses and sedges above a layer of semi-aquatic herbs. Many lack a significant woody layer due in part to periodic fires originating in the pine savanna matrix. Scattered woody plants, especially stunted *Nyssa biflora* or stems of *Cephalanthus occidentalis*, may be present. In some instances woody stems may develop sufficient density to be classified as woodlands. The following species are characteristic of this type: *Eriocaulon compressum, Xyris fimbriata, Eleocharis equisetoides, Eleocharis quadrangulata*, as well as two additional species, *Carex verrucosa* and *Rhynchospora cephalantha*, which are more frequent in other pond types. Some other species frequently found include *Eriocaulon compressum, Rhynchospora corniculata, Panicum hemitomon, Ludwigia sphaerocarpa, Xyris laxifolia var. iridifolia (= Xyris iridifolia)*, and *Sagittaria graminea*. Other herbaceous species may include *Gratiola brevifolia, Hydrolea ovata, Proserpinaca pectinata, Pluchea rosea, Ludwigia pilosa, Bacopa caroliniana, Xyris* sp., and *Rhynchospora capitellata*. Areas mapped as this system by TPWD (Elliott 2011) are likely dominated by *Panicum hemitomon, Carex* spp., *Rhynchospora* spp., *Eleocharis* spp., *Andropogon glomeratus*, and *Ludwigia* spp. On drier sites *Schizachyrium scoparium* may be present. Some sites may be dominated by the non-native *Cynodon dactylon*. A few woody species may occur, including *Nyssa biflora, Liquidambar styraciflua, Quercus nigra, Planera aquatica*, and *Cephalanthus occidentalis*. Flatwood ponds, as described by Bridges and Orzell (1989a), represent a more restricted subset of herbaceous-dominated sites with saturated soils resulting from a

perched water table due to an impermeable subsurface.
Dynamics: Water table fluctuations are probably the most important factor affecting examples of this system (Bridges and Orzell 1989a). Water collects in these depressions mostly through surface runoff after rainfall events but generally not as a result of overbank flooding. Water tends to be deepest during the wintertime when precipitation is concentrated (although other factors may also be important, such as the amount of evapotranspiration). Standing water may be evident from approximately November through May, and sporadically afterwards. This system is located within the frequently burned longleaf pine matrix and is kept at an herbaceous or mostly herbaceous state by fire.

Component Associations:
- *Aristida palustris - Panicum virgatum - Eriocaulon compressum - Eleocharis equisetoides* Herbaceous Vegetation (CEGL004577, G2G3)
- *Aristida palustris - Panicum virgatum - Eriocaulon decangulare var. decangulare - Rhynchospora elliottii* Herbaceous Vegetation (CEGL004576, G2G3)
- *Nymphoides aquatica - Nymphaea odorata - Gratiola brevifolia* Herbaceous Vegetation (CEGL004601, G3?)
- *Nyssa biflora - Crataegus opaca - (Fraxinus caroliniana) / Rhynchospora mixta* Woodland (CEGL007873, G2?)
- *Nyssa biflora / Panicum hemitomon - Woodwardia virginica* Woodland (CEGL004586, G3?)
- *Panicum hemitomon - Eriocaulon compressum - Rhynchospora corniculata* Herbaceous Vegetation (CEGL004578, G2)

SPATIAL CHARACTERISTICS

Size: Most are quite small features; although specific data are not available, most are believed to be less than 1 acre in size.

WEST GULF COASTAL PLAIN HERBACEOUS SEEP AND BOG (CES203.194)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: West Gulf Coastal Plain; Seepage-Fed Sloping; Very Short Disturbance Interval; Graminoid
Non-Diagnostic Classifiers: Herbaceous; Palustrine
National Mapping Codes: ESLF 9298

CONCEPT

Summary: This wet, small-patch, fire-maintained, hillside seepage system occurs in the Gulf Coastal Plain west of the Mississippi River where it is documented from east-central Texas to western Louisiana, and adjacent areas of southern Arkansas. This oligotrophic wetland is maintained by seepage at the zone between an overlaying, permeable sandy layer and a lower layer of relatively impermeable material such as sandstone or clay. The vegetation of intact examples is dominated by a dense, species-rich graminoid-forb layer less than 1 m tall with continuous to nearly continuous cover, typically 80-90%. This type is intended to encompass the range of variation present in West Gulf Coastal Plain seepage bogs, although various authors have recognized a number of different subtypes. One of the most distinct variants that is included here for now is the "muck bog" of the Post Oak Savanna and Cross Timbers regions. It differs in a number of ways from most other examples of this system and may need to be recognized as a distinct ecological system.

Related Concepts:

- Pineywoods: Herbaceous Seepage Bog (2307) [CES203.194.7] (Elliott 2011) Equivalent

DESCRIPTION

Environment: This small patch oligotrophic wetland is maintained by seepage at the zone between an overlaying, permeable sandy layer and a lower layer of relatively impermeable material such as sandstone or clay. Examples are often associated with Eocene sand formations such as Queen City, Sparta, and particularly Carrizo sands. It is generally found on slopes, as well as on valley floors and toeslopes where seepage from upslope occurs through the deep sands on site. Soils are sands. Deep Sand, Very Deep Sand, or Wet Sandy Draw Ecological Sites are typical of this system and surrounding areas.

Vegetation: This small-patch system typically presents as an herbaceous wetland, though sometimes significant shrub cover by *Morella cerifera* and/or other species may be conspicuous. The herbaceous layer is dominated by a dense, species-rich, graminoid-forb layer less than 1 m tall with continuous to nearly continuous cover, typically 80-90%. Seepage, which controls the floristic composition, results from the percolation of water through a porous sand layer until it encounters a more impermeable layer and flows to the surface. *Sarracenia alata* is often the aspect dominant of this system. Grass species present may include *Andropogon glomeratus, Dichanthelium scoparium, Panicum anceps, Panicum brachyanthum, Panicum virgatum, Paspalum laeve, Saccharum giganteum,* and *Steinchisma hians*. Sedges and rushes are well-represented and may include *Cyperus strigosus, Eleocharis acicularis, Fuirena squarrosa, Juncus dichotomus, Juncus diffusissimus, Juncus effusus,* and *Rhynchospora* spp. (including *Rhynchospora gracilenta, Rhynchospora oligantha,* and/or *Rhynchospora rariflora*). A diverse forb assemblage is typically present and may include *Eryngium integrifolium, Eupatorium perfoliatum, Habenaria repens, Hypericum mutilum, Ludwigia alternifolia, Lycopodiella* spp., *Osmunda cinnamomea, Osmunda regalis, Pogonia ophioglossoides, Polygala cruciata, Rhexia mariana, Sarracenia alata, Symphyotrichum dumosum var. dumosum, Woodwardia* spp., and/or *Xyris* spp. (*Xyris ambigua, Xyris baldwiniana, Xyris difformis, Xyris jupicai, Xyris laxifolia,* and/or *Xyris torta*). Seeps may feed downslope depressional wetlands which may be overtaken by shrub species such as *Morella cerifera* or may be dominated by *Eleocharis* spp., *Juncus* spp., *Panicum hemitomon,* and/or *Rhynchospora* spp. (Elliott 2011).

The bog of portions of East-Central Texas Plains Post Oak Savanna and Woodland (CES205.679), commonly referred to as "muck bogs," differ from similar bogs within the West Gulf Coastal Plain by a decrease in species richness towards the west. These bogs can become dominated by woody species such as *Morella cerifera, Ilex vomitoria,* and *Smilax laurifolia*. East of the Post Oak Savanna, other woody species such as *Toxicodendron vernix, Magnolia virginiana, Persea borbonia,* and *Pinus palustris* may form a sparse emergent canopy, even in well-burned examples. Sites east of the Post Oak Savanna may contain broad-leaved evergreen woody species such as *Magnolia virginiana, Cyrilla racemiflora, Morella caroliniensis, Persea palustris,* and *Ilex coriacea*. Herbaceous species more characteristic of eastern occurrences include *Gelsemium sempervirens, Hypericum galioides, Lachnocaulon anceps, Ludwigia hirtella, Marshallia graminifolia, Rhexia petiolata, Rhynchospora inexpansa, Rhynchospora plumosa, Rudbeckia scabrifolia,* and *Xyris drummondii*. Woody shrubs have a cover of less than 10% in frequently burned examples but increase greatly with reductions in fire frequency. This type is intended to encompass the range of variation present in West Gulf Coastal Plain seepage bogs, although various authors have recognized a number of different subtypes. For more information, see Bridges and Orzell (1989a).

Dynamics: This system is maintained by groundwater seepage. The size of the recharge zone helps determine the amount of groundwater present within the system. Frequent fires are essential to control invasion by wetland shrubs, although the wettest areas may persist in an herbaceous-dominated condition without fire. However, fire may also be necessary to stimulate growth, flowering and seed production of many herbaceous species found in this community. In the absence of fire, these bogs may become heavily

wooded, resulting in the eventual elimination of the bog (Folkerts 1982). Increased development of woody species suppresses herbaceous species and potentially produces some drying effect by pumping larger volumes of water.

Component Associations:
- *Carex lurida - Andropogon glomeratus - Sarracenia alata - Symphyotrichum puniceum var. scabricaule - Doellingeria sericocarpoides* Herbaceous Vegetation (CEGL008417, G1)
- *Dichanthelium scoparium - Boehmeria cylindrica / Sphagnum* spp. - *Polytrichum commune* Herbaceous Vegetation (CEGL004916, G2Q)
- *Sarracenia alata - Rhynchospora gracilenta - Rudbeckia scabrifolia - Schoenolirion croceum* Herbaceous Vegetation (CEGL004175, G2G3)

WESTERN GREAT PLAINS CLOSED DEPRESSION WETLAND (CES303.666)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Clay Subsoil Texture; Impermeable Layer; Saturated Soil; Lowland [Lowland]; Playa; Herbaceous; Depressional; Isolated Wetland [Strictly Isolated]; Depression
National Mapping Codes: ESLF 9252

CONCEPT

Summary: Communities associated with the playa lakes in the southern areas of this province and the rainwater basins in Nebraska characterize this system. They are primarily upland depressional basins. This hydric system is typified by the presence of an impermeable layer such as a dense clay, hydric soil and is usually recharged by rainwater and nearby runoff. They are rarely linked to outside groundwater sources and do not have an extensive watershed. Ponds and lakes associated with this system can experience periodic drawdowns during drier seasons and years, and are often replenished by spring rains. *Eleocharis* spp., *Hordeum jubatum*, along with common forbs such as *Coreopsis tinctoria, Symphyotrichum subulatum (= Aster subulatus),* and *Polygonum pensylvanicum (= Polygonum bicorne)* are common vegetation in the wetter and deeper depression, while *Pascopyrum smithii* and *Buchloe dactyloides* are more common in shallow depressions in rangeland. Species richness can vary considerably among individual examples of this system and is especially influenced by adjacent land use, which is often agriculture, and may provide nutrient and herbicide runoff. Dynamic processes that affect these depressions are hydrological changes, grazing, and conversion to agricultural use.
Classification Comments: Open and emergent marshes may be a separate system from wet meadows and wet prairies. This system needs to be more clearly distinguished from the similar open depressional wetlands of the western Great Plains, as well as from Great Plains Prairie Pothole (CES303.661).
Similar Ecological Systems:
- Inter-Mountain Basins Alkaline Closed Depression (CES304.998)
- North American Arid West Emergent Marsh (CES300.729)
- Tamaulipan Closed Depression Wetland (CES301.197)
- Western Great Plains Open Freshwater Depression Wetland (CES303.675)
- Western Great Plains Saline Depression Wetland (CES303.669)

Related Concepts:
- Bluestem Prairie (601) (Shiflet 1994) Intersecting. Spartina pectinata wet swales occur as inclusions in this SRM type, but are classed into a wetland ecological system.
- Western Great Plains Closed Depression Wetland (Rolfsmeier and Steinauer 2010) Equivalent

DESCRIPTION

Environment: This system is typified by circular upland depressional basins with an impermeable layer such as dense clay which slows infiltration and promotes retention of water. Soils are hydric and fine-grained. Rainwater and runoff recharge this system and it is rarely linked to outside groundwater sources. Water is lost through both evapotranspiration and percolation to aquifers. It has been estimated that 20-80% of water in playas infiltrates into the aquifers, principally along the margins of the wetlands where subsurface clay content is less (Osterkamp and Wood 1987). Playas are shallow, generally less than 1 m deep, with very shallow sloping sides. This results in nearly equal water depths throughout the playa, and small changes in water depth have effects across a relatively large surface area. Playas in the Southern High Plains average 6.3 ha in area. These ephemeral wetlands have small watersheds. The average watershed size is 55.5 ha (Guthery and Bryant 1982). Playas are isolated, with no surface outflow except in unusually wet periods.
Vegetation: Species richness varies considerably among individual examples of this system. Commonly, *Eleocharis* spp., *Hordeum jubatum*, along with *Coreopsis tinctoria, Symphyotrichum subulatum (= Aster subulatus),* and *Polygonum pensylvanicum (= Polygonum bicorne)* are found in the wetter and deeper depression. Shallower depressions in rangelands commonly contain *Pascopyrum smithii* and *Buchloe dactyloides.*
Dynamics: Playas have a large change in hydrologic status over much of their areas. That is, most of the area of an individual playa is wet or flooded at one point in the growing season and also dry during another point in the growing season. Some do have deeper areas that are wet or flooded for nearly the entire growing season. More common is having multiple wet-dry cycles during one growing season in response to rain and dry periods. This rapid change in available moisture and in exposed soil limits the species that can grow. This often results in strong dominance by a few perennial species able to tolerate these conditions or by annuals that can go through their life cycle before conditions change (Haukos and Smith 1993). However, the unconnected nature of playas combined with the variable environmental conditions throughout the year favors the formation of differing assemblages of vegetation at any one time on playas across the landscape. This contributes to regional diversity of plant and animal habitats throughout the year (Haukos and Smith 1994). Fire can spread into this system from surrounding grasslands but it is uncommon. The surrounding grasslands are typically short and do not have sufficient fuel to carry fire well, and while playas usually have more dense vegetation cover than the

adjacent uplands, they may be wet.

WESTERN GREAT PLAINS OPEN FRESHWATER DEPRESSION WETLAND (CES303.675)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Saturated Soil; Herbaceous; Depressional; Isolated Wetland [Partially Isolated]; Depression
National Mapping Codes: ESLF 9218

CONCEPT

Summary: This Great Plains emergent marsh ecological system is composed of lowland depressions; it also occurs along lake borders that have more open basins and a permanent water source through most of the year, except during exceptional drought years. These areas are distinct from Western Great Plains Closed Depression Wetland (CES303.666) by having a large watershed and/or significant connection to the groundwater table. A variety of species are part of this system, including emergent species of *Typha, Carex, Eleocharis, Juncus, Spartina,* and *Schoenoplectus,* as well as floating genera such as *Potamogeton, Sagittaria, Stuckenia,* or *Ceratophyllum*. The system includes submergent and emergent marshes and associated wet meadows and wet prairies. These types can also drift into stream margins that are more permanently wet and linked directly to the basin via groundwater flow from/into the pond or lake. Some of the specific communities will also be found in the floodplain system and should not be considered a separate system in that case. These types should also not be considered a separate system if they are occurring in lowland areas of the prairie matrix only because of an exceptional wet year.
Classification Comments: This system occurs widely throughout the western Great Plains, but in the arid shortgrass region, it is replaced by North American Arid West Emergent Marsh (CES300.729). Open and emergent marshes may be a separate system from wet meadows and wet prairies. More clarification needs to be made between this system and other depressional wetlands occurring in Wyoming and Montana, such as the Inter-Mountain Basins Alkaline Closed Depression (CES304.998), Great Plains Prairie Pothole (CES303.661), and the other western Great Plains depressional wetland systems.
Similar Ecological Systems:
- North American Arid West Emergent Marsh (CES300.729)
- Western Great Plains Closed Depression Wetland (CES303.666)
- Western Great Plains Saline Depression Wetland (CES303.669)

Related Concepts:
- Western Great Plains Open Freshwater Depression Wetland (Rolfsmeier and Steinauer 2010) Equivalent

DESCRIPTION

Environment: This system is found within lowland depressions and along lakes that have more permanent water sources throughout the year. These areas typically have a large watershed and are connected to the groundwater sources, resulting in a relatively consistent source of water for the semi-arid climate they occur in. Examples may also drift into stream margins that are more permanently wet and linked to a basin via groundwater flow from/into a pond or lake. Those areas that are found within larger prairie matrix that are only lowland or wet because of an exceptional wet year are not part of this system. This system occurs south of the limit of recent glaciation. Salinity ranges from fresh to brackish. Soils range from clay and silt to sandy loam. Marshes with coarser soils are usually connected more directly to the water table, which prevents rapid draining of the wetland.
Vegetation: Many species can be associated with this system with *Typha* spp. and *Schoenoplectus* spp. being common.
Dynamics: Hydrology is the primary process influencing this system. Examples of this system have a core area that is saturated or flooded much or all of the growing season. In some sites, water levels exceed 1 m throughout the growing season. Examples of this system receive water from groundwater flow, surface drainage from the watershed, and direct precipitation. In the northern half of the range of this system, snowmelt can cause a relatively large influx of water in the spring. Water levels are typically highest in the spring and generally fall throughout the growing season, with occasional refilling of the basin after very heavy summer rains. Changes in precipitation over a period of years or decades (wetter or drier periods) will increase or decrease the extent of individual examples of this system and can move the range of the entire system slightly.

Fires can occur in this system, often spreading from adjacent upland prairie. Fire is more common in the fall when water levels are lower and the vegetation has dried out. Fire is also more common in the eastern portion of the range of this system where surrounding uplands had more dense upland tallgrass prairie rather than the sparser mixedgrass uplands typical of the western range of this system.

Component Associations:
- *Alnus incana* Swamp Shrubland (CEGL002381, G5)
- *Betula occidentalis - Dasiphora fruticosa ssp. floribunda* Shrubland (CEGL001083, G2Q)
- *Calamagrostis canadensis - Juncus* spp. - *Carex* spp. Sandhills Herbaceous Vegetation (CEGL002028, G3G4)
- *Calamagrostis stricta - Carex sartwellii - Carex praegracilis - Plantago eriopoda* Saline Herbaceous Vegetation (CEGL002255, G2G3)
- *Carex aquatilis - Carex* spp. Herbaceous Vegetation (CEGL002262, G4?)
- *Carex aquatilis* Herbaceous Vegetation (CEGL001802, G5)

- *Carex atherodes* Herbaceous Vegetation (CEGL002220, G3G5)
- *Carex interior - Eleocharis elliptica - Thelypteris palustris* Herbaceous Vegetation (CEGL002390, G1G2)
- *Carex nebrascensis* Herbaceous Vegetation (CEGL001813, G4)
- *Carex pellita - Calamagrostis stricta* Herbaceous Vegetation (CEGL002254, G3G5)
- *Carex prairea - Schoenoplectus pungens - Rhynchospora capillacea* Herbaceous Vegetation (CEGL002267, G2)
- *Carex* spp. - *Triglochin maritima - Eleocharis quinqueflora* Marl Fen Herbaceous Vegetation (CEGL002268, G1?)
- *Carex stricta - Carex* spp. Herbaceous Vegetation (CEGL002258, G4?)
- *Carex utriculata - Carex lacustris - (Carex vesicaria, Carex stricta)* Herbaceous Vegetation (CEGL002257, G4G5)
- *Ceratophyllum demersum - Stuckenia pectinata* Herbaceous Vegetation (CEGL004528, G4G5)
- *Cornus sericea - Salix (bebbiana, discolor, petiolaris) / Calamagrostis stricta* Shrubland (CEGL002187, G3G4)
- *Eleocharis palustris - (Eleocharis compressa) - Leptochloa fusca ssp. fascicularis* Herbaceous Vegetation (CEGL002259, GNR)
- *Eleocharis palustris* Great Plains Herbaceous Vegetation (CEGL005291, GNR)
- *Glyceria borealis* Herbaceous Vegetation (CEGL001569, G4)

WESTERN GREAT PLAINS SALINE DEPRESSION WETLAND (CES303.669)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Saline Water Chemistry; Herbaceous; Depressional; Isolated Wetland [Partially Isolated]; Depression
National Mapping Codes: ESLF 9256

CONCEPT

Summary: This ecological system is very similar to Western Great Plains Open Freshwater Depression Wetland (CES303.675) and Western Great Plains Closed Depression Wetland (CES303.666). However, strongly saline soils cause both the shallow lakes and depressions and the surrounding areas to be more brackish. Salt encrustations can occur on the surface in some examples of this system, and the soils are severely affected and have poor structure. Species that typify this system are salt-tolerant and halophytic species such as *Distichlis spicata, Sporobolus airoides*, and *Hordeum jubatum*. Other commonly occurring taxa include *Puccinellia nuttalliana, Salicornia rubra, Schoenoplectus maritimus, Schoenoplectus americanus, Suaeda calceoliformis, Spartina* spp., *Triglochin maritima*, and shrubs such as *Sarcobatus vermiculatus* and *Krascheninnikovia lanata*. During exceptionally wet years, an increase in precipitation can dilute the salt concentration in the soils of some examples of this system which may allow for less salt-tolerant species to occur. Communities found within this system may also occur in floodplains (i.e., more open depressions) but probably should not be considered a separate system unless they transition to areas outside the immediate floodplain.
Classification Comments: Open and emergent saline marshes may be a separate system from saline wet meadows and prairies. This system is often intimately associated (in space) with greasewood flats, and there is some overlap in the associations between the two. This system tends to be more of an herbaceous wetlands, whereas Inter-Mountain Basins Greasewood Flat (CES304.780) is more strongly shrub-dominated with patches of herb-dominance.
Similar Ecological Systems:
- North American Arid West Emergent Marsh (CES300.729)
- Western Great Plains Closed Depression Wetland (CES303.666)
- Western Great Plains Open Freshwater Depression Wetland (CES303.675)

Related Concepts:
- Western Great Plains Saline Depression Wetland (Rolfsmeier and Steinauer 2010) Equivalent
- Wheatgrass - Saltgrass - Grama (615) (Shiflet 1994) Intersecting

DESCRIPTION

Environment: This system is found in basins and low parts of floodplains where water collects. The soils and water are moderately to strongly saline (>0.5-1%) (Ungar 1967, 1970). The salts are leached from saline soils in the watershed or, rarely, come from saline groundwater discharge. Salts accumulate as the water in which they were dissolved evaporates. Salt crusts are present on the soil surface of some stands. Soils are fine-grained, typically with a silt or clay component, and poorly drained. The wettest examples of this system are flooded through most or all of the growing season and can support aquatic species. Other aspects of the system can be flooded or saturated for short periods (Dodd and Coupland 1966, Stewart and Kantrud 1971).
Vegetation: Salt-tolerant and halophytic species such as *Distichlis spicata, Sporobolus airoides*, and *Hordeum jubatum* typify the system.
Dynamics: Unusually wet periods or high spring snowmelt may flush some salt away, shifting the boundaries of this system temporarily until more salt accumulates. Salinity varies during the growing season, decreasing in the spring or after heavy rains and increasing during dry periods. The increased salinity due to concentration of the salt as the water evaporates - common in the late summer and early fall - creates a seasonally shifting environment. Species composition is strongly linked to salinity and soil moisture, so there is usually notable zonation within this system with the species tolerant of the wettest and most saline conditions in the center, grading towards midgrass prairie at the edges (Ungar 1967, 1970). Fire may spread into this system from adjacent upland prairies and can burn areas with higher vegetation cover, but the low vegetation cover and wet soils typical of many stands do not carry fire well.

Component Associations:

WESTERN NORTH AMERICAN BOREAL FRESHWATER EMERGENT MARSH (CES105.123)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Graminoid
Non-Diagnostic Classifiers: Lake; Pond; Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2625; ESLF 9434; ESP 1625

CONCEPT

Summary: Freshwater marshes are found throughout boreal transition and boreal regions of western and northern Alaska. They are characterized by emergent herbaceous vegetation. Freshwater marshes typically occur with other wetland systems. They occur on the margins of ponds, lakes, and riparian systems and on inland deltas where rivers drain into large lakes. Inland marshes are mostly small patch, confined to limited areas in suitable floodplain or basin topography. They are typically semipermanently flooded, but some marshes have seasonal flooding. Water is at or above the surface for most of the growing season (typically 10 cm above the surface). Soils are muck or mineral, and water is nutrient-rich. These systems are highly productive and have high rates of decomposition. Freshwater marsh vegetation is dominated by emergent vegetation such as *Carex utriculata, Schoenoplectus tabernaemontani (= Scirpus validus), Typha latifolia, Menyanthes trifoliata,* and *Equisetum fluviatile*. *Arctophila fulva* becomes more common in the northern portions of boreal Alaska.
Classification Comments: This system is known as Boreal Freshwater Marsh by the Alaska Natural Heritage Program. See Viereck et al. (1992) for references on *Arctophila fulva* types.
Similar Ecological Systems:
- North American Boreal Freshwater Aquatic Bed (CES103.125)

Related Concepts:
- III.A.3.d - Fresh sedge marsh (Viereck et al. 1992) Intersecting

- III.B.3.a - Fresh herb marsh (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: Freshwater marshes are found throughout boreal transition and boreal regions of western and northern Alaska. They are characterized by emergent herbaceous vegetation. Freshwater marshes typically occur with other wetland systems. They occur on the margins of ponds, lakes, and riparian systems and on inland deltas where rivers drain into large lakes. Inland marshes are mostly small patch, confined to limited areas in suitable floodplain or basin topography. They are typically semipermanently flooded, but some marshes have seasonal flooding. Water is at or above the surface for most of the growing season (typically 10 cm above the surface). Soils are muck or mineral, and water is nutrient-rich. These systems are highly productive and have high rates of decomposition (National Wetlands Working Group 1997).
Vegetation: Freshwater marsh vegetation may be dominated by emergent sedges, forbs, or grasses. Species that often dominate or codominate include *Carex utriculata, Schoenoplectus tabernaemontani (= Scirpus validus), Arctophila fulva, Eleocharis palustris, Myriophyllum spicatum, Typha latifolia, Menyanthes trifoliata, Comarum palustre, Hippuris vulgaris,* and *Equisetum fluviatile* (Jorgenson 1999, Gracz et al. 2005). *Arctophila fulva* becomes more common in the northern portions of boreal Alaska [see Viereck et al. (1992) for references on *Arctophila fulva* types].
Dynamics: This system requires a source of freshwater. Seasonal flooding is characteristic of inland deltas. Marsh zonation is related to water depth and duration of flooding. A typical sequence progresses from open water to emergent deep marsh to shallow marsh to wet meadow or fen. Floating marsh mats may be seral to fens.

DISTRIBUTION

Range: This system is found from lowlands through subalpine valley bottoms in the boreal and boreal transition regions of Alaska.

WESTERN NORTH AMERICAN BOREAL HERBACEOUS FEN (CES105.119)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Boreal [Boreal Subcontinental]; Depressional; Eutrophic Soil; Acidic Soil; Organic Peat (>40 cm); Forb; Graminoid
Non-Diagnostic Classifiers: Seepage-Fed Sloping
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2618; ESLF 9435; ESP 1618

CONCEPT

Summary: This system occurs in shallow depressions and basins, pond margins, and thermokarst pits with an open hydrologic regime. Fens are nutrient-rich and have a thick peat layer that may be floating or submerged. Standing water is usually present. Dominant species may include *Menyanthes trifoliata, Equisetum fluviatile, Comarum palustre, Calla palustris, Eriophorum angustifolium*, and *Carex aquatilis*. Other common but non-dominant species include *Caltha palustris, Cicuta virosa (= Cicuta mackenzieana), Galium trifidum, Rumex arcticus*, and *Utricularia* spp. Shrubs, including *Myrica gale, Salix candida, Betula nana*, and *Alnus incana ssp. tenuifolia*, are occasionally present but do not exceed 25% cover. Aquatic plants such as *Myriophyllum spicatum, Hippuris vulgaris, Potamogeton* spp., and *Sparganium* spp. may be present, and aquatic mosses are often present.This system is not associated with permafrost processes.
Classification Comments: This system combines those known as Boreal Transition Herbaceous Fen and Boreal Herbaceous Fen by the Alaska Natural Heritage Program.
Related Concepts:
- III.B.3.c - Subarctic lowland herb bog meadow (Viereck et al. 1992) Intersecting

DESCRIPTION

Environment: This system occurs in shallow depressions and basins, pond margins, and thermokarst pits with an open hydrologic regime. Fens are nutrient-rich and have a thick peat layer that may be floating or submerged. Standing water is usually present (Viereck et al. 1992).
Vegetation: Dominant species may include *Menyanthes trifoliata, Equisetum fluviatile, Comarum palustre, Calla palustris, Eriophorum angustifolium*, and *Carex aquatilis* (Viereck et al. 1992). Other common but non-dominant species include *Caltha palustris, Cicuta virosa (= Cicuta mackenzieana), Galium trifidum, Rumex arcticus*, and *Utricularia* spp. (Racine and Walters 1994). Shrubs, including *Myrica gale, Salix candida, Betula nana*, and *Alnus incana ssp. tenuifolia*, are occasionally present but do not exceed 25% cover. Aquatic plants such as *Myriophyllum spicatum, Hippuris vulgaris, Potamogeton* spp., and *Sparganium* spp. may be present, and aquatic mosses are often present (Viereck et al. 1992).
Dynamics: In boreal wetlands the general successional trend is from marsh to fen to treed bog; however, succession is not necessarily directional, and environmental conditions, such as nutrient content and abundance of groundwater, may prevent fens from developing into bogs (Zoltai et al. 1988). Succession begins in ponds or low-lying wetlands formed by processes such as glacial recession and floodplain dynamics (oxbows). An organic root mat typically develops and is either anchored to the mineral soil or floating on water such as a pond's edge. Over time, peat-forming mosses and sedges may fill in the basin. As the peat layer develops, low and/or dwarf-shrubs become established. Dwarf-trees may establish on the well-developed peat and also around the margin of the peatland.

Many peatlands on the Kenai Lowland formed in kettles after remnant glacial ice melted. In this region, there is a trend toward peatlands drying and ponds shrinking and filling in (Klein et al. 2005). In the boreal region, fens are often associated with themokarst processes.

Component Associations:
- *Menyanthes trifoliata* Herbaceous Vegetation (CEGL003410, G5)

DISTRIBUTION

Range: This system is found in lowlands of the boreal transition and boreal regions of Alaska.

WESTERN NORTH AMERICAN BOREAL TUSSOCK TUNDRA (CES105.127)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Permafrost; Saturated Soil; Herbaceous; Boreal [Boreal Subcontinental]; Aquic; Tussock-forming grasses; Eriophorum vaginatum
Non-Diagnostic Classifiers: Montane [Upper Montane]; Carex bigelowii
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2629; ESLF 9436; ESP 1629

CONCEPT

Summary: This ecological system is dominated by sedges in a tussock growth form. *Eriophorum vaginatum* is the primary tussock-former in most stands and *Carex bigelowii* is also common. On wetter sites, *Vaccinium* spp. (= *Oxycoccus* spp.) and *Chamaedaphne calyculata* may be present. Total shrub cover is less than 25%, although shrubs such as *Betula nana, Ledum palustre ssp. decumbens, Ledum groenlandicum, Vaccinium vitis-idaea, Vaccinium uliginosum* may be present. Mosses (*Sphagnum* spp., *Pleurozium schreberi, Hylocomium splendens*) may form a nearly continuous mat between tussocks.
Classification Comments: This system is known as Boreal Tussock Tundra by the Alaska Natural Heritage Program.
Related Concepts:
- III.A.2.d - Tussock tundra (Viereck et al. 1992) Broader

DESCRIPTION

Environment: Permafrost is usually present at depths of 30-50 cm. Soils are generally poorly drained, gleyed, and often with a poorly decomposed organic horizon at the surface, which may constitute most of the active layer. Frost scars are common. Tussock bog communities occur on lowlands of boreal and boreal transition Alaska, on filled-in sloughs on floodplains and on cold, poorly drained slopes and terraces. These sites are underlain by wet, silty mineral soils with a surface peat layer 10 to 40 cm thick surrounding the tussocks (Viereck et al. 1992).
Dynamics: The fuel layer in sedge-shrub tussock tundra is dense and continuous and leads to large, fast-spreading fires (Racine et al. 1987, Duchesne and Hawkes 2000). Differences in topography, moisture, vegetation composition, and organic matter depth cause variation in burn severity and lead to a patchy burn pattern (Racine 1979). Fire severity in *Eriophorum* tussock tundra types tends to be light because of the wet soil profile (Wein 1976). Burns in this type usually consume all aerial woody and herbaceous plant material and litter; regeneration is vigorous via rhizomes and root sprouts. In most areas of tussock-shrub tundra on the Seward Peninsula, less than one half of accumulated organic soil layer was removed by fire (Racine 1979). Thaw depths increased to reach into the mineral soil, but were not greatly increased except where organics were removed. Subsidence and thermal erosion following fire are usually minimal in tundra ecosystems (Walker 1996).

Estimates of the mean fire-return interval for tussock tundra ecosystems range from 50-600 years (Racine et al. 1983, Payette et al. 1989). The fire regime of tundra systems are likely variable from one region to another making generalizations difficult (Viereck and Schandelmeier 1980).

On interior and south-central Alaska tussock tundra sites, the thaw pond cycle and paludification are important disturbances. On the Seward Peninsula and western Alaska, frost action creates polygonal ground and other periglacial features and is a widespread, small-scale and continuous disturbance. Change in the arctic and subarctic climate is another source of disturbance that is currently affecting tundra ecosystems.

After a severe fire, it would be possible to get paper birch and low shrubs.

DISTRIBUTION

Range: This system is found in lowland through subalpine zones of boreal and boreal transition (northern portion and higher elevation) regions of Alaska.

WESTERN NORTH AMERICAN BOREAL WET MEADOW (CES105.124)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saturated Soil [Periodicity/Seasonality]; Boreal [Boreal Subcontinental]; Seepage-Fed Sloping [Mineral]; Eutrophic Soil; Muck; Graminoid
Non-Diagnostic Classifiers: Montane; Lowland; Herbaceous; Mineral: W/ A-Horizon >10 cm
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2626; ESLF 9437; ESP 1626

CONCEPT

Summary: This ecological system is common throughout the boreal and boreal transition regions of Alaska in wet depressions, low-lying areas, and shallow drainage ways. These systems are minerotrophic with high nutrient levels and high rates of decomposition. Soils are mineral or muck and are saturated at some point during the growing season, but do not have standing water (water may be up to 5-10 cm deep during portions of the growing season, but it is not persistent). Wet meadows typically have a well-developed organic mat but not deep enough to be considered peatlands. Wet meadow vegetation may be seral to fens. Dominant species include *Carex aquatilis, Carex utriculata, Carex lasiocarpa, Eriophorum angustifolium, Calamagrostis canadensis*, and *Equisetum palustre*. *Comarum palustre, Menyanthes trifoliata, Equisetum fluviatile* are often present but not dominant. Shrubs may be a minor component of the canopy cover (less than 25% cover) and include *Myrica gale, Alnus incana ssp. tenuifolia*, and *Salix* spp.
Classification Comments: This system is known as Boreal Wet Meadow by the Alaska Natural Heritage Program. Wet meadows are closely related to freshwater marshes but have less standing water.
Similar Ecological Systems:
- Rocky Mountain Alpine-Montane Wet Meadow (CES306.812)

WILLAMETTE VALLEY WET PRAIRIE (CES204.874)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Herbaceous Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Saturated Soil; Lowland [Lowland]; Herbaceous; Extensive Wet Flat; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 9221

CONCEPT

Summary: This system is largely restricted to the Willamette Valley of Oregon and adjacent Washington. It is nearly extirpated from the Puget Trough of Washington. These are high-nutrient wetlands that are temporarily and seasonally flooded. They are dominated primarily by graminoids, especially *Deschampsia caespitosa*, *Camassia quamash*, *Carex densa*, and *Carex unilateralis*, and to a lesser degree by forbs (e.g., *Isoetes nuttallii*) or shrubs (e.g., *Rosa nutkana*). Wet prairies historically covered large areas of the Willamette Valley where they were maintained by a combination of wetland soil hydrology and frequent burning. They have been reduced to tiny fragments of their former extent.

DESCRIPTION

Environment: This ecosystem occurred in areas with seasonally high water tables often perched on clay-rich soils (e.g., local depressions, swales and low-gradient riparian areas) within the matrix of a fire-maintained prairie landscape.
Dynamics: Given their location within a fire-maintained, open grassland landscape, these wet prairies experienced periodic fire, which is what distinguishes them from similar wetland types found elsewhere in western Washington and Oregon. This system was productive and likely dynamic due to frequency of fire.

Component Associations:
- *Camassia quamash* Wet Prairie Herbaceous Vegetation (CEGL003341, G3)
- *Carex aperta* Herbaceous Vegetation (CEGL001801, G1?)
- *Deschampsia caespitosa - Artemisia lindleyana* Herbaceous Vegetation (CEGL003425, G1)
- *Deschampsia caespitosa - Danthonia californica* Herbaceous Vegetation (CEGL001604, G2)
- *Eleocharis palustris - Carex unilateralis* Herbaceous Vegetation (CEGL003411, G2)
- *Eleocharis palustris* Herbaceous Vegetation (CEGL001833, G5)
- *Isoetes nuttallii* Herbaceous Vegetation (CEGL003343, G3)
- *Rosa nutkana / Oenanthe sarmentosa* Shrubland (CEGL003457, G1)

DISTRIBUTION

Range: Restricted to the Willamette Valley of Oregon and adjacent Washington.
Divisions: 204:C
Nations: US
Subnations: OR, WA

MIXED UPLAND AND WETLAND

ACADIAN SUB-BOREAL SPRUCE BARRENS (CES201.561)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Sandplains/Glacial Outwash or Flats; Glaciated; Acidic Soil; Picea (glauca, mariana, rubens) - Abies
Non-Diagnostic Classifiers: Acidic Water; Lowland; Toeslope/Valley Bottom; Oligotrophic Soil; Mineral: W/ A-Horizon >10 cm; Udic; Unconsolidated; Long Disturbance Interval; F-Landscape/Medium Intensity; Needle-Leaved Tree; Broad-Leaved Deciduous Shrub; Broad-Leaved Evergreen Shrub
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2464; ESLF 9133; ESP 1464

CONCEPT

Summary: These barrens occur at the southeastern periphery of the boreal forest in northeastern North America. They form on sandplains and coarse outwash that often have undulating topography. Substrate microtopography can result in wetland pockets interspersed with upland areas. North of the range of most pine (except *Pinus banksiana*), *Picea mariana* tends to be the dominant tree. *Picea rubens* and red/black spruce hybrids are also common in the southern part of the range. Dwarf heath shrubs are extensive and diagnostic. Lichens, especially reindeer lichens, are often abundant in the ground layer. Vegetation physiognomy can vary within sites and can range from nearly closed forest to sparse trees over a dense dwarf heath understory. Fire is an important disturbance vector.
Classification Comments: This system is ecologically similar to open expressions of Boreal Jack Pine-Black Spruce Forest (CES103.022) of the upper Midwest and adjacent Canada but differs in lacking *Pinus banksiana* and in frequently having *Picea rubens* or its hybrids.
Related Concepts:
- Black Spruce Woodland (Gawler and Cutko 2010) Finer
- Blueberry - Lichen Barren (Gawler and Cutko 2010) Finer
- Spruce - Heath Barren (Gawler and Cutko 2010) Finer

Component Associations:
- *Picea mariana - Picea rubens / Rhododendron canadense / Cladina* spp. Woodland (CEGL006421, GNR)
- *Vaccinium (angustifolium, myrtilloides, pallidum) - Cladina rangiferina* Dwarf-shrubland (CEGL006426, GNR)

DISTRIBUTION

Range: This system is found in far-northern New England and is more widely distributed in adjacent eastern Canada.
Divisions: 103:C; 201:C
Nations: CA, US
Subnations: ME, NB, NH, QC, VT
Map Zones: 66:C

ACADIAN SUB-BOREAL SPRUCE FLAT (CES201.562)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Lowland; Forest and Woodland (Treed); Toeslope/Valley Bottom; Glaciated; Picea (glauca, mariana, rubens) - Abies
Non-Diagnostic Classifiers: Short (<5 yrs) Flooding Interval [Short interval, Spring Flooding]; Extensive Wet Flat; Isolated Wetland [Partially Isolated]; Mesotrophic Soil; Acidic Soil; Mineral: W/ A-Horizon >10 cm; Udic; Very Long Disturbance Interval; F-Landscape/Medium Intensity; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2465; ESLF 9134; ESP 1465

CONCEPT

Summary: These spruce-fir forests are found in the colder regions of the northern Appalachians-Acadian region, in areas of imperfectly drained soils where they often form extensive flats along valley bottoms. The nutrient-poor acidic soils are typically saturated at snowmelt but are moderately well-drained for much of the growing season and may be reasonably dry at the soil surface. The mostly closed-canopy forests have *Picea rubens*, *Picea mariana*, and *Abies balsamea* as the dominant trees; other conifers are often present. Bryophytes are abundant in the ground layer; other layers are typically rather sparse. Many occurrences may be jurisdictional wetlands due to seasonal saturation, but the vegetation is primarily made up of upland or facultative species. The distribution in the Laurentian-Acadian Division is mostly Canadian.
Classification Comments: This might be considered as a component of Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565) but differs from that type *sensu stricto* in its hydrology (wetland vs. upland) and in that its range is somewhat more boreal. Alternatively, it shares some characteristics with Northern Appalachian-Acadian Conifer-Hardwood Acidic Swamp (CES201.574) but is more boreal in nature and appears to be typically not on consistently saturated soils. Information from Quebec and New Brunswick would be helpful in assessing its placement.
Similar Ecological Systems:
- Acadian Low-Elevation Spruce-Fir-Hardwood Forest (CES201.565)
- Laurentian-Acadian Swamp Systems (CES201.637)
- Northern Appalachian-Acadian Conifer-Hardwood Acidic Swamp (CES201.574)

BOREAL ICE-SCOUR RIVERSHORE (CES103.589)

CLASSIFIERS

Classification Status: Standard

Primary Division: Boreal (103)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Intermittent Flooding [Intermittent interval, Spring Flooding]; Intermittent Flooding [Intermittent interval, Summer Flooding]; Moderate (100-500 yrs) Persistence; Shrubland (Shrub-dominated); Herbaceous; Riverine / Alluvial; Glaciated; Very Short Disturbance Interval; Flood Scouring
Non-Diagnostic Classifiers: Mesotrophic Water; Saturated Soil; Lowland; Toeslope/Valley Bottom; Mesotrophic Soil; Circumneutral Soil; Acidic Soil; Mineral: W/ A-Horizon <10 cm; Udic
National Mapping Codes: ESLF 9332

CONCEPT

Summary: This riparian system occurs in the extreme northeastern and north-central U.S. and adjacent Canada. It develops along the shores of northern rivers, where early spring snowmelt and ice-scour exert a strong influence on the vegetation. The ice prevents floodplain forests from developing; the vegetation consists of shrublands, tall grasslands, graminoid-forb-dwarf shrub shoreline seeps, and rivershore outcrops. Characteristic shrubs include *Alnus incana* and *Alnus viridis ssp. crispa (= Alnus crispa), Myrica gale, Spiraea alba, Cornus sericea, Salix eriocephala* and many other *Salix* spp., and *Dasiphora fruticosa ssp. floribunda*. Characteristic herbaceous species vary with the setting; *Calamagrostis canadensis* is ubiquitous, and other herbs include *Symphyotrichum novi-belgii, Carex* spp. (including *Carex flava, Carex garberi, Carex viridula*), *Deschampsia caespitosa, Andropogon gerardii, Schizachyrium scoparium, Allium schoenoprasum, Triantha glutinosa, Spartina pectinata, Solidago uliginosa, Doellingeria umbellata (= Aster umbellatus), Agrostis scabra*, and many others. Soils in some areas remain saturated; other patches are well-drained for most of the growing season. The location and extent of shrub versus herb cover will vary in time and space according to how recent and severe the scour events have been. The continual weathering of glacial deposits in the river channel can produce relatively high pH conditions; this and periodic natural disturbance create conditions for many regionally rare plant species.
Classification Comments: Need to clarify the conceptual boundaries between this and the boreal rivershores in central and eastern Canada. This ecological system undoubtedly occurs further west into central Canada, as far west as northern Alberta. It was not mapped in the SunCor Alberta boreal forest mapping project.

Non-Diagnostic Classifiers: Floodplain; Fluvial; Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Herbaceous; Toeslope/Valley Bottom; Silt Soil Texture; Sand Soil Texture; Aquic; Udic; Very Short Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2151; ESLF 9101; ESP 1151

CONCEPT

Summary: This system occurs in the floodplains of rivers of California's Central Valley. Alluvial soils and late winter/early spring flooding (usually every year) from snowmelt typify this system. Communities are predominantly floodplain woodlands, but also include shrublands, wet meadows and gravel/s and flats. Important trees and shrubs include *Populus fremontii, Platanus racemosa, Quercus lobata, Salix gooddingii, Acer negundo, Cephalanthus occidentalis*, and *Vitis californica*. *Juglans nigra* hybrids and *Ailanthus altissima* are problem invasive trees. *Tamarix* spp. extend as far north as Shasta County. Herbaceous components can include *Carex barbarae, Artemisia douglasiana*, and various marsh species along riverbanks and backwater (*Schoenoplectus californicus (= Scirpus californicus), Typha* spp.). *Arundo donax* is another common invasive and introduced forage species that often invades degraded areas within the floodplains. Periodic flooding and associated sediment scour are necessary to maintain growth and reproduction of vegetation. Flooding regimes have been significantly altered in all but a few tributaries that support this system.
Related Concepts:
- Riparian Woodland (203) (Shiflet 1994) Broader

DESCRIPTION

Environment: This system is found on alluvial soils adjacent to perennial rivers and streams and their associated floodplains and riverbanks below approximately 550 m (1800 feet).
Dynamics: Periodic flooding and associated sediment scour are necessary to maintain growth and reproduction of vegetation (Sawyer et al. 2009). Major flood events and consequent flood scour, overbank deposition of water and sediments, and stream meandering are the key fluvial processes that provide new substrates, remove old banks and stimulate renewed growth of cottonwood and willow species (Sawyer et al. 2009). Natural fire-return interval was long or moderate with low-intensity surface fires.

DISTRIBUTION

Range: Occurs in the floodplains of rivers of California's Central Valley.
Divisions: 206:C
Nations: US
Subnations: CA

CENTRAL APPALACHIAN RIVER FLOODPLAIN (CES202.608)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Intermittent Flooding; Short (<5 yrs) Flooding Interval; Forest and Woodland (Treed); Toeslope/Valley Bottom; Riverine / Alluvial; Broad-Leaved Deciduous Tree
Non-Diagnostic Classifiers: 1-29-day hydroperiod; 30-180-day hydroperiod; Moderate (100-500 yrs) Persistence; Lowland; Temperate; Eutrophic Soil; Deep Soil; Mineral: W/ A-Horizon >10 cm; Silt Soil Texture; Udic; Ustic; Unconsolidated; Short Disturbance Interval; Flood Scouring
National Mapping Codes: ESLF 9333

CONCEPT

Summary: This system encompasses floodplains of medium to large rivers in Atlantic drainages from southern New England to Virginia. This system can include a complex of wetland and upland vegetation on deep alluvial deposits and scoured vegetation on depositional bars and on bedrock where rivers cut through resistant geology. This complex includes floodplain forests in which *Acer saccharinum, Populus deltoides*, and *Platanus occidentalis* are characteristic, as well as herbaceous sloughs, shrub wetlands, riverside prairies and woodlands. Microtopography and soil texture determine how long the various habitats are inundated. Depositional and erosional features may both be present depending on the particular floodplain.
Classification Comments: This system is distinguished from related floodplain systems; northward, Laurentian-Acadian Floodplain Forest (CES201.587) is characterized by the lack or unimportance of *Platanus occidentalis* and *Betula nigra*, for example; and westward, North-Central Interior Floodplain (CES202.694) drains to the midwestern rivers rather than northeastern rivers. Determining the distinctions from South-Central Interior Large Floodplain (CES202.705), which overlaps the southern and western portions of this system, needs work.
Similar Ecological Systems:
- Central Appalachian Stream and Riparian (CES202.609)
- Laurentian-Acadian Floodplain Forest (CES201.587)
- North-Central Interior Floodplain (CES202.694)
- South-Central Interior Large Floodplain (CES202.705)

- Sugarberry - American Elm - Green Ash: 93 (Eyre 1980) Finer
- Sycamore - Sweetgum - American Elm: 94 (Eyre 1980) Finer

DESCRIPTION

Environment: This system forms on broad, relatively flat floodplains along medium-sized to large rivers. Rivershores often exhibit development of one or more terraces formed in relation to hydroperiod and height from river channel. Backswamps may occur in poorly drained depressions behind the main river channel, where substrate is deep muck. Soils range from sandy and silty on point bars to deep muck in backswamps.
Dynamics: Spring and summer flooding brings large amounts of sediment carried from tributaries, as well as other debris that is deposited on the floodplain as flood waters recede. Floodplain canopy trees often topple as a result of prolonged saturation of sediments; vegetation structure is highly variable and dynamic as a result. Dynamic disturbance regime and high fertility make this system highly susceptible to invasions of non-native plants.

Component Associations:
- *(Hypericum prolificum, Leucothoe racemosa) / Schizachyrium scoparium - Solidago simplex var. racemosa - Ionactis linariifolius* Sparse Vegetation (CEGL006491, G2)

CENTRAL APPALACHIAN STREAM AND RIPARIAN (CES202.609)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Intermittent Flooding; Lowland; Riverine / Alluvial; Very Short Disturbance Interval; Flood Scouring
Non-Diagnostic Classifiers: Short (<5 yrs) Flooding Interval; Short (50-100 yrs) Persistence; Forest and Woodland (Treed); Sideslope; Toeslope/Valley Bottom; Temperate; Mesotrophic Soil; Udic; Ustic
National Mapping Codes: ESLF 9331

CONCEPT

Summary: This riparian system ranges from southern New England to Virginia and West Virginia and occurs over a wide range of elevations. It develops on floodplains and shores along river channels that lack a broad flat floodplain due to steeper sideslopes, higher gradient, or both. It may include communities influenced by flooding, erosion, or groundwater seepage. The vegetation is often a mosaic of forest, woodland, shrubland, and herbaceous communities. Common trees include *Betula nigra* and *Platanus occidentalis*. Open, flood-scoured rivershore prairies feature *Panicum virgatum* and *Andropogon gerardii*, and *Carex torta* is typical of wetter areas near the channel.
Classification Comments: This is a high-gradient system, unlike the low-gradient system described in Central Appalachian River Floodplain (CES202.608). To the south in the Appalachians and interior, this system is replaced by South-Central Interior Small Stream and Riparian (CES202.706).
Similar Ecological Systems:
- Central Appalachian River Floodplain (CES202.608)
- Cumberland Riverscour (CES202.036)
- South-Central Interior Small Stream and Riparian (CES202.706)

Related Concepts:

- Eastern Hemlock: 23 (Eyre 1980) Finer
- Sycamore - Sweetgum - American Elm: 94 (Eyre 1980) Finer

DESCRIPTION

Environment: This alluvial system forms on the shores of rivers and streams influenced by flood scour and deposition. It includes vegetation on various substrates ranging from silty sediments low on the channel to rock outcrops, gorge walls, and cobbles.
Vegetation: The vegetation is often a mosaic of forest, woodland, shrubland, and herbaceous communities. Common trees include *Betula nigra, Platanus occidentalis*, and *Acer negundo*. Open, flood-scoured rivershore prairies feature *Panicum virgatum* and *Andropogon gerardii*, and *Carex torta* is typical of wetter areas near the channel.
Dynamics: High-gradient waterflow causes scouring of rivershores, removing soils and depositing them in slower-moving portions of the river. High amounts of debris cause flood-battering of trees and shrubs, and removal of woody vegetation during extreme flooding events. Seepage from uplands may emerge from shores, and the often specialized flora of these environments is maintained by repeated removal, or prevention of establishment, of woody vegetation. Flood-battering of trees prevents succession; scouring by water, and sometimes ice, exposes substrate.

Component Associations:
- *Acer rubrum - Fraxinus (pennsylvanica, americana) / Lindera benzoin / Symplocarpus foetidus* Forest (CEGL006406, G4G5)

CENTRAL FLORIDA PINE FLATWOODS (CES203.382)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Woody-Herbaceous; Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2453; ESLF 9122; ESP 1453

CONCEPT

Summary: This system is endemic to Florida, ranging from Levy and St. Johns counties in the north (ca. 30 degrees N latitude) southward to Hillsborough, Osceola and Polk counties. It was once an extensive system within its historic range. As currently conceived, this system includes both "scrubby flatwoods" that occur on well-drained soils and typical flatwoods that occur on more poorly drained soils. The vegetation is naturally dominated by either *Pinus palustris* or *Pinus elliottii var. elliottii*, and less frequently includes *Pinus serotina*. Examples vary in aspect from well-developed understory layers or scrub species to more herbaceous, savanna-like conditions. There is a dense ground cover of low shrubs, grasses, and herbs. Frequent, low-intensity fire is the dominant natural ecological force.
Classification Comments: This system includes at least two predominant expressions which could individually constitute distinct systems. Scrubby flatwoods are much more well-drained, uplands with characteristically shrubby understories, while flatwoods are much more poorly drained and savanna-like in aspect (Abrahamson et al. 1984).
Similar Ecological Systems:
- East Gulf Coastal Plain Near-Coast Pine Flatwoods (CES203.375)--is closely related and found to the north.

Related Concepts:
- Longleaf Pine - Slash Pine: 83 (Eyre 1980) Finer
- Longleaf Pine: 70 (Eyre 1980) Finer
- Pond Pine: 98 (Eyre 1980) Finer
- Slash Pine: 84 (Eyre 1980) Finer

DESCRIPTION

Environment: As currently conceived, this system includes both "scrubby flatwoods" that occur on well-drained soils and typical mesic and wet flatwoods that occur on more poorly drained soils. Wetter pine flatwoods sites with an herbaceous ground cover are included, these are sometimes called wet pine savannas.
Vegetation: The southern limit of this system marks the approximate natural distribution limit for both *Pinus serotina* and *Pinus elliottii var. elliottii* (Abrahamson and Hartnett 1990). The associations comprising this system are not well documented; more information is needed to describe additional communities that are believed to be present. The vegetation varies between examples of this system based on fire history, geographic location, and the soils on which it occurs. The most well-drained examples may be considered "scrubby flatwoods" that support a characteristic understory layer of xeromorphic adapted species, such as *Quercus geminata, Lyonia fruticosa, Lyonia ferruginea, Sideroxylon tenax (= Bumelia tenax)*, and *Persea humilis*; *Quercus inopina* is especially diagnostic (Abrahamson et al. 1984). These conditions range to examples on more poorly drained soils that include scattered *Pinus elliottii var. elliottii* or *Pinus palustris* over *Serenoa repens* and other species such as *Panicum abscissum* and *Aristida beyrichiana*.
Dynamics: Fire is naturally frequent, with a fire-return time of from one to four years. Disturbances are an important part of the natural functions of this system. In order for these habitats to burn frequently there needs to be enough fine fuel, such as needles from *Pinus palustris* trees, healthy populations of native warm-season grasses, and evergreen shrubs with volatile oils in their leaves, such as *Ilex glabra, Lyonia* spp., *Morella cerifera (= Morella pumila), Quercus geminata, Quercus minima, Serenoa repens*, and *Vaccinium* spp. The frequent fires promote flowering, seed production, and seed germination of many plants and provide open areas in patches (Van Lear et al. 2005).

Component Associations:
- *Pinus elliottii var. densa / Quercus minima / Panicum abscissum* Woodland (CEGL003650, G2?)
- *Pinus elliottii var. elliottii / Serenoa repens - Ilex glabra* Woodland (CEGL003643, G4?)
- *Pinus palustris - (Pinus elliottii var. elliottii) / Quercus (chapmanii, myrtifolia) - Serenoa repens / Aristida beyrichiana - Chapmannia floridana* Woodland (CEGL007750, G2G3)
- *Pinus palustris - Pinus serotina / Ilex glabra - Lyonia lucida - (Serenoa repens)* Woodland (CEGL004791, G3G4)
- *Pinus serotina / Gordonia lasianthus - Persea palustris* Saturated Woodland (CEGL007996, G3?Q)
- *Pinus serotina / Ilex glabra / Aristida beyrichiana* Woodland (CEGL003795, G2G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:

- Central Florida Herbaceous Pondshore (CES203.890)
- Central Florida Wet Prairie and Herbaceous Seep (CES203.491)
- Florida Longleaf Pine Sandhill (CES203.284)
- Southern Coastal Plain Hydric Hammock (CES203.501)

DISTRIBUTION

Range: Endemic to Florida, ranging in the north from Levy and St. Johns counties southward to Hillsborough and Polk counties. It was once an extensive ecological system within its historic range (Stout and Marion 1993).
Divisions: 203:C
Nations: US

CENTRAL TEXAS COASTAL PRAIRIE RIPARIAN (CES203.714)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Riverine / Alluvial; Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 9390

CONCEPT

Summary: This system occurs in upland drainages as they coarse through the relatively level landscape of the coastal prairie in Texas. It represents vegetation bordering upland drainages that are mostly incised, erosional features with very little alluvial deposition. Woody vegetation often shares composition with that of floodplains along larger rives and streams of the region. Species may include *Celtis laevigata, Ulmus crassifolia, Carya illinoinensis, Salix nigra, Prosopis glandulosa, Acacia farnesiana, Quercus nigra, Quercus fusiformis, Prosopis glandulosa, Acacia farnesiana, Diospyros texana, Condalia hookeri, Ziziphus obtusifolia,* and *Aloysia gratissima*. The herbaceous layer may contain species such *Elymus virginicus, Chasmanthium latifolium, Calyptocarpus vialis, Verbesina virginica*, and *Chloracantha spinosa*. Though woody vegetation is the predominant vegetation type in this system, it may also include small areas that lack a significant woody component.
Classification Comments: The relationship of the vegetation of this system (CES203.714) needs further differentiation from the vegetation of Central Texas Coastal Prairie River Floodplain (CES203.713). They are currently separated more on site conditions and processes rather than vegetation dominants. More information is needed.
Similar Ecological Systems:
- Central Texas Coast River Terrace Sandyland Grassland (CES203.712)
- Central Texas Coastal Prairie River Floodplain (CES203.713)

Related Concepts:
- Central Texas Coastal Prairie Riparian Deciduous Forest and Woodland (4604) (Elliott 2011) Finer. As described for the system, where deciduous canopy species predominate.
- Central Texas Coastal Prairie Riparian Deciduous Shrubland (4606) (Elliott 2011) Finer. Primarily disturbance shrublands of upland drainages dominated by species such as *Prosopis glandulosa, Acacia farnesiana,* small *Celtis laevigata, Salix nigra,* or *Cephalanthus occidentalis*.
- Central Texas Coastal Prairie Riparian Evergreen Shrubland (4605) (Elliott 2011) Finer. Upland drainages where shrubs such as *Ilex vomitoria, Zanthoxylum fagara, Rosa bracteata,* or *Acacia farnesiana* dominate. *Celtis laevigata, Celtis pallida (= Celtis ehrenbergiana),* and *Prosopis glandulosa* are often present.
- Central Texas Coastal Prairie Riparian Herbaceous Vegetation (4607) (Elliott 2011) Finer. Sites on upland drainages that often represent managed grasslands dominated by *Cynodon dactylon, Paspalum notatum,* or *Bothriochloa ischaemum var. songarica*.
- Central Texas Coastal Prairie Riparian Herbaceous Wetland (4617) (Elliott 2011) Finer. Herbaceous-dominated wetlands along upland drainages.
- Central Texas Coastal Prairie Riparian Live Oak-Deciduous Forest and Woodland (4602) (Elliott 2011) Finer. About 12% of this system is composed of this type, where *Quercus fusiformis* or, in some cases *Ehretia anacua* dominates the overstory.
- Central Texas Coastal Prairie Riparian Live Oak-Deciduous Forest and Woodland (4603) (Elliott 2011) Finer. Forests or woodlands where canopy dominance is shared by broadleaf evergreen species such as *Quercus fusiformis* or *Ehretia anacua* and deciduous species such as *Celtis laevigata, Ulmus crassifolia,* and others.

DESCRIPTION

Environment: This system represents vegetation bordering upland drainages occurring in the unconsolidated sediments of the Beaumont or Lissie geologic formations. These areas accumulate flow from the surrounding landscape but rarely accrete significant alluvial deposition. They occupy locally low landscape positions and accumulate moisture from the surrounding landscape but are not bottomland sites.
Vegetation: Forested sites typically have a deciduous canopy with species such as *Celtis laevigata, Ulmus crassifolia, Carya illinoinensis, Salix nigra, Prosopis glandulosa, Acacia farnesiana*, and/or *Quercus nigra*. *Quercus fusiformis* may share, or sometimes dominate, the canopy. The shrub layer may be well-developed and include species such *Prosopis glandulosa, Acacia farnesiana, Diospyros texana, Condalia hookeri, Ziziphus obtusifolia*, and/or *Aloysia gratissima*. Some areas may lack a significant overstory and be mapped as shrublands of these species. The herbaceous layer may contain species such *Elymus virginicus, Chasmanthium latifolium, Calyptocarpus vialis, Verbesina virginica*, and *Chloracantha spinosa*.

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Texas-Louisiana Coastal Prairie (CES203.550)

DISTRIBUTION

Range: This system occurs in upland drainages on the Coastal Prairie surface of the Lissie and Beaumont geologic formations in the Coastal Plain of Texas.
Divisions: 203:C
Nations: US
Subnations: TX

CENTRAL TEXAS COASTAL PRAIRIE RIVER FLOODPLAIN (CES203.713)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Riverine / Alluvial; Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 9389

CONCEPT

Summary: This system occurs in the Gulf Coast Prairies and Marshes region of Texas. It occupies alluvial settings along rivers, streams and larger drainages. This wetland and upland transition area supports a correspondingly similar mixture of wetland/upland vegetation types that are primarily deciduous or mixed evergreen-deciduous forests. In addition, this system also expresses a transition from northeast to southwest. In the northeastern parts of the range, *Quercus fusiformis* is a common component, as are a few other trees and shrubs with a more eastern affinity such as *Celtis laevigata, Ulmus crassifolia, Sabal minor, Cephalanthus occidentalis, Forestiera acuminata,* and/or *Cornus drummondii*. In the southwestern parts of the range, trees and shrubs with a western and subtropical affinity such as *Fraxinus berlandieriana, Prosopis glandulosa, Acacia farnesiana,* and *Ehretia anacua* become more prominent.

Similar Ecological Systems:
- Central Texas Coast River Terrace Sandyland Grassland (CES203.712)
- Central Texas Coastal Prairie Riparian (CES203.714)

Related Concepts:
- Central Texas Coastal Prairie River Floodplain Deciduous Forest and Woodland (4504) (Elliott 2011) Finer
- Central Texas Coastal Prairie River Floodplain Deciduous Shrubland (4506) (Elliott 2011) Finer. dominated by species such as *Prosopis glandulosa, Acacia farnesiana, Cephalanthus occidentalis, Forestiera acuminata*, and/or *Cornus drummondii*). Some sites mapped as this type may be dominated by *Chloracantha spinosa*. *Celtis laevigata* and *Ulmus crassifolia* are common within this type.
- Central Texas Coastal Prairie River Floodplain Evergreen Shrubland (4505) (Elliott 2011) Finer. shrubland with *Sabal minor, Rosa bracteata, Zanthoxylum fagara, Ehretia anacua, Baccharis halimifolia, Acacia farnesiana*.
- Central Texas Coastal Prairie River Floodplain Herbaceous Vegetation (4507) (Elliott 2011) Finer. More than 22% of this system is mapped as this type, though most sites represent managed pasture and may be dominated by species such as *Cynodon dactylon, Bothriochloa ischaemum var. songarica*, and *Paspalum notatum.*
- Central Texas Coastal Prairie River Floodplain Herbaceous Wetland (4517) (Elliott 2011) Finer. Wetlands typically dominated by sedges, wetland grasses, such as *Paspalum lividum (= Paspalum denticulatum)* or *Zizaniopsis miliacea*, and wetland forbs such as *Polygonum* spp.
- Central Texas Coastal Prairie River Floodplain Live Oak Forest and Woodland (4502) (Elliott 2011) Finer. canopy dominated by *Quercus fusiformis*.
- Central Texas Coastal Prairie River Floodplain Live Oak-Hardwood Forest and Woodland (4503) (Elliott 2011) Finer. mix of broadleaf and evergreen trees, including *Quercus fusiformis* and *Ehretia anacua*.

DESCRIPTION

Environment: This system occurs on bottomland soils along rivers, streams and larger drainages. It typically occupies Quaternary alluvium that forms terraces adjacent to the Beaumont or Lissie geologic formations. It is found in bottomland ecological site types with loamy, clayey, and sandy soils.

Vegetation: This system is characterized by woodlands and forests dominated by species such as *Celtis laevigata, Celtis laevigata var. reticulata, Ulmus crassifolia, Carya illinoinensis, Ulmus americana, Prosopis glandulosa*, and *Fraxinus berlandieriana* or *Fraxinus pennsylvanica*. The mixed deciduous-evergreen canopy may include *Quercus fusiformis* and *Ehretia anacua* as significant components of the overstory. Sites dominated by *Quercus fusiformis* typically occur on less-saturated sites such as slightly elevated situations. Less common species in the canopy may include *Acer negundo, Gleditsia triacanthos, Quercus macrocarpa, Populus deltoides, Platanus occidentalis, Morus rubra*, and *Acacia farnesiana*. Some wetter sites may be dominated by *Salix nigra* or, less commonly, *Taxodium distichum*. *Acer negundo, Sapindus saponaria var. drummondii, Ungnadia speciosa*, and saplings of the overstory species may form a subcanopy. The shrub layer is often not well-developed and contains species such as *Sabal minor, Ilex vomitoria, Ilex decidua, Diospyros texana, Sideroxylon lanuginosum, Prosopis glandulosa, Acacia farnesiana, Condalia hookeri,* and/or *Cornus drummondii*. *Sabal minor* or *Ilex vomitoria* may sometimes form a dense shrub understory. Some sites may represent dense shrublands dominated by *Cephalanthus occidentalis* or *Forestiera acuminata*, with a sparse overstory. Vines are commonly encountered, including species such as *Ampelopsis arborea, Vitis mustangensis, Smilax bona-nox, Toxicodendron radicans,* and *Campsis radicans*. The ground layer can be well-developed and often dominated by graminoids, including *Carex cherokeensis, Carex crus-corvi, Elymus virginicus, Phanopyrum gymnocarpon, Chasmanthium latifolium, Leersia* spp., *Paspalum langei, Panicum obtusum, Tripsacum dactyloides, Carex bulbostylis, Carex tetrastachya, Oplismenus hirtellus*, and *Dichanthelium sphaerocarpon*.

Forbs, such as *Malvaviscus arboreus var. drummondii, Chloracantha spinosa, Verbesina virginica, Calyptocarpus vialis, Commelina erecta, Allium canadense var. canadense, Myosotis macrosperma, Nemophila phacelioides*, and the somewhat rare *Tauschia texana* and *Spigelia loganioides (= Spigelia texana)*, may also be found in these woodlands. *Chloracantha spinosa* may sometimes form large, nearly monotypic in aspect stands. Wetter, herbaceous-dominated sites occur in these floodplains and may contain species such as *Cyperus* spp., *Eleocharis* spp., *Zizaniopsis miliacea, Paspalum lividum (= Paspalum denticulatum),* and *Typha domingensis*. The non-native *Triadica sebifera* may be present to dominant in the canopy of occurrences of this system. Non-native grasses such as *Cynodon dactylon, Bothriochloa ischaemum var. songarica, Urochloa maxima*, and *Sorghum halepense* may also be present and sometimes dominate the ground layer to the exclusion of other species.

Spatial Characteristics

Adjacent Ecological Systems:

- Columbia Bottomlands Forest and Woodland (CES203.715)
- Southeastern Great Plains Floodplain Forest (CES205.710)
- Tamaulipan Floodplain (CES301.990)
- Texas-Louisiana Coastal Prairie (CES203.550)

Adjacent Ecological System Comments: Upstream, beyond the Pleistocene formations traversed by ##Central Texas Coastal Prairie River Floodplain (CES203.713), floodplain forests transition to Southeastern Great Plains Floodplain Forest (CES205.710). The Nueces River shares some affinity with Tamaulipan Floodplain (CES301.990) to the south, which occurs along drainages further to the south and west of the Nueces, as well as the Nueces upstream of the prairie geologic formations. Floodplain systems north and east of the Navidad River are included in Columbia Bottomlands Forest and Woodland (CES203.715).

Distribution

Range: This system occurs along the Texas coast where it occupies bottomland soils along the coastal portions of the Navidad, Lavaca, Guadalupe, San Antonio, Mission, Aransas, and Nueces rivers (and their tributaries) as they cross the prairie surface of the Lissie and Beaumont geologic formations.

CHIHUAHUAN-SONORAN DESERT BOTTOMLAND AND SWALE GRASSLAND (CES302.746)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Lowland [Lowland]; Herbaceous; Swale; Toeslope/Valley Bottom; Depressional
Non-Diagnostic Classifiers: Clay Subsoil Texture; Intermittent Flooding [Intermittent interval, Summer Flooding]; Mesa; Plain; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Continental]; Temperate [Temperate Xeric]; Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2504; ESLF 9411; ESP 1504

CONCEPT

Summary: This ecological system is named based on the regions (Chihuahuan and Sonoran deserts) where it is best developed and occupies significant areas, however, it does occur well outside these regions, at least as far north and east as the Rolling Plains of Texas. The system occurs in relatively small depressions or swales and along drainages throughout the northern and central Chihuahuan Desert and adjacent Sky Islands and Sonoran Desert, as well as limited areas of the southern Great Plains on broad mesas, plains and valley bottoms that receive runoff from adjacent areas. Occupying low topographic positions, these sites generally have deep, fine-textured soils that are neutral to slightly or moderately saline/alkaline. During summer rainfall events, ponding is common. Vegetation is typically dominated by *Sporobolus airoides, Sporobolus wrightii, Pleuraphis mutica* (tobosa swales), or other mesic graminoids such as *Pascopyrum smithii* or *Panicum obtusum*. With tobosa swales, sand-adapted species such as *Yucca elata* may grow at the swale's edge in the deep sandy alluvium that is deposited there from upland slopes. *Sporobolus airoides* and *Sporobolus wrightii* are more common in alkaline soils and along drainages. Other grass species may be present, but these mesic species are diagnostic. Scattered shrubs such as *Atriplex canescens, Prosopis glandulosa, Ericameria nauseosa, Fallugia paradoxa, Krascheninnikovia lanata,* or *Rhus microphylla* may be present.
Classification Comments: NRCS Ecological Site Description MLRA 42 SD-2 Bottomland Ecological Site (NRCS 2006) describes this system on the Jornada Experimental Range with State-and-Transition Model showing shifts in species composition with land use.

This bottomland/depressional wetland system can be similar to the upland Chihuahuan Loamy Plains Desert Grassland (CES302.061) but is restricted to moist depressions and intermittently flooded drainage terraces and adjacent flats. Alkali sacaton (*Sporobolus airoides*) is often associated with more alkaline (to gypsic), poorly drained areas and giant sacaton (*Sporobolus wrightii*) with less alkaline better drained areas. *Distichlis spicata, Allenrolfea occidentalis,* and *Suaeda* spp. are characteristic of more saline and alkaline sites.

Similar Ecological Systems:
- Chihuahuan Loamy Plains Desert Grassland (CES302.061)

Related Concepts:
- Alkali Sacaton - Tobosagrass (701) (Shiflet 1994) Broader
- Grama -Muhly - Threeawn (713) (Shiflet 1994) Intersecting
- Southwest: Tobosa Grassland (407) [CES302.746.9] (Elliott 2011) Equivalent

DESCRIPTION

Environment: This ecological system occurs in relatively small depressions or swales and along drainages on broad mesas, plains and valley bottoms that receive runoff from adjacent areas. These sites occupy low topographic positions and generally have deep, fine-textured soils that are neutral to slightly or moderately saline/alkaline. The system typically occurs in local topographic lows that may be associated with drainages, or may represent swales or basins, but typically receives run-off from the surrounding landscape. Soils are generally clayey, and in some cases the shrink-swell characteristics of the soil may limit the development of woody species. Stands of the system typically occur on Quaternary alluvium, but may be local in nature and mapped within various geological formations. It is generally found on local topographic lows that may be associated with a drainage or may occur as basins or swales. Soils are typically tight ones, and Clay Flat Ecological Sites are typical.
Vegetation: The vegetation of this grassland system is typically dominated by *Sporobolus airoides, Sporobolus wrightii, Pleuraphis mutica* (in tobosa swales), or other mesic graminoids such as *Pascopyrum smithii* or *Panicum obtusum*. In tobosa swales, sand-adapted species such as *Yucca elata* may grow at the swale's edge in the deep sandy alluvium that is deposited there from upland slopes. *Sporobolus airoides* and *Sporobolus wrightii* are more common in alkaline soils and along drainages. Other grass species may be present, but these mesic species are diagnostic. *Prosopis glandulosa* may be present and, in some cases, may develop into a significant canopy. Other scattered shrubs such as *Atriplex canescens, Ericameria nauseosa, Fallugia paradoxa, Krascheninnikovia lanata,* or *Rhus microphylla* may be present. *Sporobolus airoides* is often associated with more alkaline (to gypsic), poorly drained areas and *Sporobolus wrightii* with less alkaline better drained areas. *Distichlis spicata, Allenrolfea occidentalis,* and *Suaeda* spp. are characteristic of more saline and alkaline sites.

Component Associations:

COLUMBIA BOTTOMLANDS FOREST AND WOODLAND (CES203.715)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9391

CONCEPT

Summary: This system occupies a generally level landscape encompassing the historic floodplains of the Brazos, Colorado, and San Bernard rivers of the Coastal Prairie region of Texas. The level to gently rolling uplands are punctuated by a series of swales, depressions, terraces, and natural levees. Significant local topographic relief can be associated with these features. Much of the flooding experienced by this system results from seasonal precipitation and tropical storms, not from overbank flooding. A range of communities are expressed along a moisture gradient ranging from the wettest sites along stream margins and depressions, to somewhat drier sites on ridges and natural levees. Soils are frequently clayey or loamy bottomlands.

Related Concepts:

- Columbia Bottomlands Deciduous Forest and Woodland (4704) (Elliott 2011) Finer. Forest and woodland characterized by a deciduous canopy of species described for the system.
- Columbia Bottomlands Deciduous Shrubland (4706) (Elliott 2011) Finer. Shrub-dominated sites that may have a sparse woody overstory with species in the shrub layer such as *Cephalanthus occidentalis, Salix nigra, Forestiera acuminata,* and/or *Cornus drummondii*. *Triadica sebifera* may be a conspicuous component of these shrublands, which often result from disturbance.
- Columbia Bottomlands Evergreen Shrubland (4705) (Elliott 2011) Finer. Shrublands or sparse woodlands with a well-developed shrub layer with species such as *Ilex vomitoria, Sabal minor, Quercus virginiana, Rosa bracteata,* or *Baccharis* spp. These shrublands are often the result of disturbance. This subtype may include areas where cover in the shrub layer is dominated by *Triadica sebifera*. Species such as *Celtis laevigata, Quercus virginiana,* and *Salix nigra* may also be present.
- Columbia Bottomlands Herbaceous Vegetation (4707) (Elliott 2011) Finer. These are herbaceous-dominated sites occupying bottomland soils and lacking significant shrub or overstory canopy cover. They are mostly managed grasslands dominated by grasses such as *Cynodon dactylon, Paspalum notatum*, and *Lolium perenne*.
- Columbia Bottomlands Herbaceous Wetlands (4717) (Elliott 2011) Finer. Wetlands dominated by herbaceous species such as *Carex crus-corvi*, other *Carex* spp., *Eleocharis quadrangulata, Rhynchospora* spp., *Juncus* spp., *Sagittaria* spp., *Saururus cernuus, Echinodorus cordifolius, Typha* spp., and/or *Polygonum* spp.
- Columbia Bottomlands Live Oak Forest and Woodland (4702) (Elliott 2011) Finer. This type typically occupies slightly drier sites on levees and ridges and is dominated by *Quercus virginiana*.
- Columbia Bottomlands Mixed Evergreen-Deciduous Forest and Woodland (4703) (Elliott 2011) Finer. Forest and woodland with the canopy shared between *Quercus virginiana* and hardwood species described for the system.
- Columbia Bottomlands Riparian Deciduous Forest and Woodland (4714) (Elliott 2011) Finer. Forests and woodlands with a deciduous canopy that occupy sites along drainages but outside of bottomland soils.
- Columbia Bottomlands Riparian Deciduous Shrubland (4716) (Elliott 2011) Finer. Shrublands dominated by deciduous species along drainages that are outside of bottomland soils and are often the result of disturbance. Species such as *Sapindus saponaria var. drummondii, Cephalanthus occidentalis, Cornus drummondii*, or *Sesbania drummondii* may be dominant. Disturbed sites may be dominated by *Prosopis glandulosa, Acacia farnesiana,* or *Triadica sebifera*.
- Columbia Bottomlands Riparian Evergreen Shrubland (4715) (Elliott 2011) Finer. Evergreen shrublands, often resulting from disturbance, that occupy sites along drainages but outside of bottomland soils. Species such as *Baccharis* spp., *Rosa bracteata, Ilex vomitoria,* or small *Quercus virginiana* sometimes dominate this type.
- Columbia Bottomlands Riparian Herbaceous Vegetation (4727) (Elliott 2011) Finer. These are typically managed grasslands on upland drainages. Most are dominated by non-native species such as *Bothriochloa ischaemum var. songarica, Cynodon dactylon, Paspalum notatum,* and *Lolium perenne.*
- Columbia Bottomlands Riparian Herbaceous Wetland (4737) (Elliott 2011) Finer. Herbaceous wetlands along upland drainages outside of bottomland soils. These wetlands are often dominated by sedges, rushes, and forbs such as *Polygonum* spp.
- Columbia Bottomlands Riparian Live Oak Forest and Woodland (4712) (Elliott 2011) Finer. Forests or woodlands along drainages outside of bottomland soils, but within the Columbia Bottomlands landscape, where the canopy is dominated by *Quercus virginiana*.
- Columbia Bottomlands Riparian Mixed Evergreen-Deciduous Forest and Woodland (4713) (Elliott 2011) Finer. Forests or woodlands along drainages outside of bottomland soils, but within the Columbia Bottomlands landscape, where the canopy is codominated by *Quercus virginiana* and deciduous species.

DESCRIPTION

Environment: This system occurs on Quaternary alluvium and adjacent Pleistocene terraces (Beaumont and Lissie formations) along

the Brazos, San Bernard, and Colorado rivers (as they pass through these Pleistocene formations), and adjacent streams such as Oyster Creek, Caney Creek, and Linnville Bayou. It occupies a generally level landscape, punctuated by a series of swales, depressions, and natural levees. Much of the flooding experienced by this system results from seasonal precipitation and tropical storms. Overbank flooding is infrequent, occurring about every 15 to 25 years. Soils are frequently clayey bottomlands (such as Pledger or Brazoria clays) or loamy bottomlands (such as those of the Asa or Norwood series), but also found on blackland and claypan soils within the basin.

Vegetation: Herbaceous communities and open water typically characterize the wettest sites in this system, with species such as *Eleocharis quadrangulata, Sagittaria graminea, Sagittaria platyphylla, Ludwigia* spp., *Saururus cernuus, Azolla caroliniana,* and *Lemna obscura*. Such very wet sites may have *Taxodium distichum* and *Salix nigra* in the overstory, or may be shrub swamps dominated by *Cephalanthus occidentalis* and/or *Forestiera acuminata*. Sites inundated somewhat less frequently, such as meander scars, abandoned oxbows, and channels, are often dominated in the overstory by species including *Fraxinus pennsylvanica, Ulmus americana,* and *Carya aquatica*, while the woody understory of these sites are typically open and may be dominated by *Cephalanthus occidentalis* and/or *Forestiera acuminata*. Rarely, *Leitneria floridana* may be a conspicuous component of the shrub layer. Herbaceous cover is often patchy and can include species such as *Phanopyrum gymnocarpon, Echinodorus cordifolius, Carex* spp., *Rhynchospora corniculata, Saururus cernuus, Polygonum punctatum, Hygrophila lacustris, Boehmeria cylindrica, Mikania scandens,* and *Lemna obscura*. Flats and ridges that are only occasionally flooded are often dominated by *Celtis laevigata, Ulmus crassifolia, Quercus nigra,* and *Quercus shumardii*. Shrubs on these sites include *Ilex vomitoria, Sapindus saponaria var. drummondii, Malvaviscus arboreus var. drummondii, Symphoricarpos orbiculatus,* and *Callicarpa americana*. *Sabal minor* and *Carex cherokeensis* are more abundant on these sites, and other species such as *Toxicodendron radicans, Chasmanthium sessiliflorum, Chasmanthium latifolium, Calyptocarpus vialis, Oplismenus hirtellus ssp. setarius,* and *Polygonum virginianum* may be present. Clay backflats in this landscape may be dominated by *Quercus virginiana* and *Carya illinoinensis,* and *Quercus virginiana* may also share dominance with other canopy species on natural levees of these river systems. Blackland soils on the Pleistocene surface (such as those of the Lake Charles series) are often occupied by a forest dominated or codominated by *Quercus nigra, Celtis laevigata, Ulmus crassifolia, Fraxinus pennsylvanica,* and less frequently *Quercus virginiana*. The shrub layer on these sites is often well-developed and typically dominated by *Ilex vomitoria,* sometimes with *Sabal minor, Cornus drummondii,* and *Prunus caroliniana* also present. Vines are commonly encountered, including species such as *Vitis mustangensis, Toxicodendron radicans, Ampelopsis arborea,* and *Berchemia scandens*. *Chasmanthium sessiliflorum, Carex cherokeensis, Carex crus-corvi, Urochloa platyphylla, Juncus* spp., and numerous other species are commonly found in the herbaceous layer. It is unclear whether these typically prairie-dominated surfaces are now occupied by woodland and forest due to a disruption in natural fire cycle and disturbance, or whether the unique hydrology or other environmental factors of the Columbia Bottomlands leads to this incongruity. *Tillandsia usneoides* is a frequently encountered epiphyte in these forests. Riverside woodlands, along major rivers, have *Platanus occidentalis* and *Populus deltoides* in the canopy. The non-native tree *Triadica sebifera* may often be encountered, sometimes as a significant or dominant component of the canopy.

Component Associations:
- *Cephalanthus occidentalis / Carex* spp. - *Lemna* spp. Southern Shrubland (CEGL002191, G4)
- *Fraxinus pennsylvanica - (Carya aquatica) / Forestiera acuminata / Phanopyrum gymnocarpon* Depression Forest (CEGL007926, G2?)
- *Platanus occidentalis - Salix nigra / Conyza canadensis* Forest (CEGL004612, G4?)
- *Quercus virginiana - Quercus nigra / Chasmanthium latifolium* Forest (CEGL002107, G2G3)
- *Quercus virginiana / Ilex vomitoria - Sabal minor / Carex cherokeensis - Malvaviscus arboreus var. drummondii* Forest (CEGL007830, G2G3)
- *Salix nigra - (Fraxinus pennsylvanica, Acacia farnesiana)* Forest (CEGL008481, G4?)
- *Taxodium distichum - Fraxinus pennsylvanica* Gallery Forest (CEGL007928, G2Q)
- *Ulmus crassifolia - Carya illinoinensis - Celtis laevigata / Chasmanthium sessiliflorum - Carex cherokeensis* Forest (CEGL002388, G2G3)

Spatial Characteristics

Adjacent Ecological Systems:
- Central Texas Coastal Prairie River Floodplain (CES203.713)

Distribution

Range: This system occupies a large area encompassing the historic floodplains of the Brazos, Colorado, and San Bernard rivers in the Coastal Prairie region of the Texas Gulf Coast. Chocolate Bayou represents the eastern extent of this system as the forest grades into systems more closely resembling West Gulf Coastal Plain Small Stream and River Forest (CES203.487) to the northeast. Tres Palacios Creek represents the southwestern limit of this system, as floodplains further south and west share closer affinity to coastal rivers such as the Mission and Aransas.

EAST GULF COASTAL PLAIN DUNE AND COASTAL GRASSLAND (CES203.500)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Herbaceous; Depressional; Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2435; ESLF 7148; ESP 1435

CONCEPT

Summary: This system includes vegetation of coastal dunes along the northern Gulf of Mexico, including the northwestern panhandle of Florida, southern Alabama, and southeastern Mississippi. The vegetation consists largely of herbaceous and embedded shrublands on barrier islands and other near-coastal areas where salt spray, saltwater overwash, and sand movement are important ecological forces. This vegetation differs from that of other regions of the Gulf, and this region forms a natural unit with similar climate and substrate. There are a number of diagnostic and endemic plant species which characterize this system, including *Ceratiola ericoides*, *Chrysoma pauciflosculosa*, *Schizachyrium maritimum*, *Paronychia erecta*, and *Helianthemum arenicola*.

Similar Ecological Systems:

- Southern Scrub Oak: 72 (Eyre 1980) Finer

DESCRIPTION

Environment: The vegetation consists largely of herbaceous vegetation and patches of shrublands on barrier islands and other near-coastal areas where salt spray, saltwater overwash, and sand movement are important ecological forces. This vegetation differs from that of other regions of the Gulf, and this region forms a natural unit with similar climate and substrate (Johnson 1997).

Vegetation: There are a number of diagnostic and endemic plant species which characterize this system, including *Ceratiola ericoides*, *Chrysoma pauciflosculosa*, *Schizachyrium maritimum*, *Paronychia erecta*, and *Helianthemum arenicola* (Johnson and Barbour 1990).

Dynamics: The natural coastal dynamics include the movement of sand from wind, tides, and storm surge. This includes transport of sand along the coast (primarily from east to west), and movement of sand by wind or water between the dunes, beach and subtidal areas, and the movement of sand from the foredunes to the interior. If not restricted by infrastructure or engineered hard structures, beaches and dunes can migrate as coastlines change over time in response to the action of wind and water. The Gulf of Mexico coast is affected by one tide per day. Coastal grassland develops as a barrier island builds seaward, developing new dune ridges along the shore which protect the inland ridges from sand burial and salt spray, or as a beach recovers after storm overwash and a new foredune ridge builds up along the shore, protecting the overwashed area behind it from sand burial and salt spray (FNAI 2010a). Wrack and seaweed deposited along the shore is an important source of nutrients for the coastal ecosystem, and helps promote revegetation in newly disturbed areas (Defeo et al. 2009). Fire is rare and local to small areas.

Component Associations:
- *(Iva imbricata) / Sporobolus virginicus - Spartina patens - (Paspalum distichum, Sesuvium portulacastrum)* Herbaceous Vegetation (CEGL007839, G3?)
- *Ceratiola ericoides - (Chrysoma pauciflosculosa) / Polygonella polygama / Cladonia leporina* Shrubland (CEGL003864, G2?)
- *Chrysoma pauciflosculosa - Paronychia erecta* Dwarf-shrubland (CEGL003947, G1G2)
- *Fuirena scirpoidea - Panicum tenerum - Dichanthelium wrightianum - Andropogon capillipes* Herbaceous Vegetation (CEGL004953, G2?)
- *Ilex vomitoria - Quercus (geminata, virginiana) - Morella cerifera - Serenoa repens* Shrubland (CEGL003813, G2G3)
- *Quercus myrtifolia - Quercus geminata - Ceratiola ericoides - Conradina canescens* Shrubland (CEGL003824, G2)
- *Schizachyrium maritimum - (Heterotheca subaxillaris)* Herbaceous Vegetation (CEGL004057, G2)
- *Spartina patens - Schizachyrium maritimum - Solidago sempervirens* Herbaceous Vegetation (CEGL008445, G3?)
- *Spartina patens - Setaria parviflora - Hydrocotyle bonariensis* Herbaceous Vegetation (CEGL004257, G3)

EAST GULF COASTAL PLAIN NEAR-COAST PINE FLATWOODS (CES203.375)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Extensive Wet Flat; Short Disturbance Interval; Needle-Leaved Tree
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2454; ESLF 9123; ESP 1454

CONCEPT

Summary: This system of open forests or woodlands occupies broad, sandy flatlands in a relatively narrow band along the northern Gulf of Mexico coast east of the Mississippi River. This range corresponds roughly to the Gulf Coast Flatwoods (EPA Ecoregion 75a). These areas predominantly occur on poorly drained acidic Spodosol soils, which are subject to seasonal inundation as well as droughty conditions. Often called "flatwoods" or "flatlands," they are subject to short fire-return intervals and seasonally high water tables. Overstory vegetation is characterized by *Pinus palustris* and, to a lesser degree, by *Pinus elliottii*. Understory structure ranges from densely shrubby to open and herbaceous-dominated, with variation in soils and drainage. The variation includes Scrubby Flatwoods, Mesic Flatwoods, Wet Flatwoods, and Maritime Flatwoods. Fire is naturally frequent; many sites have a fire-return time of from one to four years.
Classification Comments: There was some consideration of splitting out the slash pine flatwoods from this system due to presumed differences in both moisture status and fire history when compared with typical longleaf. There is considerable variation between wet and "non-wet" flatwoods implied in this system.
Similar Ecological Systems:
- Central Florida Pine Flatwoods (CES203.382)
- East Gulf Coastal Plain Interior Upland Longleaf Pine Woodland (CES203.496)
- Southern Atlantic Coastal Plain Wet Pine Savanna and Flatwoods (CES203.536)

- Mesic Flatwoods (FNAI 1990) Intersecting
- Pond Pine: 98 (Eyre 1980) Finer
- Pondcypress: 100 (Eyre 1980) Finer
- Scrubby Flatwoods (FNAI 1990) Intersecting
- Slash Pine: 84 (Eyre 1980) Finer
- Wet Flatwoods (FNAI 1990) Intersecting

DESCRIPTION

Environment: This system occupies broad, sandy flatlands which are subject to short fire-return intervals even though they are subject to seasonally high water tables. Spodosols encourage seasonal saturation, acidity, and high soil iron and aluminum concentrations. These areas are often called "flatwoods" or "flatlands."
Vegetation: Overstory vegetation is characterized by *Pinus palustris* and to a lesser degree by *Pinus elliottii*. Some stands include *Pinus serotina*. Shrubs include *Quercus geminata, Quercus minima, Quercus pumila, Serenoa repens, Cyrilla racemiflora, Ilex coriacea, Ilex glabra, Ilex vomitoria*, and *Lyonia lucida*. Herbaceous species may include *Aristida beyrichiana, Ctenium aromaticum, Muhlenbergia expansa, Schizachyrium scoparium, Sporobolus floridanus, Carphephorus pseudoliatris, Sarracenia alata, Agalinis filicaulis, Polygala cymosa, Rhynchospora* spp., and *Helianthus radula*.
Dynamics: Fire is naturally frequent, with a fire-return time of from one to four years. Disturbances are an important part of the natural functions of wet pine savanna and flatwoods. In order for these habitats to burn frequently (every 2-3 years), there needs to be enough fine fuel, such as needles from *Pinus palustris* trees, healthy populations of native warm-season grasses, and evergreen shrubs with volatile oils in their leaves, such as *Gaylussacia frondosa, Ilex coriacea, Ilex glabra, Lyonia* spp., *Serenoa repens*, and *Vaccinium* spp. The frequent fires promote flowering, seed production, and seed germination of many plants and provide open areas in patches (Van Lear et al. 2005).

Component Associations:
- *Pinus (palustris, elliottii var. elliottii) / (Quercus geminata) / Serenoa repens / Aristida beyrichiana* Woodland (CEGL007714, G3?)
- *Pinus elliottii var. elliottii - (Pinus palustris) / Ilex vomitoria - Serenoa repens - Morella cerifera* Woodland (CEGL004658, G2G3)
- *Pinus elliottii var. elliottii - (Pinus serotina) / Aristida beyrichiana - Rhynchospora oligantha - Sarracenia (flava, minor, psittacina)* Woodland (CEGL003673, G2?)
- *Pinus elliottii var. elliottii - Taxodium ascendens / Polygala cymosa - Rhynchospora* spp. Woodland (CEGL004556, G2?)

- *Pinus elliottii var. elliottii / Serenoa repens - Ilex glabra* Woodland (CEGL003643, G4?)
- *Pinus palustris - (Pinus elliottii var. elliottii) / Ctenium aromaticum - Carphephorus pseudoliatris - (Sarracenia alata)* Woodland (CEGL003645, G3?)
- *Pinus palustris - (Pinus elliottii var. elliottii) / Ilex coriacea - Cyrilla racemiflora* Woodland (CEGL003656, G3G4)
- *Pinus palustris - (Pinus elliottii var. elliottii) / Ilex vomitoria / Muhlenbergia expansa - Agalinis filicaulis* Woodland (CEGL004792, G1?)

EASTERN BOREAL FLOODPLAIN (CES103.588)

CLASSIFIERS

Classification Status: Standard

Primary Division: Boreal (103)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval [Short interval, Spring Flooding]; Forest and Woodland (Treed); Riverine / Alluvial; Flood Scouring; Picea (glauca, mariana, rubens) - Abies
Non-Diagnostic Classifiers: Mesotrophic Water; Circumneutral Water; Acidic Water; Lowland; Shrubland (Shrub-dominated); Toeslope/Valley Bottom; Glaciated; Mesotrophic Soil; Oligotrophic Soil; Circumneutral Soil; Acidic Soil; Deep Soil; Mineral: W/ A-Horizon >10 cm; Silt Soil Texture; Very Short Disturbance Interval
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2444; ESLF 9113; ESP 1444

CONCEPT

Summary: These southern boreal floodplains are found in the extreme northern portions of the eastern U.S., and believed to be more widespread in Canada. They consist of floodplains along medium-sized northern rivers, in areas not strongly influenced by ice-scour (i.e., depositional), where topography and process have resulted in a complex of upland and wetland alluvial vegetation. This complex includes floodplain forests dominated by northern trees such as *Populus balsamifera* and *Fraxinus nigra*, as well as herbaceous sloughs and shrub wetlands. (*Acer saccharinum* is uncommon or absent.) Most areas are underwater each spring; microtopography determines how long the various habitats are inundated. The distribution in Division 201 appears to be primarily Canadian, with incursions into northern Maine and northern Minnesota.
Classification Comments: Where this system transitions to Western Canadian Boreal Mixed Hardwood-Conifer Swamp and Floodplain (CES103.523) is not clear, and perhaps they should be combined. As written, this system does have some different floristics than the western boreal one.

GREAT LAKES WET-MESIC LAKEPLAIN PRAIRIE (CES202.027)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Herbaceous; Depressional [Lakeshore]; Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2411; ESLF 7124; ESP 1411

CONCEPT

Summary: This system is found on the lakeplain near the southern central Great Lakes of the United States and Canada. Stands occur on level, sandy glacial outwash, sandy glacial lakeplains, and deposits of dune sand in silty/clayey glacial lakeplains. The soils are sands and sandy loams, loams with poor to moderate water-retaining capacity, typically occurring over less permeable silty clays . There is often temporary inundations after heavy rains or in the spring, followed by dry conditions throughout much of the remaining growing season. The vegetation of this system is dominated by graminoid species typically 1-2 m high. Trees and shrubs are very rare. There is very little bare ground. *Andropogon gerardii, Calamagrostis canadensis, Carex* spp. (*Carex aquatilis, Carex bicknellii, Carex buxbaumii, Carex pellita (= Carex lanuginosa)*), *Panicum virgatum, Spartina pectinata, Schizachyrium scoparium*, and *Sorghastrum nutans* are the most abundant graminoid species. Many of the sites that this system formerly occupied are now urban and/or agricultural. Areas around Chicago and Detroit were likely in this system but are heavily converted now and few sites remain. Remnant sites have been impacted by woody encroachment of native and non-native species.

DESCRIPTION

Environment: Stands occur on level, sandy glacial outwash, sandy glacial lakeplains, and deposits of dune sand in silty/clayey glacial lakeplains. The soils are sands, sandy loams, and loams with poor to moderate water-retaining capacity and typically occur over less permeable silty clays. The shallow, less permeable silty clays and the flat landscape combine to favor temporary inundations after heavy rains or in the spring. The coarser surface soils then dry out throughout much of the remaining growing season. These occurred in a patchy landscape of both drier oak woodland/savanna and more mesic beech-maple forest. Pin oak depressions were common in these prairies.
Dynamics: The cycle of soils being temporarily inundated and then drying out during the growing season is important for this system. Great Lakes water levels also affected this system with longer-term increases and decreases creating wetter and drier baseline conditions, respectively. Graminoids and forbs can thrive under these conditions but woody species are inhibited. The dry conditions and abundance of herbaceous vegetation creates conditions well-suited for burning and fires further reduced woody vegetation. Drier sites and those in a drier landscape burned more frequently. Fires were most likely in dry years after a productive year(s) when biomass was higher. Fire regime was probably related to the adjacent oak savannas but likely a little less frequent. Water levels were highly variable and boundaries of this system probably shifted across the landscape in response to fire, Great Lakes water levels, and wetter or drier climatic cycles.

Component Associations:
- *Andropogon gerardii - Calamagrostis canadensis - Pycnanthemum virginianum - Oligoneuron ohioense* Herbaceous Vegetation (CEGL005095, G2)
- *Andropogon gerardii - Sorghastrum nutans - Schizachyrium scoparium - Aletris farinosa* Herbaceous Vegetation (CEGL005096, G2)
- *Quercus alba - Quercus velutina - Quercus palustris / Carex pensylvanica* Woodland (CEGL005054, G2)
- *Spartina pectinata - Carex* spp. *- Calamagrostis canadensis* Lakeplain Herbaceous Vegetation (CEGL005109, G2G3)

DISTRIBUTION

Range: This system is found near the southern central Great Lakes of the United States and Canada, from southeastern Wisconsin and northeastern Illinois to southern Michigan and southwestern Ontario. This does not go farther east than northwestern Ohio (glacial Lake Maumee).
Divisions: 202:C
Nations: CA, US
Subnations: IL, IN, MI, OH, ON, WI

GREAT LAKES WOODED DUNE AND SWALE (CES201.726)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Laurentian-Acadian (201)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: 30-180-day hydroperiod; Coastal Dune Mosaic; Forest and Woodland (Treed); Dune (Substrate); Glaciated; Sand Soil Texture
Non-Diagnostic Classifiers: Shallow (<15 cm) Water; Lowland [Lowland]; Shrubland (Shrub-dominated); Herbaceous; Temperate [Temperate Continental]; Depressional [Lakeshore]; Isolated Wetland [Partially Isolated]; Intermediate Disturbance Interval; W-Patch/High Intensity
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2466; ESLF 9135; ESP 1466

CONCEPT

Summary: This system is found in nearly 100 occurrences throughout the Great Lakes shorelines of the United States and Canada. It consists of a foredune, followed by a series of low to high dunes (uplands) and swales (wetlands). The system is often best developed where post-glacial streams entered an embayment and provide a dependable sand source. The combination of along-shore currents, waves, and winds form foredunes along the shoreline. The foredunes of most dune-and-swale complexes are commonly 1-2 m high, with *Ammophila breviligulata, Calamovilfa longifolia, Salix serissima, Salix cordata,* and *Populus balsamifera* most common. The swale immediately behind the foredune is influenced by short-term variation in lake levels and can be partially or occasionally completely filled by dune sands following major storm events. Species common to this first swale include *Juncus balticus, Juncus pelocarpus, Juncus nodosus, Eleocharis acicularis,* and *Schoenoplectus americanus (= Scirpus americanus)*. Occasionally, such swales may contain lake-influenced, calcareous sands and may contain moderately alkaline indicators.

A low dune field with more advanced plant succession often follows the first open dunes and swales. *Pinus banksiana, Pinus strobus,* and *Pinus resinosa* often form a scattered overstory canopy, while *Juniperus communis, Juniperus horizontalis, Arctostaphylos uva-ursi,* and *Koeleria macrantha* form a scattered ground layer. Following the dune-field zone, both dunes and swales are typically forested. Moist swales are often forested, and soil organic material has often begun to accumulate. *Thuja occidentalis, Alnus incana, Salix* spp., and *Acer rubrum* dominate the partial overstory canopy and understory. In contrast to the dry or moist swales, wetter swales (where standing water is present through most of the year) may be dominated by Carices, such as *Carex aquatilis* and *Carex stricta*. Forested beach ridges, with soils of medium to course sand, tend to be dominated by species common to dry-mesic and mesic northern forest. Complexes located in embayments protected from prevailing winds tend to be formed entirely of low, water-lain beach ridges. As a result, even the beach ridges within these complexes support wetland vegetation.

Six major subtypes of Great Lakes Dune and Swale were described for Michigan, including the Lake Superior high dune type, the Lake Superior low dune type, the North Lake Michigan high dune type, Northern Lake Huron-Lake Michigan low dune type, the Southern Lake Huron type, and the Northern Great Lakes low dune type. These subtypes represent patterns of floristic variation resulting from latitude and sand dune/beach ridge characteristics that constrain floristic and structural attributes. High dune types may support predominantly upland vegetation, while low dune types may support predominantly wetland vegetation.
Classification Comments: Six major subtypes of Great Lakes Dune and Swale were described for Michigan, including the Lake Superior high dune type, the Lake Superior low dune type, the North Lake Michigan high dune type, Northern Lake Huron-Lake Michigan low dune type, the Southern Lake Huron type, and the Northern Great Lakes low dune type. These subtypes represent patterns of floristic variation resulting from latitude and sand dune/beach ridge characteristics that constrain floristic and structural attributes.

This system has rather strong variation between northern and southern Great Lakes examples (north and south of Bailey's 210-220 division line). Those occurring along the southern Lake Michigan shoreline of Indiana and Illinois have been altered significantly, but likely reflect a distinct ecological system type with oak woodland and savanna on beach ridges and wet prairie in swales.
Similar Ecological Systems:
- Great Lakes Dune (CES201.026)
- Great Lakes Sand Beach (CES201.149)
- Northern Great Lakes Interdunal Wetland (CES201.034)--may not be a distinct system.

Related Concepts:

- Northern White-Cedar: 37 (Eyre 1980) Finer

DESCRIPTION

Environment: The system consists of a foredune, followed by a series of low to high dunes (uplands) and swales (wetlands). The system is often best developed where post-glacial streams entered an embayment and provide a dependable sand source. The combination of along-shore currents, waves, and winds form foredunes along the shoreline. With gradual long-term drops in water

level, combined with post-glacial uplifting of the earth's crust, these low dunes gradually rise above the direct influence of the lakes, and new foredunes replace them. Over several thousand years, a series of ridges and swales is created. For most complexes, the flow of surface streams and groundwater maintain the wet conditions in the swales. With time, plant succession has proceeded to the point where the beach ridges are now forested while the wet swales are either forested or open wetlands. Along the Lake Superior shoreline, where post-glacial uplift is greatest, many of the complexes consist primarily of dry, forested swales. The dunes and swales differs depending on fetch and the amount of sediment available. The influence of Great Lakes water-level fluctuations is probably limited to the first few swales inland from the shoreline. For most of the complexes, the water occupying the swales comes from streams flowing from the adjacent uplands or from groundwater seepage.

Vegetation: The foredunes of most dune-and-swale complexes are commonly 1-2 m high, with *Ammophila breviligulata, Calamovilfa longifolia, Salix serissima, Salix cordata*, and *Populus balsamifera* most common. The swale immediately behind the foredune is influenced by short-term variation in lake levels and can be partially or occasionally completely filled by dune sands following major storm events. Species common to this first swale include *Juncus balticus, Juncus pelocarpus, Juncus nodosus, Eleocharis acicularis*, and *Schoenoplectus americanus (= Scirpus americanus)*. Occasionally, such swales may contain lake-influenced, calcareous sands, and the shallow swale may contain moderately alkaline indicators, such as *Cladium mariscoides, Myrica gale, Dasiphora fruticosa ssp. floribunda (= Pentaphylloides floribunda)*, and others.

A low dune field with more advanced plant succession often follows the first open dunes and swales. *Pinus banksiana, Pinus strobus*, and *Pinus resinosa* often form a scattered overstory canopy, while *Juniperus communis, Juniperus horizontalis, Arctostaphylos uva-ursi*, and *Koeleria macrantha* form a scattered ground layer.

Following the dune-field zone, both dunes and swales are typically forested. Moist swales are often forested, and soil organic material has often begun to accumulate. *Thuja occidentalis*, *Alnus incana*, *Salix* spp., and *Acer rubrum* dominate the partial overstory canopy and understory. In contrast to the dry or moist swales, wetter swales (where standing water is present through most of the year) may be dominated by Carices, such as *Carex aquatilis* and *Carex stricta*.

Forested beach ridges, with soils of medium to course sand, tend to be dominated by species common to dry-mesic and mesic northern forest. Soil moisture conditions appear to change dramatically with slight elevational changes and are reflected in the development of soil organic material and changing plant species. On higher, drier ridges, soils often have less than 3 cm of organic material. *Pinus resinosa, Pinus strobus*, and *Quercus rubra* are often codominant, while *Betula papyrifera, Populus grandidentata, Abies balsamea*, and *Acer rubrum* are subdominant or understory species. *Pteridium aquilinum, Gaylussacia baccata, Vaccinium myrtilloides, Cornus canadensis*, and *Gaultheria procumbens* occur in the shrub and ground layers.

Complexes located in embayments protected from prevailing winds tend to be formed entirely of low, water-lain beach ridges. As a result, even the beach ridges within these complexes support wetland vegetation.

Dynamics: Foredune and immediate back dune areas are influenced by active dune processes of wind-caused "blowouts" and subsequent restabilization. Forested beach ridges may support fire regimes characteristic of similar upland forest systems outside of these complexes. Due to lakeshore proximity, heavy winds and resultant windthrow are common in forested ridges. Great Lakes water-level fluctuations likely influence water levels in swales closest to the shoreline, if at all. The hydrology of interdunal swales is driven largely by lateral flow through the porous beach ridges. Older swales (farthest from current lakeshores) in larger complexes support peat-forming bogs.

GREAT PLAINS PRAIRIE POTHOLE (CES303.661)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Non-Diagnostic Classifiers: Lowland [Lowland]; Pothole; Herbaceous; Temperate [Temperate Continental]; Depressional; Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2482; ESLF 9203; ESP 1482

CONCEPT

Summary: The prairie pothole system is found primarily in the glaciated northern Great Plains of the United States and Canada, and is characterized by depressional wetlands formed by glaciers scraping the landscape during the Pleistocene era. This system is typified by several classes of wetlands distinguished by changes in topography, soils and hydrology. Many of the basins within this system are closed basins and receive irregular inputs of water from their surroundings (groundwater and precipitation), and some export water as groundwater. Hydrology of the potholes is complex. Precipitation and runoff from snowmelt are the principal water sources, with groundwater inflow secondary. Evapotranspiration is the major water loss, with seepage loss secondary. Most of the wetlands and lakes contain water that is alkaline (pH >7.4). The concentration of dissolved solids result in water that ranges from fresh to extremely saline. The flora and vegetation of this system are a function of the topography, water regime, and salinity. In addition, because of periodic droughts and wet periods, many wetlands within this system undergo vegetation cycles. This system includes elements of aquatic vegetation, emergent marshes, and wet meadows that develop into a pattern of concentric rings. This system is responsible for a significant percentage of the annual production of many economically important waterfowl in North America and houses more than 50% of North American's migratory waterfowl, with several species reliant on this system for breeding and feeding. Much of the original extent of this system has been converted to agriculture, and only approximately 40-50% of the system remains undrained.
Classification Comments: More data from Canada is needed to really define this system completely.

DESCRIPTION

Environment: This system is characterized by closed basins, potholes, that receive irregular inputs of water from the surroundings and may export water as groundwater. The climate for the range of this system is characterized by mid-continental temperature and precipitation extremes. Across the range of this system, precipitation triples from 30 cm to 90 cm (west to east) and average annual temperature increases from 1 to 10 degrees C (north to south). Snowmelt and spring rains typically fill many of the potholes in examples of this system. The region in the range of this system is distinguished by a thin mantle of glacial drift overlying stratified sedimentary rocks of the Mesozoic and Cenozoic ages; these form a glacial landscape of end moraines, stagnation moraines, outwash plains and lakeplains. The glacial drift ranges 30 to 120 m thick and forms steep to slight local relief with fine-grained, silty to clayey soils. Soils in outwash plains are coarser. Limestone, sandstone, and shales predominate as bedrock, and highly mineralized water can discharge from these rocks. The hydrology of this system is complex with salinity ranging from fresh to saline, and chemical characteristics varying seasonally and annually. Sites with substantial surface or groundwater outlet are typically fresh while sites with little or no outlet tend to accumulate salts. Rain and snowmelt are the primary water sources with evapotranspiration being the source of major water loss. Some potholes are connected to groundwater sources and can serve as groundwater recharge sources, some receive groundwater outflow, and some have both. Water depth in most potholes is shallow. Many have a maximum depth of <2 m and most are <1 m deep (Sloan 1970). Seasonal water level fluctuations mean that the depth during much of the growing season is less than these maximums.
Vegetation: The vegetation within this system is highly influenced by hydrology, salinity and dynamics. Potholes found within this system can vary in depth and duration, which will determine the local gradient of species. Likewise, plant species found within individual potholes of this system will be strongly influenced by periodic drought and wet periods. Deeper potholes with standing water throughout most of the year have a central zone of submersed aquatic vegetation. Potholes that dry during droughty times can have central zones dominated by either tall emergents or mid-height emergents depending on the depth of the marsh. Wet meadow species such as grasses, forbs and sedges can be found in potholes that are only flooded briefly in the spring. All of these types of potholes can be found within an example of this system. Grazing, draining, and mowing of this system can influence the distribution of these types of potholes and plant species within this system.
Dynamics: A cycle of flooding and drying is the primary natural dynamic influencing this system. Snowmelt contributes substantially to the seasonal water input. In addition to runoff from snow melting within the watershed, snow tends to accumulate within the pothole due to the slightly more sheltered landscape position and the typically heavier and taller vegetation cover present in at least parts of the pothole. Spring rains contribute additional water, and potholes consistently have their yearly maximum water depth in late spring. Heavy rains in the summer can fill potholes, but the tendency is for water levels to fall as the growing season progresses. This fluctuation of water level during the year results in very different flooding regimes for different parts of the pothole. At the driest edge, the ground may be flooded or saturated for only a few weeks during the growing season, while the wettest parts of some potholes are flooded year-round. These different flooding regimes create environments favoring different types of plants and

many potholes have strong zonation of vegetation (Johnson et al. 1987). From driest to wettest, these zones are wet meadow, shallow marsh, deep marsh, aquatic, and deep water. Many potholes do not have enough water to support the wetter vegetation zones so individual potholes may have shallow marsh at the center with a ring of wet meadow or deep marsh surrounded by shallow marsh which in turn is surrounded by wet meadow. The changes in water volume in a given pothole are also reflected in the salinity of the water. Prairie potholes are least saline in the spring when snowmelt and spring rains fill the wetland, and possibly flush water out of the basin through seasonal overflow, but salinity increases as evapotranspiration reduces the volume of water in the basin throughout the growing season (Stewart and Kantrud 1972).

In addition to seasonal water level fluctuations, there are longer-term changes in water levels that affect prairie potholes (Kantrud et al. 1989a). Multi-year patterns of above or below average precipitation result in shifting vegetation zones within a single site. A multi-year dry period will cause a pothole to shrink, and the environments suitable for each vegetation zone will move towards the center, possibly eliminating the wettest zones altogether. A multi-year wet period will fill potholes, moving the environments conducive to each vegetation zone away from the center and possibly creating habitats for new, wetter zones in the middle. Changes in water depth of several feet are possible over a few to several years (Stewart and Kantrud 1972). These multi-year changes in the location of vegetation zones promote floristic diversity by creating shifting environments at any one place on the landscape. During the wetter seasonal or multi-year periods, temporary connections may be formed among otherwise discontinuous wetlands, allowing the spread of species and possibly affecting water chemistry through flushing of salts or other dissolved chemicals into or out of basins (Leibowitz and Vining 2003).

Component Associations:
- *Carex lasiocarpa - Carex oligosperma / Sphagnum* spp. Herbaceous Vegetation (CEGL002265, G3G4)
- *Schoenoplectus acutus - (Schoenoplectus fluviatilis)* Freshwater Herbaceous Vegetation (CEGL002225, G4G5)
- *Schoenoplectus maritimus - Schoenoplectus acutus - (Triglochin maritima)* Herbaceous Vegetation (CEGL002227, G3G5)
- *Schoenoplectus maritimus* Herbaceous Vegetation (CEGL001843, G4)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Northwestern Great Plains Mixedgrass Prairie (CES303.674)

DISTRIBUTION

Range: This system can be found throughout the northern Great Plains ranging from central Iowa northwest to southern Saskatchewan and Alberta, and extending west into north-central Montana. It encompasses approximately 870,000 square km with approximately 80% of its range in southern Canada. It is also prevalent in North Dakota, South Dakota, and northern Minnesota.

GREAT PLAINS WOODED DRAW AND RAVINE (CES303.680)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Ravine; G-Patch/Medium Intensity; Draw
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2385; ESLF 4328; ESP 1385

CONCEPT

Summary: This ecological system is typically found associated with permanent or ephemeral streams though it may occur on steep northern slopes or within canyon bottoms that do not experience periodic flooding. Soil moisture and topography allow greater moisture conditions compared to the surrounding areas. Occurrences can be either tree-dominated or predominantly shrubland. *Fraxinus pennsylvanica* with *Ulmus rubra* or *Ulmus americana* typically dominate this system, although *Juniperus scopulorum* can dominate the canopy in the western Great Plains and *Juniperus virginiana* in the east. *Populus tremuloides, Betula papyrifera,* or *Acer negundo* are commonly present in portions of the northwestern Great Plains, for example in areas of central and eastern Montana. In south-central and east-central portions of the Great Plains, *Quercus macrocarpa* can also be present. Wetter areas within this system can have significant amounts of *Populus deltoides*. Component shrubs can include *Cornus sericea, Crataegus douglasii, Crataegus chrysocarpa, Crataegus succulenta, Elaeagnus commutata, Prunus virginiana, Rhus* spp., *Rosa woodsii, Shepherdia argentea, Symphoricarpos occidentalis,* or *Viburnum lentago*. Common grasses can include *Calamagrostis stricta, Carex* spp., *Pascopyrum smithii, Piptatherum micranthum, Pseudoroegneria spicata,* or *Schizachyrium scoparium*. This system was often subjected to heavy grazing and trampling by both domestic animals and wildlife and can be heavily degraded in some areas. In addition, exotic species such as *Ulmus pumila* and *Elaeagnus angustifolia* can invade these systems.
Classification Comments: More information from the broader division and from the Rocky Mountain division will be needed to determine if those areas dominated by ash and elm should be separated from areas dominated by *Juniperus scopulorum*. Those areas dominated by *Juniperus* are typically found in the Badlands and the western portions of North Dakota and Nebraska, and should probably be described based on data from the Great Plains Steppe or Rocky Mountain division. However, *Juniperus* can occur in stands with elm and ash in Nebraska and North Dakota. Expanded range into the central Great Plains (parts of Provinces 332 and 251). Possibly consider splitting the western Great Plains stands from the central Great Plains stands but there are currently not enough floristic and environmental differences known between stands in the two areas to justify that.

- Paper Birch: 18 (Eyre 1980) Finer
- Rocky Mountain Juniper: 220 (Eyre 1980) Intersecting

DESCRIPTION

Environment: This system is associated with permanent or ephemeral streams. It also can occur on steep northern slopes or within canyon bottoms that do not experience periodic flooding. Soils are primarily wet to mesic, and the more sheltered and lower landscape position allows for greater moisture conditions compared to the surrounding areas.
Vegetation: Species composition can vary across the range of this system. *Fraxinus pennsylvanica* and *Ulmus* spp. typically dominate this system. In some western areas of the Great Plains Division, *Juniperus* spp. can dominate, and in the south-central and east-central portions of the Great Plains, *Quercus macrocarpa* can also be important. *Tilia americana* and *Ostrya virginiana* are also common associates in the eastern portion of this system's range. Exotic species, such as *Ulmus pumila* and *Elaeagnus angustifolia*, can be present in degraded examples. Wetter areas within this system can have significant amounts of *Populus deltoides*.
Dynamics: Fire can influence this system; however, grazing is the most prevalent dynamic process influencing this system. Overgrazing can heavily degrade this system, particularly the understory, and allow for the invasion of exotic species.

HAWAI'I 'IHI'IHILUAKEA VERNAL POOL (CES412.223)

CLASSIFIERS

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval [Short interval, Winter Flooding]; Vernal Pool Mosaic; Herbaceous; Tropical/Subtropical; Depressional [Vernal Pool]; Isolated Wetland [Partially Isolated]; Clay Soil Texture; Basin; Marsilea villosa
Non-Diagnostic Classifiers: Lowland [Lowland]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - forbland, Perennial forb grassland
National Mapping Codes: EVT 2805; ESLF 9439; ESP 1805

CONCEPT

Summary: This rare, intermittently wet fern wetland develops in lowland vernal pools and areas that get flooded periodically. It occurs in shallow depressions in clay soil, cinder craters, or lithified sand dunes overlain with alluvial clay common in dry areas of most islands where winter rains create seasonal pools at elevations between 424 and 1032 m (1391-3385 feet). Now restricted to O'ahu and Molokai'i, the wetland is characterized by the dominance of the federally endangered endemic fern *Marsilea villosa*. On Molokai'i, it occurs in rocky areas that never hold standing water but get flushed out annually or less often. On the seasonal floodplain in Lualualei Valley, O'ahu, scattered depressions support *Marsilea* mats under scattered *Prosopis pallida* and among *Sida fallax*. At 'Ihi'ihilauÃ¢kea Crater, O'ahu, the crater floor is thickly covered with *Marsilea* when seasonal rains saturate the soil, sometimes submerging the habitat. During dry periods the fern becomes a dormant rhizomatous mat, and the area appears to be a weedy dryland of grasses and forbs, including *Amaranthus spinosus*, *Xanthium strumarium*, *Setaria verticillata*, *Cynodon dactylon*, *Chloris barbata*, and *Merremia aegyptia*. Sexual reproduction of *Marsilea* may occur as infrequently as once every ten or more years, due to the infrequency of sufficiently heavy rains in lowland areas. Historic populations on O'ahu were destroyed by drainage of ponding areas, habitat degradation, competition from alien plants, off-road vehicle use, and development.

DISTRIBUTION

Range: This system occurs at elevations between 424 and 1032 m (1391-3385 feet) on O'ahu and Moloka'i. Historically it also occurred on Ni'ihau.
Divisions: 412:C
Nations: US

Classification Status: Standard

Primary Division: Northern Polynesia (412)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval; Riparian Mosaic; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Stream terrace (undifferentiated); Riverine / Alluvial
Non-Diagnostic Classifiers: Clay Subsoil Texture; Montane; Lowland; Sideslope; Toeslope/Valley Bottom; Tropical/Subtropical; Muck; Mineral: W/ A-Horizon >10 cm
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2802; ESLF 9336; ESP 1802

CONCEPT

Summary: This ecological system occurs as narrow bands of terrestrial vegetation bordering perennial streams from near sea level to 915 m (0-3000 feet) elevation on Kaua'i, O'ahu, Moloka'i, LGna'i, Maui, and Hawai'i. At montane elevations, there is little vegetation distinction between the plants in the riparian corridor and plants in wet gulch bottoms of surrounding montane rainforest. Vegetated forest corridors are generally broken by a series of waterfalls and may reach 48.3 km (30 miles) long. Soils are generally well-drained basaltic lava with varying depths of clay and organic horizons that usually contain rock and organic sediments carried down from steep adjacent slopes. Riparian corridors are vegetated by native species that occur in surrounding native communities, the majority of which are *Metrosideros*-dominated forest communities with an assortment of endemic ferns, shrubs and trees. Distinct riparian corridors dominated by *Pipturus albidus* form linear patches in montane and upper lowland areas, sometimes sharing dominance with other urticaceous shrub species such as *Touchardia latifolia, Boehmeria grandis*, and *Urera glabra*. Other areas possess a diverse understory of ferns and bryophytes. The lower reaches of a few lowland gulches remain overtopped by a native association of *Pisonia / Charpentiera* surrounded by dry and mesic forest. Windward riparian corridors are colonized by patches of *Hedychium* spp. (ginger). In the pre-European setting, riparian forests may be invaded by and ultimately dominated by *Aleurites moluccana*, and include the Polynesian introduced tree *Syzygium malaccense*.

DESCRIPTION

Environment: This ecological system occurs as narrow bands of terrestrial vegetation bordering perennial streams from near sea level to 915 m (0-3000 feet) elevation. At montane elevations, there is little vegetation distinction between the plants in the riparian corridor and plants in wet gulch bottoms of surrounding montane rainforest. Climate is variable depending on where the stand occurs, ranging from arid to very wet (Zones 1-7) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). Annual precipitation may vary from less than 500 mm to over 4500 mm. Vegetated forest corridors are generally broken by a series of waterfalls and may reach 48.3 km (30 miles) long. Soils are generally well-drained basaltic lava with varying depths of clay and organic horizons that usually contain rock and organic sediments carried down from steep adjacent slopes.

Component Associations:
- *Pipturus albidus* Lowland Wet Shrubland (CEGL008051, G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Hawai'i Freshwater Aquatic Bed (CES412.225)

Adjacent Ecological System Comments: Hawaiian aquatic freshwater biota is unique and includes fish, shrimp and mollusks descended from marine forms and native damselflies, which colonized from continental freshwater habitats. Damselfly (*Megalagrion*) and dragonfly (*Anax, Pantala*) naids utilize stream sediments as habitats, while adults utilize emergent vegetation. Shore bugs (*Saldula* spp.), freshwater snails (*Nertera* spp.), freshwater shrimp (*Halocaridina, Atyoida, Machrobrachium, Metabetaeus, Caligus, Hyalella, Penaeus*, and *Calappa*), and five endemic amphidromous freshwater fishes (*Awaous, Lentipes, Sicyopterus, Stenogobius*, and *Eleotris*) are part of the aquatic stream system. Plunge pools along the steeper gradient sections of Hawaiian streams serve as important habitat to the federally endangered Hawaiian duck (*Anas wyvilliana*).

DISTRIBUTION

Range: This system occurs from near sea level to 915 m (3000 feet) elevation on Kaua'i, O'ahu, Moloka'i, LÃ¢na'i, Maui, and Hawai'i.

INTER-MOUNTAIN BASINS GREASEWOOD FLAT (CES304.780)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Toeslope/Valley Bottom; Alkaline Soil; Deep Soil; Xeromorphic Shrub
Non-Diagnostic Classifiers: Deep (>15 cm) Water; Alluvial flat; Alluvial plain; Alluvial terrace; Temperate [Temperate Continental]; Depressional; Isolated Wetland [Partially Isolated]; Saline Substrate Chemistry; Sarcobatus vermiculatus
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Evergreen shrubland
National Mapping Codes: EVT 2153; ESLF 9103; ESP 1153

CONCEPT

Summary: This ecological system occurs throughout much of the western U.S. in Intermountain basins and extends onto the western Great Plains and into central Montana. It typically occurs near drainages on stream terraces and flats or may form rings around more sparsely vegetated playas. Sites typically have saline soils, a shallow water table and flood intermittently, but remain dry for most growing seasons. The water table remains high enough to maintain vegetation, despite salt accumulations. This system usually occurs as a mosaic of multiple communities, with open to moderately dense shrublands dominated or codominated by *Sarcobatus vermiculatus*. Other shrubs that may be present to codominant in some occurrences include *Atriplex canescens, Atriplex confertifolia, Atriplex gardneri, Artemisia tridentata ssp. wyomingensis, Artemisia tridentata ssp. tridentata, Artemisia cana ssp. cana*, or *Krascheninnikovia lanata*. Occurrences are often surrounded by mixed salt desert scrub or big sagebrush shrublands. The herbaceous layer, if present, is usually dominated by graminoids. There may be inclusions of *Sporobolus airoides, Pascopyrum smithii, Distichlis spicata* (where water remains ponded the longest), *Calamovilfa longifolia, Poa pratensis, Puccinellia nuttalliana*, or *Eleocharis palustris* herbaceous types.

LAURENTIAN-ACADIAN FLOODPLAIN FOREST (CES201.587)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval [Short interval, Spring Flooding]; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Woody-Herbaceous; Herbaceous; Riverine / Alluvial; Flood Scouring
Non-Diagnostic Classifiers: Mesotrophic Water; Moderate (100-500 yrs) Persistence; Lowland; Toeslope/Valley Bottom; Glaciated; Eutrophic Soil; Mesotrophic Soil; Circumneutral Soil; Acidic Soil; Deep Soil; Mineral: W/ A-Horizon >10 cm; Silt Soil Texture; Udic; Unconsolidated; Very Short Disturbance Interval; Broad-Leaved Deciduous Tree; Broad-Leaved Shrub; Graminoid
National Mapping Codes: ESLF 9328

CONCEPT

Summary: This system encompasses north-temperate floodplains in the northeastern and north-central U.S. and adjacent Canada at the northern end of the range of silver maple. They occur along medium to large rivers where topography and process have resulted in the development of a complex of upland and wetland temperate alluvial vegetation on generally flat topography. This complex includes floodplain forests, with *Acer saccharinum* characteristic, as well as herbaceous sloughs and shrub wetlands. In areas subject to more scour, sparse non-wetland vegetation may develop on sandbars or exposed rock. Most areas are underwater each spring; microtopography determines how long the various habitats are inundated. Associated trees include *Acer rubrum* and *Carpinus caroliniana*, the latter frequent but never abundant. On terraces or in more calcareous areas, *Acer saccharum* or *Quercus rubra* may be locally prominent, with *Betula alleghaniensis* and *Fraxinus* spp. *Salix nigra* is characteristic of the levees adjacent to the channel. Common shrubs include *Cornus amomum* and *Viburnum* spp. The herb layer in the forested portions often features abundant spring ephemerals, giving way to a fern-dominated understory in many areas by mid-summer. Non-forested wetlands associated with these systems include shrub-dominated and graminoid-herbaceous vegetation.
Classification Comments: These floodplains are similar to those to the south in the Central Interior, North-Central Interior Floodplain (CES202.694) and Appalachian Division, Central Appalachian River Floodplain (CES202.608) in having *Acer saccharinum* as a characteristic species; however, they are generally more depauperate and lack certain tree species that characterize central Appalachian floodplains such as *Platanus occidentalis*, *Betula nigra*, and *Quercus palustris*. This system can include areas of scour along sandbars or rivershore rock outcrops as well as the more typical floodplain vegetation.
Similar Ecological Systems:
- Central Appalachian River Floodplain (CES202.608)
- North-Central Interior Floodplain (CES202.694)

MEDITERRANEAN CALIFORNIA FOOTHILL AND LOWER MONTANE RIPARIAN WOODLAND AND SHRUBLAND (CES206.944)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Riparian Mosaic; Forest and Woodland (Treed); Mediterranean [Mediterranean Xeric-Oceanic]; Riverine / Alluvial; Very Short Disturbance Interval; Flood Scouring
Non-Diagnostic Classifiers: Short (<5 yrs) Flooding Interval; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Shallow Soil; Aquic; Udic; Broad-Leaved Deciduous Tree
National Mapping Codes: ESLF 9330

CONCEPT

Summary: This system is found throughout Mediterranean California within a broad elevation range from near sea level up to 300 m (900 feet) in the Coast Ranges and inland to 1500 m (4545 feet). This system often occurs as a mosaic of multiple communities that are tree-dominated with a diverse shrub component and open shrublands. This system includes open channels and bare alluvial bars as well. The variety of plant associations connected to this system reflects elevation, stream gradient, floodplain width, and flooding events. Dominant trees may include *Alnus rhombifolia*, *Acer negundo*, *Alnus rubra* (in Coast Ranges), *Populus fremontii*, *Salix laevigata*, *Salix gooddingii*, *Pseudotsuga menziesii*, *Platanus racemosa*, *Quercus agrifolia*, and *Acer macrophyllum* (in central and south coast). Dominant shrubs include *Salix exigua* and *Salix lasiolepis*. Exotic trees *Ailanthus altissima*, *Eucalyptus* spp., and herbs such as *Arundo donax* occur. These are disturbance-driven systems that require flooding, scour and deposition for germination and maintenance.
Classification Comments: It is unclear if riparian woodlands and shrublands occur in the upper montane and subalpine regions of the Sierras and possibly the Transverse Ranges, and if they do, if they are significantly different in composition to be distinguished as an ecological system. Some literature indicates that, if they do occur, the woodlands at least are not at all common. For now, there is no "subalpine-upper montane Sierran riparian" system described. Lower elevation (low montane and foothill) riparian systems on the east side of the Sierras are treated in Great Basin Foothill and Lower Montane Riparian Woodland and Shrubland (CES304.045).

MEDITERRANEAN CALIFORNIA SERPENTINE FOOTHILL AND LOWER MONTANE RIPARIAN WOODLAND AND SEEP (CES206.945)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Intermittent Flooding; Short (<5 yrs) Flooding Interval; Serpentine; Mediterranean [Mediterranean Xeric-Oceanic]; Seepage-Fed Sloping; Riverine / Alluvial; Cupressus sargentii
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Toeslope/Valley Bottom; Aquic; Very Short Disturbance Interval; Flood Scouring
National Mapping Codes: ESLF 9325

CONCEPT

Summary: This ecological system is found mostly in the central and inner northern Coast Ranges of California and Sierra Nevada foothills. It includes springs, seeps, and perennial and intermittent streams in serpentine substrates (true serpentinite but also other related substrates). Characteristic species include *Salix breweri, Cupressus sargentii, Frangula californica ssp. tomentella (= Rhamnus tomentella), Umbellularia californica, Cirsium fontinale, Stachys albens, Solidago* spp., *Packera clevelandii (= Senecio clevelandii), Mimulus glaucescens, Mimulus guttatus, Aquilegia eximia*, and *Carex serratodens*. Riparian portions of this system are disturbance-driven and require limited flooding, scour and deposition for germination and maintenance.
Related Concepts:
- Port Orford-Cedar: 231 (Eyre 1980) Intersecting
- Riparian Woodland (203) (Shiflet 1994) Broader. Serpentine substrates are not specifically mentioned in Shiflet (1994) for this type, but they are likely included in SRM concept.

DESCRIPTION

Environment: This system is found in creek bottoms and stream terraces with serpentine-derived alluvium. Elevations range from 300-3000 m. Soils are saturated to moist throughout the growing season (Sawyer et al. 2009).
Dynamics: Steady groundwater flow and fire primarily disturb stands of this ecosystem. Plants resprout after flooding disturbance. Most serpentine riparian areas have moderate rather than large flooding events, and most serpentine riparian has low perennial flows not subject to vacillating events as non-serpentine areas. Serpentine riparian are less likely to be susceptible to drought and drying since the serpentine geology tends to release water slowly over time (T. Keeler-Wolf pers. comm. 2013). *Frangula californica* resprouts vigorously after fire (Sawyer et al. 2009). However, it is not known how often fires historically occurred in *Frangula californica*-dominated systems. Fire is less of a disturbance issue in willow-dominated systems, but fire does occur, and *Salix* generally resprouts after fires (Stromberg and Rychener 2010). Fires probably occur relatively frequently even though serpentine chaparral surrounding the riparian has lower fuels than typical non-serpentine chaparral (T. Keeler-Wolf pers. comm. 2013).

Component Associations:
- *Chamaecyparis lawsoniana / Rhododendron occidentale / Carex* spp. Temporarily Flooded Forest (CEGL000047, G2)

DISTRIBUTION

Range: This system occurs in the central and inner northern Coast Ranges of California and Oregon and Sierra Nevada foothills.

NORTH-CENTRAL INTERIOR FLOODPLAIN (CES202.694)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Floodplain; Forest and Woodland (Treed); Herbaceous; Glaciated; Clay Soil Texture; Sand Soil Texture; Udic
National Mapping Codes: ESLF 9338

CONCEPT

Summary: This system is found along rivers across the glaciated Midwest. It occurs from river's edge across the floodplain or to where it meets a wet meadow system. It can have a variety of soil types found within the floodplain from very well-drained sandy substrates to very dense clays. It is this variety of substrates and flooding that creates the mix of vegetation that includes *Acer saccharinum, Populus deltoides*, willows, especially *Salix nigra* in the wettest areas, and *Fraxinus pennsylvanica, Ulmus americana*, and *Quercus macrocarpa* in more well-drained areas. Within this system are oxbows that may support *Nelumbo lutea* and *Typha latifolia*. Understory species are mixed, but include shrubs, such as *Cornus drummondii* and *Asimina triloba* (in Kansas), sedges and grasses, which sometimes help form savanna vegetation. Flooding is the primary dynamic process, but drought, grazing, and fire have all had historical influence on this system. Federal reservoirs have had a serious and negative effect on this system, along with agriculture that has converted much of this system to drained agricultural land.
Classification Comments: The distribution limit northward is considered to be the Laurentian region boundary. This system is distinguished from floodplain systems northeastward, Laurentian-Acadian Floodplain Forest (CES201.587), and eastward, Central Appalachian River Floodplain (CES202.608). *Celtis* and *Populus deltoides* are absent (or essentially so) from the Laurentian-Acadian type.
Similar Ecological Systems:
- Central Appalachian River Floodplain (CES202.608)
- Laurentian-Acadian Floodplain Forest (CES201.587)

DESCRIPTION

Environment: This ecological system occurs in floodplains of medium to large rivers. It is found on alluvial soils ranging from sandy to very dense clays. Soil texture reflects the upstream substrate through which the river and its tributaries flow and water velocity. Sandy sediments can be carried by faster-flowing water, while slow-moving rivers can only carry fine-textured sediment. Water velocity and volume change greatly during the year as rains and snowmelt deliver pulses of water and seasonal droughts (typically including winter in the northern portion of this system's range when most precipitation is frozen) result in low water. Within a short distance on a river floodplain, different soil textures can be found. Coarser-textured soils are typically adjacent to the main channel where they are deposited first by rising or falling floodwaters. Finer-textured soils are further away from the main channel, deposited when floodwaters have spread out and slowed down. Within the space of a few years, floods of differing magnitude can deposit sand over silt or vice versa, resulting in complex soil topology.
Vegetation: The variety of soil properties associated with this system can create a mixture of vegetation. *Acer saccharinum* occurs on the wetter soils of floodplains in the eastern portion of this system, with *Populus deltoides* and willows, especially *Salix nigra*, occurring more in the western range of this system. *Fraxinus pennsylvanica, Ulmus americana*, and *Quercus macrocarpa* occur in more well-drained areas. Understory species can vary across the range of this system but can include shrubs such as *Cornus drummondii* and *Asimina triloba*, and sedge and grass species. Oxbows within this system may have species such as *Nelumbo lutea* and *Typha latifolia*.
Dynamics: This system is primarily controlled by moderate to frequent flooding. Flood frequency depends on precipitation patterns within the watershed and proximity to the main channel. Areas adjacent to the main channel or low islands within the channel can be flooded every year or even more than once per year. Those areas further from the channel on terraces or behind natural levees may only be flooded once every several years. Free-flowing rivers migrate across their floodplain, cutting new channels or eroding the bank on one side while building up the bank on the other, so the flooding regime of any one point in the floodplain will change over time. Flooding redeposits alluvium, eroding some areas and aggrading others, can bury or wash away small plants, and redistributes

nutrients, especially in less frequently flooded zones where silt and clay tend to be deposited. These processes open up new areas for colonization. Where trees can grow (i.e., not in permanent or semi-permanent backwater wetlands), there is a common succession sequence of annual herbaceous species followed by shrub *Salix* spp., followed by *Populus deltoides, Salix nigra*, and *Acer saccharinum*, followed by a number of trees, including *Acer negundo, Carya illinoinensis, Celtis laevigata, Celtis occidentalis, Fraxinus pennsylvanica, Quercus macrocarpa*, and *Ulmus americana*. This sequence can be reset by major floods and erosion/deposition. Frequent minor to moderate flooding holds the system at the intermediate forest stage, and large areas of this floodplain system are dominated by *Populus deltoides, Salix nigra*, and *Acer saccharinum*.

Fire could impact parts of this system. Most of the forests in this system were not fire-prone due to the lack of litter, frequent flooding, and relatively protected landscape position in the river valley with wetlands often near, but forests on higher, coarser soils or wet-mesic prairies on the margins of the floodplain could become dry in late summer and burn, if an ignition source was present (Weaver 1960).

Component Associations:
- *Acer saccharinum - Celtis laevigata - Carya illinoinensis* Forest (CEGL002431, G3G4)

- *Schoenoplectus tabernaemontani - Typha* spp. - (*Sparganium* spp., *Juncus* spp.) Herbaceous Vegetation (CEGL002026, G4G5)
- *Typha* spp. Midwest Herbaceous Vegetation (CEGL002233, G5)

DISTRIBUTION

Range: This system is found along medium and large river floodplains throughout the glaciated Midwest ranging from eastern Kansas and western Missouri to western Ohio and north along the Red River basin in Minnesota and the eastern Dakotas. This system is essentially restricted to USFS Provinces 251 and 222, though it may go further west in larger rivers in the Great Plains, notably the Missouri and Platte rivers.

NORTHERN ATLANTIC COASTAL PLAIN CALCAREOUS RAVINE (CES203.069)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Ravine; Slope; Seepage-Fed Sloping; Calcareous
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: ESLF 4156

CONCEPT

Summary: This system occurs on dry to mesic slopes and saturated bottoms of dissected ravine systems in the northern Atlantic Coastal Plain where erosion has exposed Tertiary-aged shell deposits, limesands, or aboriginal shell middens. These calcium-bearing sediments produce soils that range from slightly acidic to circumneutral and moderately to very strongly calcareous. The fertile soils support a rich diversity of plant species that distinguishes this system from the more widespread dry-mesic, acidic (poor) ravines. This system includes mostly deciduous upland forests and woodlands on slopes and low interfluves and forested seepage wetlands found in saturated stream valley bottoms. Species composition varies with the environmental setting , but all habitats are characterized by species indicative of high base status soils. The communities of this system often contain species that are disjunct from their primary ranges in the mountains or Piedmont, such as Erigeron pulchellus, *Actaea pachypoda, Caltha palustris, Pedicularis lanceolata, Solidago flexicaulis, Quercus muehlenbergii, Verbesina virginica var. virginica, Hexalectris spicata, Corallorhiza wisteriana, Campanulastrum americanum, Celastrus scandens, Muhlenbergia sobolifera, Muhlenbergia tenuiflora, Sanicula marilandica*, and *Thalictrum revolutum*.

Related Concepts:

DESCRIPTION

Environment: This system occurs on dry to mesic slopes and saturated bottoms of dissected ravine systems in the northern Atlantic Coastal Plain where erosion has exposed Tertiary-aged shell deposits, limesands or aboriginal shell middens that have been exposed by downcutting streams or on river fronting bluffs along the northern Atlantic Coastal Plain of Virginia, Maryland, Delaware and New Jersey. It includes mesic and dry uplands and groundwater-saturated wetlands associated with these fertile, base-rich soils. Occurrences are typically linear or small patch and uncommon.

Vegetation: Forests of mesic slopes and low interfluves are characterized by *Fagus grandifolia, Liriodendron tulipifera, Quercus alba, Carya cordiformis*, and *Quercus rubra* in the overstory. Other canopy dominants and associates may include *Quercus muehlenbergii, Fraxinus americana, Tilia americana*, and *Acer barbatum*. The understory is often dense and may include *Asimina triloba, Lindera benzoin, Viburnum prunifolium, Ulmus rubra, Ilex opaca, Magnolia tripetala*, and *Cercis canadensis var. canadensis*. The ground cover is lush though sometimes patchy and may include *Podophyllum peltatum, Arisaema triphyllum, Sanguinaria canadensis, Circaea lutetiana ssp. canadensis, Maianthemum racemosum ssp. racemosum, Cardamine concatenata*, and *Polystichum acrostichoides*. More locally abundant herbs include *Cystopteris protrusa, Deparia acrostichoides, Diplazium pycnocarpon, Actaea racemosa (= Cimicifuga racemosa), Phegopteris hexagonoptera, Nemophila aphylla*, and *Actaea pachypoda*.

Drier, more southerly facing convex slopes are characterized by a more open canopy of *Quercus muehlenbergii*; common associates may include *Acer barbatum, Carya cordiformis, Fagus grandifolia, Fraxinus americana, Quercus alba, Quercus rubra*, and *Quercus prinus*. The understory may include *Juniperus virginiana var. virginiana, Cercis canadensis var. canadensis, Dirca palustris, Ilex opaca var. opaca, Sideroxylon lycioides*, and *Viburnum rufidulum*. The herb layer is usually patchy but contains a diversity of species, including *Aquilegia canadensis, Erigeron pulchellus var. pulchellus, Bromus pubescens, Dichanthelium boscii, Verbesina virginica var. virginica, Campanulastrum americanum, Smallanthus uvedalius, Silphium trifoliatum var. trifoliatum, Desmodium pauciflorum, Hexalectris spicata*, and *Piptochaetium avenaceum*.

Forested seepage wetlands are often found along stream bottoms and at the base of slopes. Braided streams and hummock-and-hollow microtopography are characteristic of the environmental setting. The tree canopy is characterized by *Fraxinus pennsylvanica, Acer rubrum, Liquidambar styraciflua, Nyssa biflora*, and others. The shrub layer is comprised of *Lindera benzoin, Morella cerifera (= Myrica cerifera)*, and *Cornus foemina*. Vines are abundant, especially *Decumaria barbara*. The herbaceous layer is characterized by *Caltha palustris, Carex bromoides, Packera aurea (= Senecio aureus), Scirpus lineatus, Thelypteris palustris, Pedicularis lanceolata, Carex tetanica, Liparis loeselii*, and *Carex granularis* on drier hummocks, and *Saururus cernuus, Bidens laevis, Pilea fontana, Glyceria striata*, and *Impatiens capensis* in wetter hollows and seepage rivulets.

Dynamics: Natural erosion of steep bluffs exposed by downcutting streams.

Component Associations:
- *Acer rubrum - Fraxinus pennsylvanica / Packera aurea - Carex bromoides - Pilea fontana - Bidens laevis* Forest (CEGL006413, G2)

- *Fagus grandifolia - Acer barbatum - Quercus muehlenbergii / Sanguinaria canadensis* Forest (CEGL007181, G2?)
- *Fagus grandifolia - Liriodendron tulipifera - Carya cordiformis / Lindera benzoin / Podophyllum peltatum* Forest (CEGL006055, G4?)
- *Quercus muehlenbergii / Cercis canadensis / Dichanthelium boscii - Bromus pubescens - Erigeron pulchellus var. pulchellus - Aquilegia canadensis* Forest (CEGL007748, G1)

SPATIAL CHARACTERISTICS

Spatial Summary: Small, linear patch.

DISTRIBUTION

Range: This system is known from the northern Atlantic Coastal Plain of Virginia and Maryland, possibly ranging north into Delaware and New Jersey.

NORTHERN ATLANTIC COASTAL PLAIN DUNE AND SWALE (CES203.264)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch, Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: North Atlantic Coastal Plain; Beach (Substrate); Graminoid; Coast
Non-Diagnostic Classifiers: Herbaceous; Depressional; Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2436; ESLF 7149; ESP 1436

CONCEPT

Summary: This system consists of vegetation of barrier islands and other coastal areas, ranging from northernmost North Carolina northward to southern Maine (where extensive sandy coastlines are replaced by rocky coasts). A range of plant communities may be present, but natural vegetation is predominately herbaceous, with *Ammophila breviligulata* diagnostic. Shrublands resulting from succession from grasslands may occur in limited areas. Both dune uplands and non-flooded wetland vegetation of interdunal swales are included in this system. In the northern portion of the range, these swales are often characterized by *Vaccinium macrocarpon*, while south of New Jersey, swales are characterized by a variety of graminoids and forbs, usually including *Schoenoplectus pungens*, *Fimbristylis castanea*, *Fimbristylis caroliniana*, *Juncus* spp. and others. Small patches of natural woodland may also be present in limited areas, especially in the northern range of this system. Dominant ecological processes are those associated with the maritime environment, including frequent salt spray, saltwater overwash, and sand movement.
Classification Comments: This system was separated from Southern Atlantic Coastal Plain Dune and Maritime Grassland (CES203.273) to parallel broad-scale biogeographic and climatic differences believed to be important in this environment. This system occupies the northern part of this broad transition which was labeled by Cowardin et al. (1979) as the Virginian Province, although the demarcated boundary differs somewhat from that used here. A useful vegetation indicator of this transition is the shift in herbaceous dominance on the dunes from *Uniola paniculata* in the south to *Ammophila breviligulata* in the north. Although the location of this shift itself is somewhat imprecise because of widespread planting of both species on artificially enhanced dunes, this boundary appears to be well approximated by Omernik Ecoregion 63g vs. 63d (EPA 2004). There is extensive south-to-north turnover of associations in TNC Ecoregion 58 with very little overlap southward. *Quercus virginiana* is only occasional in this system at its extreme southern end (southern Virginia) and should not be thought of as characteristic.

This system is distinguished from Northern Atlantic Coastal Plain Maritime Forest (CES203.302) by the lack of dominant woody vegetation. This distinction becomes blurred where dunes have been artificially enhanced and an unnatural succession to woody vegetation is occurring. The boundary at the northern end is the end of extensive sandy coastlines and the beginning of rocky coasts.

Southeastern Coastal Plain Interdunal Wetland (CES203.258) may occur with this system in northern North Carolina and southern Virginia. Where the ranges overlap, Southeastern Coastal Plain Interdunal Wetland (CES203.258) is distinguished from this system by the presence of standing water for a significant part of the growing season. This corresponds to a break between open-water and tall-graminoid marsh vegetation in the ponds and low-graminoid- or forb-dominated vegetation in the grasslands. North of Virginia, interdunal wetlands are smaller and more integrated into the dune systems and are included in this system.
Similar Ecological Systems:
- Northern Atlantic Coastal Plain Heathland and Grassland (CES203.895)
- Northern Atlantic Coastal Plain Maritime Forest (CES203.302)
- Northern Atlantic Coastal Plain Sandy Beach (CES203.301)--occurs between this system and the high tide line.
- Southeastern Coastal Plain Interdunal Wetland (CES203.258)
- Southern Atlantic Coastal Plain Dune and Maritime Grassland (CES203.273)--occurs to the south.

DESCRIPTION

Environment: This system occurs on coastal strands and barrier islands, on sand dunes and sand flats. Strong salt spray is an important influence on vegetation in many parts. Overwash by sea water during storms is important on sand flats not protected by continuous dunes. On dunes, present or recent sand movement is an important factor. The combination of these factors prevents the dominance of woody vegetation. Sites may be either dry or saturated by freshwater from rainfall and the local water table. Areas connected to tidal influence are placed in other systems. Soils are sandy, with little organic matter and little or no horizon development. Soils may be excessively drained on the higher dunes. Soils are low in nutrient-holding capacity, but aerosol input of sea salt provides a continuous source of nutrients.

Vegetation: Vegetation consists of a set of grassland and herbaceous to shrubby associations. *Ammophila breviligulata* is the characteristic dominant on the youngest dunes and those most exposed to salt spray. Shrublands resulting from succession from grasslands may occur in limited areas, but they are generally not natural components of this system in the southern part of its range (M. Schafale pers. comm.). These communities tend to be low in plant species richness but have a characteristic set of forbs and occasional low shrubs associated with them. Wetter sand flats and dune swales may be dominated by a variety of herbs and sometimes have fairly high species richness.
Dynamics: The environment of this system is one of the most dynamic in existence for terrestrial vegetation. Reworking of sand by storms or by slower eolian processes may completely change the local environment in a short time, changing one association to another. Many of these sites are fairly early in the process of primary succession on recent surfaces. Chronic salt spray is an ongoing stress. Overwash and extreme salt spray in storms are frequent disturbances. Vegetation interacts strongly with geologic processes; the presence of grass is an important factor in the development of new dunes. Alteration of dynamic processes, such as artificial enhancement of dunes by planting or sand fencing, can have drastic effects on this system, causing large areas to succeed to woody vegetation. Fire is probably not a major natural factor in this system, but may have been important locally. Most vegetation is too sparse to carry fire well.

Component Associations:
- (*Morella cerifera*) / *Panicum virgatum - Spartina patens* Herbaceous Vegetation (CEGL004129, G2G4)
- *(Morella pensylvanica) / Schizachyrium littorale - Aristida tuberculosa* Shrub Herbaceous Vegetation (CEGL006161, GNR)

- *Salix nigra* Seasonally Flooded Forest (CEGL006348, G2G3)
- *Schoenoplectus pungens - Fimbristylis (castanea, caroliniana)* Herbaceous Vegetation (CEGL004117, G1G2)
- *Schoenoplectus pungens var. pungens - Juncus canadensis* Herbaceous Vegetation (CEGL006935, GNR)
- *Smilax glauca - Toxicodendron radicans* Vine-Shrubland (CEGL003886, G1G2)
- *Spartina patens - Eleocharis parvula* Herbaceous Vegetation (CEGL006342, G2G4)
- *Spartina patens - Schoenoplectus pungens - Solidago sempervirens* Herbaceous Vegetation (CEGL004097, G2G3)
- *Spartina patens - Thinopyrum pycnanthum* Herbaceous Vegetation (CEGL006149, GNR)
- *Vaccinium corymbosum - Rhododendron viscosum - Clethra alnifolia* Shrubland (CEGL006371, G3)
- *Vitis rotundifolia / Triplasis purpurea - Panicum amarum - Schizachyrium littorale* Mid-Atlantic Coastal MedaÃ±o Sparse Vegetation (CEGL004397, G1)

SPATIAL CHARACTERISTICS

Spatial Summary: Occurs as a large-patch or linear system.
Size: Occurs in narrow to broad bands, extending along the length of coastal shores and barrier islands. Individual patches may cover a thousand or more acres. However, some of the best remnants are naturally small.
Adjacent Ecological Systems:
- Northern Atlantic Coastal Plain Heathland and Grassland (CES203.895)
- Northern Atlantic Coastal Plain Maritime Forest (CES203.302)
- Northern Atlantic Coastal Plain Sandy Beach (CES203.301)

DISTRIBUTION

Range: This system ranges from northernmost North Carolina (EPA ecoregion 63d) and southeastern Virginia to southern Maine. The southern portion is a transition zone from around Kitty Hawk, North Carolina, to the Virginia-North Carolina border. The

northern limit is Merrymeeting Bay, Maine.

NORTHERN ATLANTIC COASTAL PLAIN RIVERINE PEAT SWAMP (CES203.070)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Riverine / Alluvial
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Stream terrace (undifferentiated)
FGDC Crosswalk: Vegetated, Tree-dominated, Closed tree canopy, Deciduous closed tree canopy
National Mapping Codes: ESLF 4157

CONCEPT

Summary: This ecological system is found throughout the northern Atlantic Coastal Plain, ranging from Virginia to New Jersey. Examples occur along low-gradient streams and rivers. Floodplain development varies from little to moderate according to stream size. This system is influenced by overbank flooding, groundwater seepage and occasional beaver impoundments. The vegetation is a mosaic of forests, woodlands, shrublands, and herbaceous communities. Canopy composition and cover can vary within and among examples of this system, but typical tree species may include *Quercus palustris, Quercus phellos, Chamaecyparis thyoides, Acer rubrum, Fraxinus pennsylvanica, Nyssa sylvatica, Betula nigra, Liquidambar styraciflua*, and *Platanus occidentalis*. Shrubs and herbaceous layers can vary in richness and cover. Some characteristic shrubs may include *Alnus maritima, Carpinus caroliniana, Lindera benzoin*, and *Viburnum nudum*. Seepage forests dominated by *Acer rubrum* and *Magnolia virginiana* can often be found within this system, especially at the headwaters and terraces of streams.
Classification Comments: New Jersey's Pine Barrens riverside savannas, not covered in other ecological systems, fit this concept and are explicitly included, pending further review.
Similar Ecological Systems:
- Atlantic Coastal Plain Blackwater Stream Floodplain Forest (CES203.247)
- Atlantic Coastal Plain Brownwater Stream Floodplain Forest (CES203.248)
- Atlantic Coastal Plain Small Blackwater River Floodplain Forest (CES203.249)
- Atlantic Coastal Plain Small Brownwater River Floodplain Forest (CES203.250)
- Southern Atlantic Coastal Plain Large River Floodplain Forest (CES203.066)

Related Concepts:
- Atlantic White-Cedar: 97 (Eyre 1980) Finer
- River Birch - Sycamore: 61 (Eyre 1980) Finer
- Sycamore - Sweetgum - American Elm: 94 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on Coastal Plain flood terraces of streams and rivers, and is also influenced by groundwater seepage. In New Jersey, this system occurs in the Pine Barrens matrix.
Dynamics: This system is hydrologically influenced primarily by groundwater seepage, but is also subjected to periodic overbank flooding. The system is maintained by a natural disturbance regime of flooding and periodic fires of varied intensity. High-intensity fires may consume peat and limit re-establishment of Atlantic white-cedar.

Component Associations:
- *Acer negundo* Forest (CEGL005033, G4G5)

NORTHERN ROCKY MOUNTAIN AVALANCHE CHUTE SHRUBLAND (CES306.801)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Avalanche chute; Very Short Disturbance Interval [Periodicity/Nonrandom Disturbance]; Avalanche
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Temperate [Temperate Continental]; Seepage-Fed Sloping [Mineral]; Forb
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Deciduous shrubland
National Mapping Codes: EVT 2168; ESLF 5327; ESP 1168

CONCEPT

Summary: This ecological system occurs in the mountains throughout the northern Rockies, from Wyoming north and west into British Columbia and Alberta. It is composed of a diverse mix of deciduous shrubs or trees, and conifers found on steep, frequently disturbed slopes in the mountains. Occurrences are found on the lower portions and runout zones of avalanche tracks, and slopes are generally steep, ranging from 15-60%. Aspects vary, but are more common where unstable or heavy snowpack conditions frequently occur. Sites are often mesic to wet because avalanche paths are often in stream gullies, and snow deposition can be heavy in the run-out zones. The vegetation consists of moderately dense, woody canopy characterized by dwarfed and damaged conifers and small, deciduous trees/shrubs. Characteristic species include *Abies lasiocarpa*, *Acer glabrum*, *Alnus viridis ssp. sinuata* or *Alnus incana*, *Populus balsamifera ssp. trichocarpa*, *Populus tremuloides*, or *Cornus sericea*. Other common woody plants include *Paxistima myrsinites*, *Sorbus scopulina*, and *Sorbus sitchensis*. The ground cover is moderately dense to dense forb-rich, with *Senecio triangularis*, *Castilleja* spp., *Athyrium filix-femina*, *Thalictrum occidentale*, *Urtica dioica*, *Erythronium grandiflorum*, *Myosotis asiatica (= Myosotis alpestris)*, *Veratrum viride*, *Heracleum maximum (= Heracleum lanatum)*, and *Xerophyllum tenax*. Mosses and ferns are often present.

Component Associations:
- *Abies lasiocarpa* - *Acer glabrum* Avalanche Chute Shrubland (CEGL000984, G5)
- *Acer glabrum* Avalanche Chute Shrubland (CEGL001061, G5)
- *Alnus* spp. Avalanche Chute Shrubland (CEGL001158, G5)
- *Alnus viridis ssp. sinuata / Athyrium filix-femina* - *Cinna latifolia* Shrubland (CEGL001156, G4)
- *Alnus viridis ssp. sinuata* / Mesic Forbs Shrubland (CEGL002633, G3G4)
- *Populus balsamifera ssp. trichocarpa / Cornus sericea* Forest (CEGL000672, G3G4)
- *Populus tremuloides / Amelanchier alnifolia* Avalanche Chute Shrubland (CEGL005886, G3?)
- *Populus tremuloides / Cornus sericea* Forest (CEGL000582, G4)

DISTRIBUTION

Range: This ecological system occurs in the mountains throughout the northern Rockies, from Wyoming north and west into British Columbia and Alberta. It is likely to occur in the Colorado Rockies, but no association from that area have been classified as "avalanche chute" communities.

NORTHWESTERN GREAT PLAINS ASPEN FOREST AND PARKLAND (CES303.681)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Woody-Herbaceous; Boreal; Glaciated
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2009; ESLF 4146; ESP 1009

CONCEPT

Summary: This system ranges from the North Dakota/Manitoba border west to central Alberta and is considered part of the boreal-mixedgrass prairie grassland transition region. The climate in this region is mostly subhumid low boreal with short, warm summers and cold, long winters. Much of this region is covered with undulating to kettled glacial till. *Populus tremuloides* dominates this system. Common associates are *Betula papyrifera* and *Populus balsamifera* with an understory of mixedgrass species and tall shrubs. More poorly drained sites may contain willow (*Salix* spp.) and sedges (*Carex* spp.). Fire constitutes the most important dynamic in this system and prevents boreal conifer species such as *Picea glauca* and *Abies balsamea* from becoming too established in this system.
Classification Comments: This system can grade into Eastern Great Plains Tallgrass Aspen Parkland (CES205.688) to the east, which has a predominance of tallgrass species in the understory compared to the more mixedgrass species in this system. More data from Canada are needed to fully describe this system. In spring 2006, it was determined by Steve Cooper, Marion Reid and Gwen Kittel that this system does not occur in north-central Montana, mapzone 20. However, it does occur along the lower-elevation slopes of the Montana Front Range, in mapzone 19.
Similar Ecological Systems:
- Eastern Great Plains Tallgrass Aspen Parkland (CES205.688)
- Rocky Mountain Aspen Forest and Woodland (CES306.813)

Related Concepts:
- Aspen: 16 (Eyre 1980) Finer
- Aspen: 217 (Eyre 1980) Broader
- Fescue Grassland (613) (Shiflet 1994) Intersecting. *Festuca campestris* grasslands occur as small inclusions in this ecological system.
- Paper Birch: 18 (Eyre 1980) Finer

DESCRIPTION

Environment: Climate in the range of this system is mostly subhumid low boreal with short, warm summers and long, cold winters. Undulating to kettled glacial till predominates this region.
Vegetation: *Populus tremuloides* dominates this system. Common associates are *Populus balsamifera* and *Betula papyrifera* along with an understory of mixedgrass and tall-shrub species.
Dynamics: Fire is likely the most important natural dynamic allowing for a more open structure and preventing this system from containing more conifer species.

Component Associations:
- *Betula papyrifera / Corylus cornuta* Forest (CEGL002079, G2G3)
- *Betula papyrifera / Corylus cornuta* Woodland (CEGL002128, G2G3)
- *Festuca altaica - (Hesperostipa* spp., *Achnatherum* spp.) Herbaceous Vegetation (CEGL002436, GNR)
- *Festuca campestris - Pseudoroegneria spicata* Herbaceous Vegetation (CEGL001629, G4)
- *Populus tremuloides - Populus balsamifera / Calamagrostis canadensis - Spartina pectinata* Forest (CEGL002097, G3G4)
- *Populus tremuloides / Calamagrostis rubescens* Forest (CEGL000575, G5?)
- *Populus tremuloides / Prunus virginiana* Woodland (CEGL002130, G4G5)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Eastern Great Plains Tallgrass Aspen Parkland (CES205.688)

Adjacent Ecological System Comments: This system can grade into Eastern Great Plains Tallgrass Aspen Parkland (CES205.688) to the east.

DISTRIBUTION

Range: This system is found in the boreal-grassland transition region from the North Dakota/Manitoba border west to central Alberta. and south along the eastern slopes of the Front Range of Montana, where it occurs below lower treeline.
Divisions: 205:C; 303:C

NORTHWESTERN GREAT PLAINS RIPARIAN (CES303.677)

CLASSIFIERS

Conf.: 3 - Weak
Classification Status: Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 9326

CONCEPT

Summary: This system is found in the riparian areas of medium and small rivers and streams throughout the northwestern Great Plains. It is likely most common in the Northern Great Plains Steppe. This system occurs in the Upper Missouri and tributaries starting at the Niobrara, White, Cheyenne, Belle Fourche, Moreau, Grand, Heart, Little Missouri, Yellowstone, Powder, Tongue, Bighorn, Wind, Milk, Musselshell, Marias, and Teton rivers; and in Canada, the Southern Saskatchewan, Red Deer and Old Man rivers to where they extend into Rocky Mountain Lower Montane-Foothill Riparian Woodland and Shrubland (CES306.821) or Northern Rocky Mountain Lower Montane Riparian Woodland and Shrubland (CES306.804). These are found on alluvial soils in highly variable landscape settings, from deep cut ravines to wide, braided streambeds. Hydrologically, these tend to be more flashy with less developed floodplain than on larger rivers, and typically dry down completely for some portion of the year. Dominant vegetation shares much with generally drier portions of larger floodplain systems downstream, but overall abundance of vegetation is generally lower. Communities within this system range from riparian forests and shrublands to gravel/sand flats. Dominant species include *Populus deltoides*, *Populus balsamifera ssp. trichocarpa*, *Salix* spp., *Artemisia cana ssp. cana*, and *Pascopyrum smithii*. These areas are often subjected to heavy grazing and/or agriculture and can be heavily degraded. Another factor is that groundwater depletion and lack of fire have created additional species changes.
Classification Comments: This system needs to be more clearly delineated from Northwestern Great Plains Floodplain (CES303.676). The component plant association list is incomplete. All the riparian/floodplain/alluvial systems of the Great Plains region need to be revisited for naming conventions, along with better definitions of conceptual boundaries. There is much apparent overlap in their concepts and distribution, and the names add to the confusion. In particular, the difference between "riparian" and "floodplain" usage in the names needs revisiting and possible changing. These systems include Northwestern Great Plains Floodplain (CES303.676), Northwestern Great Plains Riparian (CES303.677), Western Great Plains Floodplain (CES303.678), and Western Great Plains Riparian (CES303.956).
Related Concepts:
- Northwestern Great Plains Riparian (Rolfsmeier and Steinauer 2010) Equivalent
- Sagebrush - Grass (612) (Shiflet 1994) Intersecting. Most *Artemisia cana ssp. cana* shrublands occur on stream terraces.

Component Associations:
- *Artemisia cana / Pascopyrum smithii* Shrubland (CEGL001072, G4)
- *Pascopyrum smithii - (Elymus trachycaulus)* Clay Pan Herbaceous Vegetation (CEGL002239, GNR)
- *Populus deltoides - Fraxinus pennsylvanica* Forest (CEGL000658, G2G3)
- *Populus deltoides / Cornus sericea* Forest (CEGL000657, G2G3)
- *Populus deltoides / Symphoricarpos occidentalis* Woodland (CEGL000660, G2G3)

DISTRIBUTION

Range: This system occurs throughout the northwestern Great Plains, north of the North Platte River basin in eastern Wyoming. It is found in eastern Wyoming and eastern Montana along the upper Missouri, Yellowstone, Powder, Tongue, Bighorn, Wind, Milk, Musselshell, Marias, and Teton rivers; in northern Nebraska and the Dakotas on the Niobrara, upper Missouri, White, Cheyenne, Belle Fourche, Moreau, Grand, Heart, Little Missouri rivers; and in Canada the Southern Saskatchewan, Red Deer and Old Man rivers.

OZARK-OUACHITA RIPARIAN (CES202.703)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Ozark/Ouachita
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Stream terrace (undifferentiated)
National Mapping Codes: ESLF 9337

CONCEPT

Summary: This system is found along streams and small rivers within the Ozark and Ouachita regions. In contrast to larger floodplain systems, this system has little to no floodplain development and often contains cobble bars and steep banks. It is higher gradient than larger floodplains and experiences periodic, strong flooding. It is often characterized by a cobble bar with forest immediately adjacent with little to no marsh development. Canopy cover can vary within examples of this system, but typical tree species include *Liquidambar styraciflua, Platanus occidentalis, Betula nigra, Acer* spp., and *Quercus* spp. The richness of the herbaceous layer can vary significantly, ranging from species-rich to species-poor. Likewise, the shrub layer can vary considerably, but typical species may include *Lindera benzoin, Alnus serrulata*, and *Hamamelis vernalis*. Small seeps and fens can often be found within this system, especially at the headwaters and terraces of streams. These areas are typically dominated by primarily wetland obligate species of sedges (*Carex* spp.), ferns (*Osmunda* spp.), and other herbaceous species such as *Impatiens capensis*. Flooding and scouring strongly influence this system and prevent the floodplain development found on larger rivers.
Classification Comments: A separate Ozark-Ouachita fen/seep system (CES202.052) has also been developed.
Similar Ecological Systems:
- South-Central Interior Small Stream and Riparian (CES202.706)

Related Concepts:
- River Birch - Sycamore: 61 (Eyre 1980) Finer
- Sugar Maple: 27 (Eyre 1980) Finer

DESCRIPTION

Environment: This system has little to no floodplain development and often contains cobble bars and steep banks. It is often characterized by a cobble bar with forest immediately adjacent with little to no marsh development. Because these habitats are moister than adjacent uplands, the streamside zones have much higher plant and animal diversity. Orchids and many other species of mesic habitats can be found here. At the larger end of the size continuum, these streams can have gravel and even sand bottoms that support a range of species, including *Salix* spp., *Justicia americana*, and others. Pools provide refugia for invertebrate and vertebrate species that can then rapidly recolonize the stream during high water.
Vegetation: Typical tree species in examples of this system include *Liquidambar styraciflua, Platanus occidentalis, Betula nigra*, maples (*Acer* spp.), and oaks (*Quercus* spp.). The richness of the herbaceous layer can vary significantly, ranging from species-rich to species-poor. Likewise, the shrub layer can vary considerably, but typical species may include *Lindera benzoin, Alnus serrulata*, and *Hamamelis vernalis*.
Dynamics: Flooding and scouring strongly influence this system and prevent the floodplain development found on larger rivers. It is traditionally higher gradient than larger floodplains and experiences periodic strong flooding. The distinctive dynamics of stream flooding are presumably the primary reason for the distinctive vegetation of this system, though not all of the factors are well known. Small rivers and streams, with small watersheds, have more variable flooding regimes that larger rivers. Floods tend to be of short duration and unpredictably variable as to season and depth. In addition to disturbance, floods bring nutrient input, deposit sediment, and disperse plant seeds. Fire does not appear to be a dominant factor, and most floodplain vegetation is not very flammable. Historical references to canebrakes dominated by *Arundinaria gigantea* suggest that fire may have once been more possible and more important in at least some portions.

Flooding is the major process affecting the vegetation, with the substrate more rapidly drained than in flat floodplain areas. The higher gradients of most of these streams and rivers limit floods to fairly short duration. Flooding is most common in the winter, but may occur in other seasons particularly in association with hurricanes, tornados, or microbursts from thunderstorms. Flood waters may have significant energy in higher gradient systems, but scouring and reworking of sediment are important in maintaining the small non-forested patches of the bar and bank communities. Flooding can act as a replacement disturbance in areas where beavers impounded a channel or in rare years with severe prolonged flood events. There are two general types of floods: occasional catastrophic, prolonged floods (due to beaver activity or other severe event); and more frequent repeated minor flooding (i.e., several minor floods within a 10-year period).

The wind disturbance associated with flooding is very significant along small streams because of wet and less dense soils and shallow-rooted trees. Canopy tree mortality from more common windstorms would have resulted in tree-by-tree or small group replacement. Windthrow is the primary cause of mortality in bottomlands. Major storms or hurricanes occurring at approximately 20 year intervals would have impacted whole stands.

In this system, the fire-return interval varies greatly. Except in canebrakes, most fires were very light surface fires, creeping in hardwood or pine litter with some thin, patchy cover of bottomland grasses. Flame lengths were mostly 15-30 cm (6-12 inches). Fire-scarred trees can be found in most small stream sites except in the wettest microsites. Stand-replacement fires are almost unknown in this type. Except where Native American burning was involved, fires likely occurred primarily during drought conditions and then often only when fire spread into bottomlands from more pyrophytic uplands. Trees may be partially girdled by fire in duff, followed by bark sloughing. While fire rarely killed the tree, this allowed entry of rot, which, in the moist environment, often resulted in hollow trees, providing nesting and denning habitat for many species of birds and animals. Surface fires occurred on a frequency ranging from about 3-8 years in streamside canebrake, streamside hardwood/canebrake, or pine, to 25 years or more in hardwood litter. Low areas having a long hydroperiod, islands, and areas protected from fire by back swamps and oxbows were virtually fire-free. Fire effects were largely limited to top-kill of shrubs and tree saplings less than 5 cm (2 inches) diameter, and formation of hollow trees.

RIO GRANDE DELTA THORN WOODLAND (CES301.716)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Madrean Semidesert (301)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Lowland [Lowland]; Forest and Woodland (Treed); Tropical/Subtropical; Riverine / Alluvial
Non-Diagnostic Classifiers: Broad-Leaved Evergreen Tree
National Mapping Codes: ESLF 4164

CONCEPT

Summary: This diverse, usually broad-leaved evergreen woodland is found on resaca banks and old natural levees on the Rio Grande delta in southern Texas. Sites are well-watered, somewhat elevated relative to the surrounding landscape, and tend to occupy loamy or clayey bottomland soils. This system includes evergreen, mixed and deciduous woodlands and shrublands with a typically open upper canopy of broadleaf evergreen species such as *Ebenopsis ebano* and *Ehretia anacua* and a dense shrub layer of numerous species present. Mature occurrences will often support epiphytes such as *Tillandsia recurvata, Tillandsia usneoides*, and rarely *Tillandsia baileyi*.

Classification Comments: Younger occurrences, especially those occupying drier sites, tend to present as shrublands, often dominated by similar, though shorter, canopy species. These occurrences also tend to be less diverse, lack the layered structure, and usually support fewer epiphytes.

Similar Ecological Systems:

- Tamaulipan Floodplain (CES301.990)

Related Concepts:

- Rio Grande Delta Deciduous Thorn Woodland and Shrubland (7804) (Elliott 2011) Finer. Woodlands with increased dominance of deciduous species such as *Celtis laevigata, Ulmus crassifolia*, and *Celtis pallida (= Celtis ehrenbergiana)*.
- Rio Grande Delta Dense Shrubland (7805) (Elliott 2011) Finer. Dense shrublands often representing younger occurrences and occurrences occupying slightly less well-watered sites. *Phaulothamnus spinescens, Guajacum angustifolium, Celtis pallida*, and *Diospyros texana* are often conspicuous components.
- Rio Grande Delta Evergreen Thorn Woodland and Shrubland (7802) (Elliott 2011) Finer. Much of this system (>90%) is mapped as this type with broadleaf evergreen species such as *Ebenopsis ebano* and *Ehretia anacua* making up a significant portion of the overstory canopy and a dense shrub layer of numerous species present.

DESCRIPTION

Environment: This system occurs in the historic floodplain of the Rio Grande delta on Quaternary-aged alluvium. It is found on slight rises such as old natural levees or resaca banks often on Clayey or Loamy Bottomland Ecological Sites, but occasionally on Clay Loam or Gray Sandy Loam types. Sites are well-watered, somewhat elevated relative to the surrounding landscape, and tend to occupy loamy or clayey bottomland soils. Occasionally occurrences can be found on clay loams (such as Raymondville or Racombes soils) or gray sandy loams (such as Hidalgo sandy clay loam).

Vegetation: The sometimes patchy canopy of these woodlands often contains species such as *Ebenopsis ebano, Ehretia anacua, Celtis laevigata, Ulmus crassifolia*, and *Celtis pallida (= Celtis ehrenbergiana)*, and may reach heights of 15 m. Species such as *Phaulothamnus spinescens, Amyris madrensis, Amyris texana, Diospyros texana, Leucaena pulverulenta, Guajacum angustifolium, Malpighia glabra, Adelia vaseyi, Bernardia myricifolia, Sideroxylon celastrinum, Condalia hookeri, Forestiera angustifolia, Havardia pallens, Iresine palmeri, Trixis inula, Xylosma flexuosa*, and *Randia rhagocarpa* may occur as shrubs or in the subcanopy, and some individuals of a few of these species may reach heights of 4 to 5 m. This shrub or understory layer can be extremely dense, almost impenetrable. Woody cover, including the patchier overstory canopy and the almost continuous shrub/understory layer, often reaches greater than 90%. This system is sometimes referred to as a tall shrubland, since shrubs are often the dominant lifeform, but frequently reach heights resembling the stature of woodland. *Prosopis glandulosa* may occasionally be absent or uncommon in the canopy, and is generally not dominant except in disturbed situations. The herbaceous layer is generally represented by a only a few species and is relatively sparse, with species such as *Rivina humilis, Plumbago scandens, Celosia nitida, Chromolaena odorata, Leersia monandra, Digitaria californica, Setaria* spp., *Salvia coccinea, Petiveria alliacea, Malvastrum americanum, Urtica chamaedryoides, Verbesina microptera, Calyptocarpus vialis*, and *Siphonoglossa pilosella (= Justicia pilosella)* sometimes present. Vines such as *Serjania brachycarpa, Urvillea ulmacea, Cocculus diversifolius, Mikania scandens, Cardiospermum* spp., *Chiococca alba, Cissus trifoliata*, and *Passiflora* spp. may also be commonly encountered. The rather rare epiphyte *Tillandsia baileyi* may be found in these woodlands, along with the more common *Tillandsia recurvata* and *Tillandsia usneoides*. Younger occurrences, especially those occupying drier sites, tend to present as shrublands, often dominated by similar, though shorter, canopy species. These occurrences also tend to be less diverse, lack the layered structure, and usually support fewer epiphytes.

Dynamics: The major processes in this system were flooding and drought (Diamond 1998). Freezes can have significant impacts on canopy species such as *Ebenopsis, Sabal* and *Leucaena pulverulenta* in the delta. Hurricanes may not significantly affect dense *Ebenopsis ebano - Ehretia anacua* forest, except through flood effects. Lengthy droughts (lasting 10 years) can influence this system

but most species are drought-tolerant. Infrequent fires may also occur.

This system was modeled as part of the Tamaulipan Riparian Systems group by Landfire (2007a) using three classes: early-, mid- and late-seral. Fire frequency is likely over-emphasized in this model for this system, as other ecologists suggest fire was historically infrequent in the Rio Grande delta (Diamond 1998).

Early-seral class (0-12 years): Herbaceous species dominant where there are high sunlight conditions. Woody species begin establishing in the understory. Duration of this stage is 12 years. Flooding at an interval of 500 years is modeled for this stage (Landfire 2007a).

Mid-seral class (13-33 years): Species composition would contain canopy species of an earlier successional type such as *Acacia farnesiana, Ehretia anacua, Leucaena pulverulenta, Celtis laevigata* and *Celtis pallida*. Shrub cover would be increased due to openness of the canopy. Duration of this stage is 20 years. Flooding at an interval of 500 years moves to early-seral class. Surface fires every 30 years maintain this mid-seral class (Landfire 2007a).

The late-seral class (34+ years): Canopy becomes more closed and includes *Ehretia anacua, Ebenopsis ebano, Ulmus crassifolia*, and *Celtis laevigata*. Gap succession does occur as individual tree mortality occurs (maintenance/ every 500 years) and moves class to mid-seral. Freezes will reduce canopy of ebony and other subtropical species. Freezes (every 50 years) and surface fires (every 30 years) occur but do not cause transitions to other structural or floristic states. Flooding at an interval of 500 years takes class to early-seral (Landfire 2007a).

Component Associations:
- *Celtis laevigata - Ulmus crassifolia - (Fraxinus berlandieriana) / Rivina humilis - Chromolaena odorata* Forest (CEGL007752, G1G2)
- *Ebenopsis ebano - Ehretia anacua / Condalia hookeri* Forest (CEGL002054, G1)
- *Ebenopsis ebano - Phaulothamnus spinescens* Scrub (CEGL002169, G2)

Spatial Characteristics

Spatial Summary: This system was apparently much wider spread historically, forming a matrix type in the Rio Grande delta of southern Texas. It is currently only known from smaller patches.
Size: Historically: Matrix. Currently: Small patch
Adjacent Ecological Systems:
- Tamaulipan Floodplain (CES301.990)

Distribution

Range: This system is currently on known from remnant occurrences in the historic delta of the Rio Grande in southern Texas. It may also occur in Mexico.

SONORAN FAN PALM OASIS (CES302.759)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Forest and Woodland (Treed); Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Seepage-Fed Sloping; Palm or Sabal
Non-Diagnostic Classifiers: Lowland [Foothill]; Lowland [Lowland]; Isolated Wetland [Partially Isolated]; Udic
National Mapping Codes: ESLF 9327

CONCEPT

Summary: This ecological system occurs on highly localized, spring-fed depressions along canyon waterways and tectonic fault lines below 900 m in elevation in the Sonoran and Mojave deserts. Permanent subsurface water is required to maintain *Washingtonia filifera*, a relict species. Salinity is low in the root zone, but increases near the surface where evaporation leaves salt accumulations. These oases woodlands are distinctively dominated by *Washingtonia filifera* with variable understory conditions. Other trees that may be present include *Platanus racemosa*, *Quercus chrysolepis*, *Populus fremontii*, and *Fraxinus velutina*. A subcanopy of *Salix lasiolepis*, *Salix gooddingii*, *Salix exigua*, or *Prosopis glandulosa* is often present. Reproduction of *Washingtonia filifera* is limited by water supply, surface salinity, rainfall, and fire. Fan palms are fire-tolerant, while the understory species are not, and fires open up the understory allowing palm seedlings to establish. Removal of the understory also decreases competition for water. There are currently 80 known occurrences in California and probably 100 throughout its range including Arizona and Nevada.

DESCRIPTION

Environment: Desert springs in canyon waterways or along fault lines where underground water is continuously available. Salinity is low in the root zone, but increases near the surface where evaporation leaves salt accumulations.
Dynamics: Reproduction of *Washingtonia filifera* is limited by water supply, surface salinity, rainfall, and fire. Fan palms are fire-tolerant, while the understory species are not, and fires open up the understory allowing palm seedlings to establish. Removal of the understory also decreases competition for water. Fire is essential in the regeneration of *Washingtonia filifera* (Sawyer et al. 2009). Natural fires started by lighting as well as those set by Native Americans prior to 1900s created favorable germination sites and increased the flow of springs. Flash floods probably had similar effect (Sawyer et al. 2009).

Component Associations:
- *Washingtonia filifera* Woodland (CEGL000001, G3?)

DISTRIBUTION

Range: Below 900 m in elevation in the Sonoran and Mojave deserts.

SOUTH FLORIDA PINE FLATWOODS (CES411.381)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Needle-Leaved Tree
Non-Diagnostic Classifiers: Woody-Herbaceous; Extensive Wet Flat
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Evergreen open tree canopy
National Mapping Codes: EVT 2446; ESLF 9115; ESP 1446

CONCEPT

Summary: This system is endemic to Florida, ranging from Lee, Desoto, Highlands, and Okeechobee counties southward. It was once an extensive system within its historic range. The vegetation is naturally dominated by *Pinus elliottii var. densa*, being largely outside the natural range of *Pinus serotina, Pinus elliottii var. elliottii*, and *Pinus palustris*. In natural condition, examples are generally open with a variety of low shrub and grass species forming a dense ground cover. Frequent, low-intensity fire was the dominant natural ecological force, but most areas have undergone long periods without fire, resulting in greater dominance of shrubs and saw palmetto, as well as denser canopies of slash pine.
Classification Comments: No associations have currently been described in the USNVC for this system. More information is needed. The floristic composition of this system overlaps Florida Dry Prairie (CES203.380); the primary difference lies in taller and denser shrub cover (especially of *Serenoa repens*) (Huffman and Judd 1998). There is considerable variation between wet and "non-wet" flatwoods implied in this system.
Similar Ecological Systems:
- Florida Dry Prairie (CES203.380)
- South Florida Pine Rockland (CES411.367)--is also dominated almost exclusively by *Pinus elliottii var. densa* in the canopy, but occurs on limestone and has a richer, diverse mix of tropical and temperate species in the understory.

Related Concepts:
- Mesic Flatwoods (FNAI 1990) Intersecting
- Pine Forest (Duever et al. 1986) Finer
- Scrubby Flatwoods (FNAI 1990) Intersecting
- Wet Flatwoods (FNAI 1990) Intersecting

DESCRIPTION

Environment: This system occurs on sandy soils, including Spodosols, which are prone to some saturation or short periods of flooding after summer rains. These flatwoods occur in areas which have some creeks, which provide some natural firebreaks. Similar areas which are very extensive without creeks tend to be Florida Dry Prairie (CES203.380), which naturally burns more frequently.
Vegetation: According to Huffman and Judd (1998), examples of this system have generally open canopies composed of *Pinus elliottii var. densa* and, more rarely, *Pinus palustris*. *Serenoa repens, Lyonia lucida, Lyonia fruticosa, Ilex glabra, Vaccinium darrowii, Vaccinium myrsinites*, and *Quercus minima* are common shrubs. Grasses are typically abundant, including *Aristida beyrichiana* and *Schizachyrium scoparium var. stoloniferum*; most other grass and herbaceous species found are in common with Florida Dry Prairie (CES203.380).
Dynamics: Frequent, low-intensity fire was the dominant natural ecological force, but most areas have undergone long periods without fire, resulting in greater dominance of shrubs and saw palmetto, as well as denser canopies of slash pine (Huffman and Judd 1998, Noel et al. 1998). Disturbances are an important part of the natural functions of pine flatwoods. In order for these habitats to burn frequently (every 2-3 years), there needs to be enough fine fuel, such as needles from *Pinus elliottii var. densa* or *Pinus palustris* trees, healthy populations of native warm-season grasses, and evergreen shrubs with volatile oils in their leaves, such as *Gaylussacia frondosa, Hypericum reductum, Ilex glabra, Lyonia ferruginea, Lyonia fruticosa, Serenoa repens*, and *Vaccinium myrsinites*. The frequent fires promote flowering, seed production, and seed germination of many plants and provide open areas in patches (Van Lear et al. 2005).

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- South Florida Depression Pondshore (CES411.054)

DISTRIBUTION

Range: This system is found in southern Florida, extending north to mid-peninsula (e.g., Lee, Desoto, Highlands, and Okeechobee counties).
Divisions: 203:C; 411:C
Nations: US
Subnations: FL

SOUTH-CENTRAL INTERIOR LARGE FLOODPLAIN (CES202.705)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Floodplain; Forest and Woodland (Treed); Herbaceous
National Mapping Codes: ESLF 9334

CONCEPT

Summary: This floodplain system is found in the Interior Highlands as far west as eastern Oklahoma, as well as throughout the Interior Low Plateau, Cumberlands, Southern Ridge and Valley, and Western Allegheny Plateau, and lower elevations of the Southern Blue Ridge. Examples occur along large rivers or streams where topography and alluvial processes have resulted in a well-developed floodplain. A single occurrence may extend from river's edge across the outermost extent of the floodplain or to where it meets a wet meadow or upland system. Many examples of this system will contain well-drained levees, terraces and stabilized bars, and some will include herbaceous sloughs and shrub wetlands resulting, in part, from beaver activity. A variety of soil types may be found within the floodplain from very well-drained sandy substrates to very dense clays. It is this variety of substrates in combination with different flooding regimes that creates the mix of vegetation. Most areas, except for the montane alluvial forests, are inundated at some point each spring; microtopography determines how long the various habitats are inundated. Although vegetation is quite variable in this broadly defined system, examples may include *Acer saccharinum*, *Platanus occidentalis*, *Liquidambar styraciflua*, and *Quercus* spp. Understory species are mixed, but include shrubs, such as *Cephalanthus occidentalis* and *Arundinaria gigantea ssp. gigantea*, and sedges (*Carex* spp.). This system likely floods at least once annually and can be altered by occasional severe floods. Impoundments and conversion to agriculture can also impact this system.

Classification Comments: Montane alluvial forests may be difficult to place within this system because they share traits with both this system and Southern and Central Appalachian Cove Forest (CES202.373), at least in the southern Appalachians. This split from Central Appalachian River Floodplain (CES202.608) may appear somewhat arbitrary but is based on the freshwater systems classification, using roughly the Mid-Continental Divide. This means that Ecoregions 50 and 51 are included in this system, whereas Ecoregions 52 and 59 are considered part of Central Appalachian River Floodplain (CES202.608) (except for a small part of southernmost Ecoregion 59 in West Virginia that drains to the Ohio River).This system grades into Western Great Plains Floodplain (CES303.678) in the Crosstimbers region of east-central Oklahoma as eastern cottonwood (*Populus deltoides*) and willows (*Salix* spp.) become more dominant.

Similar Ecological Systems:
- Central Appalachian River Floodplain (CES202.608)
- South-Central Interior Small Stream and Riparian (CES202.706)
- Southern Piedmont Large Floodplain Forest (CES202.324)
- Southern Piedmont Small Floodplain and Riparian Forest (CES202.323)
- Western Great Plains Floodplain (CES303.678)

DESCRIPTION

Environment: This system inhabits broad floodplains along large creeks and rivers that are usually inundated for at least part of each year. Flood frequency depends on precipitation patterns within the watershed and proximity to the main channel. Areas adjacent to the main channel or low islands within the channel can be flooded every year or even more than once per year. Those areas further from the channel on terraces or behind natural levees may only be flooded once every several years. Free-flowing rivers migrate across their floodplain, cutting new channels or eroding the bank on one side while building up the bank on the other, so the flooding regime of any one point in the floodplain will change over time. Flooding redeposits alluvium, eroding some areas and aggrading others, can bury or wash away small plants, and redistributes nutrients, especially in less frequently flooded zones where silt and clay tend to be deposited. These processes open up new areas for colonization.

Vegetation: Vegetation varies quite widely, encompassing shrubby and herbaceous communities, as well as forested communities with a wide array of canopy types. Examples may include *Acer saccharinum, Platanus occidentalis, Liquidambar styraciflua*, and *Quercus* spp. Understory species are mixed but include shrubs, such as *Cephalanthus occidentalis* and *Arundinaria gigantea ssp. gigantea*, and sedges (*Carex* spp.).

Dynamics: Flooding dynamics are an important factor in the development and maintenance of this system. Flood frequency depends on precipitation patterns within the watershed and proximity to the main channel. Areas adjacent to the main channel or low islands within the channel can be flooded every year or even more than once per year. Those areas further from the channel on terraces or behind natural levees may only be flooded once every several years. Free-flowing rivers migrate across their floodplain, cutting new channels or eroding the bank on one side while building up the bank on the other, so the flooding regime of any one point in the floodplain will change over time. Flooding redeposits alluvium, eroding some areas and aggrading others, can bury or wash away small plants, and redistributes nutrients, especially in less frequently flooded zones where silt and clay tend to be deposited. These processes open up new areas for colonization.

SOUTH-CENTRAL INTERIOR SMALL STREAM AND RIPARIAN (CES202.706)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Forest and Woodland (Treed); Stream terrace (undifferentiated)
National Mapping Codes: ESLF 9335

CONCEPT

Summary: This system is found throughout the Interior Low Plateau, Southern Ridge and Valley, Western Allegheny Plateau, lower elevations of the Southern Blue Ridge, and parts of the Cumberlands. Examples occur along small streams and floodplains with low to moderately high gradients. There may be little to moderate floodplain development. Flooding and scouring both influence this system, and the nature of the landscape prevents the kind of floodplain development found on larger rivers. This system may contain cobble bars with adjacent wooded vegetation and rarely have any marsh development, except through occasional beaver impoundments. The vegetation is a mosaic of forests, woodlands, shrublands, and herbaceous communities. Canopy cover can vary within examples of this system, but typical tree species may include *Platanus occidentalis, Acer rubrum var. trilobum, Betula nigra, Liquidambar styraciflua,* and *Quercus* spp. Shrubs and herbaceous layers can vary in richness and cover. Some characteristic shrubs may include *Hypericum densiflorum, Salix* spp., and *Alnus* spp. Small seeps dominated by sedges (*Carex* spp.), ferns (*Osmunda* spp.), and other herbaceous species can often be found within this system, especially at the headwaters and terraces of streams.
Classification Comments: This system is closely related to Central Appalachian Stream and Riparian (CES202.609) but has been distinguished based on the precepts of the Freshwater Systems classification. This system has been divided from Central Appalachian Riparian roughly by the Mid-Continental Divide. This means that Ecoregions 50 and 51 are included in this system, whereas Ecoregions 52 and 59 are considered part of Central Appalachian Riparian (except for a small part of southernmost Ecoregion 59 in West Virginia that drains to the Ohio River). In contrast to floodplain systems, this system has little to no floodplain development. In comparison with South-Central Interior Large Floodplain (CES202.705), this system typically has somewhat higher gradients, is sometimes rocky, and may experience flash floods. Stands from somewhat larger rivers have been placed here if the river lacks substantial floodplain development (e.g., the New River of West Virginia and the Ocoee Gorge of Tennessee).
Similar Ecological Systems:
- Central Appalachian Stream and Riparian (CES202.609)
- Cumberland Riverscour (CES202.036)--is essentially a more extreme and local variant of this broader concept, found in the major rivers of the Cumberland Plateau and related areas of Tennessee, Kentucky, and adjacent states.
- Ozark-Ouachita Riparian (CES202.703)--is the Ozark-Ouachita equivalent of this system.
- South-Central Interior Large Floodplain (CES202.705)

DESCRIPTION

Environment: This system is found along fairly high-energy streams and rivers with steep banks, this system is subject to frequent flooding and can be subject to scouring depending upon the substrate. Some associations do not flood but instead are saturated zones or patches near the streams.
Vegetation: There is wide variation in vegetation depending upon the frequency of the flooding cycle (more frequent flooding creates a better environment for forbs and shrubs, less frequent may create a better environment for the establishment of trees). Typical tree species may include *Platanus occidentalis, Acer rubrum var. trilobum, Betula nigra, Liquidambar styraciflua,* and *Quercus* spp. Shrubs and herbaceous layers can vary in richness and cover. Some characteristic shrubs may include *Hypericum densiflorum, Salix* spp., and *Alnus* spp. Small seeps dominated by sedges (*Carex* spp.), ferns (*Osmunda* spp.), and other herbaceous species can often be

found within this system, especially at the headwaters and terraces of streams. These areas are not typically flooded or scoured but saturated.

Dynamics: Flooding and seed propagule dispersal caused by flooding events are the two most important processes affecting this system. The two processes vary widely depending upon size of stream, upstream land use and topography, presence or absence of invasive exotics that may displace native community types, etc.

Spatial Characteristics

Spatial Summary: Small, linear patch.
Size: Can be quite long but never very wide.

Distribution

Range: This system ranges from the Interior Low Plateau to the Southern Blue Ridge and north into the Western Allegheny Plateau and portions of the Cumberlands. There would be limited and peripheral presence in the Upper East Gulf Coastal Plain. It also is present on Crowley's Ridge, an anomalous and distinct upland topographic feature that is embedded within the Mississippi River Alluvial Plain.

TEXAS COAST DUNE AND COASTAL GRASSLAND (CES203.465)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Herbaceous; Depressional; Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2437; ESLF 7150; ESP 1437

CONCEPT

Summary: This ecological system consists of wetland and upland herbaceous and shrubland vegetation of barrier islands, near-coastal areas, and the Coastal Sand Plain along the Texas coast in the northern Gulf of Mexico. Plant communities of primary and secondary dunes, interdunal swales, barrier flats, and adjacent mainland are included. Salt spray, saltwater overwash, and sand movement are important ecological forces. Some examples of this system naturally occurred as an open matrix of midgrass species within native mesquite - acacia shrublands dominated by *Prosopis glandulosa, Acacia farnesiana,* and *Acacia rigidula* but have become shrub-dominated due to the lack of fire.

Similar Ecological Systems:
- Central and South Texas Coastal Fringe Forest and Woodland (CES203.464)--shares many taxa, but each seems to have a suite of unique species not found in the other.

Related Concepts:
- Active Sand Dune (6200) [CES203.465.1] (Elliott 2011) Finer
- Coastal and Sandsheet: Deep Sand Shrubland (6306) [CES203.465.6] (Elliott 2011) Finer
- Coastal and Sandsheet: Dune and Coastal Grassland (6307) [CES203.465.7] (Elliott 2011) Finer

DESCRIPTION

Environment: This system occupies deep eolian sands and Pleistocene barrier island and beach deposits that sit on top of underlying geologic formations, especially the Beaumont Formation. This includes deep sands well inland on the South Texas Sand Sheet, which represents by far the largest continuous patch of this type. It is found on primary and secondary dunes, as well as relatively level areas such as barrier flats, and on the mainland on deep sands of stranded beach ridges. Significant local topography, in the form of swales and pothole wetlands, may be present. Significant surface drainages are generally scarce. Soils are deep or coastal sands (Elliott 2011).
Vegetation: This system includes upland, grass-dominated vegetation on deep sands. Dunes are often dominated by *Uniola paniculata*, with other species such as *Croton punctatus, Panicum amarum, Ipomoea pes-caprae, Ipomoea imperati, Tidestromia lanuginosa, Cakile* spp., and *Sesuvium portulacastrum* also present. Upland grasslands are often dominated by *Schizachyrium littorale* and *Paspalum monostachyum*. Numerous other species, such as *Sorghastrum nutans, Paspalum plicatulum, Muhlenbergia capillaris, Cenchrus spinifex, Elionurus tripsacoides, Eragrostis secundiflora, Bothriochloa laguroides ssp. torreyana, Heteropogon contortus, Andropogon glomeratus, Spartina patens,* and *Dichanthelium* spp., may also be common. Numerous forbs, including such species as *Heterotheca subaxillaris, Croton* spp., *Chamaecrista fasciculata, Rayjacksonia phyllocephala, Physalis* spp., *Helianthus argophyllus, Gaillardia pulchella, Solidago sempervirens, Baptisia* spp., *Indigofera miniata, Eriogonum multiflorum, Conoclinium betonicifolium,* and *Rudbeckia hirta*, are also commonly encountered. Some woody species are found in the system but typically make up very little cover. Cover of woody species is limited but may include *Baccharis* spp., *Opuntia engelmannii var. lindheimeri, Morella cerifera, Quercus fusiformis, Quercus virginiana*, and stunted *Prosopis glandulosa*. Non-native woody species such as *Tamarix* spp., *Schinus terebinthifolius*, and *Triadica sebifera* may be present to dominant. Small areas may have sufficient woody cover to be mapped as a shrubland (Elliott 2011).
Dynamics: Substrate, hydrology, drought, coastal processes (including tropical storms) and fire play a role in maintaining this ecological system (Lonard et al. 2004, Morton et al. 2004, Britton et al. 2010). Composition and structure vary depending on these processes.

Component Associations:
- *Acacia rigidula* Shrubland (CEGL003874, G4G5)
- *Panicum amarum - Paspalum monostachyum* Herbaceous Vegetation (CEGL004970, G3?)
- *Schizachyrium littorale - Paspalum monostachyum* Herbaceous Vegetation (CEGL002207, G3?)
- *Spartina patens - Fimbristylis (caroliniana, castanea) - (Panicum virgatum)* Herbaceous Vegetation (CEGL007836, G2G3)
- *Spartina patens - Panicum amarum - Hydrocotyle bonariensis* Herbaceous Vegetation (CEGL004971, G2?)
- *Uniola paniculata - (Panicum amarum) - Croton punctatus* Herbaceous Vegetation (CEGL002218, G3?)

SPATIAL CHARACTERISTICS

TEXAS-LOUISIANA COASTAL PRAIRIE (CES203.550)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Herbaceous; Deep Soil; Graminoid
Non-Diagnostic Classifiers: Extensive Wet Flat; Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Herbaceous / Nonvascular-dominated, Herbaceous - grassland, Perennial graminoid grassland
National Mapping Codes: EVT 2434; ESLF 7147; ESP 1434

CONCEPT

Summary: This system encompasses non-saline tallgrass prairie vegetation that developed over Pleistocene terraces flanking the Gulf Coast of Louisiana and Texas. It is sometimes characterized by a ridge-and-swale or mound-and-intermound microtopography and encompasses both upland and wetland plant communities. Upland dominants typically include *Schizachyrium scoparium, Paspalum plicatulum*, and *Sorghastrum nutans*. Wetland dominants in undisturbed occurrences include *Panicum virgatum* and *Tripsacum dactyloides*. Fire is an important ecological process in this system.
Classification Comments: The concept of this system includes the Kleberg prairie of Johnston (1963) and the clay prairie concept of McClendon (1991) (in part) that were formerly included in Tamaulipan Clay Grassland (CES301.987).
Similar Ecological Systems:
- Central Texas Coast River Terrace Sandyland Grassland (CES203.712)
- Texas-Louisiana Coastal Prairie Pondshore (CES203.541)

Related Concepts:
- Gulf Coast: Coastal Prairie (5207) [CES203.550] (Elliott 2011) Equivalent

DESCRIPTION

Environment: This mid- to tallgrass prairie occupies Pleistocene surfaces of the Texas and Louisiana coast, on non-saline soils. The occurrence of this system is generally coincident with the distribution of the Pleistocene Beaumont and Lissie formations in Texas (Prairie and Intermediate allogroups in Louisiana). It is usually found on level to gently rolling landscapes, with slopes generally less than 5%. Microtopography plays an important role in local variation in the system, with ridges, swales, mounds, depressions, mima (or pimple) mounds, and gilgai leading to a mosaic of drier and wetter plant communities. Typical soils are non-saline Vertisols, Alfisols, and (less extensively) Mollisols (Diamond and Smeins 1984, Smeins et al. 1992). Vertisols are often characterized by gilgai, resulting from shrink-swell attributes of the montmorillonitic clays of which they are composed. Historically, rivers and streams dissected this vegetation type, breaking it into large compartments with species composition shifting across the range. A moisture gradient occurs from northeast (average 120 cm/year) to southwest (average 100 cm/year) across the range of this system (Diamond and Smeins 1984).
Vegetation: Stands are dominated by graminoid species, such as *Andropogon gerardii, Andropogon glomeratus, Bouteloua curtipendula, Cyperus entrerianus, Dichanthelium oligosanthes, Fimbristylis puberula, Muhlenbergia capillaris, Panicum virgatum, Paspalum floridanum, Paspalum plicatulum, Paspalum setaceum, Rhynchospora* spp., *Schizachyrium scoparium, Sorghastrum nutans, Sporobolus compositus, Tridens strictus*, and *Tripsacum dactyloides*. *Axonopus* spp., *Andropogon virginicus, Bothriochloa laguroides ssp. torreyana, Nassella leucotricha*, and *Sporobolus indicus* may be particularly noticeable on overgrazed sites; disturbed occurrences may be dominated by *Andropogon glomeratus*. Non-native graminoids that may be conspicuous to dominant components include *Cynodon dactylon, Bothriochloa ischaemum var. songarica, Dichanthium* spp., *Lolium perenne, Lolium arundinaceum (= Schedonorus phoenix), Paspalum notatum*, and *Paspalum dilatatum*. Forbs that may often be encountered include *Liatris* spp., *Sabatia campestris, Ambrosia psilostachya, Euphorbia bicolor, Solidago* spp., *Rudbeckia hirta, Ruellia humilis, Asclepias viridis, Chamaecrista fasciculata, Helianthus angustifolius, Euthamia* spp., *Ratibida columnifera, Symphyotrichum ericoides, Silphium laciniatum, Baptisia* spp., *Iva angustifolia, Eryngium yuccifolium, Boltonia diffusa*, and *Neptunia lutea*. Woody species may invade this typically herbaceous vegetation, including *Rosa bracteata, Acacia farnesiana, Triadica sebifera, Baccharis halimifolia, Celtis laevigata*, and *Prosopis glandulosa* (Elliott 2011).
Dynamics: The impacts and interaction of fire, drought, competition, and possibly grazing constitute the major natural dynamics influencing this system (Smeins et al. 1992, USGS 2013). Frequent fires every 2-5 years of both lightning and anthropogenic origins prevent woody species from establishing and favor grassland species adapted to fire for reproduction and vigor. Microtopographic and moisture variability interacted with fire to produce variable fire effects influencing the distribution of flora and fauna. Grazing by bison and other ungulates also played an important role in maintaining the vegetation composition and structure of this system. This system is important for a suite of wildlife, many of which are declining, that are dependent on native grasslands (TPWD 2012a).

Component Associations:
- *Andropogon gerardii - Panicum virgatum - Schizachyrium scoparium - Schizachyrium tenerum - Helianthus mollis* Herbaceous Vegetation (CEGL007938, G1)
- *Euthamia leptocephala - Helianthus angustifolius - Boltonia asteroides - Spartina patens* Herbaceous Vegetation (CEGL007936,

G1)
- *Muhlenbergia capillaris* Herbaceous Vegetation (CEGL004607, G1G2)
- *Panicum virgatum - Tripsacum dactyloides - (Panicum hemitomon)* Herbaceous Vegetation (CEGL007937, G1)
- *Schizachyrium scoparium - Paspalum plicatulum - Sorghastrum nutans - Dichanthelium oligosanthes - Paspalum setaceum - Symphyotrichum pratense* Alfisol Herbaceous Vegetation (CEGL002208, G1)
- *Schizachyrium scoparium - Sorghastrum nutans - Paspalum plicatulum - Carex microdonta - Neptunia lutea* Vertisol Herbaceous Vegetation (CEGL004519, G1)
- *Schizachyrium scoparium - Triplasis purpurea - Eriogonum multiflorum - Liatris elegans var. carizzana* Herbaceous Vegetation (CEGL008483, G1)

Spatial Characteristics

Adjacent Ecological Systems:
- Central Texas Coastal Prairie Riparian (CES203.714)
- Central Texas Coastal Prairie River Floodplain (CES203.713)
- West Gulf Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.191)

Adjacent Ecological System Comments: In Louisiana, this system grades coastward into marshes of the chenier plain and inland into West Gulf Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.191). In Texas this system generally grades coastward into a saline prairie or salt marsh system and inland into West Gulf Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.191), or oak woodland vegetation. Degraded examples are often dominated by the invasive exotic *Triadica sebifera*. Relatively undisturbed natural depressions (potholes) occurring within the upland matrix units of this system are included in Texas-Louisiana Coastal Prairie Pondshore (CES203.541).

Distribution

Range: This system occurs within 50 to 150 miles of the Gulf Coast from southwestern Louisiana to south-central Texas encompassing approximately 10 million acres.

WEST GULF COASTAL PLAIN PINE-HARDWOOD FLATWOODS (CES203.278)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Pimple mounds; Forest and Woodland (Treed); Extensive Wet Flat; Needle-Leaved Tree; Broad-Leaved Deciduous Tree
Non-Diagnostic Classifiers: Isolated Wetland [Partially Isolated]
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Mixed evergreen-deciduous open tree canopy
National Mapping Codes: EVT 2458; ESLF 9127; ESP 1458

CONCEPT

Summary: This ecological system represents predominantly mesic to dry flatwoods of limited areas of inland portions of the West Gulf Coastal Plain. These areas are usually found on Pleistocene high terraces that are located above current floodplains. The hydrology is controlled by local rainfall events and not by overbank flooding. Soils are fine-textured, and hardpans may be present in the subsurface. The limited permeability of these soils contributes to shallowly perched water tables during portions of the year when precipitation is greatest and evapotranspiration is lowest. Soil moisture fluctuates widely throughout the growing season, from saturated to very dry, a condition sometimes referred to elsewhere as xerohydric. Saturation occurs not from overbank flooding but typically whenever precipitation events occur. Local topography is a complex of ridges and swales, often in close proximity to one another. Ridges tend to be much drier than swales, which may hold water for varying periods of time. Within both ridges and swales, there is vegetation variability relating to soil texture and moisture and disturbance history. The driest ridges support *Pinus taeda* and *Quercus stellata*; more mesic ridges have *Pinus taeda* with *Quercus alba* and species such as *Symplocos tinctoria* and *Viburnum dentatum*. Fire may have been an important natural process in some examples of this system.
Classification Comments: Embedded swales tend to support hardwood forests or swamps, often heavily oak-dominated with species tolerant of some inundation, such as *Quercus phellos* and *Quercus laurifolia*, with sparse coverage of wetland herbs such as *Carex glaucescens*. Some swales support unusual pockets of *Fraxinus caroliniana* and *Crataegus* spp. These latter vegetation types are linked to West Gulf Coastal Plain Nonriverine Wet Hardwood Flatwoods (CES203.548). In Arkansas (at least), this system is most closely affiliated with these Soil Associations: "Adaton-Felker-Gore" (MUID=AR035); "Wrightsville-Acadia-Louin" (MUID=AR036); "Amy-Pheba-Savannah" (MUID=038); "Amy-Pheba-Guyton" (MUID=AR040); "Smithdale-Savannah-Sacul" (MUID= AR041); "Sacul-Savannah-Sawyer" (MUID= AR042); "Calloway-Henry-Grenada" (MUID=AR044); "Wrightsville-Kolin-Gore" (MUID=AR063); "Bussy-Tillou-Guyton" (MUID=AR069). Apparently, this system occurs within the historic range of longleaf pine [see USFS ecomap attributions]. Within this range, more information is needed to identify the toposequence between longleaf pine-dominated flatwoods/savannas/uplands and hardwood/loblolly-dominated flatwoods. The distribution of this system in the South Central Plains Flatwoods and Southern Tertiary Uplands (EPA 35e and f) needs to be better defined.
Similar Ecological Systems:
- West Gulf Coastal Plain Nonriverine Wet Hardwood Flatwoods (CES203.548)
- West Gulf Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.191)

Related Concepts:

DESCRIPTION

Environment: Areas occupied by this system are usually found on nonriverine, Pleistocene high terraces. These are mapped in the northern portion of East Texas as Quaternary Fluviatile Terrace (or Tile) Deposits. It is found on very gently undulating to flat surfaces, with local topographic relief provided by ridges and swales. Soils tend to be fine-textured and typically have a somewhat impermeable subsurface horizon, which leads to a perched water table. Saturation results from local rainfall run-on, and alternates with seasonal drying, leading to a xerohydric hydroperiod. The limited permeability of these soils contributes to shallowly perched water tables during portions of the year when precipitation is greatest and evapotranspiration is lowest. Soil moisture fluctuates widely throughout the growing season, from saturated to very dry, a condition sometimes referred to elsewhere as xerohydric. Saturation occurs not from overbank flooding but typically whenever precipitation events occur. Local topography is a complex of ridges and swales, often in close proximity to one another. Ridges tend to be much drier than swales, which may hold water for varying periods of time.
Vegetation: There is vegetation variability between and among ridges and swales, as well as within them, relating to soil texture and moisture and disturbance history. This woodland or forest system is often dominated by more mesic species on interior ridges,

including *Pinus taeda, Pinus echinata, Pinus elliottii, Quercus stellata, Quercus alba, Quercus falcata,* and *Carya texana* (Elliott 2011). Within the range of *Pinus palustris*, occurrences that represent West Gulf Coastal Plain Wet Longleaf Pine Savanna and Flatwoods (CES203.191) may be mapped as this system. The driest ridges support *Pinus taeda* and *Quercus stellata*; more mesic ridges have *Pinus taeda* with *Quercus alba* and understory species such as *Symplocos tinctoria* and *Viburnum dentatum*. On the somewhat wetter sites of the swales, species such as *Quercus nigra, Quercus phellos, Quercus laurifolia, Nyssa sylvatica, Liquidambar styraciflua,* and *Fraxinus pennsylvanica* may be dominant. Sites that are even wetter would likely be mapped as West Gulf Coastal Plain Nonriverine Wet Hardwood Flatwoods (CES203.548). Midstory species that may be encountered include *Acer rubrum, Ilex opaca, Ulmus alata,* and small members of the overstory. *Morella cerifera, Ilex decidua*, and *Ilex vomitoria* are commonly encountered shrubs. Herbaceous cover is generally sparse, with species such as *Chasmanthium* spp., *Andropogon glomeratus*, and *Gelsemium sempervirens*. Sites dominated by *Pinus taeda* or *Pinus elliottii* may often represent plantations or managed forests (Elliott 2011). *Triadica sebifera* may invade this system. Embedded swales (which are, in effect, smaller interfingered examples of West Gulf Coastal Plain Nonriverine Wet Hardwood Flatwoods (CES203.548)) tend to support hardwood forests or swamps, often heavily oak-dominated with species tolerant of some inundation, such as *Quercus phellos* and *Quercus laurifolia,* with sparse coverage of wetland herbs, such as *Carex glaucescens*. Some swales support unusual pockets of *Fraxinus caroliniana* and *Crataegus* spp.

Dynamics: The difference in the dynamics between this system and the "wet" hardwood flatwoods of the region, i.e., West Gulf Coastal Plain Nonriverine Wet Hardwood Flatwoods (CES203.548), is the different structure: the wetter type occurs as a closed forest, the dry/mesic (xero-hydric) one as a more open forest or woodland (with an open canopy, a full herbaceous expression, and few shrubs). The fire regime is different as well: the xero-hydric type is short-interval, low-intensity, low-severity versus medium- to long-interval, low-intensity, high-severity for the wet one (D. Zollner pers. comm. 2006).

Component Associations:
- *(Crataegus opaca) / Schizachyrium scoparium - Panicum virgatum - Croton capitatus* Seasonally Flooded Herbaceous Vegetation (CEGL003974, G2G3)
- *Panicum hemitomon - Ludwigia sphaerocarpa* Herbaceous Vegetation (CEGL008478, G1)
- *Pinus taeda - Quercus alba - (Fagus grandifolia) / Ilex opaca / Smilax pumila - Mitchella repens* Forest (CEGL007525, G3G4)
- *Pinus taeda - Quercus stellata / Crataegus* spp. Woodland (CEGL002112, G2G3)
- *Quercus alba - Carya alba / Symplocos tinctoria / Mitchella repens* Forest (CEGL007980, G3?)
- *Quercus stellata - Pinus taeda* Flatwoods Depression Forest (CEGL008587, G2G3)

Spatial Characteristics

Spatial Summary: This system forms a matrix in the Arkansas Coastal Plain in terraces along the lower Ouachita River (D. Zollner pers. comm. 2006). This dry (to mesic) pine-hardwood system is a matrix one, the wetter type (CES203.548) is a small- to large-patch system (D. Zollner pers. comm. 2006).

Adjacent Ecological Systems:
- Red River Large Floodplain Forest (CES203.065)
- West Gulf Coastal Plain Nonriverine Wet Hardwood Flatwoods (CES203.548)

Distribution

Range: This system is found in the inland portions of the West Gulf Coastal Plain, on nonriverine, Pleistocene high terraces.
Divisions: 203:C
Nations: US
Subnations: AR, LA, OK, TX
Map Zones: 36:C, 37:C, 44:C

WESTERN CANADIAN BOREAL ASPEN PARKLAND (CES103.517)

CLASSIFIERS

Classification Status: Standard

Primary Division: Boreal (103)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
National Mapping Codes: ESLF 9395

CONCEPT

Summary: This ecological system ranges from the Peace River Parkland region of west-central Alberta, west into British Columbia along lower elevation river valleys. It occurs well within the boreal forest region of Alberta, and while it has some structural and floristic similarities to Northwestern Great Plains Aspen Forest and Parkland (CES303.681), the environmental setting and climate regime are distinctly different. The climate in this region is mostly subhumid low boreal with short, warm summers and cold, long winters. It is apparently slightly drier in this region than in the surrounding Dry Mixedwood region of Alberta. Much of this region is covered with undulating to kettled glacial till. In Alberta, this parkland is characterized by gently rolling glacio-lacustrine plains, and steep south-facing grassy and forested slopes along the Peace River. Elevations range from 300 m along the Peace River near Peace River townsite, to 800 m in the Grande Prairie area; they are probably a bit higher in eastern British Columbia. *Populus tremuloides* is the predominant tree in this system, although *Picea glauca* also occurs. Common associates are *Betula papyrifera* and *Populus balsamifera* with an understory of mixedgrass species and tall shrubs. More poorly drained sites may contain *Salix* spp., *Calamagrostis canadensis*, and *Carex* spp. Some of the common shrubs include *Amelanchier alnifolia, Symphoricarpos albus, Symphoricarpos occidentalis, Prunus virginiana, Salix bebbiana*, and *Rosa acicularis*. Prairie communities can occur in and around the patches of forest, with species composition of *Koeleria macrantha, Danthonia californica, Hesperostipa comata* (drier sites), *Hesperostipa curtiseta, Hesperostipa spartea*, and *Artemisia frigida*. Much of the area where this system once occurred has been converted to agricultural lands. Fire may have constituted an important dynamic in this system and prevents boreal conifer species such as *Picea glauca* and *Abies balsamea* from becoming too established in this system.
Classification Comments: This system can grade into Eastern Great Plains Tallgrass Aspen Parkland (CES205.688) to the east, which has a predominance of tallgrass species in the understory compared to the more mixedgrass species in this system.

DESCRIPTION

Environment: Climate in the range of this system is mostly subhumid low boreal with short, warm summers and long, cold winters. It is apparently slightly drier in this region than in the surrounding Dry Mixedwood region of Alberta. Undulating to kettled glacial till predominates this region.
Vegetation: *Populus tremuloides* dominates this system. Common associates are *Populus balsamifera* and *Betula papyrifera* along with an understory of mixedgrass and tall-shrub species.
Dynamics: Fire is likely the most important natural dynamic allowing for a more open structure and preventing this system from containing more conifer species. However, much of the area where this system once occurred has been converted to agricultural lands. Some small patches of the aspen parkland remain along the edges of the agricultural areas above the Peace River, but much of the prairies have been completely eliminated.

DISTRIBUTION

Range: This system is found in the boreal-grassland transition region of the Peace River Parkland in west-central Alberta, extending west into British Columbia along the river and its major tributaries. Its distribution elsewhere in Canada needs to be explored and clarified.
Divisions: 103:C
Nations: CA
Subnations: AB, BC
TNC Ecoregions: 140:C

WESTERN GREAT PLAINS RIPARIAN (CES303.956)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Mixed Upland and Wetland
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Riparian Mosaic; Woody-Herbaceous; Riverine / Alluvial; Very Short Disturbance Interval; Flood Scouring
Non-Diagnostic Classifiers: Intermittent Flooding; Short (<5 yrs) Flooding Interval; Floodplain; Fluvial; Lowland [Lowland]; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Alluvial fan; Toeslope/Valley Bottom; Arroyo; Temperate [Temperate Xeric]; Broad-Leaved Deciduous Tree; Broad-Leaved Deciduous Shrub; Evergreen Sclerophyllous Shrub; Graminoid
National Mapping Codes: ESLF 9329

CONCEPT

Summary: This ecological system is found in the riparian areas of medium and small rivers and streams throughout the western Great Plains. It is most common in the Shortgrass Prairie and extends west as far as the Rio Grande in New Mexico, north into the Wyoming Basins and east into southwestern Nebraska, western Kansas and panhandles of Oklahoma and Texas. It includes primarily small, often narrow feeder streams that originate on the plains. However, it also includes reaches of major rivers, including the North and South Platte, portions of the Arkansas, Cimarron, Canadian and upper Pecos rivers, that have relatively narrow floodplains when compared to the Platte, for example. This system is found on alluvial soils in highly variable landscape settings, from deep cut ravines to wide, braided streambeds. The smaller streams hydrologically tend to be flashy and may dry down completely for some portion of the year. Main-stem larger rivers have a less well-developed floodplain than their downstream counterparts (e.g., the Platte and Missouri rivers), that are classified as floodplain systems. Water sources for this riparian system include snowmelt runoff, springs and summer rains. This system includes numerous smaller prairie rivers and streams that are often groundwater-fed, such as the Arikaree River and the Republican River. Dominant vegetation shares much with generally drier portions of larger floodplain systems downstream, but overall abundance of vegetation is generally lower. Communities within this system range from riparian forests and shrublands to herbaceous vegetation and gravel/sand bars. Dominant species include *Artemisia cana ssp. cana, Forestiera pubescens, Panicum obtusum, Panicum virgatum, Pascopyrum smithii, Populus deltoides, Salix amygdaloides, Salix exigua, Schizachyrium scoparium*, and *Sporobolus cryptandrus*. On the North Platte in southeastern Wyoming, *Fraxinus pennsylvanica* may be present to dominant. These areas are often subjected to heavy grazing and/or agriculture and can be heavily degraded. *Tamarix* spp., *Elaeagnus angustifolia*, and less desirable grasses and forbs can invade degraded examples up through central Colorado. Groundwater depletion and reduction in overbank flooding has resulted in additional species changes. In Texas, several cover types are represented within this system, including forest, woodland, shrubland, and herbaceous vegetation. Forests and woodlands may have species such *Populus deltoides, Salix nigra, Celtis laevigata, Juniperus ashei*, and *Juniperus pinchotii*. *Quercus fusiformis* occurs here at the western edge of its range but may be locally dominant. Shrubland portions are frequently dominated by *Prosopis glandulosa* but may also contain species such as *Salix nigra* and *Sapindus saponaria var. drummondii*. Herbaceous vegetation may be represented by marshes associated with small drainages and dominated by *Schoenoplectus* spp., *Eleocharis* spp., and other sedges.
Classification Comments: All the riparian/floodplain/alluvial systems of the Great Plains region need to be revisited for naming conventions, along with better definitions of conceptual boundaries. There is much apparent overlap in their concepts and distribution, and the names add to the confusion. In particular, the difference between "riparian" and "floodplain" usage in the names needs revisiting and possible changing. These systems include Northwestern Great Plains Floodplain (CES303.676), Northwestern Great Plains Riparian (CES303.677), Western Great Plains Floodplain (CES303.678), and Western Great Plains Riparian (CES303.956).
Similar Ecological Systems:
- Edwards Plateau Riparian (CES303.652)
- Southeastern Great Plains Riparian Forest (CES205.709)

- High Plains: Riparian Live Oak Forest (2702) [CES303.678.3] (Elliott 2011) Finer

DESCRIPTION

Environment: This riparian system lacks a broad, well-developed floodplain. It includes primarily small, often narrow feeder streams that originate on the plains. However, it also includes reaches of major prairie rivers, including the North and South Platte, portions of the Arkansas, Cimarron, Canadian and upper Pecos rivers, that have relatively narrow, less well-developed floodplain when compared to their downstream counterparts (e.g., the Platte and Missouri rivers) that are classified as floodplain systems. Water sources for this

riparian system include snowmelt runoff, springs and summer rains. The substrates are highly variable depending on landscape settings that range from deep-cut ravines to wide, braided streambeds, but tend to occur on relatively young alluvial substrates. In Texas this system occurs along headwater streams and generally occurs over upland soils that have developed in place over a variety of bedrock types, often limestone in parts of Texas (TPWD Phase 1). This system occurs along drainages that may be intermittent and tend to be dominated by erosional processes (as opposed to depositional processes) for example within the drainage of the Clear Fork of the Middle Brazos River of Texas (Elliott 2011). As this system is mapped by TPWD (Elliott 2011), it by definition occurs outside of areas mapped as bottomland soils. Soils are therefore mapped with soils of the surrounding uplands.

Vegetation: In Texas, the TPWD Phase 1 mapping represents the southeasternmost part of the range of the system and shares some similarity with Edwards Plateau Riparian (CES303.652) and Southeastern Great Plains Riparian Forest (CES205.709) to which it is adjacent. In the Phase 1 mapping project, this system is restricted to the drainages of the Clear Fork of the Middle Brazos River (Elliott 2011). Several cover types are represented within this system, including forest, woodland, shrubland, and herbaceous vegetation. Forests and woodlands may have species such *Populus deltoides, Salix nigra, Celtis laevigata, Juniperus ashei*, and *Juniperus pinchotii*. *Quercus fusiformis* occurs here at the western edge of its range but may be locally dominant (Elliott 2011). Shrubland portions are frequently dominated by *Prosopis glandulosa* but may also contain species such as *Salix nigra* and *Sapindus saponaria var. drummondii*. Herbaceous vegetation may be represented by marshes associated with small drainages and dominated by *Schoenoplectus* spp., *Eleocharis* spp., and other sedges. Grasslands associated with riparian corridors may also be present and will generally be somewhat more mesic than grasslands of the surrounding landscape (Elliott 2011).

Dynamics: Hydrologically, these sites tend to have a more flashy flood regime hydrology and narrow, less well-developed floodplains than those found on larger rivers, which are classified as floodplain systems. These streams may dry down completely for some portion of the year. Water sources for this riparian system are largely snowmelt runoff, springs and summer rains. This system includes numerous smaller prairie rivers and streams that are often also groundwater-fed, such as the Arikaree River and the Republican River.

From CNHP (2010b): Fluvial processes such as channel narrowing, meandering, and flood deposition play a key role in the dynamics of Western Great Plains streams (Friedman et al. 1996, Scott et al. 1996). Various combinations of these three factors may be acting at any particular site, depending on geologic and climate factors, including flow variability, sediment load, and gradient. Channel narrowing results when the stream abandons a portion of the former channel bed or when flow ceases in a channel. Narrowing happens when a period low flow prevents the reworking of the entire channel bed, and allows vegetation to establish. Newly established vegetation reduces erosion and promotes the deposition of fine sediment. On meandering streams, cutbanks on the outside bends gradually erode and the sediments are deposited downstream as point bars on the insides of bends. Vegetation is able to establish on these newly created moist surfaces. Flood deposition can produce bare, moist surfaces for tree establishment that are above the normal channel bed, and protected from normal flow-related disturbance.

Streamflows are highly variable in Western Great Plains streams. It is not known how much flows have changed since settlement, but a certain amount of intra- and inter-annual variation appears to be normal (Matthews 1988). Nearly all prairie steams are susceptible to lack of water during some years, if not annually. Although most streams receive groundwater inflow, recharge to groundwater is low due to limited precipitation, and water loss to evapotranspiration can be significant. The minimal to moderate groundwater inflow and the large loss of both groundwater and surface water to evapotranspiration resulted in many high plains streams having little to no flow under presettlement conditions, except during spring floods (Covich et al. 1997). Since settlement, variation in water flow is regulated by dams and diversions, groundwater levels have been reduced, agricultural activities have increased siltation rates and introduced both non-native species and chemical changes, and native grazers have been largely replaced by domestic cattle. Possible effects of altered fire regime in uplands are not known.

Additional factors affecting the dynamics of this system include drought and grazing. Riparian vegetation is affected by climatic drought that reduces soil moisture in the unsaturated zone and decreases streamflows, which reduces recharge and lowers the alluvial water table (Friedman et al. 1997). The elimination of beavers from most of the plains watersheds probably decreased water storage and increased variability in plains streams, although some of these changes were later reversed by dam construction (Friedman et al. 1997). The replacement of native grazers, especially bison, with fenced cattle has changed the regeneration patterns of cottonwood since settlement.

Component Associations:

- *Artemisia cana / Pascopyrum smithii* Shrubland (CEGL001072, G4)
- Great Plains Riverine Gravel Flats Sparse Vegetation (CEGL005223, GNR)
- *Populus deltoides (ssp. wislizeni, ssp. monilifera) / Salix exigua* Woodland (CEGL002685, G3)
- *Populus deltoides / Panicum virgatum - Schizachyrium scoparium* Woodland (CEGL001454, G2)
- *Symphoricarpos occidentalis* Shrubland (CEGL001131, G4G5)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:

- Northwestern Great Plains Canyon (CES303.658)
- Southeastern Great Plains Riparian Forest (CES205.709)

DISTRIBUTION

Range: This system is found in riparian areas of medium and small rivers and streams throughout the western Great Plains. It is most common in the Central Shortgrass Prairie and Southern Shortgrass Prairie, but extends west as far as the Rio Grande in New Mexico and into the Wyoming Basins. This system occurs on the North Platte, South Platte, Cache La Poudre, Arkansas, Purgatoire, middle

Rio Grande, the upper reaches of the Cimarron, Canadian, and Pecos rivers, and smaller prairie rivers and streams, such as the Arikaree and Republican rivers. Its occurrence is confirmed for Texas (Elliott 2011).

SPARSELY VEGETATED

ACADIAN-NORTH ATLANTIC ROCKY COAST (CES201.573)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Rocks and Derived Substrates of the Immediate Coast
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Long (>500 yrs) Persistence; Lowland; Glaciated; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Consolidated; Unconsolidated; W-Landscape/Medium Intensity
National Mapping Codes: ESLF 3189

CONCEPT

Summary: This system encompasses non-forested uplands along the immediate Atlantic Coast, from north of Cape Cod to the Canadian Maritimes. It is often a narrow zone between the high tide line and the upland forest; this zone becomes wider with increasing maritime influence. The substrate is rock, sometimes with a shallow soil layer, and tree growth is prevented by extreme exposure to wind, salt spray, and fog. Slope varies from flat rock to cliffs. Cover is patchy shrubs, dwarf-shrubs and sparse vascular vegetation, sometimes with a few stunted trees. Many coastal islands have graminoid-shrub areas that were maintained by sheep grazing and now persist even after grazing has ceased.

ALASKA ARCTIC ACTIVE INLAND DUNE (CES102.212)

CLASSIFIERS

Conf.: 1 - Strong
Classification Status: Standard
Primary Division: Arctic (102)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Diagnostic Classifiers: Dune (Substrate); Polar [Polar Continental]; W-Patch/High Intensity
Non-Diagnostic Classifiers: Sand Soil Texture; Unconsolidated
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Unconsolidated material
National Mapping Codes: EVT 2713; ESLF 3195; ESP 1713

CONCEPT

Summary: Inland active dunes are a minor but widespread system across the Alaskan arctic. The dunes or blowouts are dry to mesic sand deposits, and the slacks may be wet silts and sands. This system's patch size is small. Some common vegetation types include those dominated by low and tall willows, mesic herbaceous meadows, and wet sedge meadows. Low- and tall-willow communities are dominated by *Salix glauca, Salix alaxensis*, and *Salix niphoclada (= Salix brachycarpa ssp. niphoclada)*, along with *Bromus inermis var. pumpellianus (= Bromus pumpellianus)*. The mesic herbaceous meadows include *Leymus mollis, Bromus inermis var. pumpellianus*, and *Chamerion latifolium (= Epilobium latifolium)*. Additional herbaceous species include *Carex obtusata, Carex lachenalii, Festuca rubra, Festuca brachyphylla, Astragalus alpinus*, and others. Ponds and wet depressions may occur in the slacks and support wet herbaceous communities dominated by *Carex aquatilis* and *Arctophila fulva*.
Classification Comments: This system is known as Active Inland Dune by the Alaska Natural Heritage Program.
Related Concepts:

- III.A.3.a - Wet sedge meadow tundra (Viereck et al. 1992) Intersecting
- III.B.1.a - Seral herbs (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: Active inland dunes occur as remnants of a larger system of dunes and sandsheets that developed under the climatic conditions of the late Pleistocene. Strong storm winds carried glacio-fluvial silts and sands across vast areas of northwestern North America. Most of these sand deposits have been stabilized by forest and tundra vegetation, but areas of active transport and deposition still exist. Some of the most noteworthy active areas are the Kobuk Dunes in western Alaska and the Carcross Dunes in southern Yukon. Dunes are also common where rivers have cut through sandsheets, and new dunes are still forming along rivers with high sediment loads and outwash deposits. These active dunes share many floristic elements and geomorphic processes (Parker and Mann 2000). The main disturbance process is the transport and deposition of sand. Common landforms include transverse and longitudinal dunes, sandsheets, desert pavements, blowouts, and interdune slacks. The dunes or blowouts are dry to mesic sand deposits, and the slacks may be wet silts and sands. Tundra vegetation has stabilized most of these sand deposits, but small blowouts and areas of active transport and deposition still exist.

DISTRIBUTION

Range: This system occurs throughout arctic Alaska, from the Bristol Bay lowlands in southwestern Alaska to the North Slope on the Arctic Ocean.

ALASKA ARCTIC TIDAL FLAT (CES102.208)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Arctic (102)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Wetland
Diagnostic Classifiers: Tidal flat; Polar [Polar Hyperoceanic]; Tidal / Estuarine; Alga
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Alga
National Mapping Codes: EVT 2710; ESLF 3197; ESP 1710

CONCEPT

Summary: Tidal flats are subject to regular tidal inundation, have <10% vascular species cover, and are dominated by bare ground or algae. This system often forms a narrow band along oceanic inlets, deltas, and tidal marshes. Algae are the dominant vegetation.
Classification Comments: This system is known as Tidal Flat by the Alaska Natural Heritage Program, and also includes Aleutian Tidal Flat.
Similar Ecological Systems:
- Temperate Pacific Intertidal Flat (CES204.879)

Related Concepts:

ALASKAN PACIFIC MARITIME ALPINE FLOODPLAIN (CES204.161)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Alpine/AltiAndino; Riparian Mosaic [Trees, shrublands, meadows]; Temperate [Temperate Oceanic]; Riverine / Alluvial
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); Alluvial terrace; Braided channel or stream
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Unconsolidated material
National Mapping Codes: EVT 2676; ESLF 3198; ESP 1676

CONCEPT

Summary: This system includes active alpine and subalpine floodplains and consists of a complex of riparian vegetation, including gravel bars, herbaceous vegetation, and dwarf-, low, or tall shrub. Riparian zones are characterized by frequent flooding, shifting channels, and transport and deposition of alluvium. Tall and low shrubs reach their maximum elevation in riparian zones. This may be due to protection of the valley bottom and deeper winter snowpack or the favorable growing conditions of the riparian zone. Flooding regime and soil moisture control the pattern of vegetation cover. Common species occurring in frequently flooded areas include *Chamerion latifolium*, *Chamerion angustifolium*, *Lupinus nootkatensis*, *Salix* spp., and *Alnus viridis ssp. sinuata*. Species occurring in more stabilized areas of the floodplain may include *Salix reticulata*, *Salix arctica*(?), *Phyllodoce aleutica*, *Harrimanella stelleriana*, *Luetkea pectinata*, and *Sanguisorba canadensis*.
Classification Comments: This system is known as Alpine Floodplain by the Alaska Natural Heritage Program.

ALASKAN PACIFIC MARITIME ROCKY COASTLINE (CES204.167)

CLASSIFIERS

Classification Status: Standard

Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear, Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Rocks and Derived Substrates of the Immediate Coast; Temperate [Temperate Oceanic]; Salt Spray; Beach (Landform); Coast
Non-Diagnostic Classifiers: Sea cliff; Shoreline; Cliff (Landform)
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Unconsolidated material
National Mapping Codes: EVT 2667; ESLF 3199; ESP 1667

CONCEPT

Summary: Sea cliffs, rocky headlands, and cobble beaches occur commonly along the North Pacific coastline. Cobble beaches are associated with cliff and bluff systems or coarse-textured glacial deposits (i.e., coastal moraines). Beaches are often steep and feature distinct storm berms. These are typically high-energy environments exposed to wave action and storm swell. Cobble beaches may have a mixture of silts and sands below the surface (particularly in outwash plains), but the fine material is buried and not subjected to wind and water transport. Beach meadows may occupy well-drained stable portions of the upper beach. Vegetation typically includes herbaceous species with varying degrees of tolerance for salt spray and wind abrasion. Common species found on beach meadows on cobble substrates include *Leymus mollis, Lathyrus japonicus var. maritimus, Honckenya peploides, Mertensia maritima, Ligusticum scoticum, Potentilla villosa,* and *Lupinus nootkatensis.*

Sea cliffs and rocky headlands are sparsely vegetated or barren landscapes that are usually exposed to wind and salt spray. Forbs, grasses, shrubs, and stunted trees establish on ledges and in cracks. A variety of species may occur depending on level of salt exposure, steepness, aspect, and available microsites. Shrubs such as *Alnus viridis ssp. sinuata* or *Rubus spectabilis* may be present but usually account for less than 5% of the total vascular plant cover. Herbaceous cover is diverse and may include many of the following species: *Aruncus dioicus var. acuminatus, Heuchera glabra, Potentilla villosa, Phegopteris connectilis, Carex macrochaeta, Deschampsia* spp., *Lupinus nootkatensis, Campanula* spp., *Prenanthes alata, Rhodiola rosea,* and *Chamerion latifolium*. *Picea sitchensis* may also occupy these rocky headlands and often does. They are characterized by somewhat stunted growth, usually with branches from top to bottom of bole. Epiphytic lichens are abundant in this system.
Classification Comments: This system is known as Rocky Coastline by the Alaska Natural Heritage Program. It is distinguished from sandy beach systems by the absence of sand deposition and transport.
Related Concepts:
- III.B.2.a - Mixed herbs (Viereck et al. 1992) Broader. not a good match

DESCRIPTION

Environment: Sea cliffs, rocky headlands, and cobble beaches occur commonly along the North Pacific coastline. Cobble beaches are associated with cliff and bluff systems or coarse-textured glacial deposits (i.e., coastal moraines). Beaches are often steep and feature distinct storm berms. These are typically high-energy environments exposed to wave action and storm swell. Cobble beaches may have a mixture of silts and sands below the surface (particularly in outwash plains), but the fine material is buried and not subjected to wind and water transport. Beach meadows may occupy well-drained stable portions of the upper beach.
Vegetation: Vegetation typically includes herbaceous species with varying degrees of tolerance for salt spray and wind abrasion. ALEUTIAN ROCKY HEADLAND AND SEA CLIFF (CES105.305)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Boreal [Boreal Oceanic]; Salt Spray
Non-Diagnostic Classifiers: Headland; Sea cliff
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Boulder, gravel, cobble, or talus
National Mapping Codes: EVT 2716; ESLF 3200; ESP 1716

CONCEPT

Summary: This ecological system includes rocky headlands and sea cliffs. Sea cliffs typically occur below 50 m elevation; however, on some extremely exposed cliffs, such as those on outer headlands, salt spray from winter storms may affect cliffs at 100-200 m elevation. Vegetation cover is typically sparse to absent. Frequent exposure to salt spray distinguishes this system from inland and alpine rock outcrops and cliffs. In addition to salt spray, wind and wave erosion, desiccation, and slope failures create a harsh growing environment. Forbs, grasses and shrubs establish on ledges and in cracks. On Amchitka Island, Shacklette et al. (1969) described several sea cliff communities, including *Eurhynchium-Puccinellia-Caloplaca*, *Potentiea-Draba-Saxifraga, Xanthoria-Ramalina*, and (on less steep cliffs) *Leymus-Ligusticum-Anemone*. On the Alaska Peninsula, dominance may shift to *Alnus viridis ssp. sinuata, Rubus spectabilis, Aruncus dioicus var. acuminatus, Heuchera glabra, Potentilla villosa, Phegopteris connectilis, Carex macrochaeta, Deschampsia* spp., *Lupinus nootkatensis, Campanula* spp., and *Chamerion latifolium*.
Classification Comments: This system is known as Rocky Headland and Sea Cliff by the Alaska Natural Heritage Program.

CENTRAL ATLANTIC COASTAL PLAIN SANDY BEACH (CES203.064)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Beach (Substrate); Coast
National Mapping Codes: ESLF 3162

CONCEPT

Summary: This system includes ocean beaches along the Mid-Atlantic coast ranging from approximately Bodie Island, North Carolina, to approximately Myrtle Beach, South Carolina, a range which is largely represented by Omernik Level IV Ecoregion 63g (EPA 2004). Examples of this system generally include the outermost zone of coastal vegetation extending seaward from foredunes on barrier islands and also limited wash-over flats behind breached foredunes. Substrates consist of unconsolidated sand and shell sediments that are constantly shifting. Although these habitats are situated just above the mean high tide limit, they are constantly impacted by waves and are prone to major impact from storm surges and hurricane events. Under normal conditions constant salt spray and rainwater maintain generally moist conditions. Dynamic disturbance regimes largely limit vegetation to pioneering, salt-tolerant, succulent annuals.
Classification Comments: To the north this system is replaced by Northern Atlantic Coastal Plain Sandy Beach (CES203.301) and to the south by Southern Atlantic Coastal Plain Sea Island Beach (CES203.383). This system provides habitat for the threatened plant seabeach amaranth (*Amaranthus pumilus*).
Similar Ecological Systems:
- Northern Atlantic Coastal Plain Sandy Beach (CES203.301)

DESCRIPTION

Environment: The beach includes the sand intertidal shore, and the low-gradient sand above the daily high tide line, which is between the foredune and the Atlantic Ocean. This area of upper beach is affected by wind and salt spray, seasonal high tides, and storm surge. Examples of this system generally extend seaward from foredunes on barrier islands and also limited overwash flats behind breached foredunes. Substrates consist of unconsolidated sand and shell sediments that are constantly shifting.
Dynamics: The process of sand movement due to the forces of wind and water are part of the natural dynamics of beach ecosystems. This includes transport of sand along the coast, and movement of sand by wind or water between the dunes, beach and subtidal areas. If not restricted by infrastructure or engineered hard structures, beaches and dunes can migrate as coastlines change over time in response to the action of wind and water. The beaches of the coast of the Carolinas are affected by two tides per day. Extensive construction of high, artificial dunes along the Atlantic Coast has reduced the extent of these habitats by increasing oceanside beach erosion and eliminating the disturbance regime that creates and maintains overwash flats.

Component Associations:
- *Cakile edentula ssp. edentula - Chamaesyce polygonifolia* Sparse Vegetation (CEGL004400, G4G5)
- *Sesuvium portulacastrum - Atriplex* spp. - *Suaeda* spp. Sparse Vegetation (CEGL004406, G3)

DISTRIBUTION

Range: This system ranges along the Mid-Atlantic coast ranging from approximately Bodie Island, North Carolina, to approximately Myrtle Beach, South Carolina, a range which is largely represented by Omernik Level IV Ecoregion 63g, Carolinian Barrier Islands and Coastal Marshes (EPA 2004), but extends southward into the coastal portion of 63h, Carolina Flatwoods (EPA 2004) in Horry County, South Carolina.

CENTRAL CALIFORNIA COAST RANGES CLIFF AND CANYON (CES206.903)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Canyon Mosaic; Cliff (Substrate); Talus (Substrate); Mediterranean [Mediterranean Xeric-Oceanic]; Canyon
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Xeric; Landslide; Cliff (Landform)
National Mapping Codes: ESLF 3169

CONCEPT

Summary: Found from foothill and montane elevations of California's Coast Ranges, these are barren and sparsely vegetated areas (<10% plant cover) of steep cliff faces, narrow canyons, and smaller rock outcrops of various igneous, sedimentary, and metamorphic bedrock. This system also includes unstable scree and talus slopes typically occurring below cliff faces. Scattered vegetation may include *Pseudotsuga menziesii*, *Pinus contorta var. murrayana*, *Pinus ponderosa*, and *Pinus jeffreyi*. There may be shrubs including species of *Arctostaphylos* or *Ceanothus*. Soil development is limited as is herbaceous cover.

DISTRIBUTION

CENTRAL INTERIOR ACIDIC CLIFF AND TALUS (CES202.689)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Non-Diagnostic Classifiers: Talus (Landform); Acidic Soil; Cliff (Landform)
National Mapping Codes: ESLF 3149

CONCEPT

Summary: This system is found primarily in the Interior Highlands, including the Ozarks, Ouachita, and Interior Low Plateau ecoregions, extending marginally north and west along the Missouri and Mississippi rivers. Sandstone outcrops and talus ranging from moist to dry typify this system. It is typically sparsely vegetated; however, on moister sites with more soil development, several fern species and sedges (*Carex* spp.) can establish. Wind and water erosion are the major dynamic processes influencing this system.
Classification Comments: In Kentucky, this system covers the sandstone cliffs of the Shawnee Hills (Interior Low Plateau). In Illinois, one exemplary example is the "Garden of the Gods" in the Shawnee National Forest.
Similar Ecological Systems:
- North-Central Appalachian Acidic Cliff and Talus (CES202.601)

Related Concepts:
- Dry Sandstone Cliff (Evans 1991) Intersecting
- Moist Sandstone Cliff (Evans 1991) Intersecting

DESCRIPTION

Environment: Sandstone outcrops and talus ranging from moist to dry typify this system. Examples range from sparsely to moderately well-vegetated. Soil development is limited to cracks and ledges. Slope aspect and angle are strongly related to the amount of available moisture on a site. Steep, south- or west-facing slopes are drier than less steep east- or north-facing slopes. Some sites have seepage along the cliff face. Shading by adjacent forests can impact cliffs below the height of nearby trees.
Vegetation: This system is typically sparsely vegetated; however, on moister sites with more soil development, several fern species and sedges (*Carex* spp.) can establish. Some taxa that could be present include *Ribes cynosbati, Deschampsia flexuosa, Dryopteris marginalis*, and *Dennstaedtia punctilobula*, as well as *Carex interior, Carex lurida, Carex leptalea, Parnassia grandifolia, Rhynchospora capillacea, Osmunda cinnamomea, Rhynchospora capitellata, Heuchera parviflora var. puberula*, and *Xyris jupicai* on wetter sites.
Dynamics: Wind and water erosion are the major dynamic processes influencing this system.

Component Associations:
- *(Carex interior, Carex lurida) - Carex leptalea - Parnassia grandifolia - Rhynchospora capillacea* Herbaceous Vegetation (CEGL002404, G2G3)
- *(Hydrangea arborescens, Ribes cynosbati) / Deschampsia flexuosa - Dryopteris marginalis - Dennstaedtia punctilobula* Shrubland (CEGL007820, G2?)
- Chert Ozark Dry Cliff Sparse Vegetation (CEGL002285, G3?)
- Chert Ozark Moist Cliff Sparse Vegetation (CEGL002288, G2G3)
- Igneous Ozark Dry Cliff Sparse Vegetation (CEGL002286, G4)
- Igneous Ozark Moist Cliff Sparse Vegetation (CEGL002289, G4Q)
- Igneous Ozark Talus Sparse Vegetation (CEGL005203, G4)
- *Osmunda cinnamomea - Rhynchospora capitellata - Heuchera parviflora var. puberula - Xyris jupicai* Herbaceous Vegetation (CEGL007837, G1Q)
- Sandstone Interior Highlands Talus Sparse Vegetation (CEGL002309, G4G5)
- Sandstone Midwest Dry Cliff Sparse Vegetation (CEGL002045, G4G5)
- Sandstone Midwest Moist Cliff Vegetation (CEGL002287, G4G5)

DISTRIBUTION

Range: This system is found primarily in the Interior Highlands, including the Ozark, Ouachita, and Interior Low Plateau ecoregions. It extends marginally into the Central Tallgrass Prairie Ecoregion along the Missouri and Mississippi rivers.

CENTRAL INTERIOR CALCAREOUS CLIFF AND TALUS (CES202.690)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
National Mapping Codes: ESLF 3148

CONCEPT

Summary: This system is found primarily in non-Appalachian portions of the Central Interior Division. It ranges from the Ouachitas east to the Cumberlands and north into the Western Allegheny Plateau and Lake states. Limestone and dolomite outcrops and talus distinguish this system. Examples range from moist to dry and from sparsely to moderately well-vegetated. Woodland species such as *Thuja occidentalis* can establish along the ridgetops, on ledges, and talus. Understory species can range from grassland species, such as *Andropogon gerardii* on drier slopes, to more mesic species in areas with higher moisture and more soil development. Wind and water erosion along with fire are the primary natural dynamics influencing this system. Some associations included here are rocky openings in forest stands, sometimes with moisture present from groundwater seepage. Also included are wet and dry cliffs. The flora of these wetter examples may include (across the broad range of the system) *Aconitum noveboracense, Adiantum capillus-veneris, Adoxa moschatellina, Aquilegia canadensis, Asplenium rhizophyllum, Boehmeria cylindrica, Chrysosplenium iowense, Cystopteris bulbifera, Cystopteris bulbifera, Dichanthelium depauperatum, Heuchera americana, Heuchera americana var. hirsuticaulis, Heuchera villosa var. arkansana, Hydrangea arborescens, Impatiens pallida, Lobelia siphilitica, Toxicodendron radicans*, and *Woodsia obtusa*.
Classification Comments: Similar examples in the driftless region of Minnesota, Wisconsin, Iowa and Illinois should be considered part of Paleozoic Plateau Bluff and Talus (CES202.704).
Similar Ecological Systems:
- North-Central Appalachian Circumneutral Cliff and Talus (CES202.603)
- Paleozoic Plateau Bluff and Talus (CES202.704)
- Southern Interior Calcareous Cliff (CES202.356)--includes circumneutral cliff and talus communities from southern Virginia south.
- Southern Interior Sinkhole Wall (CES202.357)

Related Concepts:
- Dry Limestone Cliff (Evans 1991) Finer
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Moist Limestone Cliff (Evans 1991) Finer
- Northern White-Cedar: 37 (Eyre 1980) Finer

DESCRIPTION

Environment: Limestone and dolomite outcrops and talus distinguish this system. Examples range from moist to dry and from sparsely to moderately well-vegetated. Soil development is limited to cracks and ledges. Slope aspect and angle are strongly related to the amount of available moisture on a site. Steep, south- or west-facing slopes are drier than less steep east- or north-facing slopes. Some sites have seepage along the cliff face. Shading by adjacent forests can impact cliffs below the height of nearby trees.
Vegetation: Examples range from moist to dry and from sparsely to moderately well-vegetated. Woodland species such as *Thuja occidentalis* can establish along the ridgetops. Understory species can range from grassland species, such as *Andropogon gerardii* on drier slopes, to more mesic species in areas with higher moisture and more soil development. The flora of some moister examples (e.g., rocky openings in forest stands, with moisture present from groundwater seepage as well as wet cliffs) includes (across the broad range of the system) *Aconitum noveboracense, Adiantum capillus-veneris, Adoxa moschatellina, Aquilegia canadensis, Asplenium rhizophyllum, Boehmeria cylindrica, Chrysosplenium iowense, Cystopteris bulbifera, Cystopteris bulbifera, Dichanthelium depauperatum, Heuchera americana, Heuchera americana var. hirsuticaulis, Heuchera villosa var. arkansana, Hydrangea arborescens, Impatiens pallida, Lobelia siphilitica, Toxicodendron radicans*, and *Woodsia obtusa*.
Dynamics: Wind and water erosion along with fire are the primary natural dynamics influencing this system. Fires could spread from more vegetated communities adjacent to calcareous cliffs and could burn vegetation on the edges of this community. A study in a similar cliff system in southern Ontario found no relationship between cliff patch size and diversity or richness (Haig et al. 2000).

Component Associations:
- *(Hydrangea arborescens, Toxicodendron radicans) / Heuchera americana - (Dichanthelium depauperatum, Woodsia obtusa)* Shrubland (CEGL004395, G3?)
- *Acer saccharum - Tilia americana - Fraxinus americana / Ostrya virginiana / Geranium robertianum* Woodland (CEGL005058, G3G5)
- *Adiantum capillus-veneris - Boehmeria cylindrica - Lobelia siphilitica* Herbaceous Vegetation (CEGL004728, G2G3)
- *Andropogon gerardii - Chasmanthium latifolium - Amsonia tabernaemontana var. salicifolia* Herbaceous Vegetation (CEGL004739, G2G3)

- *Hydrangea arborescens / Heuchera (americana var. hirsuticaulis, villosa var. arkansana) - Aquilegia canadensis* Shrubland (CEGL007819, G3?)
- *Hydrangea arborescens / Impatiens (capensis, pallida) - Heuchera villosa* Shrubland (CEGL004708, G3)
- *Impatiens pallida - Cystopteris bulbifera - Adoxa moschatellina - (Chrysosplenium iowense, Aconitum noveboracense)* Algific Talus Herb Vegetation (CEGL002387, G2)
- Limestone - Dolostone Midwest Dry Cliff Sparse Vegetation (CEGL002291, G4G5)
- Limestone - Dolostone Midwest Moist Cliff Vegetation (CEGL002292, G4G5)
- Limestone - Dolostone Midwest Talus Vegetation (CEGL002308, G4G5)
- *Quercus muehlenbergii - (Juniperus virginiana var. virginiana)* Unglaciated Bluff Woodland (CEGL004267, G2G3)
- *Rhus aromatica - Celtis tenuifolia / Carex eburnea* Shrubland (CEGL004393, G3)
- *Schizachyrium scoparium - Bouteloua curtipendula* Bedrock Bluff Herbaceous Vegetation (CEGL002245, G3G4)
- *Schizachyrium scoparium - Sporobolus compositus var. compositus - Rudbeckia fulgida var. fulgida* Wooded Herbaceous Vegetation (CEGL004078, G2)
- Small Eroding Bluffs Midwestern Sparse Vegetation (CEGL002315, GNR)
- *Thuja occidentalis / Carex eburnea - Pellaea atropurpurea* Woodland (CEGL002596, G2G3)
- *Thuja occidentalis* Cliff Woodland (CEGL002451, G3)

COLORADO PLATEAU MIXED BEDROCK CANYON AND TABLELAND (CES304.765)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Barren
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Sedimentary Rock; Temperate [Temperate Xeric]; Alkaline Soil; Aridic
Non-Diagnostic Classifiers: Moss/Lichen (Nonvascular); Cliff (Substrate); Talus (Substrate)
National Mapping Codes: ESLF 3183

CONCEPT

Summary: The distribution of this ecological system is centered on the Colorado Plateau where it is comprised of barren and sparsely vegetated landscapes (generally <10% plant cover) of steep cliff faces, narrow canyons, and open tablelands of predominantly sedimentary rocks, such as sandstone, shale, and limestone. Some eroding shale layers similar to Inter-Mountain Basins Shale Badland (CES304.789) may be interbedded between the harder rocks. The vegetation is characterized by very open tree canopy or scattered trees and shrubs with a sparse herbaceous layer. Common species includes *Pinus edulis, Pinus ponderosa, Juniperus* spp., *Cercocarpus intricatus,* and other short-shrub and herbaceous species, utilizing moisture from cracks and pockets where soil accumulates.
Classification Comments: Geographically restricted and distinct from the related, but broader Inter-Mountain Basins Cliff and Canyon (CES304.779). Shale areas are not as extensive as in shale badlands.
Similar Ecological Systems:
- Colorado Plateau Pinyon-Juniper Shrubland (CES304.766)
- Inter-Mountain Basins Cliff and Canyon (CES304.779)

Related Concepts:
- Littleleaf Mountain-Mahogany (417) (Shiflet 1994) Intersecting
- Pinyon - Juniper: 239 (Eyre 1980) Intersecting

DESCRIPTION

Environment: This system includes limestone escarpments and plateaus occurring in a relatively narrow band of unvegetated or sparsely vegetated badlands formed by the red beds of the Claron (Wasatch) Formation along the eastern edge of the Pausaugunt Plateau (Bryce Canyon) and the western edge of the Markagunt Plateau (Cedar Breaks National Monument) (Graybosch and Buchanan 1983). It includes areas of which often 90% of the exposed surface consists of barren rock. It forms, or includes, areas of fixed bedrock forming the vertical or near-vertical parts on the plateau faces. The rocks forming such areas are predominantly limestone-capped plateaus. These areas are highly erodible and form the basic scenic structure of Bryce Canyon and Cedar Breaks national parks. The area is generally too steep to allow any significant soil development. Scattered plants obtain a precarious foothold in the crevices of the rocks. Knolls may form at the base of the cliffs.

This ecological system also includes sandstone and shale escarpments, which form, or include, areas of fixed bedrock forming the vertical or near-vertical parts of canyon walls and plateau faces. The scenic cliffs of the East Tavaputs area, e.g., the Book Cliffs, are excellent examples of this. The rocks forming such areas are predominantly sandstone and shale with some limestone and marlstone. These areas are unstable and rocks are frequently rolling down onto the talus slopes below (often forming Inter-Mountain Basins Shale Badland (CES304.789)). The area is generally too steep to allow any significant soil development. Scattered plants obtain a precarious foothold in the crevices of the rocks. Knolls may form at the base of the cliffs. The larger drainages (e.g., East Fork Parachute Creek) plunge several hundred feet at this escarpment, which creates scenic and lush hanging gardens. Many of these escarpments are over 1000 feet in height and provide excellent habitat for cliff-nesting birds such as peregrine falcons and golden eagles.

The Claron limestone, a Tertiary deposit, is divisible into Red Eocene beds and White Oligocene beds, which differ somewhat in presence or absence of pigmentation in the form of iron and manganese oxides, and in amounts of sand and conglomerates in the limestone (Graybosch and Buchanan 1983). The Claron Formation is characterized by a rapid rate of erosion, largely a function of creep resulting from winter freeze-thaw activity and wash away by summer thunderstorm runoff (Graybosch and Buchanan 1983). Freeze-thaw cycles are most pronounced on south-facing slopes. Soil development is limited. Infiltration rates are low and runoff high.
Vegetation: For the most part, this system is sparsely vegetated. Small patches of scattered trees and shrubs may occur. These small vegetated patches are usually dominated by conifer trees and may include *Abies concolor, Juniperus scopulorum, Picea pungens, Pinus flexilis, Pinus longaeva, Pinus ponderosa,* and *Pseudotsuga menziesii*. If a shrub layer exists, it may include *Acer glabrum, Amelanchier utahensis, Arctostaphylos patula, Ceanothus martinii, Cercocarpus montanus, Cercocarpus intricatus, Juniperus communis, Mahonia repens, Purshia tridentata, Ribes cereum,* and *Gutierrezia sarothrae*. Grasses and forbs, if present, may include *Astragalus kentrophyta, Cirsium arizonicum, Clematis columbiana, Leymus salinus, Eriogonum panguicense, Achnatherum hymenoides,* and *Linum kingii*.

This ecological system is noted for its high rate of endemic species of forbs, especially in Bryce Canyon. Nine of the eleven endemic species occur in the *Pinus longaeva* community, three are found in the *Pinus ponderosa - Arctostaphylos patula* plant association, and two occur in the mixed conifer type. Species that occur only in the *Pinus longaeva* type have the narrowest geographic distributions, although *Eriogonum panguicense var. panguicense* is an exception (Graybosch and Buchanan 1983). Within Bryce Canyon, most of these endemics are restricted to the Claron Formation (Graybosch and Buchanan 1983). The majority of endemic species found in southern Utah are restricted to substrates derived from a specific geologic formation (Welsh 1979). Welsh notes that most of these taxa are found in areas of exposed parent material. The distribution of endemic species in Utah is not a random one; fine-textured substrates support more species than coarser ones, and desert and foothill vegetation is richer in endemic species than montane communities (Welsh 1979).
Dynamics: This ecological system has a naturally high rate of erosion. Fires are infrequent and not an important ecological process.

Component Associations:
- *Acer negundo / Rhus trilobata* Woodland (CEGL002750, GNR)
- *Artemisia bigelovii - Ephedra (viridis, torreyana)* Talus Shrubland (CEGL003755, GNR)
- *Atriplex canescens - (Ephedra viridis) / (Muhlenbergia porteri)* Sandstone Sparse Vegetation (CEGL002927, GNR)
- *Atriplex canescens - Ephedra viridis* Talus Shrubland (CEGL001287, G4)
- *Celtis laevigata var. reticulata* Slickrock Canyon Woodland (CEGL002359, GNR)
- *Cercocarpus intricatus* Montane Shrubland (CEGL002587, GNR)
- *Cercocarpus intricatus* Slickrock Sparse Vegetation (CEGL002977, GNR)
- *Cercocarpus montanus* Rock Pavement Sparse Vegetation (CEGL002978, GNR)
- *Chrysothamnus viscidiflorus* Talus Shrubland (CEGL002347, GNR)
- *Coleogyne ramosissima* Sparse Shrubland (CEGL003834, GNR)
- *Ephedra torreyana - (Atriplex canescens, Atriplex confertifolia)* Sparse Vegetation (CEGL005801, GNR)
- *Ephedra torreyana* - (*Atriplex* spp.) / Nonvascular Gypsum Sparse Vegetation (CEGL002349, GNR)
- *Ephedra torreyana - Artemisia bigelovii* Sparse Vegetation (CEGL002350, GNR)
- *Ephedra torreyana* Sparse Vegetation (CEGL002353, GNR)
- *Fendlera rupicola* Talus Shrubland (CEGL002765, GNR)
- *Fraxinus anomala - Rhus trilobata* Talus Shrubland (CEGL003963, GNR)
- *Juniperus osteosperma - (Pinus edulis) / Coleogyne ramosissima - Purshia stansburiana - Quercus havardii var. tuckeri* Wooded Shrubland (CEGL003774, GNR)
- *Juniperus osteosperma / Artemisia nova* / Rock Woodland (CEGL000729, G5)
- *Juniperus osteosperma / Cercocarpus intricatus* Woodland (CEGL000733, GNR)
- *Pinus edulis - Juniperus osteosperma / Cercocarpus intricatus* Woodland (CEGL000779, G3)
- *Pinus edulis - Juniperus osteosperma / Ephedra viridis* Woodland (CEGL002370, G3)
- *Pinus edulis - Juniperus osteosperma / Petradoria pumila* Woodland (CEGL002332, GNR)
- *Pinus ponderosa* / Sparse Understory Woodland (CEGL002384, GNR)
- *Pinus ponderosa* Slickrock Sparse Vegetation (CEGL002972, GNR)
- *Pseudoroegneria spicata* - Cushion Plants Herbaceous Vegetation (CEGL001666, G3?)
- *Rhus trilobata - Ephedra (viridis, torreyana)* Talus Shrubland (CEGL003776, GNR)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Inter-Mountain Basins Shale Badland (CES304.789)

Adjacent Ecological System Comments: Some eroding shale layers similar to Inter-Mountain Basins Shale Badland (CES304.789) may be interbedded between the harder rocks.

COLUMBIA PLATEAU ASH AND TUFF BADLAND (CES304.081)

CLASSIFIERS

Classification Status: Standard

Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Badlands; Alkaline Soil; Silt Soil Texture; Clay Soil Texture
National Mapping Codes: ESLF 3174

CONCEPT

Summary: This ecological system of the Columbia Plateau region is composed of barren and sparsely vegetated substrates (<10% plant cover) typically derived from highly eroded volcanic ash and tuff. Landforms are typically rounded hills and plains that form a rolling topography. The harsh soil properties and high rate of erosion and deposition are driving environmental variables supporting sparse dwarf-shrubs and forbs. Characteristic species include *Grayia spinosa, Artemisia tridentata, Salvia dorrii, Achnatherum* sp., *Eriogonum* sp., *Sarcobatus vermiculatus, Purshia tridentata*, and *Atriplex confertifolia*. Characteristic forbs are short-lived annuals, including *Cleome, Mentzelia, Camissonia*, and *Mimulus* species, although these habitats often support endemic perennial forbs.
Classification Comments: Associations assigned to this system are not well-classified, but as many support G1 and G2 plant taxa, they are well sampled.
Similar Ecological Systems:
- Inter-Mountain Basins Shale Badland (CES304.789)

CUMBERLAND ACIDIC CLIFF AND ROCKHOUSE (CES202.309)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate); Acidic Soil
National Mapping Codes: ESLF 3119

CONCEPT

Summary: This sandstone cliff ecological system is found in the Cumberland Plateau and Mountain regions of the southeastern United States. Examples are extremely steep or vertical rock faces exposed along bluffs often associated with rivers. The aspect is variable but best developed on south- and west-facing sites. Plants are infrequent due to the lack of crevices capable of accumulating soil, the highly acidic nature of the bedrock, and the frequent weathering and erosion of the substrate. Lichen cover may be extensive in places, especially on the more exposed portions. These cliffs are also prone to harsh climatic conditions; frequent disturbances include drought stress and wind and storm damage. As a result, examples are characterized by sparse herbaceous cover and few, if any, trees. Vegetation consists of scattered individuals of *Asplenium montanum*, *Silene rotundifolia*, and other species rooted in crevices and erosion pockets. In some parts of its range, this system is the primary or sole habitat for rare endemic species, such as *Minuartia cumberlandensis* and *Ageratina luciae-brauniae*. This system includes a mosaic of cavelike features (often called "rockhouses") and associated sandstone box canyons in the western Appalachian foothills regions of Kentucky, Alabama, West Virginia, and possibly southeastern Ohio. Where present, the rockhouses are a prominent and diagnostic feature of the system.
Classification Comments: It is unclear whether or not this system should range into the Interior Low Plateau. Also debatable is whether or not wet and dry cliffs should be included as well as the number of different physical settings possible. See also Southern Appalachian Montane Cliff and Talus (CES202.330).
Similar Ecological Systems:
- North-Central Appalachian Acidic Cliff and Talus (CES202.601)
- Southern Appalachian Montane Cliff and Talus (CES202.330)

Related Concepts:
- Dry Sandstone Cliff (Evans 1991) Intersecting
- Moist Sandstone Cliff (Evans 1991) Intersecting
- Virginia Pine: 79 (Eyre 1980) Finer

DESCRIPTION

Environment: The rockhouses are the most unique and diagnostic feature of the system. These unusual geologic features are created by spray and rock-cracking from seasonal flowing waterfalls at the heads of canyons amidst thick layers of sandstone from the Mississippian and Pennsylvanian geologic periods. The ceiling of the rockhouse may be 50 m tall, and they can be as much as 50 m deep (Walck et al. 1996, A. Weakley pers. comm. 2006). They require sufficient flowing water and freezing and thawing to weather the thick beds of sandstone. These conditions seem to be restricted to the western margin of the Appalachian Plateau.
Vegetation: Examples of this system usually include a vegetational mosaic that includes hemlock bluffs, sandstone cliffs, or overhangs near the base of a cliff (often with a sandy area beneath the overhang which is shaded and protected from direct rainfall, as well as gladelike vegetation at the horizontal portion of the cliffs). The rockhouses in the southern parts of the range are habitats for rare vascular plant species such as *Minuartia cumberlandensis* and *Ageratina luciae-brauniae* and sometimes support populations of rare nonvascular plants as well.
Dynamics: Within rockhouses, there are three distinct habitats: ceiling, backwall, and floor. The dripline defines the outer edge of the ceiling and floor. The ceiling generally slopes back from the dripline to the backwall, which is deeply shaded and generally stays moist. Shading in the rockhouse is greater in the summer when deciduous trees in front of the rockhouse are leafed out. Light levels vary from very low at the backwall (Farrar 1998) to relatively high, especially in winter, when leaves are down (Walck et al. 1996). The combination of shade and the stable and moderate microclimate of rockhouses has maintained a habitat suitable for unusual, disjunct and endemic plants (Walck et al. 1996), including tropical ferns and bryophytes (Farrar 1998) which may have persisted in these habitats since pre-Pleistocene times when there was a tropical or subtropical climate (Farrar 1998). Temperatures inside rockhouses are higher in the winter and lower in the summer than outside the rockhouses, and while rockhouse habitats are protected from rain, they tend to have higher humidities than the surrounding areas (Walck et al. 1996).

Component Associations:
- *Asplenium montanum - Heuchera parviflora var. parviflora - Silene rotundifolia* Sparse Vegetation (CEGL004392, G3G4)
- *Heuchera parviflora var. parviflora - Trichomanes boschianum - Thalictrum mirabile - (Ageratina luciae-brauniae, Solidago albopilosa)* Herbaceous Vegetation (CEGL004301, G2)
- *Osmunda cinnamomea - Rhynchospora capitellata - Thalictrum mirabile* Cumberland Seepage Cliff Herbaceous Vegetation (CEGL008432, G1G2Q)
- *Pinus virginiana - Pinus (rigida, echinata) - (Quercus prinus) / Vaccinium pallidum* Forest (CEGL007119, G3)

- *Schizachyrium scoparium - Danthonia sericea - Liatris microcephala - (Eurybia surculosa)* Wooded Herbaceous Vegetation (CEGL004061, G3)

DISTRIBUTION

Range: This ecological system occurs in a limited area of the Cumberland Plateau of northern Alabama, northwestern Georgia, eastern Kentucky, eastern Tennessee, West Virginia, and possibly southwestern Virginia. Rockhouses also occur in southeastern Ohio (Rockhouse 349) and in western Pennsylvania (Walck et al. 1996) along Laurel and Chestnut Ridges of the Laurel Highlands in the Central Appalachian Plateau ecoregion (E. Zimmerman pers. comm. 2013).

EAST GULF COASTAL PLAIN DRY CHALK BLUFF (CES203.492)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate)
National Mapping Codes: ESLF 3117

CONCEPT

Summary: The ecological system is endemic to the Black Belt region of Alabama and Mississippi. Examples are relatively sheer surfaces of exposed chalk. Some are generally devoid of vegetation. In most cases these bluffs extend directly to the edge of rivers or streams.

DESCRIPTION

Vegetation: More information is needed. See Gunn (1985) and Morris et al. (1993).

Component Associations:
- *Adiantum capillus-veneris* Cahaba River Bluff Herbaceous Vegetation (CEGL007796, G2G3)

DISTRIBUTION

Range: This system is endemic to the Black Belt region of Alabama and Mississippi.

EASTERN GREAT PLAINS QUARTZITE ROCKY OUTCROP (CES205.697)

CLASSIFIERS

Classification Status: Standard

Primary Division: Eastern Great Plains (205)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
National Mapping Codes: ESLF 3194

CONCEPT

Summary: This system is found along outcrops of Sioux quartzite in Minnesota and South Dakota. It is found on rocky, level or hilly areas within the Northern Tallgrass Prairie (TNC Ecoregion 35) of Minnesota and South Dakota. It is characterized by a mosaic of rocky outcrops that are sparsely vegetated with scattered succulents and other vegetation such as *Opuntia fragilis, Opuntia macrorhiza, Escobaria vivipara (= Coryphantha vivipara),* and *Lomatium orientale*, as well as *Selaginella rupestris, Talinum parviflorum, Woodsia ilvensis,* and a variety of spring- and summer-blooming annuals. Soil development is minimal and restricted to patches.
Classification Comments: This system may not hold together as a system separate from a larger, surrounding system. These rocky outcrops were split from quartzite glades found in the Baraboo Hills region of Wisconsin (CES202.699). Distribution into Manitoba needs further review.

DESCRIPTION

Environment: Soil development is minimal. Most vegetation present grows in shallow, dry soil that collects in small depressions on sloping rock faces. The outcrops are composed primarily of Sioux quartzite, granite and gneiss. Extreme drought and great fluctuations in the temperature of the ground surface occur within this system (MNNHP 1993).
Vegetation: This system contains a sparse vegetation layer, with scattered succulents and many annuals, including *Opuntia fragilis, Opuntia macrorhiza, Escobaria vivipara (= Coryphantha vivipara),* and *Lomatium orientale*, as well as *Selaginella rupestris, Talinum parviflorum, Woodsia ilvensis,* and a variety of spring- and summer-blooming annuals (MNNHP 1993).
Dynamics: Fire appears to be important in maintaining this system . Trees and shrubs invade in the absence of fire. *Juniperus virginiana* is an invader throughout the range of this type, displacing the herbs, lichens, and mosses that characterize the system (MNNHP 1993).

Component Associations:
- Boreal Glaciere Talus Sparse Vegetation (CEGL005243, G2G3)
- Quartzite - Granite Rock Outcrop Sparse Vegetation (CEGL002298, G3?)

DISTRIBUTION

Range: This system is found in a very restricted area within Minnesota and South Dakota along outcrops of Sioux quartzite.

EDWARDS PLATEAU CLIFF (CES303.653)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Diagnostic Classifiers: Herbaceous; Moss/Lichen (Nonvascular); Sedimentary Rock; Limestone; Cliff (Landform)
National Mapping Codes: ESLF 3127

CONCEPT

Summary: This ecological system occurs on limestone cliff faces and lower slopes of boxed canyons of the Edwards Plateau. It usually occurs as narrow, sometimes long bands in areas where moisture is consistently more available than on adjacent slopes. Conspicuous components of this system in seepage areas include *Adiantum capillus-veneris* along the seep and *Thelypteris ovata var. lindheimeri* on nearby moist habitats. More xeric communities dominated by *Buddleja racemosa, Ungnadia speciosa, Diospyros texana, Ageratina havanensis, Garrya ovata ssp. lindheimeri, Bernardia myricifolia, Philadelphus* spp., *Styrax* spp., and *Toxicodendron radicans ssp. eximium* occur on exposures of the Edwards Plateau Formation (or geologically similar formations) of the southern Edwards Plateau. Geology is clearly the controlling process of this system, along with moisture associated with the crevices in the underlying limestone bedrock. One factor controlling the composition of communities of this system is the amount of overstory shading at the sites. Herbaceous species that may be present include *Salvia roemeriana, Penstemon baccharifolius, Schoenus nigricans, Chaetopappa bellidifolia, Perityle* spp., and ferns in the genera *Asplenium, Astrolepis, Cheilanthes*, and *Pellaea*. Sparse grasses, including *Bouteloua hirsuta, Bouteloua rigidiseta*, and *Aristida oligantha*, may be present. This system occurs throughout the Edwards Plateau and west Texas. In the Lampasas Cutplain, this system is sparsely vegetated, and in the eastern plateau and Balcones Canyonlands, it is locally dominated by *Buddleja racemosa, Philadelphus* spp., *Styrax*, and *Perityle* spp. It is dominated in the western plateau by *Perityle* spp., *Penstemon baccharifolius*, and *Heterotheca* spp. and is associated with rivers and streams. These cliffs often serve as refugia from herbivores.
Classification Comments: Further field investigation is needed to better develop the association-level information for this system.
Similar Ecological Systems:
- Edwards Plateau Mesic Canyon (CES303.038)
- North American Warm Desert Bedrock Cliff and Outcrop (CES302.745)

Related Concepts:
- Edwards Plateau: Barren or Grassy Cliff / Bluff (807) [CES303.654.0] (Elliott 2011) Finer
- Edwards Plateau: Wooded Cliff / Bluff (806) [CES303.654] (Elliott 2011) Finer

DESCRIPTION

Environment: This system occurs on steep, vertical or near-vertical hard-bedded limestone cliff faces, sometimes alternating with slope-forming limestone members. There is little to no soil development. Some soil accumulates on ledges and in crevices. Some of these sites may be mesic, accumulating moisture from nearby slopes in crevices within the limestone substrate, and seeps may be present. They often occur as long narrow bands. Composition and cover on these cliff faces is a function of aspect, canopy cover provided by surrounding systems, local climate, and moisture available from the underlying geologic formation (Elliott 2011).
Vegetation: Seeps and mesic sites occupied by this system may have fairly dense cover of *Adiantum capillus-veneris* with patches of *Thelypteris ovata var. lindheimeri* present. More xeric sites often have significant shrub cover, with species such as *Buddleja racemosa, Ungnadia speciosa, Diospyros texana, Ageratina havanensis, Garrya ovata ssp. lindheimeri, Bernardia myricifolia, Philadelphus* spp., *Styrax* spp., and *Toxicodendron radicans ssp. eximium*. Herbaceous species that may be present include *Salvia roemeriana, Penstemon baccharifolius, Schoenus nigricans, Chaetopappa bellidifolia, Perityle* spp., and ferns in the genera *Asplenium, Astrolepis, Cheilanthes*, and *Pellaea*. Sparse grasses, including *Bouteloua hirsuta, Bouteloua rigidiseta*, and *Aristida oligantha*, may be present. These cliffs often serve as refugia from herbivores (Elliott 2011).

Component Associations:
- *Adiantum capillus-veneris - (Thelypteris ovata var. lindheimeri, Thelypteris kunthii)* Herbaceous Vegetation (CEGL004514, G2)
- *Buddleja racemosa - Ungnadia speciosa / Aquilegia canadensis - Aristolochia serpentaria* Shrubland (CEGL004531, G2?)

FLORIDA PANHANDLE BEACH VEGETATION (CES203.266)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Diagnostic Classifiers: East Gulf Coastal Plain; Beach (Substrate); Graminoid; Coast
National Mapping Codes: ESLF 3147

CONCEPT

Summary: The panhandle beach system ranges from northwestern Florida (Ochlockonee River) to southeastern Mississippi. It includes the outermost zone of coastal vegetation extending seaward from foredunes. Within the northern Gulf of Mexico, the natural boundaries of this system are fairly distinct; the western boundary is mineralogical and the eastern is defined by a region of sunken, flooded coast line where beaches are absent. In addition, these beaches are distinguished by high cover of *Uniola paniculata* and *Schizachyrium maritimum*, along with local endemic species of *Chrysoma* and *Paronychia* (Barbour et al. 1987).

Similar Ecological Systems:
- Southwest Florida Dune and Coastal Grassland (CES203.539)

Related Concepts:
- Beach Dune (FNAI 1990) Intersecting
- Unconsolidated Substrate (FNAI 1990) Intersecting

DESCRIPTION

Environment: The beach includes the sand intertidal shore and the low-gradient sand above the daily high tide line, which is between the foredune and the Gulf of Mexico. This area of upper beach is affected by wind and salt spray, seasonal high tides, and storm surge. These beaches are rich in pyroxene, epidote, and garnet (Barbour et al. 1987). Within the northern Gulf of Mexico, the sandy substrate of this system is uniquely rich in medium, nutritionally poor sands. Especially low concentrations of potassium may be of great importance to plant growth and species distributions (Barbour et al. 1987).

Dynamics: The natural coastal dynamics include the movement of sand from wind, tides, and storm surge. This includes transport of sand along the coast (primarily from east to west), and movement of sand by wind or water between the dunes, beach and subtidal areas, and the movement of sand from the foredunes to the interior. If not restricted by infrastructure or engineered hard structures, beaches and dunes can migrate as coastlines change over time in response to the action of wind and water. The Gulf of Mexico coast is affected by one tide per day. Wrack and seaweed deposited along the shore is an important source of nutrients for the coastal ecosystem, and helps promote revegetation in newly disturbed areas (Defeo et al. 2009).

Component Associations:
- *Cakile constricta* Sparse Vegetation (CEGL004398, G2G3)
- *Sesuvium portulacastrum - Atriplex* spp. - *Suaeda* spp. Sparse Vegetation (CEGL004406, G3)
- *Uniola paniculata - Panicum amarum var. amarulum - Iva imbricata* Herbaceous Vegetation (CEGL004041, G2)

DISTRIBUTION

Range: Ranges from northwestern Florida (Ochlockonee River) to southeastern Mississippi.

GREAT LAKES ACIDIC ROCKY SHORE AND CLIFF (CES201.025)

CLASSIFIERS

Conf.: 1 - Strong
Classification Status: Standard
Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Igneous Rock; Coast
Non-Diagnostic Classifiers: Lowland [Lowland]; Moss/Lichen (Nonvascular); Cliff (Substrate); Rock Outcrops/Barrens/Glades; Sedimentary Rock; Metamorphic Rock
National Mapping Codes: ESLF 3146

CONCEPT

Summary: This system is found in the Great Lakes region of the U.S. and Canada where exposed bedrock dominates the shoreline. The bedrock may consist of acidic igneous, metamorphic, or sedimentary rock. Some bedrock shorelines are solid rock, others more cobbly or fragmented. The bedrock may be relatively horizontal or tilted, rounded or blocky, and sometimes cliff-like. The leading edge of the shoreline may be heavily impacted by wave action and winter ice movement, decreasing in effect with distance inland. Vegetation varies from sparse nonvascular vegetation to open-treed or shrubby communities along the same transect.

Component Associations:
- *Corylus cornuta - Amelanchier* spp. - *Prunus virginiana* Rocky Shrubland (CEGL005197, GNR)
- Granite - Metamorphic Bedrock Great Lakes Shore Sparse Vegetation (CEGL005216, GNR)
- Granite - Metamorphic Great Lakes Shore Cliff Sparse Vegetation (CEGL005244, GNR)
- Igneous - Metamorphic Bedrock Inland Lake Shore Sparse Vegetation (CEGL002301, G4G5)
- Non-alkaline Cobble - Gravel Great Lakes Shore Sparse Vegetation (CEGL002508, G2G3)
- *Picea glauca - Abies balsamea* Basalt - Conglomerate Woodland (CEGL005214, GNR)
- Sandstone Bedrock Great Lakes Shore Sparse Vegetation (CEGL002507, G3G4)
- Sandstone Great Lakes Shore Cliff Sparse Vegetation (CEGL002503, G4G5)

DISTRIBUTION

Range: Found in the Great Lakes region of the U.S. and Canada, where exposed bedrock dominates the shoreline.

GREAT LAKES ALKALINE ROCKY SHORE AND CLIFF (CES201.995)

CLASSIFIERS

Conf.: 1 - Strong
Classification Status: Standard
Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
National Mapping Codes: ESLF 3115

CONCEPT

Summary: This system is found in the Great Lakes region of the U.S. and Canada where exposed bedrock dominates the shoreline. The bedrock may consist of alkaline igneous, metamorphic, or sedimentary rocks. Some bedrock shorelines are solid rock, others more cobbly or fragmented. The bedrock may be relatively horizontal or tilted, rounded or blocky, and sometimes cliff-like. The leading edge of the shoreline may be heavily impacted by wave action and winter ice movement, decreasing in effect with distance inland. Alkaline rocky shores are predominantly dolostone when associated with the Niagaran Escarpment along the northern Lake Michigan and Lake Huron shorelines, perhaps best developed on Drummond Island and adjacent Ontario islands. Vegetation in these type is closely related to sparsely vegetated Great Lakes alvars. Alkaline basalts characterize these systems along portions of the Lake Superior shoreline, with a generally distinguishable flora from those on dolostone. Overall, vegetation varies from sparse nonvascular vegetation to open-treed or shrubby communities along the same transect.

GREAT LAKES DUNE (CES201.026)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Non-Diagnostic Classifiers: Dune field; Foredune; Lowland [Lowland]; Interdune flat; Longshore bar; Herbaceous; Beach (Landform); Blowout
National Mapping Codes: ESLF 3137

CONCEPT

Summary: This system occurs along the Great Lakes shores region of the United States and Canada. Component plant communities vary from sparsely vegetated, active dunes to communities dominated by grasses, shrubs, and trees, depending on the degree of sand deposition, sand erosion, and distance from the lake. Many open dunes on Lake Michigan are considered "perched dunes" in that sands were deposited on top of glacial moraine located along the coast. In some instances, dunefields sit several hundred feet above current lake levels. Depositional areas, where Great Lakes beachgrass foredunes are found, are dominated by *Ammophila breviligulata* (or in the eastern part of the range *Ammophila champlainensis*); erosional areas, such as slacks in blowouts and dunefields, by *Calamovilfa longifolia*; and stabilized areas by *Schizachyrium scoparium*. In dunefields and on the most stable dune ridges, especially around northern Lake Michigan and Lake Huron, low evergreen shrubs (*Arctostaphylos uva-ursi, Juniperus communis, Juniperus horizontalis*) occupy dune crests and also the ground layer in the savanna edge of dunes; elsewhere, deciduous shrubs are dominant, including *Prunus pumila, Salix cordata*, and *Salix myricoides (= Salix glaucophylloides)*. Backdunes tend to succeed to forests and savanna indistinguishable from corresponding types found on sandy substrates further inland.
Classification Comments: The system, as described, includes the open grassland, shrubland, and woodland parts of the dune. The lee side of the dunes often contains forests on deep, moist to dry sands that resemble other forested systems. Such forests may include hemlock-hardwood and red oak forests.
Similar Ecological Systems:
- Great Lakes Sand Beach (CES201.149)
- Great Lakes Wooded Dune and Swale (CES201.726)

Related Concepts:
- Jack Pine: 1 (Eyre 1980) Finer

Component Associations:
- *Ammophila breviligulata - (Schizachyrium scoparium)* Herbaceous Vegetation (CEGL005098, G3G5)
- *Cakile edentula* Great Lakes Shore Sparse Vegetation (CEGL005162, G3?)
- *Cakile edentula var. lacustris - Argentina anserina* Sparse Vegetation (CEGL006235, GNR)
- *Juniperus horizontalis - Arctostaphylos uva-ursi - Juniperus communis* Dune Dwarf-shrubland (CEGL005064, G3G4)
- *Pinus banksiana - Pinus resinosa - Pinus strobus* Dune Forest (CEGL002589, G3Q)
- *Populus deltoides - (Juniperus virginiana)* Dune Woodland (CEGL005119, G1G2)
- *Prunus pumila - (Ptelea trifoliata)* Dune Shrubland (CEGL005075, G2Q)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Great Lakes Sand Beach (CES201.149)

DISTRIBUTION

Range: This system occurs along the Great Lakes shores of the United States and Canada on stabilized foredunes, ranging from Wisconsin to Ontario and New York in the Great Lakes, and in isolated occurrences along the shores of Lake Champlain, Vermont.

Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
National Mapping Codes: ESLF 3210

CONCEPT

Summary: This ecological system is found along the shores of the Great Lakes, particularly along Lake Michigan. It is found on sandy substrates with little or no soil development within a few meters elevation of the water. The sandy substrate is not stabilized by significant vegetation and is easily moved. Stands of this system are subject to frequent disturbance by wind, waves, and ice-scour. Stands are typically narrow and linear but may extend for miles along the lakeshore. Vegetation is absent to sparse; that which is present is short and dominated by herbaceous species. *Ammophila breviligulata* and *Cakile edentula* are among the most common species. *Chamaesyce polygonifolia, Juncus balticus, Lathyrus japonicus*, and *Argentina anserina (= Potentilla anserina)* can be found, as well.
Classification Comments: There may be small dunes within this system, but areas where dunes are more extensive should be placed within Great Lakes Dune (CES201.026) or Great Lakes Wooded Dune and Swale (CES201.726). Cobble beaches are not included in this system but are in Great Lakes Acidic Rocky Shore and Cliff (CES201.025) or Great Lakes Alkaline Rocky Shore and Cliff (CES201.095), as appropriate.
Similar Ecological Systems:
- Great Lakes Dune (CES201.026)
- Great Lakes Wooded Dune and Swale (CES201.726)

DESCRIPTION

Environment: This system is found on sandy substrates with little or no soil development within a few meters elevation of the water. It rarely extends more than 30-50 m from the water. The sandy substrate is not stabilized by significant vegetation and is easily moved. Stands are subject to frequent disturbance by wind, waves, and ice-scour.
Vegetation: Vegetation is absent to sparse; that which is present is short and dominated by herbaceous species. *Ammophila breviligulata* and *Cakile edentula* are common. *Chamaesyce polygonifolia, Juncus balticus, Lathyrus japonicus*, and *Argentina anserina (= Potentilla anserina)* can be found, as well.
Dynamics: Stands are subject to frequent disturbance by wind, waves (with storm surges), and ice-scour. This leads to erosion or deposition of the sandy substrate by wind or water. The disturbances keep the beaches nearly free of vegetation.

Component Associations:
- *Ammophila breviligulata - (Schizachyrium scoparium)* Herbaceous Vegetation (CEGL005098, G3G5)
- *Cakile edentula* Great Lakes Shore Sparse Vegetation (CEGL005162, G3?)
- *Cakile edentula var. lacustris - Argentina anserina* Sparse Vegetation (CEGL006235, GNR)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Great Lakes Dune (CES201.026)
- Great Lakes Wooded Dune and Swale (CES201.726)
- Northern Great Lakes Interdunal Wetland (CES201.034)

Adjacent Ecological System Comments: Many beaches are not associated with dunes and are adjacent to a wide variety of uplands, typically forests.

DISTRIBUTION

Range: This system is found along the margins of the Great Lakes. It is most common along Lake Michigan but is also found on the south shore of Lake Superior and in places on Lake Huron, Lake Erie, and Lake Ontario.

GULF COAST CHENIER PLAIN BEACH (CES203.544)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
National Mapping Codes: ESLF 3125

CONCEPT

Summary: This ecological system includes sparsely vegetated ocean beaches along the Gulf of Mexico from the mainland shores of the Chenier Plain of Louisiana and Texas north of Boliver peninsula. These beaches are generally eroding and narrow, and constitute the outermost zone of coastal vegetation in this area. Although these habitats are situated just above the mean high tide limit, they are constantly impacted by waves and flooded by storm surges. Dynamic disturbance regimes largely limit the vegetation to pioneering, salt-tolerant, succulent annuals or perennial vines (e.g. *Ipomoea* spp.). These beaches are generally unstable and highly impacted by attempts to limit the natural erosional processes. Sediment is carried by westerly-moving longshore currents from Louisiana to Texas, and these beaches have all been impacted by the reduction of sediment related to the altered deltaic processes of the Mississippi River.
Classification Comments: This system is distinguished more by the ecological processes that helped develop and maintain it than by its floristics. Based on floristics, it might warrant merger with other beaches of the northern Gulf of Mexico.
Related Concepts:
- Chenier: Beach (6000) [CES203.544] (Elliott 2011) Equivalent

DESCRIPTION

Environment: This ecological system includes the typically sparsely vegetated, sandy, back beach area of the mainland as it transitions into more stabilized communities. Examples are found on recent deposits of sand resulting from ongoing coastal sediment transport, as well as clays remaining on the Gulf margin after longshore transport of sand off of the sites. Sites are gently sloping towards the Gulf, with some development of foreshore dunes. This system occurs in the Chenier Plain region of Louisiana and Texas. Beaches along this part of the coast currently tend to be eroding and narrow, though historically these beaches were part of a system of alternating prograding barrier ridges and eroding tidal flats (Owen 2008). Soils are clays and sands. It is found on the narrow margin of mostly unvegetated sands receiving frequent inundation, erosion, or sediment deposition from eolian processes. The topography is low, and the substrate is dynamic, leading to reduced vegetation development. It is impacted by salt spray, tidal inundation, storm surge, and wind.
Vegetation: Dynamic disturbance regimes largely limit the vegetation to pioneering, salt-tolerant, succulent annuals or perennial vines (e.g., *Ipomoea* spp.). Other species that may be present include *Cakile geniculata, Spartina patens, Distichlis spicata, Panicum amarum*, and *Hydrocotyle bonariensis*. Other species that may be encountered include *Sesuvium* spp., *Ipomoea pes-caprae*, and *Ipomoea imperati*.
Dynamics: These beaches are generally eroding and narrow, and they are constantly impacted by waves and may be flooded by storm surges. They are generally unstable and highly impacted by attempts to limit the natural erosional processes. Sediment is carried by westerly-moving longshore currents from Louisiana to Texas, and these beaches have all been impacted by the reduction of sediment related to the altered deltaic processes of the Mississippi River. Historically, the Chenier Plain coast was place where headland ridges were either prograding or eroding based the proximity of sediment deposited by the Mississippi River as it meandered across its delta. Today, since new sediments are limited because of the control of the Mississippi River, existing headlands that comprise this ecological system are eroding (Morton et al. 2004).

Component Associations:
- *Ipomoea pes-caprae - Ipomoea imperati - (Cakile geniculata)* Herbaceous Vegetation (CEGL004402, G3?)
- *Spartina patens - Panicum amarum - Hydrocotyle bonariensis* Herbaceous Vegetation (CEGL004971, G2?)

DISTRIBUTION

Range: This system ranges from the mainland shores of the Chenier Plain of Louisiana and Texas.

HAWAI'I ALPINE BEDROCK AND SCREE (CES412.400)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Mountain(s); Lava; Cinder; Tropical/Subtropical [Tropical Xeric]
Non-Diagnostic Classifiers: Long (>500 yrs) Persistence; Ridge/Summit/Upper Slope; Basalt
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Boulder, gravel, cobble, or talus
National Mapping Codes: EVT 2829; ESLF 3207; ESP 1829

CONCEPT

Summary: This barren to sparsely vegetated ecological system occurs on alpine slopes of higher mountains of Maui and Hawai'i at 3000-4590 m (9835-14,000 feet) elevation. Sites are generally very dry and cold. Precipitation occurs infrequently during the winter months of October-March. Snow is typically present on summits during winter months and can occur down to 3000 m. Snow can remain year-round on higher-elevation northerly slopes. Nightly frosts are common and can occur down to 3000 m. Sites are wind-exposed with high solar radiation. Substrates include cinder, volcanic ash, and basaltic lava, but can include glacial moraine. Ground surface is mostly gravel and barren rock. Vegetation, if present is sparse and may include scattered grasses (e.g., *Agrostis sandwicensis*, *Trisetum glomeratum*), ferns (e.g., *Pellaea ternifolia*, *Asplenium adiantum-nigrum*, *Asplenium trichomanes*), lichens (e.g., *Lecanora melaena*), and mosses (e.g., *Grimmia* spp., *Racomitrium* spp.).

Similar Ecological Systems:
- Hawai'i Alpine Dwarf-Shrubland (CES412.401)
- Hawai'i Dry-Site Lava Flow (CES412.416)

Related Concepts:
- Hawaiian Alpine Aeolian Desert (Gon 1999) Equivalent

DESCRIPTION

Environment: This alpine ecological system is restricted to the arid zone (Zone 1) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This barren to sparsely vegetated system occurs on alpine slopes of higher mountains of Maui and Hawai'i at 3000-4590 m (9835-14,000 feet) elevation. Sites are generally very dry and cold. Precipitation occurs infrequently during the winter months of October-March. Snow is typically present on summits during winter months and can occur down to 3000 m (Gagne and Cuddihy 1990). Snow can remain year-round on higher elevation northerly slopes. Nightly frosts are common and can occur down to 3000 m. Sites are wind exposed with high solar radiation. Substrates include cinder, volcanic ash, and basaltic lava, but can include glacial moraine. Ground surface is mostly gravel and barren rock.

Vegetation: Vegetation, if present is sparse and may include scattered grasses (e.g., *Agrostis sandwicensis, Trisetum glomeratum*), ferns (e.g., *Pellaea ternifolia, Asplenium adiantum-nigrum, Asplenium trichomanes*), lichens (e.g., *Lecanora melaena*), and mosses (e.g., *Grimmia* spp., *Racomitrium* spp.) (Mueller-Dombois and Fosberg 1998).

Dynamics: Annual precipitation is low as this system occurs above the inversion layer of warmer air that frequently forms below 3000 m and dramatically reduces precipitation at higher elevations (Gagne and Cuddihy 1990). The inversion layer largely prevents moisture from the wet trade winds from reaching the alpine zone.

Component Associations:
- Hawaiian Alpine Eolian Desert Sparse Vegetation (CEGL008106, G1)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Hawai'i Montane-Subalpine Dry Forest and Woodland (CES412.402)

Adjacent Ecological System Comments: This ecological system may co-occur with the alpine dwarf-shrubland ecological system with this system occurring on less exposed, less xeric sites. The dry-site lava flow ecological system is similar, but occurs at lower elevations.

DISTRIBUTION

Range: This ecological system occurs on alpine slopes of Mauna Loa and Mauna Kea on Hawai'i and Haleakala of Maui above 3000 m (9835 feet) elevation.
Divisions: 412:C
Nations: US
Subnations: HI

HAWAI'I DRY-SITE LAVA FLOW (CES412.416)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Northern Polynesia (412)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Lava; Tropical/Subtropical [Tropical Xeric]
Non-Diagnostic Classifiers: Alpine/AltiAndino; Montane; Lowland; Basalt
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Boulder, gravel, cobble, or talus
National Mapping Codes: EVT 2831; ESLF 3208; ESP 1831

CONCEPT

Summary: This ecological system is restricted to areas of geologically recent volcanic activity on drier portions of the islands of Hawai'i and Maui, from sea level to the summit of Mauna Loa, especially in the saddle region on the Big Island and higher elevations and leeward areas of Maui. Precipitation is typically <500 mm. The dry climate and slow soil development significantly retard the rate of primary succession on these sites, which remain barren or sparsely vegetated for at least 75-100 years. The initial plants to colonize include the lichen *Stereocaulon vulcani* and ferns such as *Pellaea ternifolia, Asplenium* spp., and *Psilotum nudum*. Next the tree *Metrosideros polymorpha* and shrubs such as *Dodonaea viscosa* and *Styphelia tameiameiae* establish in cracks on pÃ¢hoehoe or more sheltered microsites on 'a'Ã¢. Later, scattered *Agrostis sandwicensis, Coprosma montana, Myoporum sandwicense, Myrsine lanaiensis, Portulaca sclerocarpa, Tetramolopium humile, Vaccinium reticulatum, Verbena litoralis*, or *Wahlenbergia marginata (= Wahlenbergia gracilis)* may become established. PÃ¢hoehoe appears to support vegetation more rapidly than 'a'Ã¢. Exotic perennial bunchgrass *Pennisetum setaceum* is invading these sites and changing natural primary succession patterns.
Classification Comments: This system does not include wet lowland lava flows that succeed to other vegetation in less than 75-100 years.
Similar Ecological Systems:
- Hawai'i Alpine Bedrock and Scree (CES412.400)

Related Concepts:
- Barren Lava (Shaw and Castillo 1997) Equivalent

DESCRIPTION

Environment: This lowland to subalpine dry lava ecological system occurs within the arid, very dry, and moderately dry zones (Zones 1, 2 and 3) of the 7 Moisture Zones developed for the Hawaiian Islands by Price et al. (2007). This ecological system is restricted to areas of geologically recent volcanic activity on drier portions of the on the islands of Hawai'i and Maui from sea level to the summit of Mauna Loa, especially in the saddle region on the Big Island and higher elevation and leeward area of Maui. Precipitation is typically <500 mm. The dry climate and slow soil development significantly retard the rate of primary succession on these sites, which remain barren or sparsely vegetated for at least 75-100 years.
Vegetation: Vegetation of this ecological systems is characterized by the early stages of primary succession on barren lava. The initial plants to colonize include the lichen *Stereocaulon vulcani* and ferns such as *Pellaea ternifolia, Asplenium* spp., and *Psilotum nudum*. Next the tree *Metrosideros polymorpha* and shrubs such as *Dodonaea viscosa* and *Styphelia tameiameiae* establish in cracks on pÃ¢hoehoe or more sheltered microsites on 'a'Ã¢ (Shaw and Castillo 1997). Later, scattered *Agrostis sandwicensis, Coprosma montana, Myoporum sandwicense, Myrsine lanaiensis, Portulaca sclerocarpa, Tetramolopium humile, Vaccinium reticulatum, Verbena litoralis*, or *Wahlenbergia marginata (= Wahlenbergia gracilis)* may become established. PÃ¢hoehoe appears to support vegetation more rapidly than 'a'Ã¢. Exotic perennial bunchgrass *Pennisetum setaceum* is invading these sites and changing natural primary succession patterns.

DISTRIBUTION

Range: This ecological system is restricted to areas of geologically recent volcanic activity on drier portions of the islands of Hawai'i and Maui from sea level to the summits of larger mountains.

INTER-MOUNTAIN BASINS ACTIVE AND STABILIZED DUNE (CES304.775)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Dune (Landform); Dune field; Dune (Substrate); Temperate [Temperate Continental]; Sand Soil Texture; Aridic; W-Landscape/High Intensity
Non-Diagnostic Classifiers: Dune (undifferentiated); Lowland [Lowland]; Shrubland (Shrub-dominated); Woody-Herbaceous
National Mapping Codes: ESLF 3160

CONCEPT

Summary: This ecological system occurs in the Intermountain western U.S. on basins, valleys and plains. Often it is composed of a mosaic of migrating, bare dunes; anchored dunes with sparse to moderately dense vegetation (<10-30% canopy cover); and stabilized dunes. The system is defined by the presence of migrating dunes or, where the dunes are entirely anchored or stabilized, evidence that the substrate is eolian and not residual, that the vegetation is early- or mid-seral, and that the substrate is likely to become actively migrating again with disturbance or increased aridity. In the Colorado Plateau, there are many small active and partially vegetated dunes along some of the larger washes and playas (where sand is blown out of wash and forms dunes) and some larger dunes such as Coral Pink Dunes in southwestern Utah. Substrates are usually eolian sand, but small dunes composed of silt and clay downwind from playas in the Wyoming Basins (which usually support greasewood vegetation) also are included here. Species occupying these environments are often adapted to shifting, coarse-textured substrates (usually quartz sand) and form patchy or open grasslands, shrublands or steppe, and occasionally woodlands. Vegetation varies and may be composed of *Achnatherum hymenoides, Artemisia filifolia, Artemisia tridentata ssp. tridentata, Atriplex canescens, Ephedra* spp., *Chrysothamnus viscidiflorus, Coleogyne ramosissima, Ericameria nauseosa, Hesperostipa comata, Leymus flavescens, Muhlenbergia pungens, Psoralidium lanceolatum, Purshia tridentata, Redfieldia flexuosa, Sporobolus airoides, Sarcobatus vermiculatus, Tetradymia tetrameres*, or *Tiquilia* spp. Herbaceous species such as *Achnatherum hymenoides, Redfieldia flexuosa*, and *Psoralidium lanceolatum* are characteristic of early-seral vegetation through much of this system's range. Shrubs are commonly dominant on mid- to late-seral stands, and *Ericameria nauseosa* can be found at any stage.
Classification Comments: Rules should be devised for deciding whether shrub or shrub-steppe vegetation on completely stabilized dunes should be considered part of this active and stabilized dune system, or part of another system. The areas include Inter-Mountain Basins Mixed Salt Desert Scrub (CES304.784), Inter-Mountain Basins Big Sagebrush Shrubland (CES304.777), and Inter-Mountain Basins Big Sagebrush Steppe (CES304.778) on sand, and Inter-Mountain Basins Greasewood Flat (CES304.780) on clay and silt.
Similar Ecological Systems:
- Inter-Mountain Basins Mixed Salt Desert Scrub (CES304.784)--some areas appear to be small stabilized dune fields or isolated dunes.
- Southern Colorado Plateau Sand Shrubland (CES304.793)

DESCRIPTION

Vegetation: Vegetation is absent or sparse on active dunes, but canopy cover may be as much as 30% on stable dunes and sandsheets. Species are often adapted to shifting, coarse-textured substrates (usually quartz sand) and form patchy or open grasslands, shrublands or steppe, and occasionally woodlands. Characteristic taxa include *Achnatherum hymenoides, Artemisia filifolia, Artemisia tridentata ssp. tridentata, Atriplex canescens, Ephedra* spp., *Chrysothamnus viscidiflorus, Coleogyne ramosissima, Ericameria nauseosa, Hesperostipa comata, Leymus flavescens, Muhlenbergia pungens, Psoralidium lanceolatum, Purshia tridentata, Redfieldia flexuosa, Sporobolus airoides, Sarcobatus vermiculatus, Tetradymia tetrameres*, or *Tiquilia* spp. Herbaceous species such as *Achnatherum hymenoides, Redfieldia flexuosa*, and *Psoralidium lanceolatum* are characteristic of early-seral vegetation throughout much of this system's range. In the Centennial Valley of southwestern Montana, where the dunes are more stable, *Artemisia tridentata ssp. tridentata* and *Artemisia tripartita ssp. tripartita* contribute a moderate amount of cover and are associated with *Hesperostipa comata* or *Festuca idahoensis* (in more mesic settings). Early- and mid-seral shrub communities in these dunes are dominated by *Ericameria nauseosa, Chrysothamnus viscidiflorus, Purshia tridentata*, and *Hesperostipa comata*. Several rare plant species occur in the Centennial Valley dunes and are associated with early-successional stages. These dunes are very similar to the St. Anthony dunes in Idaho. In the Killpecker Dunes in west-central Wyoming, *Artemisia tridentata ssp. tridentata* dominates late-seral vegetation and *Ericameria nauseosa* dominates mid-seral vegetation (Jones 2005). The Great Sand Dunes in southern Colorado consist of an active dunefield surrounded by a stabilized sandsheet dominated *Ericameria nauseosa, Sarcobatus vermiculatus*, or *Pinus ponderosa* (on a sand ramp). The stabilized areas are periodically disturbed by parabolic dunes tracking across them from blowouts caused by fire or drought (Marin et al. 2005).
Dynamics: Periodic drought influences dune migration rates by reducing vegetation cover that anchors dunes (Marin 2005, Forman et al. 2006). A typical primary successional sere on sands appears to be as follows: bare sand or sparse herbaceous vegetation on migrating sand, denser herbaceous vegetation or shrub stands of *Ericameria nauseosa* or *Ericameria nauseosa (= Chrysothamnus nauseosus)* on anchored or recently stabilized sand, and shrub vegetation of *Artemisia tridentata* on longer-stabilized sands.

Component Associations:
- *Achnatherum hymenoides - Psoralidium lanceolatum* Herbaceous Vegetation (CEGL001650, G3Q)
- *Achnatherum hymenoides - Sporobolus contractus* Herbaceous Vegetation (CEGL001652, G2G4)
- *Artemisia filifolia - Ephedra (torreyana, viridis)* Shrubland (CEGL002786, GNR)
- *Artemisia filifolia* Colorado Plateau Shrubland (CEGL002697, GNR)
- *Atriplex canescens - Ephedra viridis* Shrubland (CEGL003828, GNR)
- *Elymus lanceolatus - Phacelia hastata* Herbaceous Vegetation (CEGL001745, G2)
- *Ephedra torreyana - Achnatherum hymenoides* Hummock Shrubland (CEGL005802, GNR)
- *Ephedra torreyana / Achnatherum hymenoides - Pleuraphis jamesii* Shrubland (CEGL002352, GNR)
- *Ephedra viridis / (Achnatherum hymenoides, Hesperostipa comata)* Shrubland (CEGL002354, GNR)
- *Ephedra viridis / Pleuraphis jamesii* Shrubland (CEGL002356, GNR)
- *Ericameria nauseosa / Leymus flavescens / Psoralidium lanceolatum* Shrubland (CEGL001329, G1?)
- *Ericameria nauseosa* Sand Deposit Sparse Shrubland (CEGL002980, GNR)
- *Eriogonum leptocladon* Sparse Vegetation (CEGL002822, GNR)
- *Leymus flavescens* Herbaceous Vegetation (CEGL001563, G2)
- *Muhlenbergia pungens* Herbaceous Vegetation (CEGL002363, GNR)
- *Pinus ponderosa / (Ericameria nauseosa) / Achnatherum hymenoides* Woodland (CEGL001490, G1)
- *Pinus ponderosa / Artemisia tridentata ssp. wyomingensis / Hesperostipa comata* Woodland (CEGL000179, G1)
- *Poliomintha incana - Artemisia filifolia - Vanclevea stylosa* Shrubland (CEGL002418, GNR)
- *Populus angustifolia* Sand Dune Forest (CEGL002643, G1)
- *Psorothamnus polydenius var. polydenius / Achnatherum hymenoides* Shrubland (CEGL001353, G3G4)
- *Purshia tridentata - Artemisia tridentata ssp. tridentata* Shrubland (CEGL001054, G1)
- *Purshia tridentata - Ericameria nauseosa* Shrubland (CEGL001056, G1)
- *Purshia tridentata / Achnatherum hymenoides* Shrubland (CEGL001058, G1)
- *Purshia tridentata / Prunus virginiana* Shrubland (CEGL001060, G1?)
- *Quercus havardii var. tuckeri* Shrubland (CEGL002486, GNR)
- Redbeds (Siltstone, Sandstone, Gypsum) Sparse Vegetation (CEGL005261, GNR)
- *Redfieldia flexuosa - (Psoralidium lanceolatum)* Herbaceous Vegetation (CEGL002917, G1?)
- *Sarcobatus vermiculatus* Dune Shrubland (CEGL001364, G5?)

Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Rock Outcrops/Barrens/Glades; Cliff (Landform)
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Rockfall avalanche; Ridge/Summit/Upper Slope; Sideslope; Toeslope/Valley Bottom; Sedimentary Rock; Metamorphic Rock; Igneous Rock; Temperate [Temperate Continental]; Very Shallow Soil; Canyon
National Mapping Codes: ESLF 3173

CONCEPT

Summary: This ecological system ranges from Wyoming and Utah west to the Pacific states. It is found from foothill to subalpine elevations and includes barren and sparsely vegetated landscapes (generally <10% plant cover) of steep cliff faces, narrow canyons, and smaller rock outcrops of various igneous, sedimentary, and metamorphic bedrock types. Also included is vegetation of unstable scree and talus slopes that typically occurs below cliff faces. Widely scattered trees and shrubs may include *Abies concolor, Pinus edulis, Pinus flexilis, Pinus monophylla, Juniperus* spp., *Artemisia tridentata, Purshia tridentata, Cercocarpus ledifolius, Ephedra* spp., *Holodiscus discolor*, and other species often common in adjacent plant communities.
Similar Ecological Systems:
- Colorado Plateau Mixed Bedrock Canyon and Tableland (CES304.765)

Component Associations:
- *Cercocarpus intricatus* Montane Shrubland (CEGL002587, GNR)
- *Cercocarpus intricatus* Slickrock Sparse Vegetation (CEGL002977, GNR)
- *Cercocarpus montanus* Rock Pavement Sparse Vegetation (CEGL002978, GNR)
- *Chrysothamnus viscidiflorus* Talus Shrubland (CEGL002347, GNR)
- *Crataegus rivularis* Shrubland (CEGL002889, G2Q)
- *Glossopetalon spinescens var. aridum / Pseudoroegneria spicata* Shrubland (CEGL001100, G4)
- *Juniperus osteosperma / Cercocarpus intricatus* Woodland (CEGL000733, GNR)
- *Leymus salinus* Shale Sparse Vegetation (CEGL002745, GNR)
- *Pinus monophylla - Juniperus osteosperma* / Sparse Understory Woodland (CEGL000829, G5)
- *Pinus ponderosa* Slickrock Sparse Vegetation (CEGL002972, GNR)

INTER-MOUNTAIN BASINS PLAYA (CES304.786)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Diagnostic Classifiers: Alkaline Water; Saline Water Chemistry; Caliche Layer; Impermeable Layer; Intermittent Flooding; Lowland [Lowland]; Playa; Temperate [Temperate Xeric]; Depressional; Alkaline Soil; Saline Substrate Chemistry; Aridic
Non-Diagnostic Classifiers: Clay Subsoil Texture; Shrubland (Shrub-dominated); Herbaceous; Isolated Wetland [Partially Isolated]; Dwarf-Shrub; Forb; Graminoid
National Mapping Codes: ESLF 3179

CONCEPT

Summary: This ecological system is composed of barren and sparsely vegetated playas (generally <10% plant cover) found in the intermountain western U.S. Salt crusts are common throughout, with small saltgrass beds in depressions and sparse shrubs around the margins. These systems are intermittently flooded. The water is prevented from percolating through the soil by an impermeable soil subhorizon and is left to evaporate. Soil salinity varies greatly with soil moisture and greatly affects species composition. Characteristic species may include *Allenrolfea occidentalis*, *Sarcobatus vermiculatus*, *Grayia spinosa*, *Puccinellia lemmonii*, *Leymus cinereus*, *Distichlis spicata*, and/or *Atriplex* spp.
Classification Comments: Bjork (1997) refers to these as vernal lakes in Washington; his one example was ditched and may be artificial. There might have been these in Grand Coulee prior to Columbia Basin irrigation project.

DESCRIPTION

Dynamics: Playas are shallow, seasonal wetlands that lie in the lowest point of a closed watershed. Their basins are lined with clay soils, which collect and hold water from rainfall and runoff events. Water evaporates, leaving high salt concentrations in the soils. Some playas will only flood with water during years with high precipitation, sometimes only once or twice in a decade. Others will have standing water every spring, except in the driest of years. During flooded years, some salt-tolerant marsh plant species may grow, such as cattails (*Typha* spp.) or bulrush (*Scirpus* spp.).

Component Associations:
- *Allenrolfea occidentalis / Atriplex gardneri* Shrubland (CEGL000989, G4?)
- *Allenrolfea occidentalis* Shrubland (CEGL000988, G3)
- *Artemisia papposa / Danthonia californica - Festuca idahoensis* Shrubland (CEGL002991, GNR)
- *Artemisia tridentata ssp. tridentata / Leymus cinereus* Shrubland (CEGL001016, G2)
- *Chrysothamnus albidus / Puccinellia nuttalliana* Shrubland (CEGL001328, G3)
- *Distichlis spicata - (Scirpus nevadensis)* Herbaceous Vegetation (CEGL001773, G4)
- *Distichlis spicata* - Mixed Herb Herbaceous Vegetation (CEGL001771, G3G5)
- *Distichlis spicata* Herbaceous Vegetation (CEGL001770, G5)
- *Hordeum jubatum* Great Basin Herbaceous Vegetation (CEGL005285, G4)
- *Krascheninnikovia lanata / Poa secunda* Dwarf-shrubland (CEGL001326, G3)
- *Leymus cinereus - Distichlis spicata* Herbaceous Vegetation (CEGL001481, G3)
- *Leymus cinereus* Bottomland Herbaceous Vegetation (CEGL001480, G1)
- *Leymus triticoides - Poa secunda* Herbaceous Vegetation (CEGL001572, G2)
- *Leymus triticoides* Herbaceous Vegetation (CEGL001571, G4?)
- *Pluchea sericea* Seasonally Flooded Shrubland (CEGL003080, G3?)
- *Poa secunda - Muhlenbergia richardsonis* Herbaceous Vegetation (CEGL002755, GNR)
- *Puccinellia lemmonii - Poa secunda* Seasonally Flooded Herbaceous Vegetation (CEGL001658, G1)
- *Sarcobatus vermiculatus - Atriplex parryi / Distichlis spicata* Shrubland (CEGL002764, GNR)

INTER-MOUNTAIN BASINS SHALE BADLAND (CES304.789)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Badland; Badlands; Alkaline Soil; Shale and Mudstone; Silt Soil Texture; Clay Soil Texture
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Temperate [Temperate Continental]; Aridic; Very Short Disturbance Interval; Broad-Leaved Shrub; Dwarf-Shrub; Semi-Shrub
National Mapping Codes: ESLF 3139

CONCEPT

Summary: This widespread ecological system of the Intermountain western U.S. is composed of barren and sparsely vegetated substrates (<10% plant cover) typically derived from marine shales but also includes substrates derived from siltstones and mudstones (clay). In southern Wyoming , the shales are not marine in origin, but often have bentonite, derived from volcanic ash deposition that occurred during several eruptions of the Yellowstone volcanic fields. Landforms are typically rounded hills and plains that form a rolling topography. The harsh soil properties and high rate of erosion and deposition are driving environmental variables supporting sparse dwarf-shrubs, e.g., *Atriplex corrugata*, *Atriplex gardneri*, *Artemisia pedatifida*, and herbaceous vegetation.
Classification Comments: Exactly where this transitions to Western Great Plains Badlands (CES303.663) in central Wyoming needs to be clarified.
Similar Ecological Systems:
- Columbia Plateau Ash and Tuff Badland (CES304.081)

Component Associations:
- *Achnatherum hymenoides* Shale Barren Herbaceous Vegetation (CEGL001651, G2)
- *Artemisia arbuscula ssp. longiloba* / Cushion Plants Shrubland (CEGL005996, GNR)

INTER-MOUNTAIN BASINS VOLCANIC ROCK AND CINDER LAND (CES304.791)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Lava flow (undifferentiated); Lava; Cinder; Basalt; Temperate [Temperate Continental]; Cinder cone
Non-Diagnostic Classifiers: Montane; Lowland; Shrubland (Shrub-dominated); Herbaceous; Dune (Substrate); Igneous Rock; Very Shallow Soil; Sand Soil Texture; Aridic; W-Landscape/Medium Intensity
National Mapping Codes: ESLF 3128

CONCEPT

Summary: This ecological system occurs in the intermountain western U.S. and is limited to barren and sparsely vegetated volcanic substrates (generally <10% plant cover) such as basalt lava (malpais), basalt dikes with associated colluvium, basalt cliff faces and uplifted "backbones," tuff, cinder cones or cinder fields. It may occur as large-patch, small-patch and linear (dikes) spatial patterns. Vegetation is variable and includes a variety of species depending on local environmental conditions, e.g., elevation, age and type of substrate. At montane and foothill elevations scattered *Pinus ponderosa*, *Pinus flexilis*, or *Juniperus* spp. trees may be present. Shrubs such as *Ephedra* spp., *Atriplex canescens*, *Eriogonum corymbosum*, *Eriogonum ovalifolium*, and *Fallugia paradoxa* are often present on some lava flows and cinder fields. Species typical of sand dunes such as *Andropogon hallii* and *Artemisia filifolia* may be present on cinder substrates.

DESCRIPTION

Dynamics: This ecological system is relatively young (geologically speaking). Lichens are the primary erosion process in this system, and therefore, soil buildup is a slow process. Lichens are susceptible to changes in air quality (Brodo et. al. 2001) and are considered a good indicator of air quality.

Component Associations:
- *Andropogon hallii* Colorado Plateau Herbaceous Vegetation (CEGL002785, GNR)
- *Artemisia filifolia - Ephedra (torreyana, viridis)* Shrubland (CEGL002786, GNR)
- *Artemisia tridentata ssp. vaseyana / Poa secunda* Shrubland (CEGL001029, G3)
- *Eriogonum corymbosum* Cinder Sparse Vegetation (CEGL005803, GNR)
- *Eriogonum fasciculatum* Rock Outcrop Shrubland (CEGL001260, G5?)
- *Eriogonum ovalifolium var. depressum* Dwarf-shrubland (CEGL001401, G1)
- *Fallugia paradoxa - (Atriplex canescens, Ephedra torreyana)* Cinder Shrubland (CEGL005806, GNR)
- *Juniperus monosperma* Cinder Wooded Herbaceous Vegetation (CEGL005807, GNR)
- *Pinus flexilis / Purshia tridentata* Woodland (CEGL000814, G1?)
- *Pinus ponderosa - (Populus tremuloides) / Fallugia paradoxa - (Holodiscus dumosus)* Lava Bed Sparse Vegetation (CEGL002929, GNR)
- *Pinus ponderosa / Andropogon hallii* Woodland (CEGL005808, GNR)
- *Pinus ponderosa* / Cinder Woodland (CEGL002998, GNR)
- *Purshia tridentata / Pseudoroegneria spicata - Leymus cinereus* Shrub Herbaceous Vegetation (CEGL001497, G1?)
- *Tiquilia latior / Sporobolus airoides* Dwarf-shrubland (CEGL005809, GNR)

DISTRIBUTION

Range: This system occurs in the Intermountain western U.S. and is limited to barren and sparsely vegetated volcanic substrates. It occurs in Montana along the Rocky Mountain Front (east of the Continental Divide).

INTER-MOUNTAIN BASINS WASH (CES304.781)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Inter-Mountain Basins (304)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Wash; Toeslope/Valley Bottom; Riverine / Alluvial; Alkaline Soil; Xeromorphic Shrub; Sarcobatus vermiculatus
Non-Diagnostic Classifiers: Deep (>15 cm) Water; Temperate [Temperate Continental]; Saline Substrate Chemistry
National Mapping Codes: ESLF 3152

CONCEPT

Summary: This barren and sparsely vegetated (generally <10% plant cover) ecological system is restricted to intermittently flooded streambeds and banks that are often lined with shrubs such as *Sarcobatus vermiculatus, Ericameria nauseosa, Fallugia paradoxa, Artemisia tridentata ssp. tridentata,* and/or *Artemisia cana ssp. cana* (in more northern and mesic stands) that form relatively dense stringers in open dry uplands. *Grayia spinosa* may dominate in the Great Basin. Shrubs form a continuous or intermittent linear canopy in and along drainages but do not extend out into flats. Typically it includes patches of saltgrass meadow where water remains for the longest periods. In parts of Wyoming, stringers or patches of *Artemisia tridentata ssp. tridentata* are large and distinct enough from surrounding upland vegetation due to the influence of the wash that they can be classified separately. However, small intermittent washes may also be included with adjacent uplands if vegetation is not different enough floristically or structurally from uplands (e.g., just a little denser canopy). Soils are variable but are generally less alkaline than those found in the playa system. Desert scrub species (e.g., *Acacia greggii, Prosopis* spp.) that are common in the Mojave, Sonoran and Chihuahuan desert washes are not present. This type can occur in limited portions of the southwestern Great Plains.
Classification Comments: Where the stringers or patches of *Artemisia tridentata ssp. tridentata* are large enough to be mapped separately from both the wash and from the adjacent upland, then they should be mapped as Inter-Mountain Basins Big Sagebrush Shrubland (CES304.777) or Inter-Mountain Basins Big Sagebrush Steppe (CES304.778) . Compare this wash system with Inter-Mountain Basins Greasewood Flat (CES304.780); the wash should be restricted to the periphery of the wash and distinct from adjacent vegetation. If not, consider including with greasewood flat. Invasive, exotic shrubs shrub as *Tamarix* spp. or *Chamaebatiaria millefolium* may be present to dominant in these washes where disturbed.

KLAMATH-SISKIYOU CLIFF AND OUTCROP (CES206.902)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Woody-Herbaceous; Moss/Lichen (Nonvascular); Cliff (Substrate); Talus (Substrate); Rock Outcrops/Barrens/Glades; Mediterranean [Mediterranean Xeric-Oceanic]
Non-Diagnostic Classifiers: Canyon Mosaic; Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Forest and Woodland (Treed); Canyon; Cliff (Landform)
National Mapping Codes: ESLF 3170

CONCEPT

Summary: Found from foothill to subalpine elevations of the Klamath Range, these are barren and sparsely vegetated landscapes (<10% plant cover) of steep cliff faces, bald ridgetops and shoulder outcrops, narrow canyons, and smaller rock outcrops of various igneous, sedimentary, and metamorphic bedrock. Vegetative cover is dominated by forbs, grasses, mosses, or lichens. This also includes unstable scree and talus slopes typically occurring below cliff faces. Scattered vegetation may include *Pseudotsuga menziesii* and *Acer macrophyllum* along with herbaceous and nonvascular species such as *Achnatherum lemmonii (= Stipa lemmonii)*, *Achnatherum occidentale (= Stipa occidentalis)*, *Elymus elymoides (= Sitanion hystrix)*, *Sedum oregonense*, and *Racomitrium ericoides (= Racomitrium canescens var. ericoides)*. Soil development is limited as is herbaceous cover.

DISTRIBUTION

Range: Found from foothill to subalpine elevations of the Klamath Range.
Divisions: 206:C
Nations: US
Subnations: CA, OR

LAURENTIAN-ACADIAN ACIDIC CLIFF AND TALUS (CES201.569)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Ridge/Summit/Upper Slope; Cliff (Substrate); Talus (Substrate); Acidic Soil; Landslide
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Montane; Lowland; Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Glaciated; Very Shallow Soil; Mineral: W/ A-Horizon <10 cm; Intermediate Disturbance Interval [Periodicity/Polycyclic Disturbance]
National Mapping Codes: ESLF 3188

CONCEPT

Summary: This cliff system occurs at low to mid elevations, well below treeline, from New England west to the Great Lakes. It consists of vertical or near-vertical cliffs and the talus slopes below, formed on hills of granitic or otherwise acidic bedrock. Most of the substrate is dry and exposed, but small (occasionally large) areas of seepage are often present. Vegetation in seepage areas tends to be more well-developed and floristically different from the surrounding dry cliffs. The vegetation is patchy and often sparse, punctuated with patches of small trees (e.g., *Betula* and *Picea* spp.). Calciphilic species are absent. In north-facing or other sheltered settings where cold air accumulates at the bottom of slopes, a shrubland of heaths and reindeer lichens can develop. This system differs from the more southerly North-Central Appalachian Acidic Cliff and Talus (CES202.601) in the more boreal affinities of its flora, for example *Picea* spp. rather than *Juniperus virginiana*.

Similar Ecological Systems:
- North-Central Appalachian Acidic Cliff and Talus (CES202.601)

LAURENTIAN-ACADIAN CALCAREOUS CLIFF AND TALUS (CES201.570)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Ridge/Summit/Upper Slope; Cliff (Substrate); Talus (Substrate); Alkaline Soil; Circumneutral Soil
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Montane; Lowland; Glaciated; Very Shallow Soil; Intermediate Disturbance Interval; Landslide
National Mapping Codes: ESLF 3144

CONCEPT

Summary: This cliff system occurs at low to mid elevations, well below treeline, from New England west to the Great Lakes. It consists of vertical or near-vertical cliffs and the talus slopes below, where weathering and/or bedrock chemistry produce circumneutral to calcareous pH and enriched nutrient availability. The vegetation is often sparse but may include patches of small trees. *Thuja occidentalis* may dominate on some cliffs (and reach very old ages, upwards of 1000 years). *Fraxinus* spp. and *Tilia americana* are woody indicators of the enriched setting.

Similar Ecological Systems:
- North-Central Appalachian Circumneutral Cliff and Talus (CES202.603)

Related Concepts:
- Northern White-Cedar: 37 (Eyre 1980) Finer
- White Cedar Woodland (Gawler and Cutko 2010) Finer

DESCRIPTION

Vegetation: *Thuja occidentalis* may dominate on some cliffs (and reach very old ages, upwards of 1000 years). *Fraxinus* spp. and *Tilia americana* are woody indicators of the enriched setting (Kelly and Larson 1997).

Component Associations:
- *Acer saccharum - Tilia americana - Fraxinus americana / Ostrya virginiana / Geranium robertianum* Woodland (CEGL005058, G3G5)
- *Carex scirpoidea* Alkaline Cliff Sparse Vegetation (CEGL006526, GNR)
- Limestone - Dolostone Midwest Dry Cliff Sparse Vegetation (CEGL002291, G4G5)
- Limestone - Dolostone Midwest Moist Cliff Vegetation (CEGL002292, G4G5)
- Limestone - Dolostone Midwest Talus Vegetation (CEGL002308, G4G5)
- *Thuja occidentalis* Carbonate Talus Woodland (CEGL005172, G3G4)
- *Thuja occidentalis* Cliff Woodland (CEGL002451, G3)

DISTRIBUTION

Range: This system is found in scattered locations from New England and adjacent Canada west to the Great Lakes and northern Minnesota
Divisions: 201:C
Nations: US
Subnations: ME, MI, MN, NH, NY, VT, WI
Map Zones: 41:C, 50:C, 51:C, 63:C, 64:C, 66:C

LAURENTIAN-ACADIAN LAKESHORE BEACH (CES201.586)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Diagnostic Classifiers: Short (<5 yrs) Flooding Interval [Short interval, Irregular Flooding]; Depressional; Flood Scouring; Broad-Leaved Shrub; Dwarf-Shrub; Graminoid
Non-Diagnostic Classifiers: Lowland; Glaciated; Mesotrophic Soil; Oligotrophic Soil; Mineral: W/ A-Horizon <10 cm; Sand Soil Texture; Very Short Disturbance Interval
National Mapping Codes: ESLF 3182

CONCEPT

Summary: This system encompasses primarily upland vegetation along lakeshores or rivershores in the glaciated Northeast and upper Midwest (not including the Great Lakes). Some areas may be briefly inundated during high water periods. The substrate is sandy to gravelly, sometimes consolidated rock; there may be muddy patches. Ice-scour is not a major influence, although it may be locally important. These shores may be narrow zones of shrubs and/or sparse vegetation on rocks or sandy beaches. Descriptions of these beaches from Maine, New Hampshire, Vermont, and Minnesota suggests a variable structure and composition influenced by exposure, substrate, and how wet the substrate remains. The upper zone often features shrubs; these may include *Myrica gale, Gaylussacia baccata, Salix* spp., and *Photinia melanocarpa (= Aronia melanocarpa)*. Creeping shrubs such as *Hudsonia* spp., *Juniperus horizontalis*, and *Prunus pumila var. susquehanae* may be locally important. The herbaceous flora likewise varies; *Schizachyrium scoparium, Dichanthelium clandestinum, Cyperus* spp., *Dulichium arundinaceum*, and *Spartina pectinata* are representative graminoids; forbs may include *Argentina anserina, Lechea intermedia, Scutellaria lateriflora*, and *Mimulus ringens*, among others.
Classification Comments: Very little data on these. May not be defensible as a separate system, keep in for now as a placeholder. If it is combined with the surrounding uplands, the associations tagged to this system may become orphans.
Related Concepts:

LOUISIANA BEACH (CES203.469)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Diagnostic Classifiers: Beach (Substrate); Graminoid; Coast
National Mapping Codes: ESLF 3131

CONCEPT

Summary: Louisiana beaches are predominantly found on remnant barrier islands associated with historic delta lobes of the Mississippi River. Since normal deltaic processes have been altered, the formation of new barrier islands has been halted and Louisiana barrier islands are undergoing deterioration. Within the northern Gulf region, these barrier islands are distinguished by dominance of *Spartina patens* instead of *Uniola paniculata*. Also characteristic are *Cenchrus spinifex (= Cenchrus incertus)* and *Sporobolus virginicus*.
Classification Comments: This system is distinguished more by its dependence on the deltaic processes of the Mississippi River than by its floristics. Based on floristics, it might warrant merger with other beaches of the northern Gulf of Mexico.

DESCRIPTION

Environment: This ecological system includes the usually sparsely vegetated, sandy, back beach area in a microtidal environment (< 0.5m) as it transitions into more stabilized dune or barrier flat communities.
Vegetation: These beaches are distinguished by dominance of *Spartina patens*. Also characteristic are *Cenchrus spinifex (= Cenchrus incertus)* and *Sporobolus virginicus* (Barbour et al. 1987).
Dynamics: The primary processes controlling this system are the natural deltaic process of the Mississippi River. The process of sand movement due to the forces of wind and water are part of its the natural dynamics. This includes transport of sand along the coast, and movement of sand by wind or water between the dunes, beach and subtidal areas. If the natural supply of sediment is maintained and not restricted by infrastructure or engineered hard structures, beaches and dunes will migrate and cause coastlines to change over time in response to the action of wind and water. Based on the dependence of this system on the natural processes of the Mississippi River, and the current alteration of those processes, this system has been severely degraded; no new beaches are forming and existing beaches are eroding (Morton et al. 2004). The loss of this system will impact the many wildlife that depend on it - terns, shorebirds, wading birds, brown pelican, and sea turtles.

Component Associations:
- *Ipomoea pes-caprae - Ipomoea imperati - (Cakile geniculata)* Herbaceous Vegetation (CEGL004402, G3?)
- *Spartina patens - Panicum amarum - Hydrocotyle bonariensis* Herbaceous Vegetation (CEGL004971, G2?)

DISTRIBUTION

Range: This system is found on remnant barrier islands associated with historic delta lobes of the Mississippi River. Very few examples remain intact.
Divisions: 203:C
Nations: US
Subnations: LA
Map Zones: 98:C
TNC Ecoregions: 31:C

MEDITERRANEAN CALIFORNIA ALPINE BEDROCK AND SCREE (CES206.899)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino [Alpine/AltiAndino]; Alpine Mosaic; Ridge/Summit/Upper Slope; Temperate [Temperate Oceanic]; Nonvascular
Non-Diagnostic Classifiers: Hillslope bedrock outcrop; Peak; Periglacial boulderfield; Pinnacle; Ridgetop bedrock outcrop; Rockfall avalanche; Herbaceous; Summit; Moss/Lichen (Nonvascular); Talus (Landform); Glaciated; Periglacial; Very Shallow Soil; Landslide; Avalanche; W-Landscape/High Intensity; Cliff (Landform)
National Mapping Codes: ESLF 3172

CONCEPT

Summary: This system occurs in limited alpine environments mostly concentrated in the Sierra Nevada, but also on Mount Shasta and as far south as the Peninsular Ranges and White Mountains. Alpine elevations begin around 3500 m (10,600 feet) in the southern mountain ranges and 2700 m (8200 feet) in the southern Cascades. These are barren and sparsely vegetated alpine substrates, typically including both bedrock outcrops and scree slopes, with nonvascular (lichen)-dominated communities. This also encompasses a limited area of "alpine desert" with unstable sandy substrates and scattered individuals of *Astragalus* spp., *Arabis* spp., *Draba* spp., and *Oxytropis* spp., which mostly fall to the east of the Sierra Nevada crest. Exposure to desiccating winds, rocky and sometimes unstable substrates, and a short growing season limit plant growth.

DISTRIBUTION

Range: Concentrated in the Sierra Nevada, but also on Mount Shasta and as far south as the Peninsular Ranges and White Mountains. Alpine elevations begin around 3500 m (10,600 feet) in the southern mountain ranges and 2700 m (8200 feet) in the southern Cascades.

MEDITERRANEAN CALIFORNIA COASTAL BLUFF (CES206.906)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Headland; Sea cliff; Mediterranean [Mediterranean Xeric-Oceanic]; Salt Spray; Landslide; W-Landscape/High Intensity; Bluff; Succulent Shrub; Dwarf-Shrub
Non-Diagnostic Classifiers: Lowland [Lowland]; Herbaceous; Cliff (Substrate); Saline Substrate Chemistry; Xeric; Intermediate Disturbance Interval; Succulent Forb; Cliff (Landform); Coast
National Mapping Codes: ESLF 3166

CONCEPT

Summary: Areas of sea bluffs and rocky headlands occur just above the tidal zone throughout rugged portions of coastal Oregon, California, Baja Norte, and off-shore islands (e.g., Channel Islands). Plant communities along these often vertical slopes are typically sparse, with many succulents and prostrate shrubs, and species that readily withstand salt spray and saline soils, as well as seasonal drought. These may include *Baccharis pilularis, Dudleya* spp., *Carpobrotus chilensis, Carpobrotus edulis, Hazardia squarrosa (= Haplopappus squarrosus), Eriogonum parvifolium, Erigeron glaucus, Eriophyllum stoechadifolium*, and *Plantago maritima*. Slope instability and erosion result in severe climate, setting back succession in this system.

DISTRIBUTION

Range: Rugged portions of coastal Oregon, California, and off-shore islands (e.g., Channel Islands), and Baja Norte, Mexico.
Divisions: 206:C
Nations: MX, US
Subnations: CA, MXBC(MX), OR
Map Zones: 2:P, 3:C, 4:C

MEDITERRANEAN CALIFORNIA NORTHERN COASTAL DUNE (CES206.907)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Dune field; Coastal Dune Mosaic; Dune (Substrate); Mediterranean [Mediterranean Xeric-Oceanic]; Sand Soil Texture; Very Short Disturbance Interval; W-Patch/High Intensity; Abronia latifolia
Non-Diagnostic Classifiers: Foredune; Lowland [Lowland]; Longshore bar; Sagpond; Woody-Herbaceous; Shoreline; Spit; Salt Spray; Unconsolidated; Beach (Landform); Blowout; Coast
National Mapping Codes: ESLF 3165

CONCEPT

Summary: This coastal system occurs in scattered locations from Point Conception, California, north to Coos Bay, Oregon. Coastal dunes include beaches, foredunes, sand spits, and active to stabilizing backdunes and sandsheets derived from quartz or gypsum sands. The mosaic of sparse to dense vegetation in dune systems is driven by sand deposition, erosion, and lateral movement. Coastal dunes often front portions of inlets and tidal marshes. They may also occur as extensive dune fields dominating large coastal bays. Dune vegetation typically includes herbaceous, succulent, and low-shrub species with varying degrees of tolerance for salt spray, wind and sand abrasion, and substrate stability. Dune succession is highly variable, so species composition can vary significantly between occurrences. Generally, these dune systems can be dominated by *Leymus mollis, Abronia latifolia, Ambrosia chamissonis, Baccharis pilularis, Calystegia soldanella, Artemisia pycnocephala, Ericameria ericoides, Eriogonum latifolium, Camissonia cheiranthifolia*, and *Carpobrotus chilensis (= Carpobrotus aequilateralus)*. Disturbance processes include dune blowouts caused by wind and occasional wave overwash during storm tidal surges.

DESCRIPTION

Environment: Coastal dunes include beaches, foredunes, sand spits, and active to stabilizing backdunes and sandsheets derived from quartz or gypsum sands. The mosaic of sparse to dense vegetation in dune systems is driven by sand deposition, erosion, and lateral movement. Coastal dunes often front portions of inlets and tidal marshes. They may also occur as extensive dune fields dominating large coastal bays. Climate is both Mediterranean and maritime; temperatures are moderate year-round. Most precipitation occurs in the winter months, followed by summer drought, and mild winter temperatures permit growing season throughout most of the year (Wiedemann 1984, Christy et al. 1998, Pickart and Barbour 2007). Clouds and fog are present throughout much of the year, with fog becoming increasingly common to the south (Wiedemann 1984). The dune localities are generally associated with nearby rivers, estuaries or bays; rivers deposit sediment which is carried by ocean currents and wind and deposited on flat coastline areas with onshore winds (Pickart and Barbour 2007). Dune sands are very poor soils, with no organic matter accumulation (Wiedemann 1984). pH is about neutral and the nutrient status is so low as to be almost unmeasurable. Dune sands have poor moisture-holding capacity. A salinity gradient appears to be important in California dunes, and germination or emergence stages are more vulnerable to soil salinity or washover of saltwater than established plants. Pickart and Barbour (2007) provide a summary of studies of the physiological ecology of dune plants.

Dynamics: Disturbance processes include dune blowouts caused by wind and occasional wave overwash during storm tidal surges. Cyclical dune activity is apparently triggered by cyclical changes in sea level associated with tectonic events (Wiedemann 1984, Christy et al. 1998, Pickart and Barbour 2007). Subsidence or uplift of 1.8 to 2.7 m (6-9 feet) associated with earthquakes would initiate new successional pathways after destruction of existing dune formations and vegetation (Thilenius 1995). Generally it appears that major earthquakes occur along this coastal region at 300- to 700-year intervals, and sometimes cause tsunamis (Carver et al. 1998, as cited in Pickart and Barbour 2007).

Wind is the other major disturbance process in this system. It drives seasonal movement of large dunes, in turn causing burial of forest vegetation along the eastern edge of the dune sheet and exhumation of previously buried vegetation in interdunal troughs. Storm winds lead to windthrow of many trees in exposed areas, and windfall is commonly seen in senescing stands of *Pinus contorta var. contorta*. Wind-driven sand and salt stunt and abrade plants, and can kill both buds and leaves of shrubs or conifers. Removal of vegetation exposes the sand to wind erosion, leading to the formation of blowouts or the complete destruction of stabilized dunes. Wind patterns are an important factor; in this system the northerly summer winds are associated with the North Pacific High and bring generally fair weather with occasional high-velocity land-sea breezes in the afternoon (Wiedemann 1984). In the winter, the low pressure systems commonly occurring further north are less important in this system. These wind patterns are modified by sheltering headlands and capes in places.

Fire, insects, and pathogens appear to have relatively minor roles in this system, although some *Pinus contorta var. contorta* stands are even-aged and result from stand-replacing fires; others result from primary succession (Christy et al. 1998). Pickart and Barbour (2007) provide a summary of recent work on plant-animal interactions and the roles of nitrogen-fixing plants in California dune ecosystems; they include topics such as rodent herbivory, the roles of ground-nesting bees in providing soil nutrients and pollination, cryptogamic soil crusts, obligate or facultative relationships between insects and plants, and others.

DISTRIBUTION

Range: Occurs in scattered locations from Point Conception, California, north to Coos Bay, Oregon.
Divisions: 204:P; 206:C
Nations: US
Subnations: CA, OR
Map Zones: 2:C, 3:C, 4:C
USFS Ecomap Regions: 263A:CC
TNC Ecoregions: 1:P, 14:C, 15:C

MEDITERRANEAN CALIFORNIA SERPENTINE BARRENS (CES206.905)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Non-Diagnostic Classifiers: Montane [Lower Montane]; Herbaceous; Moss/Lichen (Nonvascular); Serpentine; Mediterranean [Mediterranean Xeric-Oceanic]; Ultramafic with low Ca:Mg ratio; Very Shallow Soil; Xeric; Unconsolidated
National Mapping Codes: ESLF 3167

CONCEPT

Summary: This uncommon system is found in the central and southern Sierra Nevada, Central and Northern Coast Ranges, and Klamath Ranges at elevations between 150 to 1800 m (450-5500 feet), where serpentine outcrops and related soils are common. Not all serpentinite outcrops support distinct vegetation. Only those with very low Ca:Mg ratio impact biotic composition. This system is usually found on steep slopes with loosely consolidated soils and harsh soil chemical conditions (large rock outcrops and gravelly soil). There is typically a very low cover (<10%) of herbaceous species, including *Streptanthus* spp., *Hesperolinon* spp., *Allium falcifolium*, *Allium cratericola*, *Asclepias solanoana*, *Eriogonum ursinum*, and *Eriogonum nudum*.
Classification Comments: This system is very similar to North Pacific Serpentine Barren (CES204.095) of the East and West Cascades (Oregon and Washington) but tends to be more herbaceous in species composition, whereas North Pacific Serpentine Barren has a more developed woody component.
Similar Ecological Systems:
- North Pacific Serpentine Barren (CES204.095)

DESCRIPTION

Environment: This system is found in central and southern Sierra Nevada, central and northern Coast Ranges, and Klamath Mountains at elevations between 150 and 1800 m (450-5500 feet), where serpentine or ultramafic outcrops and related soils are common. Not all serpentinite outcrops support distinct vegetation. Only those with very low Ca:Mg ratio impact biotic composition. This system is usually found on steep slopes where loosely consolidated soils and harsh soil chemical conditions (large rock outcrops and gravelly soil) combine with xeric conditions (low rainfall or south- or west-facing, excessively-drained). Soils on ultramafics are usually shallow and skeletal, with little profile development. Ultramafic soils impose the following stresses on plants: imbalance of calcium and magnesium, magnesium toxicity, low availability of molybdenum, toxic levels of heavy metals, sometime high alkalinity, low concentrations of some essential nutrients, and low soil water storage capacity (Kruckeberg 1984, Sanchez-Mata 2007). In some cases, the steepness of the slopes and general sparseness of the vegetation result in continual erosion. Jimerson et al. (1995) found one plant community in this system to occur on convex, ridgetop or spur ridge positions where moisture conditions are extremely dry [often south- or west-facing]; exposed bare ground, gravel and rock have high cover. Occurrences are generally physiognomically distinct from the adjacent predominant forest or shrubland/chaparral vegetation; they can cover 100s of hectares.
Dynamics: The low cover of vascular plants combined with exposed sites leads to sheet erosion and soil loss being the major disturbance processes. Fine soil materials may be "captured" by micro-terraces leading to plant establishment and slow development of an organic soil horizon (Jimerson et al. 1995). Potential for alteration from fire is very low due to the high amount of soil and rock and low vegetation cover. Due the general lack of exotic species which tend to be intolerant of the ultramafic soils, this system is rich in native and endemic flora (Safford et al. 2005, Sanchez-Mata 2007). The interaction between serpentine soils and soil algae or fungi and small invertebrates is largely unstudied; Pegtel (1980) and Hopkins (1987) found that on barrens such as these the few tolerant plants are likely to be mycorrhizal. Harrison and Shapiro (1988) describe features of population biology of butterflies occurring on serpentines in northern California.

DISTRIBUTION

Range: This system is found in the central and southern Sierra Nevada, central and northern Coast Ranges, and Klamath Ranges at elevations between 150 and 1800 m (450-5500 feet).

MEDITERRANEAN CALIFORNIA SOUTHERN COASTAL DUNE (CES206.908)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Dune field; Coastal Dune Mosaic; Foredune; Dune (Substrate); Mediterranean [Mediterranean Xeric-Oceanic]; Salt Spray; W-Patch/High Intensity; Blowout; Abronia maritima
Non-Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Sagpond; Woody-Herbaceous; Shoreline; Barrier beach; Sand Soil Texture; Xeric; Unconsolidated; Very Short Disturbance Interval; Beach (Landform)
National Mapping Codes: ESLF 3164

CONCEPT

Summary: This coastal system occurs in scattered locations from Point Conception, California, south to north-central Baja California. Coastal dunes include beaches, foredunes, sand spits, and active to stabilizing backdunes and sandsheets derived from quartz or gypsum sands. The mosaic of sparse to dense vegetation in dune systems is driven by sand deposition, erosion, and lateral movement. Coastal dunes often front portions of inlets and tidal marshes. They may also occur as extensive dune fields dominating large coastal bays. Dune vegetation typically includes herbaceous, succulent, and low-shrub species with varying degrees of tolerance for salt spray, wind and sand abrasion, and substrate stability. Dune succession is highly variable, so species composition can vary significantly between occurrences. Generally, this dune system includes fewer perennial grasses and more suffrutescent plants than more northern dune systems. This system can be dominated by *Abronia maritima, Abronia umbellata, Atriplex leucophylla, Isocoma menziesii (= Haplopappus venetus), Distichlis spicata, Croton californicus, Lupinus chamissonis,* and *Carpobrotus chilensis (= Carpobrotus aequilateralus)*. Disturbance processes include dune blowouts caused by wind and occasional wave overwash during storm tidal surges.

DESCRIPTION

Environment: Coastal dunes include beaches, foredunes, sand spits, and active to stabilizing backdunes and sandsheets derived from quartz or gypsum sands. The mosaic of sparse to dense vegetation in dune systems is driven by sand deposition, erosion, and lateral movement. Coastal dunes often front portions of inlets and tidal marshes. They may also occur as extensive dune fields dominating large coastal bays. The climate is both Mediterranean and maritime; temperatures are moderate year-round. Most precipitation occurs in the winter months, followed by summer drought, and mild winter temperatures permit growing season throughout most of the year. Clouds and fog are present throughout the year. The dune localities are generally associated with nearby rivers, estuaries or bays; rivers deposit sediment which is carried by ocean currents and wind and deposited on flat coastline areas with onshore winds (Pickart and Barbour 2007). Dune sands are very poor soils, with no organic matter accumulation (Wiedemann 1984), and poor moisture-holding capacity. pH is about neutral and the nutrient status is so low as to be almost unmeasurable. A salinity gradient appears to be important in California dunes, and germination or emergence stages are more vulnerable to soil salinity or washover of saltwater than established plants. Pickart and Barbour (2007) provide a summary of studies of the physiological ecology of dune plants.

Dynamics: Disturbance processes include dune blowouts caused by wind and occasional wave overwash during storm tidal surges. Wind is the major disturbance process in this system. It drives seasonal movement of large dunes, in turn causing burial of forest vegetation along the eastern edge of the dune sheet and exhumation of previously buried vegetation in interdunal troughs. Storm winds lead to windthrow of many trees in exposed areas. Wind-driven sand and salt stunt and abrade plants, and can kill both buds and leaves of shrubs or conifers. Removal of vegetation exposes the sand to wind erosion, leading to the formation of blowouts or the complete destruction of stabilized dunes. Wind patterns are an important factor; in this system the northerly summer winds are associated with the North Pacific High and bring generally fair weather with occasional high-velocity land-sea breezes in the afternoon (Wiedemann 1984). In the winter, the low pressure systems commonly occurring further north are less important in this system. These wind patterns are modified by sheltering headlands and capes in places.

NORTH AMERICAN GLACIER AND ICE FIELD (CES100.728)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Alpine Slopes; Alpine/AltiAndino [Alpine/AltiAndino]; Ice Fields / Glaciers; Glaciated
Non-Diagnostic Classifiers: Mediterranean [Mediterranean Xeric-Continental]; Temperate [Temperate Continental]
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated
National Mapping Codes: EVT 2735; ESLF 3130; ESP 1735

CONCEPT

Summary: This widespread ecological system is composed of unvegetated landscapes of annual/perennial ice and snow in the North American arctic, and south into the highest elevations of the Rocky Mountains, Pacific coastal ranges, and the Sierra Madre of Mexico. They occur where snowfall accumulation exceeds melting. The primary ecological processes include snow/ice retention, wind desiccation, and permafrost. The snowpack/ice field never melts or, if so, then for only a few weeks. In places the ice fields are extensive, covering huge areas, while in the alpine, ice fields are part of the alpine mosaic consisting of alpine bedrock and scree, tundra dry meadow, wet meadow, fell-fields, and dwarf-shrubland. There are no vascular plants occurring in this system; biotic composition may include algal blooms, insect communities, and birds or mammals foraging on the insects.
Classification Comments: The barren rock and rubble within the glaciers is part of this system, not the alpine rock and scree systems.

DISTRIBUTION

Range: This ecological system is found throughout North America where high latitude or altitude results in permanent ice and snow fields, from the arctic and boreal regions south into the mountains of Alaska south and east through the cordillera of the Cascades and the Rocky Mountains. It also occurs in the alpine areas of the Sierra Madre in Mexico.

NORTH AMERICAN WARM DESERT ACTIVE AND STABILIZED DUNE (CES302.744)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Dune (Landform); Dune field; Dune (Substrate); Temperate [Temperate Xeric]; Sand Soil Texture; W-Landscape/High Intensity
Non-Diagnostic Classifiers: Dune (undifferentiated); Lowland [Lowland]; Shrubland (Shrub-dominated); Herbaceous; Tropical/Subtropical [Tropical Xeric]; Gypsiferous; Aridic
National Mapping Codes: ESLF 3121

CONCEPT

Summary: This ecological system occurs across the warm deserts of North America and is composed of unvegetated to sparsely vegetated (generally <10% plant cover) active dunes and sandsheets derived from quartz or gypsum sands. Common vegetation includes *Ambrosia dumosa, Abronia villosa, Artemisia filifolia, Atriplex canescens, Eriogonum deserticola, Larrea tridentata, Pleuraphis rigida, Poliomintha* spp., *Prosopis* spp., *Psorothamnus* spp., *Rhus microphylla,* and *Sporobolus flexuosus*. Dune "blowouts" and subsequent stabilization through succession are characteristic processes.
Similar Ecological Systems:
- Chihuahuan Gypsophilous Grassland and Steppe (CES302.732)

Component Associations:
- *Abronia villosa* Sparse Vegetation (CEGL003001, G2G3)
- *Artemisia filifolia - Psorothamnus scoparius - Dalea lanata* Gypsum Dune Shrubland (CEGL004561, G1G2)
- *Artemisia filifolia / Andropogon hallii - Achnatherum hymenoides* Gypsum Dune Shrubland (CEGL004559, G1G2)
- *Artemisia filifolia / Sporobolus flexuosus* Shrubland (CEGL001547, G5)
- *Artemisia filifolia / Sporobolus giganteus* Shrubland (CEGL001078, G5)

NORTH AMERICAN WARM DESERT BADLAND (CES302.743)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Badland; Badlands; Alkaline Soil; Shale and Mudstone; Silt Soil Texture; Clay Soil Texture
Non-Diagnostic Classifiers: Lowland [Lowland]; Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Aridic; Very Short Disturbance Interval
National Mapping Codes: ESLF 3123

CONCEPT

Summary: This ecological system occurs from Arizona to Texas and adjacent Mexico. It is restricted to barren and sparsely vegetated (generally <10% plant cover) substrates typically derived from marine shale or mudstone (badlands and mudhills). The harsh soil properties and high rate of erosion and deposition are driving environmental variables supporting sparse shrubs and dwarf-shrubs e.g., *Atriplex hymenelytra*, and herbaceous vegetation.

Component Associations:
- *Atriplex hymenelytra* Shrubland (CEGL001317, G5)
- *Cleome isomeris - Ephedra californica - Ericameria linearifolia* Shrubland (CEGL003056, G1G3)

NORTH AMERICAN WARM DESERT BEDROCK CLIFF AND OUTCROP (CES302.745)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Rock Outcrops/Barrens/Glades; Temperate [Temperate Xeric]; Canyon; Cliff (Landform)
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Rockfall avalanche; Ridge/Summit/Upper Slope; Sideslope; Toeslope/Valley Bottom; Granitic Rock; Sedimentary Rock; Metamorphic Rock; Igneous Rock; Tropical/Subtropical [Tropical Xeric]; Very Shallow Soil
National Mapping Codes: ESLF 3120

CONCEPT

Summary: This ecological system occurs from California to Texas and adjacent Mexico. It is found from subalpine to foothill elevations and includes barren and sparsely vegetated landscapes (generally <10% plant cover) of steep cliff faces, narrow canyons, and smaller rock outcrops of various igneous, sedimentary, and metamorphic bedrock types. Also included are unstable scree and talus slopes that typically occur bellow cliff faces. Species present are diverse and may include *Bursera microphylla*, *Fouquieria splendens*, *Nolina bigelovii*, *Opuntia bigelovii*, and other desert species, especially succulents. Lichens are predominant lifeforms in some areas. May include a variety of desert shrublands less than 2 ha (5 acres) in size from adjacent areas.
Similar Ecological Systems:
- Edwards Plateau Cliff (CES303.653)

Component Associations:
- *Fouquieria splendens / Bouteloua hirsuta* Shrubland (CEGL001377, G3?)
- *Fouquieria splendens* Shrubland (CEGL004452, GNR)
- *Larrea tridentata - Jatropha dioica var. graminea* Shrubland (CEGL004566, G3?)
- *Larrea tridentata - Opuntia schottii* Shrubland (CEGL004567, G4?)
- *Opuntia bigelovii* Shrubland (CEGL003065, G4?)

NORTH AMERICAN WARM DESERT PAVEMENT (CES302.750)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Lowland [Lowland]; Playa; Desert Pavement; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; W-Landscape/High Intensity
Non-Diagnostic Classifiers: Shrubland (Shrub-dominated); Toeslope/Valley Bottom; Aridic
National Mapping Codes: ESLF 3143

CONCEPT

Summary: This ecological system occurs throughout much of the warm deserts of North America and is composed of unvegetated to very sparsely vegetated (<2% plant cover) landscapes, typically flat basins where extreme temperature and wind develop ground surfaces of fine to medium gravel coated with "desert varnish." This sparsely vegetated system may surround playas in valley bottoms or near washes and, less commonly, on dissected, eroding alluvial fans. Very low cover of desert scrub species such as *Larrea tridentata* or *Eriogonum fasciculatum* is usually present. However, ephemeral herbaceous species may have high cover in response to seasonal precipitation, including *Chorizanthe rigida*, *Eriogonum inflatum*, and *Geraea canescens*.

Component Associations:
- *Ambrosia deltoidea / Simmondsia chinensis* Shrubland (CEGL000953, G4)
- *Ambrosia dumosa - Larrea tridentata var. tridentata* Dwarf-shrubland (CEGL000956, G4)
- *Eriogonum fasciculatum - Purshia glandulosa* Shrubland (CEGL001259, G4)
- *Eriogonum fasciculatum* Shrubland (CEGL001258, G5)

DISTRIBUTION

Range: Occurs throughout much of the warm deserts of North America.
Divisions: 302:C
Nations: MX, US
Subnations: AZ, CA, MXCH(MX), MXSO(MX), NM, NV, TX
Map Zones: 13:C, 14:C, 15:?, 24:?, 25:C, 26:C

NORTH AMERICAN WARM DESERT PLAYA (CES302.751)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Diagnostic Classifiers: Alkaline Water; Saline Water Chemistry; Caliche Layer; Impermeable Layer; Intermittent Flooding; Lowland [Lowland]; Playa; Desert Pavement; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]; Depressional; Alkaline Soil; Aridic
Non-Diagnostic Classifiers: Clay Subsoil Texture; Shrubland (Shrub-dominated); Woody-Herbaceous; Isolated Wetland [Partially Isolated]; Dwarf-Shrub; Forb; Graminoid
National Mapping Codes: ESLF 3161

CONCEPT

Summary: This ecological system is composed of barren and sparsely vegetated playas (generally <10% plant cover) found across the warm deserts of North America, extending into the extreme southern end of the San Joaquin Valley in California. Playas form with intermittent flooding, followed by evaporation, leaving behind a saline residue. Salt crusts are common throughout, with small saltgrass beds in depressions and sparse shrubs around the margins. Subsoils often include an impermeable layer of clay or caliche. Large desert playas tend to be defined by vegetation rings formed in response to salinity. Given their common location in windswept desert basins, dune fields often form downwind of large playas. In turn, playas associated with dunes often have a deeper water supply. Species may include *Allenrolfea occidentalis, Suaeda* spp., *Distichlis spicata, Eleocharis palustris, Oryzopsis* spp., *Sporobolus* spp., *Tiquilia* spp., or *Atriplex* spp. Ephemeral herbaceous species may have high cover periodically. Adjacent vegetation is typically Sonora-Mojave Mixed Salt Desert Scrub (CES302.749), Chihuahuan Mixed Salt Desert Scrub (CES302.017), Gulf of California Coastal Mixed Salt Desert Scrub (CES302.015), Baja California del Norte Gulf Coast Ocotillo-Limberbush-Creosotebush Desert Scrub (CES302.014), or Chihuahuan Creosotebush Desert Scrub (CES302.731).
Related Concepts:
- Saltbush - Greasewood (501) (Shiflet 1994) Intersecting. Desert playas can have salt desert scrub in low cover.

Component Associations:
- *Allenrolfea occidentalis* Shrubland (CEGL000988, G3)
- *Atriplex polycarpa / Pleuraphis mutica* Shrubland (CEGL001319, GU)
- *Atriplex polycarpa* Shrubland (CEGL001318, G5)
- *Bouteloua breviseta* Sparse Vegetation (CEGL004609, G3?)
- *Sesuvium verrucosum* Sparse Vegetation (CEGL004595, G3?)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Baja California del Norte Gulf Coast Ocotillo-Limberbush-Creosotebush Desert Scrub (CES302.014)
- Chihuahuan Creosotebush Desert Scrub (CES302.731)
- Chihuahuan Mixed Salt Desert Scrub (CES302.017)
- Gulf of California Coastal Mixed Salt Desert Scrub (CES302.015)
- Sonora-Mojave Mixed Salt Desert Scrub (CES302.749)

Adjacent Ecological System Comments: Adjacent vegetation is typically Sonora-Mojave Mixed Salt Desert Scrub (CES302.749), Chihuahuan Mixed Salt Desert Scrub (CES302.017), Gulf of California Coastal Mixed Salt Desert Scrub (CES302.015), Baja California del Norte Gulf Coast Ocotillo-Limberbush-Creosotebush Desert Scrub (CES302.014), or Chihuahuan Creosotebush Desert Scrub (CES302.731).

DISTRIBUTION

Range: Found across the warm deserts of North America, extending into the extreme southern end of the San Joaquin Valley in California.
Divisions: 302:C
Nations: MX, US
Subnations: AZ, CA, MXBC(MX), MXCH(MX), MXSO(MX), NM, NV, TX

NORTH AMERICAN WARM DESERT VOLCANIC ROCKLAND (CES302.754)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Warm Desert (302)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Lava; Cinder; Basalt; Tropical/Subtropical [Tropical Xeric]; Temperate [Temperate Xeric]
Non-Diagnostic Classifiers: Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Ridge/Summit/Upper Slope; Sideslope; Toeslope/Valley Bottom; Aridic
National Mapping Codes: ESLF 3180

CONCEPT

Summary: This ecological system occurs across the warm deserts of North America and is restricted to barren and sparsely vegetated (<10% plant cover) volcanic substrates such as basalt lava (malpais) and tuff. Vegetation is variable and includes a variety of species depending on local environmental conditions, e.g., elevation, age and type of substrate. Typically scattered *Larrea tridentata*, *Atriplex hymenelytra*, or other desert shrubs are present.

Component Associations:
- *Aloysia wrightii / Perityle staurophylla* Shrubland (CEGL001280, GNRQ)
- *Opuntia bigelovii* Shrubland (CEGL003065, G4?)

DISTRIBUTION

Range: Occurs across the warm deserts of North America.
Divisions: 302:C
Nations: MX, US
Subnations: AZ, CA, MXBC(MX), MXCH(MX), MXSO(MX), NM, NV, TX
Map Zones: 13:C, 14:C, 15:P, 17:?, 25:C, 26:C

NORTH ATLANTIC COBBLE SHORE (CES201.051)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: <24-hour hydroperiod; Lowland [Lowland]; Boreal [Boreal Hyperoceanic]; Salt Spray; Beach (Landform)
National Mapping Codes: ESLF 3132

CONCEPT

Summary: This system encompasses areas of varying exposure that include boulder, cobble, and gravel shores, often adjacent to bedrock shoreline and rocky intertidal areas. Cobble shores may have >75% cobble bottom. Some occurrences are mixed sand and gravel beaches, others have different combinations of particle sizes. These areas have sufficient exposure to winnow out the fine sand-, silt- and clay-sized particles without removing the larger grain sizes. The bottom is usually comprised of cobble and gravel, although shell hash may also be present in various amounts. These areas have low diversity, probably due to insufficient nutrition for and high disturbance of infauna. Diagnostic species include species colonizing from nearby rocky areas if present, e.g., Irish moss (*Chondrus crispus*), rockweed (*Fucus vesiculosus*), knotted wrack (*Ascophyllum nodosum*), coralline algae (*Corallina officinalis*), and kelp (*Laminaria* spp.). Fauna is composed of the following: segmented worms (*Enchytraeus* spp.), collembola (mostly *Anurida maritima*), blue mussels (*Mytilus* spp.), periwinkles (*Littorina littorea*, *Littorina obtusata*, *Littorina saxatilis*), limpets (*Tectura testudinalis*), and barnacles (*Semibalanus balanoides*), among others.
Similar Ecological Systems:

NORTH ATLANTIC INTERTIDAL MUDFLAT (CES201.050)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Wetland
Non-Diagnostic Classifiers: <24-hour hydroperiod; Lowland [Lowland]; Herbaceous
National Mapping Codes: ESLF 3133

CONCEPT

Summary: Mudflats are usually located in quiet pockets of bays and protected by headlands. Sand-sized particles are mixed with silt and clay. These flats can be highly productive of clams and other invertebrates, and are important habitats for many shorebird species, including the semipalmated sandpiper, semipalmated plover, short-billed dowitcher, black-bellied plover, and least sandpiper. In the summer, *Enteromorpha intestinalis* can cover these mudflats. Other characteristic species include *Enteromorpha prolifera, Ulva lactuca, Rhizoclonium riparium, Ruppia maritima*, and *Zostera marina*.
Classification Comments: This system currently extends from Cape Hatteras to the Canadian Maritimes. Compositional variation is known to exist across this range; it is left as one system pending finalization of NatureServe's marine/estuarine classification and determination of how the two classifications relate. For example, on the more local scale of the Gulf of Maine, it has been suggested that mudflats east of the Penobscot River contain somewhat different assemblages of organisms than do mudflats west of the Penobscot River (Brown 1993). Some factor (perhaps temperature) would be necessary to separate these communities.
Similar Ecological Systems:
- North Atlantic Tidal Sand Flat (CES201.049)

Component Associations:
- Intertidal Mudflats Sparse Vegetation (CEGL006614, G5)
- *Zostera marina* Herbaceous Vegetation (CEGL004336, G4G5)

DISTRIBUTION

Range: This system occurs along the mid- and north Atlantic coasts from North Carolina north into Canada.
Divisions: 103:P; 201:C; 202:C; 203:C
Nations: CA, US
Subnations: CT, DE, LB, MA, MD, ME, NB, NC, NH, NJ, NS, NY, QC?, RI, VA

NORTH ATLANTIC ROCKY INTERTIDAL (CES201.048)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Saltwater (Polyhaline); <24-hour hydroperiod; Moss/Lichen (Nonvascular); Tidal flat; Lichen; Alga
Non-Diagnostic Classifiers: Lowland [Lowland]; Nonvascular
National Mapping Codes: ESLF 3190

CONCEPT

Summary: This ecological system represents the intertidal zone with solid rock substrates that can experience extremes of exposure to winds, waves, currents, and ice-scour. This encompasses both exposed and partially exposed habitats. Lichens (often *Xanthoria* spp., *Verrucaria* spp., and *Vaucheria* spp.) and blue-green algae (*Caliothrix* spp.) are present in the supralittoral and high littoral zones, respectively. Barnacles, usually *Semibalanus balanoides*, are found in the mid-intertidal zone, usually in crevices that offer some protection from the extreme elements. Mussels are found in the lower intertidal, also appearing mostly in crevices. Diagnostic species include Irish moss (*Chondrus crispus*), rockweed (*Fucus vesiculosus*, *Fucus evanescens*, and *Fucus spiralis*), knotted wrack (*Ascophyllum nodosum*), hollow-stemmed kelp (*Laminaria* spp.), blue mussels (*Mytilus edulis*), common periwinkles (*Littorina littorea*), dogwhelks (*Nucella lapillus*), and springtails (*Anurida maritima*). In the low-intertidal zone, small fronds of kelp may be present, but short, torn stipes are often all that remain. Rockweed and knotted wrack, which are typically found in less exposed rocky habitats, are small, restricted to crevices, or missing. Tidepools are frequently found in these habitats and are inhabited by both intertidal and subtidal species. Tidepools are nurseries for lumpfish, sea snails, and pollock. Many other fish have also been identified in tidepools. Many species of birds are found on these rocky shores. Purple sandpipers are found in the winter; ruddy turnstone and sanderlings are the main species in spring and fall migrations. Other shorebirds that also use rocky shores include black-bellied plovers, American oystercatchers, and pectoral sandpipers.
Classification Comments: This system currently extends from New York to the Canadian Maritimes. Compositional variation may exist across this range; it is left as one system pending finalization of NatureServe's marine/estuarine classification and determination of how the two classifications relate.
Similar Ecological Systems:
- North Atlantic Cobble Shore (CES201.051)--is similar but on a loose rock substrate.

Component Associations:
- *Ascophyllum nodosum - Fucus vesiculosus* Tidal Algal Nonvascular Vegetation (CEGL006341, GNR)

DISTRIBUTION

Range: This system is found throughout the Gulf of Maine and extending sporadically down to New York.
Divisions: 103:C; 201:C; 202:C
Nations: CA, US
Subnations: CT, LB, MA, ME, NB, NH, NS, NY, QC?, RI

NORTH ATLANTIC TIDAL SAND FLAT (CES201.049)

CLASSIFIERS

Classification Status: Standard

Primary Division: Laurentian-Acadian (201)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Wetland
Diagnostic Classifiers: Boreal [Boreal Hyperoceanic]; Unconsolidated; Alga
Non-Diagnostic Classifiers: Lowland [Lowland]
National Mapping Codes: ESLF 3134

CONCEPT

Summary: This system of intertidal sand flats occurs primarily in the embayed areas of the mid-Atlantic and north Atlantic coasts. Rocky or sandy barriers help create protected sounds and lagoons, providing areas for colonization of hydromorphic herbaceous vegetation. Local habitats range from small guts, shallow tributary creeks, and large saline pools to shallow estuarine bays, tidal creeks, and estuary pools. *Zostera marina* is the dominant plant species in saline habitats, but not all sand flats are vegetated. The invertebrate diversity in these sheltered habitats is higher than that of exposed and partially exposed sandy beaches. These habitats are frequently used by shorebirds, such as sanderlings, semipalmated sandpipers, black-bellied plovers, red knots, and semipalmated plovers.
Classification Comments: This system currently extends from Cape Hatteras to the Canadian Maritimes. Compositional variation is known to exist across this range; it is left as one system pending finalization of NatureServe's marine/estuarine classification and determination of how the two classifications relate.
Similar Ecological Systems:
- North Atlantic Intertidal Mudflat (CES201.050)
- Northern Atlantic Coastal Plain Seagrass Bed (CES203.246)

Component Associations:
- *Zostera marina* Herbaceous Vegetation (CEGL004336, G4G5)

DISTRIBUTION

Range: This system occurs primarily in the embayed regions of mid- and north Atlantic coast from North Carolina north into Canada.
Divisions: 103:C; 201:C; 202:C; 203:C

NORTH PACIFIC ACTIVE INLAND DUNE (CES204.861)

CLASSIFIERS

Conf.: 3 - Weak **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Dune (Substrate); Very Short Disturbance Interval; Graminoid
Non-Diagnostic Classifiers: Lowland [Lowland]; Temperate [Temperate Continental]; Unconsolidated
National Mapping Codes: ESLF 3157

CONCEPT

Summary: Active inland dunes occur near the terminus of glaciers and on the edge of outwash plains, located mostly in south-central and southeastern Alaska; one rare remnant outlier example occurs in the western Columbia River Gorge of Oregon. Species composition is variable, ranging from *Leymus arenarius (= Elymus arenarius)* to *Betula papyrifera* to *Alnus* species. Disturbance is primarily from dune blowouts and the deposition of sand and loess. The Oregon occurrence is now mostly stabilized by vegetation because sand resupply from the Columbia River has been cut off by hydroelectric dams, but about 20 acres of open dunes remain active because of perennially strong winds. Dune creep continues to bury a bottomland forest of *Populus balsamifera ssp. trichocarpa*, *Fraxinus latifolia*, and *Cornus sericea*. This dune is 24-30.5 m (80-100 feet) tall, and a stabilized dune nearby is about 49 m (160 feet) tall.
Classification Comments: In Alaska, active inland dunes (as opposed to coastal dunes) have not been identified for the maritime region. It's now unclear whether this system occurs in Alaska, or only in one location in Oregon. Inland dunes apparently do not occur in the Cook Inlet Basin.

DISTRIBUTION

Range: This system is found from the Columbia River Gorge north. In Washington, only coastal dunes occur.
Divisions: 204:C
Nations: US
Subnations: AK?, OR

NORTH PACIFIC ACTIVE VOLCANIC ROCK AND CINDER LAND (CES204.092)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Lava; Cinder; Basalt
National Mapping Codes: ESLF 3140

CONCEPT

Summary: This ecological system includes active volcanic landscapes dominated by ash, pyroclastic deposits, lava, landslides and other exposed bare mineral and rock. Periodic eruptions and earthquakes are the primary processes maintaining a primarily barren environment. Decades of inactivity slowly provide opportunity for development of other systems, such as North American Glacier and Ice Field (CES300.728) or North Pacific Wooded Volcanic Flowage (CES204.883), or primary successional stages of surrounding vegetated systems to develop.
Classification Comments: Mount St. Helens is the prototype. Barren volcanic landscapes on the Alaska Peninsula and Aleutian Islands have been placed into Aleutian Volcanic Rock and Talus (CES105.308).
Similar Ecological Systems:
- Aleutian Volcanic Rock and Talus (CES105.308)

DISTRIBUTION

Range: This system is found in the Cascade Range from northern California north to Washington and is limited to barren and sparsely vegetated volcanic substrates.
Divisions: 204:C
Nations: US
Subnations: CA?, OR, WA
Map Zones: 1:C, 2:P, 6:P, 7:C, 8:P, 9:P

NORTH PACIFIC ALPINE AND SUBALPINE BEDROCK AND SCREE (CES204.853)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine Slopes; Alpine/AltiAndino; Talus (Substrate); Rock Outcrops/Barrens/Glades; Oligotrophic Soil; Very Shallow Soil
Non-Diagnostic Classifiers: Temperate [Temperate Continental]; Glaciated; Unconsolidated
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Boulder, gravel, cobble, or talus
National Mapping Codes: EVT 2734; ESLF 3118; ESP 1734

CONCEPT

Summary: This ecological system includes all the exposed rock and rubble above the forest line (subalpine parkland and above) in the North Pacific mountain ranges and is restricted to the highest elevations in the Cascade Range, from southwestern British Columbia south into northern California, and also north into southeastern Alaska. It is composed of barren and sparsely vegetated alpine substrates, typically including both bedrock outcrops and scree slopes, upper mountain slopes, summits and nunataks. Nonvascular- (lichen-) dominated communities are common. Exposure to desiccating winds, rocky and sometimes unstable substrates, and a short growing season limit plant growth. In Alaska, this system usually occurs above alpine dwarf-shrub, herbaceous meadow, and dwarf-shrub-herbaceous systems typically at elevations higher than 915 m (3000 feet) (possibly higher in southeastern Alaska). There can be sparse cover of forbs, grasses, lichens, shrubs and small trees, but the total vascular plant cover is typically less than 25% due to the high cover of exposed rock. Species composition is variable and may include *Artemisia arctica, Astragalus alpinus, Carex microchaeta, Minuartia arctica, Salix rotundifolia, Saxifraga sibirica (= Saxifraga bracteata), Saxifraga bronchialis, Sibbaldia procumbens*, and *Silene acaulis*. Common nonvascular genera include *Racomitrium* and *Stereocaulon*.
Classification Comments: This system now includes the type known as Maritime High Alpine Herbaceous by the Alaska Natural Heritage Program.

NORTH PACIFIC COASTAL CLIFF AND BLUFF (CES204.094)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Headland; Sea cliff; Talus (Substrate); Rock Outcrops/Barrens/Glades; Oligotrophic Soil; Salt Spray; Very Shallow Soil; Landslide; W-Landscape/High Intensity; Bluff
Non-Diagnostic Classifiers: Lowland [Lowland]; Cliff (Substrate); Temperate [Temperate Oceanic]; Saline Substrate Chemistry; Xeric; Cliff (Landform); Coast
National Mapping Codes: ESLF 3158

CONCEPT

Summary: This ecological system includes unvegetated or sparsely vegetated rock cliffs and very steep bluffs of glacial deposits along the Pacific Ocean and associated marine and estuarine inlets. It is restricted to degrading slopes from southwestern British Columbia south into central Oregon. It is composed of barren and sparsely vegetated substrates, typically including exposed sediments, bedrock, and scree slopes. Exposure to waves, eroding and desiccating winds, slope failures and sheet erosion create gravelly to rocky substrates that are often unstable. There can be sparse cover of forbs, grasses, lichens and low shrubs.
Classification Comments: Small areas of rock outcrop within a mosaic of vegetated systems are best considered part of an adjacent system, e.g., within herbaceous balds and bluffs. In Washington, North Pacific Hypermaritime Shrub and Herbaceous Headland (CES204.088) and this cliff system sometimes occur adjacent or in a mosaic together, but not always. It is quite frequent to get cliffs without the vegetated part. The shrub and herbaceous component is less common. In Mediterranean California these two types of systems are split from each other (coastal grassland from coastal bluff). As far as biodiversity goes, the vegetated versus the nonvegetated are very different. This system is distinguished from Mediterranean California Coastal Bluff (CES206.906) by being further north in areas where summers are typically cooler, and winters may include some snow.

DISTRIBUTION

Range: This system is found from central Oregon north along the immediate coast into British Columbia.

NORTH PACIFIC MARITIME COASTAL SAND DUNE AND STRAND (CES200.881)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Herbaceous; Dune (Substrate); Beach (Substrate); Temperate [Temperate Oceanic]; Salt Spray
Non-Diagnostic Classifiers: Lowland [Lowland]
National Mapping Codes: ESLF 3177

CONCEPT

Summary: Coastal sand dunes are found throughout the northern Pacific Coast, from south-central Alaska to the central Oregon coast (roughly Coos Bay). This system covers large areas of the southern Washington and central Oregon coasts, but coastal dunes in Alaska have been placed into a different system. Coastal dunes include beach strand (not the beach itself but sparsely or densely vegetated areas behind the beach), foredunes, sand spits, and active to stabile backdunes and sandsheets derived from quartz or gypsum sands. The mosaic of sparse to dense vegetation in dune systems is driven by sand deposition, erosion, and lateral movement. Disturbance processes include dune blowouts caused by wind and occasional wave overwash during storm tidal surges. Coastal dunes often front portions of inlets and tidal marshes. Dune vegetation typically includes herbaceous, succulent, shrub, and tree species with varying degrees of tolerance for salt spray, wind and sand abrasion, and substrate stability. Dune succession is highly variable, so species composition can vary significantly among occurrences. These dunes can be dominated by *Leymus arenarius (= Elymus arenarius)*, *Festuca rubra*, *Leymus mollis*, or various forbs adapted to salty dry conditions. *Gaultheria shallon* and *Vaccinium ovatum* are major shrub species. Forested portions of dunes are included within this system and are characterized (at least in the south) by *Pinus contorta var. contorta* early in succession, *Picea sitchensis* somewhat later in the sere, and in some cases *Tsuga heterophylla* later still. *Pseudotsuga menziesii* sometimes codominates in Oregon. In many cases, occurrences have thin, fragile layers of lichens and mosses covering the sand in between clumps of grasses or shrubs. Disturbance processes include dune blowouts caused by wind and occasional wave overwash during storm tidal surges. Late-sere forests, dominating stabilized dune systems where active dune processes are nearly absent and that compositionally represent the adjacent matrix system, are excluded from this dune system. Interdunal wetlands occur commonly within the matrix of this system and sometimes are extensive in deflation plains or old dune troughs, but are considered part of various separate wetland ecological systems depending on their hydrology, and are not part of this upland system.
Classification Comments: Concept has been revised with input from John Christy. We include forested dunes here and put wetlands in other wetland systems. Forested dunes eventually become very similar to the matrix forest, i.e., *Picea sitchensis* basically late-successional forest dunes. Mapping issues are expected as forested dunes lose the *Pinus contorta var. contorta* component and become completely dominated by *Picea sitchensis* and/or *Tsuga heterophylla* (old-growth or late-successional forest composition). As long as *Pinus contorta var. contorta* is a prominent component, the forested dune continues to be part of the dune system.
Similar Ecological Systems:
- Alaskan Pacific Maritime Coastal Dune, Beach and Beach Meadow (CES204.166)

Related Concepts:
- Lodgepole Pine: 218 (Eyre 1980) Intersecting
- Sitka Spruce: 223 (Eyre 1980) Intersecting

DESCRIPTION

Environment: These dunes are found in about 23 localities along the North American Pacific Northwest Coast, from just north of Coos Bay, Oregon, north into Washington near the Copalis River (Wiedemann 1984). Coastal dunes include beach strand (not the beach itself but sparsely or densely vegetated areas behind the beach), foredunes, sand spits, and active to stabile backdunes and sandsheets derived from quartz or gypsum sands. Climate is both Mediterranean and maritime; temperatures are moderate year-round. Most precipitation occurs in the winter months, followed by summer drought, and mild winter temperatures permit growing season throughout most of the year (Wiedemann 1984, Christy et al. 1998). Clouds and fog are present throughout the year, with fog becoming increasingly common to the south (Wiedemann 1984). The dune localities are generally associated with nearby rivers, estuaries or bays (Wiedemann 1984); rivers deposit sediment which is carried by ocean currents and wind and deposited on flat coastline areas with on-shore winds. Dune sands are very poor soils, with no organic matter accumulation (Wiedemann 1984). pH is about neutral and the nutrient status is so low as to be almost unmeasurable. In this system, the rainfall is so high that, combined with rapid drainage, salinity is not an important factor even in areas just above the beach (Wiedemann 1984). Dune sands have poor moisture-holding capacity; however, these dunes are underlain by groundwater aquifers that maintain a high water table (Christy et al. 1998).
Dynamics: The north Pacific coastal dunes are dynamic, transgressive, wind-controlled systems in their natural condition (citations in Zarnetske et al. 2010). These communities are dependent upon longshore drift and wind (WNHP 2011). Most occurrences are spits or berms behind sandy beaches. The mosaic of sparse to dense vegetation in dune systems is driven by sand deposition, erosion, and lateral movement. Disturbance processes include dune blowouts caused by wind and occasional wave overwash during storm tidal

surges. Cyclical dune activity is apparently triggered by cyclical changes in sea level associated with glaciation and tectonic events (Wiedemann 1984, Christy et al. 1998). Subsidence or uplift of 1.8 to 2.7 m (6-9 feet) associated with earthquakes would initiate new successional pathways after destruction of existing dune formations and vegetation (Thilenius 1995). Generally it appears that major earthquakes occur along this coastal region at 300- to 700-year intervals (Christy et al. 1998), and sometimes cause tsunamis.

Wind is the major disturbance process in this system. It drives seasonal movement of large dunes, in turn causing burial of forest vegetation along the eastern edge of the dune sheet and exhumation of previously buried vegetation in interdunal troughs. Storm winds lead to windthrow of many trees in exposed areas, and windfall is commonly seen in senescing stands of *Pinus contorta var. contorta*. Wind-driven sand and salt stunt and abrade plants, and can kill both buds and leaves of shrubs or conifers. Removal of vegetation exposes the sand to wind erosion, leading to the formation of blowouts or the complete destruction of stabilized dunes. Wind patterns are an important factor; in this system northerly summer winds are associated with the North Pacific High and bring generally fair weather with occasional high-velocity land-sea breezes in the afternoon (Wiedemann 1984). In the winter low pressure systems dominate the weather patterns, bringing heavy rains and strong southerly winds. These wind patterns are modified by sheltering headlands and capes in places.

Fire, insects, and pathogens appear to have relatively minor roles in this system, although some *Pinus contorta var. contorta* stands are even-aged and result from stand-replacing fires; others result from primary succession (Christy et al. 1998).

Component Associations:
- *Artemisia campestris - Festuca rubra / Racomitrium canescens* Herbaceous Vegetation (CEGL003370, G1)
- *Baccharis pilularis / Artemisia pycnocephala - Scrophularia californica* Shrubland (CEGL001426, G1G2)
- *Carex macrocephala* Herbaceous Vegetation (CEGL003368, G1G2)
- *Chamaecyparis lawsoniana / Vaccinium ovatum* Forest (CEGL000048, G1)
- *Empetrum nigrum - Gaultheria shallon* Dwarf-shrubland (CEGL000971, G2)
- *Festuca rubra* Stabilized Dune Herbaceous Vegetation (CEGL001774, G1)
- *Gaultheria shallon - Vaccinium ovatum / Pteridium aquilinum* Shrubland (CEGL000972, G3)
- *Juncus falcatus - Trifolium wormskioldii* Herbaceous Vegetation (CEGL001570, G4)
- *Leymus mollis ssp. mollis - Abronia latifolia* Herbaceous Vegetation (CEGL001796, G2?)
- *Lupinus littoralis* Dune Herbaceous Vegetation (CEGL001974, G3)

NORTH PACIFIC MONTANE MASSIVE BEDROCK, CLIFF AND TALUS (CES204.093)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate); Talus (Substrate); Rock Outcrops/Barrens/Glades; Temperate [Temperate Oceanic]; Canyon
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Boulder, gravel, cobble, or talus
National Mapping Codes: EVT 2733; ESLF 3155; ESP 1733

CONCEPT

Summary: This ecological system is found from foothill to subalpine elevations and includes barren and sparsely vegetated landscapes (generally <10% vascular plant cover) of steep cliff faces, narrow canyons, and larger rock outcrops of various igneous, sedimentary, and metamorphic bedrock types. Also included are unstable scree and talus that typically occur below cliff faces. The dominant process is drought, especially farther south in its distribution, and other extreme growing conditions created by exposed rock or unstable slopes typically associated with steep slopes. Alaskan montane rock and talus probably has a significant component on nonvascular species, and is not drought-limited. Fractures in the rock surface and less steep or more stable slopes may be occupied by small patches of dense vegetation, typically scattered trees and/or shrubs. Characteristic trees includes *Chamaecyparis nootkatensis*, *Tsuga* spp., *Thuja plicata*, *Pseudotsuga menziesii* (not in Alaska), or *Abies* spp. There may be scattered shrubs present, such as *Acer circinatum*, *Alnus viridis*, and *Ribes* spp. Soil development is limited as is herbaceous cover. Mosses or lichens may be very dense, well-developed and display cover well over 10%.
Classification Comments: This system was distinguished from montane cliffs and barrens in the Rockies based on a change in floristic division and the apparent abundance of nonvascular cover on rocks compared to drier divisions. It also includes cliffs, barrens and rock outcrops in coastal southeastern Alaska, if they are not covered with snow and ice.

DISTRIBUTION

Range: This system occurs from northern California (north of Sierra Nevada Cliff and Canyon (CES206.901)) to southeastern Alaska.

NORTH PACIFIC SERPENTINE BARREN (CES204.095)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Non-Diagnostic Classifiers: Montane [Lower Montane]; Herbaceous; Moss/Lichen (Nonvascular); Serpentine; Ultramafic with low Ca:Mg ratio; Very Shallow Soil; Xeric; Unconsolidated
National Mapping Codes: ESLF 3159

CONCEPT

Summary: This uncommon ecological system is found in the east and west Cascades. It is usually found on steep slopes with loosely consolidated soils and harsh soil chemical conditions (large rock outcrops and gravelly soil), although exposed ridges occur. This system occurs primarily in the Wenatchee Mountains in the east Cascades between 760 and 2100 m elevation (2500-7000 feet) on thin rocky, ultramafic (peridotite, serpentinite) soils of varying extent up to several square km. Most sites support often stunted conifers, typically stress-tolerant species. Not all ultramafic outcrops support a distinct vegetation. Only those with very low Ca:Mg ratio impact biotic composition, whereas others reflect increased influence of soil drought on ultramafic material. These systems are highly variable and are described here to include barren slopes to patches of nearly closed forests. Low-elevation sites support *Pseudotsuga menziesii*, *Pinus ponderosa*, and *Pinus monticola* trees with a sparse ground cover with *Aspidotis densa*, *Arctostaphylos nevadensis*, and *Pseudoroegneria spicata*. Higher elevations have *Pinus contorta var. latifolia*, *Pinus albicaulis*, *Abies lasiocarpa*, and *Tsuga mertensiana* with *Juniperus communis*, *Ledum glandulosum*, *Vaccinium scoparium*, *Poa curtifolia*, and *Festuca viridula*.
Classification Comments: This is very similar to Mediterranean California Serpentine Barrens (CES206.905) of California and southern Oregon but tends to have a more developed woody component, whereas the California serpentine barrens are more herbaceous.
Similar Ecological Systems:
- Mediterranean California Serpentine Barrens (CES206.905)

Component Associations:
- *Pinus ponderosa / Aspidotis densa* Woodland (CEGL000847, G1)
- *Pseudotsuga menziesii / Aspidotis densa* Woodland (CEGL000896, G1)

DISTRIBUTION

Range: This uncommon system is found in the east and west Cascades of Washington.
Divisions: 204:C
Nations: US
Subnations: WA

NORTH-CENTRAL APPALACHIAN ACIDIC CLIFF AND TALUS (CES202.601)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate); Talus (Substrate); Temperate; Acidic Soil
Non-Diagnostic Classifiers: Lowland; Sideslope; Very Shallow Soil; Ustic; Landslide
National Mapping Codes: ESLF 3154

CONCEPT

Summary: This system comprises sparsely vegetated to partially wooded cliffs and talus slopes in the Central Appalachians and adjacent ecoregions, occurring on rocks of acidic lithology and lacking any indicators of enriched conditions. This cliff system occurs at low to mid elevations from central New England south to Virginia, and up to 1500 m in West Virginia. It consists of vertical or near-vertical cliffs and the talus slopes below, formed on hills of granitic, sandstone, or otherwise acidic bedrock. In some cases, especially in periglacial areas, this system may take the form of upper-slope boulderfields without adjacent cliffs, where talus forms from freeze/thaw action cracking the bedrock. Most of the substrate is dry and exposed, but small (occasionally large) areas of seepage are often present. Vegetation in seepage areas tends to be more well-developed and floristically different from the surrounding dry cliffs. The vegetation is patchy and often sparse, punctuated with patches of small trees that may form woodlands in places. *Juniperus virginiana* is a characteristic tree species, *Toxicodendron radicans* a characteristic woody vine, and *Polypodium virginianum* a characteristic fern. Within its range, *Pinus virginiana* is often present.
Classification Comments: More complete data are needed to clarify the diagnostic differences between this system and similar systems to the north, south, and west: Laurentian-Acadian Acidic Cliff and Talus (CES201.569), Cumberland Acidic Cliff and Rockhouse (CES202.309), and Central Interior Acidic Cliff and Talus (CES202.689).
Similar Ecological Systems:
- Central Interior Acidic Cliff and Talus (CES202.689)--occurs farther west.
- Cumberland Acidic Cliff and Rockhouse (CES202.309)--occurs to the south.
- Laurentian-Acadian Acidic Cliff and Talus (CES201.569)

Related Concepts:

NORTH-CENTRAL APPALACHIAN CIRCUMNEUTRAL CLIFF AND TALUS (CES202.603)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate); Talus (Substrate); Temperate; Alkaline Soil
Non-Diagnostic Classifiers: Moderate (100-500 yrs) Persistence; Lowland; Sideslope; Circumneutral Soil; Very Shallow Soil; Ustic; Landslide
National Mapping Codes: ESLF 3153

CONCEPT

Summary: This cliff system occurs at low to mid elevations from central New England south to Virginia and West Virginia. It consists of vertical or near-vertical cliffs and steep talus slopes where weathering and/or bedrock lithology produce circumneutral to calcareous pH and enriched nutrient availability. Substrates include limestone, dolomite and other rocks. The vegetation varies from sparse to patches of small trees, in places forming woodland or even forest vegetation. *Fraxinus* spp., *Tilia americana*, and *Staphylea trifolia* are woody indicators of the enriched setting. *Thuja occidentalis* may occasionally be present but is more characteristic of the related Laurentian-Acadian system to the north. The herb layer is typically not extensive but includes at least some species that are indicators of enriched conditions, e.g., *Impatiens pallida*, *Pellaea atropurpurea, Asplenium platyneuron*, or *Woodsia obtusa*.

Similar Ecological Systems:
- Central Appalachian Alkaline Glade and Woodland (CES202.602)--overlaps with this system in all but the northernmost portions of the range; it is closely related but distinguished by being in a setting other than cliff/talus (e.g., rocky ridges) and by having a greater prominence of graminoids in the ground layer.
- Central Interior Calcareous Cliff and Talus (CES202.690)
- Laurentian-Acadian Calcareous Cliff and Talus (CES201.570)--occurs farther north.
- Southern Interior Calcareous Cliff (CES202.356)--includes circumneutral cliff and talus communities from southern Virginia south.

NORTHEASTERN EROSIONAL BLUFF (CES203.498)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Deep Soil; Unconsolidated; Bluff
National Mapping Codes: ESLF 3209

CONCEPT

Summary: These steep, linear cliffs form where erosion in deep glacial or alluvial deposits has left tall (>3 m), nearly vertical banks of sand, silt, clay, or a mixture. They typically develop in landscapes that are otherwise of rather low relief. The substrate is unconsolidated and provides habitat for certain animals that burrow into steep banks, such as bank swallows and certain invertebrates. Vegetation is very sparse, mostly herbaceous, and variable in composition. Characteristic herbs are those adapted to the unstable substrate and regular disturbance, such as *Schizachyrium scoparium, Andropogon gerardii, Danthonia spicata, Agrostis gigantea, Carex tonsa var. rugosperma (= Carex rugosperma), Ionactis linariifolius, Lespedeza capitata, Polygonella articulata*, and *Lechea intermedia*, as well as weedy herbs such as *Elymus repens (= Elytrigia repens), Veronica officinalis*, and *Oenothera biennis*. Scattered individuals of the low shrub *Comptonia peregrina* may occur, and less frequently individuals of *Vaccinium angustifolium* or *Vaccinium pallidum*. The somewhat more stable portions of the bank may have sparse and usually small trees of *Betula papyrifera, Betula populifolia*, or *Populus tremuloides*. A few New England occurrences support populations of the state-rare plants *Lupinus perennis* and *Hudsonia ericoides*. Known examples occur in the Chesapeake Bay, some maritime bluffs along the Northern Atlantic Coast, the Lake Erie and Lake Ontario coastlines, and some of the larger northeastern rivers.
Classification Comments: These features are very narrow but may extend over hundreds of meters or more. They are distinctly different from adjacent habitats. They are sometimes referred to as cliffs; the usage of "cliff" and "bluff" is colloquially inconsistent, though in some references "bluff" refers to features in unconsolidated material and "cliffs" involve consolidated rock. There is high floristic heterogeneity across the range of this system.
Related Concepts:
- Dry River Bluff (Sperduto and Nichols 2004) Undetermined
- Dry Riverside Bluff (Swain and Kearsley 2001) Undetermined
- Erosional River Bluff (Thompson and Sorenson 2000) Undetermined
- Erosional Slope/Bluff (Edinger et al. 2002) Broader

DESCRIPTION

Dynamics: This system is subject to continuing erosion from wind or water such that persistent vegetation rarely develops. Instability can also lead to slumps where large sections of the bank let go.

Component Associations:
- Eroding Clay Bank Sparse Vegetation (CEGL002584, GNR)
- Maritime Erosional Bluffs and Cliffs Sparse Vegetation (CEGL006618, GNR)

SPATIAL CHARACTERISTICS

Spatial Summary: Linear features that may extend for only a few tens of meters to hundreds of meters or more.

DISTRIBUTION

Range: This system is currently documented from the Chesapeake Bay north to Maine and along the shores of Lakes Erie and Ontario.
Divisions: 201:C; 202:C; 203:C
Nations: CA, US
Subnations: CT?, MA, MD, ME, NH, NY, PA, VA?, VT
Map Zones: 60:C, 63:C, 64:P, 65:C, 66:C
USFS Ecomap Regions: 211E:CC, 221A:CC, 222I:CC, 232H:CC
TNC Ecoregions: 48:C, 58:C, 62:C, 63:C, 64:C

NORTHERN ATLANTIC COASTAL PLAIN SANDY BEACH (CES203.301)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Beach (Substrate); Graminoid; Coast
National Mapping Codes: ESLF 3124

CONCEPT

Summary: This system includes sparsely vegetated ocean beaches constituting the outermost zone of coastal vegetation ranging from northern North Carolina (north of Bodie Island) northward to the terminus of extensive sandy coastlines and the beginning of rocky coasts. Examples generally extend seaward from foredunes but may include flats behind breached foredunes. Although these habitats are situated just above the mean high tide limit, they are constantly impacted by waves and may be flooded by high spring tides and storm surges (Fleming et al. 2001). Constant salt spray and rainwater maintain generally moist conditions. Substrates consist of unconsolidated sand and shell sediments that are constantly shifted by winds and floods. Dynamic disturbance regimes largely limit vegetation to pioneering, salt-tolerant, succulent annuals. *Cakile edentula ssp. edentula* and *Salsola kali (= Salsola caroliniana)* are usually most numerous and characteristic. Other scattered associates include *Sesuvium maritimum, Polygonum glaucum, Polygonum ramosissimum var. prolificum, Suaeda linearis* and *Suaeda maritima*, and *Atriplex cristata (= Atriplex pentandra)*.
Classification Comments: In Virginia, this system is distributed along the ocean side of the Eastern Shore (Accomack and Northampton counties) and on Cape Henry and False Cape (City of Virginia Beach).
Similar Ecological Systems:
- Central Atlantic Coastal Plain Sandy Beach (CES203.064)--is found to the south.
- Northern Atlantic Coastal Plain Dune and Swale (CES203.264)

Related Concepts:
- Beach Strand (Gawler and Cutko 2010) Finer

DESCRIPTION

Environment: This system includes sparsely vegetated ocean beaches that constitute the outermost zone of coastal vegetation ranging from northern North Carolina northward to the northern end of extensive sandy coastlines and the beginning of rocky coasts in southern Maine. Examples generally extend seaward from foredunes but may include flats behind breached foredunes. The beach includes the sand intertidal shore and the low-gradient sand above the daily high tide line, which is between the foredune and the Atlantic Ocean. This area of upper beach is affected by wind and salt spray, seasonal high tides, and storm surge.
Dynamics: The process of sand movement due to the forces of wind and water are part of the natural dynamics of beach ecosystems. This includes transport of sand along the coast, and movement of sand by wind or water between the dunes, beach and subtidal areas. If not restricted by infrastructure or engineered hard structures, beaches and dunes can migrate as coastlines change over time in response to the action of wind and water. The beaches of the Atlantic coast are affected by two tides per day. Extensive construction of high, artificial dunes along the Atlantic coast has reduced the extent of these habitats by increasing oceanside beach erosion and eliminating the disturbance regime that creates and maintains overwash flats.

Component Associations:
- *Cakile edentula ssp. edentula - Chamaesyce polygonifolia* Sparse Vegetation (CEGL004400, G4G5)
- *Sesuvium portulacastrum - Atriplex* spp. - *Suaeda* spp. Sparse Vegetation (CEGL004406, G3)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Northern Atlantic Coastal Plain Dune and Swale (CES203.264)

DISTRIBUTION

Range: This system ranges from northern North Carolina northward to the northern end of extensive sandy coastlines and the beginning of rocky coasts in southern Maine.

NORTHWESTERN GREAT PLAINS CANYON (CES303.658)

CLASSIFIERS

Classification Status: Standard

Primary Division: Western Great Plains (303)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Non-Diagnostic Classifiers: Very Shallow Soil; Flood Scouring; Canyon
FGDC Crosswalk: Vegetated, Tree-dominated, Open tree canopy, Deciduous open tree canopy
National Mapping Codes: EVT 2341; ESLF 4148; ESP 1341

CONCEPT

Summary: This system occurs primarily along springbranch and dry canyons. Soils can range from deep loams to alluvial to sandy. Limestone and sandstone rock outcrops and cliffs are common. This system often contains elements of other systems that form a complex, small-patch or linear mosaic. Ecological processes are related to canyon landforms and patchy vegetation. Examples of this system are found along the Niobrara and North Platte rivers in Nebraska. Areas along the tributaries of the White River and within the Black Hills region of South Dakota also may be considered part of this system. Vegetation varies locally depending on aspect, slope position and substrate and can range from riparian vegetation to xeric or mesic woodlands. Rock outcrops with sparse vegetation are also common. Dominant tree species include *Quercus macrocarpa, Populus deltoides, Fraxinus pennsylvanica, Ulmus rubra, Pinus ponderosa*, and *Juniperus scopulorum* and *Juniperus virginiana*; shrub species may be present as well. This system can grade into areas dominated by *Pinus ponderosa*. Other system elements contained in this system include Western Great Plains Cliff and Outcrop (CES303.665) on south aspects and rims; Western Great Plains Riparian (CES303.956) in drainages, and Rocky Mountain Lower Montane-Foothill Shrubland (CES306.822) and Northwestern Great Plains Shrubland (CES303.662), but unique geology and dynamics bring these together to form this canyon system. Occasionally, fens may occur in canyon bottom seeps.

- Great Plains Wooded Draw, Ravine and Canyon (Rolfsmeier and Steinauer 2010) Broader
- Paper Birch: 18 (Eyre 1980) Finer

DESCRIPTION

Vegetation: Vegetation can vary locally with aspect, slope position and substrate. It can range from riparian to mesic to xeric woodlands. Several tree species, such as *Quercus macrocarpa, Populus deltoides, Betula papyrifera, Fraxinus pennsylvanica, Ulmus rubra*, and *Pinus ponderosa*, and shrub species, such as *Juniperus virginiana* and *Juniperus scopulorum*, can occur within this system. Cover of these species can range from less than 10% on rock outcrops to greater than 60%.

Component Associations:
- *Betula papyrifera - (Tilia americana, Quercus macrocarpa)* Canyon Forest (CEGL002013, G2?)
- *Carex pellita - Carex* spp. - *Schoenoplectus tabernaemontani* Fen Herbaceous Vegetation (CEGL002041, G1)
- *Cercocarpus montanus / Bouteloua curtipendula* Shrubland (CEGL001086, G5)
- *Populus deltoides (ssp. wislizeni, ssp. monilifera) / Distichlis spicata* Woodland (CEGL000939, G2)
- *Populus deltoides (ssp. wislizeni, ssp. monilifera) / Salix exigua* Woodland (CEGL002685, G3)
- *Populus deltoides - (Salix amygdaloides) / Salix (exigua, interior)* Woodland (CEGL000659, G3G4)
- *Populus deltoides - Fraxinus pennsylvanica* Forest (CEGL000658, G2G3)
- *Populus deltoides / Carex pellita* Woodland (CEGL002649, G2)
- *Populus deltoides / Panicum virgatum - Schizachyrium scoparium* Woodland (CEGL001454, G2)
- *Quercus macrocarpa / Andropogon gerardii - Hesperostipa spartea* Woodland (CEGL002053, G2G3)
- *Quercus macrocarpa / Andropogon gerardii - Panicum virgatum* Woodland (CEGL002052, G1G2)
- *Quercus macrocarpa / Cornus drummondii / Aralia nudicaulis* Forest (CEGL002072, G4)
- *Salix exigua* / Mesic Graminoids Shrubland (CEGL001203, G5)

SPATIAL CHARACTERISTICS

Adjacent Ecological Systems:
- Northwestern Great Plains Shrubland (CES303.662)
- Rocky Mountain Lower Montane-Foothill Shrubland (CES306.822)
- Western Great Plains Cliff and Outcrop (CES303.665)
- Western Great Plains Riparian (CES303.956)

Adjacent Ecological System Comments: Other system elements contained in this system include Western Great Plains Cliff and Outcrop (CES303.665) on south aspects and rims; Western Great Plains Riparian (CES303.956) in drainages, and Rocky Mountain

Lower Montane-Foothill Shrubland (CES306.822) and Northwestern Great Plains Shrubland (CES303.662), but unique geology and dynamics bring these together to form this canyon system.

DISTRIBUTION

Range: This system occurs along springbranch and dry canyons along the Niobrara and North Platte rivers in Nebraska and likely ranges north along the tributaries of the White River and areas within the Black Hills region of South Dakota.

ROCKY MOUNTAIN ALPINE BEDROCK AND SCREE (CES306.809)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Alpine Slopes; Alpine/AltiAndino [Alpine/AltiAndino]; Talus (Substrate); Rock Outcrops/Barrens/Glades; Oligotrophic Soil; Very Shallow Soil
Non-Diagnostic Classifiers: Temperate [Temperate Continental]; Glaciated; Unconsolidated
National Mapping Codes: ESLF 3135

CONCEPT

Summary: This ecological system is restricted to the highest elevations of the Rocky Mountains, from Alberta and British Columbia south into New Mexico, west into the highest mountain ranges of the Great Basin. It is composed of barren and sparsely vegetated alpine substrates, typically including both bedrock outcrop and scree slopes, with nonvascular- (lichen) dominated communities. Exposure to desiccating winds, rocky and sometimes unstable substrates, and a short growing season limit plant growth. There can be sparse cover of forbs, grasses, lichens and low shrubs.
Related Concepts:

ROCKY MOUNTAIN CLIFF, CANYON AND MASSIVE BEDROCK (CES306.815)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Rocky Mountain (306)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Ridgetop bedrock outcrop; Talus (Substrate); Rock Outcrops/Barrens/Glades; Oligotrophic Soil; Very Shallow Soil; Landslide; Canyon; Cliff (Landform)
Non-Diagnostic Classifiers: Escarpment; Long (>500 yrs) Persistence; Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Temperate [Temperate Continental]; Butte
National Mapping Codes: ESLF 3129

CONCEPT

Summary: This ecological system of barren and sparsely vegetated landscapes (generally <10% plant cover) is found from foothill to subalpine elevations on steep cliff faces, narrow canyons, and smaller rock outcrops of various igneous (intrusives), sedimentary, and metamorphic bedrock types. It is located throughout the Rocky Mountains and northeastern Cascade Ranges in North America. Also included are unstable scree and talus slopes that typically occur below cliff faces. In general these are the dry sparsely vegetated places on a landscape. The biota on them reflect what is surrounding them, unless it is an extreme parent material. There may be small patches of dense vegetation, but it typically includes scattered trees and/or shrubs. Characteristic trees includes species from the surrounding landscape, such as *Pseudotsuga menziesii, Pinus ponderosa, Pinus flexilis, Populus tremuloides, Abies concolor, Abies lasiocarpa*, or *Pinus edulis* and *Juniperus* spp. at lower elevations. There may be scattered shrubs present, such as species of *Holodiscus, Ribes, Physocarpus, Rosa, Juniperus*, and *Jamesia americana, Mahonia repens, Rhus trilobata*, or *Amelanchier alnifolia*. Soil development is limited, as is herbaceous cover.
Classification Comments: This has a very broad elevation range (<3350 m) for a system; consider dividing into foothills/montane and subalpine. And/or by floristic division. This is in the Okanagan and Rockies as the montane sparse. North Pacific Montane Massive Bedrock, Cliff and Talus (CES204.093) includes everything in the Cascades and west, except the northeastern Cascades, where occurrences are this system (CES306.815). Inter-Mountain Basins Cliff and Canyon (CES304.779) occurs in the dry foothills on the east side of EDC MapZone1.

SIERRA NEVADA CLIFF AND CANYON (CES206.901)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate); Talus (Substrate); Rock Outcrops/Barrens/Glades; Mediterranean [Mediterranean Xeric-Oceanic]; Canyon
Non-Diagnostic Classifiers: Canyon Mosaic; Montane [Upper Montane]; Montane [Montane]; Montane [Lower Montane]; Lowland [Foothill]; Forest and Woodland (Treed); Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Ridge/Summit/Upper Slope; Very Shallow Soil; Landslide; Needle-Leaved Tree; Broad-Leaved Evergreen Shrub; Graminoid; Nonvascular; Cliff (Landform)
National Mapping Codes: ESLF 3171

CONCEPT

Summary: Found from foothill to subalpine elevations throughout the Sierra Nevada and nearby mountain ranges, these are barren and sparsely vegetated areas (<10% plant cover) of steep cliff faces, narrow canyons, and smaller rock outcrops of various igneous, sedimentary, and metamorphic bedrock. This system also includes unstable scree and talus slopes typically occurring below cliff faces. Scattered vegetation may include *Abies magnifica*, *Pseudotsuga menziesii*, *Pinus contorta var. murrayana*, *Pinus ponderosa*, *Pinus jeffreyi*, *Populus tremuloides*, or *Pinus monophylla*, *Juniperus osteosperma*, and *Cercocarpus ledifolius* at lower elevations. There may be shrubs including species of *Arctostaphylos* or *Ceanothus*. Soil development is limited as is herbaceous cover.

DISTRIBUTION

Range: Found from foothill to subalpine elevations throughout the Sierra Nevada and nearby mountain ranges.

SOUTH FLORIDA SHELL HASH BEACH (CES411.271)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Beach (Substrate); Graminoid; Coast
National Mapping Codes: ESLF 3138

CONCEPT

Summary: This system represents carbonate sand beaches of the Florida Keys and south Florida mangrove islands (after Johnson and Barbour 1990). The vegetation is poorly known but apparently includes at least one endemic species, *Chamaesyce garberi*. Other diagnostic species may include *Piscidia piscipula* and *Pithecellobium keyense*.
Classification Comments: No associations have currently been described in the NVC for this system. More information is needed. See Johnson and Barbour (1990) for more information.
Related Concepts:
- Unconsolidated Substrate (FNAI 1990) Broader

Component Associations:
- *Uniola paniculata* - *Hymenocallis latifolia* Herbaceous Vegetation (CEGL003966, G1?)

DISTRIBUTION

Range: The range of this system includes Cape Sable (the southernmost point of mainland Florida), Ten Thousand Islands (Collier County), Florida Keys, and islands in Biscayne Bay (near Miami).

SOUTH TEXAS SALT AND BRACKISH TIDAL FLAT (CES301.461)

CLASSIFIERS

Classification Status: Standard

Primary Division: Madrean Semidesert (301)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Wetland
Diagnostic Classifiers: Tidal / Estuarine [Haline]
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated
National Mapping Codes: EVT 2500; ESLF 3113; ESP 1500

CONCEPT

Summary: This system includes regularly to irregularly flooded hypersaline tidal flats (often exceeding a thousand acres in size). Dominants include a variety of vascular and nonvascular species. The cyanobacteria (blue-green algae) *Lyngbya* spp. may dominate thousands of acres. Total vegetative cover is quite variable, from near total absence of vascular plants to a dense cover of one of several dominant species including *Batis maritima, Monanthochloe littoralis, Spartina spartinae, Borrichia frutescens*, and *Sarcocornia perennis*. In addition to the dominants, other halophytic plants of this system include *Atriplex matamorensis, Distichlis spicata, Sarcocornia perennis, Sporobolus virginicus, Maytenus phyllanthoides, Prosopis reptans, Borrichia frutescens, Suaeda linearis, Suaeda conferta, Monanthochloe littoralis, Lycium carolinianum var. quadrifidum, Spartina spartinae, Sesuvium portulacastrum, Rayjacksonia phyllocephala*, and *Blutaparon vermiculare*. In addition to dominating non-vegetated areas, algal mats of blue-green and sometimes green algae are characteristically present, visible even in densely vegetated pannes. Blue-green algae may contribute significantly more biomass than vascular species. Widely scattered *Avicennia germinans* (and, less frequently, other mangroves) may occur.

- South Texas: Wind Tidal Flats (6600) [CES301.461.1] (Elliott 2011) Finer

DESCRIPTION

Environment: This system occurs in tidal and other hypersaline situations along upper marsh edges and in tidal flats ranging in scale from narrow bands to hundreds of hectares along the Gulf Coast of southern Texas and Mexico. It is regularly to irregularly flooded by shallow brackish waters as a result of lunar, wind and storm tides. As these waters evaporate, high concentrations of salt accumulate, producing hypersaline conditions, forming "salt pannes." It is found on recent wind-distributed coastal sands along barrier island and mainland shores of hypersaline lagoons and bays where evaporation often exceeds freshwater input. Tidal fluctuations and wind continue to redistribute these sands. Landforms are extensive, very gentle (nearly flat) slopes.
Vegetation: Some sites may have sparse vegetation consisting of *Salicornia bigelovii, Salicornia virginica (= Salicornia depressa), Batis maritima, Suaeda linearis, Sesuvium portulacastrum, Monanthochloe littoralis*, and/or *Distichlis spicata*, but are typically unvegetated or covered by a layer of *Lyngbya* spp. The development of vast areas dominated by *Lyngbya* spp. occurs with appropriate frequency and duration of inundation. Higher flats may be too dry to support the algae, and at lower elevation, flats may remain inundated for extended periods. Occasionally flats (usually not those supporting extensive blue-green algae) may develop a substantial herbaceous cover, especially during years of increased rainfall. Development of significant areas of marsh grasses such as *Spartina patens* or *Spartina alterniflora* is generally lacking. Scattered individuals of *Avicennia germinans* occur within these flats.

Component Associations:
- *Avicennia germinans / Batis maritima* Shrubland (CEGL007757, G3?)
- *Batis maritima - Sarcocornia pacifica* Dwarf-shrubland (CEGL003956, G5)
- *Borrichia frutescens / Spartina spartinae* Shrubland (CEGL004617, G3G4)
- *Lyngbea* spp. Wind-Tidal Flat Nonvascular Vegetation (CEGL007840, G4)
- *Sarcocornia pacifica* - (*Batis maritima, Distichlis spicata*) Dwarf-shrubland (CEGL002278, G4)
- *Spartina spartinae - Monanthochloe littoralis - Suaeda linearis* Herbaceous Vegetation (CEGL004614, G3?)

DISTRIBUTION

Range: This system ranges south of Corpus Christi Bay along the northern Gulf of Mexico.

SOUTHEAST FLORIDA BEACH (CES411.272)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Beach (Substrate); Graminoid; Coast
National Mapping Codes: ESLF 3136

CONCEPT

Summary: This beach ecological system is the southernmost of its kind along the mainland coast of North America. Its southerly location distinguishes it from other types along the Atlantic Coast, primarily due to the prevalence of the tropical flora it supports. This type is related to Southwest Florida Beach (CES411.276) but is affected directly by much higher wave energy from the Atlantic. This region has some of the highest wave energy along the entire Atlantic Coast.
Classification Comments: Apparently few, if any, associations have currently been described in the NVC for this system. More information is needed.
Similar Ecological Systems:
- Southwest Florida Beach (CES411.276)

DESCRIPTION

Environment: Its southerly location distinguishes this system from others along the Atlantic Coast, primarily due to the prevalence of the tropical flora it supports. This system is affected directly by much higher wave energy from the Atlantic than the beaches on the southwest coast of Florida. The southeast coastal region has some of the highest wave energy along the entire Atlantic Coast (Tanner 1960).
Dynamics: This region has some of the highest wave energy along the entire Atlantic Coastal Plain (Tanner 1960). The process of sand movement due to the forces of wind and water are part of the natural dynamics of beach ecosystems. This includes transport of sand along the coast, and movement of sand by wind or water between the dunes, beach and subtidal areas. If not restricted by infrastructure or engineered hard structures, beaches and dunes can migrate as coastlines change over time in response to the action of wind and water. The beaches of southeast Florida are affected by two tides per day.

Component Associations:
- *Ipomoea pes-caprae - Cakile lanceolata* Herbaceous Vegetation (CEGL004403, G3G4)

DISTRIBUTION

Range: Endemic to south Florida.
Divisions: 411:C
Nations: US
Subnations: FL
Map Zones: 56:C
TNC Ecoregions: 54:C

SOUTHEASTERN COASTAL PLAIN CLIFF (CES203.398)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate)
National Mapping Codes: ESLF 3206

CONCEPT

Summary: This ecological system consists of steep to vertical or overhanging outcrops of unconsolidated sediment or rock in the Gulf and Atlantic coastal plains. They occur on lower bluffs adjacent to rivers or streams. The vegetation is generally sparse, limited to plants growing on bare substrate, small ledges, and other favorable microsites. The flora is a mix of herbs, shrubs, vines, tree seedlings, and some larger trees, with bryophytes potentially dominant in some examples. It typically includes opportunistic species of open and disturbed areas, along with species from adjacent forest communities and other species of wet and dry open areas. Dense shrubby or woodland vegetation may occur on the edges. Occasional examples may have denser bryophyte vegetation.
Classification Comments: More information is needed on the associations that belong to this system. Compared to cliffs of other regions, the soft Coastal Plain cliffs tend to be more frequently disturbed and more dynamic. Soil development and primary succession would quickly replace any examples that are not periodically disturbed and renewed by slumping, generally caused by undercutting by streams. Smaller slumps and active erosion by upland runoff may also disturb the communities. This is the primary rock outcrop system of the Coastal Plain, but small shaded outcrops of limestone or sandstone may be included in other systems.
Similar Ecological Systems:
- Southern Coastal Plain Mesic Slope Forest (CES203.476)
- Southern Piedmont Cliff (CES202.386)

DESCRIPTION

Environment: These cliffs occur on steep to vertical or overhanging outcrops of coastal plain substrates, usually sand, clay, or sandstone. Outcrops typically occur along rivers or streams, where undercutting causes slumps that periodically renew the bare substrate. Most of these cliffs are dry, but small zones of seepage are often present, especially at the top. One association represents small clay cliffs that are kept wet by seepage. Lower portions of cliffs may periodically flood.
Dynamics: Coastal plain cliffs appear to be dynamic on a moderate time scale. Due to the soft substrate, groundwater discharge, and stream undercutting, periodic slumping of part or all of the cliff occurs. This slumping is likely necessary to prevent erosion, soil development, and primary succession from developing a forest system on the site. Microsite disturbance may also come from erosion by runoff and potentially by windthrow of trees on the edge. The types of plants that may grow on cliffs is limited by the harsh conditions to those with adaptations to drought and limited nutrients (Edwards et al. 2013).

Component Associations:
- Coastal Plain Acidic Cliff Sparse Vegetation (CEGL004388, G2?)

SPATIAL CHARACTERISTICS

Spatial Summary: This is a small-patch system, most examples covering less than one acre. Examples tend to occur as isolated small patches.
Size: Most examples naturally cover an acre or less. Size is somewhat ambiguous for this system, in that vertical surfaces may be as extensive as horizontal surfaces.
Adjacent Ecological Systems:
- Atlantic Coastal Plain Blackwater Stream Floodplain Forest (CES203.247)
- Atlantic Coastal Plain Brownwater Stream Floodplain Forest (CES203.248)
- Atlantic Coastal Plain Small Blackwater River Floodplain Forest (CES203.249)
- Southern Atlantic Coastal Plain Dry and Dry-Mesic Oak Forest (CES203.241)
- Southern Atlantic Coastal Plain Mesic Hardwood Forest (CES203.242)

Adjacent Ecological System Comments: Bordered by upland forest systems above and laterally, and by floodplain forest systems or a river below.

DISTRIBUTION

Range: This system is potentially scattered throughout the Gulf and Atlantic coastal plains.

SOUTHERN APPALACHIAN GRANITIC DOME (CES202.297)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Rock Outcrops/Barrens/Glades
National Mapping Codes: ESLF 3126

CONCEPT

Summary: This ecological system consists of smooth, curved, exfoliated outcrops of massive granite and related rocks in the Southern Blue Ridge and adjacent upper/inner Piedmont. Smooth rock without crevices is the primary factor in the distinctive ecological character of this system. The outcrop surface is largely bare rock but has thin soil mats around the edges and patchily throughout. Mats vary in depth with age and level of development. Granitic domes have a distinctive pattern of cyclical primary succession. The resulting vegetation is a complex of small patches of different species and structure on soil mats of different depths, ranging from mosses and lichens to herbs to shrubs and trees. Deeper soils often have pine-dominated vegetation with dense shrubs.
Classification Comments: Granitic domes are clearly related to other rock outcrop systems in the southern Appalachians. Most similar in the region are Southern and Central Appalachian Mafic Glade and Barrens (CES202.348), which are distinguished by having more continuous vegetation and only a minority of bare rock, resulting from a more irregular rock surface or less steep slope. Glades and barrens occur on a wider range of rock types, but it is possible that granitic domes develop into glades over long periods of time (probably centuries or longer) if exfoliation ceases to occur. Southern Appalachian Montane Cliff and Talus (CES202.330) and Southern Appalachian Rocky Summit (CES202.327) differ in having more fractured rock, with vegetation dominated by plants rooted in fixed microsites related to crevices, ledges, and other small features. Southern Piedmont Granite Flatrock and Outcrop (CES202.329) is most similar to Southern Appalachian Granitic Dome (CES202.297) in occurring on smooth, exfoliated outcrops and having vegetation driven by soil mat dynamics. Some species are shared, but biogeography and climatic differences make for vegetation that is different.

Deeper soils often have pine-dominated vegetation with dense shrubs, resembling that of Southern Appalachian Montane Pine Forest and Woodland (CES202.331). These communities should be treated as part of this system if they are closely associated with exfoliation outcrops with the more distinctive granitic dome communities. The same is true of closely associated islands and stunted patches of vegetation resembling Southern Appalachian Oak Forest (CES202.886).

While this system as a whole is characterized by sparse vegetation, individual plots may have decidedly non-sparse vegetation, with as much as 70% total cover, mostly herbaceous; this is a typical problem when scaling up from a plot to a system.

Similar Ecological Systems:
- Southern and Central Appalachian Mafic Glade and Barrens (CES202.348)
- Southern Appalachian Montane Cliff and Talus (CES202.330)
- Southern Appalachian Montane Pine Forest and Woodland (CES202.331)
- Southern Appalachian Rocky Summit (CES202.327)
- Southern Piedmont Granite Flatrock and Outcrop (CES202.329)

Related Concepts:
- Chestnut Oak: 44 (Eyre 1980) Finer
- Northern Red Oak: 55 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on exfoliated granitic outcrops. In the upper/inner Piedmont, it usually occurs as isolated hills (inselbergs or monadnocks) that stand above the surrounding landscape. In the Blue Ridge, it usually occurs as part of larger mountain ranges but often still as somewhat distinctive knobs. Granite, granitic gneiss, and related rocks without many internal joints tend to fracture in thin sheets parallel to the surface, forming curved outcrops with smooth surfaces largely lacking crevices. Granitic dome outcrops develop on upper to midslopes, and most face south. Most individual outcrops grade from nearly level to very steep. The outcrop surface is largely bare rock but has thin soil mats around the edge and in patches throughout. Mats vary in depth with age and level of development. The smooth rock without crevices is the primary factor in the distinctive ecological character of this system. Distinct microenvironments are created by small irregularities in the rock surface and by areas of seepage at the edge. Elevation is an important factor affecting different associations within the system.
Vegetation: Most of the rock surface is bare or has only crustose or foliose lichen cover. Vegetation occurs as a series of small patches in the thin soil mats, with the kind of vegetation closely related to depth of the mat. Bare rock may have moss patches. The thinnest soils usually have a set of fine forbs, many of them annual. Slightly deeper soils often have grasses dominating. Deeper soils support shrubs or small trees. The flora shares some species with other rock outcrops of similar elevations but has some distinctive species and different dominance of species. Some characteristic plants of Southern Appalachian granitic domes include grasses and graminoids *Carex biltmoreana* and *Bulbostylis capillaris*; *Schizachyrium scoparium* is a frequent grass at lower elevations. Forbs include *Pycnanthemum* spp., *Krigia montana, Hypericum gentianoides*, and *Houstonia longifolia*. Some other unusual plants include

the lichens *Lasallia papulosa, Umbilicaria caroliniana*, and the mat-forming fern allies *Selaginella tortipila* and *Selaginella rupestris*.
Dynamics: Granitic domes have a distinctive pattern of cyclical primary succession. Soil mats appear and deepen over time in a process that links vegetational and soil development, but are eventually destroyed by wind throw, drought, other natural disturbances, or simply falling off the rock. The result is a pattern with mats of different levels of development at any given time. Mat dynamics are different in different parts of the rock, with older mats and more permanent patterns near the edges, and sparser and younger mats in the interior. The dynamics are further modified by microtopography and the presence of seepage. The overall vegetation patterns likely respond to climatic cycles and natural disturbance events. The thin soils make these communities sensitive to drought, especially the long-lived woody species.

Component Associations:
- *(Quercus prinus) / Vaccinium pallidum / Schizachyrium scoparium - Danthonia spicata / Cladonia* spp. Herbaceous Vegetation (CEGL004990, G1G2)
- *Carex biltmoreana - Pycnanthemum* spp. - *Krigia montana* Herbaceous Vegetation (CEGL004523, G2G3)
- *Lasallia papulosa - Umbilicaria caroliniana* Nonvascular Vegetation (CEGL004386, G2?)
- *Quercus rubra / Rhododendron catawbiense - Rhododendron arborescens* Woodland (CEGL004503, G2)
- *Selaginella rupestris - Schizachyrium scoparium - Hypericum gentianoides - Bulbostylis capillaris* Herbaceous Vegetation (CEGL007690, G2)
- *Selaginella tortipila - Krigia montana - Houstonia longifolia* Herbaceous Vegetation (CEGL004283, G2G3)

SPATIAL CHARACTERISTICS

Spatial Summary: Large-patch system, most examples covering a few acres.
Size: Most examples naturally cover a few acres, with a few examples up to 10 or more acres. Most examples occur in a few clusters where geology is suitable (e.g., the Blue Ridge escarpment at the South Carolina-North Carolina border and the Brushy Mountains in North Carolina), but most examples in these clusters are probably far enough apart to be considered separate occurrences. Individual knobs may have a cluster of several closely associated outcrops separated by small patches of forest.
Adjacent Ecological Systems:
- Southern and Central Appalachian Mafic Glade and Barrens (CES202.348)
- Southern Appalachian Oak Forest (CES202.886)

Adjacent Ecological System Comments: Surrounded by forest systems on deeper soils less influenced by bedrock, most typically Southern Appalachian Oak Forest (CES202.886). Patches of oak forests may occur in a mosaic with the granitic domes.

DISTRIBUTION

Range: This system is restricted to the Southern Blue Ridge and adjacent upper/inner Piedmont in the Carolinas and Georgia.
Divisions: 202:C
Nations: US
Subnations: GA?, NC, SC
Map Zones: 57:C, 59:C

SOUTHERN APPALACHIAN MONTANE CLIFF AND TALUS (CES202.330)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Moss/Lichen (Nonvascular); Cliff (Substrate)
National Mapping Codes: ESLF 3186

CONCEPT

Summary: This system consists of steep to vertical or overhanging rock outcrops (and related steep talus slopes) of the Southern Blue Ridge and adjacent parts of other ecoregions. It occurs on lower slopes, usually in river gorges or bluffs. The sparse vegetation is limited to plants growing on bare rock, small ledges, and crevices. Vegetation is primarily bryophytes, lichens, and herbs, with sparse trees and shrubs rooted in deeper soil pockets and crevices.
Classification Comments: This system is distinguished from other rock outcrops by a combination of low topographic position, vertical orientation, large amount of bare rock, and absence of specialized environments such as exfoliated granite, limestone or dolomite, and spray from waterfalls. In contrast, Southern Appalachian Rocky Summit (CES202.327) occurs in high topographic positions; they have more horizontal rock but may have some substantial vertical surfaces. Southern and Central Appalachian Mafic Glade and Barrens (CES202.348) are more horizontally oriented and have much more vegetation cover. Southern Appalachian Granitic Dome (CES202.297) may have steep portions but has smooth, unfractured rock surfaces with soil largely confined to mats adhering to the rock surface. The division of rock outcrop systems may be too fine and warrant combining some; however, each system has distinctive characteristics of structure and some distinctive flora.

The primary variation within this system, which could be the basis for further subdivision, is the distinction between mafic and felsic rock. The distribution north and west needs review. See also Cumberland Acidic Cliff and Rockhouse (CES202.309).

- Southern Piedmont Cliff (CES202.386)

Related Concepts:
- Dry Sandstone Cliff (Evans 1991) Intersecting
- Moist Sandstone Cliff (Evans 1991) Intersecting

DESCRIPTION

Environment: This system occurs on steep rock outcrops on lower slopes and occasionally higher in topographically sheltered sites. River gorges are probably the most common landforms, with bluffs of more open river valleys or meandering rivers also common. The substrate is mostly bare bedrock, which is steep to vertical or overhanging. Most examples are on felsic metamorphic rock such as gneiss or schist, a smaller number on mafic metamorphic rock or felsic or mafic igneous rock. [Examples may occur on any kind of rock except limestone and dolomite, with felsic metamorphic rock the most common in the Southern Blue Ridge and sandstone the most common in the Cumberland Mountains. Mafic metamorphic rocks form a less common but important fraction of examples, along with some more extreme rocks such as quartzite.] The physical structure of cliffs of metamorphic rock is usually irregular, with some ledges and crevices. [Sedimentary rocks often form more vertical cliffs, but with bedding planes and joints forming deep crevices that provide rooting sites.] Moisture levels vary drastically over short distances. Seepage of groundwater from adjacent soils or through rock fractures often creates permanently or seasonally flooded microsites, while lack of soil makes other portions extremely dry. In less sheltered topography, slope aspect affects overall moisture levels to some degree. Rock or soil chemistry appears to be the most important factor affecting different associations on sites that have the physical structure to belong to this system. Elevation may also be an important factor causing variation, though few examples are known at high elevation.
Vegetation: Vegetation is sparse. Bryophytes and lichens may cover portions of the open rock. Vascular plants are limited to sparse rooting sites in soil pockets, ledges, and crevices. Some of these microsites may be deep enough to support shrubs or even stunted trees, while most support only herbs. The woody plants are usually species from surrounding forests, and may be mesophytic or xerophytic. The herbs include a suite of rock outcrop specialists such as *Saxifraga michauxii, Hylotelephium telephioides, Asplenium montanum,* and *Polypodium* spp. Mafic rock outcrops have an additional suite of specialist herbs, a number of them rare. Herbs from the surrounding forest are often also present and may make up a significant fraction of the flora.
Dynamics: The dynamics of this system have received little study. Most cliff communities are probably stable over long periods of time, with fine-scale disturbances affecting microsites. Rock falls, slides, and other mass movement are rare, but represent catastrophic disturbance to part or all of a cliff, and may be important in the long term for keeping cliffs open. Animal movements may be locally

important. Fire probably has little effect on cliffs, which have too little vegetation to carry fire and which tend to occur in topography that is not conducive to fire spread. Because of the limited natural disturbance and the fragility of soil and vegetation, human disturbance by trampling edges and by climbing may be particularly destructive.

Component Associations:

SOUTHERN APPALACHIAN ROCKY SUMMIT (CES202.327)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Rock Outcrops/Barrens/Glades
National Mapping Codes: ESLF 3178

CONCEPT

Summary: This system represents treeless rock outcrops of the southern Appalachian Mountains, primarily in western North Carolina and eastern Tennessee. Outcrops may be vertical to horizontal, rugged or fractured rock outcrops of peaks, ridgetops, upper slopes, and other topographically exposed locations (Schafale and Weakley 1990). Higher elevation examples occur from 1200 to 2030 m in elevation; other examples may be found at elevations of 305 m (1000 feet) or lower on foothills. These outcrops occur on felsic to mafic rocks and are distinguished from surrounding systems by the prevalence of bare or lichen-encrusted rocks. The vegetation component of this system is generally characterized by a mixture of low-growing lifeforms, especially lichens, mosses, and short-statured forbs. Less commonly, graminoids and low shrubs are encountered. Species common to all outcrop vegetation types include *Carex misera, Saxifraga michauxii*, and *Vaccinium corymbosum* (Wiser and White 1999).
Classification Comments: The primary variation within this system, which could be the basis for further subdivision, is the distinction between low and high elevation. High-elevation rocky summits may have a unique biogeographic history of having been adjacent to alpine tundra that existed in the region during the Pleistocene and of now providing a refugium for some of its flora. Their climate is substantially different from the lower elevation examples. However, their structure and the dynamics that results from it are probably similar.
Similar Ecological Systems:
- Southern and Central Appalachian Mafic Glade and Barrens (CES202.348)
- Southern Appalachian Granitic Dome (CES202.297)
- Southern Appalachian Montane Cliff and Talus (CES202.330)
- Southern Piedmont Cliff (CES202.386)
- Southern Piedmont Glade and Barrens (CES202.328)
- Southern Piedmont Granite Flatrock and Outcrop (CES202.329)

Related Concepts:
- High Elevation Rocky Summit (Schafale and Weakley 1990) Finer
- Low Elevation Rocky Summit (Schafale and Weakley 1990) Finer

DESCRIPTION

Environment: This system occurs on rugged rock outcrops on peaks, ridgetops, upper slopes, and other topographically exposed landforms. Elevations may range from nearly the highest in the region (1200-2030 m), down to 305 m (1000 feet) or lower on foothills. The rock outcrops are irregular, with substantial horizontal surfaces, as well as often vertical surfaces, and generally with fractures. This structure allows soil accumulation in local pockets, sometimes to fair depth, even though most of the substrate is bare rock. Bedrock may be a variety of types. Erosion-resistant rocks such as felsic gneisses and schists or quartzite are most common, but mafic rocks such as amphibolite are also important substrates. Granite and granitic gneiss sometimes form rocky summits, but more often form the smoother outcrops that support Southern Appalachian Granitic Dome (CES202.297) or Southern and Central Appalachian Mafic Glade and Barrens (CES202.348). Moisture conditions are generally quite dry due to lack of soil but may be heterogeneous. Local deep crevices may accumulate water funneled from bare rock. Seepage is occasionally present but is usually minor. Climate varies substantially with elevation and has a strong effect on variation within the system. Higher elevation sites have high rainfall and receive substantial additional moisture from fog and rime ice.
Vegetation: Vegetation is sparse or patchy, with substantial expanses of lichen-covered or bare rock. Vegetation cover may be >25% (i.e., not technically "sparse") in local areas (including some plots), but the overall effect is of sparse vegetation. Mosses are usually present but often do not have substantial cover. A suite of typical rock outcrop herbs, including *Saxifraga michauxii, Carex misera, Paronychia argyrocoma, Heuchera villosa, Krigia montana*, and *Hylotelephium telephioides (= Sedum telephioides)*, is usually present, along with more widespread herbs of open areas such as *Danthonia spicata, Danthonia compressa, Schizachyrium scoparium, Potentilla canadensis*, and *Houstonia caerulea*. High-elevation examples have an additional suite of herbs, which include some northern disjunct species such as *Minuartia groenlandica, Sibbaldiopsis tridentata, Trichophorum caespitosum*, and *Huperzia selago*. A suite of narrow endemic herbs is also characteristic of many high-elevation examples. Herbs of the adjacent forests may be present in small numbers. Shrubs and stunted trees are usually present in patches, where crevices or deeper soil accumulations are present. A few shrubs, such as *Leiophyllum buxifolium*, are largely limited to this system, but most are widespread species of dry forests and woodlands. Shrubs in the Ericaceae family are particularly prominent. Wiser and White (1999) found that in high-elevation rocky summits, less than a third of the flora was limited to rock outcrop sites.
Dynamics: The dynamics of this system have received little study. Most rocky summit sites are probably stable over long periods of

time, but variations in the always stressful environment may disturb and change vegetation. The role of crevices and soil in depressions as the primary rooting site makes for a relatively stable pattern of plant distribution and potentially long-lived individuals. This is in contrast to the shallow soil mats predominating in granitic domes. Between disturbances, accumulation of soil and succession of vegetation to greater woody abundance may occur. Fire may naturally be uncommon or fairly common. The topographically high location of this system would make it likely that fires would spread into it, though the sparse fuels would allow only patchy burning. Fires have been indicated to be important in preventing dense woody growth from encroaching on open outcrops in at least some instances. Rock falls or other mass movements are rare, but may be important in creating rock outcrops and keeping them open in the long term. Periodic drought is probably a significant disturbance. Animals and freeze-thaw action may be important disturbances at a local scale. Because of the fragility of soil and vegetation, human disturbance by trampling edges and by climbing may be particularly destructive.

Component Associations:
- *Leiophyllum buxifolium - (Hudsonia montana) / Selaginella tortipila - Carex umbellata* Quartzite Outcrop Dwarf-shrubland (CEGL007010, G1)
- *Minuartia groenlandica - Paronychia argyrocoma - Saxifraga michauxii* Herbaceous Vegetation (CEGL008509, G1)
- *Saxifraga michauxii - Carex misera - Calamagrostis cainii* Herbaceous Vegetation (CEGL004278, G1)
- *Saxifraga michauxii - Carex misera - Danthonia spicata - Krigia montana* Herbaceous Vegetation (CEGL004279, G2)
- *Saxifraga michauxii - Carex misera - Oclemena acuminata - Solidago glomerata* Herbaceous Vegetation (CEGL004277, G1)
- *Saxifraga michauxii - Cheilanthes lanosa - Hylotelephium telephioides* Herbaceous Vegetation (CEGL004989, G1)
- *Saxifraga michauxii* Herbaceous Vegetation (CEGL004524, G3?)
- *Schizachyrium scoparium - Saxifraga michauxii - Coreopsis major* Herbaceous Vegetation (CEGL004074, G1)

Spatial Characteristics

Adjacent Ecological Systems:

SOUTHERN APPALACHIAN SPRAY CLIFF (CES202.288)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate)
National Mapping Codes: ESLF 3145

CONCEPT

Summary: This system consists of rock outcrops that are kept wet by spray from waterfalls, primarily in the Southern Blue Ridge, and possibly elsewhere in the Southern Appalachians region. The rocks are often densely or moderately covered with bryophytes or algae. The sparse vascular vegetation is limited to plants growing on bare rock, small ledges and crevices.
Classification Comments: This system is distinguished from all others in its range by its being kept wet by spray. Other outcrop systems, especially Southern Appalachian Montane Cliff and Talus (CES202.330), may have local wet areas created by seepage but will be dominated by dry microsites. Other interpretations of this system are that it could be combined with other cliff systems of the Appalachians.
Similar Ecological Systems:
- Southern Appalachian Montane Cliff and Talus (CES202.330)

Related Concepts:
- Moist Sandstone Cliff (Evans 1991) Broader

DESCRIPTION

Environment: Vegetation of this system occurs on rock outcrops adjacent to waterfalls, where spray from the falls keeps the rock wet for long periods. These outcrops are usually near-vertical, but horizontal surfaces at the base, boulder piles, and grottos are also common. The rock may be of any type, and the substrate may occasionally be saprolite rather than hard rock. Soil is limited to accumulations in crevices and on ledges. The rock may be permanently wet or may be wet seasonally when stream flow is high. Wetness is constant enough that this system may be considered a wetland, though some of the impacts of soil saturation do not occur. Seepage often makes portions of the rock wetter than areas covered just by spray. The typical topographic setting, in narrow gorges or enclosed valleys, makes for high local humidity and moderated temperature fluctuations.
Vegetation: Vegetation is usually a mix of growth forms and may be very patchy. Bryophytes, both mosses and liverworts, are often dense. Vascular vegetation may be sparse, but some examples are dense. Characteristic rock outcrop herbs such as *Saxifraga michauxii, Asplenium montanum*, and *Heuchera* spp. are usually present, along with some herbs of moist forests and seeps, such as *Galax urceolata, Thalictrum clavatum, Houstonia serpyllifolia, Circaea alpina*, and *Impatiens capensis*. A few examples are grassy. Examples on basic rock or with basic seepage have additional calciphilic herbs. A number of rare species, especially mosses, liverworts, and ferns but also including some forbs, grasses, and sedges, may be present. These spray cliffs can be exceptionally diverse in mosses and liverworts of widely differing biogeographic origins (Zartman and Pittillo 1998). Shrubs and trees are usually present, at least on edges and often also rooted in crevices and ledges. *Rhododendron maximum, Kalmia latifolia*, and *Tsuga canadensis* are among the most frequent. Woody vines may also be prominent.
Dynamics: The dynamics of this system have received little study. The spray cliff environment is probably unusually stable (Schafale and Weakley 1990), with its sheltered topographic position limiting wind influence, dryness, and extreme temperatures. Most individual plants are probably long-lived. The presence of tropical disjunct bryophytes and ferns at some spray cliffs is related to the very stable, moderate environment, and to the dispersal abilities of those species (Zartman and Pittillo 1998). Droughts affect streamflow and must affect moisture levels, but most streams large enough to support spray cliffs will probably never dry up. Occasional rockfalls and scouring related to flash floods represent infrequent disturbances to occurrences or parts of them. Physical evidence of flooding and erosion observed at many spray cliff sites includes uprooted trees and detached soil mats, suggesting that flood conditions have the potential to influence community structure and spatial arrangement of spray cliff vegetation (Zartman and Pittillo 1998). Distance from the stream edge forms a gradient from high flooding frequency on streamside sites to minimal flooding on elevated sites. This disturbance gradient seems to explain, in part, differences in species composition patterns between certain spray cliff associations (Zartman and Pittillo 1998).

Component Associations:
- *Trichophorum caespitosum - Osmunda regalis - Rhynchospora capitellata - Oxypolis rigidior* Herbaceous Vegetation (CEGL008490, G1Q)
- *Vittaria appalachiana - Heuchera parviflora var. parviflora - Houstonia serpyllifolia / Plagiochila* spp. Herbaceous Vegetation (CEGL004302, G2)

SPATIAL CHARACTERISTICS

Spatial Summary: Small-patch system, most examples covering less than one acre. Examples tend to occur as isolated small patches.
Size: Most examples naturally cover well less than one acre, and well-developed and diverse examples may be as small as 100 square

meters. Complexes of multiple patches are almost never found. Size is somewhat ambiguous for this system, in that vertical surfaces may be as extensive as horizontal surfaces.

Adjacent Ecological Systems:

- Southern and Central Appalachian Cove Forest (CES202.373)
- Southern Appalachian Montane Cliff and Talus (CES202.330)

Adjacent Ecological System Comments: This system is usually surrounded by mesic forest systems, including Southern and Central Appalachian Cove Forest (CES202.373). Some may be associated with Southern Appalachian Montane Cliff and Talus (CES202.330) on drier rock exposures.

DISTRIBUTION

Range: This system occurs scattered throughout the Southern Appalachians and incidentally into adjacent ecoregions, from northern Alabama and Georgia through Virginia.
Divisions: 202:C
Nations: US
Subnations: AL, GA, KY, NC, SC, TN, VA, WV?

SOUTHERN ATLANTIC COASTAL PLAIN FLORIDA BEACH (CES203.535)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
National Mapping Codes: ESLF 3181

CONCEPT

Summary: This beach ecological system is found along the Atlantic Coast from the St. Johns River in northeastern Florida south to approximately Cape Canaveral. Unlike Southern Atlantic Coastal Plain Sea Island Beach (CES203.383) north of the St. Johns River, this system is subject to higher wave energy and a greater component of sand. The vegetation of this area is distinct from that farther south along the coast of Florida, lacking the tropical element found south of Cape Canaveral.
Classification Comments: Apparently few, if any, associations have currently been described in the NVC for this system. More information is needed.
Similar Ecological Systems:
- Southern Atlantic Coastal Plain Sea Island Beach (CES203.383)--dovetails this system to the north.

Related Concepts:
- Unconsolidated Substrate (FNAI 1990) Broader

DESCRIPTION

Environment: The beach includes the sand intertidal shore and the low-gradient sand above the daily high tide line, which is between the foredune and the Atlantic Ocean. This area of upper beach is affected by wind and salt spray, seasonal high tides, and storm surge.
Vegetation: Characteristic species include mostly annual herbs, such as *Cakile edentula ssp. harperi, Chamaesyce polygonifolia, Chamaesyce bombensis, Sesuvium portulacastrum, Salsola kali ssp. kali (= Salsola caroliniana),* and *Amaranthus pumilus*. On Cumberland Island National Seashore in southeastern Georgia, perennials such as *Croton punctatus* and *Uniola paniculata* also can be important. The vegetation of this area is distinct from that farther south along the coast of Florida, lacking the tropical element found south of Cape Canaveral (Johnson and Muller 1993a).
Dynamics: The process of sand movement due to the forces of wind and water are part of the natural dynamics of beach ecosystems. This includes transport of sand along the coast, and movement of sand by wind or water between the dunes, beach and subtidal areas. If not restricted by infrastructure or engineered hard structures, beaches and dunes can migrate as coastlines change over time in response to the action of wind and water. The beaches of the east coast of Florida are affected by two tides per day.

Component Associations:
- *Cakile edentula ssp. harperi* Sparse Vegetation (CEGL004401, G3)

DISTRIBUTION

Range: This system is found along the Atlantic Coast from the St. Johns River in northeastern Florida south to approximately Cape Canaveral.

SOUTHERN ATLANTIC COASTAL PLAIN SEA ISLAND BEACH (CES203.383)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Beach (Substrate); Coastal plain
National Mapping Codes: ESLF 3150

CONCEPT

Summary: This ecological system represents beaches and overwash flats in the Sea Island region of South Carolina and Georgia. The entire region is distinctive, and wave energy is generally lower here than any other point along the Atlantic coast. Huge quantities of fine-textured sediments are deposited by the region's alluvial rivers, many of which drain relatively large interior areas of the Piedmont, where clay is an abundant by-product of weathering and erosion. These beaches are distinguished from others of the Atlantic coast by the prevalence of fine-textured sediments. The low wave energy and high tidal range create relatively short barrier islands (as opposed to the long narrow islands of North Carolina and the Gulf of Mexico). In addition, the extensive Continental Shelf coupled with low wave energy contributes to a paucity of shell components of the beach substrates.

Similar Ecological Systems:

- Southern Atlantic Coastal Plain Florida Beach (CES203.535)--dovetails this system to the south.

DESCRIPTION

Environment: Sea island beaches are found on the true barrier islands present in the region. Wave energy is generally lower here than any other point along the Atlantic coast (Tanner 1960). Low wave energy and high tidal range create relatively short barrier islands (as opposed to long narrow islands of North Carolina and the Gulf of Mexico).
Vegetation: See descriptions in Hillestad et al. (1975) from Cumberland Island.
Dynamics: The process of sand movement due to the forces of wind and water are part of the natural dynamics of beach ecosystems. This includes transport of sand along the coast, and movement of sand by wind or water between the dunes, beach and subtidal areas. If not restricted by infrastructure or engineered hard structures, beaches and dunes can migrate as coastlines change over time in response to the action of wind and water. The beaches of the Atlantic coast are affected by two tides per day.

Component Associations:

- *Cakile edentula ssp. harperi* Sparse Vegetation (CEGL004401, G3)
- *Ipomoea imperati - Cakile edentula ssp. harperi* Herbaceous Vegetation (CEGL007009, G3?)

DISTRIBUTION

Range: This system is found in the Sea Island region of South Carolina and Georgia, extending to the St. Johns River in northern Florida.

SOUTHERN ATLANTIC COASTAL PLAIN XERIC RIVER DUNE (CES203.497)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Dune (Substrate)
FGDC Crosswalk: Vegetated, Shrub-dominated, Shrubland, Mixed evergreen-deciduous shrubland
National Mapping Codes: EVT 2388; ESLF 5319; ESP 1388

CONCEPT

Summary: This system encompasses a range of vegetation present on inland sand dunes of the Atlantic Coastal Plain of Georgia. These dunes are associated with certain rivers such as the Ohoopee and Canoochee and are apparently eolian in origin, formed of riverine alluvial sands. The sandy soils are deep, coarse, and xeric in nature. The vegetation consists of an assemblage of xeric communities that also occur in other xeric habitats in the Coastal Plain. These include *Pinus palustris - Quercus laevis* communities and a scrub community akin to Inland Florida Scrub, but lacking *Pinus clausa*. This system is distinguished from more typical xeric sandhills of the Coastal Plain by its occurrence on the deep sands of river dunes. Xeric river dunes have a similar fire-return interval to other upland systems of which *Pinus palustris* is a component, but the fuels are fires tend to be patchy, leaving some unburned areas.

Related Concepts:
- Dwarf oak-evergreen shrub forest (Wharton 1978) Equivalent
- Longleaf Pine: 70 (Eyre 1980) Finer
- Southern Scrub Oak: 72 (Eyre 1980) Finer

DESCRIPTION

Environment: These dunes are apparently eolian in origin, formed of reworked riverine alluvial sands. The sandy soils are deep, coarse, and xeric in nature. These deep coarse sand dunes have formed from winds blowing exposed sand from the riverbars in the Pleistocene (Edwards et al. 2013). They occur on the east and northeast sides of rivers which flow southeast (Bozeman 1971) in south Georgia, such as the Altamaha, Ohoopee, Flint, Satilla and Canoochee (Edwards et al. 2013). The dune system is most developed along the east side of the Ohoopee River, which is 35 miles long and about 40,000 acres (Edwards et al. 2013).

Vegetation: Upland plant communities include longleaf pine - turkey oak, dwarf oak, oak hammock, and rosemary scrub (Wharton 1978). On the Altamaha River, there is *Pinus palustris, Pinus elliottii, Quercus laevis, Aristida beyrichiana, Quercus hemisphaerica,* and *Quercus virginiana* (these last two may be from examples from which fire has been excluded) (J. Thompson, GDNR, pers. comm.)

Dynamics: About half of the woody species are evergreen, but there is greater cover of deciduous shrubs, and there are more shrubs than herbs (Harper 1906). This contrasts with other *Pinus palustris* habitats, which tend to be grass-dominated with a high diversity of herbs. Both *Ceratiola ericoides* and *Chrysoma pauciflosculosa* are evergreen shrubs and are fire-sensitive. *Chrysoma pauciflosculosa* seeds are able to spread to newly available open sandy and unburned habitat in local areas where they occur, but *Ceratiola ericoides* seeds are heavy, landing mostly near the mother plant, are inhibited by allelopathy, and generally start germinating after death of mother shrub, in same vicinity (M. Hodges pers. comm.). These shrubs may persist with the sparse *Pinus palustris* due to their metapopulation dynamics; certain subpopulations may be lost to occasional wildland fires, but new subpopulations also form where seeds germinate. While *Ceratiola ericoides* will generally not persist if burned more frequently than every 20 years (Johnson 1982), in some Florida habitats, population models of *Ceratiola ericoides* on Georgia xeric river dune sandhills suggest that burns at least as frequently as every 10 years may be important for maintaining open habitat and promoting recruitment of new shrubs (Schmidt 2006). These river dune habitats are naturally topographically isolated by a river on one (west or southwest) side and typically are adjacent to pine flatwoods on the other (east or northeast) side. Consequently, they have been partially protected from large wildland fires and may have a similar or lower fire-return interval than typical dry *Pinus palustris* habitats. The accumulation of fuel in these xeric river dune habitats is slow and does not support the frequent continuous fires that can occur in *Pinus palustris* habitats which have higher nutrient availability. The natural fire-return interval may have varied from 5 to 10 years depending on the fertility of the site and accumulation of fuels (Edwards et al. 2013). Where xeric river dunes are connected to pine flatwoods, fires would have been more frequent, and fires were patchy, leaving many unburned patches (M. Hodges pers. comm.). Fuels include *Pinus palustris* needles and dead leaves of *Aristida purpurascens, Aristida beyrichiana, Quercus laevis, Triplasis americana,* and other plants. Small areas along the Altamaha River sand ridge have broadleaf evergreen tall-shrub and small-tree vegetation, called the Georgia River Dune Myrtle Oak Scrub NVC Association (Bozeman 1971). These areas apparently burn only rarely (perhaps at high intensity), if at all, and are somewhat similar to oak scrub found in Florida.

Component Associations:
- *Ceratiola ericoides - (Chrysoma pauciflosculosa) / Polygonella polygama / Cladonia leporina* Shrubland (CEGL003864, G2?)
- *Chrysoma pauciflosculosa - (Clinopodium coccineum)* Dwarf-shrubland (CEGL003946, G1G2)
- *Pinus palustris / Quercus laevis - Quercus geminata / Ceratiola ericoides* Woodland (CEGL004491, G1G2)
- *Quercus myrtifolia - Quercus geminata - Hamamelis virginiana - (Elliottia racemosa)* Shrubland (CEGL004715, G1Q)

DISTRIBUTION

Range: This system is endemic to river-associated dunes in the South Atlantic Coastal Plain of Georgia, such as along the Ohoopee and Canoochee rivers (Wharton 1978), as well as other watersheds. Reports of similar or related vegetation from North and South Carolina are being investigated.

SOUTHERN CALIFORNIA COAST RANGES CLIFF AND CANYON (CES206.904)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: Mediterranean California (206)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Canyon Mosaic; Mediterranean [Mediterranean Xeric-Oceanic]; Xeric; Landslide
Non-Diagnostic Classifiers: Montane [Lower Montane]; Lowland [Foothill]; Lowland [Lowland]; Shrubland (Shrub-dominated); Moss/Lichen (Nonvascular); Cliff (Substrate); Talus (Substrate); Rock Outcrops/Barrens/Glades; Very Shallow Soil; Canyon; Cliff (Landform)
National Mapping Codes: ESLF 3168

CONCEPT

Summary: Found from foothill and montane elevations of California's Transverse and Peninsular ranges, these are barren and sparsely vegetated areas (<10% plant cover) of steep cliff faces, narrow canyons, and smaller rock outcrops of various igneous, sedimentary, and metamorphic bedrock type. This system also includes unstable scree and talus slopes typically occurring below cliff faces. Scattered vegetation may include shrub species from surrounding coastal chaparral, such as *Ceanothus megacarpus, Ceanothus leucodermis, Cercocarpus montanus var. minutiflorus (= Cercocarpus minutiflorus), Arctostaphylos glauca*, and *Xylococcus bicolor*. Soil development is limited as is herbaceous cover.

DISTRIBUTION

Range: Found from foothill and montane elevations of California's Transverse and Peninsular ranges.

SOUTHERN COASTAL PLAIN SINKHOLE (CES203.495)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Diagnostic Classifiers: Rock Outcrops/Barrens/Glades
Non-Diagnostic Classifiers: Depressional; Isolated Wetland [Partially Isolated]
National Mapping Codes: ESLF 3184

CONCEPT

Summary: This system consists of deep sinkhole depressions with steep vertical walls of exposed limestone in the Gulf Coastal Plain of Florida and Georgia (other depressions formed in karstic regions that are shallow and lacking in steep vertical walls with exposed rock are accommodated by other systems). These cylindrical- or conical-shaped depressions form in karstic environments where cavities have been eroded in underlying limestone. As cavities enlarge, cavern roofs eventually collapse forming these steep-sided depressions. Some examples drain readily and contain standing water for short periods of time, while others contain permanent lakes. The steep-sided limestone walls are typically sparsely vegetated with mosses, liverworts, and ferns, with occasional herbs and shrubs in crevices where organic soils have developed (FNAI 1990). The steepness and depth of these depressions help create a generally moist microclimate which is often enhanced by seepage from surrounding uplands, and the presence of standing water.
Classification Comments: Excluded from this system are sinkholes of extreme southern Florida and the Mid-Atlantic Coastal Plain of the Carolinas which do not develop such extreme depth and microclimatic features.
Similar Ecological Systems:
- East Gulf Coastal Plain Depression Pond (CES203.558)
- East Gulf Coastal Plain Sandhill Lakeshore Depression (CES203.292)

Related Concepts:
- Sinkhole (FNAI 1990) Equivalent
- Water Tupelo - Swamp Tupelo: 103 (Eyre 1980) Finer

DESCRIPTION

Environment: Examples may be found in cylindrical- or conical-shaped limesink depressions with steep vertical walls of exposed limestone in northern and possibly central Florida. These depressions form in karstic environments where cavities have been eroded in underlying limestone. As cavities enlarge, cavern roofs eventually collapse forming these steep-sided depressions. Some examples drain readily and contain standing water for short periods of time, while others contain permanent lakes. The steep-sided limestone walls are typically sparsely vegetated with mosses, liverworts, and ferns, with occasional herbs and shrubs in crevices where organic soils have developed (FNAI 1990). The steepness and depth of these depressions help create a generally moist microclimate which is often enhanced by seepage from surrounding uplands and the presence of standing water.
Vegetation: The steep-sided limestone walls are typically sparsely vegetated with mosses, liverworts, and ferns, with occasional herbs and shrubs in crevices where organic soils have developed (FNAI 1990). In the East Gulf Coastal Plain, *Adiantum capillus-veneris* and *Thelypteris kunthii* are generally the dominant herbs. *Decumaria barbara* is often a common to codominant festooning vine. Other species may include *Aristolochia serpentaria*, *Selaginella ludoviciana*, *Carex* spp., and others. Bryophytes are abundant and lush, usually dominated by the thallose liverwort *Dumortiera hirsuta*. In Panhandle Florida, *Thelypteris ovata, Toxicodendron radicans, Decumaria barbara*, and *Parthenocissus quinquefolia* are also reported in association with *Adiantum*. Southern examples contain *Adiantum tenerum*, which dominates the herb layer, with scattered individuals of *Parietaria praetermissa, Arenaria lanuginosa*, and other ferns. Calciphilic mosses, especially *Anomodon rostratus*, are abundant.
Dynamics: These limesink depressions where this ecological system is found form in karstic environments where cavities have been eroded in underlying limestone. As the cavities enlarge, cavern roofs eventually collapse forming these steep-sided depressions. Some examples drain readily and contain standing water for short periods of time, while others contain permanent lakes. The steep-sided limestone walls are typically sparsely vegetated with distinctive mosses, liverworts, and ferns, with occasional herbs and shrubs in crevices where organic soils have developed (FNAI 1990). The steepness and depth of these depressions help create a generally moist microclimate which is often enhanced by seepage from surrounding uplands and the presence of standing water.

Component Associations:
- *Adiantum capillus-veneris - Thelypteris kunthii / Dumortiera hirsuta* Herbaceous Vegetation (CEGL004717, G3?)
- *Adiantum tenerum - Parietaria praetermissa - Arenaria lanuginosa* Herbaceous Vegetation (CEGL004469, G2?)

DISTRIBUTION

Range: This ecological system is restricted to the Gulf Coastal Plain of Alabama, Florida and Georgia.

SOUTHERN INTERIOR CALCAREOUS CLIFF (CES202.356)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate)
National Mapping Codes: ESLF 3185

CONCEPT

Summary: This ecological system encompasses calcareous cliffs of the Southern Ridge and Valley and adjacent areas of the Cumberland Plateau with a few disjunct localities in the Southern Appalachians. This system includes vertical to near-vertical rock faces of limestone and dolomite. These cliffs are typically dry but may contain relatively small embedded seepage patches. Both wet and, more commonly, dry expressions are included. Due to harsh edaphic conditions, including verticality, these cliffs are nearly unvegetated, however, *Asplenium ruta-muraria* and *Pellaea atropurpurea* may be characteristic plants. Some cliffs have scattered *Thuja occidentalis* trees which may be very old (>800 years) and more genetically diverse than northern populations. This system also covers a narrow zone of vegetation, often herbaceous, at the horizontal clifftop where growing conditions are harsh and often gladelike.

Similar Ecological Systems:
- Central Interior Calcareous Cliff and Talus (CES202.690)
- North-Central Appalachian Circumneutral Cliff and Talus (CES202.603)

Related Concepts:
- Dry Limestone Cliff (Evans 1991) Intersecting
- Eastern Redcedar: 46 (Eyre 1980) Finer
- Moist Limestone Cliff (Evans 1991) Intersecting
- Northern White-Cedar: 37 (Eyre 1980) Finer

DESCRIPTION

Environment: This system includes vertical to near-vertical rock faces of limestone and dolomite. These cliffs are typically dry but may contain relatively small embedded seepage patches. Both wet and, more commonly, dry expressions are included. Disjunct examples in the southern Appalachians attributed to this system include Hot Springs and Linville Caverns area. It presumably includes both the Bull Cave and Calf Cave area in the Smokies.

Vegetation: Due to harsh edaphic conditions, including verticality, these cliffs are nearly unvegetated; however, *Asplenium ruta-muraria* and *Pellaea atropurpurea* may be characteristic plants. Some cliffs have scattered *Thuja occidentalis* trees which may be very old (>800 years) and genetically diverse. This system also covers a narrow zone of vegetation, often herbaceous, at the horizontal clifftop where growing conditions are harsh and often gladelike. Some other plant species that may be found include calciphilic herbs such as *Aquilegia canadensis, Dodecatheon meadia, Symphyotrichum ericoides, Symphyotrichum oblongifolium, Cystopteris bulbifera, Bouteloua curtipendula, Pellaea atropurpurea, Dryopteris marginalis, Allium cernuum, Heuchera americana, Carex oligocarpa, Asplenium trichomanes, Arabis hirsuta, Arabis lyrata, Phlox subulata, Hylotelephium telephioides (= Sedum telephioides),* and *Saxifraga virginiensis*. Woody species may occur scattered throughout or at the margins; these species include *Juniperus virginiana, Rhus aromatica, Toxicodendron radicans, Hydrangea arborescens, Fraxinus americana, Parthenocissus quinquefolia, Cercis canadensis, Tilia americana, Carya* spp., *Quercus muehlenbergii, Ostrya virginiana*, and *Cornus florida*.

Component Associations:
- *Asplenium ruta-muraria - Pellaea atropurpurea* Sparse Vegetation (CEGL004476, G3G4)
- *Carex leptalea - Parnassia grandifolia - Juncus coriaceus - Solidago patula* Ridge and Valley Herbaceous Vegetation (CEGL004944, G2)
- *Rhus aromatica - Celtis tenuifolia / Carex eburnea* Shrubland (CEGL004393, G3)
- *Schizachyrium scoparium - Sporobolus compositus var. compositus - Rudbeckia fulgida var. fulgida* Wooded Herbaceous Vegetation (CEGL004078, G2)
- *Thuja occidentalis / Carex eburnea - Pellaea atropurpurea* Woodland (CEGL002596, G2G3)
- *Thuja occidentalis* Limestone Seepage Woodland (CEGL003675, G2G3Q)

DISTRIBUTION

Range: This system is found in the Southern Ridge and Valley and adjacent areas of the Cumberland Plateau with a few disjunct localities in the Southern Appalachians.

SOUTHERN INTERIOR SINKHOLE WALL (CES202.357)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate); Alkaline Soil
National Mapping Codes: ESLF 3163

CONCEPT

Summary: This system represents vertical shaft sinkholes and the characteristic vegetation associated with their steep walls in the southern Ridge and Valley and adjacent Interior Low Plateau regions of the southeastern United States. Related examples in the Southern Blue Ridge are also covered here. Examples are normally dominated by *Cystopteris bulbifera* and *Asplenium rhizophyllum* or the liverwort *Dumortiera hirsuta*.

Similar Ecological Systems:
- Central Interior Calcareous Cliff and Talus (CES202.690)--may be in effect a subset of CES202.690.

Related Concepts:
- Moist Limestone Cliff (Evans 1991) Broader

DESCRIPTION

Environment: This system represents vertical shaft sinkholes and their steep walls.
Vegetation: Examples are normally dominated by *Cystopteris bulbifera* and *Asplenium rhizophyllum* or the liverwort *Dumortiera hirsuta*. An example from the Chattahoochee National Forest contains *Heuchera villosa, Adiantum pedatum, Asplenium rhizophyllum, Carex platyphylla, Cystopteris protrusa, Hepatica nobilis var. acuta, Laportea canadensis*, and *Solidago flexicaulis*. Additional species at a similar site in Great Smoky Mountains National Park include *Sedum ternatum, Physocarpus opulifolius, Pellaea atropurpurea*, and *Packera obovata*. Additional types may be developed as more information becomes available.

Component Associations:
- *Cystopteris bulbifera - (Asplenium rhizophyllum)* Sparse Vegetation (CEGL004394, G3G4)
- *Cystopteris bulbifera / Dumortiera hirsuta* Sinkhole Wall Sparse Vegetation (CEGL004988, G1)

DISTRIBUTION

Range: This system is found in the Southern Ridge and Valley and adjacent Interior Low Plateau regions of the southeastern United States and the Southern Blue Ridge, with rare and limited occurrences in the Upper East Gulf Coastal Plain.

SOUTHERN PIEDMONT CLIFF (CES202.386)

CLASSIFIERS

Classification Status: Standard

Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Cliff (Substrate)
National Mapping Codes: ESLF 3156

CONCEPT

Summary: This ecological system consists of steep to vertical or overhanging rock outcrops in the Piedmont. They occur on lower to midslopes, usually in river gorges or bluffs. The sparse vegetation is limited to plants growing on bare rock, small ledges, and crevices. Vegetation is primarily bryophytes, lichens, and herbs, with sparse trees and shrubs rooted in deeper soil pockets and crevices. The types of plants that may grow on cliffs are limited by the harsh conditions to those with adaptations to drought and limited nutrients. Examples of this system occur on steep rock outcrops on lower slopes, occasionally higher in topographically sheltered sites. River bluffs are the primary setting. Cliffs may have any aspect, but north-facing cliffs seem to be more common. The substrate is mostly bare bedrock, which is steep to vertical or overhanging. Most examples are on felsic metamorphic rock such as gneiss or schist, but a smaller number occur on mafic metamorphic rock, felsic or mafic igneous rock, or sedimentary rock. Vascular plants are limited to sparse rooting sites in soil pockets, ledges, and crevices.
Classification Comments: More information is needed on the associations that belong to this system.

This system is distinguished from other rock outcrops by a combination of low topographic position, vertical orientation, large amount of bare rock, and absence of specialized environments such as exfoliated granite, limestone or dolomite, and spray from waterfalls. In contrast, Southern Appalachian Rocky Summit (CES202.327) occurs in high topographic positions; they have more horizontal rock but may have some substantial vertical surfaces. Southern Piedmont Glade and Barrens (CES202.328) is more horizontally oriented and have much more vegetation cover. The division of rock outcrop systems may be too fine and warrant combining some; however, each system has distinctive characteristics of structure and some distinctive flora.

This system is distinguished from Southern Appalachian Montane Cliff and Talus (CES202.330) by floristic differences. Southern Appalachian Montane Cliff and Talus (CES202.330) has a number of species absent or scarce in the Piedmont, differences that may be related to elevation, regional climate, or to biogeography. However, upper Piedmont cliffs that have Appalachian flora are included in that system (CES202.330).

The primary variation within this system, which could be the basis for further subdivision, is the distinction between mafic and felsic rock, with the rare sedimentary rock examples a third category. Sedimentary rock examples in the Piedmont resemble other Piedmont cliffs more than they resemble cliffs of sedimentary rocks in the interior ecoregions.
Similar Ecological Systems:
- Southeastern Coastal Plain Cliff (CES203.398)
- Southern Appalachian Montane Cliff and Talus (CES202.330)
- Southern Appalachian Rocky Summit (CES202.327)
- Southern Piedmont Glade and Barrens (CES202.328)
- Southern Piedmont Granite Flatrock and Outcrop (CES202.329)

DESCRIPTION

Environment: Examples of this system occur on steep rock outcrops on lower slopes, occasionally higher in topographically sheltered sites. River bluffs are the primary setting. Cliffs may have any aspect, but north-facing cliffs seem to be more common. The substrate is mostly bare bedrock, which is steep to vertical or overhanging. Most examples are on felsic metamorphic rock such as gneiss or schist, a smaller number on mafic metamorphic rock, felsic or mafic igneous rock, or sedimentary rock. The physical structure of most cliffs in the Piedmont is irregular, with some ledges and crevices, and with steep, vertical, and even overhanging portions intermixed. Moisture levels vary drastically over short distances. Seepage of ground water from adjacent soils or through rock fractures often creates permanently or seasonally flooded microsites, while lack of soil makes other portions extremely dry. In less sheltered topography, slope aspect affects overall moisture levels to some degree. Rock or soil chemistry appears to be the most important factor affecting different associations on sites that have the physical structure to belong to this system.
Vegetation: No vascular plant associations have yet been defined for this system. Vegetation is sparse. Bryophytes and lichens may cover portions of the open rock. Vascular plants are limited to sparse rooting sites in soil pockets, ledges, and crevices. Some of these microsites may be deep enough to support shrubs or even trees, while most support only herbs. The woody plants are usually species from surrounding forests, and may be mesophytic or xerophytic. The herbs include a variety of species of open dry habitats, such as *Schizachyrium scoparium, Danthonia spicata, Houstonia purpurea*, and *Coreopsis major*, along with a few rock outcrop specialists such as *Polypodium virginianum, Saxifraga virginiensis,* and *Heuchera* spp. A number of bryophyte species may be present. Mafic rock outcrops have an additional suite of specialist herbs, including *Aquilegia canadensis, Arabis lyrata, Anemone berlandieri*, and *Sedum glaucophyllum*. Herbs from the surrounding forest are often also present and may make up a significant fraction of the flora.

Dynamics: The dynamics of this system have received little study. Most cliff communities are probably stable over long periods of time, with fine-scale disturbances affecting microsites. Rock falls, slides, and other mass movement are rare, but represent catastrophic disturbance to part or all of a cliff, and may be important in the long term for keeping cliffs open. The types of plants that may grow on cliffs are limited by the harsh conditions to those with adaptations to drought and limited nutrients (Edwards et al. 2013). Animal movements may be locally important. Fire probably has little effect on cliffs, which have too little vegetation to carry fire and which tend to occur in topography that is not conducive to fire spread. Because of the limited natural disturbance and the fragility of soil and vegetation, human disturbance by trampling of edges and by climbing may be particularly destructive.

Component Associations:
- *Cystopteris bulbifera - (Asplenium rhizophyllum)* Sparse Vegetation (CEGL004394, G3G4)
- *Lasallia papulosa - Lasallia pensylvanica* Nonvascular Vegetation (CEGL004385, G2?)
- Piedmont Acidic Cliff Sparse Vegetation (CEGL003979, G2?)
- Piedmont Mafic Cliff Sparse Vegetation (CEGL003982, G2?)

SPATIAL CHARACTERISTICS

Spatial Summary: Small-patch system, most examples covering less than one acre. Examples tend to occur as isolated small patches, occasionally as small clusters.
Size: Most examples naturally cover an acre or less. A few occur as complexes of closely associated patches, but the aggregate size is still small. Size is somewhat ambiguous for this system, in that vertical surfaces may be as extensive as horizontal surfaces.
Adjacent Ecological Systems:
- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)
- Southern Piedmont Large Floodplain Forest (CES202.324)
- Southern Piedmont Mesic Forest (CES202.342)
- Southern Piedmont Small Floodplain and Riparian Forest (CES202.323)

Adjacent Ecological System Comments: Surrounded by forest systems on deeper soils less influenced by bedrock, most typically Southern Piedmont Dry Oak-(Pine) Forest (CES202.339) above and Southern Piedmont Large Floodplain Forest (CES202.324) or Southern Piedmont Small Floodplain and Riparian Forest (CES202.323) below.

DISTRIBUTION

Range: Scattered throughout the Piedmont and incidentally into the Coastal Plain, from northern Alabama and Georgia north into Virginia.
Divisions: 202:C; 203:C
Nations: US
Subnations: AL, GA, NC, SC, VA

SOUTHERN PIEDMONT GRANITE FLATROCK AND OUTCROP (CES202.329)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Central Interior and Appalachian (202)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland; Wetland
Diagnostic Classifiers: Rock Outcrops/Barrens/Glades
Non-Diagnostic Classifiers: Seepage-Fed Sloping; Isolated Wetland [Strictly Isolated]
National Mapping Codes: ESLF 3175

CONCEPT

Summary: This ecological system consists of smooth, exfoliated outcrops of massive granite and related rocks in the eastern and central Piedmont of the southeastern United States, and rarely in the adjacent Atlantic Coastal Plain, there confined to the fall-line where erosion has exposed underlying rocks. Examples occur from Virginia south to Alabama but are found most abundant in the upper Piedmont of Georgia. Some noteworthy examples in central Georgia include Stone Mountain, Panola Mountain, and Arabia Mountain in DeKalb, Henry, and Rockdale counties. Depending upon the location, examples may rise above the surrounding landscape by as much as 200 m, or may lie flush with the surrounding land surface. The vegetation is a complex of small-patch communities of different species and structure occupying different microhabitats which are present on the outcrops, ranging from mosses and lichens, to herbs, to shrubs and trees. In some areas, these microhabitats include solution pits or depressions that retain water and form a distinctive wetland community. This outcrop system supports a relatively large number of endemic plants.
Classification Comments: Granitic domes are clearly related to other rock outcrop systems in the Piedmont but are distinct in their flora and vegetation mat succession. The smooth rock surface is crucial to their development. More fractured granitic rocks do not form this distinct system. In contrast, Southern Piedmont Cliff (CES202.386) has vertically oriented rock outcrops that tend to have fractures and ledges. Southern Piedmont Glade and Barrens (CES202.328) is similarly horizontally oriented but has denser vegetation and rather different flora. Southern Appalachian Rocky Summit (CES202.327), which barely overlaps the range of this system, has fractured rock and occurs in topographically high settings in rugged topography.

This system is closely related to Southern Appalachian Granitic Dome (CES202.297), with which it shares the distinctive structure and vegetation mat dynamics of exfoliated outcrops. The flat orientation of the flatrocks makes pools more important in them. Climatic and biogeographic differences lead to floristic differences between the two systems. The massive Piedmont outcrops in the Atlanta vicinity (Wharton 1978) are included here, the distinction between "dome" (CES202.297) and "flatrock (CES202.329) perhaps being an overly specific use of vague and conceptual terminology.

Similar Ecological Systems:
- Southern Appalachian Granitic Dome (CES202.297)
- Southern Appalachian Rocky Summit (CES202.327)
- Southern Piedmont Cliff (CES202.386)
- Southern Piedmont Glade and Barrens (CES202.328)

Related Concepts:
- Rock Outcrops (Wharton 1978) Broader
- Virginia Pine: 79 (Eyre 1980) Finer

DESCRIPTION

Environment: This system occurs on exfoliated granitic outcrops; these are Precambrian metamorphic rocks generally found in the Piedmont Plateau (McVaugh 1943). Outcrops are level or gently sloped, occurring as low domes up to 200 m above the surrounding landscape or as flatrocks varying considerably in size (Shure 1999). Smooth rock without crevices is the primary factor in the distinctive ecological character of this system. Granite, granitic gneiss, and related granitoid rocks (Edwards et al. 2013) without many internal joints tend to fracture into thin sheets parallel to the surface, forming outcrops with smooth surfaces largely lacking crevices. The outcrop surface is largely bare rock but has thin soil mats around the edges and in patches throughout. Mats vary in depth with age and level of development. Distinct microenvironments are created by small irregularities in the rock surface and by areas of seepage at the edge. Some examples (e.g., in central Georgia) may have prominent seepage-related features, where areas of perennial herbaceous vegetation are very wet in the winter and spring. In these cases, the only vegetated areas on the granite outcrop are seepage-related. One possible substrate is the Lilesville granite.
Vegetation: Most of the rock surface is bare or has only crustose or foliose lichen cover. Vegetation occurs as a series of small patches in the thin soil mats, or seasonal pools, with the community type dependent on the nature of the depression and depth of the soil mat (if any). Bare rock may have moss patches or straggling vines including *Gelsemium sempervirens*. The thinnest soils usually have a set of fine forbs, many of them annual. Slightly deeper soils often have grasses dominating. Deeper soils support shrubs or small trees, including *Vaccinium arboreum* and *Pinus virginiana*. A distinctive woodland of pines or pines and oaks occurs on the continuous shallow soils surrounding the outcrop. The flora shares some species with other rock outcrops of the Piedmont, but has some distinctive species and different dominance of species. Some characteristic plant species include the forbs *Minuartia glabra*, *Minuartia uniflora*, and *Packera tomentosa*; one common grass is *Schizachyrium scoparium*. Other unusual plants include the

mat-forming fern ally *Selaginella rupestris*, the unusual floating aquatic annual *Amphianthus pusillus*, the quillworts *Isoetes melanospora* and *Isoetes tegetiformans*, the diminuitive succulents *Diamorpha smallii* and *Talinum teretifolium*, as well as *Cyperus granitophilus*, *Diodia teres*, and *Croton willdenowii*.

Dynamics: Large numbers of soil island depression may be scattered across the surface of granite outcrops and occasional pools of shallow water may stand in certain depressions which trap rainfall (McVaugh 1943, Shure 1999). Where soil accumulates in depressions formed by exfoliating surface rock, a distinctive and fairly predictable pattern of successional changes occurs [see references in Shure (1999)]. Soil mats appear and deepen over time in a process that links vegetational and soil development, but are eventually destroyed by windthrow, drought, other natural disturbances. The result is a mosaic with mats of different levels of development at any given time. Mat dynamics are different in different parts of the rock, with older mats and more permanent patterns near the edges and sparser and younger mats in the interior. The dynamics are further modified by microtopography and the presence of seepage. The larger vegetation patterns such the relative amount of different stages likely respond to climatic cycles and natural disturbance events. The thin soils make these communities sensitive to drought, especially the long-lived woody species. Fire is probably rare in the interior, given the sparse fuel, but may be important in determining the size of the open area and may affect the dynamics of the bordering woodlands.

Severe droughts kill tree saplings growing in cracks and potholes, helping to retain the open character of the glades (Quarterman et al. 1993). There is an apparent zonation or patchiness to glade/barren vegetation, with different zones that may be identified by their characteristic plant species (Quarterman et al. 1993). These zones are apparently relatively stable, with woody plant encroachment evident only in relation to the invasion of shrubs and trees into potholes or crevices where soil accumulates more rapidly.

Component Associations:

- *Amphianthus pusillus - Isoetes melanospora - Isoetes tegetiformans* Herbaceous Vegetation (CEGL004342, G1)
- *Diamorpha smallii - Minuartia glabra - Minuartia uniflora - Cyperus granitophilus* Herbaceous Vegetation (CEGL004344, G3)
- *Packera tomentosa - Croton willdenowii - Schizachyrium scoparium - (Selaginella rupestris)* Herbaceous Vegetation (CEGL004298, G3)
- *Pinus (virginiana, taeda) / Juniperus virginiana - Chionanthus virginicus - Ulmus alata* Granitic Flatrock Border Forest (CEGL003993, G3?)
- *Talinum teretifolium - Minuartia glabra - Diodia teres - Croton willdenowii* Herbaceous Vegetation (CEGL003857, G2)

Spatial Characteristics

Spatial Summary: Small-patch system, most examples covering one to a relatively few acres.

Size: Most examples naturally cover one to a few acres, some less than one acre. A few examples exceed 10 acres. Most examples occur in a few clusters where geology is particularly suitable, such as central Georgia and northeastern North Carolina. A few examples are more isolated. Individual flatrocks may occur in complexes, separated by small patches of forest.

Adjacent Ecological Systems:

- Southern Piedmont Dry Oak-(Pine) Forest (CES202.339)

Adjacent Ecological System Comments: Surrounded by forest systems on deeper soils less influenced by bedrock, most typically Southern Piedmont Dry Oak-(Pine) Forest (CES202.339).

Distribution

Range: This system is found scattered in the eastern and central Piedmont, from Alabama to Virginia. Rare examples occur in the upper Piedmont. A few, occurring surrounded by Tertiary sediments in the Fall Zone, may be considered to be in the Coastal Plain.

SOUTHWEST FLORIDA BEACH (CES411.276)

CLASSIFIERS

Classification Status: Standard

Primary Division: Caribbean (411)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Beach (Substrate); Coast
Non-Diagnostic Classifiers: Graminoid
National Mapping Codes: ESLF 3151

CONCEPT

Summary: This system ranges from Anclote Key southward to Cape Romano, Florida (Johnson and Barbour 1990). Within the northern Gulf of Mexico region, these beaches are distinguished by the highest species richness, greatest cover of succulents, and high cover of *Iva imbricata* and several tropical species (Barbour et al. 1987). Sands are relatively coarse and, unlike other beach systems of the northern Gulf of Mexico, are extremely rich in calcium from an abundance of calcareous shell fragments.
Classification Comments: Apparently, few associations have currently been described in the NVC for this system. More information is needed.
Similar Ecological Systems:
- Southeast Florida Beach (CES411.272)

Related Concepts:
- Beach Dune (FNAI 1990) Broader
- Unconsolidated Substrate (FNAI 1990) Broader

DESCRIPTION

Environment: The substrate of these beaches is composed of relatively coarse sands and, unlike other beach systems of the northern Gulf of Mexico, are extremely rich in calcium from an abundance of calcareous shell fragments.
Vegetation: These beaches are dominated by *Uniola*, but less so than other beach systems of the northern Gulf of Mexico. Other important species are *Iva imbricata*, *Oenothera humifusa*, *Scaevola plumieri*, and *Sesuvium portulacastrum*.

Component Associations:
- *Ipomoea pes-caprae* - *Cakile lanceolata* Herbaceous Vegetation (CEGL004403, G3G4)
- *Scaevola plumieri / Uniola paniculata* - *Iva imbricata* - *Cenchrus spinifex* Herbaceous Vegetation (CEGL003897, G3?)

DISTRIBUTION

Range: This system ranges from Anclote Key (border of Pasco and Pinellas counties) southward to Cape Romano, Florida (Collier County).
Divisions: 411:C

SOUTHWESTERN GREAT PLAINS CANYON (CES303.664)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Canyon
Non-Diagnostic Classifiers: Very Shallow Soil; Flood Scouring
National Mapping Codes: ESLF 3176

CONCEPT

Summary: This ecological system occurs in both perennial and intermittent stream canyons of the southwestern Great Plains. Soils can range from deep loams to alluvial to sandy. The mosaic of soil types which have developed from sandstone, limestone, basalt, and shale parent materials creates a complex mosaic of grasslands, shrublands and woodlands within the canyon system (Shaw et al. 1989). Although the system combines many elements from Southern Rocky Mountain Juniper Woodland and Savanna (CES306.834), Rocky Mountain Lower Montane-Foothill Shrubland (CES306.822), Western Great Plains Shortgrass Prairie (CES303.672), and other shrublands, the varied geology, diverse soil types, and topographic dynamics together form a distinct ecological system characteristic of the canyons and dissected mesas of the southwestern Great Plains.

Vegetation varies both regionally and locally depending on latitude, aspect, slope position and substrate and can range from riparian vegetation to xeric or mesic woodlands and shrublands. Rock outcrops with sparse vegetation are also common. Open to moderately dense pinyon-juniper woodlands occupy most of the canyonland slopes. Scattered *Pinus edulis* may occur within these community types but are never dominant. Woodlands may be floristically similar to and intergrade with Southern Rocky Mountain Juniper Woodland and Savanna (CES306.834) but are distributed along rocky outcrops, canyon slopes and mesas. *Juniperus monosperma* is the most common tree species and forms extensive woodlands with a grassy understory of *Bouteloua eriopoda, Bouteloua gracilis, Bouteloua hirsuta, Bouteloua curtipendula,* and *Pleuraphis jamesii*, or sometimes with an open shrub layer dominated by *Cercocarpus montanus*. In Kansas, *Juniperus virginiana* can become more dominant and replace *Juniperus monosperma*. Isolated patches of *Pinus ponderosa* or *Populus tremuloides* are found in some locations. Shrublands occur on canyon bottoms, in narrow side canyons, and integrate with woodlands on upper slopes. A mosaic of shrub species is characteristic of canyon walls and slopes and varies with substrate and moisture availability. Common species include *Artemisia bigelovii, Cercocarpus montanus, Rhus trilobata, Ribes* spp., *Ptelea trifoliata, Philadelphus microphyllus*, and *Yucca glauca*. *Frankenia jamesii* and *Glossopetalon spinescens var. meionandrum* form a community restricted to gypsiferous and calciferous soils. Canyon floors often support a degraded shrubby grassland of *Ericameria nauseosa* and *Opuntia imbricata* with a grassy understory.

Because of the varied topography, relatively permanent water along streambeds and southern location, these canyonlands have a rich herpetofauna (Mackessy 1998). This system provides good habitat for a number of snake species that are otherwise uncommon in the Central Shortgrass Prairie ecoregion. Occasional seeps and springs of the canyon walls provide habitat for rare ferns.
Classification Comments: A new system (10-09), Llano Estacado Caprock Escarpment and Breaks Shrubland and Steppe (CES303.725), was created for the escarpment and breaks that follow the eastern edge of the Llano Estacado (Texas Panhandle) and includes the canyons along this escarpment (e.g., Palo Duro Canyon).
Similar Ecological Systems:
- Llano Estacado Caprock Escarpment and Breaks Shrubland and Steppe (CES303.725)
- Northwestern Great Plains Shrubland (CES303.662)
- Western Great Plains Cliff and Outcrop (CES303.665)

Related Concepts:
- Pinyon - Juniper: 239 (Eyre 1980) Finer. Pinyon is very scattered and not dominant so probably not extensive within this system.

Component Associations:
- *Artemisia bigelovii / Achnatherum hymenoides* Shrubland (CEGL000990, G3Q)
- *Cercocarpus montanus - Rhus trilobata / Andropogon gerardii* Shrubland (CEGL002912, G2G3)
- *Cercocarpus montanus / Achnatherum scribneri* Shrubland (CEGL002913, G3)
- *Cercocarpus montanus / Bouteloua curtipendula* Shrubland (CEGL001086, G5)
- *Cercocarpus montanus / Hesperostipa comata* Shrubland (CEGL001092, G2)
- *Cercocarpus montanus / Hesperostipa neomexicana* Shrubland (CEGL002911, G2G3)
- *Juniperus monosperma / Bouteloua curtipendula* Woodland (CEGL000708, G5)
- *Juniperus monosperma / Bouteloua eriopoda* Woodland (CEGL000709, GNR)
- *Juniperus monosperma / Bouteloua gracilis* Woodland (CEGL000710, G5)
- *Juniperus monosperma / Cercocarpus montanus - Ribes cereum* Woodland (CEGL000714, GU)
- *Juniperus monosperma / Cercocarpus montanus* Woodland (CEGL000713, GNR)
- *Juniperus monosperma / Hesperostipa neomexicana* Woodland (CEGL000722, G4)
- *Quercus gambelii / Symphoricarpos oreophilus* Shrubland (CEGL001117, G5)

- *Rhus trilobata* Rocky Mountain Shrub Herbaceous Vegetation (CEGL002910, G2)

Spatial Characteristics

Adjacent Ecological System Comments: This system can grade into in areas dominated by *Pinus* spp.

Distribution

Range: This system occurs in dry canyons and mesas in the southwestern portion of the Western Great Plains, ranging from Purgatoire and Apishipa canyons, tributaries of the Arkansas River in Colorado, and east into Kansas, Oklahoma and possibly north Texas.

TEMPERATE PACIFIC FRESHWATER MUDFLAT (CES200.878)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Wetland
Diagnostic Classifiers: Herbaceous; Temperate [Temperate Oceanic]; Extensive Wet Flat
Non-Diagnostic Classifiers: Lowland [Lowland]
National Mapping Codes: ESLF 3122

CONCEPT

Summary: Freshwater mudflats are found scattered throughout the temperate regions of the Pacific Coast of North America. In the Pacific Northwest, they occur primarily in seasonally flooded shallow lakebeds on floodplains, especially along the lower Columbia River. During any one year, they may be absent because of year-to-year variation in river water levels. Mudflats must be exposed before the vegetation develops from the seedbank. They are dominated mainly by low-stature annual plants. They range in physiognomy from sparsely vegetated mud to extensive sods of herbaceous vegetation. The predominant species include *Eleocharis obtusa*, *Lilaeopsis occidentalis*, *Crassula aquatica*, *Limosella aquatica*, *Gnaphalium palustre*, *Eragrostis hypnoides*, and *Ludwigia palustris*.
Classification Comments: Revised to eliminate overlap with North Pacific Intertidal Freshwater Wetland (CES204.875) and to better clarify the type, with input from John Christy.

Component Associations:
- *Euthamia occidentalis* Herbaceous Vegetation (CEGL003328, G3)
- *Ludwigia palustris - Polygonum hydropiperoides* Herbaceous Vegetation (CEGL003330, G2)

DISTRIBUTION

Range: This system is found throughout the temperate regions of the Pacific Coast of North America.
Divisions: 204:C; 206:C

TEMPERATE PACIFIC INTERTIDAL FLAT (CES204.879)

CLASSIFIERS

Conf.: 2 - Moderate
Classification Status: Standard
Primary Division: North American Pacific Maritime (204)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Wetland
Diagnostic Classifiers: Saline Water Chemistry; Temperate [Temperate Hyperoceanic]; Temperate [Temperate Oceanic]; Tidal / Estuarine [Haline]; Tidal / Estuarine [Oligohaline]
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Unconsolidated material
National Mapping Codes: EVT 2669; ESLF 3116; ESP 1669

CONCEPT

Summary: Coastal flats are found along the north Pacific Coast from Kodiak Island and Cook Inlet, Alaska, south to central California. Tidal flats form a narrow band along oceanic inlets and are more extensive at the mouths of larger rivers. Algae are the dominant vegetation on mud or gravel flats where little vascular vegetation is present due to the daily (in some cases twice daily) tidal flooding of salt or brackish water. Characteristic species include *Vaucheria longicaulis* and *Enteromorpha* spp. Vascular species are sparse, if present, and may include salt-tolerant species such as *Eleocharis palustris, Salicornia* spp., *Plantago maritima, Glaux maritima*, and other plants common to lower salt marshes; cover is less than 10%. The dominant processes are tectonic uplift or subsidence, isostatic rebound, and sediment deposition.

TEXAS COAST BEACH (CES203.463)

CLASSIFIERS

Classification Status: Standard

Primary Division: Gulf and Atlantic Coastal Plain (203)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland; Wetland
Non-Diagnostic Classifiers: Forest and Woodland (Treed)
National Mapping Codes: ESLF 3192

CONCEPT

Summary: This ecological system includes sparsely vegetated ocean beaches constituting the outermost zone of coastal vegetation ranging from and including Boliver peninsula south to include Padre Island in Texas. These beaches are typically located on barrier islands and peninsulas, and they are generally well-developed with an established dune system behind them. Examples generally extend seaward from foredunes but may include flats behind breached foredunes. Although these habitats are situated just above the mean high tide limit, they are constantly impacted by wind and salt spray and may be flooded by storm surges. Characteristic dominants are xerophytes and include the perennials *Ipomoea pes-caprae* and *Ipomoea imperati* and the annual *Cakile geniculata*.
Related Concepts:
- Coastal Beach (6100) [CES203.463] (Elliott 2011) Equivalent

DESCRIPTION

Environment: This ecological system includes the typically sparsely vegetated, back beach area of the mainland and barrier islands composed of sand and shell fragments in a microtidal environment (<0.5m) as it transitions into more stabilized coastal communities. These areas generally lie near mean sea level (1 m) and are often found between foredunes and tidal waters. Examples are found on retreating, prograding and aggradating sandy barrier segments. In the case of beaches along bay margins, an active dune system is generally lacking and beaches lie between tidal waters and near-shore vegetation. Recently deposited sands are transported by gulf currents and distributed and redistributed by onshore winds. Landforms are very gently sloping and restricted to the margins of the Gulf of Mexico as well as interior bays. Soils are recently deposited sands.
Vegetation: Species such as *Ipomoea pes-caprae, Ipomoea imperati, Cakile* spp., and *Tidestromia lanuginosa* provide sparse vegetative cover.
Dynamics: This system is dependent on highly dynamic coastal geomorphology. The process of sand movement due to the forces of wind and water are part of the natural dynamics of beach ecosystems. This includes transport of sand along the coast, and movement of sand by wind or water between the dunes, beach and subtidal areas. If not restricted by infrastructure or engineered hard structures, beaches and dunes can migrate as coastlines change over time in response to the action of wind and water. Some beaches in this system are eroding and some are accreting (Morton et al. 2004). Beaches require a supply of sand and in some cases this supply has been altered through control of river outflow into the Gulf of Mexico (e.g., the diversion of the mouth of the Brazos River). Loss of this supply of sand and sediments results in a lack of sand to replenish natural beach erosion and loss of beach systems.

Component Associations:
- *Ipomoea pes-caprae - Ipomoea imperati - (Cakile geniculata)* Herbaceous Vegetation (CEGL004402, G3?)

DISTRIBUTION

Range: Outermost zone of coastal vegetation ranging from and including Boliver peninsula south to include Padre Island in Texas.

WESTERN GREAT PLAINS BADLANDS (CES303.663)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Badland; Badlands
Non-Diagnostic Classifiers: Temperate [Temperate Continental]; Ustic; Flood Scouring; W-Patch/High Intensity
National Mapping Codes: ESLF 3114

CONCEPT

Summary: This ecological system is found within the northern Great Plains region of the United States and Canada with some of the better known and extensive examples in North and South Dakota. In contrast to Western Great Plains Cliff and Outcrop (CES303.665), this system is typified by extremely dry and easily eroded, consolidated clay soils with bands of sandstone or isolated consolidates and little to no cover of vegetation (usually less than 10% but can be as high as 20%). Vegetated patches within the badlands system may have cover higher than 20%. In north-central Montana, badlands often are a mosaic of bare substrate with small patches of grasses and/or shrubs that may exceed 10% cover. In those areas with vegetation, species can include scattered individuals of many dryland shrubs or herbaceous taxa, including *Grindelia squarrosa*, *Gutierrezia sarothrae* (especially with overuse and grazing), *Sarcobatus vermiculatus*, *Atriplex gardneri*, *Artemisia pedatifida*, *Eriogonum* spp., *Muhlenbergia cuspidata*, *Pseudoroegneria spicata*, and *Arenaria hookeri*. Patches of *Artemisia* spp. can also occur. This system can occur where the land lies well above its local base level or below and is created by several factors, including elevation, rainfall, carving action of streams, and parent material.
Classification Comments: It has been proposed to change the name of this system to include "shale barrens." As with all predominantly "barren" systems, there will be patches of vegetated areas within the overall system. Small areas of "badlands" or "shale barrens" can also occur without major erosional processes actively taking place. An example location is Bitter Creek Area of Environmental Concern (BLM designation), which is much like a badland but not so eroded. The vegetation is sparse with *Juniperus horizontalis* and much bare ground; there is some grass cover as well. The driving process is erosion. Exactly where this transitions to Inter-Mountain Basins Shale Badland (CES304.789) in central Wyoming needs to be clarified.
Similar Ecological Systems:
- Western Great Plains Cliff and Outcrop (CES303.665)

Related Concepts:
- Western Great Plains Badlands (Rolfsmeier and Steinauer 2010) Equivalent

DESCRIPTION

Environment: A combination of factors such as elevation, rainfall, carving action of streams and parent material can contribute to the development of this system. This system is primarily a type of mature dissection with finely textured drainage pattern and steep slopes. This system contains extremely dry and easily erodible, consolidated clayey soils with bands of sandstone or isolated consolidates. This system is found within an arid to semi-arid climate with infrequent, but torrential, rains that cause erosion.
Vegetation: Vegetation in this system is limited by climate and soils and often is less than 10% cover. Scattered individuals of *Grindelia squarrosa*, *Gutierrezia sarothrae*, or *Eriogonum* spp. and/or patches of *Artemisia* spp. may occur.
Dynamics: This system contains highly erodible soils that can be strongly influenced by infrequent, but often torrential, rains.

Component Associations:
- *Arenaria hookeri* Barrens Herbaceous Vegetation (CEGL001951, GU)
- *Artemisia longifolia* Badlands Sparse Vegetation (CEGL002195, GNR)
- *Artemisia pedatifida - Atriplex gardneri* Shrubland (CEGL001525, G3?)
- *Atriplex gardneri - Picrothamnus desertorum* Dwarf-shrubland (CEGL001439, G2G3)
- *Atriplex gardneri / Artemisia tridentata* Dwarf-shrubland (CEGL001440, G3)
- *Atriplex gardneri / Monolepis nuttalliana* Dwarf-shrubland (CEGL001443, G3?)
- *Atriplex gardneri / Pascopyrum smithii* Dwarf-shrubland (CEGL001445, G3)
- *Eriogonum pauciflorum - Gutierrezia sarothrae* Badlands Sparse Vegetation (CEGL005270, G4G5)
- Eroding Great Plains Badlands Sparse Vegetation (CEGL002050, G4G5)
- *Panicum virgatum - (Pascopyrum smithii)* Herbaceous Vegetation (CEGL001484, G2Q)
- *Sarcobatus vermiculatus / Atriplex gardneri* Shrubland (CEGL001360, G4?)
- *Sarcobatus vermiculatus / Pseudoroegneria spicata* Shrubland (CEGL001367, G3)
- *Shepherdia argentea* Shrubland (CEGL001128, G3G4)

DISTRIBUTION

Range: This system ranges throughout the northern Great Plains region of the United States and Canada. Some of the best and well-known examples occur in North and South Dakota. Its western-most occurrence in Wyoming needs to be clarified, but it does

occur in the eastern portion of that state.

WESTERN GREAT PLAINS CLIFF AND OUTCROP (CES303.665)

CLASSIFIERS

Conf.: 2 - Moderate **Classification Status:** Standard
Primary Division: Western Great Plains (303)
Land Cover Class: Barren
Spatial Scale & Pattern: Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Non-Diagnostic Classifiers: Very Shallow Soil; Ustic; Flood Scouring; W-Patch/High Intensity; Cliff (Landform)
National Mapping Codes: ESLF 3142

CONCEPT

Summary: This system includes cliffs and outcrops throughout the Western Great Plains Division. Substrate can range from sandstone and limestone, which can often form bands in the examples of this system. Vegetation is restricted to shelves, cracks and crevices in the rock. However, this system differs from Western Great Plains Badlands (CES303.663) in that often the soil is slightly developed and less erodible, and some grass and shrub species can occur at greater than 10%. Common species in this system include short shrubs such as *Rhus trilobata* and *Artemisia longifolia* and mixedgrass species such as *Bouteloua curtipendula* and *Bouteloua gracilis* and *Calamovilfa longifolia*. Drought and wind erosion are the most common natural dynamics affecting this system.
Classification Comments: The granite glades and rock outcrops of the Llano Uplift of Texas have been reclassified to Llano Uplift Acidic Forest, Woodland and Glade (CES303.657). The carbonate glades, barrens, and cliffs of the Edwards Plateau of Texas have been reclassified to Edwards Plateau Carbonate Glade and Barrens (CES303.655) and Edwards Plateau Cliff (CES303.653), respectively.
Similar Ecological Systems:
- Southwestern Great Plains Canyon (CES303.664)
- Western Great Plains Badlands (CES303.663)

Related Concepts:
- Western Great Plains Cliff and Outcrop (Rolfsmeier and Steinauer 2010) Equivalent

DESCRIPTION

Environment: This system is includes cliff and outcrops throughout the Western Great Plains Division with substrate ranging from sandstone to limestone. Areas of shelves, cracks, and crevices accumulated materials and allow soils to develop enough to support more vegetation.
Vegetation: Short shrubs and mixedgrass species dominate the vegetation of this system. Common species include *Rhus trilobata, Artemisia longifolia, Bouteloua curtipendula, Bouteloua gracilis*, and *Calamovilfa longifolia*, although species can vary somewhat with substrate and exposure.
Dynamics: Drought and wind erosion are the major influences affecting this system.

Component Associations:
- *Arenaria hookeri* Barrens Herbaceous Vegetation (CEGL001951, GU)
- *Artemisia longifolia - Calamovilfa longifolia* Sparse Vegetation (CEGL001521, G3G4)
- *Lesquerella (gordonii, ovalifolia) - Schizachyrium scoparium* Herbaceous Vegetation (CEGL004917, G2G3)
- Limestone Butte Sparse Vegetation (CEGL002296, GNR)
- Sandstone Butte Sparse Vegetation (CEGL002297, GNR)
- Sandstone Great Plains Dry Cliff Sparse Vegetation (CEGL005257, G4G5)
- Sandstone Great Plains Xeric Butte - Bluff Sparse Vegetation (CEGL002290, GNR)
- Sandstone Midwest Dry Cliff Sparse Vegetation (CEGL002045, G4G5)

WESTERN NORTH AMERICAN BOREAL ACTIVE INLAND DUNE (CES105.116)

CLASSIFIERS

Conf.: 1 - Strong **Classification Status:** Standard
Primary Division: Montane Boreal (105)
Land Cover Class: Barren
Spatial Scale & Pattern: Large patch, Small patch
Required Classifiers: Natural/Semi-natural; Unvegetated (<10% vasc.); Upland
Diagnostic Classifiers: Dune (Landform); Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Unconsolidated material
National Mapping Codes: EVT 2613; ESLF 3202; ESP 1613

CONCEPT

Summary: Active inland dunes occur in boreal Alaska and western Canada as remnants of larger systems of dunes and sandsheets that developed under the climatic conditions of the late Pleistocene. Strong storm winds carried glacio-fluvial silts and sands across vast areas of northwestern North America. Most of these sand deposits have been stabilized by forest and tundra vegetation, but areas of active transport and deposition still exist. Some of the most noteworthy active areas are the Kobuk Dunes in western Alaska, the Carcross Dunes in southern Yukon, and the Lake Athabasca Dunes in northern Saskatchewan. These active dunes share many floristic elements and geomorphic processes. The main disturbance process is the transport and deposition of sand. Common landforms include transverse and longitudinal dunes, sandsheets, desert pavements, blowouts, and interdune slacks. Three dominant habitat types occur within boreal active dune systems: grassy, dry mountainous and boreal forest.
Classification Comments: This system is known as Boreal Active Inland Dune by the Alaska Natural Heritage Program.

DESCRIPTION

Environment: Active inland dunes occur in boreal Alaska as remnants of a larger system of dunes and sandsheets that developed under the climatic conditions of the late Pleistocene. Strong storm winds carried glacio-fluvial silts and sands across vast areas of northwestern North America. Most of these sand deposits have been stabilized by forest and tundra vegetation, but areas of active transport and deposition still exist. Some of the most noteworthy active areas are the Kobuk Dunes in western Alaska, the Carcross Dunes in southern Yukon, and the Lake Athabasca Dunes in northern Saskatchewan. These active dunes share many floristic elements and geomorphic processes (Parker and Mann 2000). Common landforms include transverse and longitudinal dunes, sandsheets, desert pavements, blowouts, and interdune slacks. Three dominant habitat types occur within boreal active dune systems: grassy, dry mountainous and boreal forest (Parker 1998).
Vegetation: Active dunes support a unique assemblage of plant species, but plant cover is typically sparse and discontinuous. Three dominant habitat types occur within boreal active dune systems: grassy, dry mountainous and boreal forest (Parker 1998). Dunes of the Kobuk Valley feature four plant species listed as imperiled in Alaska: *Lupinus kuschei, Oxytropis kobukensis, Symphyotrichum yukonense (= Aster yukonensis)*, and *Corispermum ochotense var. alaskanum*. *Leymus mollis (= Leymus arenarius ssp. mollis)* usually restricted to a narrow strip along the coast, is also common on the Kobuk Dunes. Several Beringian endemics and species which are widely disjunct from their known distributions have also been documented (Parker and Mann 2000). *Carex sabulosa*, a sedge known from only four other sites in North America, can be found in Yukon Territory in dune systems near Carcross and Kusawa Lake; however, it does not occur in the Kobuk Dunes.
Dynamics: The main disturbance process is the transport and deposition of sand. In western Alaska, the prevailing sand transport direction is from southeast to northwest. Vegetation on the downwind side of the dune is gradually being buried in sand, while on the windward side vegetation is reestablishing. Within the dune complex, a wide variety of moisture regimes and successional stages occurs. Interdune slacks may feature wetland habitats, while xeric conditions prevail on active deposition surfaces. Along the dune margins, varying stages of boreal forest succession exist. Fire is not a major disturbance on active dunes; however, dunes now covered by forest and tundra may revert to active dunes after fire.

DISTRIBUTION

Range: Active inland dunes occur as isolated features in western Alaska and western Canada.
Divisions: 103:C; 105:C
Nations: CA, US
Subnations: AB, AK, BC?, SK, YT

WESTERN NORTH AMERICAN BOREAL ALPINE FLOODPLAIN (CES105.135)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Barren
Spatial Scale & Pattern: Linear
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Wetland
Diagnostic Classifiers: Alpine/AltiAndino; Riparian Mosaic; Floodplain; Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Unconsolidated material
National Mapping Codes: EVT 2637; ESLF 3203; ESP 1637

CONCEPT

Summary: This system includes active alpine and subalpine floodplains. Frequent river channel migration and associated flooding and fluvial processes constitute the major disturbances in this type. Soils develop on alluvium and are typically shallow and well-drained. This system includes a range of floodplain vegetation including shrubs (dwarf-, low, and tall), mesic herbaceous meadow, early-seral forbs, and barren gravel. Common shrubs include *Salix alaxensis, Salix* spp., *Betula nana*, and *Alnus viridis ssp. sinuata*. Common herbaceous species include *Chamerion latifolium, Lupinus* spp., *Mertensia paniculata, Erigeron acris, Achillea millefolium var. borealis*, and *Crepis* spp. (*Crepis nana* and *Crepis elegans*).
Classification Comments: This system is known as Alpine Floodplain by the Alaska Natural Heritage Program.

- III.B.1.a - Seral herbs (Viereck et al. 1992) Intersecting

DESCRIPTION

Dynamics: This system is found along glacially- and non-glacially-fed streams.

DISTRIBUTION

Range: This system occurs in alpine and subalpine valleys of the boreal and boreal transition regions of Alaska.
Divisions: 104:C; 105:C; 204:C
Nations: CA, US
Subnations: AK
Map Zones: 68:?, 69:C, 70:C, 71:C, 72:?, 73:C, 74:C, 75:C, 76:P

WESTERN NORTH AMERICAN BOREAL ALPINE TALUS AND BEDROCK (CES105.130)

CLASSIFIERS

Classification Status: Standard

Primary Division: Montane Boreal (105)
Land Cover Class: Barren
Spatial Scale & Pattern: Matrix
Required Classifiers: Natural/Semi-natural; Vegetated (>10% vasc.); Upland
Diagnostic Classifiers: Alpine/AltiAndino; Hillslope bedrock outcrop; Ridgetop bedrock outcrop; Herbaceous; Talus (Landform); Boreal [Boreal Subcontinental]
FGDC Crosswalk: Vegetated, No dominant lifeform, Sparsely vegetated, Unconsolidated material
National Mapping Codes: EVT 2632; ESLF 3204; ESP 1632

CONCEPT

Summary: This ecological system occurs on talus- and bedrock-dominated sites above the dwarf-shrub zone, and also on early-seral alpine sites near glaciers. Sites are well-drained to excessively drained, and there is little soil development. They are often rocky and sparsely vegetated with forbs and graminoids such as *Draba* spp., *Saxifraga* spp., *Oxyria digyna, Festuca brachyphylla, Carex pyrenaica ssp. micropoda (= Carex micropoda),* and *Luzula* spp. Dwarf-shrubs are uncommon.
Classification Comments: This system is known as High Alpine Herbaceous by the Alaska Natural Heritage Program. In the Alaska classification, this is an herbaceous system, but cover of vascular plants is low (although not specifically mentioned in the description). NatureServe is treating this as part of the mosaic of alpine bedrock and talus in the boreal region. If the "high alpine herbaceous" really should be kept as its own system, then a "boreal alpine talus and bedrock" system will still need to be kept in the systems classification and described.
Related Concepts:

DESCRIPTION

Environment: This ecological system occurs on talus- and bedrock-dominated sites above the dwarf-shrub zone, and also on early-seral alpine sites near glaciers. Sites are well-drained to excessively drained, and there is little soil development (Viereck et al. 1992, DeVelice et al. 1999).
Vegetation: Sites are often rocky and sparsely vegetated with forbs and graminoids such as *Draba* spp., *Saxifraga* spp., *Oxyria digyna, Festuca brachyphylla, Carex pyrenaica ssp. micropoda (= Carex micropoda),* and *Luzula* spp. Dwarf-shrubs are uncommon.

DISTRIBUTION

Range: This system occurs in the high alpine (>1000 m elevation) of the boreal and boreal transition regions of Alaska.
Divisions: 105:C; 204:C
Nations: CA, US
Subnations: AK
Map Zones: 69:C, 70:C, 71:C, 73:C, 74:C, 75:C
TNC Ecoregions: 70:C, 71:C, 72:C, 74:C, 75:C, 76:C, 77:?, 78:C, 79:C
