National Individual Tree Species Atlas

James R. Ellenwood, Frank J. Krist Jr., Sheryl A. Romero

United States Forest Service

Forest Health Protection, Forest Health Technology Enterprise Team

The Forest Health Technology Enterprise Team (FHTET), Fort Collins, CO, was created in 1995 by the Deputy Chief for State and Private Forestry, USDA, Forest Service, to develop and deliver technologies to protect and improve the health of American forests. <http://www.fs.fed.us/foresthealth/technology>

THE USE OF TRADE, FIRM, OR CORPORATION NAMES in this publication is for the information and convenience of the reader. Such use does not constitute an official endorsement or approval by the U.S. Department of Agriculture of any product or service to the exclusion of others that may be suitable.

Cover design by Sheryl A. Romero, contractor for the U.S. Forest Service, Forest Health Technology Enterprise Team.

Cover Map and illustrations of quaking aspen (*Populus tremuloides*)

National Individual Tree Species Atlas. 2015, FHTET-15-01. Fort Collins, CO: U.S. Department of Agriculture, Forest Service, Forest Health Technology Enterprise Team.

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, sex, religion, age, disability, political beliefs, sexual orientation, or marital or family status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at 202-720-2600 (voice and TDD).

To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326-W, Whitten Building, 1400 Independence Avenue, SW, Washington, D.C. 20250-9410 or call 202-720-5964 (voice and TDD). The USDA is an equal opportunity provider and employer.

Dedication

Although it took nearly five years to produce this atlas, my love of forests and trees goes back many decades.

In 1994, as a forester on the Kaibab National Forest in Arizona, I had the good fortune to meet and observe Dr. Elbert Little in Flagstaff at a conference on piñon-juniper ecosystems. Between sessions, I introduced myself and joined him in an impassioned conversation about pine nuts—with him relating the fact that the edible piñon nut from *Pinus edulis* was far superior in flavor and nutrition to the imported, mass-marketed, store-bought, and inferior stone pine nuts (*Pinus pinea*). The conversation remained highly one-sided, and I took with me some of the passion Little had for the piñon pine. Sadly, Dr. Little passed away in 2004. He was 96.

Even before that, as a student of forestry I elected to take a course, Dendrology I, taught by Dr. Edwin Ketchledge, or “Ketch” as he was known to his students. Ketch taught the course with incredible knowledge, dedication, and enthusiasm. He was nominated and selected as a Distinguished Teaching Professor for the State University of New York. His incredible enthusiasm transcended unto his students: It has stayed with me throughout my professional career. It was his lessons that motivated me in developing this publication. I wish I could have shared this book with him, but Ketch passed away in 2010. He was 85.

This project came at an opportune moment in my career when I could address a specific need with a task that I was both passionate and enthusiastic about. Having drawn upon the energy of these two individuals, I dedicate this atlas to them. I hope for the next version of this atlas, however many years in the future it might be, that the author can ride a similar wave. --- Jim Ellenwood

Acknowledgements

For the review of species distributions—Alaska Paul Hennon, Robin Mulvey, Steve Swenson, Dustin Witwer, Ken Zogas; **Intermountain Region** Carl Jorgensen, Holly Kearns, Laura Lazarus, Daniel Ryerson; **Northeast Region** Roger Mech, Jim Steinman; **Southern Region** Carlton Cobb, Jim Meeker, Dale Starkey; **Western Region** Rod Hart, Jeff Mallory, Michael Simpson, Meghan Woods. In addition to the unnamed people they contacted for review of species distributions.

For having the vision and leadership to support this monumental effort Frank J. Sapio

For the process guidance (and keeping us based in reality) Dr. Eric L. Smith

For data development and support (the building blocks of any good geospatial product) Nathan Edberg, Aneetha Jayaraman, Arpad Lazar, and Vern Thomas

For validating the treed area layer and managing the bales of feedback Vern Thomas.

For Forest Inventory and Analysis support (without FIA, projects like this would never be possible) Elizabeth Lapoint, Andy Lister, and Richard McCullough

For doing what is necessary (it's the little things that make it just right) Mark Zweifler

For the review of the manuscript (you have made it an easy read) Mark Zweifler, Marla Downing, Cynthia Ellenwood, Andrew McMahan, and Chuck Benedict

For copy editing, photographic image support, and final preparation (it's the final touches that can make a difference) Chuck Benedict

For the final checkup (nothing goes out the door without the last thorough review) Andrew McMahan

Preface

As often happens during the course of developing something new, this *National Individual Tree Species Atlas* took shape within the context of another project. This came about while developing the *2013–2027 National Insect and Disease Forest Risk Assessment* (NIDRM, Krist et. al. 2014). My colleagues and I discovered we needed to create what would ultimately be a considerable refinement to the known extent of each major individual tree species in the United States. Specifically, not only would we need to identify precisely where each species of tree is likely to grow, but also where it *is not likely to grow*. We further discovered we were not the only people who could benefit from this new precision. Silviculturists, foresters, geneticists, researchers, botanists, wildlife habitat biologists, landscape ecologists—essentially anyone involved in natural resources management, monitoring impacts of climate change (Ellenwood et. al. 2012), or simply visiting America’s forests—also would benefit. Hence, this *Atlas*.

We began by consulting what was at the time the most definitive source for the geography of trees, the *Atlas of United States Trees* series (Atlas), by U.S. Forest Service Chief Dendrologist Dr. Elbert J. Little. Published in six volumes between 1971 and 1981, this landmark compendium became our “base of operations” in 2009. During the years leading up to its publication, Little filed through untold thousands of pages of information. He understood the relationship between tree species distributions and environmental conditions. Yet, limited as he was by the technology of a paper map, he knew too much information printed on a single plate (map) would not be useful. His solution to this problem was quite clever. He separated the information that portrayed the natural range of tree species’ distributions from information that represented the environmental conditions, such as rivers, lakes, and plant hardiness zones. The natural range of individual tree species became the maps bound in his Atlas and the environmental conditions were printed separately on nine, nearly transparent vellum sheets (overlays), found in an envelope at the back. By laying a vellum over a map, the reader could make a visual comparison and correlation between the natural range of a tree species and the environmental condition as defined on that overlay. Thus, in all cases, it was up to the reader to establish a relationship (if any) between an individual tree-species distribution on the map and what was depicted on a vellum overlay. By today’s standards the overlays might seem primitive, but they were the best technology available at that time.

There were other shortcomings, as well. Early on, Little recognized that some of the detailed records he produced lost their precision when transferred to the coarse-scaled maps (1:10,000,000 U.S., 1:27,000,000 North America) in his Atlas. As well, he took liberal artistic license when he “connected the dots” between points around an area, within which a tree species was known to exist.

Fast forward to 2009. We could not afford to take the artistic license with the NIDRM project that Little took with his Atlas. More to the point, neither the data Little used nor the maps he produced were dependable or accurate enough for us to use in the NIDRM project. Fortunately, we had access to advanced technology with which to acquire, process, and produce more-precise data. Using data from the Forest Service’s Forest Inventory and Analysis program (FIA), and from a predictor dataset consisting of climate, terrain,

soils, and satellite imagery, we developed unique statistical models that predicted the spatial distribution for each of the individual tree species in the United States, as measured by FIA. Using these models, we were able to represent precisely where individual species were likely to occur. In turn we were able to use this information to make reliable assessments of risks of mortality, due to insects and diseases, faced by each tree species. As a basis for comparison, we include Little’s original mapped distributions on our maps. We have no doubt that Little would have used geospatial models such as ours in the 1970s, had they been available. They simply weren’t.

Some might think it odd that, at this point in history, 2014, we would produce an atlas in print form. With electronic media being firmly established in the daily lives of most citizens, a digital version might seem adequate to the task. We don’t dispute that assessment. However, as we look forward to a point in time that is long after the technologies used to create and assemble both the electronic and print versions of this *Atlas* have been replaced, the print version will still be on the shelf in many libraries, accessible by anyone. What is more, this very well could be the last atlas of its kind ever printed. Time will tell.

To accommodate the need for electronic media, we have made versions of this *Atlas* available electronically. There are several digitized versions of Little’s Atlas online and there are (at least) two versions of this *Atlas* available as well. One version is a static Adobe® Portable Document Format (pdf) file, nearly identical to this print version, found online (http://www.fs.fed.us/foresthealth/technology/remote_sensing.shtml). The other version is an interactive online mapping version (<http://foresthealth.fs.usda.gov/host>). With this version, you can view, download, incorporate other data, and conduct analysis of what you can see in this printed version of the *Atlas*, but at a much finer detail than with any other version. You will find the on-line, interactive *Atlas* more functional than an ordinary paper atlas. I invite you to access and examine both on-line versions and welcome your feedback.

Inevitably, the information printed on these pages will become obsolete, at which time this printed *Atlas* will become just a physical point in the historical record—a baseline from which anyone interested in where the trees were in the United States at the turn of the 21st Century can begin to look. To that end, it’s how I began both this project and my lifelong career in forestry.

Suffice it to say that the maps we present here and online are as precise as we could make them. So as this publication goes to press, and with much respect and many thanks to Dr. Little and others both before and after him, we believe our *National Individual Tree Species Atlas* belongs on the same shelf with Little’s *Atlas of United States Trees*.

USDA Forest Service

March, 2014

Introduction

For over four decades the *Atlas of United States Trees* series (Little 1971, Viereck and Little 1975, Little 1976, Little 1977, Little 1978, Little 1981; henceforth referred to as the *Mapped Atlas*), has been a key reference for tree-species distributions. However, due to inherent mapping inaccuracies and the spatial coarseness of the maps, we could not use the *Mapped Atlas* to produce the 2013–2027 *National Insect and Disease Forest Risk Assessment* (NIDRM, Krist et al. 2014). Furthermore, it was clear that many other applications and analyses requiring accurate tree-species information could benefit from a more current, spatially refined dataset. And so the task was launched to create an updated Atlas, one with better spatial accuracy and finer spatial resolution. The result is this *National Individual Tree Species Atlas*, henceforth referred to as the *Modeled Atlas*.

The original *Mapped Atlas* included six volumes and featured over 700 species, many of which are mapped to just states or counties. This *Modeled Atlas* includes 264 species which are mapped to more precise locations.

The methods Little used to develop the *Mapped Atlas* (see, “*Mapped Atlas Methods*”) built upon the methods used by others and were derived from recorded observations, county botanical records, and established species distributions. Objective as they might seem, often such records do not fully represent the actual distribution of a species because it is observed only sporadically throughout its actual range. Therefore, Little and his predecessors necessarily took artistic license to “connect the dots” around locations where a tree species was observed, and considered the species present within the entire delineated area. This process had inherent inconsistencies between observers, between species, and even between different areas within a given species range.

Information and technology has advanced considerably since the *Mapped Atlas* was published. The installation of a nationwide inventory of forestlands, together with the collection of climate, terrain, and remotely sensed data at the same national scale, provided an opportunity to apply a new statistical approach for estimating the potential distribution of individual tree species. Unbiased observations from the Forest Inventory and Analysis (FIA) permanent plot data provided a complete national representation from which we were able to determine not only where a specific species occurs, but also *where it does not occur*. Using these objective observations of tree

species occurrence (presence or absence), we could use other data (see “Predictor Layers,” page 6, and “Appendix–A”) to statistically model the distribution of individual tree species. In turn, these modeled species distributions provide us with a spatial refinement that greatly improves upon the *Mapped Atlas*.

There are significant differences between Little’s atlas and ours. There are several reasons for this, but putting reasons aside, the major differences between them are (1) the amount of bias in the samples (tree species observations) used to build the maps, and (2) assumptions about what exists between points of observation. For the *Mapped Atlas*, a given species-range polygon is delineated around individual observational data points derived from un-systematic methods. Statistically speaking, these observations are generally considered “biased”. Thus, a polygon on a map in the *Mapped Atlas* is biased towards delineating areas where we know the species to be present and away from other places where the species might be present, but for which we don’t have an observation. Also, the species-range boundary surrounding the points embodies the assumption that the species occurs everywhere inside the polygon. We know from personal observations that this assumption is not always true.

We do not make such assumptions in the *Modeled Atlas*. With the *Modeled Atlas*, the tree species observations are measured on a systematic, unbiased installation of FIA plots. Predictor variable conditions are obtained for the FIA plot locations, and relationships between predictor variables and species presence are derived via sophisticated modeling techniques described in detail, below (see “*Modeled Atlas Methods*”). These relationships are then applied to all areas to predict tree species presence for all areas “in-between” measured observations. Ultimately, what this means is the *Modeled Atlas* is much more precise than the *Mapped Atlas*.

Other reasons for differences between the *Mapped Atlas* and the *Modeled Atlas* include actual locational differences in tree species presence versus the original observation (some were made as early as 1885), mapping errors in the original dataset, survey errors, and errors developed in the modeling process. In addition, the modeling process does not distinguish between “native” species distributions and observed distributions of species planted outside of their historical range.

Mapped Atlas Methods

Until now the *Mapped Atlas* was the most current atlas in a long line of tree atlases of the United States dating back to 1885 (Sargent 1884). Since then, each new effort relied on a compilation of individual accounts of tree species taken from known survey records, such as county botanical records, professional observation records, and established species distributions. The *Mapped Atlas* was intended to depict the pre-Euro-American settlement extents of individual tree species and are predicated on the assumption that post-Euro-American, human-influence changes in range limits either can be determined from known activities, or are negligible in the amount of change to the species range. Tree ranges of Canada and Mexico were also included.

OVERLAYS

Little included with his *Atlas* nine transparent vellum overlays (factors or predictor variables) kept in a sleeve inside the back cover. The overlays included rivers and natural lakes, physical subdivisions or Land Surface Forms, topographic relief, plant hardiness zones, lengths of growing seasons, precipitation, climates of the United States (as a precipitation effectiveness index), maximum extent of glaciation in the Wisconsin glacial stage (Pleistocene Epoch), and major forest types. The reader placed an overlay over a map and deduced the relationship (if any) between the species on the map and the physical attribute depicted in the overlay.

MAP PREPARATION

During the years leading up to the *Mapped Atlas* publication, Little and his associates painstakingly amassed, sorted, and analyzed thousands of pages of printed information from both published and unpublished reports, and supplemented this with direct field observations in several states. They gathered additional information from state-published distribution maps; state, county, and local herbaria records; published forest survey distribution maps of commercial forests; and unpublished forest survey records by counties. They sifted through the records and transferred the data cartographically to a 1:10,000,000-scale base map of the United States, or a 1:27,000,000-scale base map of North America. During the process, Little recognized that some of the detailed records lost their precision when transferred to such a coarse-scaled map. Terrain-driven distributions were difficult to convey at such a small scale.

Compiling the data was a long process, during which Little consulted over 300 references in a multitude of formats. He observed during the process that the most reliable sources of information for species distributions were published taxonomic monographs and published accounts of single species. Unfortunately, these sources covered only a few tree species. The next-best source was state-specific publications on trees and plants. Herbarium specimens came next.

Sample criteria varied among all the sources. Conflicting information sometimes appeared. Furthermore, the taxonomic classification system was dynamic, so scientific names of species changed from time to time. Little noted that, in order to be useful, the process of aggregating all this material required considerable maintenance and regular updates. The maps were compiled through the years along with other work by Little and an assistant. Dots were connected, interpolated into polygons, and traced onto paper maps.

Elbert Little's Atlas of United States Trees, Volume 1.

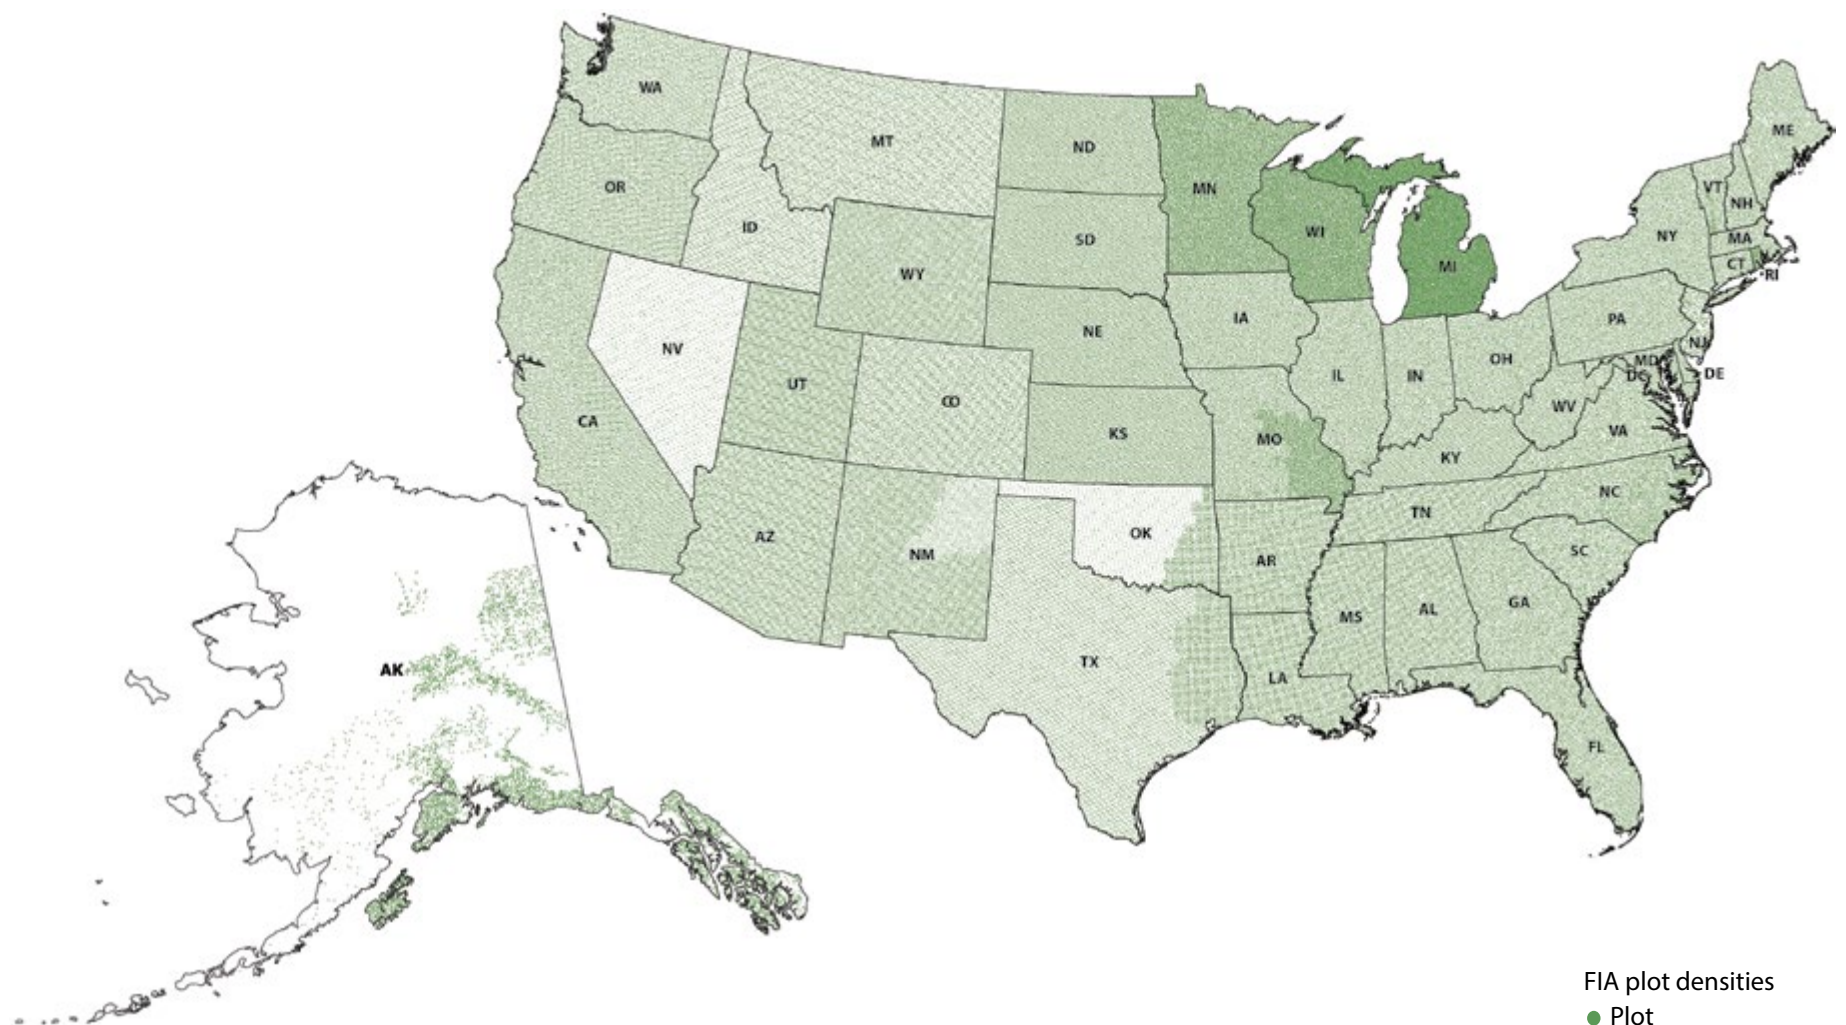

Modeled Atlas Methods

We developed individual tree-species datasets for use in the 2013–2027 NIDRM assessment (Krist et. al. 2014).

These datasets included estimates of tree species presence, size-weighted density (as basal area in square feet per acre), and stand density index (as number of equivalent 10-inch diameter trees per acre). The *Modeled Atlas* presents our estimates of tree species occurrence for 264 of the 387 tree species codes sampled by FIA. The remaining 123 tree species codes not included in the *Modeled Atlas* are listed in Appendix–B1. These consist of species, genera, families, and broad classification identifiers. The datasets were modeled from ground plot data measured by FIA and from predictor datasets consisting of climate, terrain, soils, and satellite imagery, described in detail below (see “Predictor Layers,” page 6), and summarized in Appendix–A.

Each individual tree species was statistically modeled (see “Individual Species Modeling,” page 8). Our approach used data-mining software (See5, Quinlan 2012) and an archive of geospatial information to find and model the complex relationships between independent predictor layers and the occurrence of individual tree species, as measured on over 300,000 FIA plot locations. We then applied the resultant **statistical models** to the predictor layers to generate **geospatial products** (such as Geographic Information System [GIS] raster layers and the mapped distributions you see in this *Atlas*) representing tree-species presence for the entire coterminous United States and Alaska. Post-processing techniques were performed to eliminate isolated predictions, fill-in isolated absences, limit the species distribution to treed areas, and limit the species distribution to known species occurrence from Little (1971) or sampled areas (FIA).

Distribution of FIA plot data used to create tree species parameters.

PREDICTOR LAYERS

The occurrence of an individual tree species within any given area depends upon a number of factors related to the environmental conditions, cultural practices, and the biogeography of the species (Ellenwood 1984). The approach for many species distribution models has been to model representations of these factors. A number of different predictive techniques and variables have been analyzed, and few standard modeling approaches have been accepted (Austin 2007, Elith and Graham 2009).

For comparison, a predictor layer is to *the Modeled Atlas* what a vellum overlay is to the *Mapped Atlas*. Predictor layers used in the *Modeled Atlas* were derived from four national datasets and created at a 30-meter resolution (Appendix–A).

1. National Climate Data Center U.S. standard normal climate data for 7,937 climate stations in the US (NOAA-NCDC 2002).
2. National Elevation Dataset (Gesch et al. 2009).
3. USDA Natural Resource Conservation Service (NRCS) soils dataset, Soil Survey Geographic Database (SSURGO), and a regionalized dataset, STATSGO2 (Digital General Soil Map of the United States) (NRCS 2011).
4. Multi-Resolution Land Characteristics Consortium (MRLC) Landsat imagery used for the National Land Cover Database (NLCD) dataset (Homer 2004).

UNITED STATES GEOLOGICAL SURVEY (USGS) MAPZONE

The NLCD dataset is organized by USGS mapzone. The mapzones roughly follow ecological zones and their use aims to group ecologically common areas, add efficiency to the mapping process, and produce manageable file sizes. Each of the predictor datasets was organized by mapzone and the **geospatial products** were aggregated to the coterminous United States or Alaska. There are 66 USGS mapzones in the coterminous United States and 12 mapzones in Alaska. In Alaska, two zones and a portion of a third zone were not modeled, due to the limited amount of treed land (crosshatched zones in map below).

USGS mapzones.

CLIMATE

We spatially modeled monthly climate normals (three-decade averages of climatological variables) for the period of 1971 to 2000. We used a statistical technique from ANUSPLIN (Hutchinson 1991) to create 30-meter resolution data for precipitation, average mean temperature, average maximum temperature, and average minimum temperature. To produce 12 monthly layers for each of the four climate variables (48 total), we used a technique known as thin-plate spline regression, which closely follows the techniques developed by Rehfeldt (2006), on the climate variables extracted from the monthly normals from 7,939 stations in the CLIM81 30-year climate-normal dataset (NOAA-NCDC 2002).

Example climate layers [from upper-left, clockwise]: total average temperature degree-days below 0 °C, total minimum temperature degree-days below 0 °C, seasonal moisture index, mean annual temperature.

We separated the monthly station normals into two sets: one for the coterminous United States and the other for Alaska. For the coterminous United States, regression splines were built for precipitation from 7,467 stations. For the three temperature variables (monthly average mean, monthly average maximum, and monthly average minimum), regression splines were built using 5,332 stations. For Alaska, regression splines for precipitation were built from 124 stations, and regression splines for the three temperature variables were built using 119 stations. For the Southeast Alaska panhandle, the narrow nature of the landform in relation to the climate data stations proved to be problematic when creating splined surfaces that reflect expected climate surfaces. So, Rehfeldt's (2006) spline models for western North America were utilized for this area.

The modeled regression splines were applied to the 30-meter National Elevation Dataset (NED) to produce 12 monthly rasters for each of the four climate variables, for a total of 48 climate layers. From the 48 climate layers, 18 generalized climate variables were derived utilizing techniques from Rehfeldt (2006). Due to model over-fitting, 13 of the 18 generalized variables were removed from the **statistical models**, leaving a subtotal of five climate variables. Two additional climatic predictor variables were derived by creating a principal components analysis of the 12 monthly precipitation

variables, with the first two principal components being utilized for the modeling. The resultant seven climate variables are

1. the maximum temperature in the warmest month (tenths of degrees C),
2. growing season precipitation (during the frost-free months, inclusive, mm),
3. degree-days below 0 °C,
4. annual moisture index (the ratio of variable degree-days greater than 5 °C to mean annual precipitation),
5. seasonal moisture index (the ratio of degree-days greater than 5 °C accumulating within the frost-free period to growing season precipitation),
6. the first principal component of the average monthly precipitation, and
7. the second principal component of the average monthly precipitation.

Climate is a broad characterization of conditions over a long period of time and over a large area. Therefore, it is difficult to represent with any degree of certainty the local conditions at the time of plant germination and establishment. Climate at the fine scale is considered micro-climate and can be better represented with terrain variables. Terrain can be considered an extension of the climate layers because, depending upon the steepness and direction of terrain or the spatial relationship with surrounding terrain, the effect of terrain on localized weather can be substantial.

TERRAIN

We utilized elevation data and slope position data from the NLCD dataset. Other terrain variables were derived from the elevation data using both standard spatial routines and some customized routines. Standard routines were utilized for curvature and slope-position index. Aspect was represented via two variables using slope-weighted sine and cosine of azimuth (for north-south slope and east-west slope, respectively) to allow for the linear modeling of an otherwise non-linear

Example terrain and soil layers [from upper-left, clockwise]: topographic scale, soil drainage index (modeled), Landform, Digital Elevation Model.

variable. Direct and indirect solar radiation variables were derived from latitude, elevation, slope, and aspect using techniques developed by Kumar and corrected by Zimmerman (Kumar et. al. 1997, Zimmerman et. al. 2007). Topographic scale calculates topographic features (ridge, slope, toe slope, etc.) at various spatial scales and hierarchically integrates these features into a single grid. The resulting grid displays the most extreme deviations from a homogenous surface from the various spatial scales. For the *Modeled Atlas*, topographic scale was computed for three spatial windows of 150-, 300-, and 450-meter radii and combined into a single predictor variable. In addition, the elevation, slope-weighted bi-directional aspect, slope-position index, curvature, direct and indirect shortwave radiation brings to eight the total number of terrain predictor layers used in the selected models.

SOILS

We extracted soils data from the SSURGO and STATSGO dataset and utilized them in the initial analysis. Two layers were created, one for drainage index (Schaetzl et al. 2009), and another for forest productivity index (Schaetzl et al. 2012). These two variables proved to be significant for many species (see Appendix-B2 and B3); however, they were problematic in developing the **geospatial products**, so they were not utilized in the **statistical models**.

IMAGERY

We utilized Landsat imagery from the NLCD 2002 project which consists of six-band imagery from the visible, near-infrared, and shortwave infrared spectrums. The NLCD project prioritized Landsat 7 cloud-free imagery collected between 1999 and 2003. Imagery gaps were filled with imagery from Landsat 5. For the coterminous United States, three-season imagery was collected between 1999 and 2004. Two-season imagery was utilized for most of Alaska, but in two of the Alaskan mapzones single-season imagery was utilized. All of the Landsat images in Alaska were collected between 1994 and 2006. The tree-species models were built with Landsat bands 1, 4, 5, and 7, and tasseled-cap transformed greenness

Example imagery layers [from upper-left, clockwise]: Spring Landsat (bands 4,3,2), Leaf-on Landsat (bands 4,3,2), Tasseled-cap Transformed Leaf-on Landsat (Bands W,C,B), Leaf-off Landsat (bands 4,3,2).

bands (Appendix–A). Texture was computed for an alternative vegetative index (bands 5 and 2) using a seven-pixel kernel. The combination of the four bands, one tasseled cap band, and one texture band for each of the three seasons brings the total number of imagery predictor layers to 18.

GROUND DATA

We utilized Forest Inventory and Analysis (FIA) ground sampled plot data (Woudenberg et al. 2010) to determine the occurrence of individual tree species at FIA subplot locations. Tabular plot and tree data records were extracted from the FIA database (extracted 2/2011). Plot data were limited to state inventory cycles that were aligned most closely with imagery dates, and generally ranged from 1999 to 2005, with some plots in the western United States sampled as recently as 2009. Approximately 80% of the FIA plots were sampled within five years of the corresponding Landsat imagery collection date. Tree data records were limited to live trees of 1-inch diameter or greater (measured at breast height, 4.5 feet above ground [DBH]). For Alaska, annualized FIA inventories were limited to south-central and southeast-panhandle areas, from 2004 to 2009.

A perturbed FIA subplot cluster (set of 4 circles) is super-imposed upon a high resolution image with a 240-meter grid (blue square) [Left] and 30-meter grid [Right] to illustrate the spatial relationships among the ground data, the predictor layer ground resolution [30m], and the Mapped Atlas product [240m].

We improved spatial coverage of tree occurrence data by supplementing the FIA datasets described above with additional inventories. These included

- historical FIA plots from FIA-Alaska for interior Alaska collected from 1968 to 1991 in limited areas,
- intensified grid plots for U.S. Forest Service Pacific Northwest (WA and OR) and Pacific Southwest (CA) Regions, and the Bureau of Land Management (BLM) Oregon State Office, and
- the Great Plains Initiative (GPI) non-forestry inventory (Lister et al. 2012).

For the Pacific Northwest and Pacific Southwest Regions and BLM plots, locations coincidental to FIA locations were eliminated. For the Great Plains states, the Great Plains Initiative (GPI) dataset utilized single plots, while the other non-FIA datasets used a 5-point, cluster-plot design installed on an intensified grid.

FIA plots are composed of four subplots. Subplot coordinates were computed from actual plot coordinates, based upon the FIA plot design and the magnetic declination at the time the subplots were installed. Each subplot was used as a sample of the predictor layers. For each tree species modeled, all subplots within each mapzone were used to predict species presence if any subplot within the mapzone contained the species. Accordingly, the number of samples used to

model each species varied based upon the occurrence of a species across mapzones. Note that the pool of samples used to model each species contains both *presence samples* (plots containing the species) and *absence samples*.

INDIVIDUAL SPECIES MODELING

We linked subplot coordinates to predictor layers to create sample data files for statistical modeling. Statistical models were developed for each individual species by USGS mapzone and are referred to as “zonal-models.” In addition, “global models” were built for each individual species using all mapzones. For each species/mapzone combination, **geospatial products** were built from the **statistical models**.

The statistical modeling involved a progression of trial and error processes. Early iterations in the modeling process utilized all 89 predictor variables, and many of the **statistical models** created **geospatial products** that were less than adequate. To help reduce the number of predictor variables, a single model iteration was created with less-redundant predictor layers to determine which variables were significant in modeling individual species distributions (Appendix–A, column e). This was utilized to select a consistent, narrower, predictor-layer dataset and reduce overall processing time. Predictor variables which produced significant over-fitting for a majority of the species were dropped from subsequent models. The final iteration produced zonal-models which utilized 33 predictor variables (Appendix A – column i). Zonal-models were also developed for the treed area and utilized 35 predictor variables (Appendix A – column j). The **geospatial products** created from the treed area zonal models were used as a tree “mask” to limit all individual tree-species distributions.

We used See5 (version 2.06 from Quinlan, 2012), a classification and regression tree modeling method, to independently model occurrence of live tree basal area for trees over 1-inch DBH. The See5 models were built utilizing “boosting” and “costing” functions. For poor models, these functions were adjusted to improve model outputs.

For a zonal-model that did not produce a valid **statistical model** or a valid **geospatial product**, the global-model was utilized instead for that mapzone. Two “flavors” of global models were built: one with USGS mapzone as a predictor variable and one without (Appendix A – column k and column g, respectively). If the global model with the mapzone variable did not produce a valid **statistical model** or a valid **geospatial product**, then the global model without the mapzone variable was utilized for that species mapzone.

The number of samples is critical if data mining software is to be successful. Morgan et. al. (2003) demonstrated sample sizes of 10,000 or more were adequate for data mining models; however, 3000 seems to adequately represent many applications. To give the user an idea of the adequacy of the data, Table 1 summarizes, for all 387 FIA-species models, the number of species by class of sample size used to model species occurrence. What Table 1 shows is that for a majority of the species, there may be a less-than-adequate number of samples (fewer than 3000). Generally speaking, the more samples the better the model. Infrequent species have fewer plots and would be expected to produce poorer models (Appendix B1).

The selected species-mapzone model built from the **statistical models** were converted to a raster surface using the RSAC Cubist/See5 toolset (Ruefenacht et al. 2008). All individual tree-species presence maps were generated at a 30-meter resolution. The raster surfaces were filtered to fill in isolated holes and buffered by two pixels (60 meters) to be more inclusive.

Table 1 - Summary of plots per species.

Summary of Sample Intensity per Species - All Species Codes						
Number of samples	Number of species within subplot sample group	Number of species within subplot sample group (presence only)	Number of Atlas species within plot sample group	Number of species within subplot sample group for Alaska	Number of species within subplot sample group (presence only) for Alaska	Number of Atlas species within plot sample group for Alaska
3000+	359	113	59	18	4	
300+	28	102	104	1	9	8
30+		80	68		2	5
3+		66	33		3	3
<3		26			1	
Total	387	387	264	19	19	16

Total subplots includes both total (presence + absence) subplots as well as presence-only subplots used by the statistical models. In addition, the numbers of presence-only plots used for the sensitivity validation are summarized for the 264 Modeled Atlas **geospatial products**.

The 30-meter outputs were resampled to 240-meters and buffered by four pixels to facilitate their observation at a national scale. Contiguous pixels were clumped and compared to known inventory plots and to the *Mapped Atlas*. Clumped areas outside a frequency-based distance from known locations were eliminated. The **geospatial product** depicts the remaining buffered areas.

VALIDATION

Validation is defined as the process of ensuring that a product conforms to a user's specific need or requirement. The initial objective of this project was to identify the distributions of individual or groups of tree species in order to map their potential risk of mortality from insect and diseases.

We utilized over 1.2 million subplots to model individual species and produce the *Modeled Atlas*. A comparable dataset would be needed in order to conduct a scientifically valid accuracy assessment; ultimately, the cost of producing such a dataset is prohibitive. Instead, we used the plot version of the ground dataset as a validation. This gives the reader an idea of how well the *Modeled Atlas* represents what is on-the-ground.

The validation involves the use of the original FIA plot data (with the subplot components), rather than the disaggregated FIA subplot data.

Whereas the **statistical models** we developed used the individual subplots as a plot-independent sample, the validation data utilized the subplots as a *unit of the plot*. That is, if a species was modeled as being present on any of the subplots composing a plot, and the species is actually present (in the FIA sample) on any of the subplots composing the plot, then the plot was considered in agreement. Likewise, if both the model and the inventory indicate a species absence, then the model is considered in agreement. In addition, two types of disagreement can occur. The species may be modeled as being present on a plot and the inventory may indicate its absence; conversely, the species may be modeled as being absent but the inventory may indicate its presence.

A statistical classification function, termed "sensitivity," was used to determine the percentage of agreement between the modeled extent and the FIA field plots. A high percentage would be considered good. Sensitivity was calculated for both the statistical model (global model only) and the **geospatial product** and is summarized in Appendices B2 and B3 in columns "Global" and "Validation," respectively. The statistical model sensitivity can give a sense of how strong the data were in producing the species-occurrence relationship, while the modeled geospatial extent product sensitivity reflects the soundness of the **geospatial product**.

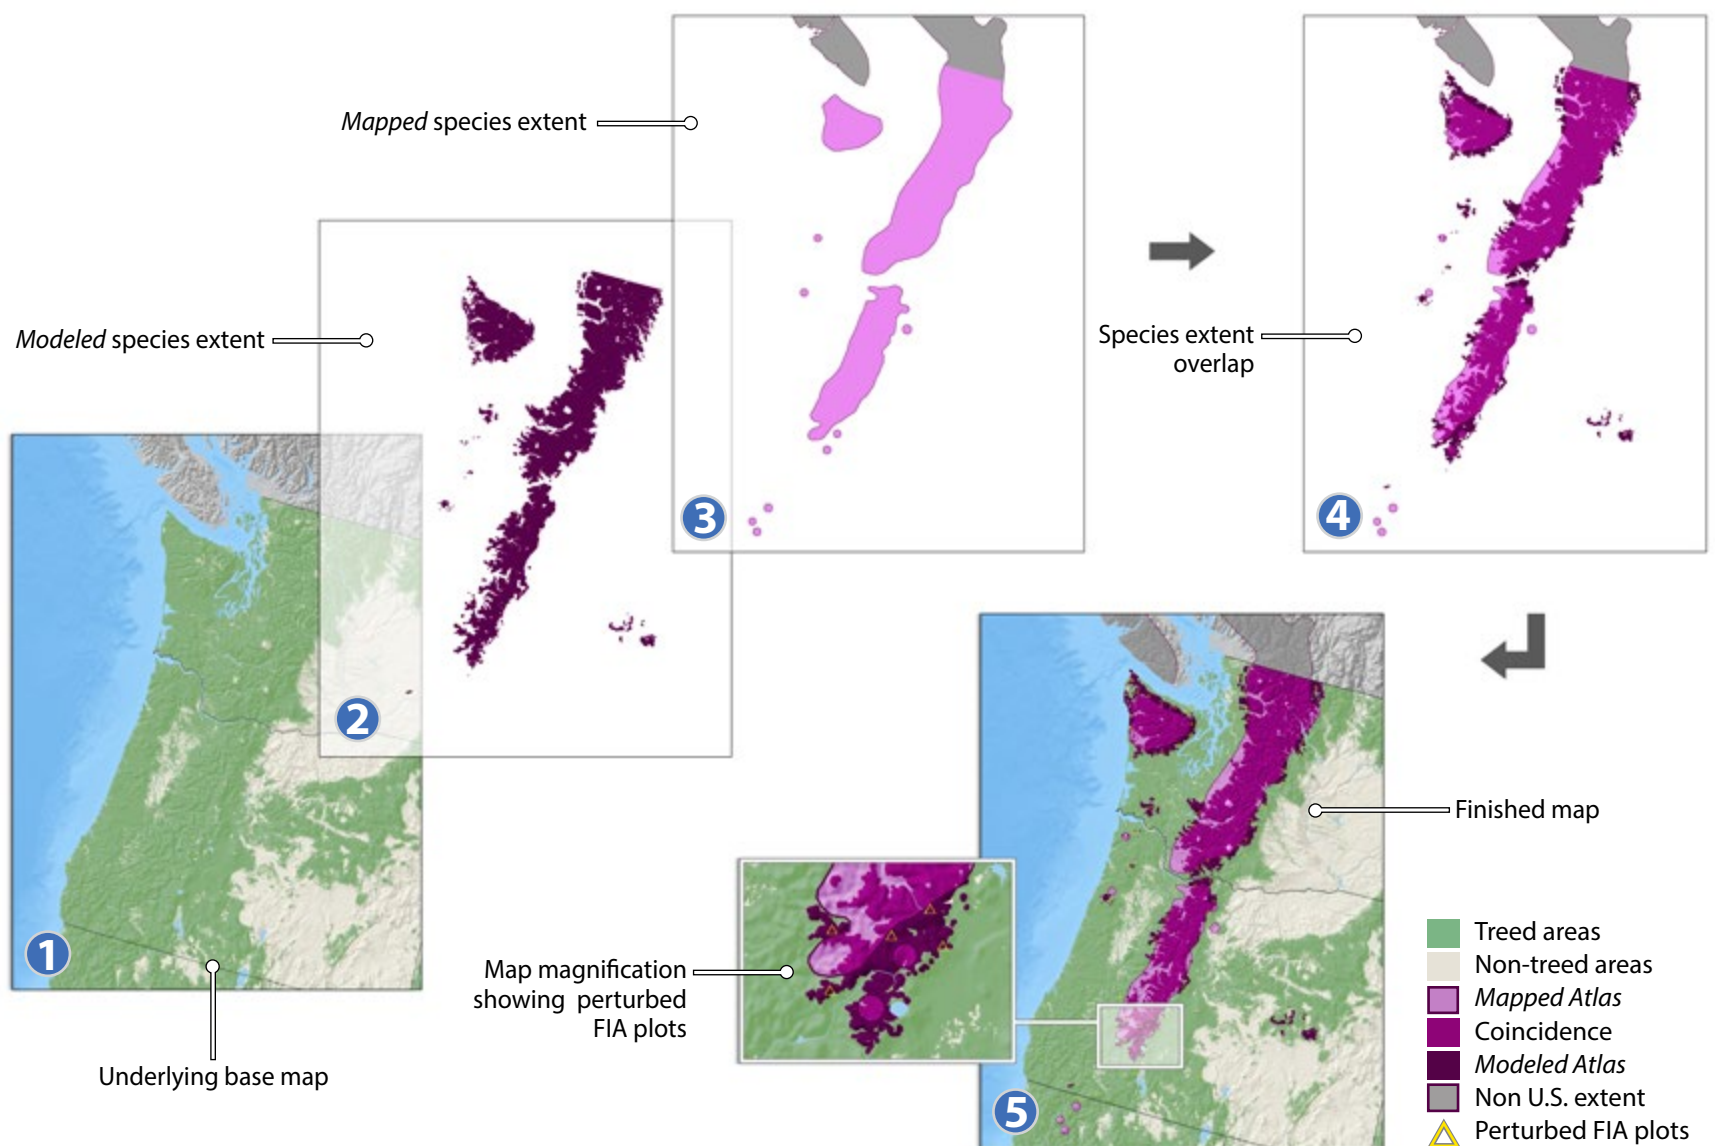

Application of the Maps

COLOR SCHEME

What the *Modeled Atlas* does well is enable the reader to quickly differentiate the previously *mapped* species extent (*Mapped Atlas*) from the recently *modeled* species extent (*Modeled Atlas*). We use contrasting colors to highlight agreement and differences. A color contrast is used in the underlying base map to differentiate treed areas (darker) from non-treed areas (lighter) (item 1). Each map features the *Modeled Atlas* extent (item 2) for the given species and the *Mapped Atlas* extent (item 3) (if previously mapped).

The color range varies with relief to illustrate the underlying terrain. A blended color indicates where the two extents overlap (item 4). For areas where the *Modeled Atlas* extent exceeds the *Mapped Atlas* extent, approximate locations of plots having the species are shown (item 5). The plot locations are based upon perturbed FIA plot coordinates for the coterminous United States and LANDFIRE cover plots for Interior Alaska (LANDFIRE 2011).

Color scheme layers used to create the Modeled Atlas.

MODEL FIT

An inset on each map allows the user to assess the relative fitness of that individual species for a given mapzone (item 10, pages 15 and 117). The inset represents the individual model correlations for each USGS mapzone (item 11, pages 15 and 117), which is an indication of how well the model fit the predictor layers, and may be an indication of how well the model predicts the actual occurrence of the individual species. Darker colors represent stronger models and lighter colors represent weaker models. The lightest gray indicates mapzones where the species did not occur. A validation summary is included in Appendices B2 and B3.

LEAVES

A representative photo of the natural foliage is included (item 16, pages 15 and 117). The photos are not intended for tree identification, but to represent what the user would see from the ground. Next to the leaf photo is a color chip (item 17, pages 15 and 117). It represents the natural-color (red, green, blue) average values of the summer Landsat image for plots wherein the species occurs. It is what the species would look like if you observed it from space, and represents not only the foliage, but the geology, soils, terrain, associated species, and morphological characteristics of that species. Although insignificant from a modeling standpoint, the color chip offers a curiosity and unique perspective on the data used to produce the *Modeled Atlas*.

OTHER DATA

The species common name, scientific name, botanical authority, family, and FIA species code are included for reference for each map (item 12-15, pages 15 and 117). Map scale is not included on the maps because visual scale is indicated by the state lines. However, map scale is stated in the section, “List of Maps” (page vi–viii). Additional species information about plot frequency, overall model sensitivity, validation sensitivity, and the most significant predictor variables is included in Appendix B2 for Alaska and Appendix B3 for the coterminous United States. The most significant variables are included for a glimpse behind the underlying models.

SPECIFIC NOTES

Digital representations of the *Mapped Atlas* (USGS 1999) were incorporated in the *Modeled Atlas* maps for comparative purposes for each species included in the *Mapped Atlas*. The *Modeled Atlas* map extents were limited to mapzones with occurrence on FIA plots and limited to mapzones that coincided with the *Mapped Atlas*. Tree species, such as Colorado blue spruce grown or planted well outside their natural range for commercial or landscaping purposes, were not included in the *Modeled Atlas* map extents. Additionally, map extents were limited to the United States and species extents in Canada and Mexico were not included in the *Modeled Atlas* maps. For species not originally in the *Mapped Atlas*, county data was utilized from the USDA NRCS Plants database (NRCS 2014). An additional map for cherrybark oak (*Quercus pagoda* Raf.) was digitized from a map online at <http://www.efloras.org>.

Differences between the *Mapped Atlas* extents and the *Modeled Atlas* extents can be due to a number of reasons. For non-overlapping areas where the *Mapped Atlas* does not show the presence of a given species (and the *Modeled Atlas* does), range extension may be suggested if the species reproduces aggressively. Other reasons could be the extensive planting of a commercially desirable species or an infrequent species that was previously not mapped very well. In

cases where the *Modeled Atlas* does not show the presence of a given species (and the *Mapped Atlas* does), inventory field crews may have incorrectly identified a species, in which case the models would not accurately represent that species. It is also possible that the plot samples with the predictor variables may not have produced an adequate “signal” to accurately represent the species extent. Finally, it is also conceivable that the species no longer exists in the area delineated by the *Mapped Atlas*.

There are several possibilities why a species is omitted by the *Modeled Atlas* in areas where it is known to exist. Perhaps the species occurs infrequently and does not model well. The species may have been reduced by an invasive species, such as the near extinction of the American Chestnut (*Castanea dentata* (Marsh.) Borkh.) due to chestnut blight. Or perhaps the coarse mapping of the *Mapped Atlas* has been subject to error, something that is very apparent in the West, especially in the Basin and Range Province. And probably the most significant is widespread farming practices, which have altered many natural ranges of individual species.

CHANGES TO SPECIES CLASSIFICATIONS

Appendix B4 describes noted changes from the *Mapped Atlas* in particular to species classifications. For these descriptions FIA was utilized as the nomenclature authority, because it was the origin of the ground data. It should be noted that the official nomenclature from the International Code of Nomenclature for algae, fungi, and plants (ICN) can be more current than the FIA records, because they are the authority of botanical names.

NOTABLE DIFFERENCES IN RANGE

Little recognized that three species—black locust (*Robinia pseudoacacia* L.) (Page 287), northern catalpa (*Catalpa speciosa* (Warder) Warder ex Engelm.), and Osage-orange (*Maclura pomifera* (Raf.) C.K. Schneid.) (Page 197)—had been widely planted and had become so thoroughly naturalized that the extents of the original native species were difficult to determine. Of the three species, northern catalpa was dropped from the *Modeled Atlas* because the models were not very reliable. For the two other species, the range differences are apparent when comparing how they are depicted in the *Mapped Atlas* with how they are depicted in the *Modeled Atlas*. Other species have become conspicuous because they have been extensively planted beyond their natural ranges. This can be said for loblolly pine (*Pinus taeda* L.), slash pine (*Pinus elliottii* Engelm.), red pine (*Pinus resinosa* Aiton), Fraser fir (*Abies fraseri* (Pursh) Poir.), pecan (*Carya illinoensis* (Wangenh.) K. Koch), honeylocust (*Gleditsia triacanthos* Marsh.), Kentucky coffee tree (*Gymnocladus dioica* (L.) K. Koch), and white spruce (*Picea glauca* (Moench) Voss). Some species have extended their ranges naturally through aggressive reproduction in disturbed areas. A good example of this is red maple (*Acer rubrum* L.). In the East, many western species, such as blue spruce (*Picea pungens* Engelm.), Douglas-fir (*Pseudotsuga menziesii* (Mirb.) Franco), white fir (*Abies concolor* (Gord. & Glend.) Lindl. ex Hildebr.), and ponderosa pine (*Pinus ponderosa* C. Lawson), have been planted. Many species have been planted as shelterbelts in the Great Plains; however, due to the narrow nature of shelterbelts, and with the exception of jack pine (*Pinus banksiana* Lamb.) in Nebraska, most did not model well.

Taxonomic differences are noted between white fir (*A. concolor* (Gord. & Glend.) Lindl. ex Hildebr.) and grand fir (*Abies grandis* (Dougl. ex D. Don) Lindl.) in Central Oregon. Hybridization is problematic for several closely related species with overlapping ranges, and makes field identification difficult for, and subject to inconsistencies among, field crews.

Some species—American chestnut (*C. dentata* (Marsh.) Borkh.) and butternut (*Juglans cinerea* L.), to name just two—have been decimated by diseases and their original ranges substantially reduced. Other species, such as longleaf pine (*Pinus palustris* Mill.), could have been reduced through management practices which tended to favor slash pine over longleaf pine. The extent of western white pine (*Pinus monticola* Douglas ex D. Don) has been altered by a combination of management and disease (Harvey 2008).

SPECIES OBSERVED

The selected inventory cycle (complete set of annual inventory panels) included 387 different species codes, of which 264 were utilized in the creation of this *Modeled Atlas*. Of the 123 FIA species codes not included in the Atlas (Appendix B1), 37 species codes were not individual species but codes for trees where the precise species could not be determined at the time of inventory. These include (1) broad-based codes used for unknown dead conifer, unknown dead hardwood, unidentified hardwoods, other tropical species, or scrub oak; (2) most species of palm trees, (representing a family of species) which had been lumped into a single FIA species code; and (3) 31 classifications at the genus level, used when either no species code was available or the species was not determined. Models were built for the remaining 86 species codes; however, the resultant **geospatial products** were deemed inadequate. Sixty one species had too few samples (less than 30 subplots with presence); ten were non-native species; 13 species had poor models (even with more than 30 subplots with presence); and three species were combined into one species as they represented three different varieties of the same species (American basswood *Tilia americana* L.). All non-native species except tree-of-heaven (*Ailanthus altissima* (Mill.) Swingle), Chinese tallow tree (*Triadica sebifera* (L.) Small), and empress-tree (*Paulownia tomentosa* (Thunb.) Siebold & Zucc. ex Steud.) were excluded from the *Modeled Atlas*.

SPECIES NOTES

Even with extensive training and highly regimented quality assurance and control procedures in place, species can still be misidentified. Procedurally, we intended to accept the field calls as completely valid; however, a number of exceptions were applied.

Page 32—Atlantic white-cedar (*Chamaecyparis thyoides* (L.) Britton, Sterns & Poggenb.) has been recorded by FIA in the states of Kentucky, Ohio, West Virginia, Tennessee, Northern Georgia, Northern Alabama, Pennsylvania, Northern New York, and Northern Vermont. This puts it far outside what is recorded in the *Mapped Atlas*. These areas were removed from the *Modeled Atlas*.

Page 79—Great Basin bristlecone pine (*Pinus longaeva* D.K. Bailey) and Rocky Mountain bristlecone pine (*Pinus aristata* Engelm.) were once considered the same species, but were regionally separated as two distinct species during the past few decades. A single Rocky Mountain bristlecone pine was coded by FIA in an area that is considered Great Basin bristlecone pine. We corrected this for the analysis.

Page 96—Virginia pine (*Pinus virginiana* Mill.) was miscoded by FIA for 172 field plots in Texas, Louisiana, Mississippi, and Southern Alabama, which are far outside the distribution in the *Mapped Atlas*. Subsequently, field crews corrected these records during re-measurement; however, as of February, 2014, some plots had yet to be re-measured and records exist of Virginia pine in these areas. We anticipate that these records will be modified at the next field visit. Updated **statistical models** and **geospatial products** were re-created for this *Modeled Atlas*.

Page 269—Chinkapin oak (*Quercus muehlenbergii* Engelm.) is an eastern species and giant chinkapin (page 165) is a western species. A number of FIA records in the western region were miscoded as chinkapin oak and the statistical model built for chinkapin oak included these miscoded records. The Chinkapin oak **geospatial products** for the western mapzones were ultimately dropped from the *Modeled Atlas* and the published map includes only the eastern extent. (Note: In subsequent updates to the FIA database, most of the miscoded records were corrected.)

Page 290—Species in the willow genus are difficult for field crews to distinguish and many of the species are considered shrubs. Black willow (*Salix nigra* Marsh.) is the largest and the most common of the willow tree species. In North Carolina, the field crews code all willows using a generic code. For this reason, black willow was not modeled in the coastal zone associated with North Carolina. To mitigate this discrepancy, we utilized the generic **geospatial product** instead for black willow in the coastal zone of North Carolina.

Page 294—For American basswood (*Tilia americana* L.), three separate species codes, including three recognized varieties, American basswood (*Tilia americana* L. var. *americana*), Carolina basswood (*Tilia americana* L. var. *caroliniana* (Mill.) Castigl.) and white basswood (*Tilia americana* L. var. *heterophylla* (Vent.) Loudon), were utilized. The **geospatial products** for each of the varieties substantially overlapped with one another which suggested an inconsistency in the field calls. For this reason, all varieties were lumped together to create a single **geospatial product** for American basswood in the *Modeled Atlas*.

Artifacts in the models may be associated with field-crew calls rather than the actual species distribution. This may occur where closely related species are identified as one species in certain counties and a different species in another. We suggest that field crews should be able to recognize these minor anomalies in the *Atlas* and see them as an opportunity to gather additional expert opinions on future field calls.

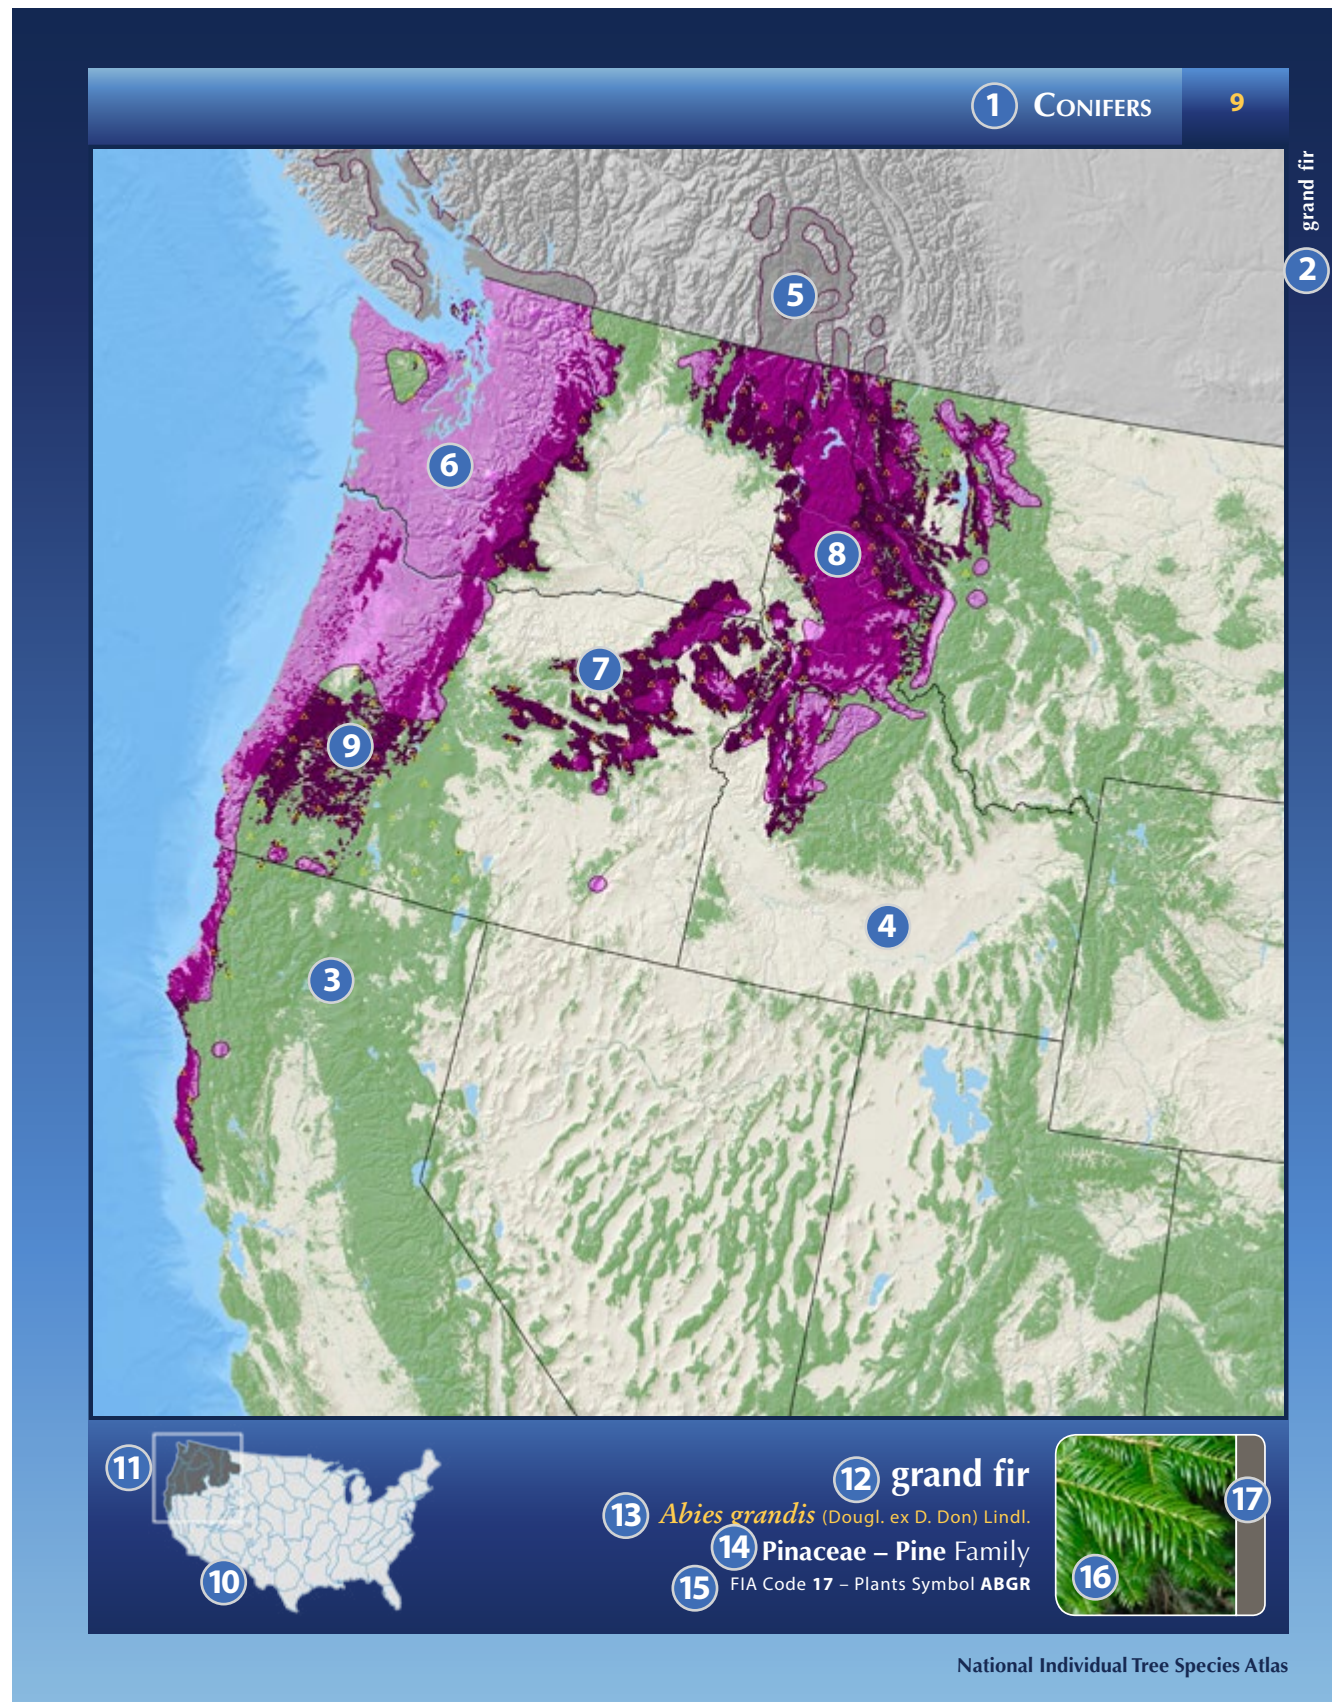

FEEDBACK

As Little did in his *Atlas of United States Trees*, we welcome your feedback. Please let us know of any errors, omissions or anomalies you find in this publication, so that we can update the electronic versions, and include them in any revised print editions. NOTE: Tree presence/absence is from the j models; individual tree models are from the i, k, g models. Models e, k, and g are global models with all zones merged together. Top = the top variable from the e models, Top5 = one of the top five variables from the e models.

Appendix – B (Species Metadata)

B1 — Species observed on an FIA plot but not included in the *Modeled Atlas*

Broad	scrub oak spp., other tropical, unknown dead conifer, unknown dead hardwood, unknown hardwood tree
Family	other palms
Genus	apple spp., ash spp., basswood spp., birch spp., buckeye, catalpa spp., cherry and plum spp., cottonwood and poplar spp., citrus spp., cypress, elm spp., eucalyptus spp., fir spp., hackberry spp., hawthorn, hemlock spp., hickory spp., honeylocust spp., larch spp., magnolia spp., maple, mesquite, mountain-ash spp., mulberry spp., oak/deciduous, pine spp., redcedar / juniper, spruce spp., tupelo spp., walnut, willow
Too Few	Allegheny chinkapin, Arizona madrone, Arizona pine, Australian pine, Baker cypress, balsam willow, blackbead ebony, camphor tree, Canada plum, Carolina silverbell, Chinese chestnut, Chisos oak, citrus spp., common serviceberry, drooping juniper, dwarf chinakapin oak, European alder, European mountain-ash, fish poison tree, Florida poison tree, Ginkgo/maidenhair tree, grand eucalyptus, Graves oak, gumbo limbo, Java plum, key thatch palm, Monterey cypress, northern mountain-ash, nutmeg hickory, Oglethorpe oak, Ozark chinkapin, painted buckeye, peach, prairie crabapple, red hickory, red stopper, royal palm spp., saltcedar, Santa Lucia fir, Scouler's willow, September elm, silver poplar, smoketree, Northern California black walnut, southern catalpa, southern crabapple, southern redcedar, southern shagbark hickory, Tasmanian bluegum, Texas buckeye, Texas madrone, Texas mulberry, Texas sophora, Texas walnut, tung oil tree, two-wing silverbell, umbrella magnolia, water birch, weeping willow, white willow, yellowwood
Poor Fit	Bebb willow, chittamwood gum bumelia, cockspur hawthorn, Delta post oak, downy hawthorn, northern catalpa, peachleaf willow, sand hickory, serviceberry, shellbark hickory, silverbell, sweet crabapple, white mulberry
Introduced	Austrian pine, chinaberry, melaleuca, mimosa/silk tree, Norway maple, Norway spruce, Russian-olive, Scotch pine, Siberian elm, sweet cherry/domesticated

B2 — Alaska Model Fit Validation Summary

Page	Common name	Scientific name	FIA code	Plots	Global	Validation	Five most significant variables*

18	<i>Abies lasiocarpa</i> var. <i>arizonica</i>	Variety of <i>A. lasiocarpa</i> mapped by FIA	Plants
21	<i>Abies shastensis</i>	Not mapped by Little, recongized by FIA, NRCS Plants recognizes as <i>A. magnifica</i> var. <i>shastensis</i> .	Plants
42	<i>Chamaecyparis nootkatensis</i>	NRCS Plants recongizes genus as <i>Callitropsis</i> .	
58	<i>Juniperus pinchotii</i>	Changed from Little (<i>J. erythrocarpa</i>).	
59	<i>Juniperus coahuilensis</i>	Changed from Little (<i>J. erythrocarpa</i> var. <i>coahuilensis</i>).	
81	<i>Calocedrus decurrens</i>	Changed genus from <i>Libocedrus</i> (Little).	
134	<i>Pinus discolor</i>	Formerly <i>P. cembroides</i> var. <i>discolor</i> , now mapped by FIA.	Plants
137	<i>Pinus washoensis</i>	Recongized by NRCS-Plants as <i>P. ponderosa</i> var. <i>washoensis</i> .	
141	<i>Pinus remota</i>	Formerly <i>P. cembroides</i> var. <i>remota</i> , now mapped by FIA.	Plants
143	<i>Pinus monophylla</i> var. <i>fallax</i>	Variety of <i>P. monophylla</i> , now mapped by FIA.	
222	<i>Taxodium ascendens</i>	Formerly <i>T. distichum</i> var. <i>imbricarium</i> , now mapped by FIA.	Plants
332	<i>Aesculus flava</i>	Changed species from <i>A. octandra</i> (Little).	
341	<i>Ailanthus altissima</i>	Tree-of-heaven, introduced, not mapped by Little.	Plants
409	<i>Carya alba</i>	Changed species from Little (<i>C. tomentosa</i>).	
431	<i>Chrysolepis chrysophylla</i> var. <i>chrysophylla</i>	Not mapped by Little.	Other
463	<i>Celtis laevigata</i> var. <i>reticulata</i>	Changed species from Little (<i>C. reticulata</i>).	
661	<i>Malus fusca</i>	Changed species from <i>M. diversifolia</i> (Little).	
694	<i>Nyssa biflora</i>	Formerly <i>N. sylvatica</i> var. <i>biflora</i> , now mapped by FIA.	Plants
712	<i>Paulownia tomentosa</i>	Empress-tree, introduced, not mapped by Little.	
745	<i>Populus deltoides</i> ssp. <i>monilifera</i>	Variety of <i>P. deltoides</i> , mapped by FIA.	
747	<i>Populus balsamifera</i> ssp. <i>trichocarpa</i>	Changed species from Little (<i>P. trichocarpa</i>).	
756	<i>Prosopis glandulosa</i>	Formerly <i>P. juliflora</i> var. <i>glandulosa</i> , now mapped by FIA.	
757	<i>Prosopis velutina</i>	Variety of mesquite, mapped by FIA, no longer inventoried in New Mexico by FIA.	Plants
808	<i>Quercus sinuata</i> var. <i>sinuata</i>	Changed species from Little (<i>Q. durandii</i>).	
813	<i>Quercus pagoda</i>	Former var. of <i>Q. falcata</i> .	eFloras.org
816	<i>Quercus ilicifolia</i>	Texas FIA inventory erroneously codes "scrub oak," which is a common name for five other species of oaks not listed in their official coding lists.	
828	<i>Quercus texana</i>	Changed species from Little (<i>Q. nuttallii</i>).	
840	<i>Quercus margarettiae</i>	Former var. of <i>Q. stellata</i> , NRCS-Plants recongizes species to <i>margarettae</i> .	Plants
841	<i>Quercus minima</i>	Former var. of <i>Q. virginiana</i> .	Plants
846	<i>Quercus grisea</i>	Not inventoried in New Mexico 2002 (considered a shrub).	
8513	<i>Quercus buckleyi</i>	Species not mapped by Little.	Plants
8514	<i>Quercus laceyi</i>	Changed species from <i>Q. glaucooides</i> .	
902	<i>Robinia neomexicana</i>	No longer inventoried in New Mexico (as of 2004 considered a shrub).	
919	<i>Sapindus saponaria</i> var. <i>drummondii</i>	Species mapped by Little, variety recorded by FIA .	
951	<i>Tilia americana</i>	<i>Tilia americana</i> var. <i>caroliniana</i> ; <i>Tilia americana</i> var. <i>heterophylla</i> ; <i>Tilia americana</i> var. <i>americana</i> combined for modeled Atlas.	
994	<i>Triadica sebifera</i>	Chinese tallowtree, introduced, not mapped by Little.
