Another comment urged the Forest Service to "conduct a comparative economic analysis of the short and long term economic impacts of leaving unprotected roadless areas as intact wilderness or having these same areas logged." Another comment requested that the environmental and opportunity costs of opening an area to intensive resource development be quantified in the overall feasibility evaluations of opening any new areas to this type of development.

Response: There are trade-offs or opportunity costs associated with all of the alternatives evaluated in the EIS. The decision to allocate an area to one type of use or management often precludes another use, although this isn't always necessarily the case. The EIS analysis evaluates the potential environmental impacts of the proposed alternatives by resource and, as a result, implicitly includes the trade-offs or opportunity costs associated with each alternative. The EIS does not, however, provide a Forest-wide inventory of resources that would be available assuming that existing Congressionally-mandated land designations and other management policies were not in place because these designations and policies will remain in place regardless of the alternative selected. As a result, this type of inventory would not contribute to the decision making process that the EIS is designed to facilitate.

The alternatives evaluated in the Final EIS examine a broad range of options concerning roadless areas and logging. Although the EIS does not provide a comparative analysis of the economic impacts of preserving existing roadless areas or logging all of these areas, Alternative 1 in the Final EIS protects all roadless areas and may be compared with the other alternatives that each include varying levels of harvest in roadless areas (see the *Economic and Social Environment* section in the Final EIS).

The analysis presented in this EIS is programmatic and provides overall Forest-wide direction. Project-specific analyses are conducted for specific projects, such as a timber sales or recreation developments. Project-level analyses do not typically use the term “opportunity costs”, but essentially quantify all the impacts—negative and positive—of a proposed project. Potential impacts may include impacts to subsistence, wildlife, or particular sectors of the economy.

Comment: One comment noted that the data included in the Socioeconomic Setting section on page 3-8 of the Draft EIS were from 1999 and pointed out that these data should be updated in the Final EIS. The comment author stated that the updated data will show that the economy is even worse now then it was in 1999 and will show that it is “crucial that the (Forest Plan) do everything possible to help the economy.”

Response: The data identified in this comment have been updated in the Final EIS. These data simply identify total population and the largest economic sectors in the region based on employment. More detailed analysis of economic and social trends is provided in the *Economic and Social Environment* section of the EIS. The *Economic and Social Environment* section in the Draft EIS included the most recent data available when the Draft EIS was prepared, and these data have been updated for the Final EIS, as appropriate.

Comment: One comment requested that the introduction to the Economic and Social Environment section of the EIS (page 3-403 in the Draft EIS) identify “adequate infrastructure” as an essential element of a healthy economic and social environment.

Response: The introduction to the *Economic and Social Environment* section provides a brief overview of the contribution of resources from the Tongass National Forest to local communities and the regional economy. A general statement about infrastructure is not consistent with the intent of this short section. Potential impacts to transportation and utilities are discussed in the Environmental Consequences part of the *Economic and Social Environment* section of the EIS, as well as in the *Transportation and Utilities* section.

Comment: One comment stated that commercial fishing is the largest natural resource industry in Southeast Alaska, not recreation and tourism, as stated in the Draft EIS. The comment also stated that the number of pages spent discussing each natural resource sector in the economic impact analysis reflects the relative level importance assigned by the Forest Service, as well as the level of analysis, with Timber assigned 16 pages and Commercial Fishing less than 1 page.

Response: Natural resource-based industries and their relative contribution to the regional economy of Southeast Alaska are discussed in detail in the subsection titled “Natural Resource-Based Industries” in the *Economic and Social Environment* section of the Draft and Final EIS documents. Based on estimates for 2004 presented in the Draft EIS, the recreation and tourism sector employed more people than the commercial fishing sector (see Table 3.22-3 and Figure 3.22-2 in the Draft EIS). These estimates have been updated in the Final EIS.

The relative number of pages allocated to a subject is not a reliable indicator of the importance assigned to an issue by the Forest Service. However, the commercial fishing section of the economic impact analysis is relatively short because: 1) it is not one of the key issues identified through the 2005 Court ruling or the 5-Year Forest Plan Review (see Chapter 1 of the Draft and Final EIS documents for details); and 2) there are no effects to commercial fishing employment anticipated over the 10 year timeframe of this analysis. This conclusion draws upon the analysis prepared for the 1997 Final EIS, which is incorporated in this EIS by reference.

In contrast, the supply of timber is a major focus of this EIS. Key Issue 2 for the EIS responds to the requirement under TTRA that the Forest Service seek to meet market demand for timber in Southeast Alaska. Estimating market demand is a difficult and contentious task and this is reflected in the Draft and Final EIS documents. The timber section of the economic impact analysis assesses the alternatives with respect to a number of different demand indicators and other measures of demand and supply.

Comment: A number of comments emphasized that the timber industry provides relatively highly paid jobs that last all year round. This type of comment often involved a comparison with recreation and tourism-related employment, which was typically characterized as relatively low paid and seasonal. One comment also argued that employment in the timber industry is more stable than that in other natural resource sectors.

Response: Wood products jobs do tend to be relatively high paid, with recreation and tourism-related employment often relatively low paid and seasonal, but this is not necessarily always the case. The Final EIS looks at a wide range of alternatives built around the issue of timber harvesting. Three alternatives feature a reduced land base available for logging while two alternatives increase the lands available.

Multipliers

Comment: **One comment stated that the economic impact analysis presented in the Draft EIS is "fatally flawed" because it uses economic multipliers, derived from the IMPLAN economic model, to estimate indirect and induced employment and income impacts. They cite several studies, both empirical and theoretical, to support their claim that impact multipliers in general, and input-output models in particular, do not provide accurate estimates of total economic impact. The comment also argued that IMPLAN does not provide comparable details for all resource-based sectors of the economy and is biased toward timber. The comment author sees evidence of this bias in the structure of the model data, which provides data for the lumber and wood products sector, but does not identify a recreation sector.**

Response: Some professional economists disagree on the utility of static impact multipliers of the type produced by IMPLAN and similar input-output models. These models are, however, a standard tool for a broad range of regional analyses conducted by government agencies, academics, and other entities interested in estimating the economic impacts of different policy options. IMPLAN in particular has been used in numerous and various policy analyses and research settings. The economic impact analysis presented in the EIS follows standard analysis procedures by using the IMPLAN model. The analysis in the EIS is accompanied by an explicit caveat recognizing that some economists may have reservations about the validity of this methodology. As noted in the Draft EIS (pg. 3-410):

> "Concerns have been raised with respect to the ability of IMPLAN and similar input-output models to accurately predict indirect and induced effects. Alternate techniques for estimating these effects are, however, subject to the same, or similar, criticisms and more accurate estimates are not readily available for this analysis. While the multipliers presented here should be viewed with caution, the resulting estimates of indirect and induced employment provide a basis for comparison between alternatives."

In addition, the EIS is careful to distinguish between direct effects on one hand and indirect and induced effects on the other.

The multipliers used to assess timber impacts are easier to derive from the IMPLAN model than those used to assess recreation and tourism, as noted in the comment. As noted in the same comment document, "recreation is scattered among a variety of industries generally classified in services and retail, with some in transportation." The IMPLAN model uses data compiled from standard economic sources and it is more likely that the absence of a single recreation sector in the model reflects the form of the source data, rather than a deliberate bias toward timber.

Comment: Another comment also urged caution in the use of IMPLAN data noting that employment and income multipliers for Southeast Alaska can be highly variable from year-to-year and provided examples of employment multipliers based on 2004 IMPLAN data: logging (2.18), sawmills (2.1), gold/silver mining (1.92), commercial fishing (1.22), and seafood processing (1.94). The same comment also provided examples of income multipliers.

Response: As noted in the above comment and on page 3-410 of the Draft EIS, the actual magnitude of the estimated multipliers should be viewed with caution.

The numbers provided in the above comment are different from those used in the EIS, which are based on IMPLAN data from 1998. The differences are less than 0.5 in all cases, except sawmill income where the difference is 0.78. The use of different multiplier coefficients would affect the total employment estimates across all alternatives, but would not affect the relative ranking of the alternatives. Using the employment coefficients for timber (sawmills and logging) provided in the comment instead of those used in the EIS would, for example, increase the total employment estimate for each alternative by about 8 percent. As noted in response to the preceding comment: the EIS is careful to distinguish between direct effects on one hand and indirect and induced effects on the other.

The main purpose of using multipliers in this analysis is to acknowledge that economic activity in one sector has impacts elsewhere in the economy and these potential impacts should be taken into account when considering the employment impacts of the alternatives.

Comment: One comment noted that a study of the multiplier effect in Southeast Alaska found that the multiplier effect with respect to jobs in Southeast Alaska was effectively zero. Another comment noted that: "IMPLAN, while useful for appraising the total economic impacts of a Forest Plan is insufficient for evaluating impacts on communities."

Response: The Forest Service is not aware of a study with the finding that the multiplier effect in Southeast Alaska is effectively zero. Research conducted in Southeast Alaska communities did, however, find that indirect employment coefficients while applicable at large scales, such as large regional or statewide assessments, are not useful at small local scales and may be misleading (Robertson 2003). This may be the study that the comment author is referring to.

The multipliers derived from IMPLAN are used in the EIS analysis to assess the total economic impacts of the Forest Plan (as recommended in the comment) at the regional level (Southeast Alaska as whole). They are not used to evaluate impacts at the community level.

Comment: One comment noted that inadequate supplies of timber not only affect loggers and mills, but also specialized support businesses and other elements of the timber industry infrastructure. The comment notes that if these people leave the industry will fail.

Response: The economic impact analysis presented in the EIS uses economic multipliers to account for potential indirect and induced employment and income impacts. The indirect component for the timber industry includes employment and income in industries that provide specialized support and other inputs for the timber industry. This type of analysis does not establish levels of economic activity necessary to sustain particular industries or support services, but it seems reasonable to assume that the size of an industry or business is directly related to its market.

Timber

Comment: The statement on page 3-415 of the Draft EIS that the overall patterns of harvest levels shown in Figure 3.22-5 generally reflects broader trends in the wood products market oversimplifies the situation. Market trends were just one of many factors influencing harvest levels, equally important were reductions in timber supply from the Tongass.

Response: The comment takes the cited statement out of context. The EIS acknowledges that timber demand and harvest has been influenced by a number of factors. The overall trend shown in Figure 3.22-5 does, however, mirror broader trends in the wood products market, as discussed in the Draft and Final EIS documents.

Comment: Table 3.22-8 in the Draft EIS compares the ASQ on the Tongass from 1994 to 2005 with actual harvest levels. One comment observed that the Ketchikan Pulp Corporation would have logged "a lot more in the 1990s" if the volume had been available and noted that "1995 was the highest market of all time."

Response: The table referenced in the comment compares actual harvest levels from 1994 through 2005 with the ASQ for those years. Harvest volumes from 1986 to 2005 are shown graphically in Figure 3.22-5 in the Draft EIS. (Note: this table and figure have been updated in the Final EIS). These data are provided to illustrate the discrepancy between ASQ levels and actual harvest and display trends over time. As noted in response to the preceding comment, the EIS acknowledges that timber demand and harvest have been influenced by a number of factors.

Comment: The wood products employment projections in the EIS assume a linear relationship between harvest and employment levels, with a one percent change in harvest resulting in a one percent change in employment. One comment was concerned that given current trends in automation, there is no direct linear relationship between harvest and employment and the use of this assumption may lead to an overestimate of timber employment under the higher volume alternatives.

Response: As noted in the Draft and Final EIS documents, the linear relationship between harvest and employment is an approximation assumed for the purposes of analysis to allow a comparison between alternatives. The relationship between harvest and jobs expressed in the Final EIS as jobs/MMBF is based on data collected from 2000 to 2005 (Alexander 2007). The logging and sawmill jobs/MMBF coefficients were revised between the Draft and Final EIS documents. These coefficients are believed to be representative of current conditions and are suitable for a comparison of alternatives.

While the resulting projections are suitable for a comparison of alternatives, the absolute values should be treated with caution, especially those for the higher volume alternatives. The main reason for this caution pertains to the jobs/MMBF coefficients, rather than the idea that ongoing automation could sever the relationship between harvest volume and related employment. The existing job/MMBF coefficients are based on the current industry structure. The higher volume alternatives assume that a veneer mill and some other form of "demand stimulation", such as an MDF plant, will also be in operation. The jobs/MMBF coefficients associated with these facilities are likely different than those associated with the sawmills that comprised the industry from 2000 to 2005. Other changes in industry structure or outputs, such as an increase in value added products oriented toward local markets, could also result in different coefficients.

Comment: One comment noted that many logging jobs go to people from out of state and do not contribute to the local economy. This, they stated, is probably not considered in the Draft EIS analysis.

Response: As noted in the Draft and Final EIS documents, nonresidents account for approximately 35 percent of the employment in the logging industry. This is not accounted for in the direct employment estimates, but the total employment estimates are based on region-specific multipliers that take into account the fact that some of the income generated through logging employment is spent outside the region. Non-resident participation is high for all resource-based employment in Southeast Alaska (see Figure 3.22-2 in the Final EIS).

Recreation and Tourism

Comment: One comment stated that the Draft EIS incorrectly used studies by McDowell Group (1999) and Global Insight (2004) to estimate the economic activity associated with the recreation and tourism sector in Southeast Alaska. The comment notes that both studies include resident and non-resident business travel, as well as vacation travelers and, therefore, estimates developed using these studies overestimate recreation and tourism-related economic activity.

Response: The basic approach and estimated coefficients from the 1999 McDowell Group study were used to develop estimates of recreation and tourism-related economic activity for 1999 and 2001 in the Draft and Final Tongass SEIS documents, respectively. The findings of this study were used indirectly in the Draft EIS to help estimate the current contribution of recreation and tourism to the regional economy. The McDowell Group study addressed vacationers, business travelers, and those combining business and pleasure, as noted in the comment. However, the study identified the relative share of the total visitor impacts associated with what they termed the “vacation/pleasure visitor component” and this ratio was used to adjust the data used in the Draft EIS analysis. The resulting estimates were, as a result, broadly representative of recreation and tourism (or vacation/pleasure visitors), and not all visitors. This estimate and discussion has been substantially revised in the Final EIS, which presents employment data for the Leisure and Hospitality sector as a proxy for recreation and tourism.

Comment: One comment stated that the Draft EIS does not account for the differences in the value of different types of recreational experiences. The comment cited a recent study that compared sportfishing expenditures in unroaded areas around Bristol Bay with those in road-accessible areas on the Kenai Peninsula and found that expenditures in the unroaded areas were 38 times higher than those in road-accessible areas.

Response: As discussed in the Draft EIS (page 3-429), the recreation and tourism economic analysis is based on a number of simplifying assumptions, including the following:

> “This approach assumes that the average amount of employment generated by a single RVD is constant over time and that this number is the same for both Tongass-related recreation and the region as a whole, as well as for different types of recreation on the Tongass.”

The Draft and Final EIS documents explain that: “While these assumptions may not accurately reflect underlying realities, they are necessary to produce a quantified estimate of the relation between recreation activity and employment.”

Comment: One respondent presented the following comments. The analysis assumes that the projected reduction in the supply of primitive and semi-primitive recreation opportunities would not be severe enough to limit consumption because it assumes that demand would only increase by 18 percent over the 2005 to 2010 period. Evidence from California suggests that the demand for wilderness hiking and camping by residents increased by 42 percent between 1990 and 1998

(Outdoor Industry Foundation n.d.). The EIS should at a minimum include a sensitivity analysis that assesses the relative impacts of different projected consumption growth rates.

In addition, given the long-term impacts of timber harvest and other development activities, the recreation component of the economic impact analysis should extend beyond 2010. Even at the low growth rates assumed by the analysis, projected demand would begin to exceed supply in 2017 under Alternative 7 and 2019 under Alternative 1.

Response: The recreation and tourism component of the economic impact analysis presented in the EIS is based on projected future demand and changes to Recreation Opportunity Spectrum (ROS) settings in recreation places by alternative. The key assumptions used in this analysis include the use of a linear projection based on 1984 to 1995 data collected for recreation places to project future demand (see Figures 3.22-7 and 3.22-8 in the EIS) and a series of assumptions about the effects that timber harvest would have on ROS settings to estimate the effects of the alternatives on recreation supply.

The demand projection used for the analysis in the EIS relies upon a number of simplifying assumptions (as noted in response to the preceding comment and in the Draft and Final EIS documents), but is based on Tongass-specific data and is the best currently available information for the Tongass. The analysis in the Final EIS has been adjusted and compares projected changes in ROS supply for the first decade following implementation (presented as annual average estimates by alternative) with projected demand for 2015.

The demand projection used in this model assumes that overall recreation demand would increase by 36 percent from 2005 to 2015. This analysis suggests that demand for ROS1 opportunities would begin to exceed supply in 2020 under Alternative 7 and in 2022 under Alternative 1. Increasing the expected growth rate in ROS1 demand, as suggested in the comment, results in demand for these opportunities exceeding projected supply sooner under all alternatives, but does not increase the differences between the alternatives. Projected ROS1 supply under all alternatives would be exceeded within a two to three year period and, therefore, the overall effects would remain similar.

It is also important to recognize that, as explained in the Draft and Final EIS documents, the purpose of this analysis is to allow a quantitative comparison between alternatives. The likelihood of demand for primitive and semi-primitive recreation opportunities exceeding supply on the 16.9 million acre Tongass National Forest in the foreseeable future is low for at least two reasons. First, the analysis discussed in the comment is for identified recreation places only (see the *Recreation and Tourism* section of the EIS for details), not the entire forest. In other words, ROS1 supply is assumed to be limited to just 2.2 million acres from the total of 13.4 million acres of ROS1 available on the Forest (see Table 3.15-3 in the *Recreation and Tourism* section of the EIS), which viewed in RVDs (using the same assumptions as the model) is seven times the projected demand in 2015.

Second, in order to emphasize the differences between the alternatives, the analysis assumes that 25 percent of the change in ROS settings projected to occur over a 160 year analysis period would happen in the first decade following implementation (by 2015 in the Final EIS). This would not happen, but without this assumption there is very little difference between alternatives.

This analysis is designed to assess the programmatic effects of the alternatives and the finding that there is little difference between the alternatives is consistent with this scale of analysis, with standards and guidelines expected to minimize potential impacts on cruise ship routes and popular activities and reduce the potential for overcrowding in wilderness areas under all alternatives. There could, however, be important differences between alternatives on a project-by-project basis, with the alternatives that permit more intensive timber harvest potentially impacting existing or potential outfitter/guide use areas and other nature-based activities. These potential impacts are identified with respect to important recreation places in the *Recreation and Tourism* section of the EIS.

Commercial Fishing

Comment: Several comments questioned the finding that there would be no impact to the commercial fishing industry.

One comment referenced a recent study prepared for Trout Unlimited (Curley and Bristol 2006), which suggests that the majority of salmon originate on the Tongass and depend on roadless watersheds. This study, they argue, suggests that timber harvest and road building in roadless watersheds would have negative impacts on fish and the commercial fishing industry. The comment also pointed out that the fact that much of the future of the fishing industry in Alaska is expected to be dependent on factors outside of the Tongass National Forest is beside the point. The EIS, they argue, needs to evaluate the potential impacts of the alternatives with all other things assumed to be equal.

Another comment stated that the conclusion that there would be no impact to the commercial fishing industry under any of the alternatives ignores a number of issues, including harvest on steep slopes with unstable soils and problems with road maintenance and culverts, among others.

Response: The economic impact analysis presented in the Draft and Final EIS documents does discuss broader trends that are likely to affect commercial fishing in the future, but also states: "There is not expected to be any significant effect to the commercial fishing or fish processing industries over the next decade as a result of National Forest activities" (Draft EIS, page 3-457). This, as explained in the Draft and Final EIS documents, is because the projected levels of timber harvest represent a relatively small proportion of the remaining productive old growth (POG) on the Tongass and an even smaller proportion of the entire Forest. In addition, the Riparian Management Standards and Guidelines established in the current Forest Plan and included in the Final Proposed Forest Plan are designed to protect salmon habitat and prevent impacts to salmon and other aquatic species.

Risks to aquatic resources would increase with more harvest (see the *Fish* section in the Draft and Final EIS documents). Site-specific evaluations would occur with each timber sale to evaluate potential adverse impacts to aquatic resources and identify mitigation measures to reduce any potential impacts. One of the goals of project-specific NEPA documents is to ensure that project actions do not result in significant adverse impacts to important resources. The potential impacts of the alternatives on fish are discussed in more detail in the *Fish* section of the Draft and Final EIS documents. The study referenced in this comment is discussed in the Fish section of this comment response appendix.

The potential impacts of the past practices and related management actions identified in the last part of the comment are part of the baseline for all of the alternatives and would not vary by alternative. These potential impacts are discussed in the Fish section of this comment response appendix and the *Fish* section of the EIS.

Comment: One comment stated that in addition to direct timber harvest-related impacts to fish, the commercial fishing industry would also be severely impacted if any species of concern, such as the marbled murrelet, were listed as endangered under the Endangered Species Act (ESA) as a result of timber harvest practices.

Response: As discussed in response to comments on the *Wildlife* section of the EIS, the potential effects of timber harvest on old-growth habitat are discussed under the marbled murrelet subsection of the wildlife analysis, and tables indicating the distribution and protected status of this habitat are provided in the *Biodiversity* section. The potential effects of the proposed alternatives on other species of concern are also addressed in the *Wildlife* section of the EIS. None of the alternatives are expected to result in fish or wildlife species on the Tongass being listed as endangered under ESA.

Comment: One comment questioned why the discussion of the commercial fishing and seafood processing industries in the Draft EIS focuses on salmon, even though the text acknowledges that other species comprise about one-quarter of the region's total catch on a total value basis. The comment also expressed concern that the Draft EIS uses data from 1994 to discuss salmon's share of the commercial fishing industry and requested that this information be updated in the Final EIS.

Response: The rationale for this decision on page 3-431 of the Draft EIS (and cited by the above comment author) is as follows:

> "While commercial salmon fishing comprises the bulk of Southeast Alaska's fishing industry, halibut, crab and herring fishing combined makes up a substantial proportion of the region's total catch (approximately 24 percent in 1994 on a value basis). There is an important connection between salmon and other wildlife and fish species on the Tongass. Crab, halibut, herring, bears, eagles, and other species depend on the annual return of millions of salmon and on the juvenile salmon produced in the Tongass streams and lakes. As a result, management decisions that affect salmon indirectly affect other species that are commercially fished. These relationships are, however, poorly understood and difficult to quantify. The commercial fishing discussion presented in this section, therefore, focuses on the salmon fishery. Data available for the seafood processing industry, however, do not allow for an easy distinction between salmon processors and other firms. Data presented for the seafood processing sector, therefore, include the entire seafood processing industry."

This statement is also included in the Final EIS. This is consistent with the analysis presented in the 1997 Final EIS and the 2003 SEIS.

Salmon comprised approximately 42 percent of the commercial fishing industry in 2005 based on ex-vessel value. Halibut, crab, and herring combined, comprised 30.7 percent of the industry in 2005, 6.7 percent more than in 1994 (Alaska DOL 2007e). From 2000 to 2006, salmon harvesting ranged from 41 percent to 48 percent of total fish harvesting employment in Southeast Alaska, comprising 47 percent of the total in 2006 (Alaska DOL 2007d). This information has been added to the Final EIS. Employment data have also been added for the non-salmon components of the commercial fishing industry. However, as noted above, the focus of the commercial fishing impact discussion remains on the salmon fishery.

Comment: One comment was concerned that self-employed commercial fishermen were not included in Tables 3.22-1, 3.22-3, and 3.22-4 in the Draft EIS. The comment asked: "how is it … that whole fisheries and their self-employed participants have … 'disappeared' from the … employment estimates presented in the Draft EIS?" The comment author states that the analysis is "hopelessly flawed and patently dishonest" because it fails to include these numbers.

Response: As stated in the Draft EIS and contrary to the concern raised in the comment, self-employed salmon fishermen <u>are</u> included in the salmon harvesting employment estimates (see, for example, page 3-410, final paragraph or page 3-432, footnote 3). These totals were calculated using data from the Alaska Commercial Fisheries Entry Commission and the methodology employed in the 1997 Forest Plan Revision Final EIS analysis (see, for example, Table 3.22-3 in the Draft EIS, note 4).

Employment data were presented in the Draft EIS for the salmon component of the commercial fishing industry only. Employment data associated with other components of fishing industry were not included in these totals. Salmon harvesting continues to be the focus of the commercial fishing discussions in the Final EIS. Employment data are, however, provided for the entire commercial fishing sector in Southeast Alaska in the Natural Resource-Based Industries overview presented in the Final EIS.

The following paragraphs address the specific tables referenced in the comment.

Table 3.22-1: This table provides an overview of the Southeast Alaska economy and does not present data by industry. The average annual employment data presented for Southeast Alaska are from data compiled by the U.S. Bureau of Economic Analysis (BEA) and include self-employed workers.

Table 3.22-2: The data presented in this table were also compiled by BEA. These data are compiled and made available in accordance with the North American Industry Classification System (NAICS), which groups the industries, as shown. Self-employed workers are included in the "proprietors employment" category. This information is not available by industrial sector at the borough/census area level.

Table 3.22-4: This table presents employment and income multipliers for various natural resource sectors in Southeast Alaska, including the salmon harvesting and seafood processing sectors. It does not present employment estimates.

Natural Amenities and Quality of Life

Comment: One comment states that while the Draft EIS acknowledges that natural amenities and quality of life are important for attracting and retaining residents, it does not quantify this impact in the economic impact analysis because the Forest Service essentially claims it would be too hard to do so. The Draft EIS does not provide any data, studies, or explanation that supports the contention that the proposed alternatives would have no significant effect on the economic activity that these amenities are believed to generate.

Further, the comment continues, the Draft EIS "seems to have made up its own science in support of the sophism that protecting natural amenities will somehow degrade quality of life" by stating that: "changes in the local economy such as a shift to tourism may impact local atmosphere and amenities… These impacts are largely assumed to be negative as tourism leads to crowding and the loss of traditional charm, but this need not always be the case" (Draft EIS, page 3-437).

Response: The Draft EIS concludes that in most cases and localities the effects of the action alternatives relative to the no action alternative are not expected to be significant enough in of themselves to result in measurable changes to amenity-driven economic activity. This conclusion is based on the standards and guidelines that are designed to protect and/or mitigate negative effects to natural resources on the Tongass, as well as the relatively small proportion of the Forest that would be disturbed under any of the proposed alternatives.

The importance of the standards and guidelines are discussed with respect to quality of life and other difficult to quantify values in the *Economic and Social Environment* section of the EIS (under Ecosystem Services).

Potential harvest activities under the proposed alternatives would affect a relatively small proportion of the Tongass and would be unlikely to affect the predominantly wild and undeveloped nature of the region and the role it presently plays in attracting visitors and residents. The EIS notes that this is likely to be the case in most cases and localities, but it is possible that this type of impact could potentially occur at a local level, if timber harvest were to occur in a presently undeveloped location that is used and valued by local residents. This type of impact would be more likely to occur under Alternatives 4 and 7, which include more timber harvest, but quantifying the possible extent of this effect would require site-specific analysis that is beyond the scope of this programmatic EIS.

In addition, it should be noted that the existing literature does not provide much direction with respect to this type of analysis. Studies to date have tended to focus on a comparison between rural counties that include designated Wilderness, and those that do not (see, for example, the literature reviews included in Rudzitus and Johnson 2000, Colt 2001, and Sonoran Institute 2006). These broad macro-scale analyses have important implications, as discussed in the EIS. However, even proponents of this relationship caution that while data suggest that rural counties with Wilderness outperform those without, "a correlation does not imply a cause and effect relationship" or "guarantee that economic prosperity ... (in a county) … will automatically rise following the designation of Wilderness" (Sonoran Institute 2006; 28).

Indeed, the same comment author who submitted this comment also provided a copy of a paper prepared on their behalf, *Greater than Zero: Toward the Total Economic Value of Alaska's National Forest Wildlands*, in which the authors (Phillips and Silverman 2007, 20) explain that they do not attempt to estimate these types of values because Alaska presents a "particular econometric problem" in this regard, with the uniform and high presence of "wildlands" across the region preventing a "comparison of communities with and without nearby wildlands, because almost all communities fall into the category 'with nearby wildlands'."

The Draft EIS (page 3-437) states:

> "Although it is difficult to directly measure the importance of natural amenities in attracting and keeping residents, proximity to natural environments and the recreational activities they support are undeniably a benefit enjoyed by residents, especially in the more rural communities of Southeast Alaska."

The paragraph continues to explain that changes in traditional economies may not always be perceived as positive and uses the example of tourism, which can lead to overcrowding and a loss of traditional charm. The discussion also notes that some aspects of tourism development such as restaurants, meeting centers, or entertainment facilities that are also used by local residents may have positive effects on local residents. It is not clear why the comment author believes this discussion is the result of made-up science and it is not the intent of the EIS authors to convey that "protecting natural amenities will somehow degrade quality of life." The statement quoted in the comment has been revised in the Final EIS to discourage this misinterpretation.

Comment: One respondent noted that the Draft EIS discusses the role of natural amenities and quality of life factors attracting new residents to the region. Anecdotal evidence suggests that this has happened in Southeast Alaska. The comment notes that this has had positive impacts, as suggested in the EIS (e.g., local purchases, human capital), but there is another side to this issue with impacts to life-long residents, who may experience increases in home and property values and property taxes, as well as a change in collective attitudes, with new residents favoring policies that do not necessarily reflect the positions of long-time residents who may make their living from the surrounding Forests. The comment states that if this issue is "really relevant to Tongass management issues it ought to be addressed in appropriate detail rather than speculatively."

Response: The issue of natural amenities and quality of life is relevant to the Forest Plan to the extent that proposed management decisions may impact these values and affect local residents and communities. There are potential downsides associated with retirees and others moving to small communities, including those noted in the comment. The discussion presented in the EIS is intended to provide a balanced perspective on this issue, but the main point is to assess the potential effects of the proposed alternatives on the economic aspects of this issue. As noted in the EIS, local amenities and quality of life do not provide employment or generate income in the same way as a sawmill or a tourist lodge, but they can serve to attract and keep residents. The EIS concludes that the effects of the action alternatives relative to the no action alternative are not expected to be significant enough in of themselves to result in measurable changes to amenity-driven economic activity. This is discussed further in response to the preceding comment.

Economic Efficiency Analysis

General

Comment: One comment noted that the calculation of net public benefits is missing or has been conflated with the economic efficiency analysis summarized in Table 3.22-29. The comment author observed that "(i)n order to accurately represent the PNV (Present Net Value) of alternatives it must include all Forest Service costs for all program areas, not just variable costs of timber." Another comment noted that the analysis should include the costs, as well as the benefits of non-timber programs, such as recreation and commercial fishing.

Response: The net public benefit analysis conducted for the EIS is presented in the Economic Efficiency portion of the *Economic and Social Environment* section of the EIS. The introduction to this section has been revised to explain the relationship between net public benefits and the economic efficiency analysis. The economic efficiency analysis has been expanded in the Final EIS to include program costs for: Inventory and Monitoring; Minerals and Geology; Recreation, Heritage, and Wilderness Management; Land Management Planning and Land Ownership Management; Vegetation and Watershed Management; and Wildlife and Fisheries Habitat Management, in addition to variable timber costs. The costs assigned to these categories are estimated based on the average 2005/2006 costs for these cost categories and are assumed to remain constant across all alternatives.

Comment: One comment stated that recent District Court decisions indicate that it is "erroneous to presume that monetary values need to be assigned to non-timber resources as you have attempted to do in the Draft EIS" and the presentation of this "flawed and misleading" information "permeates the Draft EIS and will unduly influence the ultimate outcome without basis in law or fact." The comment further stated with reference to Table 3.22-29 in the Draft EIS that the "assumptions, conclusions and management directions based on this table are problematic throughout the plan."

Response: The economic efficiency analysis summarized in Table 3.22-29 assigned monetary values to those goods and services where they could be reasonably assigned in accordance with the 1982 Forest Planning rules (36 CFR 219). These resources and the associated potential impacts were important factors in formulating the alternatives evaluated in the Draft EIS, but the difference in estimated values between timber and recreation and tourism, as shown in Table 3.22-29, did not have an undue bearing on this process. As noted in response to the preceding comment, the economic efficiency analysis has been expanded in the Final EIS.

Comment: A number of comments were concerned that the economic efficiency analysis presented in the Draft EIS is misleading and represents an "apples and oranges" comparison, with actual projected timber receipts and costs compared to hypothetical willingness-to-pay values for recreation that are based on outdated survey data from 1988. Comments disagreed on how this was misleading. Some felt that the analysis incorrectly suggests that "non-timber uses of the Tongass are grossly more beneficial than timber uses from an economic standpoint." Others felt that the comparison overvalues timber harvest relative to other non-timber uses not included in the table.

One comment stated that the following statement on page 3-461 of the Draft EIS was particularly misleading: "Recreation and tourism estimates range from approximately 76 times (Alternative 7) to 380 times (Alternative 1) higher than those for timber, indicating the importance of the Tongass National Forest as a recreation resource for both local residents and outside visitors."

Response: The economic efficiency analysis has been revised in the Final EIS. The analysis includes the consumer surplus (willingness-to-pay) estimates for recreation and tourism, but also includes receipts to the Forest from recreation activities as a separate category, as well as recreation program costs. Program costs are also included for: Inventory and Monitoring; Minerals and Geology; Heritage and

Wilderness Management (this category also includes recreation costs); Land Management Planning and Land Ownership Management; Vegetation and Watershed Management; and Wildlife and Fisheries Habitat Management.

The high consumer surplus values estimated for recreation and tourism on the Tongass are believed to reflect the importance of these activities to local visitors and outside residents. There is, however, little variation in these estimated values by alternative, as discussed in the Draft EIS. The text in the Final EIS has been revised to further emphasize this point.

Comment: One comment noted that Table 3.22-29 suggests that recreation and tourism revenues are a reflection of the amount of timber harvest and also suggests that rather than being a broad-based plan that seeks to balance multiple uses this plan is an analysis of the effects of timber harvest on other uses. The comment further noted that the table also suggests that other program costs are not expected to vary by alternative. Another comment stated that the summary in Table 3.22-29 "denies the multiple use concept" by suggesting that recreation and tourism and the timber industry cannot work side-by-side without impacting one another. In addition, the comment author felt that the values in this table indicate that the "non-use" values of nonresidents are given priority over employment opportunities for state residents.

Response: The analysis summarized in Table 3.22-29 in the Draft EIS has been expanded in the Final EIS, as discussed in response to preceding comments on this issue. The revised table provides estimated costs and revenues for other Tongass program elements, as well as timber and recreation and tourism. While it is likely that program costs would vary by alternative, it is not possible to project these variations at this time.

The table presented in the Draft EIS was not intended to convey that recreation and tourism and timber cannot co-exist. However, higher timber harvest levels, especially those projected under Alternatives 4 and 7, would affect recreation and tourism over the 160 year planning horizon considered in the economic efficiency analysis. Timber harvest and road building in unroaded areas would result in an increase in Roaded Modified (RM) recreation opportunities, and a corresponding decrease in the availability of unroaded recreation opportunities. This is discussed in the Environmental Consequences part of the *Recreation and Tourism* section of the Draft and Final EIS documents under Recreation Opportunity Spectrum.

Comment: One comment stated that the economic efficiency analysis incorrectly suggests that the Tongass National Forest should be managed to achieve maximum economic return. The Forest Service is required to manage NFS lands for multiple uses, but not necessarily the combination of multiple uses that returns the greatest dollar returns or unit outputs.
Response: The economic efficiency analysis is not intended to suggest that the Tongass National Forest should be managed to achieve maximum economic return. More discussion regarding the purpose of and requirement for the economic efficiency analysis has been added to the introduction to the Economic Efficiency section in the Final EIS.

Timber

Comment: Several comments noted that the net timber benefits shown in the economic efficiency analysis only include direct sale revenues paid to the government and do not capture the full benefits of the Tongass timber program. One comment stated that the timber benefit estimate should also include the impacts of the money spent harvesting and manufacturing the timber, which the comment author estimated as approximately $600 to $700 per MBF. Another comment suggested that the benefit estimate should include federal payroll taxes and associated corporate income taxes.

Response: The economic efficiency analysis has been revised in the Final EIS. The timber portion of the analysis has been adjusted and revenues to the federal government are now estimated using base rate values by species and the average species composition of timber on the Tongass. The base rate is the minimum value that must be bid for timber to be sold or cut. This rate is lower than the average value per MBF harvested in 2005/2006 that was used in the Draft EIS ($7.12/MBF versus $11.69/MBF).

The regional economic impact benefits of the various alternatives are evaluated in the economic impact analysis presented in the Draft and Final EIS documents. This analysis includes the jobs and income generated by the money spent to harvest and manufacture the projected timber sale volumes under each alternative. As noted in the timber part of the Economic Efficiency section in the Draft and Final EIS documents, industry revenues are omitted from the timber benefit calculation "because efficiency analysis commonly assumes perfect competition in the private sector. This implies, in turn, that competing purchasers of federal timber will bid up the price of stumpage to the point where all economic profits (i.e., profits over and above a competitive rate of return to capital) are dissipated." Federal payroll taxes and corporate income taxes are associated with all economic activities supported by Tongass resources. No attempt is made to estimate these tax revenues in the Draft or Final EIS documents.

Comment: Other factors than just stumpage values need to be included in timber appraisals. These factors include direct and indirect jobs in the timber industry, as well as other multiplier effects. When the value of recreation, tourism, and fishing are estimated these factors are always included, but the costs of these other uses versus the user fees are never shown.

Response: The procedures used for timber appraisals are outside the scope of this Forest Plan Amendment. With respect to the Forest Plan Amendment and this EIS, potential timber-industry related impacts are discussed in two sections, along with impacts to other resources (recreation and tourism, commercial fishing, etc.). These sections are the Economic Impact Analysis and Economic Efficiency Analysis parts of the *Economic and Social Environment* section of the EIS. The economic efficiency analysis has been expanded in the Final EIS and includes the costs of administering other programs on the Tongass. The economic impacts of the alternatives are evaluated in terms of jobs and income (including multiplier effects) in the economic impact analysis.

Comment: One comment stated that the cost of future remediation for roads and logging should be factored in and borne by those who profit from the logging and road building.

Response: The costs associated with planning, implementing, and administrating timber sales, as well as associated mitigation activities, are included in the projected costs used in the economic efficiency analysis presented in the EIS. These costs include sale preparation, environmental assessments, and cultural resource surveys, among others. A second group of costs related to the actual harvest of the timber are included in the purchaser's contract requirements and are reflected in the stumpage value received. These costs include the costs of reforestation, road obliteration, and culvert removal among others. A third group of costs are largely fixed costs associated with long-term forest management and Forest Plan implementation and monitoring, and are not expected to vary significantly by alternative.

Comment: One comment stated that the Draft EIS fails to identify the true costs of the Tongass timber program because it does not disclose the costs of building roads that are necessary for a timber sale to go forward ("pre-roading"). Pre-roading contracts are let in advance of timber sales and nearly all large sales, especially those in roadless areas, are dependent on this practice. Other sales are dependent on advance road improvements to existing logging roads that are contracted under maintenance contracts, although this maintenance has no purpose other than to facilitate future timber sales. The comment states that these costs need to be disclosed in the Draft EIS.

Response: Pre-roading is a process whereby roads are constructed into a NEPA cleared project area prior to and separate from a timber sale or other resource activity. The intent of pre-roading is to develop or expand the transportation network without requiring one resource to carry the entire burden of road construction costs. Pre-roading is an administrative decision that requires funding from Congress and is subject to the same environmental laws and regulations (NEPA, NFMA, etc.) as other federal actions. This practice is best addressed at the project level and is outside the scope of this programmatic EIS.

Comment: One comment stated that the Draft EIS failed to accurately account for the costs associated with the proposed levels of harvest. They argue that the $101/MBF figure used to estimate timber costs in the economic efficiency analysis is based on an undocumented estimate, which "any examination of expenditures in relation to outputs over the last decade" shows to be an underestimate. In addition, this cost per MBF derived from budget allocations assumes that all planned sales are actually sold, which is not the case. The Forest Service plans for more volume than is actually cut and even projects that make it through the planning phase may not necessarily be sold, as was the case with 30 percent of the sales offered between 1998 and 2003.

Response: The economic efficiency analysis presented in the EIS uses the $101/MBF figure cited in the comment to estimate the timber sale costs for each alternative and assumes for the purposes of analysis that all sales offered are sold. This estimate is based on historic timber sale preparation costs and includes costs for NEPA preparation, sale preparation, sale administration, and engineering support. The Forest Service uses the $101/MBF figure to estimate costs as part of its timber sale planning process at the individual timber sale level. The use of this figure in this EIS to assess potential costs is consistent with these practices and provides an adequate basis to allow a comparison between alternatives, recognizing that economic efficiency analyses conducted at the Forest Plan level project outcomes and assign approximate valuations to costs and benefits more than 100 years into the future and require numerous simplifying assumptions.

The timber component of the economic efficiency analysis has been revised in the Final EIS. This revised version uses the base rates—the minimum value that must be bid for timber to be sold or cut—to estimate timber revenues. The average base rate value per MBF used in the Final EIS ($7.12/MBF) was estimated using 2006 base rates by species and the average timber sale composition. The benefits estimated in the economic efficiency analysis using this value are the absolute minimum that must be bid for a timber sale to go forward. These estimated cost and benefit figures indicate that viewed in terms of direct costs and revenues to the Forest Service, timber harvest results in a net loss per MBF. These flat rates are used to evaluate the alternatives and result in the total projected net loss increasing as the projected harvest volume increases.

Comment: One comment pointed out that a large component of the costs that make logging uneconomical on the Tongass are the costs associated with court litigation brought by opposition groups.

Response: These costs are not directly factored into the average timber sale costs used in the economic efficiency analysis presented in the EIS. However, litigation has increased the timber sale preparation costs incurred by the government and has also had the effect of interrupting the supply of timber to local mills.

Comment: One comment stated that the Draft EIS failed to consider that the effects of non-competitive bidding reduce estimates of timber revenues. The comment also pointed out that almost 50 percent of new sales offered between 1998 and 2005 did not sell and that 20 of the sales that did sell were returned to the Forest Service.

Response: The economic efficiency analysis in the Draft EIS implicitly considered the effects of non-competitive bidding in the Draft EIS by using the average stumpage value ($11.69/MBF) from actual sales to estimate revenues. This portion of the economic efficiency analysis has been adjusted in the Final EIS and revenues to the federal government are now estimated using base rate values by species and the average species composition of timber on the Tongass. The base rate is the minimum value that must be bid for timber to be sold or cut. This rate is lower than the average value per MBF harvested in 2005/2006 that was used in the Draft EIS ($7.12/MBF versus $11.69/MBF).

Comment: One comment stated that the timber industry has manipulated stumpage prices in the past and that this could happen again. They recommended that the Forest Service look into this practice.

Response: Analyzing stumpage prices is beyond the scope of this analysis. The economic efficiency analysis presented in the Final EIS has been revised to use base rate values to estimate potential revenues to the Federal government.

Recreation

Comment: One comment identified the following specific concerns with the "contingent valuation" methodology used to estimate the net benefit of recreation/tourism activity:

- **The estimated sport fishing "willingness-to-pay" value of $1,025.27 (1988 survey data adjusted to 2005 dollars) per Recreation Visitor Day (RVD) "defies reason" because it is "highly unlikely" that guided and unguided fishing operators would so "vastly under-price their product."**
- **Willingness-to-pay methodologies employ survey research to place hypothetical dollar values on non-market goods. Use of these values in economic analysis is contentious because this type of analysis produces hypothetical, unverifiable values and research has found that stated willingness-to-pay is often very different to actual willingness-to-pay.**
- **If tourists were willing to pay additional money to visit the Tongass the tourism businesses would already be charging them that money**.

Response: There is an extensive academic literature that addresses contingent valuation with respect to outdoor recreation and benefit cost analysis, and a number of methodological concerns have been identified, including those identified in the above comment. There is, however, broad consensus surrounding the use of willingness-to-pay measures with respect to recreation in the academic literature and various Federal agency planning regulations and guidance documents, including the Forest Service Handbook (FSH 1909.17, Chapter 10).

The analysis presented in the EIS uses the average net willingness-to-pay value used in the 1997 Final EIS (USDA Forest Service 1997a) adjusted for inflation. This value was originally developed based on survey research conducted at the national level and then adapted for the Tongass. This is the best information currently available for the Tongass. While the estimated sport fishing value is high, as noted in the comment, the analysis uses an aggregated figure of $69.13 per RVD.
The analysis presented in the Draft and Final EIS documents illustrates that there is little difference between estimated recreation consumer surplus values by alternative. The overall intent of this analysis is to compare alternatives and, while different levels of timber harvest affect the types of recreation that may be available in the future, the analysis is not intended to compare the relative values of different resources.

Non-Market Values and Ecosystem Services

Comment: A number of comments expressed concern that the Draft EIS did not adequately address non-market values, which they thought should be assigned monetary values and treated on a par with market timber values. Several comments provided lists of “important net benefits” that the comment authors felt had been incorrectly excluded from the Draft EIS analysis. The most detailed list identified the following “unpriced benefits” that the comment author felt the Draft EIS “largely overlooked”:

> **“biological diversity; cultural connection to the land such as subsistence; quality of life; endangered/threatened species protection; water quality; special non-timber forest products; passive use values such as bequest, option, and existence values; educational and scientific values; unearned income; ecological services such as carbon sequestration; hydrological services; irreversible consequences and lack of substitutes; property values and offsite benefits; and visual amenities”**

Response: The items listed in the above comment are all discussed and evaluated in the Draft and Final EIS documents and will be considered in the overall decision-making process, as appropriate. The fact that these items are not assigned monetary values and quantified in the economic efficiency analysis does not lessen their importance to the overall process. This is discussed further in the Economic Efficiency section of the Final EIS.

While the EIS does not attempt to assign monetary values to the non-use values potentially associated with each alternative, the text does acknowledges that the non-use values associated with the Tongass are likely to be high, especially given the national importance of this issue. The fact that no monetary value is attached to non-use values does not lessen their importance in the decision making process; decision-makers routinely choose alternatives that do not maximize PNV. Many forest benefits are incorporated into forest planning decisions in a qualitative fashion. Also, a large proportion of the Draft and Final EIS documents are devoted to revealing impacts to the forest resource that cannot be readily expressed in monetary terms. The Forest Service Manual states that decision makers must “[c]onsider economic efficiency, *along with other factors* (emphasis added), in making decisions and in implementing and reviewing projects, programs, and budgets” (FSM 1970.3(3)).

Comment: Several comments stated that the Forest Service is required by the 1982 planning regulations to assign monetary values to non-market goods and services. Two comments supported this contention by quoting the following definition of net public benefits from 36 CFR 219.3:

> **“An expression used to signify the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not”**

One comment supported this position with the following:

> **“Economists have made great advances in developing methods to estimate the economic benefits generated from the production and conservation of non-commodity resources. Therefore, in addition to qualitative descriptions of all non-commodity benefits and costs the decision documents must quantitatively estimate the benefits (costs) of conserving (damaging) non-market resources.”**

Response: The introduction to the Economic Efficiency Analysis subsection has been revised in the Final EIS and highlights the 1982 planning regulations and their relationship to this analysis. The revised section explains that the approach taken in the EIS is consistent with the 1982 planning regulations, which state that “quantitative and qualitative criteria” may be used to evaluate alternative outputs “when monetary values may not be reasonably assigned” (36 CFR 219.12(g)(3)(ii)). This approach is also consistent with the definition of net public benefits cited in the above comment, which allows that not all effects can be "quantitatively valued" (36 CFR 219.3). As noted in the response to the preceding question, the economic efficiency analysis is one piece of information for the decision maker to consider, but is by no means the only one and a large portion of the EIS is spent evaluating potential effects that cannot be reasonably assigned a monetary value at this time.

Comment: One comment submitted an unpublished draft report that presented the commenting organization's own assessment of non-market values on the Tongass and Chugach National Forests (*Greater than Zero: Toward the Total Economic Value of Alaska's National Forest Wildlands*, Phillips and Silverman 2007). The comment stated that this report estimates that the value of wildlands on the Tongass ranges from $1.5 billion to $1.8 billion per year and provided a summary of the results (adapted from the Phillips and Silverman draft report). The comment expressed surprise that the Forest Service had not included similar estimates in the Draft EIS and argued that not including these types of monetary estimates in the Final EIS would "constitute a violation of NEPA for failing to disclose significant effects."

Response: The analysis prepared by Phillips and Silverman (2007, 3) takes a benefit-transfer approach and applies values developed elsewhere and broad macro-scale dollar figures to, in their own words, estimate "the total benefits of the wildlands on the Tongass and Chugach National Forests" at "an admittedly coarse scale—a first approximation." In some cases, they note that they were unable to provide separate estimates for each forest, instead providing one estimate that covers both forests. This analysis provides a rough approximation of total economic values for various "benefit categories" (e.g., subsistence, passive use, ecosystem services not otherwise counted, etc.) that are included in the Final EIS as illustrations of one set of possible total economic values, where appropriate. The Phillips and Silverman analysis also illustrates the difficulties in developing accurate estimates suitable for policy analyses that require data at a finer resolution than this type of "coarse scale" approach and, in effect, supports the Forest Service's decision to use these types of estimates to support a qualitative discussion of potential impacts to these resources, rather than use these very general values to attempt to quantify differences between alternatives in monetary terms.

In addition to the problems with the total value estimates, Phillips and Silverman (2007) do not address or even mention one of the main challenges in implementing this type of analysis in a policy or management context, namely, identifying the impacts of the proposed alternatives in units or outputs that can be accurately measured in sufficient detail to allow meaningful comparison between alternatives. The ecological impact assessments presented in the Draft and Final EIS documents follow standard scientific approaches to these types of analysis and typically assess impacts in terms of probability and risk, not in numbers of affected deer or salmon, etc. The difficulties associated with identifying production relationships and the corresponding units of measurement is generally considered one of the main challenges currently facing ecosystem services analyses (Kline 2006).

Interest in ecosystem services has increased in recent years and, as noted in the preceding comment summary, economists have made useful progress in developing and improving methods and techniques that can be used to value non-market ecosystem services. Recognizing the potential utility of the ecosystem services concept, the Forest Service recently proposed that ecosystem services be used as a framework for describing and evaluating the many benefits associated with NFS lands and established an Ecosystem Services web site (http://www.fs.fed.us/ecosystemservices/) that provides detailed information and resources, identifies and discusses Forest Service efforts in this area, and issues a regular Ecosystem Services newsletter. In addition, the PNW Research Station recently issued a technical report that attempts to define an economics research program to describe and evaluate ecosystem services (Kline 2006). One of the long-term goals of this type of agenda is to allow these types of non-market ecosystem services values to be incorporated into management decisions in the future. We are just not there yet.

With respect to the Tongass National Forest, scientists from the PNW Research Station in Juneau have recently initiated an ecosystem services research program that is aimed at using the Tongass as a case study of the impacts of forest management on the long-term provision of ecosystem services and goods.

The initial phase of this program has involved working with the MIMES (Multiscale Integrated Models of Ecosystem Services) model developed by leading ecosystem services researchers at the University of Vermont. Initial work has focused on developing a simplified, dynamic model of forests and ecosystem services and goods. Future research plans involve adapting MIMES to model the impacts of management decisions on the flow of ecosystem services and goods.

Tongass National Forest Budget

Comment: One comment stated that the Final EIS should disclose the detailed budget (by EBLI) and staffing projections needed for each alternative. At least one alternative, they argue, should have a smaller budget and ASQ than Alternative 5 (No Action) and mirror more closely what will be possible in the future with reduced budgets. The comment notes that: "The plan alternatives are all built on a budget and staffing level that will expand to meet potential accomplishments; this is unrealistic."

Response: The Draft and Final EIS documents evaluate three alternatives (Alternatives 1 though 3) with an ASQ that would be lower than is currently the case.

As discussed in the Draft and Final EIS documents, the Forest Service budget is appropriated through Congress on an annual basis. National Forest budget requests are considered as part of total budget requests submitted to the United States Congress by the executive branch each year, with Congress having final say. The overall forest budget would be affected by variations in the projected level of timber harvest, with timber-related budget requirements likely higher under Alternatives 4, 5, 6, and 7, and Alternative 1 requiring the lowest level of funding. Budget shortfalls are likely in the future, especially for the more timber-intensive alternatives.

The information presented in the Draft and Final EIS documents is sufficient to allow a comparison between alternatives. Detailed budget estimates will continue to be developed on an annual basis following the selection of a preferred alternative.

Comment: Several comments stated that the Forest Service should use the funds presently spent managing the timber program to fund programs that manage recreation and tourism. These funds should also be used to repair damage from past logging practices and sustain wild salmon runs.

Response: As noted in response to the preceding comment, the Forest Service budget is appropriated through Congress on an annual basis. Funds provided in the budget are allocated for specific purposes. Funds allocated to the timber program, for example, are used for that program and the Tongass does not have budget authority to reallocate these funds to other uses. Other Tongass programs address recreation and tourism, restoration, and salmon, and are also funded by Congress.

Payments to the State

Comment: One comment stated that the 2000 Secure Rural Schools Act provided a safety net for communities that have historically depended on revenue from timber sale receipts. This legislation expired in 2006 and unless the act is reauthorized, Southeast Alaska communities will experience a loss of revenues, which at current harvest levels would be approximately $9 million annually. This would include about $400,000 the Ketchikan Gateway Borough uses to fund its school system.

Response: The 2000 Secure Rural Schools Act has been extended to 2007, as noted in the Final EIS. Future government funding or legislation will be decided in Congress and is beyond the scope of this EIS. This Act has provided funds to counties hard hit by reductions in timber harvest throughout the Pacific Northwest and other regions, as well as Southeast Alaska.

Communities

Comment: One comment stated that the "community use areas" used to assess potential effects to Sitka and Kake do not appear to adequately represent what these communities consider their use areas.

Response: The community use areas identified in the Draft EIS were originally identified for the 1997 Forest Plan Revision EIS. These areas are intended to generally represent the areas commonly used or related to by community residents in their local, day-to-day work, recreation, and subsistence activities. The community use areas are used to provide a more localized representation of data provided elsewhere in the Draft EIS. These identified areas may not fully encompass all areas used by local residents, but they provide a useful overview of LUD designations and suitable acres within the immediate vicinity of each community. Local residents concerned about potential impacts in areas outside the identified community use areas can find comparable information for these areas elsewhere in the EIS.

Comment: One comment expressed concern that the Communities subsection of the Draft EIS fails to adequately assess the economic effects of the alternatives on each community. The comment stated that the "section is focused subsistence use of deer and contradictory and not substantiated." Another comment stated that the Draft EIS does "little to nothing to show the effects of each alternative on individual Southeast Alaska communities."

Response: The comment does not identify what type of analysis the author thinks would be appropriate at the community scale, and does not provide any specific comments that can be addressed or examples of how the sections might be considered contradictory. As a result it is not possible to provide a specific response. The introduction to the Communities subsection in the Draft and Final EIS documents identifies some of the difficulties involved in trying to predict the effects of forest-wide management alternatives on community economies and explains that the community analyses do not attempt to quantify economic impacts in absolute terms because this is simply not possible (see the subsection titled: Analyzing Impacts to Communities).

The community analyses presented in the Draft and Final EIS documents do, however, provide a considerable amount of information about each community and illustrate how each community might be affected by the various alternatives. This analysis is consistent with those presented in the 1997 Forest Plan EIS and the 2003 SEIS.

Comment: A number of comments stated that the existing sawmills in Southeast Alaska require an economically viable wood supply from the Tongass to operate at full capacity and provide jobs in local communities. One comment also stated that the EIS analysis needs to evaluate impacts on a community-by-community basis and must not: "claim that the benefits from a growing community that does not depend on the timber industry somehow offset the negative impacts on communities that depend on the timber industry."

Response: The Draft and Final EIS documents evaluate the potential impacts of the proposed alternatives on a community-by-community basis in the Communities subsection of the *Subregional Overview and Communities* section. The EIS analysis is programmatic and not site-specific, which limits the ability of the analysis to project impacts at the community level. This is discussed further in the Communities subsection of the EIS (see the subsection titled: "Analyzing Impacts to Communities"). The EIS does not make any "claims" that suggest that benefits to one community outweigh negative effects to another. The positive impacts of Forest-wide planning decisions may not, however, be distributed evenly across the Forest, with some communities, those in the south, for example, bearing a larger share of the negative impacts associated with timber harvest than those to the north.

Comment: One comment pointed out that the discussion of the Silver Bay sawmill in Wrangell in the Communities subsection of the Draft EIS needs to be updated. Silver Bay came out of bankruptcy in 2004 and has stated that the mill would like to operate at capacity (65 MMBF annually).

Response: This section has been updated in the Final EIS and now states that Silver Bay continues to operate. The updated section also provides summary data based on the 2006 mill survey, which included the Silver Bay mill. The facility processed an estimated 6 MMBF in 2006 and employed 30 people (Juneau Economic Development Council 2007).

Comment: One comment noted that the discussion of Hoonah in the Communities subsection of the Draft EIS did not mention the Icy Straits Lumber Company mill and its role in the economy of Hoonah, and requested that this be added to the Final EIS.

Response: The Icy Straits mill and its location in Hoonah are discussed elsewhere in the Draft EIS (see Table 3.22-5, for example), but the mill was not specifically identified in the general discussion of Hoonah's economy presented in the Communities subsection. This information has been added to this discussion in the Final EIS.

Comment: The Draft EIS states that: "Tenakee Springs residents have been vocal in their opposition to tourism development." One comment noted that small-scale, locally-owned businesses catering to independent travelers are a large part of the Tenakee Springs economy. Local residents opposed cruise ship development, not all tourism development. This should be clarified in the Final EIS.

Response: The cited statement is attributed to Dugan et al. (2006) in the Draft EIS and is taken directly from their report: *Nature-Based Tourism in Southeast Alaska: Results from 2005 and 2006 Field Study*. The report presented the results of interviews with nature-based tourism businesses in Southeast Alaska communities, including Tenakee Springs. A note of clarification citing the comment author (Chichagof Conservation Council) has been added to this statement in the Final EIS.

Comment: One comment requested a balanced Forest Plan that provides employment opportunities in local communities. The comment author noted that people are moving from villages to larger urban areas for work and cited the examples of people moving from Hydaburg, Craig, and Klawock to Ketchikan, and people moving from Hoonah, Angoon, Kake, and Yakutat to Juneau.

Response: Population data are presented by community in the Communities subsection of the Draft and Final EIS. These data indicate that all of the communities referenced in the comment, with the exception of Juneau and Hoonah, experienced a net loss in population from 2000 to 2005. Ketchikan also lost population over this period. The seven alternatives presented in the Draft and Final EIS documents each provide a balance between different land uses on the Tongass, but the balance is weighted differently under the different alternatives.

Comment: Several comments stated that the data provided in the *Subregional Overview and Communities* and Environmental Justice sections of the Draft EIS indicate that Southeast Alaska is "in dire economic straits and fully justifies that the … (Forest Service) … should do everything possible to improve the viability of the forestry and mineral industries."

Response: This represents one perspective. Others providing comments believe that the future health of Southeast Alaska's economy is predicated on recreation and tourism and commercial fishing. These comments argue that continued large-scale logging and mineral exploration seriously jeopardize this future. These represent contrasting visions for the future of the region. The Forest Service has proposed a range of alternatives that try to balance these competing visions.

Comment: Many general comments were received expressing concern about the economic plight of small isolated communities that have few well paying year-round jobs. One respondent focused especially on the community of Hyder in this respect and had a number of requests that might improve the situation such as designating a minerals development overlay LUD for the historic mining area near Hyder.

Response: As noted in response to the preceding comment, there are a number of competing visions for the future of the region. The EIS evaluates a range of alternatives that try to balance these competing visions. A minerals overlay has been added to the Hyder area under all of the action alternatives in the Final EIS.

Comment: One organization providing comments included several lists of "core principles" the authors believed the Forest Plan should address and implement with respect to community use. These lists included the following:

- **"Establish a shared and balanced vision of the values and uses of the Tongass National Forest**
- **Protect customary and traditional uses of the forest**
- **Protect key community use areas which Southeast Alaskans cherish and benefit from economically, socially, and culturally**
- **Provide a long-term management vision of the forest which ends the unsustainable practice of logging Inventoried Roadless Areas and seeks to meet the needs and benefit all who care about the forest, including residents, visitors, and other stakeholders."**

Response: The proposed Forest Plan alternatives evaluated in this EIS are designed to meet the goals identified in the above comment, to the extent possible, recognizing that the Forest Service is required to manage the Tongass for multiple uses and also seek to meet demand for timber under TTRA. The alternatives considered in this EIS range from Alternative 1, which involves the lowest projected levels of timber harvest and would not involve logging in roadless areas, to Alternative 7, which involves the highest projected levels of timber harvest and includes logging in roadless areas. The potential impacts of the proposed alternatives on customary and traditional uses of the forest and community use areas are assessed in the *Subsistence* and *Communities* sections of the EIS.

Fish and Watersheds

The Fish and Watersheds comment and response subsection is divided into the following categories:

- General
- Buffers
- Culverts and Roads
- Watersheds
- Forest Plan and EIS Revisions

General

Comment: Some comments disagreed with the assessment that none of the alternatives would result in significant declines of major fish and marine resources. Concern was expressed that none of the alternatives adequately protect fish and their habitat because all alternatives include some development LUDs in primary fish producing watersheds. Further, one comment stated that under all of the alternatives there would be large changes in temperature, sediment, and physical conditions in watersheds that supply important habitat for rearing fish.

Response: The suite of Forest-wide and LUD-specific standards and guidelines that have been in place since 1997 have proven through monitoring and research to be effective in protecting fish habitat and fish populations. These protections and monitoring efforts will continue under all alternatives. The Final Proposed Forest Plan does, however, include a number of changes to the standards and guidelines for riparian areas and for fish management, based on information developed in the 5-Year Forest Plan Review.

The EIS acknowledges that risks to aquatic resources would increase with more harvest and would vary by alternative (see the *Fish* section). Site-specific evaluations, and, if needed based on standard and guidelines, watershed analysis would be conducted for all timber sale proposals to evaluate if specific adverse affects would occur and identify how best to modify the actions to minimize these specific effects. One of the goals of the site-specific timber sale NEPA assessments is to ensure that significant adverse effects do not occur to important resources as a result of the timber sale.

Comment: One comment stated that the Draft EIS overstated possible impacts to fish passage and karst (page 2-53, Table 2-18) given the protective measures found in the Forest Plan.

Response: Table 2-18 (Summary of Effects Matrix) in the Draft EIS displays the effects of the seven alternatives on all potentially affected resources, including Karst and Fish, in a consistent manner to aid in comparison of the alternatives. Forest Plan standards and guidelines are implemented to protect or minimize the potential effects at the project level. Specific comments with respect to fish passage are addressed elsewhere in this section. Specific comments about karst are addressed in the Geology, Soils, Karst, and Caves section of this comment and response appendix. Table 2-18 has been updated in the Final EIS to reflect changes made between the Draft and Final EIS and for the Final Proposed Forest Plan.

Comment: One comment requested that additional discussion of the potential effects of the alternatives on fish populations and fisheries be provided. Another comment requested additional discussion of the potential effects of the alternatives on stream flow, temperature, transport of nutrients and feed from headwaters to fish rearing habitat, and the influence of large woody debris and beaver dams on fish productivity. One comment also questioned whether there really has been no effect on fish or fish populations from past harvest over the last 30 years.

Response: A general discussion of the types of effects that occur from timber harvest has been added to the *Fish* section of the Final EIS. This discussion includes potential impacts to many of these factors (e.g. temperature, nutrients, large woody debris). The effects of the alternatives on these factors are addressed indirectly by quantifying the relative difference in risk factors that influence these parameters. These factors include acres of harvest and miles of roads, which may, for example, influence temperature and large woody debris in streams. The likely effects at specific sites would be addressed through the project-specific NEPA process for any future timber sale or other development projects.

Additional discussion has been added to the Final EIS concerning the effects of past timber harvest practices on fish or fish populations. (Also see the cumulative effects subsection of the *Fish* section in the Final EIS for overall factors, including past, present, and reasonably foreseeable future actions that could affect fish). Effects to fish populations from future actions cannot be directly quantified given the number of outside variables, such as ocean conditions and population fluctuations. However, past, present and future actions are discussed by quantifying factors known to have increased risk to fish habitat. It should be noted that all of the proposed alternatives have a substantial number of measures that would be implemented during timber harvest to protect fish habitat, many of which were not in place during most of the past timber harvest.

Comment: One comment requested that the EIS acknowledge the importance of salmon and their carcasses as input to the ecosystem of the forest and streams. The comment also stated that indirect and cumulative effects to salmon should be considered as part of the EIS analysis.

Response: Additional information has been added to the Final EIS discussing how salmon carcasses contribute to production in forest and stream ecosystems. Some general discussion of local effects to some anadromous and resident fish populations from older harvest methods has also been added. Cumulative effects are addressed relative to the effects of overall timber harvest-related actions with respect to risks to fish habitat. Overall effects to fish populations and returning salmon to streams cannot be directly determined from this analysis, but the relative direction of effects among the alternatives can be inferred.

Comment: Several comments raised the concern that timber harvest would adversely affect spawning fish in upper Tenakee Inlet, noting that this appeared to have occurred in other local streams. One comment suggested that the success of salmon production in Tenakee Inlet is due to the pristine conditions and noted that cool water is essential for salmon spawning.

Response: The amount of timber harvest in the Tenakee Inlet area varies by alternative (as shown in the alternative maps that accompany the Final EIS). Forest Plan standards and guidelines are intended to minimize or eliminate adverse effects to important aquatic resources. Further, specific effects to these resources would be evaluated during the project-specific NEPA process for timber sales and other projects.

Comment: One comment stated that the claim that logging harms fishing is contradicted by harvest data, which indicates that catch was much higher after most of the heavy harvest occurred then it was before.

Response: Some information has been added to the text in the *Fish* section discussing likely effects of past logging actions on fish numbers. Information is supplied that indicates there have been adverse effects from old logging practices on numbers of fish at specific sites. However, changes in the number of returning salmon are the result of many factors, including climate and ocean conditions, which play a large role and can change returns dramatically. Also there has been dramatic increase in hatchery fish production in recent years, affecting overall harvest. Additionally, the total amount of area directly affected by timber harvest, relative to the entire Tongass National Forest, is small so that any local changes in salmon runs would likely not be apparent in total harvest numbers from Southeast Alaska. These concepts are discussed in a number of the references cited in the Final EIS.

Comment: One comment recommended that the information used to summarize sport fishing effort and demand in the introduction to the Fish section in the Draft EIS be updated using the Alaska Department of Fish and Game (ADF&G) Statewide Harvest Survey. The comment also requested that Dolly Varden and cutthroat trout be added to Table 3.5-1, which lists commonly harvested sport, subsistence, and commercial fish.

Response: This information has been added to the Final EIS.

Comment: One respondent wanted to know when and how known problems with siltation from forest roads and deposits of detritus from log transfer facilities would be remedied.

Response: Potential siltation from forest roads would be addressed on a site-specific basis during the NEPA process for specific timber sales. Siltation would be controlled using Best Management Practices (BMPs) for roads, with these practices applied on a site-specific basis. This would also be the case for log transfer facilities. Additional information has been added to the text in the *Fish* section in the Final EIS. (See also the *Transportation and Utilities* section for more detail on potential log transfer facility effects.)

Comment: One comment noted that the latest definition of Essential Fish Habitat in Alaska should be used in the text. Another comment clarified how Essential Fish Habitat and the Magnuson-Stevens Act applies to this Forest Plan Amendment.

Response: The current definition of Essential Fish Habitat is included in the Final EIS**.** The Final EIS also discusses the Magnuson-Stevens Act and how it applies to the Forest Plan Amendment.

Comment: One comment provided a citation they believed was important relative to addressing fish die offs in Southeast Alaska streams. The paper noted that adult returning salmon mortalities were from natural conditions and not directly related to past harvest conditions.

Response: This information has been added to the *Fish* section of the Final EIS under the Important Components of Fish Habitat subsection.

Comment: One comment recommended that the Forest Service, in consultation with the State, develop objective criteria and protocols to use for stream classification, and train Forest Service staff in the application of these protocols. The comment also urged the Forest Service to maintain existing flexibility in the Class III guidelines to protect water quality and downstream fish habitat in a manner that is practical for timber harvesting.

Response: The Final Proposed Forest Plan includes objective criteria and protocols for stream classification. The Forest Service agrees that taking measures to promote consistent interpretation and application is important. A Forest Plan implementation training program will be developed and used to promote consistency after the Amendment is completed. That effort will be done collaboratively with the State and others.

Comment: One comment expressed concern over adequate funding for the maintenance of BMPs designed to protect fish. The comment author also felt that more protection, beyond BMPs, is needed on smaller streams, and pointed out that even non-fish streams have valuable riparian functions and also contribute wildlife habitat.

Response: Overall Forest Service funding is declining but implementation of standards and guidelines is not funding-dependent. Protection of fisheries is a high priority and adherence to standards and guidelines and monitoring of results will continue. Monitoring has not identified a problem with the current level of protection.

Comment: One respondent was concerned that hatchery fish would compete with wild fish to the detriment of wild fish. The comment stated that the Forest Service is standing by and allowing hatcheries to destroy the integrity of the wild habitat.

Response: The Forest Service manages habitat for wild fish (and other wildlife) within the Tongass National Forest. It does not manage hatcheries. This is a state issue and beyond the scope of this analysis.

Comment: Several comments wanted the Forest Service to reprioritize activities to make maintaining and enhancing salmon runs a top priority.

Response: The Forest Service in the Final EIS and Final Proposed Forest Plan is placing more emphasis on habitat restoration, including that relating to salmon habitat. This also includes prioritizing culvert replacement for areas that have the greatest need. Funding for this activity is dependent on Congress and Forest Service Management decisions. The Final Proposed Forest Plan includes standards and guidelines that are intended to protect aquatic resources and prevent effects that would inhibit maintaining fish runs.

Buffers

Comment: Some respondents felt that global warming may raise stream temperatures and could harm anadromous fish. One comment recommended that stream buffers be expanded to ensure waters stay cool and fish die offs are not caused by forest practices.

Response: Generally, stream temperatures on the Tongass are well below the point where fish would be affected. Some streams do have periods when they exceed optimal temperatures and the warming trend could compound this problem. The stream buffers required by the Final Proposed Forest Plan would provide shade which would help keep temperatures cool. Conversely, some streams in Southeast Alaska are colder than optimum, and the warming trend may improve conditions for salmon in these streams.

Past fish die offs have been documented in both harvested and unharvested watersheds and were reported to be primarily the result of flow conditions, air temperature, and the density of fish, not specifically the lack of shade or other harvest-related conditions. Future harvest practices are likely to have little direct effect on the occurrence of fish die offs during spawning. The current buffering system will supply abundant shade along fish streams under all alternatives and widening the buffers would not substantially change the shading. The one exception is Alternative 7, which would not require buffers on Class III streams, which may affect temperature.

Comment: One comment stated with respect to the importance of cool water temperatures for fish that there is an optimum temperature within which temperature changes are not harmful and may even be beneficial.

Response: The text in the *Water* section of the Final EIS was modified to discuss the importance of optimum temperatures**.**

Comment: Some comments stated that where logging occurs there should be wide stream buffers and units should be no larger than 20 to 30 acres.

Response: Current standards and guidelines require large wind firm buffers on streams. These are included in all alternatives. The average opening size is approximately 11 acres currently, primarily due to stream buffers.

Comment: Several comments noted the importance of headwater streams to the whole system. One comment supported including buffers on all Class III streams as recent evaluations and literature suggest that these streams require wood to properly function and Class III streams are important to the whole system by supplying fish food downstream, and are important to water quality.

Response: All the alternatives except Alternative 7 retain buffers on Class III streams. The effects of not having Class III stream buffers on sediment, water quality, and fish food supply are noted in the EIS.

Comment: A number of comments wanted the plan to ensure that buffer areas were present along streams and that roads were not allowed along river banks to ensure good quality habitat and prevent water heating and pollution.

Response: The current Forest Plan provides adequate buffers to ensure temperature is not changed as a result of logging. Trees in buffers are only removed where roads cross streams, and guidelines ensure that long lengths of stream buffer are not removed for road placement.

Comment: Several comments requested that riparian and beach buffers recommended in the Draft EIS be developed in consultation with the Alaska Department of Natural Resources to ensure that they are consistent with Alaska Forest Resources and Practices Act when implemented adjacent to non-federal lands.

Response: The process of establishing riparian buffers and beach and estuary buffers included addressing the concerns of State of Alaska relative to this issue. The establishment of buffer sizes considered many factors including the benefits and deficits of various buffers widths. These buffers were primarily established to protect natural resources, including fish and wildlife. With the exception of Alternative 7, the buffer widths proposed in this Amendment are the same as those under the current Forest Plan and monitoring has shown these buffers to be effective. Reducing buffers adjacent to non-federal lands to make them consistent with State requirements would not provide the level of protection needed to meet the objectives of the Forest conservation strategy.

Comment: One comment stated that no harvest should be allowed along streams or along the beach. Another comment requested that the Forest Service increase stream buffers from 200 to 500 feet depending on the stream channel.

Response: All alternatives except Alternative 7 provide no-harvest buffers along Class I, II, and many III streams and a 1,000-foot, no-harvest buffer along the beach. Alternative 7 provides no-harvest buffers along Class I and II streams and a 500-foot no-harvest buffer along the beach. Stream buffers vary in width, depending on site-specific conditions, including stream class, channel type, and the risk of windthrow. See Appendix D of the Final Proposed Forest Plan.

Comment: One comment questioned whether a 100-foot buffer on Class III streams was needed. The comment noted that studies suggest that 90 percent of sediment runoff was successfully filtered with a 10-foot buffer, and thought a 60-foot buffer would be more than sufficient to filter out contaminants.

Response: There are multiple reasons for buffers on Class III stream, not just for filtering. The Final EIS notes some of the purposes. A recent review by the Forest Service (Paustian et al. 2006) evaluated the appropriateness and need for buffers on Class III streams and the importance of Class IV streams. One of the items noted was that large wood was needed in Class III streams for them to properly function. Wood from adjacent riparian areas enters these streams in many ways, but requires a riparian source.

Typical mature tree height is often in the range of 100 feet, so reducing the buffer width has the potential to reduce wood supply. Some wood from Class III streams, depending on valley morphology, enters fish streams and contributes to habitat in those areas as well. The wood in Class III streams also controls rates of sediment entry into fish streams. Additionally, more than 50 percent of the water in a basin originates in Class III and IV streams. So effects such as changes in water temperature, possibly from small buffers, have potential to affect downstream temperature. Much of the food supply in fish streams originates from Class III streams and a significant portion of that food source is terrestrial, entering from riparian vegetation. A substantial reduction in riparian trees could affect this supply. Alternative 7, however, does not require buffers on Class III streams. This alternative would likely have additional adverse effects to fish resources not common to the other alternatives.

Culverts and Roads

Comment: Several comments were received concerning culverts that block fish passage. A concern was expressed that funds for the replacement of past passage problems at existing culverts have decreased. Some comments requested that the Forest Service commit to replacing existing culverts that currently block fish passage and fund maintenance of existing roads before constructing new roads; others suggested that restoring passage at culverts not currently meeting fish passage criteria should be a high priority for the Forest and that plans to repair passage problems in future timber sales should be included in the Proposed Forest Plan. Some respondents requested that an analysis identifying how culverts influence cumulative effects to fish resources be included in the Final EIS.

One comment requested that a recently developed model for determining the biological significance of not meeting passage at individual culverts be included in the EIS analysis, as well as the cost of fixing past culvert passage problems. The comment also requested that specific citations concerning road and culvert effects on fish be noted in the EIS text.

Response: The Forest Service considers fish passage to be an important priority and has an ongoing program to eliminate or replace culverts that do not provide passage. The Forest Service plans to continue to address past culvert problems as funding is available. The budget for this work is appropriated through Congress on an annual basis. National Forest budget requests are considered as part of total budget requests submitted to the U.S. Congress by the executive branch each year, with Congress determining the annual appropriation. Determining funding levels is outside the scope of this Forest Plan Amendment EIS. Current standards and guidelines for culvert installation have requirements to ensure fish passage is provided when fish are present at the crossing areas. These guidelines differ from the guidelines that were in place when most of culverts that have fish passage problems were installed. As a result, fish passage problems from future installations are expected to be comparatively rare.

Additional information on the status of the current culvert inventory relative to fish passage has been added to the *Fish* section of the Final EIS. The number of potential stream crossings identified in the EIS provides a relative approximation of the potential number of culverts by alternative; an exact number of future culverts cannot be determined prior to site-specific analyses. The exact number of culverts would be determined for each specific timber sale or other project and the potential effects would be addressed as part of the project-specific NEPA analysis at that time. The Forest has a substantial database that identifies the status of nearly all existing culverts and includes fish passage information. Two citations were added to the *Fish* section in the Final EIS, as requested; however, some of the other citations were not added because the issues they addressed had already been discussed in the analysis, and the information these documents provided on the number and status of culverts on the Tongass was less exact and older than the specific data reported in the Final EIS.

Comment: One comment questioned the use of the term "restored" for improving fish passage for culvert replacement. The comment stated that in a substantial number of cases passage conditions before culvert replacement would have allowed most fish to pass most of the year, and replacement in many of these cases was intended only to ensure passage at infrequently occurring flow conditions.

Response: The discussion of culvert replacement presented in the *Fish* section under Fish Habitat Enhancement has been expanded in the Final EIS to provide additional information with respect to culvert replacement.

Comment: One comment stated that the characterization of road effects on stream sedimentation in the *Fish* section under General Effects, Roads, was exaggerated. The comment included a document containing data from some specific sediment studies. Additionally, the comment noted that the Draft EIS statement that roads could contribute to overharvest of fish should be excluded because fish harvest is a fish management issue and not a direct result of road development.

Response: The text does not specifically quantify the magnitude of road effects on sediment and, therefore, the EIS does not exaggerate the effects. Potential sediment effects are evaluated on a site-specific basis during the NEPA evaluation of timber sales. The general statements on road/sediment effects and the effects to fish harvest in the Draft EIS were retained in the Final EIS. Fish harvest is a management issue, but increased access can lead to overharvest in the absence of harvest management actions and it cannot necessarily be assumed that ADF&G harvest management would change fishing regulations in areas where new roads are built. Again, site-specific effects would be evaluated through the NEPA process for each timber sale.

Comment: One comment stated that using the number of road crossings and road miles by alternative as an index of sediment input and fish passage problems was not justified. The comment stated that new culvert designs ensure fish passage and road management would ensure sediment runoff meets standards.

Response: The standards and guidelines in the Final Proposed Forest Plan are intended to achieve these goals. However, even with the best practices not all goals are completely achieved. For example, the EIS notes that culverts installed under the new guidelines are very good at achieving the passage guidelines, with 93 percent meeting current passage criteria. Therefore, if the percent not meeting the criteria (e.g., 7 percent) remains the same the greater the number of culverts installed, the greater the number of potential fish passage problems. Also, monitoring indicates that even under new standards for road construction some short term increases in turbidity occur. Therefore, as with culverts, the greater the number of road miles, the greater the likelihood of exceeding the sediment (turbidity) standards. Thus, the comparison is a reasonable way to assess the alternatives on a forest wide basis. Site-specific evaluations of potential passage and sediment problems would be made for any future timber sale through the NEPA process and more specific information would be used at that time to evaluate potential effects.

Comment: One comment noted that there are always impacts to water from road construction or presence and that the EIS should display a habitat reduction factor for every mile of road constructed.

Response: The EIS acknowledges the risks of roads to fish habitat and states the greater the number of road miles the greater the risk. But with new guidelines for construction, the plan is to keep these risks to low levels with measures such as avoiding steep unstable slopes, taking roads out of use after harvest is complete, including removal or bypassing culverts, and ensuring new culverts meet more stringent fish passage criteria. Therefore it is not reasonable or possible to develop a reduction of habitat amount based on the number of road miles. The specific effects of proposed road systems will be evaluated during the NEPA process for timber sales and other projects, and as needed adjustments will be made to the individual plan to reduce the risks and ultimately the effects of roads to fish habitat.

Watersheds

Comment: Several comments wanted the Forest Plan to prevent all road building and logging in primary salmon producing watersheds as identified by ADF&G and specify that watershed analyses be completed prior to any timber sale. Some comments noted that entire watersheds need to be protected from development to ensure the protection of anadromous fish resources. Some comments recommended that additional protections should be applied to 23 specific watersheds. The suggested protections primarily relate to new roads .

Many respondents asked that watersheds be protected. Some mentioned high value watersheds while others discussed the importance of protecting "intact" watersheds—those that have all their ecological parts and functions—from timber harvest and road construction. One comment included a summary of the findings of the 1997 Panel that evaluated potential harvest alternative guidelines and the potential concerns for these actions, and also cited a document by Bryant and Everest (1998) that discusses the likely effects of past and future harvest on fish stocks in Southeast Alaska.

Response: The Forest Service does not dispute that watersheds without disturbance have a greater chance of having consistent runs of salmonid stocks than those that are highly disturbed. However, current standards and guidelines for timber harvest and road construction are greatly improved over past methods, and comparing past impacts to salmon stocks from old harvesting methods to current ones is not an appropriate comparison. While there is a legacy of some problems from past actions, future conditions in newly harvested watersheds would not have marked impacts. The EIS acknowledges the potential problems, concerns, and risks identified by the 1997 panel and many of the panel recommendations for protecting fish resources and watersheds were included in the alternatives.

Comparisons provided by Bryant and Everest (1998) consider the effects of past harvest practices, as well as those that were implemented at that time (1998). They note the importance of maintaining pristine watersheds, but they also indicated that 75 percent of the Tongass National Forest is in relatively protective LUDs. Current analysis based on road miles indicates that 70 percent of all Tongass National Forest Value Comparison Units (VCUs) have no roads, and are, therefore, undeveloped. The alternatives considered in this EIS could reduce this percent over a 100 year period to between 51 and 68 percent, depending on the alternative. This would only occur if the alternative is fully implemented and it may be noted that harvest over the last decade has been much less than predicted in the current plan. In any case, the majority of the Tongass would remain pristine under any alternative.

As noted in the EIS, the National Marine Fisheries Service (1996) considers most watersheds with less than 2 miles of road per square mile to be "properly functioning" with respect to ESA-listed salmon and steelhead. Currently, less than 3 percent of the VCUs on the Tongass National Forest exceed this road density. Under the alternatives considered in this EIS, this percent could increase to about 6 to 10 percent over a 100 year harvest period if site-specific NEPA analysis indicated that exceeding this road level would not significantly affect the watershed. It is likely that over 90 percent of watersheds within the Tongass would still be considered "properly functioning" 100 years from now even under Alternative 7.

ADF&G (1998) developed a list of VCUs that met certain requirements relative to importance for fisheries, wildlife, and other community factors. They identified about 26 percent of all VCUs in Southeast Alaska as "Primary Salmon Producing Watersheds." The state used this document to provide a request to the Forest Service for revisions to the 1997 Forest Plan. The Forest Service considered the request by the State, which made the following recommendation:

> "work with communities to determine which of these areas should have appropriate management prescriptions that protect community use and fish and wildlife values. Avoiding or minimizing timber

harvest in areas of high community use will increase predictability and reliability of the timber supply and ensure the viability of all forest uses."

The watersheds referred to include the primary salmon-producing watersheds. The quote above indicates there was not a specific request to prevent all harvest and road building in all of the primary salmon producing watersheds, but to work with communities in development of specific harvest plans. The Forest Service has done this in the past and will work with communities in the future. As illustrated by the preceding quote, it is apparent from the ADF&G (1998) document that total elimination of harvest in all these watersheds was not the intent of the evaluation or recommendations at that time.

The Forest Service believes that the standards and guidelines and the NEPA analysis for specific timber sales will adequately protect the fish resources in these watersheds. Reclassifying these watersheds to different LUDs is not required to meet resource protection objectives. Watershed analysis is designed to help set the stage for project planning and associated environmental analysis; however, requiring complete watershed analysis prior to any timber sale is not required to meet Plan objectives. Additional analysis was done for the Final EIS to determine the effect of each alternative on intact watersheds. This type of analysis will help ensure that watershed functions are maintained whatever project may be planned.

Comment: One comment noted that although the proposed Forest Plan includes increased protection for headwater streams, watershed analysis and cumulative effects analysis should be conducted before any significant resource extraction takes place.

Response: The Forest Service believes that the proposed standards and guidelines would adequately protect fish and water resources on the Tongass National Forest and does not see a need for additional restrictions at the Forest Plan level. Analysis conducted under the NEPA process would evaluate site-specific resource impacts and cumulative effects from individual timber sales or other extractive activities, and adjustments would be made as needed to ensure protection of these resources. The amount and location of land available for timber harvest varies greatly by alternative. Forest Plan standards and guidelines protect watershed resources and watershed analysis can be conducted where conditions indicate the need.

Comment: One comment provided information on the status of development in flood plain forests and stated the information provided indicated that some areas that have already been moderately developed should get greater watershed scale protections for flood plain forests associated with anadromous fish streams. They also noted this is justification for protecting a greater number of intact watersheds with high salmon values and pointed out that active restoration should occur in these areas.

Response: The current standards and guidelines include large buffers for floodplain streams, much larger than existed in past decades. The Forest Service believes that these are adequate to protect anadromous fish resources in flood plain areas. Additionally, the level of past development within watersheds is one of the factors considered when developing timber sales. These factors are all considered during the site-specific timber sale NEPA process. As noted in the Final EIS, there already are large tracts of watershed within the Tongass Forest that are not included in any harvest plan. At this time the Forest Service does not believe setting aside additional specific watersheds is needed to protect anadromous fish resources.

Comment: One comment noted that a recent Trout Unlimited document "Where the Wild lands are: Southeast Alaska" (Curley and Bristol 2006) states that 72 percent of all salmon populations in southeast Alaska are found in undeveloped watersheds. Another comment noted that the salmon and steelhead population distribution relative to roadless watersheds ranges from 67 to 76 percent, depending on the fish stock.

Response: Currently, approximately 70 percent of all VCUs in the Tongass National Forest have no roads (see Table 3.6-9 in the EIS), while the remaining 30 percent have varying amounts of roads. The ratio of "roaded" to "unroaded" VCUs is similar to the ratio of where salmon populations occur. Seventy-two percent of the salmon are in 70 percent of the VCUs. One implication of this comparison could be that the relative distribution of salmon populations is independent of roads and other development. We are not implying that past harvest has had no effect on fish resources; only that interpretation of this general statement does not present a good measure of effects of development.

Comment: Several comments requested that certain watersheds be restored. One comment included an ecologically based list of watershed restoration projects they would like the Forest Service to consider.

Response: The Forest Service has increased emphasis on restoration considerations in the Final Proposed Forest Plan. There are several ongoing actions in place, such as road decommissioning and repair, culvert improvement for fish, and various habitat enhancement projects. All of the activities are dependent on funding and overall assessment of needs with consideration of which specific watershed areas have priority for restoration activities. There are general plans to improve the common watershed problems related to roads forest wide.

Comment: One comment recommended that the Forest form one watershed analysis team to perform consistent, high quality watershed analyses prior to any timber harvest.

Response: The Forest uses an interdisciplinary approach to analysis, as required by NEPA. The Forest intends to provide training to ensure that analysis teams provide consistent analysis across the Forest.

Forest Plan and EIS Revisions

Comment: One comment asked why the word "assured" has been removed from before "protect riparian habitat" in Riparian standard and guideline 1.II.A.1?

Response: Numerous minor edits have been made throughout the Proposed Forest Plan to provide clarity, promote consistent interpretation, and to reduce redundancy. These minor edits were carefully considered so as to not significantly change the basic intent of the text or Plan itself. "Protect riparian habitat" is a direct, clear statement, while "Assure the protection of riparian habitat" is a somewhat convoluted way of saying the same thing. The basic objective remains the same.

Comment: One respondent suggested adding a fish restoration section to the Fish Standards and Guidelines in the Proposed Forest Plan.

Response: Fish restoration has been a priority on the Tongass for many years. It is one of the primary goals listed in the Proposed Forest Plan (see page 2-3). Standards and guidelines for fish restoration are included in the Fish section of the Final Proposed Forest Plan.

Comment: Concern was expressed that Class II fisheries value identified in the Proposed Forest Plan might be too closely tied to economic value and not consider ecological, genetic and other values.

Response: The intention was to simply contrast the value of Class II streams with Class I streams. While they all have important values, Class II streams clearly have less overall value to fisheries because, as stated in the text, they are not anadromous and often have natural barriers to fish movement.

Comment: One comment stated that steelhead should be listed as a species of concern in the EIS.

Response: A species of concern is a specific Federal ESA designation used by the U.S. Fish and Wildlife Service or the National Oceanic and Atmospheric Administration (NOAA) Fisheries. No steelhead population in Alaska is currently identified by either agency as a species of concern under this designation. Assigning this type of designation is outside the Forest Service's responsibility and the scope of this Forest Plan Amendment. The Forest Service does, however, develop a list of "sensitive species" which includes some fish, as noted in the EIS. No steelhead stocks have been determined to meet this designation on the Tongass National Forest. This species list is periodically reviewed and if warranted based on the status or sensitivity of a stock, the species on this list can be changed.

Comment: One comment recommended that "bankfull width" be changed to "average bankfull width" in the Fish Standards and Guidelines. They also recommend that the Proposed Forest Plan distinguish between restoration and improvement because they believe that the Forest should focus on restoration activities.

Response: Bankfull width is the correct term. The word "average" from "average bankfull width" was removed from the equation in the next line to be consistent. Restoration was added to the Fish Habitat Improvement section and the following statement: "Give priority to restoration projects" was added under Fish Habitat Restoration and Improvement.

Comment: One comment recommended that the Watershed Resources Improvement subsection in the Soil and Water Standards and Guidelines be changed to Watershed Restoration and that several similar changes be made in the text.

Response: These changes have been made in the Final Proposed Forest Plan.

Comment: One comment recommended that a passage and citation be added to Appendix G concerning the potential harmful effects of bark debris near Log Transfer Facilities.

Response: This change has been made in the Final Proposed Forest Plan.

Comment: One comment stated that the term "riparian project areas" used in Riparian Planning II, B. 3 (on page 4-62 of the Proposed Forest Plan) should be further described.

Response: This term is not used in the standards and guidelines. The term "Riparian Management Areas" is used throughout, including the location referenced in the comment. This term is defined in the glossary to the Proposed Forest Plan.

Comment: One comment recommended that the Riparian Management Area be expanded to include the "entire floodplain for unconfined alluvial flood plain channels, alluvial fan channels, and glacial outwash channel, high mass-movement hazard soils and wetland fens."

Response: As noted in Appendix D of the Final Proposed Forest Plan, the areas identified in the comment are generally included in the riparian buffers.

Comment: One comment stated that some of the groups involved with habitat enhancement activities were not identified in the *Fish* section under Fish Habitat Enhancement.

Response: This section has been modified in the Final EIS to identify additional groups involved in habitat enhancement.

Comment: One comment requested that several edits be made to the subsection of the Draft EIS *Fish* section that addresses invasive aquatic species. These changes included the addition of a specific citation and the addition of cordgrass and green crab to the discussion of invasive species.

Response: This information has been included in the Final EIS.

Geology, Soils, Karst and Caves

Comment: Several comments cited the unique and valuable nature of karst lands in the Tongass National Forest, the connection between karst lands and fisheries resources, and a legacy of damage to karst lands caused by historic timber harvest as justification for further protections of karst lands in the Proposed Forest Plan. Some comments favored no additional timber harvest or road construction activities on karst lands and one suggested that substantial portions of second-growth karst forests should be allowed to return to old-growth conditions. Several comments called for additional research into karst systems and potential impacts of land management before allowing any further timber harvest on karst lands. One comment noted that the Draft EIS did not present permanent protection of karst lands as the best way to ensure ecological integrity. Another suggested greater protections for moderate vulnerability karst lands, including avoiding road construction and rehabilitating and restoring existing roads.

Response: The Forest Service considered a range of alternatives that included differing degrees of potential timber harvest and road construction activities. All but Alternative 5 (the No Action Alternative) would move about 42,870 acres of high vulnerability karst lands into the Special Interest Area LUD. Geologic Special Interest Areas have unique geologic features, including caves. Chapter 3 of the Final Proposed Forest Plan states that Special Interest Areas would be classified as unsuitable for timber production. Under the action alternatives, limited salvage of windthrown timber would be allowed along existing roads within these areas, as long as karst and cave resource values were met. Opportunities for management of the young-growth stands in these areas are emphasized consistent with protection of karst and cave resources.

The Draft EIS evaluated the potential effects of each alternative on karst resources. These alternatives did not exclude harvest from all karst lands, in part based on the findings of the Karst Review Panel that the implementation of the Karst and Cave Standards and Guidelines from the current Forest Plan had ensured a high level of protection for karst resources overall (Griffiths et al. 2002). The Panel noted high standards in both the philosophy of management and the way that specific management practices were formulated and applied. Implementation of specific policies and procedures was found to be very good and in general compliance with the stated goals and objectives of the karst program. The Panel also noted the extent to which high vulnerability karst had been protected since 1997. In addition, the Panel outlined the actions required to more actively manage karst landscapes covered with second growth stands and recommended a new procedure for assessing the autogenic (precipitation on carbonate rocks) recharge component of karst units. These suggestions were incorporated into the action alternatives. Refer to the EIS for additional information.

The Karst and Cave section of Appendix B to the Final Proposed Forest Plan identifies several research needs, including studies that better define the effects of timber harvest and road construction on karst lands, and studies to determine the influences of forest road construction on sediment and woody debris delivery to karst drainage systems. The Proposed Forest Plan requires an adaptive management approach for managing karst resources that will allow incorporation of research results in management approaches. More information is provided in Chapters 4, 5, and 6 of the Proposed Forest Plan.

Comment: A number of comments expressed concern about the lack of enforceable standards in the proposed Karst and Cave Resources Forest-wide Guidelines (and related Appendix H). Several comments noted that this section of the Proposed Forest Plan differed from others by providing only guidelines, as opposed to standards and guidelines. Many offered that the Proposed Forest Plan was significantly improved with respect to karst management, but several comments suggested that the language in the proposed Karst and Cave Resources Forest-wide Guidelines (and related Appendix H) allowed too much flexibility in karst management through the use of terms like "should" and "may" instead of "shall". A few comments noted that the Equivalent Clear-cut Area approach described in Appendix H could mitigate impacts from previous timber harvest on karst lands but that the approach was "hypothetical" and not enforceable.

Many suggested that the adaptive management approach would allow politics to sway decisions to the detriment of karst resources. Furthermore, two comments noted the lack of detailed monitoring requirements to implement the adaptive monitoring approach.

Response: The Proposed Forest Plan includes both standards and guidelines but generally requires managing karst lands with an adaptive management approach. The title of the section has been revised to Karst and Cave Resource Standards and Guidelines to reflect that Karst and Cave Standards and Guidelines are consistent with, and as enforceable as, standards and guidelines related to other resources in the Forest Plan. The Karst and Cave Resource Standards and Guidelines (Chapter 4) allow karst managers to exercise their professional judgment in developing karst management strategies and prescriptions. As knowledge is gained from implementation, monitoring, research, and studies, recommended practices will be modified to reflect the needed changes.

Chapter 5 of the Proposed Forest Plan describes monitoring and evaluation as key aspects of adaptive management, which provide feedback on implemented activities and the effectiveness of associated resource protection or mitigation measures. Additional sources of feedback include scientific literature and studies, resource inventories, changes in technology, and public concerns. Chapter 6 describes the monitoring and evaluation plan for Karst and Cave Resources. The monitoring and evaluation plan is not intended to depict all monitoring, inventorying, and data gathering activities undertaken on the Tongass, or to limit monitoring. Many other monitoring activities are conducted under direction contained in site-specific project plans developed under the programmatic guidance of the Forest Plan.

Comment: One comment supported the Autogenic Recharge Area Assessment Procedure and Equivalent Clear-cut Acre approaches described in Appendix H of the Proposed Forest Plan. These approaches allow for consideration of past timber harvest and other management activities on karst lands in evaluating karst lands for potential future activities. The comment expressed concern, however, that these approaches may not be implemented as proposed.

Response: The Proposed Forest Plan establishes the adaptive management strategy for managing karst resources. Using this approach, the Autogenic Recharge Area Assessment Procedure, Equivalent Clear-cut Acre, and other approaches would be overseen by qualified karst managers. See also the response to the preceding comment.

Comment: One comment stated that impacts from roads on moderate vulnerability karst lands should be monitored, and road maintenance activities, including culvert replacement, should not damage karst areas. Another comment noted that road construction seems to be addressed fairly well in the Proposed Forest Plan, but stated that standards and guidelines should require maintenance of existing roads to include construction of drainage systems that meet current

guidelines. The comment also stated that retired roads should include drainage systems that are protective of karst lands. A third comment requested that a standard be added requiring adequate "restocking on stored roads", and the exploration of restoration options, such as road obliteration, on moderate and high vulnerability karst lands.

Response: The Proposed Forest Plan is programmatic, meaning that it provides forest-wide management direction. Chapter 6 of the Proposed Forest Plan lists monitoring of compliance of land-disturbing projects (which would include roads) with Karst and Cave Forest-wide Standards and Guidelines, as well as monitoring of the effects of management activities (which would include roads) on karst resources. Road maintenance activities and any reconstruction or restoration activities would be covered under a project-specific plan which would be evaluated through a separate NEPA process. Road-related management activities would be implemented under the Karst and Cave Forest-wide Standards and Guidelines.

Comment: One comment stated that no recreation development should be allowed on high vulnerability karst lands and pointed out that the Proposed Forest Plan allows limited recreation development on high vulnerability karst lands.

Response: Section 3 (High Vulnerability Karst Lands), subsection b (Karst Management Objectives and Appropriate Land Uses) describes the limited recreational development that may be appropriate on high vulnerability karst lands. This section further explains that recreational facilities and trails would have to consider karst resource values and objectives, particularly with respect to reducing disturbance of significant epikarst features and sensitive soils, and the use of construction methods that avoid erosion and diversion of natural drainage waters into karst features. The Forest Service believes that this consideration would sufficiently limit recreational developments to protect high vulnerability karst lands.

Comment: One comment applauded the focus on managing second growth on karst lands, but wanted to see thorough scientific studies (including monitoring and evaluation) before any large-scale second-growth management is implemented. The comment stated that road construction for management would damage karst lands, and expressed concern that research be conducted to determine whether pre-commercial or commercial thinning would benefit karst lands and to assess the potential impacts.
Another comment noted that funds for pre-commercial thinning are limited, and that the Forest Service should prioritize thinning on second-growth areas that will be available for future harvesting and can benefit wildlife, rather than on karst areas where timber harvest is not allowed. Other comments stated that implementation and effectiveness monitoring of young-growth management on karst lands should be required to assess whether karst management objectives can be met.

Response: The Proposed Forest Plan notes that pre-commercial thinning is appropriate on all karst lands when the karst management objectives can be met. It does not attempt to prioritize funding for pre-commercial thinning projects on or off karst lands. The specific benefit of pre-commercial thinning projects on wildlife or timber potential would be assessed during the project-specific planning process. Chapter 6 of the Proposed Forest Plan describes implementation and effectiveness monitoring under karst and caves. This includes monitoring the compliance of land-disturbing projects with Karst Standards and Guidelines, and monitoring of effects of management activities on caves and karst landscapes, both of which would address young-growth management on karst lands.

As described in the response to a previous comment summary, the Karst and Cave section of Appendix B identifies the need for research to better define the effects of timber harvest and road construction on karst lands. The results of these studies will be incorporated into management decisions through the adaptive management approach described in the karst sections of the Proposed Forest Plan, as well as in Chapter 5. Finally, all the alternatives except Alternative 5 (the No Action Alternative) would move about 42,870 acres of high vulnerability karst lands into the Special Interest Area LUD. These areas would be classified as unsuitable for timber production.

Comment: One comment stated that the Draft EIS failed to take into account past timber harvest on karst lands, and instead of protecting the remaining karst forest by strengthening standards and guidelines, it proposes to weaken them. The comment specifically notes that future timber harvests are proposed on karst lands in Tuxekan, Hecata, northwest Prince of Wales Island, and Kosciusko. Another comment notes that the cumulative effects of previous timber harvest and road construction on karst lands were not considered in developing the standards and guidelines for future timber harvest.

Response: The Final EIS takes into account past timber harvest activities. Furthermore, the EIS discloses that all but Alternative 5 (the No Action Alternative) would move about 42,870 acres of high vulnerability karst lands into the Special Interest Area LUD. As noted in response to a previous comment summary, Chapter 3 of the Final Proposed Forest Plan states that Special Interest Areas would be classified as unsuitable for timber production. The EIS includes a discussion of cumulative effects, including the effects of previous and proposed timber harvest and road construction activities on karst lands by alternative. This discussion has been expanded in the Final EIS. Site-specific activities, such as specific timber harvests, are beyond the scope of this document and are instead addressed at the local level under separate NEPA processes.

Comment: One comment expressed concern about the following statement under Karst in Table 2-18 (Summary Effects Matrix) of the Draft EIS: "The relative effects on karst resources are proportional to the amount of karst lands in the mapped suitable forest land base." The comment asserted that timber harvest would have no significant impact on karst and that construction would have very minimal impacts on karst.

Response: The Draft EIS states: "Potential effects on karst lands from planned timber harvesting, associated road construction, and quarry development may occur; however, with careful implementation of the current or proposed standards and guidelines (as modified through ongoing monitoring and adaptive management), and site-specific mitigation measures (designed and implemented at the project level), the Forest expects to mitigate the effects of any proposed activity. Site-specific mitigation measures include protection of the high vulnerability karst areas and features, partial cutting, reduced harvest unit size, use of logging systems that achieve at least partial suspension, reductions in rate of harvest, and other changes in logging practices."

This text in Table 2-18 has been clarified in the Final EIS.

Comment: One comment noted that the Tongass does not have a catchment area management strategy for autogenic recharge areas and asked what steps were in process to develop this strategy.

Response: The Proposed Forest Plan provides the direction necessary to protect and manage autogenic recharge areas and other specific needs associated with karst and cave resources.

Comment: Based on the Federal Cave Resource Protection Act, one comment requested that the word "feasible" be changed to "practical" in the sentence: "Maintain, to the extent feasible, the natural karst processes and the productivity of the karst landscape while providing for other land uses where appropriate."

Response: The proposed change from feasible to practical has been incorporated in two places in the Proposed Forest Plan, as suggested.

Comment: One comment requested more specific guidance regarding when, and how many, dye trace studies are needed to credibly delineate recharge areas during karst vulnerability mapping.

Response: The Proposed Forest Plan adequately addresses the need for design criteria for dye trace studies to delineate recharge areas during karst vulnerability. It is also reasonable to assume the proper skill level and expertise will be used in all karst-related work including dye trace studies.

Comment: One comment stated that the Draft EIS lacks important information to assess impacts of the alternatives on karst resources, including: miles of road on karst lands, acres of previously harvested karst lands, how well harvested karst lands have regenerated, how well roads on karst lands have been maintained, and the current road maintenance backlog.

Response: The Draft EIS states: "GIS queries show that a total of 95,479 acres (21 percent) of the karst lands managed by the Tongass National Forest have experienced timber harvest." The Draft EIS also explains, "In some portions of the Tongass National Forest, 70 to 80 percent of the commercial forest land within specific karst blocks has been harvested. It is estimated that about 50 percent of the karst lands below 1,400 feet in elevation and on slopes less than 60 percent in the Thorne Bay Ranger District have had timber harvest (based on the GIS database)." Additional information has been added to the Final EIS, including miles of road on karst lands, and a discussion of how well harvested karst lands have regenerated and how well roads have been maintained.

Comment: One comment requested that section D.1 on page 4-22 of the Proposed Forest Plan refer to section D.2.c. This reference would clarify the proposed management of a high vulnerability feature within a low vulnerability area and the applicable karst feature buffers that would apply.

Response: This change has been made to the Proposed Forest Plan, as suggested.

Comment: One comment expressed concern over the designation of "minor" resurgences with almost no connectivity between the open atmosphere and the underground system as moderate (as opposed to high) vulnerability karst lands. The comment mentioned observations of karst systems with resurgent springs with no surface connectivity but that may merit high vulnerability status. The comment expressed doubt that sufficient field reconnaissance would be possible to accurately characterize high vulnerability areas.

Response: The Proposed Forest Plan states that resurgences can be classified as moderate or high vulnerability depending on size, habitat, and level of atmospheric connectivity between the resurgence and the underground karst system. Minor resurgences which seep out of the ground between gravels with almost no connectivity between the open atmosphere and the underground system will be classified moderate vulnerability. This designation will be made by a qualified karst management specialist, who would also design appropriate protection measures for moderate vulnerability resurgences and springs on a case-by-case basis.

Comment: One comment strongly objected to the wording in the Proposed Forest Plan that indicated that the karst lands on the Tongass National Forest were considered open to mineral development. The Proposed Forest Plan states: "It is not the intent of these standards and guidelines to restrict any lands from mineral development, though that may be appropriate if a specific project or area is allocated to the "Special Interest Area" Land Use Designation." The comment paraphrased the 1988 Federal Cave Resources Protection Act requirement that the agency responsible for land management in karst areas must protect those caves and features.

Response: The Federal Cave Resources Protection Act of 1988 states that NFS lands will be managed in a manner which, to the extent practical, protects and maintains significant cave resources in accordance with the policies outlined in the Forest Service Directive System and the management direction contained in the individual forest plans. The Proposed Forest Plan states that the impacts of any proposed mineral development within the karst landscape would be analyzed through the environmental analysis that would be triggered once a Plan of Operation was received.

Comment: One comment expressed concern that the Forest Service will continue to hold cave location information confidential and not distribute location information per the 1988 Federal Cave Resources Protection Act. The comment encouraged continued collaboration with caving organizations, including collaboration to define appropriate uses, discuss cave classifications, consider potential cave developments, and solicit volunteers.

Another comment commended the Forest Service for the extensive rewriting of the Forest Plan, noting that management of karst and cave resources was better defined and more clearly described than in the previous Forest Plan. They anticipate future collaboration and volunteer work with the Tongass.

Response: The Forest Service intends to continue to "foster communication, cooperation, and exchange of information between land managers, those who utilize caves, and the public", per Section 4 (c)(2) of the 1988 Federal Cave Resources Protection Act. The Forest Service also intends to continue to implement 36CFR 290.4 and Section 5 of the Federal Cave Resources Protection Act, which requires that it maintain the confidentiality of information concerning the nature and location of significant caves.

Comment: One comment expressed concern about the change in non-harvest buffers related to insurgent streams in moderate vulnerability karst lands between the previous Tongass Plan Implementation Team clarifications and the Proposed Forest Plan. The Tongass Plan Implementation Team clarifications suggested that non-harvest buffers extend from the edge of a sinking or losing stream and cover 100 feet plus 2 tree lengths within no less than 1 mile upstream or to the stream's source. The Proposed Forest Plan indicates that the 100-foot no-harvest buffer would extend only 0.25-mile upstream. The comment stated that this change is significant and should be reassessed and justified to the public.

Response: The Final Proposed Forest Plan provides for protection of karst and cave resources and promotes adaptive management principles achieving this. Additional buffers could be implemented where recommended by a qualified karst manager to ensure compliance with the Karst and Cave Resource Standards and Guidelines.

Comment: One comment noted that the reference to harvest on 72 percent slopes had been moved from the karst appendix (Appendix H) to the Soil and Water section of the Proposed Forest Plan. Given the potential soil loss, hydrologic change, and mass wasting impacts related to timber harvest, roads, and other development activities on steep karst lands, the comment requested that no harvest on steep slopes be the standard and not under the discretion of the District Ranger on a case-by-case basis.

Response: The Proposed Forest Plan states:

> "At the forest plan level, slope gradients of 72 percent or more are removed from the tentatively suitable timber base due to high risk of soil mass movement and accelerated erosion of Class IV channel systems. At the project planning level, the Forest Supervisor or District Ranger may approve timber harvest on slopes of 72 percent or more on a case-by-case basis, based on the results of an

onsite analysis of slope and Class IV channel stability and an assessment of potential impacts of accelerated erosion on downslope and downstream fish habitat, other beneficial uses of water, and other resources. It is anticipated that harvest of these areas will be a small percentage of the total harvest unit."

Proposed timber harvest on slopes greater than 72 percent would undergo an onsite analysis and an assessment of potential effects on downslope resources, including karst.

Comment: A number of comments noted that the Tongass should make sure that karst lands are not transferred to entities with fewer measures to ensure karst protection. They note that if karst lands are transferred, the transfer should include special considerations requiring management practices that are as protective or more protective of karst lands. Karst managers would need to work with land transfer experts to ensure that karst lands continue to receive at least the level of protection that the Forest Service currently provides. One comment noted that many of the proposed land exchanges and adjustments with Sealaska contain valuable karst lands. The comment notes that the Draft EIS does not discuss how the Forest Service will treat land exchange or adjustment requests that involve karst lands.

Response: While Appendix C discusses several proposed land exchanges, this does not mean that they are likely to occur or would occur exactly as depicted. Land exchanges are discretionary, voluntary real estate transactions between federal and non-federal parties. The Forest Service is not required to enter into a land exchange when presented with a proposal. Any exchange would require NEPA analysis, most likely an EIS, which would include public involvement and would disclose any adverse effects to karst and cave resources, as well as to other resources. The Draft EIS discloses that the Sealaska proposal presented to the Forest Service does not provide any assurances that important resources on the lands Sealaska proposes to acquire would be protected to the same degree as under national forest management. Specifically, the proposal does not include assurances that karst and cave resources would be protected.

The cumulative effects section of the Draft EIS has been expanded to include a discussion of the potential effects of future land exchanges on karst resources.

Comment: One comment supported the new Geologic Special Interest Areas. The comment noted that while legislated protections would be stronger and more protective of karst wilderness areas, the Special Interest Areas are an excellent first step in providing permanent protection for the "best of the best" karst lands. Continued collaboration was suggested to increase the protection of Special Interest Areas.

Response: The Forest Service considered a range of alternatives that included differing degrees of proposed timber harvest and road construction activities. The Draft EIS evaluated the potential effects of those alternatives on karst resources and disclosed the findings of the Karst Review Panel, which found that implementation of the Karst and Cave Standards and Guidelines from the current Forest Plan had ensured a high level of protection for karst resources overall (Griffiths et al. 2002). As noted in one of the preceding responses, the Forest Service intends to continue collaboration with those who use caves and the public.

Heritage and Sacred Sites

Comment: One comment requested that the Final EIS clarify the types of traditional use that are permitted in Conservation System Units, including designated Wilderness. The definition of traditional activities in the Region 10 Forest Service Manual (1/27/99) includes recreational pursuits. The comment authors stated that they strongly disagree with the inclusion of recreation in this definition and requested that the Forest Service adopt and implement a definition similar to that employed by the National Park Service, which defines "traditional" as an activity that occurred when ANILCA was passed and involves the consumptive use of one or more natural resources of Old Denali Park, such as hunting, trapping, fishing, berry picking, or similar activities.

Response: Traditional uses are allowed in designated wilderness as authorized by ANILCA. Updating Regional manuals and handbook definitions is beyond the scope of this Amendment.

Comment: Some respondents asked that protection of Native sacred sites be of paramount importance. They felt that working together was critical for any protection measures to succeed. One comment suggested that the Forest Service employ a tribal liaison to insure that sites are protected.

Response: We agree that protection of these sites is very important. All alternatives, except Alternative 5 (No Action), include updated heritage direction for sacred site identification and management. These changes include strong direction for communicating and working with tribal governments.

Comment: Some respondents felt that the Forest Service should seek National Historic Landmark designation, or otherwise protect, certain historic sites. Sites mentioned included the World War II site at Hunter Bay, the Russian Colonial sites at Salmon Lake, and the site near the falls of Redoubt Lake.

Response: We will share this information with our Heritage Program Manager but landmark designation is outside the scope of the Forest Plan Amendment.

Comment: One respondent felt that the Forest Service listens more to other agencies and organizations than it does to tribal governments indicating a bias.

Response: The Forest Service does not believe this to be the case. We continue to consult and communicate with tribal governments, as well as other agencies and organizations.

Comment: Some respondents expressed concern about timber harvest and new road and trail development and the potential impacts on sacred and traditional hunting, gathering and fishing sites. They wanted to be informed if new development was being considered.

Response: New development or other site-specific projects would only occur after project level analysis that includes public involvement and tribal consultation.

Comment: One respondent stated that the Forest Service needs to not only guard against future adverse impacts to native allotments but also should restore allotment lands damaged by timber harvest and road building.

Response: Native allotments are private land and beyond the scope of this Amendment.

Comment: One tribal corporation felt that the Proposed Forest Plan should have additional requirements related to sacred sites, greater specificity of disclosure, no confidentiality requirements, and a requirement to provide an annual report in person to the board of directors.

Response: The Proposed Forest Plan is consistent with updated Forest Service direction on management of sacred sites and consultation.

Lands

Comment: One comment stated that Sealaska Corporation's remaining entitlement acreage is underestimated in Appendix C and that Section 205 of the Alaska Land Transfer Acceleration Act increased the minimum additional acreage to be allocated to Sealaska. Sealaska estimates that between 65,000 and 85,000 acres is required to complete Sealaska's Alaska Native Claims Settlement Act (ANCSA) entitlement, not 64,000 acres as the Forest Service states.

Response: We recognize that the actual final acreage to be conveyed may be unknown at this time. Based on the best information available, both the Forest Service and the USDI Bureau of Land Management (BLM) agree that approximately 64,000 acres of ANCSA entitlement remain to be conveyed to Sealaska Corporation. This includes about 20,000 acres of unconveyed lands remaining from a 1988 AFN/BLM Agreement and approximately 44,000 acres of 14(h)(8) lands resulting from the 2004 Alaska Land Transfer Acceleration Act, PL 108-452. (Using exact figures, this totals 63,622.10 acres. In addition, Sealaska may be entitled to several additional acres in selected but unconveyed 14(h)(1) sites. It is unlikely that the total would exceed 63,650 acres.)

Prior to passage of PL 108-452 in 2004, BLM and the Forest Service estimated Sealaska's remaining entitlement as being between 59,000 acres and 64,000 acres. The 2004 legislation helped verify the current estimate of 64,000 acres.

Comment: One comment stated that Appendix C underestimates the public advantages of releasing the 327,000 acres of land that are withdrawn for Sealaska selections and conveyances. This large acreage remains encumbered and restricted from commercial timber production, investment, and active management while it remains withdrawn.

Response: Those lands that are withdrawn, but not selected by Native Corporations and also those lands that are selected, but not conveyed continue to be managed by the Forest Service, with certain requirements. The actual effects or public advantages of removing the encumbrances are difficult to quantify.

On lands withdrawn, but not selected by a Native Corporation, the requirements of 43 CFR, Section 2650.1(a) apply: "Prior to the Secretary's making contracts or issuing leases, permits, rights-of ways, or easements, the views of the concerned regions or villages shall be obtained and considered …" In addition, all proceeds collected from contracts (including timber sales), leases, permits, rights-of-way, or easements on lands withdrawn for Native selection are deposited in an escrow account managed by the Bureau of Indian Affairs. Road development and habitat enhancement projects may still be authorized on these lands.

On lands that have been selected, but not conveyed, Forest Service policy is to authorize no contracts, special use permits, mineral materials permits, easements, right-of-way or other third party interests without the consent of the affected native corporation, unless specific authorization is received from the Regional Forester.

Lands that are withdrawn, but not selected, are managed by the Forest Service subject to certain restrictions but they are not encumbered to the extent that the actual selected lands are.

Comment: One comment stated that Appendix C overestimates the effect on Tongass timber harvest from the completion of Sealaska's entitlement through land exchanges and adjustments, and understates the corresponding gain in available land and timber from acres transferred to the Tongass National Forest. These effects are portrayed as much larger than a potential transfer of a similar amount of acres to "unrecognized Southeast Alaska communities."

Response: This discussion was specific to the exchange proposal as submitted by Sealaska. The effects discussion was based on an actual analysis of the exchange proposal effects. Lands transferred to the Tongass (based on the proposal) would not be available for timber production but rather, were chiefly valuable for recreation and scenic values. These impacts differ to those identified for the "unrecognized Southeast Alaska communities" proposal because that analysis was hypothetical. There are no actual parcels that can be identified and analyzed. The Sealaska exchange analysis was based on actual parcels identified by Sealaska for their timber values.

Comment: One comment stated that Appendix C ignores the positive aspects of timber lands transferred to Sealaska and the corresponding positive impact to the Southeast Alaska forest industry and economy. Lands transferred to Sealaska would still be available to support the timber industry in Southeast Alaska.

Response: As virtually all timber from Sealaska lands has historically been exported in unprocessed form, it seems reasonable to assume that timber harvest from any transferred lands would support logging and transportation-related jobs, but would be unlikely to support local or regional sawmills or smaller value-added woodworking operations.

Comment: One comment stated that Appendix C mischaracterizes the change in other land allocations and resources attributed to the completion of Sealaska's entitlement by overestimating the acreage to be conveyed and by ignoring the effects of releasing the 327,000 acres of lands withdrawn and encumbered for Sealaska selections and conveyances and the benefits associated with Roadless and other lands valued for wildlife habitat, recreation, subsistence, scenery and other public uses that would be transferred to the National Forest.

Response: The discussion in Appendix C of the Draft EIS is very specific to the land exchange proposal submitted by Sealaska Corporation. The purpose of discussing the proposed exchange in Appendix C was to give a general estimate of the effects of completing the proposed exchange. It was not intended to provide a detailed accounting of the effects. As stated in Appendix C, it would be difficult to determine the actual acreage that might be transferred without an appraisal and very unlikely that all of the lands proposed for exchange would actually be transferred. Therefore, we cannot provide a full accounting of the possible effects. While there would be a benefit to some resources from acquiring the areas Sealaska proposes to exchange to the NFS, there would be a corresponding loss of these values on the 95,000 acres Sealaska wishes to acquire.

As for ignoring the benefits of releasing the 327,000 acres of encumbered land, we estimate that approximately 171,000 acres are encumbered by Sealaska selections, not 327,000 acres. We also estimate that approximately 64,000 acres of these selected lands would actually be conveyed to Sealaska Corporation, considerably less than the 95,000 acres Sealaska proposes to acquire. As noted in an earlier response in this section, the management restrictions on lands withdrawn but not selected are less than the comment suggests.

Comment: One comment stated that the adjustment to suitable timber land base shown on page 3-226 of the Draft EIS is an underestimate if the Forest Service used the 171,000 acre figure rather than the entire 327,000 acres encumbered within the Sealaska withdrawal areas. The effects to the timber program of resolving entitlement would be positive because the encumbrance on the remaining 327,000 acres would be removed and these acres could be managed for timber.

Response: As noted in the response to the preceding comment, the Forest Service believes that 171,000 acres is correct and the management restrictions that apply to withdrawn but not selected lands are less restrictive than the comment author states.

Comment: One comment stated that Appendix C erroneously suggests that heritage, karst and cave, and subsistence resources and uses could be adversely affected by conveyances to Sealaska because of differences in legal requirements applicable to Native Corporations compared to NFS lands. The comment notes that this suggestion ignores Sealaska's established leadership in heritage resource protection and in land stewardship.

Response: This discussion was specific to the land exchange proposal submitted by Sealaska Corporation. There were no assurances in the proposal or in discussions with Sealaska that resources on lands to be exchanged to Sealaska would be protected to the same degree as under current NFS management. The legal requirements for resource protection on NFS lands are different from those on private land. Information about the resource values on lands for potential exchange to the United States by Sealaska has been added to the Final EIS.

Comment: One comment stated that Appendix C does not recognize that Section 22(f) of ANCSA was included to provide for the adjustment of Native Corporation land conveyances and that legislative adjustments to ANCSA will continue until entitlements are resolved to meet the statute's original promise.

Response: Section 22(f) of ANCSA allows land exchanges with Village Corporations, Regional Corporations, individuals, or the State for the purpose of effecting land consolidations or to facilitate the management or development of the land. However, land exchanges are discretionary, voluntary real estate transactions between the federal and non-federal parties. The Forest Service is not required to enter into a land exchange when presented with a proposal. This is clarified both in the *Lands* section of the Final EIS and in Appendix C.

Comment: One comment stated that Appendix C is incorrect in stating that Sealaska is not currently authorized to receive lands outside the ANCSA withdrawal areas under ANCSA since ANCSA (Section 22[f]) clearly authorizes Sealaska to acquire lands outside the withdrawal areas through exchange. In addition the Appendix incorrectly indicates that exchanges generally must be for equal appraised market value. Both ANCSA and ANILCA contain authority for exchanges found to be in the public interest to take place for other than equal value.

Response: The Forest Service disagrees with the statement that Sealaska is currently authorized to receive lands outside the ANCSA withdrawal areas because of Section 22(f) of ANCSA. As noted in the preceding response, Section 22(f) of ANCSA allows for land exchanges with Native Corporations. Hypothetically, Sealaska could receive land outside of the withdrawal areas through a land exchange. Land exchanges are discretionary and voluntary. Currently, there is no binding land exchange agreement in effect between the Forest Service and Sealaska Corporation.

Generally, land exchanges are on an equal value basis and cash payments can be used to equalize land values up to 25 percent of the appraised value of the federal land. It is also correct that both ANCSA in Section 22(f) and ANILCA in Section 1302(h) provide that exchanges shall be based on equal value and contain provisions for cash equalization, except that exchanges can be made for other than equal value when the parties agree, and the Secretary of Agriculture determines that it is in the public interest.

Comment: One comment stated that Appendix C treats Sealaska's land entitlements and adjustment proposal as a negative encumbrance that the Forest Service will address grudgingly

and fails to recognize that completing conveyances of land to Sealaska in a sustainable configuration is an entitlement under ANCSA.

Response: The Forest Service recognizes Sealaska Corporation's right to receive its full entitlement under ANCSA and will continue to work with the BLM in processing conveyance documents for selected lands. Appendix C has been reviewed and edited in response to these concerns.

Comment: One comment stated that many of the "defects" in Appendix C also appear in the Draft EIS. The cumulative effects sections in the Draft EIS overestimates the potential adverse effects and underestimates the benefits of timber harvest on Sealaska and other Native Corporation lands by not adequately recognizing the protective BMPs that Sealaska and other owners apply.

Response: While the Forest Service agrees that the BMPs are beneficial, management on NFS lands provides a higher degree of resource protection and these differences were considered in the effects analyses included in the Draft EIS.

Comment: One comment stated that the statement on page 3-223 of the Draft EIS that a revision of the Forest Plan would be required to accommodate an exchange with Sealaska is erroneous. They noted that the Forest Plan provides for land exchanges and other adjustments.

Response: The Proposed Forest Plan does provide for land exchanges and other types of land adjustments. The referenced statement has been clarified to indicate that implementation of the Sealaska land exchange proposal would likely require a Forest Plan Amendment or Revision, based on the magnitude of the resulting changes in LUDs.

Comment: One comment stated that Appendix C did not adequately depict the real effects of the identified potential land exchanges.

Response: The purpose of Appendix C was to show that a number of Congressional bills for land conveyance and land exchanges have been proposed and that any of the proposals to convey land to the State or to Native Corporations, if enacted, could have a major impact on the mix of goods and services that the Tongass provides.

Many of the proposed land exchanges are unlikely to occur or occur exactly as depicted. Land exchanges are discretionary, voluntary real estate transactions between the federal and non-federal parties. The Forest Service is not required to enter into a land exchange when presented with a proposal. Before an exchange could occur a detailed environmental analysis, including public involvement, would have to be done. Due to the magnitude of these potential exchanges and their potential impact on the mix of goods and services, a Forest Plan Amendment would also likely be needed. We have updated Appendix C for the Final EIS and improved the analysis based on the comments received. Please keep in mind that Appendix C was not intended to be a full disclosure of site-specific environmental effects. That will come later as described above.

Comment: One comment stated that the 1995 Greens Creek Land Exchange included a 25 percent royalty paid to counties. Since there are no counties in Southeast Alaska, if there are any associated royalties, the City of Angoon should receive a share.

Response: This issue is beyond the scope of this Forest Plan Amendment.

Comment: One comment stated that the Forest Service should support hydroelectric power development in Angoon, where it is needed for economic development and to support local lifestyles.

Response: A hydroelectric project is currently being analyzed in an EIS. The Draft EIS was issued in April 2007 and the Forest is working on the Final EIS. This is a separate process from this Forest Plan Amendment and will continue regardless of which alternative is selected.

Comment: One comment stated that many of the provisions in the Plan Amendment are inconsistent with ANILCA (Off-Highway Vehicle [OHV] use restrictions, limits on the type of public recreation allowed in the wilderness, and limits on group size, restrictions on fish and wildlife management projects in Wild and Scenic River corridors, Research Natural Areas, and Experimental Forests).

Response: The travel management standard was revised in the Proposed Forest Plan to ensure that the plan did not make any travel management decisions. These decisions are made through local travel management plans. However, the Forest Service does have the authority to restrict access and use for overall sound management of public lands and to meet other laws and objectives. We believe that the proposed alternatives are compatible with ANILCA. ANILCA recognizes the need to be consistent with other laws such as the wilderness protection measures found in the Wilderness Act, the multiple use mandate found in the Multiple Use Sustained Yield Act, as well as the National Forest Management Act and TTRA. These laws give the Secretary of Agriculture considerable flexibility to provide public benefits and provide for sound management of public lands.

Consistent with Section 810 of ANILCA, the Final Proposed Forest Plan has been evaluated for potential effects on subsistence uses and needs. A cumulative effects analysis of resource developments on subsistence resources is included in the *Subsistence* section of the Final EIS. Two actions included in Section 810 were completed for the Draft EIS: (1) giving notice to the appropriate State agency, local committees and regional councils; and, (2) giving notice of, and holding, “a hearing in the vicinity of the area involved.” Because the area is the entire Tongass National Forest, such hearings were held in 23 communities throughout Southeast Alaska for the Draft EIS.

The plan does not authorize any land-disturbing activities. The continuation of subsistence opportunities, and reasonable steps to minimize effects on subsistence resources, are provided for, in each alternative, by the Forest-wide standards and guidelines for subsistence, as well as related standards and guidelines for riparian areas, fish, and wildlife. Many important subsistence areas were assigned LUDs that exclude timber harvesting. In addition, the beach and estuary fringe Forest-wide standards and guidelines apply to all beach fringe and estuarine areas not under more restrictive designations. Adverse impacts to subsistence uses and resources are minimized though these measures. Potential site-specific effects on subsistence uses and reasonable ways to minimize these effects will be considered and analyzed during project-level planning.

Minerals

Comment: A number of comments stated support for the mineral industry and noted that the industry history in Southeast Alaska included the creation of family wage jobs, as well as the provision of other economic benefits to communities. Comments also noted that mining occurs where economic deposits are found and expressed concern regarding reasonable access and cost of entry due to more restrictive LUDs. Some comments requested that the Forest Service devote resources to identifying and better understanding mineral resources on the Forest. Others were concerned about access to patented mining claims in Inventoried Roadless Areas.

Response: The Forest-wide standards and guidelines for Minerals and Geology support mineral development. The Forest Service also engages in minerals and geology-related research, with the extent of this research dependent on available funding. Mineral Resources, including the laws and regulations that provide for access to valuable mineral deposits, are discussed in the *Minerals* section of the Final EIS.

For all seven alternatives, 25 percent of the acreage of identified mineral resources is in areas that have been withdrawn. Alternatives 7 and 4 have the fewest acres of identified mineral resources in LUD allocations potentially causing higher costs for their exploration and development, and Alternative 1 by far the most. The other four alternatives fall between these two in a fairly close grouping near the middle of the range. None of the alternatives would prohibit reasonable access to patented mining claims.

Comment: Several comments suggested that compliance of the Proposed Forest Plan with the Mining and Mineral Policy Act of 1970 should be evaluated. This act, along with the General Mining Law of 1872, Federal Land Policy and Management Act of 1976, and the National Materials and Minerals Policy Research Act of 1980 were cited by several respondents in support of mineral development.

Response: The Proposed Forest Plan and the minerals analysis presented in the Draft and Final EIS documents are consistent with the Mining and Mineral Policy Act of 1970. The *Minerals* section of the Draft and Final EIS documents specifically states that the Forest Service: "recognizes that minerals are fundamental to the Nation's well being and, as policy, encourages the exploration and development of the mineral resources it manages. The Secretary of Agriculture has provided regulations (36 CFR 228) to ensure surface resource protection, while encouraging the orderly development of mineral resources on NFS lands."

Mineral Resources, including the laws and regulations that provide for access to valuable mineral deposits, are discussed in the *Minerals* section in the Draft and Final EIS documents.

Comment: Several comments were opposed to mineral exploration and development on Duke Island and suggested the area be withdrawn from mineral entry.

Response: No new withdrawals are proposed under any of the proposed alternatives. Future exploration and development on and around Duke Island would be subject to regulation by 36 CFR 228. For projects requiring a federal action (such as approval of a mining plan of operations), impacts to surface resources would be analyzed and disclosed on a site-specific basis, as required under NEPA.

Comment: One comment objected to the term "hardrock" when referring to locatable minerals and pointed out that many locatable minerals are recovered by placer mining.

Response: The term "hardrock minerals" is commonly used synonymously with locatable minerals. The comment is correct that locatable minerals are found in, and recovered from, placer deposits. The text in the Final EIS has been edited to make this clear.

Comment: One comment expressed concern related to the permitting delays of a specific project, and the process in general, as a result of public appeals.

Response: Project specific analysis, public disclosure, and response to public concerns are required of all projects as required by law. The regulations under which operating plans are processed would not be changed by any of the alternatives considered in this analysis and are beyond the scope of this analysis.

Comment: One comment suggested changing a reference to the U.S. Bureau of Mines, as it was abolished in 1996.

Response: The text in the Final EIS has been updated to reflect this.

Comment: Some comments disagreed with the *Minerals* cumulative effects finding that: "Other than mineral resources that are currently under development (specifically, the Kensington deposit), the Forest Service does not have sufficient information to identify any specific mineral development as reasonably foreseeable." They pointed out that exploration has been ongoing throughout the Tongass for years. They specifically noted the Niblack property, near Ketchikan.

Response: The Forest acknowledges that exploration is ongoing in varying degrees throughout the Tongass. As the likely development of such prospects is dependent on several factors, including the findings of exploration programs, metal prices, and private funding, it is not possible for the Forest to determine which projects are reasonably foreseeable at this time.

Comment: Some comments either opposed mining or expressed concern over potential impacts, such as water quality degradation or acid mine drainage.

Response: All existing and future exploration and development on the Forest are subject to regulation under 36 CFR 228 for the protection of surface resources. For projects requiring a federal action (such as approval of a mining plan of operations), site-specific impacts to surface resources, including wildlife and cultural resources, would be analyzed and disclosed as required by NEPA. Specific projects already analyzed and approved under NEPA are outside of the scope of this document.

Recreation, Tourism and Scenery

Comment: Several comments noted that restrictions on OHV use on inactive logging roads primarily deny local residents looking for local access and have a negative effect on local economies. Commercial operators, in contrast, are allowed wilderness access. Closing logging roads to OHV access to protect wildlife seems disingenuous when the same wildlife are regularly viewed from aircraft.

Another comment noted that all roads on the Tongass are currently open for OHV use and there has been an exponential increase in OHV use of roads on Kuiu, Baranof, and Chichagof islands where there are extensive road systems. The comment author notes that illegal OHV use of closed roads is increasing, as are detrimental effects to the environment. Others requested that OHV access be allowed only where specifically permitted.

Response: Each Ranger District will work with the state and local governments, tribes, and the public, as required by NEPA in developing their access and travel management plans. The Standard in the Final Proposed Forest Plan has been updated to state: "Each ranger district will designate the roads, trails, and areas open to motor vehicle use on a motor vehicle use map. All operations must be in accordance with those designations."

The revised Forest-wide Recreation and Tourism Standards and Guidelines also include the following directive:

3. Provide a diversity of OHV recreational opportunities across the forest where consistent with the criteria in FSM 2355 and 36 CFR 212, which include:
   a) The use is consistent with established land management and resource objectives.
   b) The use is consistent with the capability and suitability of the resource.
   c) There is demonstrated demand which cannot be better satisfied elsewhere.

More information is provided in Chapter 4 of the Final Proposed Tongass Forest Plan in the section that addresses Recreation and Tourism.

Comment: A number of people at the public hearing in Juneau commented that there is presently nowhere in the vicinity of their community where they are legally allowed to ride OHVs or snowmobiles. They requested that there be areas designated on the Forest for OHV use. Comments noted that there are more than 100 hiking trails and no authorized OHV trails/roads. One person commented that where there are potential conflicts between motorized and non-motorized uses, different uses should be authorized at different times. Others noted that the Forest Service should plan for balanced use between motorized and non-motorized uses. Others commented that hiking trails in the Juneau are fully used by hikers, bikers, runners, mountain climbers, and other non-motorized users and requested that OHV use not be permitted on the existing trail system in this area. Concern was also expressed about the impact OHV use would have on fragile soils and ecosystems along the existing trails.

Response: The Proposed Forest Plan is programmatic, meaning that it provides forest-wide management direction. Management direction with respect to OHV use is provided in the Forest-wide Recreation and Tourism Standards and Guidelines in the Final Proposed Forest Plan (Chapter 4). Site-specific activities, such as the designation of trails for OHV use, are beyond the scope of this document and are instead addressed at the local level. The issue of OHV use and access is addressed in the access and travel management plan that will be prepared for the Juneau Ranger District.

Comment: A number of comments expressed concern about resource damage caused by OHV use and requested that the Forest Service ensure that OHV use does not negatively impact wetland and habitat values. Potential negative impacts include fish habitat damage, the introduction of invasive species, alteration of successional pathways, and degradation of wetland vegetation, soils, and hydrology.

Response: As noted in response to the first comment in this section, each District is analyzing how to provide reasonable access for subsistence and other uses in their access and travel management plans and accompanying NEPA documents. See the earlier response and the Final Proposed Forest Plan for further information.

Comment: A number of comments requested that the Forest Service maintain and fix the existing cabins on the Tongass and also consider opening new cabins. In addition to this general request, comments were also submitted with respect to specific cabins that comment authors were particularly concerned about. These included the Karta River, Kook Lake, Smugglers Cove, and Helm Bay cabins.

Response: The Proposed Forest Plan provides broad strategic direction for overall management of the Forest. The Forest-wide Recreation and Tourism Standards and Guidelines in the existing and Proposed Forest Plans, for example, direct the Forest Service to identify opportunities to enhance existing, and provide additional, recreation opportunities, including those related to public recreation cabins. The Proposed Forest Plan also identifies where cabins and other types of recreation and tourism-related development can take place on a Forest-wide basis based on LUD classifications. Cabins are considered minor developments in the existing and Proposed Forest Plans. Minor developments are considered compatible with the Semi-Remote Recreation, Recreational River, Scenic Viewshed, and Scenic River LUDs and may be allowed in 10 other LUDs based on a case-by-case evaluation. Site-specific projects or activities related to specific existing or proposed cabins are addressed at the project level. More information is provided in Section 4 of the Final Proposed Tongass Forest Plan in the section that addresses Recreation and Tourism. Cabin maintenance and construction depends on funding from Congress or other sources.

Comment: Several comments requested that the Forest Service do a better job of maintaining and marking existing trails and consider creating new trails for local residents, as well as visitors, particularly in areas surrounding communities where the majority of existing recreation opportunities require a boat to access. Some respondents identified trails that they were particularly concerned about. These included the existing Beaver Lake Trail and the potential for a new trail from Skagway to White Pass City.

Another comment noted that existing logging roads could be used to provide mountain biking and hiking opportunities in the vicinity of communities. The same comment author expressed concern that the road providing access to a favorite hiking trail was not adequately maintained.

Response: As noted in response to similar requests with respect to public cabins (see the preceding comment and response), the Final Proposed Forest Plan provides broad strategic direction for Forest-wide management. Site-specific projects and activities related to trails are addressed at the project level. The revised Forest-wide Recreation and Tourism Standards and Guidelines include a number of directives that pertain to local recreation facilities and planning. Trail maintenance and construction depend on funding.

Comment: One comment identified the following concerns with respect to recreation encounter rates. Are the recreation encounter rates identified in the Proposed Forest Plan meant to guide management activities, with action taken to reduce use if rates are exceeded, or are they meant as guidelines for visitor expectations? Using encounter rates to guide management activities across the board ignores the fact that other factors—such as weather or mosquitoes—may be equally or more important in measuring user satisfaction. Similarly the impact of encounters may vary based on terrain and vegetation.

Response: The recreation encounter rates are identified by ROS class in the Final Proposed Forest Plan in the proposed ROS standards and guidelines in Appendix I. The encounter rates have been updated in the Final Proposed Forest Plan for the Primitive, Semi-Primitive Non-Motorized, and Semi-Primitive Motorized ROS settings. Encounter rates for the other ROS settings (Roaded Natural, Roaded Modified, Rural, and Urban) are unchanged from the current Forest Plan. The main purpose for these updates is to clarify commercial group sizes in these settings. The identified encounter rates are generally intended to guide management activities and may also help guide visitor expectations. Action may be taken on a case-by-case basis if these encounter rates are exceeded. Group size guidelines will be enforced.

Comment: One comment observed that the niche market for eco-tourism is likely to remain unaffected because none of the alternatives would affect Wilderness and LUD II designations and all alternatives continue to set aside vast acreages of remote and semi-remote recreation. The comment also noted that only road-based recreation opportunities are likely to vary by alternative. Other recreation activities are likely to remain unchanged. Opportunities for expanded road-based recreation could occur under Alternative 4 through 7, but are not likely to occur under Alternatives 1 through 3.

Response: The potential impacts of the proposed alternatives on recreation and tourism are evaluated in the *Recreation and Tourism* section of the EIS. The alternatives would result in shifts toward the roaded end of the ROS based on the amount of timber harvest and associated road construction that could occur. Potential road construction would be greatest under Alternatives 4 and 7. However, while there would be a relative increase in new roads, with access provided to presently undeveloped areas, nearly all new roads would be closed following harvest and not available for use by highway or high-clearance vehicles.

Comment: Several comments noted that a survey of Tongass hunting and fishing guides showed that two-thirds of them support a prohibition on logging and new road building in roadless areas. Some comments also noted that:

> **"In the view of some long-term guides operating in the Tongass, we are nearing a "now or never" point in regard to how much habitat can be lost and still be able to sustain populations of fish and game that will allow for future opportunities for hunting and fishing on the Forest."**

Response: The comments did not provide any further information with respect to the cited survey, but this sentiment has been expressed by a number of people providing comments on the Draft EIS. Alternative 1 was modified between the Draft and Final EIS documents to reduce the amount of logging and road building, with all Inventoried Roadless Areas and a number of areas of concern, such as Kuiu Island, removed from the suitable land base. The potential effects of the proposed alternatives on fish and wildlife populations are evaluated in the *Fish* and *Wildlife* sections in the EIS.

Comment: Some felt that the Tongass would be better to emphasis recreation use rather than timber harvest. One comment noted that the Forest Service should manage the land base to meet recreation demand.

Response: The Final EIS shows that recreation is a large and growing use of the Forest. Each alternative allows for this trend to continue. The existing and Proposed Forest Plans provide management direction for the Forest as a whole. The Forest-wide Recreation and Tourism Standards and Guidelines provide recreation and integrated resource planning direction. This includes direction for land managers to identify opportunities to enhance existing, and provide additional, recreation activities, opportunities, and services where desirable to meet local or Forest-wide recreation demands.

The Forest Service uses the ROS system to inventory existing and potential recreation opportunities on the Forest. The *Recreation and Tourism* section in the EIS assesses the potential impacts of the proposed alternatives on recreation and tourism in terms of ROS settings and identified recreation places.

Comment: One respondent stated that local tourism businesses should be permitted to use the forest rather than businesses associated with cruise ships where the same service is being offered. Another comment encouraged the Forest Service to give priority to small businesses offering recreation opportunities on the Tongass because large-scale tourism related to increased cruise ship activity can be very difficult to manage and large scale users tend to drive out smaller business users.

Response: The Proposed Forest Plan provides broad strategic direction for Forest-wide management with respect to Recreation and Tourism and special use permits. Forest-wide direction for public outfitter/guide services is identified in Section 4 of the Final Proposed Forest Plan in the section that addresses Recreation and Tourism. In general, the services of outfitter/guides should facilitate use, enjoyment, understanding, and appreciation of National Forest recreation settings. The Final Proposed Forest Plan direction does not specify that local businesses should be given preference over cruise ship-related activities or that small users should be given preference over large (cruise ship-related) users.

Potential permit holders are evaluated on a case-by-case basis through the special use permitting process, which generally does not allow for a business size preference.

Comment: Concern was expressed that the Wilderness direction was being changed to discourage dispersed recreation use in pristine areas as a way to resolve conflicts in areas of concentrated use.

Response: The intent of this direction is to maintain the solitude found in pristine areas. The first choice for resolving conflicts in areas of concentrated use would be to relocate that use to areas outside the wilderness boundary.

Comment: One comment noted that the Proposed Forest Plan's Recreation and Tourism Standards and Guidelines acknowledge that commercial tourism may conflict with local residents use of the same area, but do not require the Forest Service to consider the off-site impacts of activities permitted on NFS lands. The comment notes that the Forest Plan should provide an adequate framework to protect local residents and nonmotorized recreationists from commercial recreation–related noise. The Recreation and Tourism Standards and Guidelines should clearly state that "one consideration to be weighed by the Forest Service in promoting additional commercial tourism use of the Forest is the impact such increased activity could have on Juneau or other similarly situated communities." The comment also stated that "natural quiet" should be identified as a forest value or resource.

Response: The Forest Service believes that the Final EIS and Final Proposed Forest Plan adequately recognize that noise associated with commercial and other motorized recreation can have detrimental effects on other Forest users, as well as on surrounding communities. Although not explicitly spelled out in the Final Proposed Forest Plan in the way suggested in the comment, the potential noise impacts associated with commercial tourism use are an important element of project-specific evaluations.

Comment: One comment expressed concern about a proposed LUD change that would occur north of Juneau under all of the action alternatives. This change would be from Remote Recreation to Semi-Remote Recreation. The comment noted that this area includes the Herbert Glacier and Eagle Glacier recreation areas, among others. The comment also noted that the rationale for this proposed change is not explained in the Draft EIS and was concerned that the change is proposed to allow an expansion of helicopter landing sites in the area. Any changes to helicopter operations on the Juneau Icefield should be part of a separate action, as they were in 2002.

Response: The snow accumulation zone on the Juneau Icefield has retreated to higher elevations perhaps as a result of climate change. This has rendered a number of minor development sites (e.g. dog sled camps) unsuitable for use as the thinning snow layers expose crevasses during the middle of the operating season. This hazard requires removal of the camps to a more suitable location, generally higher in elevation where there is more snow. The Remote Recreation LUD does not allow development of minor developments, like dog sled camps, while the Semi-Remote Recreation LUD would allow consideration of this type of use.

This change in the LUD boundaries would allow the Forest Service to consider moving minor developments into areas where standards and guidelines for the previous LUD would not have allowed this use. It should be noted that this change in LUD boundaries would not affect the Forest Service's ability to allow an expansion of helicopter landing sites in this area, because glacier landing tours are allowed in both the Remote Recreation LUD and Semi-Remote Recreation LUD under the current and Proposed Forest Plans. This explanation has been added to the *Recreation and Tourism* section of the Final EIS.

The 2002 ROD for the Helicopter Landing Tours on the Juneau Icefield will be reviewed for consistency with this Amendment, but any changes to the 2002 ROD would have to be made in compliance with applicable NEPA regulations and Forest Service policy.

Comment: Some respondents expressed concern regarding the impacts of timber harvest on scenic resources and ultimately on the tourism/visitor industry. They urged that this be a major consideration in the decision making process.

Response: The Final EIS discloses the potential impacts of timber harvesting on scenic resources (see the *Scenery* section). This was a major consideration in the design of alternatives. Even Alternative 7, with the highest amount of timber harvest, was designed to protect key seen areas. The basic scenery management information, including seen and unseen areas from high visitation sites, was updated as part of this analysis.

Comment: One respondent noted that while they had heard stories that tourists on cruise ships do not notice clearcuts, this was not the case with the passengers who traveled on the boats they operate on the Tongass under a special use permit. The respondent noted that they receive lots of comments from customers concerned about clearcuts.

Response: As part of the Forest Plan Amendment process, the Forest Service has updated the Seen Area analysis and Visual Priority Routes and Use Areas for the Tongass (see Appendix F of the Final Proposed Forest Plan). Scenery is emphasized from these areas. Please note that many of the clearcuts visible from ships are on non-NFS lands.

It seems reasonable to assume that timber harvest may be more visible from some locations than others and that some visitors are more sensitive to the visual evidence of clearcut or other harvesting than others are. The potential impacts to Visual Priority Routes and Use Areas are evaluated for each alternative in the *Scenery* section of the EIS. In addition, site-specific visual analysis is conducted at the project-level for all projects.

Roadless Areas and Wilderness

Comment: One respondent felt that the method to map and delineate Inventoried Roadless Areas (pg 3-357 of the Draft EIS) was illogical as it failed to recognize the difference between pristine roadless watersheds and parts of developed watersheds that do not have roads.

Response: The process for defining and mapping Inventoried Roadless Areas has been established for many years and was used in the 2003 SEIS. The Forest Service recognizes the potential difference in value between roadless areas and this is reflected in our alternative development and analysis. There is no policy that would have us not consider areas as roadless just because they happen to be in a watershed that has some level of past management activity.

Comment: Several comments suggested that the Proposed Forest Plan eliminate the roadless area designation.

Response: This is beyond the scope of this Forest Plan Amendment. The identification of roadless areas and their use as an inventory is well established in Forest Service policy. Management of these areas is a significant issue that must be addressed.

Comment: Many respondents asked that roadless areas be protected (from timber harvest, oil and gas development, and road building). Some specified that all roadless areas be protected,

while others were very broad in just saying the Tongass needed to be protected. Some listed specific "special areas" they wanted protected. Many asked for wilderness designation for these areas. One comment stated that the alternatives should include recommendations for additional Wilderness.

Response: Management of Inventoried Roadless Areas was one of the three key issues used to develop alternatives. Alternatives were designed to meet different levels of timber output while limiting entry into roadless areas. In each case, the more sensitive, higher value roadless areas were avoided as much as possible. In addition, Alternative 1 was modified in the Final EIS to ensure that all Inventoried Roadless Areas are outside the land base designated suitable for timber harvest. As the timber output level increases in the other alternatives, roadless areas were added to the suitable land base as necessary, starting with those within logical extensions of the current road system working up to higher valued roadless areas necessary to achieve the higher timber output levels in Alternatives 4 and 7.

Consideration of wilderness designation was outside the scope of this analysis. Recommendations for adding wilderness to the Tongass National Forest were evaluated in the 2003 SEIS (USDA Forest Service 2003). It was concluded that such recommendations were not needed because there was no compelling need for additional wilderness on the Tongass at that time. This decision was reviewed as part of this EIS process to ascertain if that conclusion is still valid today.

Comment: Several respondents felt that the National Roadless Rule should be reinstated to apply to the Tongass.

Response: While the application of a national policy is beyond the scope of this analysis, Alternative 1 has been modified to exclude timber harvest and road building from Inventoried Roadless Areas.

Comment: One respondent felt that the Draft EIS treated Designated Wilderness and Inventoried Roadless Areas as if they were the same, even though they are clearly different.

Response: The Forest Service recognizes the significant difference in management options between Wilderness and roadless areas. Wilderness has its own LUD while roadless areas are allocated to various LUDs depending upon the alternative. While management options are clearly different, these areas are viewed similarly in terms of current wildlife habitat and biodiversity analysis. They both provide unroaded, unmodified habitat that is valuable for some species.

Comment: One comment recommended that 66 Tongass rivers be designated as Wild and Scenic Rivers in accordance with the proposal prepared by the Southeast Alaska Conservation Council and the Tongass Rivers Coalition: Tongass Rivers: the Lifeblood of the Rainforest ("Citizens' Proposal"). The comment noted that these rivers and those proposed as Wild and Scenic in the current plan should have 0.5-mile (rather than 0.25-mile) buffers to protect their outstanding values. The same comment also expressed support for the Wild and Scenic rivers proposed in the 1997 ROD to be designated as such. Where there is conflict between the classifications in the 1997 ROD and the "Citizens' Proposal" the comment author requested that the "Citizens' Proposal" take precedent.

Response: Wild and Scenic River designations are made by Congress and are outside the scope of this Amendment. The 1997 Forest Plan ROD recommended to the Chief of the Forest Service over 30 rivers and lake systems be forwarded to Congress for designation. The current list of recommended river systems is not being considered for change in this Amendment.

Subsistence

Comment: Some respondents stated that hunting and fishing access are provided for all user groups and felt that the implication that roads have negative impacts on hunting is incorrect.

Response: The EIS states that under ANILCA, only rural Alaska residents qualify for subsistence hunting and fishing on federal lands. The Final Proposed Forest Plan directs the Forest to "maintain reasonable access to subsistence resources as required by ANILCA, Section 811 and to address subsistence concerns when developing road management objectives for forest roads" (SUB-1, I). The Final EIS states that road networks provide greater access to areas previously unconnected and can affect subsistence both positively and negatively by providing access, dispersing hunting and fishing pressure, and creating the potential for increased competition.

Comment: Some comments stated that timber harvest near towns has forced subsistence users (i.e., spruce root basket weavers, deer hunters) to move further out. They believe that debris and felled trees in harvest areas have negative effects on hunting.

Response: The EIS looked at the likely effects of the different alternatives on subsistence resources in two parts: effects on subsistence resources and uses important to each rural community and overall, on a Forest-wide basis, based on general considerations of effect in terms of abundance and distribution, access, and competition. The 1997 Forest Plan EIS included discussions of 32 Southeast Alaska communities with a state land-selection base. This EIS provides brief updates of the affected environment section of the community discussions, where applicable. Each community assessment provides potential effects by Community Use Area, Economy, and Subsistence. The Final Proposed Forest Plan contains Forest-wide standards and guidelines; for example, directing the Forest to locate and manage Forest management activities that consider impacts upon rural residents who depend upon subsistence uses of the resources of the NFS lands.

Comment: It is important to some respondents that the Forest Service ensure that fish and wildlife resources do not "reach a point where continued levels of harvest would jeopardize stock to unsustainable levels and result in use-priority restrictions."

Response: With regard to this Proposed Forest Plan, deer is the only subsistence resource that is potentially significantly affected by any of the alternatives. The EIS discusses the potential effects on subsistence by alternative and within the individual community assessment discussions, as appropriate. Different alternatives may result in a significant restriction of the subsistence uses of deer, due to potential effects on abundance and distribution, and on competition. However, the Subsistence, Fish, and Wildlife Forest-wide standards and guidelines are designed to help ensure that fish and wildlife resources do not reach a point where continued levels of harvest would jeopardize stocks to unsustainable levels and result in use-priority restrictions. The Forest Service will seek to maintain abundance and distribution of subsistence resources necessary to meet subsistence user needs. The Forest Service will also continue to consult with the Southeast Alaska Federal Subsistence Board. If, for some reason, population levels drop to where restrictions in use need to occur (i.e., severe winter such as occurred in 2006/07) the Forest Service would follow the regulatory process, working with the Federal Subsistence Board.

Comment: A number of comment stated that the Final EIS should take a closer look at the cumulative effects of past, present, and future logging on deer and other subsistence resources on Prince of Wales Island. Comments also stated that the Forest Service should consider changing LUD assignments in places like Craig or Hydaburg that are surrounded by lots of private and public logging.

Response: The Forest did take a good look at the cumulative effects of past, present, and future management on deer and other subsistence resources on Prince of Wales Island. Specific to Prince of Wales Island, the EIS assessed the potential impacts for Coffman Cove, Craig, Edna Bay, Hollis, Hydaburg, Kasaan, Klawock, Naukati, Point Baker, Port Protection, Thorne Bay and Whale Pass in the Communities subsection of the *Subregional Overview and Communities* section. Summary tables are provided for each community, comparing the acres allocated to types of LUD group by alternative. For example, LUD groups in Coffman Cove's community use area (1,228,786 acres total) would range from: wilderness – 122,719 acres; mostly natural – 758,086 acres, moderate development – 98,294 acres, intensive development 249,686 acres under Alternative 1 to wilderness – 122,719 acres, mostly natural – 218,709 acres, moderate development – 340,708 acres, intensive management – 546,652 acres under Alternative 7. A summary is provided of the potential impacts on subsistence resources by alternative for each of the community use area. If, as time goes on, it looks like a change of LUD is necessary, the Forest would follow its standard amendment process for the Forest Plan.

Comment: Some comments stated that Forest Service roads open up subsistence areas to outside use which often has a negative impact on local users and resource sustainability. They would like the Forest Service to study the effect that building roads adjacent to sensitive subsistence areas has on subsistence resources. Another comment said the Final EIS needs to address the effects of competition on subsistence use.

Response: The Forest has looked at the potential impacts or effects of road building on subsistence resources, areas, and users. The Forest acknowledges in the EIS that road networks provide greater access to areas previously unconnected and can affect subsistence both positively and negatively by providing access, dispersing hunting and fishing pressure, and creating the potential for increased competition. Monitoring and evaluation of wildlife, fish, and subsistence comprise an essential feedback mechanism within an adaptive management framework to keep the Plan dynamic and responsive to changing conditions. Monitoring population trends and their relationship to habitat changes for management indicator species (MIS) (a lot of which are subsistence species), as well as analyzing if the effects of management actions on subsistence users in rural Southeast Alaska communities are consistent with those estimated in the Final Proposed Forest Plan, will provide information to be used to determine whether changes in management direction are needed. Thus, the Forest is studying the effect that building roads adjacent to subsistence areas might have on subsistence resources and will work with the appropriate state agencies, local communities, the Southeast Alaska Federal Subsistence Regional Advisory Council, and State Fish and Game Advisory Committees to analyze potential changes.

The EIS does address competition on subsistence use. Competition for the more abundant wildlife and fisheries resources near rural communities results from a combination of factors. Examples include fish and game regulations, mobility, and the natural distribution of game species across the Tongass, decreases in resource populations because of habitat reductions, decreases in resource populations because of over-harvest, and access provided to rural communities in the form of roads, ferries, and commercial air carriers. Specific assumptions were used to analyze competition in the 1997 Forest Plan Revision Final EIS, which concluded that implementation of Alternative 11 (the selected alternative) would result in a significant possibility of a significant restriction of subsistence use by increasing competition for some subsistence resources by non-rural, as well as rural residents. The possibility of a significant restriction, resulting from a change in competition, would be the same as or less than the possibility under Alternative 11 of the 1997 Forest Plan Final EIS for Alternatives 5 and 6 evaluated in this EIS. There would be a relative reduction in risk under Alternatives 1, 2, and 3, and an increase in risk under Alternative 4 and especially under Alternative 7.

Comment: There was a concern shared by some respondents that the non-subsistence areas associated with the borough of Juneau will grow as their borough boundary grows.

Response: This concern is beyond the scope of this planning effort. However, if the borough of Juneau were to grow, there should not be a change to outlying communities with regard to rural versus non-rural designation. The Federal Subsistence Board will determine if an area or community in Alaska is rural, not the Forest Service. In determining whether a specific area of Alaska is rural, the Board shall use the guidelines provided in 50 CFR Part 100.

Comment: Some respondents from various communities believe the Proposed Forest Plan needs to include a section that better protects specific fish and wildlife stocks for subsistence purposes. They state that these are areas of concern that have developed over the past few years with respect to the State's ability to continue management of 'subsistence resources' and affect the people of these communities on the Tongass.

Response: While many of the areas identified by respondents are specific sites that are important to the subsistence users of particular communities, the Forest-wide standards and guidelines for Subsistence, Wildlife, and Fish are in place to protect fish and wildlife resources for subsistence purposes, across the Forest. The Forest will seek to maintain abundance and distribution of subsistence resources necessary to meet subsistence user needs. Monitoring population trends and their relationship to habitat changes for MIS (a lot of which are subsistence species), as well as analyzing if the effects of management actions on subsistence users in rural Southeast Alaska communities are consistent with those estimated in the Final Proposed Forest Plan, will provide information to be used to determine whether changes in management direction are needed. The Forest will continue to work with the appropriate state agencies, local communities, the Southeast Alaska Federal Subsistence Regional Advisory Council, and State Fish and Game Advisory Committees to analyze if changes need to occur with regard to specific fish populations and management activities. A proposal would then go to the Federal Subsistence Board for a determination.

Comment: Some respondents believe the Proposed Forest Plan needs to plan and provide for deer populations for subsistence and that the current deer models are weak or not applicable to large-scale, landscape-level analysis involving landscape patterns, such as sizes and location and timber stands.

Response: The Forest will seek to maintain abundance and distribution of subsistence resources necessary to meet subsistence user needs. Subsistence use is addressed specifically in Forest-wide standards and guidelines and subsistence resources are covered by the Forest-wide standards and guidelines for fish, wildlife, and riparian areas and biodiversity, among others. Fish and wildlife habitat productivity would be maintained at the highest level possible under all alternatives, consistent with the overall multiple-use goals of the current Forest Plan, with improved protection under the Final Proposed Forest Plan. In addition, each of the Forest LUDs contains direction to follow the Forest-wide standards and guidelines for Subsistence. The potential effects of the alternatives on wildlife productivity are discussed in more detail in the *Wildlife* section of the EIS. The deer model used for the Plan is a tool, used to evaluate the relative differences among alternatives in the context of a risk assessment. The Forest acknowledges that there are weaknesses or limitations in the use of this model when applied at the watershed or project planning level. It is however, the most appropriate tool for analysis over large planning areas such as the entire Tongass National Forest or at the scale of a watershed analysis area (WAA). Specific concerns raised with respect to the deer model are addressed in the Wildlife, Biodiversity and Plants section of this appendix under Deer.

Comment: One comment stated that a decline in old-growth forest wildlife habitat capability due to timber harvest on Native Corporation, Tongass, and other lands does not translate into reduced abundance of deer or other subsistence resources.

Response: The potential effects of the alternatives on wildlife productivity are discussed in more detail in the *Wildlife* section of the EIS. While it's true that after the initial years following logging, there is a rapid increase in deer forage production about 20 to 30 years after harvest, the vigorously growing hemlock and spruce shade out the understory forage during the next 100- to 150-year period. However, as stated in the EIS, it is important to note that forest management on the Tongass has produced more forage than assumed by the deer model, through the management of second growth stands. The Forest is looking at young-growth management (in cooperation with the PNW Research Station) to evaluate the potential benefits of treating pre-commercial stands to increase wildlife habitat and wood production. There are still many uncertainties related to appropriate young-growth treatment designs, specific beneficial effects of such treatments, and the implications for deer. Initial results are looking promising. However, when comparing alternatives for this EIS, Alternative 7 would not include OGR and would have the largest potential long-term effects on the availability of deer for subsistence purposes.

Comment: Some felt that the Draft EIS does not adequately recognize the importance of subsistence use taking place on the Tongass National Forest, does not provide sufficient protection for this use, and does not provide enough information to evaluate the foreseeable effects of proposed timber management and increased levels of tourism and non-subsistence consumptive use.

Response: The Forest does recognize the importance of subsistence use taking place on the Forest. There are specific Forest-wide standards and guidelines related to subsistence. Other Forest-wide standards and guidelines, such as for fish, wildlife, and riparian, provide for species habitat planning and protection, which benefit subsistence species and resources. The Forest will continue to work with the appropriate state agencies, local communities, the Southeast Alaska Federal Subsistence Regional Advisory Council, and State Fish and Game Advisory Committees to analyze if changes need to occur with regard to a specific subsistence resource and any of the Forest's management activities. The *Wildlife* section of the EIS provides an in-depth discussion of the potential impacts to subsistence resources by alternative. In addition, both the *Subsistence* and *Subregional Overview and Communities* sections of the EIS discuss potential impacts to subsistence, looking at many different factors related to Forest management.

Comment: Some believe that the Proposed Forest Plan should include a subsistence land-use designation that would protect the most important subsistence use areas for rural communities. The amended Forest Plan should plan for subsistence not just assess the effects of other plan activities on subsistence.

Response: While it's true that there is not a land-use designation specific to subsistence, subsistence resources are important to the Tongass. We think it is better to manage for subsistence on all NFS lands rather than designate certain lands to a subsistence LUD. There are Forest-wide standards and guidelines set up to protect subsistence resources. Monitoring and evaluation for subsistence is designed to make sure that our actions are not negatively impacting subsistence resources. The Forest will continue to work in accordance with ANILCA Title VIII. In addition, each of the Forest LUDs contains direction to follow the Forest-wide standards and guidelines for subsistence.

Comment: Some respondents stated that the provision for periodic harvest assessments and other studies of subsistence – included in the 1997 Forest Plan – appears to have been dropped from the Proposed Forest Plan.

Response: This provision has not been dropped. The Forest-wide standard for subsistence 1.D states: "evaluate changes in subsistence use patterns and activities in cooperation with appropriate state and federal agencies by conducting periodic surveys of fish and wildlife populations and subsistence harvest and consulting with subsistence user groups."

Comment: One respondent stated that "given the importance to the rural economy of subsistence hunting, we think impacts on subsistence should be heavily weighted when deciding on an alternative.

Response: Potential impacts to subsistence resources are one of many factors that will be taken into consideration by the deciding official when reviewing the various alternatives.

Comment: One respondent stated that the Draft EIS needs to show the relative impacts of the different alternatives. The alternatives with larger amounts of harvest (Alternatives 4 and 7) would result in larger restrictions and that the Draft EIS should also consider the impacts to important subsistence use areas as these impacts would have greater effect than impacts to less important subsistence areas.

Response: The Draft does show the relative impacts of the different alternatives. Deer habitat capability in 2005 and after 100+ years of full implementation under each alternative (expressed as a percent of the 1954 habitat capability) is displayed in table form for each of the 32 individual community assessments in the *Subregional Overview and Communities* section of the EIS,. These tables show that deer habitat capability would be potentially reduced the most under Alternatives 7 and 4, within the development LUDs. These assessments specifically address the potential effects to the WAAs that are most important for subsistence for each community based on past deer harvest patterns.

Comment: A number of respondents commented that the Draft EIS fails to demonstrate that the proposed restrictions on subsistence use are necessary, that the proposed harvest would involve the minimum amount of land necessary, or how adverse impacts to subsistence uses and resources would be minimized. A number of respondents also commented that under ANILCA Section 10 three conditions need to be determined by the head of the federal agency before any significant restriction on subsistence use may be affected.

Response: The EIS is not currently proposing a restriction on subsistence use. It states that, "the 1997 deer analysis was much in line with the earlier...analyses… It indicated that deer habitat capabilities in several portions of the Tongass may not be adequate to sustain the current levels of deer harvests, and that implementation of any Forest Plan alternative could, therefore, be accompanied by a significant possibility of a significant restriction on the abundance and/or distribution of subsistence use of deer." The EIS further states: "Under the alternatives analyzed in this EIS, the possibility of a significant restriction, resulting from a change in abundance or distribution, would be the same as or less than the possibility under Alternative 11 of the 1997 Forest Plan Revision Final EIS for five of the seven alternatives. This risk would, however, likely be higher under Alternatives 4 and 7 because these alternatives anticipate a higher level of timber harvest than the current Forest Plan (Alternative 5, No Action)."

An ANILCA Section 810 evaluation and determination is not required for approval of a Forest Plan Amendment, which is a programmatic level decision that is not a determination whether to "withdraw, reserve, lease, or otherwise permit the use, occupancy, or disposition" of National Forest land. This EIS is part of the Forest Plan Amendment process and, therefore, does not require an ANILCA Section 810 evaluation and determination.

Comment: The Tongass National Forest should collaboratively identify local subsistence and community use areas on the Tongass and incorporate these areas into an expanded protected areas strategy.

Response: The EIS looked at the likely effects of the different alternatives on subsistence resources in two parts – effects on subsistence resources and uses important to each rural community and overall or on a Forest-wide basis, based on general considerations of the effects in terms of abundance and distribution, access, and competition. The 1997 Forest Plan EIS included discussions of 32 Southeast Alaska communities with a state land-selection base. This EIS provides brief updates of the affected environment section of the community discussions, where applicable. Each community assessment provides potential effects by Community Use Area, Economy, and Subsistence. Each of the Forest LUDs contains direction to follow the Forest-wide standards and guidelines for subsistence. Additional collaboration will occur at the project- or site-specific level for District projects.

Comment: Alternative 7 is better for subsistence than is portrayed in the Draft EIS. Alternative 7 would improve subsistence because of better access and timber harvest is much better for deer than is indicated in the Draft EIS.

Response: It may be that actively managed young growth is better deer habitat than the old growth based deer model predicts. That is one of the reasons young growth management has more emphasis in this Amendment. However, in the absence of a new scientifically based deer model that incorporates the ability to better account for differential habitat values, we will continue to use the best scientifically defensible information available. Old-growth habitat is still considered to be the highest value habitat for deer because of the quality of food in the understory and the high canopy cover, which results in lower snow depths on the ground during critical winter periods.

Comment: One respondent asked for a return of traditional rights to Hydaburg for the area from Cape Chacon to the Maurelle Islands.

Response: It is not clear what the comment means by “return of traditional rights” but changes to subsistence regulations are outside the scope of this Forest Plan Amendment.

Comment: Some respondents shared their opposition to subsistence regulations and their belief that the federal government does not have any authority over Indigenous tribes or Indigenous people. They talked about their rights as a sovereign nation and their opposition to subsistence rights being given to non-native residents. They feel that Indigenous people should have priority for use of natural resources. Some felt that the Forest Service should compensate tribes for cutting trees or turn over control of resources to tribal governments.

Response: These are complex legal issues that are outside the scope of this Forest Plan Amendment. The Proposed Forest Plan will continue to be consistent with current laws and regulations.

Comment: Some comments stated that the Draft EIS does not take into account the economic value of cultural and other Forest-related tribal activities.

Response: The comment does not provide any context for this statement or identify the specific values that the comment author believes the Draft EIS fails to account for. As a result, it is not possible to provide a specific response to these concerns. Other specific concerns raised with respect to subsistence and heritage values are addressed in the *Subsistence* and *Heritage* sections of this comment response volume.

Comment: One respondent was interested in an area being designated for harvest of 500 year old cedar trees for totem poles and canoes as well as bark for weaving. They also asked for an area for spruce roots for basketry.

Response: These specific needs should be brought to the attention of the local District Ranger who is in the best position to address them at the site-specific level.

Comment: One comment noted that healthy salmon stocks support commercial, subsistence, and recreational fishing activities and have been an important part of the cultural fabric of indigenous people of the Tongass for literally thousands of years, as they are in the present day.

Response: We agree that healthy salmon populations are an important component of the Tongass ecosystem that support many human uses, provide prey for a variety of wildlife species, and act as a source of nutrients for the environment.

Timber

The Timber comment and response subsection is divided into the following categories:

- Harvest Methods
- Old-Growth Timber
- Young-Growth Timber
- Alaska Yellow-Cedar
- Harvest-General
- Spectrum Model Analysis
- Timber Sale Economics
- Timber Supply
- Allowable Sale Quantity
- Tongass Futures Roundtable
- General

Harvest Methods

Comment: One comment noted that the Draft EIS did not appear to present information on how the timber would be harvested under each alternative.

Response: The Regeneration Methods subsection of the *Timber* section discusses harvest methods. Table 3.13-9 in the *Timber* section identifies the projected acres by harvest approach (even-aged, two-aged, uneven-aged) for each alternative.

Comment: Some respondents requested that the Forest Service concentrate harvest in fewer, more-intensively managed areas to avoid entering new watersheds. They noted that applying the conservation strategy forces the harvest to be spread over a larger area. Others suggested that cutting less efficiently but over more acres would be a greener approach.

Response: Concentrating harvest in fewer areas and harvesting these areas more intensively would reduce the area needed for a given harvest level. However, it could also lead to adverse effects on water quality, wildlife, visual quality and other resources in the intensively managed areas. On the other hand, cutting fewer trees per acre would disturb more acres of land for the same volume of timber and would also require more roads.

Table 3.13-9 in the *Timber* section identifies the projected acres by harvest approach (even-aged, two-aged, uneven-aged) for each alternative. All seven proposed alternatives employ a combination of harvest approaches with projected harvest levels more concentrated in some areas than others.

Comment: One respondent believed that trees retained in harvest units should be looked at as an investment in non-timber resources and should not be offset by harvesting larger units, harvesting more units, or harvesting the retention later.

Response: The Forest does view the retained trees in harvest units as important for wildlife and does not plan to harvest them later. However, one consequence of retaining trees in harvest units is a reduction in harvest per acre, which needs to be made up by harvesting more areas in order to meet a given level of demand. This is the trade off between leaving structure in harvest units as opposed to harvesting a smaller area more intensively.

Comment: One respondent stated that: "The change from removing large volumes of timber from concentrated areas using cable yarding systems to scattered small, units has affected sale economics and logging systems capabilities."

Response: Changes to timber sale design and logging systems affect harvest economics as noted in the comment. Logging large units, with no stream buffers to break up the unit, is more economical and more easily accomplished with cable logging systems.

Comment: Several comments stated that harvest should be limited to salvage logging or to previously disturbed areas with low environmental value, such as unused roads. Another comment suggested harvest should be restricted to 40 MMBF per year, the harvest rate between 1909 and 1950.

Response: The overall objective of all seven alternatives is to provide a balance between supplying enough timber to meet demand while protecting the environment. Limiting harvest to salvage logging would not meet projected demand under any of the alternatives. Alternative 1 was revised between the Draft and Final EIS documents and restricts harvest to roaded areas only. This alternative has a projected ASQ of 49 MMBF per year, which is close to the 40 MMBF identified by the comment author.

Comment: Some respondents opposed the use of clearcutting as a common harvest method. They argued that clearcuts are ugly and have negative impacts on fish and wildlife and tourism. Others argued that not clearcutting amounted to high-grading and would not produce healthy young stands.

Response: The alternatives feature a range of potential harvest methods. All alternatives include acres scheduled for even-aged harvest, also known as clearcutting (see Table 3.13-9 in the *Timber* section of the Final EIS). Even-aged harvest can be an effective harvest method in many cases because it provides regeneration of desired species, effective tree disease control, viable harvest economics, compatibility with the use of standard logging systems, and minimizes windthrow problems. The circumstances under which clearcutting is practiced on the Tongass are discussed in the Regeneration Harvest Methods subsection of the *Timber* section of the Final EIS.

Research indicates that stands that regenerate following partial harvest are healthy and provide good habitat. Uneven-aged and selective harvest treatments are established forestry practices that, if done properly, can produce healthy stands; however, the risk of windthrow and dwarf mistletoe infection is higher. This is discussed further in the *Timber* section of the Final EIS.

The potential effects of the alternatives on fish, wildlife, and tourism are evaluated in the *Fish*, *Wildlife*, and *Recreation and Tourism* sections of the Draft and Final EIS documents.

Comment: One respondent stated that there are many reasons for clearcutting besides those listed in the Draft EIS and provided a brochure the Forest Service produced in 1972 in support of this claim. Another comment stated that clearcutting is the only way to harvest on the Tongass because thinning spruce-hemlock stands results in wounded trees.

Response: Timber harvest methods are discussed in the Regeneration Methods subsection of the *Timber* section of the EIS. The brochure from 1972 provides an interesting perspective on the thinking at the time. Much additional information has been acquired on forest management in the last 35 years.

Contemporary professional forestry practices include a wide range of tools, techniques, and treatment methods that are all part of the range of tools available for managing the Tongass. Thinning can result in tree wounds, as noted in the comment; however, research indicates that if done with care, thinning can be successful. This is discussed further in the *Timber* section of the Final EIS.

Comment: One respondent stated that two-aged stands are just clearcuts with a few clumps of trees left in the units or along the boundaries. This, they argue, still results in an even-aged stand.

Response: Timber harvest methods are discussed in the Regeneration Methods subsection of the *Timber* section of the EIS. Harvest methods on the Tongass include three broad groups of methods: even-aged systems, two-aged systems, and uneven-aged systems. Two-aged harvest systems do not result in “clearcuts with few clumps of trees.” The description of two-aged harvest has been revised in the Final EIS and explains that the intent with a two-aged stand is to leave up to 30 percent of the trees in order to create a stand with two age classes. This is often done by specifying a diameter limit, for example, leaving all trees between 9 and 18 inches diameter at breast height (dbh). The reserve trees provide structural diversity and an older aggregation of trees within the otherwise young-growth stand. This system has been used on the Tongass to meet scenery and wildlife objectives.

It is possible that the comment author is confusing two-aged systems with the clearcut with reserves system, which could conceivably be described as “clearcuts with a few clumps of trees left in the units or along the boundaries.” Approximately 10 percent of the trees are left in these units but the intent is an even-aged stand. This is discussed further in the Regeneration Methods subsection of the *Timber* section of the EIS.

Comment: Some comments stated that logging practices should be limited to selective cutting. High quality trees should be used for structural timbers not chips or pulp.

Response: High quality logs are used for lumber not chips or pulp. It is the low-quality logs and the outer portions of the other logs that are used for chips (see Figure 3.13-2 in the *Timber* section in the Final EIS). There are a number of advantages to selective cutting, described here as two-aged and uneven-aged harvest, such as less potential impact on wildlife habitat and scenery. There are also some drawbacks, more acres must be disturbed for a given volume of wood compared to even-aged harvest (clearcuts and clearcuts with reserves), more roads are typically needed, and there are some concerns with respect to windthrow and logging damage to the remaining trees.

Additional information on selective harvest has been added to the *Timber* section of Final EIS. All seven proposed alternatives employ a combination of harvest approaches with projected harvest levels more concentrated in some areas than others.

Comment: One comment stated that: “Eliminating clearcutting would reduce, though not eliminate, the need to deal with low grade utility logs.”

Response: Low grade utility logs would be included in harvest units under all three of the broad groups of harvest methods (even-aged, two-aged, and uneven-aged) proposed under each alternative. Eliminating even-aged systems or clearcutting would not substantially reduce the utility log component of potential timber sales. Selectively logging only the high-quality trees could reduce the amount of utility logs harvested. This practice is often referred to as “high grading” and In the long run this approach may not result in healthy forests if only the best and healthiest trees are removed leaving the rest to reproduce. This type of selective cutting also requires more road building and more frequent entries for an equal amount of volume.

Comment: Concern was expressed that leaving low grade logs in the woods wastes resources and harms wildlife.

Response: Timber sale purchasers are only allowed to leave utility grade logs in the woods. Utility grade logs cannot be sawn into lumber due to rot and other problems. While the Forest tries to utilize low value logs, those left in the woods often provide habitat for many species for extended periods of time. The effects of leaving low value logs in the woods are evaluated for all potentially affected resources, including wildlife, at the project level.

The recently approved Limited Interstate Shipment Policy (March 2007) is expected to increase the utilization of timber harvested on the Tongass and improve the economics of timber sales by providing a market for smaller diameter and low grade material that cannot be processed profitably by sawmills in Southeast Alaska. This is discussed further in the *Economic and Social Environment* section of the Final EIS.

Comment: Concern was expressed that helicopter logging is too expensive to be practical. One comment suggested that helicopter logging can result in "high-grading" because of the high cost of removing lower value material. Others recommended helicopter logging as the best method.

Response: Helicopter logging is generally more expensive than cable logging. Many areas of the Forest are too costly to harvest with a helicopter. Some high-value stands with short yarding distances may be economical, depending on fuel costs and timber values. Helicopter yarding generally has less environmental impact than other methods and is often prescribed as a harvest method to protect resource values by reducing disturbance on the ground.

Comment: One comment expressed concern that the Draft EIS assumes that "timber stands of varying volume will be (logged) proportionate to their occurrence within biogeographic provinces or ecological subsections," but there is nothing in the Proposed Forest Plan that requires this distribution or prevents "high-grading." The comment argues that the Final EIS, therefore, needs to explicitly evaluate the potential effects of "high-grading" in the Environmental Consequences analyses. The comment notes that this practice results in unsustainable harvest levels and has detrimental effects on the environment, including wildlife.

Response: The potential environmental impacts are assessed based on the projected ASQ. Modeling indicates that all of the alternatives would harvest the suitable land base at a sustainable level, as discussed in the *Timber* section of the EIS.

Actual harvest is likely to be lower than the projected ASQ and actual volumes harvested under any of the alternatives may be affected by a range of different factors that are difficult to predict at this point. It is important to remember that the Forest Plan does not authorize any ground disturbing activities or create any environmental consequences. The main function of the Final EIS is to compare and contrast alternatives in a general way using broad projections based on full implementation of each alternative. With that in mind, the ASQ represents the maximum allowable timber harvest under each alternative and allows an appropriate and consistent comparison between alternatives. This essentially represents a worse-case approach that ensures that the potential effects of each alternative are fully accounted for. Also, the OGRs proposed in most watersheds contain high-value forests which have been set aside for wildlife habitat and legacy standards apply to VCUs that have high levels of harvest. This is discussed further in the *Wildlife* section in the EIS.

More detail on the proposed harvest methods is provided in the Regeneration Methods subsection of the *Timber* section of the Final EIS. Table 3.13-9 in the *Timber* section identifies the projected acres by harvest approach (even-aged, two-aged, uneven-aged) for each alternative.

Old-Growth Timber

Comment: Some respondents disagreed with the statement under Key Issue 3 (page 1-7 in the Draft EIS) that big tree old growth has been disproportionately harvested. They assert that big tree old growth is well distributed across the Tongass.

One comment pointed out that pulp companies were not seeking big trees and provided a graph that showed the size distribution of spruce trees harvested by the Ketchikan Pulp Corporation during selected years in the 1980s and 1990s. The comment also noted that the average tree harvested in the 1980s and 1990s was 10 inches in diameter.

Response: The text on page 1-7 in the Draft EIS states that: "Although less than 10 percent of the POG habitats on the Tongass have been converted to second growth, this percentage is much higher for certain types of old growth, such as lowland and big tree old growth." This statement is consistent with our experience on the ground and supported by the GIS analyses conducted in support of this Forest Plan Amendment EIS.

Comment: Some comments pointed out that the amount of old-growth harvest under any of the alternatives is very low and argued that this suggests that claims that the forest had been over-harvested are untrue. Some suggested that we either revise Table 2-16 on page 2-41 of the Draft EIS to show that even under Alternative 7 approximately 76 percent of the POG remains or discuss this in the text.

Response: Low is a relative term. To some, harvesting 20 percent of the old growth is a very high amount, while to others it is very low. Table 2-16 in the Draft EIS summarizes the key components of each alternative with specific reference to the conservation strategy. The amount of POG remaining under each alternative is identified in Table 2-17 on the following page in the Draft EIS.

Comment: Concern was expressed that most—with some citing as much as 96 percent—of the old growth forest has been cut and argued that the remaining old growth should be protected.

Response: This is not correct. Over 90 percent of the old-growth forest that existed on the Tongass 100 years ago still remains. Even under Alternative 7, more than 75 percent would remain after another 100 years of harvest.

Young-Growth Timber

Comment: Support was expressed for the Tongass to transition to a second-growth (young-growth) timber program. Some felt that the alternatives did not adequately develop this concept and the Draft Plan did not display a plan for managing young growth. Some felt that only second growth forest should be cut.

Response: Additional analysis has been done for the Final EIS to examine the potential for a greater reliance on young-growth timber. In general, projections show young growth becoming a major component of timber harvest in about 30 years and being the majority of timber harvested in 60 years. The Final Proposed Forest Plan has been modified to place greater emphasis on moving in this direction more quickly. While there are opportunities to both improve wildlife habitat and produce timber by thinning young stands that have reached commercial size, it will take time for these stands to reach commercial size as most young forests on the Tongass are less than 50 years old.

Comment: Some comments stated that accelerated harvest of young stands may require changing national policy and Tongass regulations to allow stands of young trees to be cut before they reach the culmination of mean annual increment (CMAI) of growth.

Response: It does not appear that CMAI is a constraint to harvesting young-growth stands. The benchmark analysis conducted for this Forest Plan Amendment shows little effect by removing this constraint. Without thinning, stands can be regenerated as young as 70 years of age. They can be commercially thinned as early as 40 years. In any case, changing the National Forest Management Act to permit stands to be harvested before they reach 95 percent of CMAI would require an act of Congress and is beyond the scope of this analysis.

Comment: Some respondents strongly support converting to young-growth management but recognize that it will be many years before stands are old enough. They believe that the rotation age should be 90 years not 160 years for young-growth stands. They believe that providing additional volume may require relaxing standards and guidelines such as selective logging in the beach fringe more than 500 feet from the shore and in riparian areas

Response: Based on Spectrum modeling, the rotation age for young-growth stands on better sites could be 60 years without precommercial thinning and 70 years with precommercial thinning. If commercial thinning is also implemented, the regeneration period is delayed. This is because thinning of either kind reduces the number of trees per acre, which extends the growth period for the remaining trees, which also extends the time it takes for them to reach CMAI. The Forest is strongly considering thinning young stands in the beach buffer and in other areas set aside for wildlife, in order to improve wildlife habitat conditions in these dense stands. Trees cut in these stands in excess of down wood habitat needs would be available to mills (this would contribute to available wood supply but not to ASQ). As noted in the Draft EIS, young-growth stands generally have much higher volumes and lower defect than old-growth stands. We anticipate that the current ASQ could be met entirely from young-growth stands by the latter part of this century.

Comment: One respondent found "The age class information provided is confusing. What is apparent is that no second growth will be available for regeneration for at least 30 years. This makes it even more important to have a standard that prevents high-grading."
Response: The age class information presentation has been revised in the *Timber* section in the Final EIS and the discussion of young-growth management has also been expanded in the Final EIS. There are some stands that could be regenerated in this planning period, though not a great deal of volume would be generated. Concerns with respect to high grading are discussed in the preceding section.

Comment: Several comments expressed support for a 200-year rotation with thinning in Scenic Viewshed and Modified Landscape LUDs because this is the minimum time needed to produce a quality saw log.

Response: Generally, modeling indicates a rotation of approximately 170 years for Scenic Viewshed; however, it may be longer in some areas, depending on site quality and stand management. Areas in the far north of the Tongass may require longer rotation periods to reach commercial size.

Alaska Yellow-Cedar

Comment: One comment expressed concern about the reported loss of 500,000 acres of yellow-cedar on the Tongass, which the comment author believed might be the result of climate change. The comment states that this offers an opportunity to salvage log dead and dying yellow-cedar instead of continuing to log healthy trees.

Another comment stated that no more live cedar should be cut and there should be no more salvage of cedar until studies show that cutting these dead trees is "sound science." Another comment argued that the Tongass mismanages yellow cedar and does not take into account its present ecological troubles. This comment also requested that the Proposed Forest Plan include a special section devoted to the careful management of this species.

Response: The EIS recognizes that the decline and mortality of yellow-cedar is one of the most widespread and important forest health problems in Southeast Alaska (refer to the *Forest Health* section). This decline is associated with wet, poorly drained sites, and research suggests that reduced snow pack in low-elevation areas associated with a warming trend that started in the 1800s has exposed fine surface roots to freezing, which in turn kills trees. As the climate continues to warm, yellow-cedar decline is likely to continue to spread, especially in the south and east. Conversely, yellow-cedar appears to be spreading northward as climate warms, into areas that retain snow longer into the spring.

Salvage logging of yellow-cedar is permitted under the current and Proposed Forest Plans. Harvest of healthy yellow-cedar is also permitted and is expected to occur under all seven alternatives. Cedar has been studied for many years. We are not aware of any studies that show harvesting cedar is more or less problematic than harvesting spruce or hemlock.

Harvest-General

Comment: Many respondents stated their opposition to logging. Some were opposed to all logging, while others were specifically opposed to logging old-growth. Many mentioned wildlife habitat protection as the primary reason while others simply said they wanted to protect the Tongass.

Response: The alternatives feature different levels of potential harvest activity which would likely result in different configurations of a wood products industry in Southeast Alaska. All of the alternatives feature some level of logging to meet the requirements of TTRA to seek to meet market demand for timber. Alternative 1 proposes the least old-growth harvest (approximately 1,180 acres per year) and Alternative 7 the most (approximately 10,000 acres per year). The Final Proposed Forest Plan places greater emphasis on harvesting young growth but a complete transition from old growth to young growth is likely several decades away.

Comment - One comment suggested that we not use the word "harvest" when discussing timber management activities. The comment author argued that the word was part of a marketing campaign to make logging of old growth forest more appealing.

Response: Timber harvest is a broadly accepted term used in a wide range of academic and professional contexts, including forestry texts, research studies, and scientific articles. The term is used to describe all forms of logging, not just logging on old growth forests.

Comment: One comment noted that one of the great things about the Tongass is the natural regeneration that follows timber harvest. Others commented that logged areas are slow to grow back, and need to be thinned, some twice. Another comment stated that trees in Southeast Alaska don't reproduce as fast as trees in other areas and harvest levels need to reflect this.

Response: The spruce-hemlock forests of Southeast Alaska are among the most productive in the world according to Silvicultural Systems for Major Forest Types of the United States (USDA Forest Service, 1983). Most areas on the Tongass regenerate naturally and very little tree planting is necessary. Most young stands need to be thinned to improve growth. Regeneration is generally rapid on the Tongass, with tree growth generally faster in the south than in the north.

Comment: One comment stated that any restrictions on harvesting timber should be based on peer-reviewed science.

Response: Standards and guidelines for timber harvest are based on science and many years of experience managing timber harvest on the Tongass.

Spectrum Model Analysis

Comment: Some respondents felt that the Forest Service failed to identify the benchmarks it uses to determine the range of alternatives. They believe the Forest Service used the benchmarks from the 1997 Plan but did not explain how these were used and did not identify: 1) the costs and benefits associated with the minimum level of management needed; 2) the maximum physical and biological outputs of forest resources and the associated costs and benefits; and 3) the estimates of the PNV of forest resources with established market value.

Response: Benchmark analyses were conducted for the Final EIS to determine the minimum and maximum physical and biological outputs of forest resources, the maximum PNV of the forest resources and the influence of management constraints on outputs of forest resources. These analyses are included in the updated AMS included in the planning record. Accordingly, the desired biological outputs of the Alternatives are set at feasible levels as determined by the analysis. Information about costs and benefits is described in detail in Appendix B of the Tongass National Forest Land Management Plan Final EIS.

Comment: One comment questioned if all withdrawn lands were properly considered in determining suitable lands. As an example, they cited land adjacent to the West Chichagof-Yakobi Island Wilderness that was purchased and should have become part of the Wilderness. The comment author noted that both the 2003 SEIS map and the 2007 Draft EIS map show this area as semi-primitive recreation instead of Wilderness.

Response: The area cited in the comment is part of the Wilderness. The mapping error that identifies this area as semi-primitive recreation has been corrected in the Final EIS. This area was not included in the suitable land base, as maps of the suitable land in the planning record show. Also, as can be seen in the alternative maps included with the Draft EIS, this area was not shown as available for harvest in any of the alternatives.

Comment: One respondent had questions about how the timber was modeled. They wanted more information about how lands identified as suitable were stratified into categories with similar costs and returns; how the level identifiers reflect the costs and returns associated with the location of suitable timber in relation to mills, one of the factors possibly contributing to the 1997 FORPLAN's overestimate of ASQ; how the agency stratified lands in the Spectrum model; how slope stability was factored into any of the 5 analysis areas; how slope stability was considered in the "operability analysis"; and whether this "operability analysis" formed the basis for the operability in Spectrum.

The comment also stated that "slope stability should appear in Spectrum as a stratification layer not as a constraint because slope divides the land into categories with similar management costs

and returns. In addition, the comment stated that the "roaded classification stratification may provide stratification for costs associated with transportation. Please explain to what extent this stratification accounts for costs associated with access limited areas. Access-limited areas are difficult to log because although the timber is operable, the costs associated with accessing and transporting logs to a mill cannot be covered by the value of the timber."

Response: Five unique level identifiers were used to stratify the landscape into Spectrum analysis areas. Slope was not used explicitly as a level identifier; rather it was considered in no fewer than three of the Spectrum modeling processes. First, lands with slopes greater than 72 percent were classified as having "extreme hazard soils" and were removed from the suitable land base (and the model) during the suitability analysis (Appendix A-3). Secondly, the logging systems and transportation analysis (LSTA) that was used to derive the operability level identifier considered slope indirectly through the road building necessary to access a stand. If an area could not be accessed by building a road (due to slopes or other factors), those analysis areas were assumed to require helicopter or cable logging at a higher cost. Finally, the Regulation Class of an analysis area is partially-derived from the slope-driven Visual Absorption Capacity (VAC) classification of the land. Regulation classes with lower VAC have more management restrictions and higher costs. We are confident that cost differences due to slope have been adequately captured in the stratification scheme and suitability analysis of the landscape.

Distances to mills and appropriate transportation costs are accounted for with the VCU level identifier. Analysis areas in VCUs farther from a mill will incur a higher transportation cost. See Appendix B for more information.

Comment: One comment questioned what legal authority allows the Forest Service to build roads with public funds in order to make sales sellable and wanted the EIS to explain: the total projected "pre-roading" and the locations of these needed roads and their purposes; what these purposes are and in what roads analysis this need is documented in; how the contract and management costs were included in Spectrum as direct costs against revenues; and requested that the Forest Service itemize contract management costs incurred for roads built since 2002.

Response: Funds for road building have been "earmarked" in annual appropriations enacted into law. The underlying authority to build roads for National Forest purposes is at 23 United States Code (USC) 205.

Pre-roading is a process whereby roads are constructed into a NEPA cleared project area prior to and separate from a timber sale or other resource activity. The intent of pre-roading is to develop or expand the transportation network without requiring one resource to carry the entire burden of road construction costs. Pre-roading is an administrative decision that requires funding from Congress and is subject to the same environmental laws and regulations (NEPA, NFMA, etc.) as other Federal actions. This practice is best addressed at the project level and is outside the scope of this programmatic EIS. Road contract and management costs have not been included in Spectrum as direct costs against revenues

The Forest Service does not track specific contract management costs on road construction. For budgeting purposes there is an estimated cost of about 10 percent of contract costs for administration of the contracts. Contract administration costs can vary depending on a number of factors, including but not limited to contract size, scope, technical complexity, and logistics.

Comment: One comment asked: "Where is the standard or guideline in the Plan that prevents high grading? Constraining this was clearly modeled in Spectrum but without a companion standard in the Forest Plan, what would prevent this from occurring. If it is the NIC 1 and NIC 2 requirement, is this a standard or a guideline? We are not aware of any language in Section 301 of TTRA that constrains or prevents this. If it is in the Forest Service Handbook (FSH 2409.18), which section prevents this? If it does, we do not consider Forest Service Handbook language a

sufficient protection from high grading considering that the Forest Service can change the handbook without public oversight or input."

Another comment expressed concern that the most valuable logs on the Tongass are being exported without primary processing because it is more profitable to export raw logs than to process them in Southeast Alaska. The comment noted that although cedar only comprises a small share of commercial forestland on the Tongass, it is the most highly valued species, and appears to be driving many Tongass timber projects. Another comment expressed the same concern and noted that the industry has been unable to find a market for anything other than the highest quality saw timber.

Response: The Multiple-Use Sustained-Yield Act requires the Forest Service to manage NFS lands in a sustainable manner. This direction is reflected in the goals and the desired condition for the Timber Production LUD on page 3-127 of the Proposed Forest Plan. Cedar occurs as a minor tree species in most stands. The comment that cedar is driving many Tongass timber sale projects is not supported by historical data.

Comment: One respondent asked how exactly was each constraint defined in Spectrum and were they defined and used in the same way for each alternative?

Response: Constraints, or limitations on management activities to motivate the model to achieve desired conditions, are complex in definition, function and application. Appendix B has been updated to more clearly address these questions. In general, constraints can be classified into four categories:

Stand-level exogenous constraints: These constraints are applied before the Spectrum model is built. They are generally applied by evaluating the entire suite of potential management prescriptions available to a stand and only giving the model a choice between those prescriptions that may make the most sense to apply on the ground. These are derived by the forest silviculturist and other specialists.

Stand-level endogenous constraints: These are typically accounting constraints applied to each stand to ensure that all acres are assigned a management prescription and that no more than the available acres of a stand get assigned to a management prescription. These are part of a standard model formulation.

Forest-level exogenous constraints: The suitability analysis used to identify potentially-manageable acres is an example of this type of constraint; typically a National Forest is not able to manage all acres within the Forest, and unsuitable acres on the Tongass were not included in the Spectrum model.

Forest-level endogenous constraints: Generally, the forest-level endogenous constraints are the ones generically referred to as "Spectrum constraints" or simply "constraints". They are often the most dynamic of the four constraint types, as the other three are usually static by the time the Spectrum model is run. Each Alternative used a unique set of forest-level endogenous constraints, although there were some that were standard and did not need to be modified between alternatives. Appendix B describes these constraints in more detail and how constraints were applied to the different alternatives.

Comment: **One respondent observed that the Spectrum model has an objective function that attempts to maximize present net worth and the present net worth of harvests is embodied in a single coefficient: Dij. They asked that we explain in detail how the grouping of analysis areas affects the value of Dij and how these coefficients were calculated.**

Response: Dij is the discounted objective function coefficient for stand "i" management regime "j" to represent the PNV of that management option. A management regime includes the management prescription associated with the stand as it exists today, as well as any and all prescriptions associated with stands regenerated in the future. Generalizing the landscape into the analysis areas is a standard part of the modeling process necessary to produce a model that can be solved in a reasonable manner.

Calculation of Dij is a standard part of the Spectrum model to account for the appropriate revenues and costs associated with each management option. Appendix B has been updated to better explain the PNV calculation and objective functions used in the model solution process.

Comment: One comment stated that "there is no information on how the management prescriptions were mapped for each alternative, nor on the exact methodology, rules, and sideboards that would allow for replication of the process with a common outcome. Please explain how the management boundaries were determined under each alternative."

Response: Table II-16, page 2-41 and the individual alternative descriptions in Chapter 2 of the Final EIS show that all the alternatives, except Alternative 2, were based on previously developed alternatives in prior analyses.

Comment: One respondent stated: "The requirements of 36 CFR 219.14(c) were not met. Lands that are not cost-efficient should not be suitable. Although Congress decided the Forest Service need not consider economic factors in identifying lands not suitable for timber production, this does not relieve the Forest Service of disclosing the costs and benefits associated with including uneconomical suitable lands in the timber base. The law does not exempt the agency from managing the Tongass on a cost-efficient basis. The Forest Service must disclose the results of the (corrected) Spectrum analysis as it pertains to cost-efficiency. There are three classes of land: 1) lands where agency revenue exceeds agency costs; 2) lands where agency costs exceed agency revenue; and 3) lands where logger costs exceed revenues to the logger. Modeling pond log values has obscured all of the above."

Response: The respondent's assertion that the requirements of 26 CFR 219.14(c) were not met is incorrect. The Spectrum model is designed to evaluate a management strategy for cost efficiency. This is most commonly addressed by an objective function that maximizes the cumulative PNV of all potential management prescriptions on all potentially suitable lands, with the requirement that the desired conditions of the forest are met (36 CFR 219.3 "*Cost efficiency*"). This is exactly the formulation used by the Tongass. One of the many desired conditions of the 2007 Tongass plan is to meet and maintain a timber demand level consistent with the Alternative being analyzed. In doing so, it may be necessary to employ management strategies on some lands where costs of the management activity are greater than the benefits realized for the timber under current market conditions. However, since the alternatives were evaluated using a linear programming optimization model (Spectrum) with an objective function to maximize PNV, the most cost-efficient management scenario is identified for each alternative in accordance with 36 CFR 219.14(c)(3).

The costs and benefits associated with each management prescription identified in the Spectrum model solution, while voluminous, are included in the planning record. Stumpage value varies according to logging system, distance from the mill, road building requirements, quality of the timber, etc. Recognizing all of the potential logger-incurred costs against the pond log value allows for site-specific stumpage values to be calculated internally by the Spectrum model in much more detail than a forest-wide externally-derived stumpage value. Factors contributing to the stumpage value in the model include the positive pond log value (adjusted downward to exclude logger profit and risk) less the logging cost, road building and reconstruction costs, felling and bucking costs, camp/commute costs, Log Transfer Facility costs, and timber hauling costs (raft, barge and/or road). Agency-incurred costs that are evaluated by the Spectrum model but do not contribute to stumpage include sale preparation and administration, precommercial thinning, and planting costs. Agency-incurred costs are included as a part of the cost-efficiency analysis outlined in 36 CFR 219.14(b). See Appendix B for further information on this calculation.

The comment author requested and has been provided with all of the information necessary to calculate stumpage value for any Analysis Area of interest. This information is sufficient to allow the comment author to identify the three classes of land they note in the comment.

Comment: One respondent asked that the Forest develop a map of lands not suitable for timber production to help implementers make sure they are not proposing timber sales in these areas.

Response: Maps of suitable acres for each alternative are included in the planning record. Suitable areas are mapped in a geographic information system (GIS). Lands not identified as "suitable" are considered to be not suitable for the purposes of timber sale planning. Further, field work is conducted as part of each timber sale planning process to determine if the map of the suitable lands in the project area is correct. There are generally features which cannot be detected without a field exam.

Comment: One comment noted that two aspects of MIRF were not accounted for in the Spectrum analysis: the habitat conservation areas (large, medium, and small), which blocks access to timber areas, and the legacy standard which requires that 10 to 30 percent of the timber in all units be left. As a result, the comment suggests that the modeling constraints significantly under estimate the adverse effects of these standards and guidelines.

Response: We believe that the Spectrum model adequately accounts for these factors. See Appendix B to the Final EIS for more information on modeling.

Comment: One comment stated that short-distance helicopter yarding should not be included in the NIC I. They believe that the definition of NIC 1 has been redefined from the 1997 Plan. There are no documents to the comment author's knowledge that "demonstrate that this "new" normal operability category would be economic under most market conditions." As a result, NIC I may have little relevance to an economic timber supply and the comment author states that Appendix B in the Draft EIS needs to be updated to fully describe the modeling process.

Response: This is not a change. NIC I under the current (1997) plan includes short span helicopter (see page 3-280 of the 1997 Final EIS). Appendix B has been revised for this Final EIS to address this and a number of other comments raised during the public comment period on the Draft EIS.

Comment: Analysis of bid price paid for sales of varying sizes from October 1, 2004 to December 31, 2005 showed a range of prices between $13.45 and $85.34 per MBF. This is in sharp contrast to the average pond log value used in Spectrum analysis of $273 per MBF. How was the timber sale revenue estimate ($11.69/MBF) used in the economic efficiency analysis estimated and was this figure used in the Spectrum analysis.

Response: To clarify, the Tongass recognized several unique pond log values in its economic analysis; for old growth this consisted of a value for each of three volume strata in each of the five geographic zones, or 15 unique values. Young growth values vary by the age at which they are harvested. However, as the respondent has pointed out, the actual bid price (stumpage value) of a timber sale has a great deal of variability associated with it. We contend that this variability is directly correlated with the costs associated with the timber removal, i.e., the logging system used, transportation requirements to get it to the mill, etc. Thus, stumpage value is an inherent calculation done by the Spectrum model to generate a unique value for each distinct geographic unit (Analysis Area). For the Final EIS, we have included a more detailed economic analysis for timber value in Appendix B Table B-2.

The $11.69/MBF average stumpage value used in the Draft EIS represents the forest-wide average price paid for timber sales in 2005/2006. This value does not consider the site-specific variability in stumpage values calculated by the Spectrum model and was not used in the Spectrum model analysis. It should be noted that the economic efficiency analysis has been updated in the Final EIS.

Comment: One comment summarized sales data from October 2004 to December 2005 and concluded that the average bid price per MBF was higher for micro sales and small sales, then for

relatively large sales. This, the comment noted, suggests that one of the alternatives in the EIS should have focused on microsales, rather than large sales. "Unfortunately," they note "none of the alternatives in the Draft EIS appear to be based on benchmark analyses that evaluate the option of shifting management resources away from large sales to micro and small sales."

Response: The seven alternatives evaluated in the Final EIS offer a broad range of potential responses to future timber demand. These alternatives do not specify the size of the sales that would be offered under each alternative. The Forest Service would continue to offer small and micro sales under all of the alternatives.

The benchmark analyses conducted show the difference in values between geographic areas, logging systems, stocking levels, maximum management size, and distances to nearest processing facilities. This is consistent with the planning rule that requires landscape stratification by factors that influence economic efficiency. Updated benchmark analyses were conducted according to this stratification.

Comment: One comment asked for more detail concerning the timber policy constraint used in the Spectrum model to ensure that all timber harvest meets sustained yield requirements. The comment asked that we explain the following:

"1. which specific constraints were applied for each alternative and in what sequence;
2. whether planners conducted a Spectrum run that does not maximize timber harvest in the first decade before maximizing present net value;
3. whether planners ask Spectrum to maximize present net value subject to the requirement that it cut the volume of timber in the above run;
4. what discount rate was applied to maximize the present net value run; and
5. whether planners used nondeclining net revenue constraints in any model runs."

Response: Regarding the constraints applied to each alternative, Appendix B has been updated to include more description as well as a table describing which constraints were applied to each Alternative. The nature of the Spectrum model allows for all constraints to be included simultaneously; there is no hierarchical order of importance assigned to the different constraints.

Regarding the timber harvest level in the first decade, the model is constrained to meet a harvest level consistent with the design of the alternative. These levels were derived independently of the maximum potential Decade 1 harvest level, save that to insure the ability to implement the plan, the level must be less than the maximum.

The model scenarios evaluated for each alternative found the maximum PNV of the alternative under the appropriate constraints, including the appropriate timber harvest level, of each Alternative.

The model used a 4 percent annual discount rate.

There is no constraint to consider non-declining revenues from decade to decade. See Appendix B "Solution Process" for more information on the Spectrum model formulation.

Comment: One comment noted that Appendix B in the Draft EIS indicates that the Spectrum analysis did not assign a value for utility logs under Alternatives 1, 2, 3, 5, and 6, but assigned utility logs a positive value under Alternatives 4 and 7 based on the assumption that there would be a market for these logs (MDF, Bioenergy, or similar facilities). Alternatives 3, 5, and 6 should also assign a positive value to utility logs because they assume there would be enough volume to operate a veneer mill. The decision to give no value to utility logs under certain alternatives also ignores the new Region 10 transshipment policy.

Response: For the Final EIS, a utility pond log value of $72 per thousand board foot volume was recognized for Alternatives 4, 5, 6, and 7. This price was based on an analysis of recent prices (see Appendix B for source information). However, we recognize that this positive revenue will rarely, if ever, outweigh the costs associated with its removal from the stand and transportation to the mill. The recently enacted Limited Interstate Shipment Policy (March 2007) allows limited interstate shipment (to the lower 48 U.S. states) of unprocessed Sitka spruce and western hemlock. This could provide a market for small diameter and low-grade material in the future under all alternatives, but the value this would add to utility logs is currently unknown. However, viewed in terms of the Spectrum analyses, utility wood value is not likely to have a large impact on the amount or timber produced or the management schedule of any Alternative.

Comment: One comment stated that the costs described in the Draft EIS Appendix B and used in the Spectrum analysis do not appear to correlate with the costs used to compare the alternatives in the economic efficiency analysis (Table 3.22-29, page 3-460).

Response: Appendix B shows two different types of costs used in Spectrum modeling; those incurred by the timber buyer and those incurred by the Forest Service. Costs incurred by the timber buyer are counted against the pond log value to determine actual stumpage value (see Final EIS Appendix B for further information on this calculation). Stumpage value calculated in the model as a function of pond log value less cost incurred by the timber buyer approximately corresponds to the historic stumpage value shown in Table 3.22-29 of the Draft EIS. The two analyses are discrete in that Spectrum uses stumpage values specific to each land area and Table 3.22-29 shows the historic average stumpage [base rate in the Final EIS] of sold wood. The analyses are similar in that ultimately they both evaluate each Alternative's anticipated revenues to the Forest Service.

Agency-incurred costs are included in the Spectrum model to determine the overall economic value of the harvest schedule associated with each Alternative. Agency-incurred costs in the model and described in Appendix B correspond to the agency-incurred costs shown in Table 3.22-29.

Comment: One comment stated that it is unclear from the documentation exactly what figures were included as revenues in Spectrum. The comment asked the following questions: Were any non-timber benefits modeled in Spectrum? Were any non-timber benefits modeled in Spectrum in determining the suitable land base and the PNV of harvest? If this occurred in either case, please explain why and what those figures were (dollar amounts).

Response: Pond log values that varied by volume class and geographic zone were the only monetary revenues modeled in Spectrum. These values are further described in the "Activities and Outputs" section of Appendix B. Only the costs and benefits described in Appendix B were used to determine the PNV of the Alternatives and Benchmarks analyzed with the Spectrum model. Pond log values were the only revenues used in the "Stage II Suitability Analysis" described in Appendix B.

Comment: One comment stated that mitigation measures to not seem to have been accounted for in the cost calculations and made the following points. The cost of mitigation activities needs to be accounted for in determining timber suitability. If the Forest Service must complete required mitigation measures then these costs should be reflected in either the stratification of analysis units according to a range of conditions or in a range of stumpage prices by mitigation requirements. The cost is especially tied to factors such as slope, proximity to streams, proximity to cultural resources, proximity to threatened and endangered plant and animal habitat, all of which can be stratified. As the mitigation costs are not the same on all sales some grouping of mitigation costs by harvest type or ecological condition or habitat location should be calculated.

Response: Appendix B describes two processes that were used to incorporate the effect of mitigation measures for each alternative. The "Regulation Class Process" describes how Scenic Integrity Objectives, Visual Absorption Capacity, Distance Zone, and LUD were used to identify lands that required varying levels of mitigation for scenery and other considerations. Regulation classes with more harvest restrictions generally have higher harvesting costs.

Secondly, the "Model Implementation Reduction Factors (MIRF)" section describes how the impacts of stream buffers, slope and soil hazards, wildlife concerns, and other factors were considered in the model. MIRF were applied to a stratification by Administration area, volume class, and harvest system.

Timber Sale Economics

Comment: A number of comments supported Alternative 7 with some modifications. They felt that some of the Conservation Strategy Standards and Guidelines lacked a basis in science and should be removed from Alternative 7. These standards and guidelines include: the 1,000-foot beach buffer, OGRs, Class III stream buffers, the Legacy standard, and the Goshawk and Marten standards. Many of these comments argued that these measures are the main reasons that the Tongass has been unable to offer economic timber sales.

Response: These recommendations were considered and evaluated as part of Alternative 7. These measures are all important components of the Forest's conservation strategy, which is an integral part of meeting our multiple use objectives and the legal requirement that we maintain viable wildlife populations. The wildlife assessments completed for the current Forest Plan found that alternatives that did not provide a comprehensive conservation strategy had a higher risk of not maintaining viable populations of some wildlife species. The U.S. Fish and Wildlife Service has indicated that the conservation strategy adopted under the 1997 Plan was a major factor in not listing the Queen Charlotte goshawk as threatened under the ESA. See Appendix D of the Final EIS for more information about the scientific rationale behind the conservation strategy.

Alternative 7 as proposed in the Draft EIS did not have these standards and guidelines except for the Class III riparian standard (see, for example, Table 2-16, page 2-41). Alternative 7 has been modified in the Final EIS and it no longer includes buffers on Class III streams.

Comment: One respondent believed that Forest Service sale design should maximize production while protecting the resources that need protection.

Response: Forest Service timber sale design is intended to meet market demand in an economically efficient manner, while protecting other resources.

Comment: One respondent felt that the timber market is cyclical so sales should be designed so that they are operable in all markets.

Response: This may not always be possible, given the high cost of operation in an island archipelago, spikes in fuel costs, and the location of the Tongass in relation to markets. One of the Proposed Forest Plan's stated goals (page 2-5) is to provide timber in an economically efficient manner.

Comment: A number of respondents stated that logging should not be subsidized with taxpayer dollars. Others stated that subsidies should be factored into the economic analysis of the alternatives. Conversely, one comment stated that subsidized logging was needed to revitalize Alaska's economy.

Response: The issue of whether or not the federal government is subsidizing the timber industry is beyond the scope of this analysis. During low market conditions the cost of planning, preparing and administering timber sales are often higher than the value paid for the timber. This is factored into the economic efficiency analysis presented in the *Economic and Social Environment* section of the EIS. One of the Forest Service's objectives for the Tongass National Forest under TTRA is to promote community stability by seeking to provide a stable supply of timber that meets annual market demand.

Comment: Some respondents felt that timber sales must be economic or it defeats the purpose of offering them. They argue that planning teams should include people with experience in planning economic sales. Some requested that a standard requiring sales to be economic be added to the Proposed Forest Plan. Not having economic sales has lead to the Forest not achieving the ASQ. Others felt that costs would always be too high to compete with other regions.

Response: We agree that timber sale expertise is important. The Forest Service is already prohibited from offering deficit timber sales. The high cost of doing business in Alaska as well as current market conditions contribute to the economics of timber sales. The Tongass will continue to work to make timber sales as economic as possible while protecting other resources. But it is not our responsibility alone. Industry needs to find new markets, develop value-added products, and become more efficient to reduce costs and improve profits.

Comment: Concerns were expressed about the difficulty of having economic harvest units in Scenic Viewshed and Modified Landscape LUDs where partial cutting is often required.

Response: The bulk of the timber harvest under all the alternatives comes from areas classified as Timber Production; these are areas that allow more intensive timber harvest, while still protecting other resources, such as fish and water quality through stream buffers and other standards and guidelines. The proposed Plan Amendment updates the Seen Area analysis and Visual Priority Routes and Use Areas as a step in this process (see Appendix F of the Final Proposed Forest Plan). While we want to foster more economic timber sales we also recognize the importance of maintaining our outstanding visual resources.

Comment: Several comments made the following general argument. The overall goal of the Tongass timber program should be to transition to second-growth timber. Full transition will take at least 50 years and in the interim the Forest Service needs to provide a sufficient, predictable supply of old-growth timber that will sustain the existing industry and have the flexibility to increase this supply if the industry were to expand. This harvest should be concentrated in intensively managed areas and standards and guidelines should be relaxed in these areas to improve timber sale economics, in exchange for more stringent guidelines applied elsewhere.

Response: The Forest Service supports the overall goal to transition to second-growth (young-growth) timber harvest over time; however, it will be decades before there are enough young stands to provide a sufficient timber supply to meet market demand in accordance with TTRA. Table 3.13-9 in the *Timber* section identifies the projected acres by harvest approach (even-aged, two-aged, uneven-aged) for each alternative. All seven proposed alternatives employ a combination of harvest approaches with projected harvest levels more concentrated in some areas than others.

None of the alternatives propose that standards and guidelines be "relaxed" in harvest areas in exchange for "more stringent guidelines" applied elsewhere. Alternative 7 does, however, exclude or relax the components of the conservation strategy—the 1,000-foot beach buffer, the Goshawk and Marten Standards and Guidelines, the 100-foot buffer on Class III streams, and the small, medium and large OGRs—that the timber industry argues result in uneconomic sales.

Comment: One comment stated that some State forests and all private forests can be managed for positive economic returns and argued that the Forest Service should also be able to move in that direction. Another comment stated that the Forest Service should avoid scheduling sales in areas that are uneconomic to harvest.

Response: NFS lands are governed by different laws than state and private forests and this affects the relative costs of harvesting timber. The Forest Service will continue to work to make timber sales as economic as possible while protecting other resources.

Comment: Several comments requested that the Forest Service set aside funds from timber harvest for post harvest treatments and studies.

Response: This program already exists. It is authorized by the Knutzen-Vandenberg Act. The Forest Service may "require any purchaser of National Forest timber to make deposits of money, in addition to the payments for the timber, to cover the cost to the United States of (1) planting...removing undesirable trees or other growth...improving the future productivity of the renewable resources of the forest..." Sale receipts in excess of base rates can be used for this program.

Comment: Some respondents requested that the Forest Service not allow round log exports. Concern was expressed about utility log exports and the recent decision to allow the export of low-grade and smaller logs. This, they argue, creates jobs and encourages investment in other states and countries not Alaska. Concern was also expressed that the Draft EIS and market demand analysis fails to take these log exports into account. One comment was also concerned that no NEPA analysis was prepared for this policy change.

Response: Export of logs is a policy decision and beyond the scope of this analysis. Issues surrounding NEPA for other projects and policy decisions are also beyond the scope of this project.

The limited interstate shipment policy referenced in this comment is not addressed in the Draft EIS because it was not approved until March 14, 2007, more then two months after the Draft EIS was published. The potential implications of this policy are discussed in a number of locations in the *Economic and Social Environment* section of the Final EIS.

People often use the term "export" to refer to the interstate shipment of logs, that is, shipment to other parts of the U.S. The shipment of these logs to other states directly supports employment in the logging and transportation sectors in Southeast Alaska. It also provides a market for low grade logs that currently are often left in the woods because there is no economical processing facility for this material in Southeast Alaska. The new policy, therefore, has the potential to indirectly support logging and sawmill employment because it improves timber sale economics and may allow sales to go forward that would otherwise not be profitable.

Comment: The Morse Report (2000) states cedar will be processed locally because the Seley Corp has a mill designed to process cedar but the Draft EIS says it will be exported.

Response: The text in the *Economic and Social Environment* section of the Final EIS has been revised to clarify that there are some local facilities that are able to process limited amounts of cedar.

Timber Supply

Comment: One comment stated that page 2-23 of the Draft EIS over estimates the amount of harvest from state and private lands under Alternative 4. The same comment author later states that the Brackley et al. (2006a) estimate of 6.8 MMBF per year from state and private lands seems reasonable, with no increase in available timber from state and private lands likely in the future.

Response: The only reference to state and private harvest on page 2-23 of the Draft EIS, or elsewhere in the referenced section, is the statement that "private and state lands also contribute to satisfying market demand". The amount is not quantified. The Brackley et al. estimate of 6.8 MMBF is referenced in the Draft and Final EIS documents. It may be noted that this estimate applies only to state lands and does not include projected future harvest on private lands in Southeast Alaska.

The analysis presented in the Draft and Final EIS documents evaluates how well the NIC I component of the ASQ available under each alternative would meet various demand-related benchmarks. This analysis focuses on Tongass timber, which is assumed for the purposes of analysis to be the only source of timber in the region.

Comment: A number of comments requested that the Forest Service provide sufficient economic timber to supply an integrated timber industry, which would support local employment and contribute to the regional economy. Some comments stressed the need for local mills that could process low-quality logs so they would not need to be exported.

Response: The EIS evaluates a range of alternatives. Alternatives 3 through 7 would provide sufficient volume to supply an integrated timber industry based on the demand projections developed by Brackley et al. (2006a). Alternatives 3, 5, and 6 would provide sufficient volume to support a Medium Integrated Industry (Brackley et al.'s Scenario 3). Alternatives 4 and 7 would provide sufficient volume to support a High Integrated Industry (Scenario 4). Timber demand is evaluated in detail in the *Economic and Social Environment* section of the Draft and Final EIS documents. Both the Medium and High integrated industry scenarios require some form of demand stimulus that would create demand for lower grade logs. Brackley et al. suggested that this might take the form of a medium density fiberboard (MDF) plant or a biomass facility established in the region.

Comment: One comment stated that development of an integrated industry would require an integrated land management policy across state, federal, trust, and private lands. The comment author offered a series of recommendations that included placing an emphasis on the most value and family wage jobs per board foot for the least volume harvested, providing incentives for local mills through tax breaks, and restricting the export of unprocessed logs, among others.

The same comment author pointed out that imported wood is used for many projects in Alaska and wanted the state to fund a state log grading agency. The comment also noted that more investment is needed to develop the local wood manufacturing industry.

Response: While the Forest coordinates management with other land owners where possible, state and private land managers often have different goals. The State of Alaska is a Cooperating Agency in this analysis effort. Although the Forest Service supports the restoration of an integrated timber industry, developing incentives and tax breaks is beyond the scope of this analysis, as is the log export policy for non-NFS landowners. Funding for state agencies is also beyond the scope of this analysis.

Alternatives 3, 4, 5, 6 and 7 are designed to provide a stable timber supply that would be sufficient to support a Medium or High integrated industry. This is discussed further in the *Economic and Social Environment* section of the EIS. The Forest Service also supports a number of initiatives and pilot programs, including the non-profit Ketchikan Wood Technology Center.

Comment: One comment suggested that the timber industry should be responsible for providing their own timber (such as fast-growing eucalyptus for pulp and bamboo) and the Forest Service should provide an incentive for this transition by charging high prices for any timber it does supply. Another comment suggested other plants or recycled material be used.

Response: The Forest Service has no control over what is grown on private lands. It may, however, be noted that neither eucalyptus nor bamboo are native to Southeast Alaska. The Tongass is required to seek to meet market demand under TTRA. Timber sales designed to meet this demand are offered using a competitive bid process, with prices determined by the interaction of supply and demand. In general, it seems reasonable to assume that recycled materials have the potential to replace some products that currently come from new lumber.

Comment: One comment pointed out that the Ketchikan Veneer Mill recently completed a successful test run of their equipment using local logs and project that the facility will initially need 2.1 MMBF of veneer-quality logs per month to operate, with this amount increasing to 3.65 MMBF per month after six months. The comment author notes that a commitment from the Forest Service is required before operations can proceed further.

Response: The Forest's goal is seek to meet the market demand for timber as required by TTRA. The projected demand identified in this comment would result in annual demand of 43.8 MMBF, approximately 13.8 MMBF higher than the installed production capacity estimated for this facility by the Juneau Economic Development Council (2007). The timber demand analysis subsection in the *Economic and Social Environment* section of the Final EIS evaluates the ability of the proposed alternatives to meet projected demand based on the PNW study (Brackley et al. 2006a) and a series of other measures, including installed capacity.

Comments: Many comments expressed support for local mills that either produce value added products or products required to serve local markets. Comments recommended that the Tongass provide enough wood to support value added mills. A number of comments stated that timber sales should be designed for small operators and spread across the forest to accommodate local operators without impacting other existing public uses. One comment expressed support for the Forest Service's recent decision to offer sales targeted at small operators.

Response: The Forest Service seeks to provide wood for mills that produce value added products and/or serve local markets as part of its requirement under TTRA to seek to meet the demand for Tongass wood. Many comments express support for some form of value added industry, but do not clearly define what they mean by value-added. The larger existing mills on the Tongass, which are not very large by most standards, produce value added products and support local employment. The demand associated with these mills is also part of the market demand that the Tongass must seek to meet under TTRA. The Final EIS identifies potential market demand for the planning cycle and identifies areas of the forest that need to be withdrawn from commercial timber production in order to protect wildlife and other resources.

The alternatives feature different levels of potential harvest activity that would likely be associated with different configurations of a wood products industry in Southeast Alaska. Projected harvest levels evaluated in the Final EIS range from 49 MMBF under Alternative 1 to 421 MMBF under Alternative 7 in the first decade following implementation.

Comment: One comment asked for specific information in the Final EIS on how each alternative would affect small mills in the Thorne Bay area.

Response: It is difficult to predict how any specific small mill would be affected by an alternative, beyond assuming that if demand is met then there will be enough wood to support small mills as well as larger mills. However, wood is sold through a competitive bidding process and there is no guarantee that a specific mill will succeed in meeting its needs in a competitive market.

Allowable Sale Quantity

Comment: One comment stated that: "if it is true that the lack of shelf stock is keeping industry from expanding then the agency has the authority to create additional shelf stock without raising ASQ. ASQ constricts the sale of timber not preparation of sales. If demand does increase, the agency can raise ASQ. Right now there is no reason to do so."

Response: While it is true that merely planning timber sales does not affect the ASQ, shelf stock that could not be sold without violating the ASQ would be of limited value. The Final EIS evaluates seven alternatives in detail. Three of those alternatives have a lower ASQ than the current plan, two are the same as the current plan, and two are higher.

Comment: Some respondents felt that the current ASQ seemed sufficient, but noted that the Forest Service should remain flexible in case demand rises.

Response: The Forest Service reviews demand on a regular basis and can amend or revise the Forest Plan as needed to meet its obligations under TTRA.

Comment: Some respondents believe that the Forest Service should act quickly to make timber available and to add timber to the "pipeline".

Response: The provision of timber is a priority under the current plan and would continue to be so under the amended Forest Plan at levels determined in the new plan and as funding and personnel allow.

Comment: Several comments stated that the ASQ is too high under the higher volume alternatives because: "Brackley et al.'s timber demand projections were used to model harvest and determine the ASQ."

One comment stated that TTRA requires the Forest Service to seek to provide "<u>a</u> supply of timber" (singular) that meets "<u>the</u> market demand" (singular) for timber from the Tongass (emphasis added in the comment), not the multiple demand amounts evaluated in the Draft EIS.

Response: The demand levels used to help develop a range of alternatives were developed by specialists at the PNW Research Station (Brackley et al. 2006a) and represent the only peer-reviewed demand estimate available. Specific concerns identified with respect to the Brackley et al. study are discussed in the *Economic and Social Environment* section of this Comments and Responses volume, under Timber Demand. Additional information on the Brackley et al. analysis is provided in an addendum report that addresses questions and concerns raised with respect to the original analysis (Brackley and Haynes, in press).

The Forest Service considered the Brackley et al. analysis and other studies of timber demand to create a broad range of alternatives. Implementation of the selected alternative will provide one supply of timber that will meet the market demand for timber from the forest in accordance with TTRA.

Comment: One comment asked for a 10 year timber sale schedule and stated that the National Forest Management Act and its implementing regulations require the Forest to publish a 10-year harvest schedule. Another comment requested that the Forest Service prepare a detailed timber harvest schedule to ramp up to the timber under contract level of 1,080 MMBF (3 years worth of timber at 360 MMBF per year).

Response: The requirement to identify a "planned timber sale program" in NFMA Section 1604(f)(2) is accomplished by the information provided in the Final EIS which displays the projected ASQ volume by Forest Plan alternative. The requirement does not mandate a compilation of individual proposed actions. The Forest Service currently prepares 5 year sale schedules to implement the Forest Plan and will continue to do so as part of the implementation process under the amended Forest Plan. The Forest Service would like to increase the volume under contract and the shelf volume (prepared but unsold sales) to help provide more stability to the timber industry. The amount of new volume to be offered to meet the Forest's general goal of having 2 to 3 years of unharvested timber under contract will depend on the selected alternative.

Comment: One comment stated that: "The Draft EIS states that it is unlikely that all acres modeled and scheduled for harvest will actually be cut. This is likely to be true as long as the federal bureaucracy controls the timber supply. This is another reason to keep the ASQ high."

Another comment stated that lawsuits by environmental groups have tied up the "few economically viable timber sales" offered on the Tongass in recent years actively leading to the "current situation." This comment argues that the Tongass should plan to offer sale volumes in excess of market demand—the comment author suggests twice the market demand volume may be necessary—to ensure that sufficient volume "make(s) it past the environmental appeals process and to the market."

Response: When crews review the areas scheduled for harvest by the model, they are likely to find some areas do not have sufficient volume to be considered commercial forest land, some areas will prove too costly to road or too uneconomic to log. This is likely to be the case regardless of who manages the land. In addition, because of the protections needed to maintain habitat for wildlife and protect viewsheds that are important to the tourist industry, additional falldown in harvest volume is anticipated and built into the model.

The ability of the alternatives to meet potential demand is assessed against a series of measures in the *Economic and Social Environment* section of the Draft and Final EIS documents. These measures include the four scenarios identified in the projections developed by Brackley et al. (2006a), current production levels, installed and active production capacity, and the minimum estimated volumes required to support various processing facilities. The comparison between the four scenarios presented in Brackley et al. and the alternatives is based on the total ASQ volume. The comparisons between the alternatives and the other measures are based on the NIC I component only, which includes lands that can be harvested with normal logging systems.

The Forest Service hopes that regional stakeholders can reach consensus and avoid lawsuits in the future and supports the efforts such as the Tongass Futures Roundtable.

Comment: Concern was expressed that the ASQ is a very poor indicator of how well each alternative would supply timber to the local industry. Actual production is historically well below the established ASQ.

Response: It is true that ASQ is a ceiling and not a guarantee of actual production. But it remains a viable measure of the potential of each alternative to supply timber to local markets. The actual amount of timber that might be sold and harvested in each alternative is always speculative as it is dependent upon numerous factors such as timber demand, volume under contract, lumber prices, Forest Service budgets and appeals and litigation.

Comment: Several comments stated that the Spectrum model analysis overstates the likely economic sale volume by more than 30 percent. This has two effects on the analyses presented in the Draft EIS. First, the ASQ volumes overestimate the amount of economic timber that would be available under each alternative. Second, this overstatement results in an overestimate of potential environmental impacts in all cases where the ASQ is used as part of the analysis. The ability of the alternatives to meet the four demand scenarios identified in Brackley et al. (2006a) and the potential environmental impacts of the alternatives should be assessed using a new category, the "Programmed Sale Quantity" (PSQ), which should be based on less than 70 percent of the ASQ.

Response: As stated in a number of locations in the Draft and Final EIS documents, the ASQ is a ceiling; not a future sale level projection or target and it does not reflect all of the factors that may influence future sale levels. Actual harvest is likely to be lower.

The ability of the alternatives to meet potential demand is assessed against a series of measures in the *Economic and Social Environment* section in the EIS. These measures include the four scenarios identified in the projections developed by Brackley et al. (2006a), current production levels, installed and active production capacity, and the minimum estimated volumes required to support various processing facilities. The comparison between the four scenarios presented in Brackley et al. and the alternatives is based on the total ASQ volume. The comparisons between the alternatives and the other measures are based on the NIC I component only. The use of NIC 1 volume in the Final EIS generally corresponds to the suggestion to use the more economic component of the ASQ for evaluation purposes.

The potential environmental impacts are assessed based on the projected ASQ. Actual harvest is likely to be lower and actual volumes harvested under any of the alternatives may be affected by a range of different factors that are difficult to predict at this point. It is important to remember that the Forest Plan does not authorize any ground disturbing activities or create any environmental consequences. The main function of the Final EIS is to compare and contrast alternatives in a general way using broad projections based on full implementation of each alternative. With that in mind, the ASQ represents the maximum allowable timber harvest under each alternative and allows an appropriate and consistent comparison between alternatives.

Comment: Concern has been expressed that the ASQ would restrict movement toward the planning cycle demand of 360 MMBF per year if it was lower than the planning cycle demand.

Response: The ASQ is a decadal ceiling and should not be confused with the average or annual sale quantity. The ASQ is the maximum amount of timber that can be sold from regulated or scheduled timber lands during each decade over the life of the Forest Plan and is typically presented as an annual average. Annual harvest is not, however, constrained to this annual average, provided that the cumulative annual harvest volume does not exceed the decadal ceiling. This may result in annual harvests that exceed the average annual ASQ for a number of years. For example, if during the first part of the decade only half of the average annual volume was sold, that volume could be made up by selling more than the average during the remainder of the decade. With the current timber harvest levels low relative to the ASQ and planning cycle demand, such decadal flexibility should allow sufficient volume to respond to increases in industry growth and demand for timber.

The Forest Service also has established procedures (Forest Service Handbook 2409.13) for analyzing departure from the established ASQ ceiling to determine whether or not it is possible to better meet multiple use objectives. Those procedures include several criteria or conditions in which evaluation of departure from the ASQ would be needed. One of the set of conditions listed is when implementation of the ASQ could have a substantial adverse impact in the economic area in which the forest is located. For example, if the level of harvest has increased and the cumulative amount of timber sale volume is approaching the decadal ceiling, there may not be sufficient new sale volume to support market demand. If this were likely to be too disruptive to the local economy, departure procedures could be triggered to sell more than the ASQ decadal ceiling. This volume could be made up in the next decadal ceiling or forest amendment processes, including public involvement, would be used to adjust the ASQ accordingly.

Comment: Is this statement in the Draft EIS true: "additional volume can be produced from, for example, wildlife habitat enhancement in young-growth forests..."

Response: Many OGRs contain old clear cuts. Thinning the young stands that have grown in these areas can enhance development of large trees. Any commercial-size wood removed from these areas would not count toward ASQ. This statement has, however, been deleted from the Final EIS because it was easy to misinterpret.

Tongass Futures Roundtable

Comment: A number of comments mentioned the need to find consensus on the lands available for timber harvest. Some mentioned the Tongass Futures Roundtable and expressed support for this group and its identified goals. As noted in the comments, one of the group's goals is to develop a 24- to 36-month supply of timber to bridge the period needed for a consensus approach among stakeholders to agree on which watersheds should be protected and which should be available for timber harvest.

Response: The Forest Service supports the goals and objectives of the Tongass Futures Roundtable and appreciates the work that this group is doing to work toward consensus on Tongass issues.

Comment: One comment expressed concern that the Tongass Futures Roundtable might have too much influence on the ROD. They felt that there was no way one group could represent all interests.

Response: As stated above, the Forest Service supports the efforts of the Roundtable to bring various interest groups together to discuss Tongass issues, but we recognize that this one group does not speak for everyone. It should be noted that as of the date of this publication the Tongass Futures Roundtable has not brought forward any specific recommendations beyond some very general goal statements. The rationale for the decision for this project will be discussed in the accompanying ROD.

General

Comment: Some respondents believe that Alternative 7 was not fairly treated in the Draft EIS. In particular they felt that the negative effects of timber harvest were overstated. A related comment was the impression that the Draft EIS has a "logging is bad" bias.

Response: As the Final EIS notes, timber harvest provides jobs and resources that people need, such as lumber for housing and also benefits species that are associated with early seral conditions. However, timber harvest, and the associated road construction, does increase the risk of negative effects on wildlife, old growth forests, streams, and other resources and the EIS attempts to depict this fairly. As Alternative 7 has the highest level of timber harvest, it also has the highest risk of possible negative effects.

Comment: Concern was expressed that Sealaska cannot be expected to continue harvesting at the same level it has been during the next decade if it does not get it's ANCSA entitlement in that period.

Response: The EIS assumes for the purposes of analysis that Private (Native Corporation) and State harvests would be 109 MMBF per year for the first decade following Forest Plan implementation under all of the alternatives (Brackley et al. 2006a). Private land management is not part of the scope of this analysis except to the extent that it informs the cumulative effects analysis for potentially affected resources. Specific questions and comments related to ANCSA and Sealaska are addressed in the Lands section of this comment and response appendix.

Comment: One comment noted the following concerns with respect to the tables presented in the Timber section of the Draft EIS:

- **Tables 3.13-1, 3.13-2, and 3.13-3 identify different numbers of total suitable acres**
- **The acres presented for items 7 and 8 in Table 3.13-8 are different under Alternative 1 than under the other alternatives**
- **The total suitable acres identified for Alternative 1 in Table 3.13-8 are slightly lower (6 acres) than those presented in Table 3.22-31**
- **Table 3.13-10 and the text on page 3-260 of the Draft EIS do not appear to match**
- **Table 3.13-14 is supposed to show age class distribution for suitable timberlands, but instead shows total timberlands**
- **Total timberlands identified in Table 3.13-14 do not match the totals for lines 13 and 14 in Table 3.13-8.**

Response: The suitable acre numbers have been updated in the Final EIS and are presented consistently throughout the document. The other identified typographical errors and inconsistencies have also been corrected in the Final EIS.

Comment: One comment stated that: "Using US Forest Service GIS data, there are over 1.8 million acres of commercial timber with an estimated 29 billion board feet of timber. This is enough to produce an annual sale volume of 365 MMBF over an 80-year rotation. Second growth will help augment this amount, easing the transition to second-growth management. Lowering the rotation age to 70 years would require less old-growth harvest."

Response: While this may be correct, not all commercial forest land is available for harvest due to the need to consider other resources and uses.

Comment: Several comments questioned why the acres in development LUDs and the ASQ for Alternative 1 in the Draft EIS do not match those for Alternative 8 in the 2003 SEIS. The number of acres increased from 1.1 million to 1.2 million, but the ASQ dropped from 96 MMBF to 52 MMBF. Concern was also expressed that the ASQ for Alternative 5 (No Action) in the Draft EIS is 267 MMBF compared to 259 MMBF for the same alternative in the 2003 SEIS.

Another comment pointed out that the statement in the Draft EIS that approximately 767,000 acres have been harvested in Southeast Alaska conflicts with the PNW Research Station General Technical Report (GTR) 386 from 2006, which states that over 1 million acres had been cut at that time.

Response: Alternative 1 in the Draft EIS included some roadless area, while Alternative 8 in the SEIS did not. Also, the ASQ under Alternative 1 was limited to the amount needed to reflect recent timber harvest levels on the Tongass. The alternative was not designed to maximize production from the roaded area. Page 3-442 of the Draft EIS mentions that this alternative has the potential to produce more timber volume. For the Final EIS we eliminated all roadless areas from the suitable land base in Alternative 1, thereby reducing the number of suitable acres while keeping the ASQ the same. We left nearly the entire roaded area in Alternative 1 even though not all of these acres would be needed to harvest at the lowest demand level.

Regarding the no action alternatives, the SEIS used an excel spreadsheet to estimate ASQ based on the old FORPLAN runs. The Draft EIS used the new Spectrum model. This accounts for the differences in the two no action alternatives. In hindsight, it appears that the no action alternative in the SEIS could produce the 267 MMBF estimated in 1997 but the excel spreadsheet estimate used in the 2003 SEIS was reasonably close (less than 3 percent difference).

Recent estimates of the amount of harvest are more accurate due to improvements in GIS technology.

Comment: Some concern was expressed about blowdown, especially in light of prediction of increased storm events due to global warming. Comments were particularly concerned about blowdown along the margins of harvest units and in the 100-foot wide stream buffers. A number of comments recommended that the Forest Service conduct research on blowdown and windthrow patterns and use this information in harvest planning.

Response: Blowdown can be a serious problem, especially in areas that are subject to catastrophic wind events. Buffers on streams require more than the 100-foot buffers on each side of the stream. Standards require a reasonable assurance of a windfirm buffer. The width of each buffer depends on the windthrow risk of the area. We will continue to monitor and acquire more information about blowdown in Southeast Alaska. In addition, the Forest Service supports research on windthrow through the PNW Research Station.

Comment: Some disagreed with the statement in the Draft EIS that alternatives with more road building and harvest are likely to result in more blowdown if climate change results in more storms, as some predict.

Response: Windthrow associated with roads and harvest units is well documented, as is the increase in storm events in the last few decades. While, to date, the increase in storm events has not resulted in a documented increase in windthrow, the potential should not be ignored when planning harvest units.

Comment: One comment stated that "because of the risk of blowdown, logging prescriptions tend to not leave strips of unharvested old growth between units. Instead new units are placed adjacent to old units, which leads to mega-units much larger than the maximum 100 acres. The Plan needs to include standards that prohibit this practice."

Response: The average opening in recent years has been approximately 11 acres. A new unit is not placed next to an old one until the trees in the existing harvest unit are established (4.5 feet tall, and free to grow), as required by existing regulations. In some cases (especially in areas subject to catastrophic windstorms) adjacent units may only be 10 or 20 years apart because the risk of blowdown results in not leaving an area of old growth between units. This has some positive and negative effects. On the one hand, concentrating harvest in a smaller area reduces fragmentation and allows wider travel corridors to be maintained. Also, it reduces the problem of blowdown, assuming the new unit is placed correctly in regards to the wind. On the other hand, it can lead to larger areas of young-growth forest, which can reduce the usefulness of portions of the area to some wildlife species, including generalist species that like edge habitat.

Comment: Several comments pointed out that the north half of the Tongass has a very different ecosystem from the south half of the Forest and should be looked at differently when it comes to timber harvest. The north part of the Forest is slower growing and there are only a few small mills to support. Some also noted that communities in the south are dependent on timber harvest while those in the north are more dependent on recreation and tourism.

Response: The seven alternatives considered in detail in the Final EIS provide a wide range of options for management of the Forest**.** Most alternatives recognize that the south part of the Forest has more accessible and economically viable timber stands and this is reflected in how the timber LUD is allocated. Modeling assumptions in the Spectrum model also reflect higher growth rates and timber volumes and lower logging costs in the south part of the Forest. The decision maker also has the option of making a decision that could further recognize the differences between the north and south halves of the Forest. The regional economy is discussed in detail in the *Subregional Overview and Communities* section of the Final EIS.

Comment: One respondent stated that they understand pine is being replanted on the Tongass and requested that the Forest Service at least plant native species.

Response: Very little pine, if any, is planted on the Tongass. Only native tree species (using local seed sources) are planted. Most regeneration is from natural seeding from trees adjacent or within the harvest unit. This is discussed on page 3-245 of the Draft EIS. While the Tongass does contain one native pine species, the Forest Service is not aware of it ever having been planted for timber production.

Comment: One respondent requested that the Forest Service supervise all timber sales on NFS lands and not privatize this task. The comment also stated that helicopter loggers should be required to clean up areas they use.

Response: Forest Service directly oversees all timber sales on the Tongass National Forest. All timber sale contracts specify the cleanup required.

Comment: One comment expressed concern about the scaling practices used by the Forest Service and suggested that corrupt scaling practices may have resulted in larger harvest areas. The comment also questioned whether the Forest Service has an accurate picture of the harvested areas on the Forest.

Response: The comment provides no detail about the alleged “corrupt” scaling practices employed by the Forest Service and, therefore, it is not possible to provide a detailed response other than to say that the Forest Service is not aware of any “corruption” in the way it scales logs. The Forest Service conducted a detailed analysis of the Tongass National Forest as part of this overall Forest Plan amendment process. This included mapping productive forest land on the Tongass based on existing NEPA analyses, aerial photographs, LiDAR, LANDSAT, and GIS data, and local knowledge.

Comment: One comment stated that logging slash should be removed and noted slash is burned or chipped in Washington and Oregon.

Response: Leaving woody debris (logging slash) on site retains important wildlife habitat components and nutrients. Burning slash would release carbon into the atmosphere and would be out of place in an environment that does not normally have fire. Chipping slash would be costly and would not result in any meaningful benefit since fire risk is very low in Southeast Alaska. Slash is treated in Oregon and Washington in areas where fire risks require fuel treatment but many areas no longer burn (or chip) slash because fire risks are low. This is the case, for example, in most areas west of the Cascades in Washington.

Comment: One comment opposed all logging until surveys of wildlife, rainfall, tree growth, and soils have been completed. Another comment recommended that a watershed analysis be completed prior to every timber sale.

Response: Site-specific analyses required prior to timber harvest include wildlife surveys and vegetation surveys, including tree growth sampling to validate the growth potential of each site where harvest is being considered. Soil surveys have been completed for the Forest and these surveys are ground-truthed for individual project areas as part of the analysis prior to approving timber harvest. Watershed analyses are completed prior to a timber sale when the existing level of disturbance indicates the need.

Comment: The Forest Service should use all tools available for managing timber, such as the size-density model and the Marxan Model.

Response: The size-density model is a potentially useful tool that the Forest is currently developing and it was used in the analysis presented in the EIS. The Forest is also looking at the Marxan Model and other tools.

Comment: One comment requested that the Forest Service restore the timber volume class designations 1-7 in the Proposed Forest Plan. The comment stated that the system used to replace these classes is much less precise.

Response: Volume classes 5, 6, and 7 were combined because there is no significant difference between them. This is discussed on page 3-244 of the Draft EIS.

Comment: Several comments stated that local industry has done a poor job of managing their lands. Extensive harvest on private lands has adversely affected subsistence, wildlife, and streams and other resources.

Response: The Forest Service has no control over management of non-NFS lands. The impacts of management practices on adjacent lands are evaluated in the Cumulative Effects discussions presented for each resource, as appropriate.

Comment: Some comments stated that they have confidence in the Forest Service to manage public forest resources. One comment expressed support for the Forest Service, but suggested that the Forest Service also consider private sustainable forestry projects, such as the Pioneer Forest in Missouri.

Response: Thank you for the expression of confidence. The Forest Service continues to conduct research and develop new management approaches and strategies. The management of private lands is outside the Forest Service's jurisdiction, but innovations in other areas may be applicable to land management on the Tongass.

Comment: One comment recommended that Congress establish a dedicated timber reserve on the Tongass.

Response: Congressional actions are beyond the scope of this Forest Plan amendment process.

Transportation and Utilities

The Transportation and Utilities comment and response subsection is divided into the following categories:

- Roads
- Transportation and Utility Corridors
- Energy and Utilities

Roads

Comment: Some respondents expressed concern about the large backlog of maintenance work that needs to be completed and thought that roads should be the focus of restoration. They believe that the EIS should include transportation alternatives that look at various reasons to deconstruct existing roads and limit new road construction, such as protecting wildlife habitat, saving maintenance money, and protecting watersheds and fish.

Response: The Forest is working through the Roads Analysis Process and Travel Management planning to identify the roads that will be needed in the future and those that should be closed, as well as to identify and correct road problems, including fish passage. Both of these processes include extensive public participation. The Draft EIS did not include alternatives for managing the existing road system because this issue is being dealt with at the local level. The issue identification process for this EIS is discussed in the *Public Issues* section of Chapter 1 of the EIS. Using the Roads Analysis Process and Travel Management planning, the Forest has already decommissioned approximately 100 miles of roads and placed into storage a significant portion of the road system. The Forest used the roads analysis process to identify maintenance needs and prioritize funding to deal with the most serious problems first.

Comment: Concern was expressed about the use of road storage. One comment stated that storage can be a valuable tool that is a vast improvement over past abandonment practices, but, at its worse, storage can fail to prevent erosion and resource damage. They note that repeatedly opening and closing roads harms wildlife and introduces "pulses of sediment" into watersheds. Another comment noted that storing roads has limited effectiveness.

Response: Roads are placed into storage when there is a long-term need for the road but the road will not be needed in the near-term. In the past, these roads were left open and often revegetated naturally, which in effect closed them to vehicle use. However, culverts sometimes plugged and this has led to roads washing out. There have also been other erosion problems and fish passage problems with many of these roads. Placing roads in storage restores natural drainage where needed and corrects erosion problems. Roads may remain in storage for one or several decades. The intent is not to repeatedly open and close them, as the comment implies. These roads quickly revegetate reducing the fragmentation that roads can cause. Alder often dominates old roadbeds, which adds nitrogen to the soil and helps forbs and other understory vegetation grow. As noted in the Final EIS, recent research indicates that areas with alder provide high-value forage areas for deer. It is true that when they are reopened, some sediment may be released but there is much less disturbance than would be the case with new construction. We believe that road storage is a valuable strategy for managing the road system.

Comment: Concern was expressed about the long-term impacts of temporary roads, especially sediment produced in the first 5 years. Others suggested that the Forest Service consider the use of lower impact temporary roads instead of "spec" roads.

Response: We agree that temporary roads can cause sediment problems and that these roads should be constructed correctly and closed as soon as practical following completion of the project that they were constructed for. This was not always done in the past. The Forest generally proposes lower impact temporary roads in areas where long-term access is not needed.

Comment: Some believe that the Plan Amendment is not consistent with ANILCA provisions of off-highway use as all areas will be closed to OHV use unless designated open. ANILCA requires that all areas be open for subsistence use, subject to reasonable regulation.

Response: The Plan Amendment will have no effect on this issue. Each Ranger District on the Tongass is analyzing how to provide reasonable access for subsistence and other uses in their Travel Management Plans and accompanying NEPA documents. The Draft EIS simply discussed what the National OHV rule states and the process for determining which areas and roads would be designated open. Each District will work with the state and local governments, tribes, and the public, as required by NEPA. The standard in the Final Proposed Forest Plan has been updated to state: "Each ranger district will designate the roads, trails, and areas open to motor vehicle use on a motor vehicle use map. All operations must be in accordance with those designations."

Comment: One comment stated that the conservation community may support some extensions of the road system into the margins of adjacent roadless areas on a case-by-case basis as long as connectivity is maintained.

Response: All alternatives except the revised Alternative 1 allow the extension of existing road systems and new road construction in roadless areas. Alternatives 2 and 3 would restrict these road extensions to lower value roadless areas. Refer to the alternative descriptions in Chapter 2.

Comment: One comment requested that the Forest Service require all roads to be constructed above grade and prohibit road-related alterations to natural surface water or ground water.

Response: The Forest has many different site-specific situations where it is best to construct roads either "above grade" or "below grade". The design and standards of roads are site specific and should be addressed and commented on during the planning phase at the project level under NEPA. The Forest will continue to coordinate management actions with the Alaska Department of Environmental Coordination (ADEC) and ADF&G in the implementation of existing BMPs and development of new BMPs.

Comment: Some comments expressed the desire for road access to the forest. Others noted the importance of roads originally built for timber harvest that connect communities.

Response: All alternatives include retaining existing roads and construction of new roads as needed for each alternative. The Draft EIS (page 3-229) acknowledges that the existing transportation system that connects communities was originally constructed largely in support of timber harvesting.

Comment: One respondent thought it would be more helpful for the Final EIS to display average road density in the individual VCUs with past harvest or proposed new harvest by alternative, and not include VCUs with no development in the average density calculation because this skews the average.

Response: The EIS displays existing and projected future road densities in many ways other than simple averages. In the *Fish* section, Table 3.6-8 presents average road densities for NFS lands, for non-NFS lands, and for all lands combined, under existing conditions and under each of the alternatives. As the comment implies, these averages are Forest-wide so they include areas with and without development. Since there are almost 950 VCUs on the Tongass, it would take many pages to present this information by VCU. Table 3.6-9 was developed (in lieu of presenting a catalogue of VCU road densities in a multi-page table) in order to provide summary information on the number of VCUs on the Tongass that have different road densities by placing each VCU into road density categories and then calculating the percentage in these categories. Each VCU was placed into one of six road density categories, ranging from 0 miles per square mile to >4 miles per square mile. This was done for existing conditions and for future conditions under each alternative (after 100+ years). It was also done for NFS lands only and for NFS and non-NFS lands combined. If the reader wants to determine the exact number of VCUs in each category, the total numbers of VCUs used in the calculations are presented in footnotes at the bottom of the table and can be multiplied by the percentages in the table to calculate actual numbers of VCUs.

In addition, Table 3.10-10 at the end of the *Wildlife* section in the EIS presents the same information by WAA for both NFS lands and NFS lands combined with non-NFS lands. Further, it also presents the same information for open roads (those that are maintained as open for vehicle traffic).

Transportation and Utility Corridors

Comment: **Some respondents felt that the Final Proposed Forest Plan should include all 34 road and utility corridors in the State's Southeast Alaska Transportation Plan. They noted that the draft plan does not include 8 of the 34 corridors. They felt that the regional intertie system will allow communities to switch from diesel to low-cost, environmental friendly energy and surplus energy could be exported. They requested that the Plan state that hydropower and other renewable energy development is a legitimate, authorized use on the National Forest.**

Response: One of the stated goals of the Proposed Forest Plan (page 3-143) is: "To provide for, and/or facilitate the development of, existing and future major public Transportation and Utility Systems." The EIS specifically mentions those corridors specified in the MOU that the Forest Service and the State of Alaska recently signed. Most of these corridors are included in a separate LUD that overrides underlying LUDs. Those not included in the Proposed Forest Plan represent alternatives to these corridors or appear to be unlikely to be developed during the life of the Forest Plan. The Forest will consider all proposals recommended by the State, as well as any reasonable alternative corridors, during project-level NEPA analysis. Some additional corridors were added to the Final EIS after further discussion with the State of Alaska.

Comment: One comment stated that given that many of the roads and utility corridors authorized by Public Law 109-59 would take priority over all underlying LUDs, including many that do not normally allow road construction, it is critically important to fully analyze the cumulative effects, along with existing roads, roads proposed under each alternative, roads on non-NFS lands, and proposed energy infrastructure under Public Law 109-59. One comment stated that: "the Draft EIS fails to analyze the adverse effects of including a road right-of-way across North Baranof. This road would cross two large Inventoried Roadless Areas and harm wildlife, soils, water, fish, and subsistence. The majority of the road would go through OGRs and the beach buffer. It would cross 5 major watersheds, 2 of which are listed as impaired due to sediment. The proposed road corridor across Baranof crosses a fault line and the engineering reports indicate it will be closed weeks to months each year due to avalanches."

Response: This Forest Plan Amendment would not approve any of these road and utility corridors. It is only ensuring that the option to construct a road or power line is maintained. When a road or power line is proposed, it will be analyzed under NEPA, along with reasonable alternatives, including No Action (i.e., not building the road), along with the cumulative effects of that project and other foreseeable projects. As of this time, the North Baranof road mentioned in the comment is one of many roads that have been discussed, but it is not being actively analyzed. Additional information has been added to the Final EIS to examine the cumulative effects of those roads believed most likely to be constructed during the life of the amended Forest Plan.

Comment: Some respondents wanted road and utility corridors north from Angoon to Greens Creek, south to Hood Bay, and north to a patented coal mine.

Response: These routes are not listed by the State in their travel management plan. But when a project is proposed and examined in detail, other alternatives such as this could be considered. The Forest Service is unlikely to support major corridors through designated wilderness and such an action would require Congressional approval.

Comment: One respondent asked that we run the utility corridor a little further along Takatz Lake as the lake is a potential hydropower source for Sitka.

Response: This option could be considered as an alternative to the State proposal if this project were to move forward to the analysis phase.

Energy and Utilities

Comment: Some felt that the amended Forest Plan should recognize and address the prohibitive cost of regulations contained in the present Forest Service Handbook that limit or prevent efficient development, production, and distribution of energy resources. Identified constraints included stream buffers and scenery protections, required appraisals and acquisition of timber in proposed corridors. One comment also noted that, due to the high administration costs, small projects should be exempted from regulation.

Response: Utility development is an important use of the National Forest; however, laws and regulations governing the use of NFS lands apply to all projects.

Comment: Some respondents felt that the amended Forest Plan should identify existing and potential hydroelectric resources and federally recognized watersheds, reserves, or permit areas. Areas of identified concern included the Soule River and North Fork River valley and drainage and the Thayer Creek Hydro Reserve

Response: As noted earlier, the Final Proposed Forest Plan supports development of hydroelectric resources. Each project needs to be evaluated individually on its own merits. As noted in the Transportation and Utilities section, the Thayer Creek hydroelectric facility and transmission line are authorized by Congress and are currently being analyzed in a separate EIS.

Comment: Some comments stated that the Forest Service failed to adequately address energy development opportunities and that the Plan should prioritize the energy resources on the Forest. One comment believed that ANILCA provided the legal mechanism to implement less expensive corridors.

Response: Potential and ongoing energy developments are discussed in the Draft and Final EIS documents. Sufficient guidance under allowable uses as defined by the LUDs is contained within the Plan itself and procedures and permit processes are in place for such development. As noted in the Final Proposed Forest Plan, the corridors within the Transportation and Utility LUD take precedence over underlying LUD standards and guidelines.

Wetlands

Comment: Concern was expressed that the Proposed Forest Plan that accompanied the Draft EIS proposed to eliminate protections for forested wetlands covering more than 100,000 acres without disclosing the effects of this change.

Response: We assume that this comment refers to the organic soils discussed in Appendix B (Information Needs) in the 1997 Plan: Maybeso, Kaikli, Karheen, and Kitkun Soil Series. Additional information on the timber productivity and response to harvest on these soils was listed as a need. The 1997 ROD stated that information related to the effects of timber harvest on these soils was incomplete and harvest was to be avoided on these soils until the ongoing research study of these issues was complete, at which point the decision would be reevaluated (or earlier if monitoring information warranted). In 2000 the Forest issued a report on this study and the Forest Supervisor issued a decision stating that these soils were suitable for timber production. The Plan Amendment does not propose any change to the existing standards and guidelines for these soils.

Wildlife, Biodiversity and Plants

The Wildlife, Biodiversity and Plants comment and response subsection is divided into the following categories:

- General
- Conservation Strategy
- Old-Growth Mapping
- Legacy and Goshawk/Marten Standards and Guidelines
- Population Viability
- Management Indicator Species
- Wildlife Cumulative Effects
- Restoration and Young-Growth Management
- Threatened, Endangered and Sensitive Species
- Endemic Species
- Birds-General
- Marbled Murrelet
- Goshawk
- Marten
- Wolf
- Deer
- Elk
- Brown Bear and Black Bear
- Plants

General

Comment: The Draft EIS contains an inadequate discussion of the effects of climate change on Tongass fish and wildlife and should include a full analysis of climate change impacts on forest species and habitat distribution, including how climate change will alter the amount and distribution of old-growth.

Response: A discussion of the impacts to wildlife species from climate change has been expanded in the Final EIS text. Climate change is described in general terms due to the many unknowns surrounding its anticipated effects, though specific examples are brought forward. Discussion of potential changes in the amount and distribution of old-growth is also provided in the *Timber* and *Biodiversity* sections of the Final EIS. Also see comments and responses in the Climate and Air section of this appendix.

Comment: Timber harvest can result in the loss of habitat for deer and bear which are important to the lives of the local human population.

Response: Effects to deer and bear habitat are discussed in the *Wildlife* section of the Final EIS; effects to subsistence and subsistence resources is discussed in the *Subsistence* section and by community in the *Subregional Overview and Communities* section of the Final EIS. Note that timber harvest affects deer and bear habitats, but rarely would result in a complete loss of habitat.

Comment: A number of comments were received suggesting topics for future research. Topics included studies of Kuiu Island marten to assess implications of forest management practices and possible mitigation measures, marbled murrelet habitat associations, and how different structural and compositional attributes of old-growth forest affect wildlife species.

Response: Appendix B of the Final Proposed Forest Plan addresses information needs including processes for prioritization and updating such programs. This framework is an ongoing process and our intent is to develop a Web-based tool to better facilitate sharing information among the many state and federal agencies, academia, and other entities involved in the study and research of Tongass National Forest topics.

Comment: Habitat changes associated with forest harvest are temporary, with rapid recovery for such variables as amounts of edge and cover for hiding and dispersal; the plan contains limited recognition of these relationships or their contribution to habitat quality.

Response: Temporary is a relative term. For some species, such as black-tailed deer, recently harvested units provide suitable habitat in the years immediately following timber harvest due to increased forage production. However, these stands provide relatively low value after about age 25 and until about age 75 years or beyond, when forests are in the stem exclusion stage of stand development, which is characterized by small, dense trees with little understory vegetation. For some other species, harvested units provide little value until they regain old-growth characteristics either because of specific structural elements (e.g., large woody debris) found in these stands, or because of the presence of prey populations that are dependent on old-growth. Once stands transition out of the stem exclusion stage, they begin to provide the components of good quality wildlife habitat, including larger trees, small canopy gaps, snags and downed logs. This can begin to occur as early as age 50, however, the literature suggests that stands do not begin to take on the characteristics of old growth until they reach at least 150 years of age (Alaback 1982). As discussed in the *Timber* and *Wildlife* sections of the Final EIS, active management of young-growth stands may reduce this time to some extent.

Comment: Growing recreation and other resource needs on the Tongass require better identification of the value of non-forested resources (e.g., high elevation, beach fringe, and wetlands). For example, Aleutian tern, arctic tern, and black oyster-catcher use areas should be identified and protected from disturbance. Special protection should also be given to watersheds that encompass beach meadows, a rare habitat type in Southeast Alaska, and peri-glacial habitats.

Response: Beach and Estuary Standards and Guidelines are provided in the 2007 Forest Plan as well as in all of the 2008 Final EIS alternatives. In the 2007 Forest Plan and the 2008 alternatives (except for Alternative 7, which has a reduced Beach and Estuary buffer of 500 feet, a 1,000-foot buffer provides a high degree of protection for shoreline and marine habitats. These standards and guidelines emphasize the protection and maintenance of the ecological integrity of shoreline and shoreline forest habitats for shorebirds, other marine-associated species, and the many upland species that make high use of these habitats. In addition, the Riparian Standards and Guidelines address the protection of streamsides, lakes, and ponds, wetlands, other non-forested habitats, and floodplain/glacial outwash habitats. The Final EIS shows that recreation is a large and growing use of the Forest. However, this analysis effort is being conducted in primarily in response to the August 2005 Ninth Circuit Court of Appeals Court Decision, which directed the Forest to take a second look at timber demand, the alternatives considered in response to timber demand, and cumulative effects. Therefore, the scope of the analysis focuses primarily on forested habitats that are likely to be affected by timber harvest and associated activities.

Comment: One comment stated: "We are very disturbed about discussions we are hearing about between the timber industry, the Forest Service, and others regarding the need for "intensive" timber management within the matrix lands. These conversations are happening outside the public arena in violation of NEPA, and appear to be based on the desire to increase timber economics rather than scientifically based publicly reviewed decisions. We consider the use of adaptive management to increase timber economics an extreme abuse of power and in clear violation of the numerous laws and public trust responsibilities the agency has." Another commenter was concerned about the Forest Service's move toward "intensive management" because the result of multiple entries into previously harvested units has often resulted in the creation of "creeping mega-cuts" which destroy wildlife corridors.

Response: The Forest Service meets with, and discusses ideas with, a wide range of stakeholders, including the State, local governments, industry groups, and environmental groups. The Forest is interested in developing economic timber sales and is willing to listen to ideas on how best to develop economic sales, while maintaining consistency with the Plan's goals and objectives, meeting the Plan's standards and guidelines, and being compliant with all laws and regulations. Modifications to certain standards and guidelines are being considered in some alternatives, but none of the alternatives include "intensive" timber management.

The "creeping mega-cuts" that the commenter refers to are a characteristic of logging that took place primarily in the 1960s through the 1980's, as well as more recently on some private lands. The adoption of the 1997 Plan created many "checks and balances" that result in avoidance of this situation on NFS lands. Adjacency requirements and watershed protection standards limit the size of clearcuts under all alternatives, and Class I, II, and III stream buffers, old-growth retention requirements, and many other standards and guidelines also limit opening size and total harvest acres per watershed. Even under Alternative 7, which includes the most intensive harvest among the alternatives, about 62 percent ((1.3 million of the 2.1 million acres) of the old growth within the matrix (development LUDs) would not be harvested, even after 100 or more years of harvesting at the maximum rate allowed by the alternative (see Table 3.9-12 in the *Biodiversity* section). This is in addition to the 2.8 million acres of old growth protected by reserves (non-development LUDs) under Alternative 7.

Comment: Fish and wildlife belong to the states and therefore identification of management objectives should be done by the State of Alaska and not the Forest Service.

Response: The Forest Service is responsible for setting management objectives for fish and wildlife habitats on NFS lands, including ensuring adequate habitat is maintained on the Tongass National Forest to sustain viable and well-distributed populations, as required under the NFMA. The Forest Service does work closely with the State of Alaska on joint matters related to management of fish and wildlife.

Comment: Roadless areas are crucial to the protection of the Nation's wildlife, fisheries, and water resources.

Response: We generally agree with this statement. However, what is more important is how the lands within roadless areas are managed through time. It is a primary purpose of forest planning to determine how best to balance the multiple-use objectives for all NFS lands, including those which are roadless. Over 90 percent of the Tongass is considered roadless; thus roadless areas are not a rare commodity on the Tongass, in contrast with roadless areas found in the national forests located in the lower 48 states.

Comment: Section II.H of the Wildlife Planning Standards and Guidelines do not require action until risk to long-term persistence is determined to exist. Also, the standards and guidelines assume that species abundances are known, but this is rarely the case on the Tongass, and the standard and guideline does not consider distribution.

Response: These standards and guidelines require evaluation of that species for designation as a Regional sensitive species by the Regional Forester, should a significant population or habitat decline occur. This does not preclude action being taken prior to that point. Additionally, they require coordination with state and other federal agencies where species concerns may be addressed well before they reach sensitive-species designation status.

Comment: We must preserve the ecological diversity of the forest, fauna, and salmon.

Response: The Forest Service agrees and strives to provide multiple resource uses while maintaining biological diversity.

Comment: To the extent possible, implementation of conservation measures should be flexible enough to enable tailoring them to site-specific conditions and facilitate design of economically feasible timber sales. Measures may vary from area to area to reflect different species concentrations and sensitivities, and to concentrate timber harvesting in intensively managed areas rather than dispersing harvest throughout the forest. Intensive timber management which minimizes the area affected by timber harvesting will have the least impact on conservation values and the best chance for broad public support.

Response: Standards and guidelines presented in the Forest Plan are purposefully general in some instances in order to allow site-specific conditions to influence their application. See also the comments and responses in the Timber section of this appendix.

Comment: As part of the The Nature Conservancy (TNC)-Audubon Alaska (Audubon) conservation assessment biological values and risks for focal resources (e.g., large trees, salmon habitat, deer habitat) were evaluated within each biogeographic province. An index of relative biological value, defined as the percent contribution of each biogeographic province to the total distribution of habitat values for each species or ecological system. Given that this suite of focal resource targets represents a range of terrestrial, freshwater, and nearshore marine ecosystems, this index provides a reasonably robust ranking of biological values associated with coastal forest ecosystems. Several comments suggested that the Forest Service incorporate the major elements of the conservation assessment and strategy, developed by Audubon and TNC (Albert and Schoen 2007), into the Final Proposed Forest Plan. This design is intended to provide watershed-scale protection to the highest ecological value intact watersheds in each biogeographic province on the Tongass and also maintain core areas of ecological value in a selection of the highest value modified watersheds. Rather than distributing timber harvest and road building across the entire forest, this design works to aggregate these activities in fewer watersheds. Comments from TNC and Audubon note that subsistence and community use areas were not incorporated into the design and that the conservation design should be fine tuned to incorporate these resources.

Response: Information from the TNC-Audubon conservation assessment has been incorporated into the Final EIS as appropriate to strengthen the biodiversity analysis, and in the modification of alternatives. The *Biodiversity* section also provides more extensive quantification of the existing levels of large-tree POG, high-volume POG, karst POG, and intact watersheds by biogeographic province; it also makes projections for these measures into the future under each alternative, on NFS lands and cumulatively, for all of Southeast Alaska. The alternatives considered in the Final EIS were not designed around the Albert and Schoen (2007) report, but Alternatives 1, 2, and 3 take into account some of the considerations raised in that report. The *Biodiversity* section cites Albert and Schoen (2007) throughout the subsection that describes the forest-wide distribution of old-growth; however, while the Audubon and TNC assessment provides a summary of recent literature related to individual wildlife species, the *Wildlife* section incorporates information from individual studies, citing them directly.

Comment: The original 21 biogeographic provinces were based largely on topographic features and generalized information about biotic communities in Southeast Alaska, rather than scientific research. This Amendment incorrectly states that the original biogeographic provinces were based on conclusions drawn about similar species comparisons. Alternative biogeographic provinces have been proposed that do rely on peer-reviewed scientific research.

Response: The respondent appears to have drawn an incomplete conclusion from how biogeographic provinces are described in the EIS. The description summarizes that they are generally characterized by similar wildlife species composition, similar distribution of wildlife species, geologic and water barriers resulting from glaciation and other events, and generally similar climatic conditions and physiographic characteristics. It is recognized that these provinces are a broad land classification. It is useful to continue using the same classification for comparison with the 1997 Final EIS and it is very similar to the provinces used in the TNC-Audubon conservation assessment.

Comment: The Biodiversity section focuses on timber and forest management and addresses biodiversity from an ecosystem-level perspective. It should address species and genetic biodiversity.

Response: As stated in the *Biodiversity* section, conserving biodiversity is about maintaining genetic, species, community or ecosystem, and landscape levels of biological organization. As the respondent noted, the *Biodiversity* section addresses conservation of species and other elements of biodiversity by using a broader "coarse filter," or ecosystem/landscape based strategy for conserving biological diversity. Finer scales of biodiversity (i.e., individual species and genetics) are addressed in the *Wildlife*, *Plant*, and *Fish* sections of the Final EIS.

Comment: In the Biodiversity section, the first paragraph of the Old-growth Conservation Strategy subsection of the Affected Environment states "Approximately 78.5 percent, or 13.2 million acres, of the Tongass is in Wilderness or mostly natural settings…" These statistics mislead rather than contribute to the discussion of the conservation strategy because the focus of the strategy is on old-growth and very little old-growth occurs under these designations. This statement does not belong here at all.

Similarly, the next paragraph states "approximately 85 percent of the old-growth existing in 1954…" This statement presents statistics for the broadest of forestland categories, old-growth, by including both POG and non-POG. The real threat is to POG and therefore this statistic should include only POG.

Response: Although these portions of the *Biodiversity* section have been revised in the Final EIS, it is appropriate to discuss both the percentage of all lands and the percentage of POG within reserves. Secondly, old-growth percentages that are discussed do represent only POG – all of the percentages given for old growth in the effects analysis are for POG or a subset of POG (e.g., large-tree POG).

Comment: The sections of the Draft EIS that discuss biodiversity and wildlife are largely devoid of any analysis and clearly do not meet the hard-look standard required by NEPA.

Response: The *Biodiversity* and *Wildlife* sections in the EIS take into account the best scientific information available. Extensive quantification of effects using GIS analysis, habitat modeling, and forest management modeling, an inventory of harvest and road development on all lands of Southeast Alaska, along with future development projections, and the application of expert wildlife viability panels. Nevertheless, the analysis presented in the Draft EIS was expanded substantially for the Final EIS and we believe these analyses are adequate.

Comment: For the discussion of forest "composition, structure, and function" the introductory section of the Draft EIS Biodiversity section refers the reader to sections of the 1997 Final EIS. This is confusing because much of that information has been updated on the following pages of the Draft EIS.

Response: It is true that much information with respect to biodiversity has been updated since 1997. The definitions of composition, structure, and function, however, have not changed from those given in the 1997 Final EIS, which is appropriately incorporated by reference because it includes further information on these components of biodiversity that might be of interest to the reader. What has changed, however, is how we take these ecosystem components into account. For example, the Size Density Model (SDM) is now available for use in the biodiversity analysis. Thus, the discussion in the *Biodiversity* section referenced in the comment differs from that in the 1997 Final EIS.

Comment: In contrast to parts of the world where significant logging has occurred, the Tongass can be an example of how sustainable logging can be conducted on public land, not only for Southeast Alaska, but for the world.

Response: We agree. The Tongass strives to manage a timber program that is sustainable, while providing for sustainability of multiple other resources.

Comment: The Draft EIS is incorrect in stating that logging will be concentrated in four biogeographic provinces; this is not true because all alternatives allow intensive logging under Timber Management as well as less intensive but still consequential logging in the Modified Landscape LUD.

Response: The majority of harvest would remain "concentrated" in these four biogeographic provinces. However, under some alternatives, logging and road construction would be more extensive in areas outside of these provinces. Alternative 1 would not enter any inventoried roadless areas whereas Alternative 7 proposes to harvest the most timber from roadless areas. The commenter also appears to be confusing biogeographic provinces with LUDs.

Comment: Increased predation occurs in logged area because there are so many more small mammals in those areas. This is good for raptors, etc. The Forest Service even issued an alert in the 1960s because they were alarmed at the dramatic increase in mice in clearcuts. The mice were allegedly eating too many of the tree seeds.

Response: It is true that timber harvest can benefit some species while adversely affecting others.

Comment: One respondent was very disappointed to see that National Monument Lands, which are fully protected from timber harvest, had relatively low value to wildlife and felt that the Forest Service depicted the alternative maps deceivingly. Another respondent made a similar comment about the inclusion of low value habitat in Wilderness and LUD II designations.

Response: The wildlife values depicted across the Tongass, including those within National Monuments, are reasonable. A National Monument is an area of land that is set aside to preserve some feature of it that makes the land important. This may include anything from scientific or historical interests to scenic beauty and wildlife protection. There are two National Monuments on the Tongass: Misty Fiords and

Admiralty Island. National Monument Lands are created by presidential proclamation, not by the Forest Service, thus the alternative maps depict these areas as they have been designated. Although Misty Fiords contains large expanses of non-forested lands, Admiralty National Monument represents one of the highest value habitat areas in all of Southeast Alaska. It contains the second highest acreage of POG among all provinces in Southeast Alaska (598,000 acres). The vast majority of Admiralty Island remains intact and, as a result of the abundance of POG in this province, including high-volume and large-tree POG, it represents a massive reserve and reservoir for biological diversity in Southeast Alaska. In addition, Wildernesses and LUD II areas are highly variable in terms of their wildlife habitat values and availability of POG. The Karta Wilderness and the Nutkwa LUD II area on Prince of Wales Island contain very high fish and wildlife habitat values and extensive areas of POG.

Comment: The Tongass manages one of the largest island archipelagos in the world and nowhere is this important point emphasized in the Proposed Forest Plan or Draft EIS, particularly in the description of the forest in Chapter 2.

Response: The point that the Tongass is an island archipelago is discussed in the *Biodiversity* and *Wildlife* sections of the EIS. The extensiveness of the island archipelago is also described in the description of the forest in Chapter 1.

Comment: There is very little young-growth on the Tongass. Converting a small portion of the old-growth to young-growth will actually add to biodiversity (i.e., broader more balanced distribution of forest age classes).

Response: At a landscape-scale, old-growth forests on the Tongass are highly diverse, typically including heterogeneous stands of productive forests within a mosaic of unproductive forests and non-forested areas comprised of shrub and herbaceous plant communities. They are also diverse at the stand-level, possessing structural attributes that provide habitats for a variety of species such as live old-growth trees, dead standing trees (snags), fallen trees/ logs, and an overstory consisting of multiple canopy layers; they also have smaller understory trees, canopy gaps, and patchy understories. Timber harvest reduces this diversity by creating a more uniform stand of young-trees. Old-growth forests can also provide ecological functions that are lacking, or less developed, in younger stands. There are opportunities to manage the more than 400,000 acres of young stands on the Tongass to increase biodiversity, which are described in the *Timber*, *Biodiversity*, and *Wildlife* sections of the Final EIS.

Comment: The Tongass National Forest should work with private and state forest managers in developing unified definitions and inventories for old-growth forest types, and accurately monitor their abundance and rates of change.

Response: The Forest Service routinely collaborates with other agencies and private landowners.

Comment: The Draft EIS does not disclose the sources and reasons for its assumptions that POG originally comprised 50 percent of all non-NFS lands and that 25 and 50 percent of the remaining private and state-owned lands, respectively, will be logged.
Response: The quantification of POG on non-NFS lands has been refined and is more accurately depicted in the Final EIS. Appendix E has been added to the Final EIS which provides a catalogue of past harvest, detailing the acres of harvest by owner by biogeographic province and by decade or period (where known), in addition to detailed information provided by the State on past harvest. An expanded cumulative effects discussion has been added to the *Biodiversity* section on future harvest on non-NSF lands.

Comment: One comment expressed concern that slash from helicopter logging could hinder wildlife movement.

Response: Silvicultural prescriptions routinely consider slash disposal requirements in light of resource issues which are tracked at the project level.

Conservation Strategy

Comment: Some respondents believe that Alternatives 1,2, 3 and 6 have better biological locations for the small OGRs, which were identified during the 2006-2007 interagency review effort and meet the 1997 Forest Plan Appendix K criteria, and believe that one of those alternatives should be selected.

Response: We agree that the changes made to old-growth reserves in these alternatives are an improvement from a biological point of view.

Comment: To help prevent the need to list the goshawk and wolf under the ESA several respondents recommended that the Forest Service select the preferred biological locations for the 48 other small OGRs as indicated by the interagency Small Old-growth Reserve Work Group (particularly if interagency review cannot be completed in time for the Final EIS) and maintain the existing elements of the conservation strategy, including the forest-wide network of OGRs, the 1000-foot beach and estuary fringe, and the existing Goshawk Foraging Habitat Standards and Guidelines; it was noted that the old-growth reserve system was cited by the Fish and Wildlife Service as reasons that these species did not warrant listing. Some respondents expressed concern that eliminating these measures would open the possibility that any decisions made by the Fish and Wildlife Service could be remanded.

Response: Alternatives that eliminate major elements of the conservation strategy are ranked as having a lower relative likelihood of sustaining well distributed goshawk and wolf populations. A detailed discussion of the existing and proposed changes to the Goshawk Standards and Guidelines is provided in Appendix D of the Final EIS. The USFWS published a new finding on the goshawk in November 2007, after the release of the Draft EIS. They found that the best available information on biological vulnerability and threats to the goshawk does not support listing the Alaska population segment as threatened or endangered at this time. This conclusion was based on conservation measures that were included in the 1997 Forest Plan. Conclusions from this finding have been considered in the goshawk subsection in the Final EIS.

Comment: The Draft EIS fails to disclose or consider findings and relevant data from recent literature or the 2006 Conservation Strategy Review workshop regarding endemics.

Response: .The discussion of endemism has been updated to include the most current literature on endemics, including information presented at the 2006 Conservation Strategy Review workshop.

Comment: A number of comments were received on the adequacy and necessity of the conservation strategy. Several respondents commented that the forest-wide conservation strategy adopted in the 1997 Forest Plan is an improvement over previous plans but is flawed. Some felt that it is overly protective and its value and effectiveness should be peer-reviewed. Respondents with this opinion viewed the conservation strategy as simply a way to give other agencies a "veto voice" in management of the forest, or felt that congressionally designated reserves or other protections (e.g., buffer and retention requirements and state BMPs) were adequate protection for plants animals, and landscape connectivity, making other reserves and species-specific standards and guidelines unnecessary. Other respondents felt it was a more

than adequate strategy to support well-distributed, viable wildlife populations. Finally, other respondents felt that the conservation strategy was not protective enough, stating that the Draft EIS does not provide science-based rationale for concluding that the conservation strategy continues to be valid. Several of these respondents suggested that the Forest should base management efforts on an island-centered model given that the Forest covers one of the largest island archipelagos in the world. These respondents felt the Draft EIS fails under NEPA to disclose the uncertainties behind the strategy.

Response: Although many uncertainties remain regarding managing wildlife on the Tongass and the effectiveness of the Tongass conservation strategy, the underpinnings of the strategy continue to be a valid model for conserving biodiversity on the Tongass. The conservation strategy was developed as an interagency effort and was peer-reviewed by independent scientists and natural resource managers using their expertise and best available science. The *Wildlife* section of the Final EIS discloses the existing uncertainties surrounding the conservation strategy. Appendix D of the Final EIS provides a summary of a review conducted by Haufler (2006) on the developments in the field of conservation science produced since 1996, which includes an evaluation of the Tongass conservation strategy.

Comment: The conservation measures proposed to provide for viability of wildlife species on the Tongass are inadequate (i.e., insufficient reserves, inadequate connectivity, too much fragmentation), as concluded by a joint statement issued by peer review committee members (Kiester and Eckhardt 1994). Any claim made in the EIS that well-distributed, viable populations are reasonably assured over the long-term under any of the alternatives is not borne out by scientific opinion

Response: Appendix D of the Final EIS summarizes the development of the conservation strategy and peer reviews conducted to date. It provides the rationale behind the reserve-based strategy and describes major steps leading to its development, including the pioneering work of the Interagency Viable Population Committee (VPOP; Suring et al. 1993) which designed an initial landscape conservation strategy they felt was capable of assuring the maintenance well-distributed wildlife populations across the Tongass. The joint statement, referred to in the above comment (Kiester and Eckhardt 1994), stemmed from an independent review of the VPOP strategy conducted by the Forest Service Pacific Northwest Research Station (PNW). This joint statement did identify several weaknesses in the strategy, as stated by the respondent. Importantly, however Kiester and Eckhardt (1994, p.3) noted that the PNW Review only considered the network of mapped VPOP large and medium HCA's and Congressionally protected areas such as Wilderness, Monuments and Legislated LUD II areas. The VPOP reserve network was not examined in the context of the entire Forest Plan or a fully articulated planning alternative containing the strategy. The scientists were unable to consider other LUDs that effectively function as reserves and conserve the old-growth ecosystem—a very important component incorporated into the development of the old-growth habitat conservation strategy in the Proposed Forest Plan and the analysis in the EIS. Please see Appendix D of the Final EIS for further discussion of the Forest Service response to the PNW review (Suring et al. 1994) and the progression from this response to the development of the final 1997 conservation strategy.

Comment: Appendix N of the 1997 EIS should be updated and this information should be incorporated into the Final EIS.

Response: Appendix D of the Final EIS serves as an update to Appendix N of the 1997 EIS and includes additional background information used to support the wildlife analysis.

Comment: Assumptions that timber harvest impacts on wildlife require restriction such as beach buffers, riparian buffers, and OGRs are simplistic because some harvest methods (e.g., selective cuts, small clear-cuts) can be conducted in these areas with minimal negative impacts.

Response: The reserve system serves two important functions in that it provides a means for protecting old-growth habitat as well as maintaining landscape connectivity. Though timber harvest can be done in a way to reduce effects to wildlife and may improve habitat quality for some species, any level of timber harvest increases the amount of habitat fragmentation which breaks large blocks of habitat into smaller parcels resulting in smaller and more isolated residual habitat patches. Open spaces left by timber harvest can act as travel barriers for some species, thus limiting interaction between subpopulations, and increase the risk of predation for other species that venture across them. For species that are sensitive to human activity or have restricted mobility, even small areas of timber harvest may create barriers to their ability to move across the landscape. A detailed discussion of fragmentation and its effects is included in the *Biodiversity* and *Wildlife* sections of the EIS.

Comment: Logging in the beach fringe causes obstructions for wildlife moving through; a reduced beach buffer would avoid this situation.

Response: Heavy log concentrations, such as that left as slash from selective logging, can obstruct the movement of larger wildlife species (i.e., deer), but benefit other species by providing places to forage, hide, seek shelter, and den. The beach fringe is classified as unsuitable for timber harvest, though a limited amount of timber harvest not counting toward the ASQ may occur (e.g., timber sold as part of a salvage sale, specialty wood products, for habitat restoration, for customary and traditional uses, etc.) Reducing the beach fringe would not reduce the amount of downed wood left from these uses, but would be more likely to increase the amount of slash by expanding the area in which timber harvest can occur.

Comment: Some commenters thought that the ecological rationale for expanding the beach buffer to 1,000 feet is not clear. Others felt that the 1,000-foot beach fringe buffer standard and guideline should be retained to support viable, well-distributed wildlife populations.

Response: The beach buffer provided under the current Forest Plan is 1,000 feet and would remain that size under Alternatives 1, 2, 3, 4, 5, and 6. None of the alternatives propose to expand it. Under Alternative 7 the beach buffer would be reduced to 500 feet. Rationale for this reduction is provided in Appendix D. The 1,000-foot buffer requirement was based on the recognized importance of the beach fringe zone as indicated by high habitat capability model ratings for a variety of species (bald eagle, marten, river otter, brown bears, black bears, and deer), observations of nesting bald eagles and radio-tagged goshawks, its high value for landscape connectivity, as well as the available scientific literature. The importance of the beach buffer to wildlife is discussed in the description of the affected environment in the *Wildlife* section.

Comment: Retaining the Tongass Conservation Strategy in its entirety will provide the Forest Service with a tool with which it can build ecosystem resilience on the Tongass and manage natural resources effectively in the face of climate change.

Response: We agree that a system of OGRs, various buffer requirements, and non-development LUDs are a means for maintaining a level of biodiversity capable of adapting to the effects of changing environmental conditions. A statement expressing this has been added to the discussion of cumulative effects in the *Wildlife* section of the EIS.

Comment: Several respondents suggested that a finer-scale analysis of landscape connectivity should be conducted at the level of ecological subsections to identify additional corridors and included in a Supplemental Draft EIS. Several respondents identified additional landscape pinch-

points or areas where landscape connectivity is an issue and suggested that these areas be addressed in the Final EIS; others requested that areas that could become pinch-points in the future due to future timber harvest be evaluated. Other respondents were not clear how the initial set of pinch-points were selected.

Response: We recognize that there are a number of additional pinch-points on the Tongass that were not addressed specifically in the Draft EIS. We provided a detailed evaluation of those pinch-points that were located in areas where a substantial amount of timber harvest has occurred and is likely to occur in the future. As noted in the *Wildlife* section, timber harvest could affect "ecological pinchpoints" or areas where habitat conditions, rather than landscape features, facilitate movement across the landscape. The detailed level of analysis required to assess effects to these areas is necessarily done at the project level when site-specific conditions and project-specific details can be taken into account.

Comment: Several respondents identified minimizing habitat fragmentation as an important issue in developing the Final EIS and Final Proposed Forest Plan.

Response: Habitat fragmentation is discussed in detail in the *Wildlife* and *Biodiversity* sections of the EIS. Alternatives that would result in the least habitat fragmentation (i.e., those with the smallest amount of timber harvest and road development) were rated as having the lowest level of effects to wildlife populations.

Comment: The timber industry requires about a quarter of the old-growth on the Tongass, which would leave the remaining old-growth for the conservation strategy; therefore the Forest should eliminate protective measures such as the Marten and Goshawk Standards and Guidelines, the old-growth reserve system, and Class III stream buffers, and should reduce the beach buffer.

Response: Providing an appropriate juxtaposition of habitats and ensuring connectivity across the landscape (both structural through buffers and reserves and functional through management of matrix lands) is essential to providing a functional landscape capable of supporting viable and well-distributed wildlife populations. Timber harvest on the Tongass has been disproportionate, focusing on forest stands at lower elevations, with the largest trees, and concentrated in certain biogeographic provinces. These areas are generally the most productive for wildlife and, therefore, timber harvest has disproportionately affected wildlife and habitat in these areas. Thus, simply allowing a quarter of the remaining old-growth to be harvested without consideration of the spatial distribution of harvest or provision for the protection of important elements within the old-growth ecosystem (i.e., legacy trees or specific forest structural stages) would result in further disproportionate effects.

Comment: The Forest Service should explicitly list the concerns and issues identified by scientists during the 2006 Tongass Conservation Strategy Review workshop and identify how each was addressed. Many issues appear to not have been incorporated in the Draft EIS or the Proposed Forest Plan.

Response: The NFMA planning regulations provide direction to conduct an evaluation of the Forest Plan after 5 years of implementation (36 CFR 219.12(g)), including a review of the effectiveness of the Plan's old-growth conservation strategy to conserve biodiversity and prevent the need to list species under the ESA. The 2006 Conservation Strategy Review workshop represented the first step in the evaluation process, with the purpose of identifying considerations to be addressed in the overall review of the strategy. A report documenting the workshop, found in the project record, represents the second step. It is one of several documents responding to the Forest Plan review that serve to provide issues and information for use in current Forest Plan Amendment process and in managing resources under the Forest Plan.

Subsequent steps will include an assessment of each consideration identified herein, based on workshop information, peer-reviewed scientific literature, the recent *Review of Conservation Science Produced Since 1997 and Its Relationship to the Tongass National Forest Land and Resources Management Plan* (Haufler 2007), as well as input from various state and federal agencies. These assessments will culminate in a determination of how each consideration will be dealt with. Some considerations have been addressed in time for incorporation in this Forest Plan Amendment Draft EIS, others in time for incorporation in the Final EIS, and others, which might require additional interagency consultation, the formation of specialized workgroups, and more detailed development, will be implemented after the Final EIS. These long term considerations could lead to conservation strategy-related adjustments to the amended Forest Plan through additional amendments or identified as information needs. This effort will be summarized in a forthcoming Conservation Strategy Review Proceedings Assessment Report, which will include a matrix of the consolidated consideration that will identify how individual considerations will be addressed. Additional scientific information presented at the workshop has been included in the Final EIS.

Comment: The Conservation Strategy and Landscape Connectivity discussion in Chapter 2 of the Draft EIS incorrectly characterizes Alternative 7 as having a poor distribution of high-quality old-growth, given that over 80 percent of the commercial old-growth and over 75 percent of the productive old-growth remain and are well scattered across the forest and the wide distribution of non-development LUDS, minimum development LUDS, and buffer requirements.

Response: The conclusion about Alternative 7 was based on what potential results would be over the long-term. Alternative 7 would have extensive areas consisting of development LUDs with no reserves and a reduced beach fringe for connectivity. Although there would be extensive old growth left within the development LUDs as a result of standards and guidelines, the lack of larger patches of old growth, as are found in reserves, is the major reason for the conclusion.

Comment: The forest-wide mapping of small OGRs could impact resources other than wildlife and should be fully analyzed in the Final EIS. Project-level adjustments to OGRs should continue to be allowed.

Response: Forest-wide small old-growth reserve mapping efforts provided an opportunity to conduct a landscape-scale review of the small OGRs. This effort was proposed primarily to develop a consistent and more efficient method of review, and to more accurately define the location of small OGRs to enhance the Proposed Forest Plan conservation strategy rather than complete the review on a project-by-project basis. The review process involved the incorporation of a biological consensus recommendation for each old-growth reserve under review, determined through interagency analysis, and was followed by another review that took into account other resource considerations, including timber and timber sale economics. Project level adjustments will be considered if significant new information becomes available.

Comment: The conservation strategy does not quantitatively assess the additional amount of productive old-growth reserved by restrictions to harvest on high hazard soils and karst lands.

Response: Standards and guidelines preclude or significantly limit timber harvest in areas of high hazard soils, steep slopes (greater than 72 percent), high vulnerability karst terrain, visually sensitive travel routes and use areas, and timber stands that are technically not feasible to harvest. The timber deferred from harvest by these standards and guidelines is determined at the project level, usually as a result of on the ground inspection during project implementation. Although it cannot be precisely determined at the forest planning level, the acreage of POG that is set-aside due to oversteepened slopes, other areas of very high mass movement potential, and karst , based on digital elevation modeling, soils mapping, and geologic mapping. In addition, estimates of the amount of additional restrictions that are implemented during a project are included in the Model Implementation Reduction

Factor. These combined reductions are used in all POG predictions and in calculations of the ASQ in the Spectrum model (see page 3-261 to 263 in the Draft EIS). These quantifications are used for describing and testing of the matrix part of the conservation strategy. The degree of old growth retained within the matrix through time, through OGRs, stream buffers, and implementation of standards and guidelines for karst, steep slopes and other resource concerns was considered and is a very important component of the overall strategy.

Comment: One comment indicated that the Draft EIS does not provide information necessary to evaluate the proposed conservation strategy and does not document the basis for the strategy, thereby violating NEPA. Some respondents requested an extension of the public comment period until the scientific rationale behind the conservation strategy is presented. The Final EIS should include additional discussion for the scientific basis for changes to the conservation strategy.

Response: The Draft EIS described the framework for the Tongass conservation strategy in detail in the Old-Growth Forest Conservation Strategy subsection of the description of the affected environment in the *Wildlife* section. The basis for the conservation strategy and overview of its development was provided in the introduction to the Environmental Consequences portion of the *Wildlife* section, followed by a description of what changes to the strategy are proposed under each of the alternatives. An analysis of effects of changes to that strategy is provided in general under the Old-Growth Forest Conservation Strategy subsection and under individual species where appropriate (i.e., goshawks and marten). The conservation strategy was also described and discussed in the *Biodiversity* section of the Draft EIS. Appendix D of the Final EIS elaborates on the information related to the conservation strategy provided in the Draft EIS and provides additional discussion of the history and background of the strategy and the scientific rationale behind changes. This appendix also provides a comparison between existing and proposed plan components.

Comment: The 2006 conservation strategy review did not allow public participation, either during or after presentations, and no final report has been prepared to date incorporating interagency review. Scientists comprising the panel of experts did not constitute an independent review body and members of the original 1997 panel were not asked to participate even though many continue to be leading experts in their field; in contrast there was a high level of participation of Forest Service employees without biological expertise.

Response: The purpose of the 2006 Conservation Strategy Review workshop was to 1) facilitate robust discussion among members of an interagency Workgroup and scientific and technical experts regarding new information attained since 1997 that may be relevant to the conservation strategy; and 2) generate and discuss science-informed “considerations” relative to the strategy. Scientists considered to be experts in their fields of study were invited to participate and were charged with the task of conducting an independent review of new scientific or other relevant information since 1997, presenting a summary of key findings regarding what the new information meant relative to the Tongass conservation strategy, and providing “considerations” for the workshop record and the Workgroup to discuss regarding the strategy. These presentations were followed by a discussion between the 6-member interagency Workgroup and the presenters, and other collaborating scientists. The Workgroup could call on other subject matter experts for input as necessary. Sometimes this included experts in resource fields other than biology who provided valuable insight into problems encountered when implementing Conservation Strategy Standards and Guidelines. A final report summarizing the workshop proceedings, including a written record of all discussion attributing comments to individual scientists and listing all considerations, is in the project record. The purpose of this report, and the workshop itself, extends beyond this Forest Plan Amendment and is intended to assist the Forest Supervisor in considering the need for adjustments to the Forest Plan Monitoring Program, Forest Plan standards and guidelines, and aspects of the conservation strategy. The results will also guide future investments in research and management studies by the Tongass National Forest and its interagency partners. Relevant new science presented during the workshop has been incorporated into the Final EIS and some considerations have been addressed as part of this effort.

The workshop was open to the public and consequently the audience included other subject matter experts, not participating in the presentations, and members of the public at large. During specific topic sessions, the audience was invited to submit written considerations for the workshop record. The same form that was being used by presenters and the Workgroup to describe considerations was provided for the audience's use. All considerations submitted by audience members were included in the workshop record. The public was also welcomed to submit considerations relevant to the conservation strategy review workshop via the project website which included PowerPoint presentations from the workshop, through April 21, 2006.

Comment: Project-level review of small OGRs that do not meet criteria in Appendix K of the 1997 Forest Plan should follow the format used by the 2006-2007 Interagency Small Old-growth Reserve Work Group (Hansen et al. 2006), including using a standardized review protocol, documenting changes made to OGRs, identifying how the proposed changes meet Appendix K criteria, assessing the effects of roads in and adjacent to OGRs, and documenting implementation of Tongass Plan Implementation Team clarification "Conveyance on Overselected Lands and the Old-growth Habitat Land Use Designation;" these items should be included in Appendix K of the Forest Plan.

Response: Appendix K has been revised in the Final Proposed Forest Plan to incorporate the format used during the 2006-2007 interagency review.

Comment: A forest-wide review of medium OGRs is warranted, comparable to that conducted for small OGRs by the Interagency Small Old-growth Reserve Work Group.

Response: There is little indication that such a review is warranted. Appendix D of the Final EIS provides a summary of a review conducted by Haufler (2007) on the developments in the field of conservation science produced since 1996. The author concluded that "the conservation strategies used in the plan are still valid at the present." New information and knowledge relative to conservation biology will continue to evolve. The amended Forest Plan, including the conservation strategy will be reviewed again in 5 years and if a more intense review to components of the strategy are warranted it can be done.

Comment: Many wildlife species live and travel through young-growth timber just as well as they do in old-growth, maintaining connectivity between OGRs; therefore Conservation Strategy Standards and Guidelines are unnecessary as roads provide travel corridors for wildlife whether closed or left open.

Response: Old-growth forest provides key habitat components for many species that are not available in young-growth (i.e., large trees, snags, downed trees, full canopy cover, and an open understory). These habitat components provide essential denning, nesting, foraging, perching, and hiding opportunities for a variety of species. Though roads may be used as travel corridors for some species, many species are extremely sensitive to activity along open roads and avoid areas near roads. Timber harvest and roads, whether closed or open, increase habitat fragmentation which breaks larger sections of forested habitat into smaller, isolated patches and reduces the effectiveness of interior habitat. Openings created by timber harvest and roads can also become travel barriers, particularly for species that are less mobile or have very limited gap-crossing abilities. Roads also increase human access and thus the susceptibility of wildlife to hunting (illegal and legal) and other disturbance. Therefore, maintaining well-connected old-growth forest across the landscape is key to maintaining well-distributed wildlife populations on the Tongass.

Comment: The Tongass conservation strategy is overly costly and is the primary reason the Forest Service has not been able to prepare economic timber sales and has resulted in the loss of hundreds of jobs. Alternatives 1, 2, 3, and 6 cannot be implemented because they include the conservation strategy that increases harvest costs.

Response: The conservation strategy is the primary means by which the Forest Service meets its multiple use objectives as required under the NFMA. It is designed to maintain viable, well-distributed wildlife populations while enabling an active timber sale program. We are not aware of evidence that the conservation strategy has resulted in the loss of hundreds of jobs.

Comment: The statement in the Draft EIS that "because of the reduction or elimination of the old-growth reserve system under Alternatives 4 and 7, respectively, these alternatives could have a low or moderate likelihood of maintaining viable, well-distributed wildlife populations" is incorrect.

Response: It is true that Alternatives 4 and 7 would have a reduced likelihood of maintaining viable, well-distributed wildlife populations relative to Alternative 5 which harvests less timber, involves less road building, and incorporates more protective conservation measures. This statement has been clarified in the Final EIS text**.**

Comment: One comment stated that the Proposed Forest Plan is focused on protecting old-growth blocks at the watershed scale, which will ultimately lead to reduced habitat diversity, increase fragmentation, increase road impacts and human access, and will generally lead to the erosion of ecosystem integrity within the watershed.

Response: During the planning process prior to the 1997 Forest Plan, small OGRs received varying levels of review but were placed within each VCU; roughly equivalent to a watershed) in an effort to ensure that the protection of old-growth habitat was well-distributed across the Forest. The 1998 Tongass Plan Implementation Team clarifications provided for further, project level evaluation and adjustment of these reserves. Initially these reviews were conducted in association with individual timber sales, focusing on specific VCUs, covered by the project area. However, more recently reviews have taken a broader focus and have been completed for all OGRs on an island or other logical geographic scale. Most recently, in 2006 and 2007 a forest-wide review of small OGRs was conducted which had the objective of enabling large-scale, landscape issues to be considered in the placement and configuration protected blocks of old-growth.

Comment: In addition to reserve lands mentioned in the Proposed Forest Plan, a number of additional reserve lands are present in Southeast Alaska and adjacent British Columbia that also provide habitat for a number of wildlife species addressed by the Forest Plan.

Response: The Forest Service agrees with this statement.

Comment: The Draft EIS recognizes that matrix lands play a vital role in providing functional connectivity across the landscape but fails to take a hard look at the impact of the alternatives. There are no alternative methods for matrix land management. Some respondents contend that because management of the matrix is important for maintaining viable populations of wide-ranging species, the matrix itself needs to be defined in terms of its role in the conservation strategy. They quoted various participants at the 2006 Conservation Strategy Review workshop who emphasized the importance of matrix lands in meeting habitat, prey, and connectivity requirements. They also felt that the Legacy Standards and Guidelines need to convey the role of matrix lands in the conservation strategy.

Response: Forest Plan standards and guidelines are the framework for matrix land management on the Tongass. Changes to standards and guidelines proposed under the alternatives are discussed under the corresponding sections in the Final EIS. Appendix D provides additional discussion of the rationale behind proposed modifications to or replacement of Wildlife Standards and Guidelines. We recognize the habitat and connectivity values of matrix lands; hence the numbers of standards and guidelines applicable to lands considered for timber harvest can contribute to longer term old growth within those lands. The sum of those ensures the functionality of the entire ecosystem from the reserves and between the reserves in the matrix. The reserves help us meet the requirement for species well distributed across the Forest; standards and guidelines applied to matrix lands help ensure we will not likely approach minimum habitat needs through time.

Comment: Some respondents felt that the Draft EIS and Proposed Forest Plan fail to take a hard look at landscape linkages and wildlife corridors and protect these areas, especially given that the ecological value of many of these areas has been reduced by historic (e.g., timber harvest) and current activities (e.g., recreation). Some felt that the Draft EIS does not cite any scientific evidence or peer-reviewed study to support the contention of the Forest Service that protected corridors (i.e., beach, riparian, estuarine buffers) will function to provide connectivity in heavily logged or roaded landscapes. Others felt that it seemed as though the Draft EIS and the Forest Pan assume these provisions will remain in pristine condition and function as corridors. One respondent commented that they would like to see patches of old growth modified so that they are associated with natural corridors for wildlife and stream protection.

Response: It is true that the effectiveness of conservation strategy reserves and buffers in relation to their size, landscape pattern, and geographic distribution has yet to be scientifically tested. A statement to this effect has been added to the Final EIS text. Landscape connectivity was an integral feature of the original VPOP landscape conservation strategy (Suring et al. 1993), one of the precursors to the current conservation strategy. VPOP reviewed the available literature and concluded that there was limited empirical support for corridors but that this should not preclude their inclusion in landscape conservation planning. They reasoned that landscape habitat connectivity was an important component of conservation planning to facilitate animal dispersal and movement, whether specifically designed as corridors or through overall management of a habitat matrix. Appendix D of the Final EIS provides a detailed review of steps leading up to the development of the conservation strategy.

Comment: The fact that roads contribute to habitat fragmentation should have been considered in the Draft EIS. Please consider additional road restoration and closures.

Response: Road-related habitat fragmentation is described throughout the *Wildlife* section of the Final EIS. A transportation objective under the Final Proposed Forest Plan is to manage and maintain roads to protect water, soil, fish, and wildlife resources. Decisions related to the restoration or closures of specific roads are made at the project level.

Comment: Several respondents feel that the Landscape Connectivity Standards and Guidelines are incomplete and lack a definition for connectivity, directives on critical aspects of connectivity (e.g., no requirement for corridor designation and no minimum corridor width or means for determining necessary width). Some suggested that the standards and guidelines should also mandate a procedure for connectivity analyses and evaluation of long-term population viability. One respondent thought there seemed to be an emphasis on connectivity within medium and large OGRs rather than between reserves, and no measurable means to ensure connectivity is provided. Several respondents pointed out that there is no requirement for connectivity between small OGRs and that connectivity is not being preserved on the ground; suggestions were made to designate physical corridors to provide direct connectivity between small OGRs and to develop standards and guidelines requiring connectivity between small OGRs.

Response: Connectivity between reserves was a consideration in the design of the Conservation Strategy and was also considered during the small old-growth reserve updates for this Plan. The Landscape Connectivity Standards and Guidelines are to be implemented during the environmental analysis for projects proposing to harvest timber, construct roads, or otherwise significantly alter vegetative cover. These standards and guidelines are purposefully general because decisions regarding connectivity are made most appropriately at the project level, when site-specific information can be incorporated. The intent of these standards and guidelines are to provide project teams with some flexibility for addressing this issue. As noted in the comment, these standards and guidelines are intended only for connectivity between medium and large OGRs. Corridors between small OGRs are not necessary because the intent of the small reserves is to provide old growth representation at the VCU or watershed scale. Connectivity throughout the matrix is an important part of the conservation strategy and is basically provided through time by a combination of Beach Fringe, Riparian Buffers, other standards and guidelines (e. g, unstable soils, low site soils, karst, etc), retention from Legacy, unscheduled timber, and other project-level retention, including patches that are not accessible due to logging system considerations.

Comment: A number of comments were received regarding proposed changes to small OGRs. Some respondents felt that changes were driven by timber production at the expense of conservation of wildlife habitat and were under the impression that the Forest Supervisor promised project-level reviews to fix inadequacies in proposed reserve design. These respondents requested discussion of the impacts of these changes on the conservation strategy. Concern was expressed that the Forest Service was in violation of NEPA by not making update maps of the proposed changes available to the public, involving the public in the decision-making process, or disclosing the objective of the review. Specific recommendations for individual reserves were also given, including use of the GIS database developed by The Nature Conservancy and Audubon Alaska. Several respondents voiced support for the original interagency review team's proposal.

Response: As part of the current Forest Plan Amendment process, the Forest worked with the State of Alaska and the USFWS to complete a more comprehensive small old-growth reserve mapping effort. The objective of the interagency team review was to develop a consensus biological recommendation on small reserve locations that is consistent with Forest Plan criteria, eliminating the need to conduct further project-level reviews in most cases. This process was conducted in 2006 and 2007 and included the development of a biological recommendation, a refinement of that proposal with Forest Service Ranger District staff, and a further refinement by the Forest Supervisor. This refinement process was conducted in order to consider multiple-use objectives in addition to pure biological ones. The result was an overall increase in Old-growth LUD acreage compared to the current plan. Appendix D of the Final EIS also includes a discussion of how these updates were made and related results.

Comment: The current strategy for designing OGRs is flawed in that it does not take into account individual island variation.

Response: Criteria for designing OGRs are provided in Appendix K of the Final Proposed Forest Plan and Appendix D of the Final EIS. The process for evaluating small OGRs on the project level is actually very location-specific in that it requires that Appendix K criteria be met on a site by site basis, taking into account local knowledge of species and habitats and thus variation among individual islands. Note that significant effort has been made during this amendment process to evaluate and adjust all of the small OGRs. Only a small number should require adjustment at the project level now.

Comment: Through the designation of small, medium, and large OGRs there is an inordinate level of emphasis placed on productive old-growth forest. This ignores the habitat value of managed forests, as well as non-productive and low-volume forests, and the fact that when harvest changes the seral stage of a forest there are "winners and losers" with respect to habitat

suitability. There will be a higher level of wildlife diversity associated with habitats found in a forest of a variety of development stages and therefore reserves should incorporate more than just productive old-growth.

Response: There are a variety of factors that go into the designation of OGRs in terms of their placement and configuration, productive old-growth habitat being one of them. Reserves provide connectivity between high and low elevation areas and between Old-Growth LUDS and other non-development LUDS, protect areas of high value winter range, and nesting habitat for goshawks and murrelets The naturally fragmented landscape of the Tongass means that many reserve incorporate forest stages other than old-growth, either created naturally through blow down or past timber harvest.

Comment: Some respondents feel that the coarse-filter component of the conservation strategy fails to recognize the MIS and Sensitive species addressed by the Proposed Forest Plan, whereas others feel that the conservation strategy fails to take into account logging on adjacent non-federal lands. Both groups of respondents suggested that the level of protection afforded by the Proposed Forest Plan should be increased or decreased accordingly.

Response: The conservation strategy was designed to provide a range of habitats within the boundaries of the Tongass National Forest in part to account for conditions or predicted conditions on adjacent or nearby non-NFS lands.

Comment: Several comments were received expressing support for maintaining some or all elements of the conservations strategy. Some respondents felt that the system of large, medium, and small OGRs, along with beach and riparian buffers, must remain the cornerstone of the conservation strategy because it provides a safety net for conservation of viable fish and wildlife populations.

Response: The array of alternatives evaluated in the Final EIS is designed to address a full range of roadless development and timber supply/demand levels. Alternatives that reduce or remove elements of the conservation strategy do so to increase the amount of harvestable timber, which increases the risk to maintaining viable populations of wildlife.

Comment: Comments were received that encouraged the Forest Service to review any remaining small OGRs (OGRs) not finalized during the forest-wide interagency review effort with an eye to timber operability as well as fish and wildlife conservation. The newly proposed locations and sizes for the reserves that were reviewed appeared better than they were previously. However, of particular concern is that project-level reviews have removed 5,100 acres of POG from the suitable land base from 1998 to 2005 (USDA 2005). This steady erosion of the timber base presents an obstacle to maintaining a viable timber industry in Southeast Alaska. Therefore the commenters indicated they supported the joint effort to finalize locations of small OGR across the Tongass and encouraged this collaboration past this planning effort and further urged that the transfer of POG from the suitable land base to small OGR be kept to a minimum to meet criteria in Appendix K.

Response: We agree that the OGRs revised during the 2006-2007 Interagency Review, with subsequent review by the Forest Plan Adjustment Interdisciplinary Team (IDT) and Forest Supervisor, are in better locations. The Forest-wide review of small OGRs was done primarily to develop a consistent and more efficient method of review and to more accurately define the location of small OGRs to enhance the Forest Plan conservation strategy, achieving consistency with criteria in Appendix K of the Forest Plan. Concerns identified as a result of the Forest Plan Maintenance Program were also addressed in this review, one of which was that total acres added to OGRs are reducing suitable acres. The net result of the review was an increase of 39,000 acres in the Old-Growth Habitat LUD (effective under Alternatives 1, 2, 3, and 6). In addition to this expansion, some areas containing Old-Growth Habitat LUD were converted to other non-development LUDs (e.g., Special Interest Area and Semi-Remote

Recreation) and remain a part of the old-growth reserve network. Appendix D of the Final EIS addresses changes in the Old-Growth Habitat LUD and other non-development LUDs resulting from this review.

Comment: Alternative 4 proposes to apply the Old-Growth Habitat LUD in four biogeographic provinces and maintain 33 percent of old-growth in the remaining provinces. It is detrimental to wildlife because it does not specify the distribution of the 33 percent retention requirement, potentially resulting in widely spaced single trees of little value to species dependent on large contiguous blocks of habitat, and disregards scientific information indicating the importance of other biogeographic provinces (Kuiu Island, Admiralty, and the mainland provinces) which contain endemic mammal populations.

Response: It is true that under Alternative 4 all VCUs (with minor exceptions) outside of the four biogeographic provinces where OGRs are required would be required to retain 33 percent of their old-growth with no requirement to consider spacing, location, size, shape, or composition in the design of the retained acres, as is the case under Alternatives 1, 2, 3, 5, and 6, where the direction provided in Appendix K of the current Forest Plan (Old-Growth Habitat Reserve Criteria) applies. The EIS discusses the effects of Alternative 4 on wildlife, including endemic mammals.

Comment: **The biodiversity analysis should also look at changes in connectivity redundancy, corridor width, and corridor effectiveness.**

Response: Corridor redundancy is addressed by the Legacy Standards and Guidelines (see Appendix D for discussion of the rationale for its development) and was also a consideration during the 2006-2007 Forest-wide interagency small old-growth reserve review (i.e., OGRs overlapping the beach fringe). Effects of proposed changes in corridor width are discussed in the *Wildlife* section of the Final EIS. There still remains uncertainty regarding the effectiveness of various elements of the conservation strategy, including connectivity requirements. This is addressed in the *Biodiversity* and *Wildlife* sections of the Final EIS.

Comment: Characteristics and outcomes that an effective conservation strategy should have were listed in the Draft EIS. This list should include: 1) it should anticipate and allow for losses of particular habitats to stochastic events (including catastrophes) on a landscape scale and, as may be appropriate for finer species, at a finer scale; (2) it should anticipate and make allowances for natural habitat losses, considering also the effects of climate change; and (3) other statements from the joint statements by the peer reviewers of the 1997 Forest Plan.

Response: The conservation strategy was developed primarily to maintain viable, well distributed old-growth associated wildlife populations. The objectives are to contribute to habitat capability of fish and wildlife resources to support sustainable human subsistence and recreational uses; maintain biodiversity and ecological processes in old growth habitats; and to restore previously harvested stands to old growth forest condition at an accelerated rate. Catastrophic events at a landscape scale would be difficult to predict and nearly impossible to plan for across the landscape. Similarly, predicting climate change effects to Southeast Alaska forests is problematic. The relatively large and comprehensive conservation strategy is expected to be resilient enough to accommodate such uncertainty. This coupled with the relatively small portion of the Tongass that is considered available for management of timber into the future deems the risk and uncertainty within acceptable limits. Additionally, the ongoing monitoring and study by state and federal agencies, academia and others along with periodic reviews of the Forest Plan provide ample opportunities to respond to such risk and uncertainty in a responsible manner into the future.

Comment: Concerns raised about the inadequacy of the old-growth reserve system (e.g., reserves not large enough to support intended number of female marten, encompass an entire wolf pack home range, or a sufficient number of female brown bears on Baranof and Chichagof islands) were not addressed in the Draft EIS.

Response: Each of these concerns emphasizes the importance of matrix management. Matrix management and the uncertainties related to the adequacy of the reserve system are discussed in the *Wildlife* section of the Final EIS. In addition, several alternatives include increases to the reserve system (Alternatives 1, 2, 3, and 6).

Comment: One respondent offered the following detailed comment: The Forest-wide old-growth reserve review erroneously excluded acreage of private lands in calculating mapped reserves. It is impossible to properly design OGRs without taking into account the cumulative impacts of logging and development of all lands within the VCU. In discussing the basic criteria for allocating small OGRs, the Proposed Forest Plan defines such reserves as "a contiguous landscape of at least 16 percent of the area of each VCU." If the intent of the Forest Plan is to create these reserves based only on Forest Service land it would clearly state so.

Response: Prior to the 2006-2007 Interagency small old-growth reserve review, there was no specific protocol describing how to complete or implement project-level interagency reviews. As a result, small old-growth reserve reviews have occurred in a variety of ways and with varying degrees of quality. One of the aspects of the review process that make it difficult to complete is that some of the Forest Plan criteria are subject to interpretation, such as the 16 percent area requirement. Some project level reviews have taken all land ownerships into account, others have not. The revised Appendix K of the Final Proposed Forest Plan clarifies that this should include only NFS lands.

Comment: The adverse effects of fragmentation, increased forest edge, small mammal isolation, and increased predation in harvest areas are greatly exaggerated and not founded in science.

Response: Additional citations of peer-reviewed literature have been added to the discussions of these topics in the Final EIS.

Comment: The Old-growth Habitat LUD allows activities that are not consistent with habitat reserves (i.e., allows roads to access adjacent timber lands if no other feasible option exists, salvage logging, and OHV use) and needs to be updated. This high likelihood of road construction through OGRs represents a failure of the old-growth reserve system and the viability strategy of the current Forest Plan and shows why legal protection of wilderness is necessary. Stronger wording should also be included in Appendix K criteria for designating small OGRs to ensure that they represent big-tree stands, and that no roading or OHV use is allowed. The Appendix K criteria for small OGRs should also be revised to require at least 800 acres of POG, rather than the minimum of 400 acres, because the 400-acre minimum is almost always chosen.

Response: The conservation strategy is one developed through an interagency approach along with the best available science information at that time. Through a series of science review panels and many other efforts it was deemed to provide for a moderate to high likelihood of achieving its objectives. The 2006 review of the conservation strategy brought forward new science and much other information relative to the strategy since 1997. The review also brought together many of the foremost experts on subjects relative to the conservation strategy and its implementation. That effort, which included a paper reviewing published research on conservations strategy design (Haufler 2006), resulted in the Forest Service being able to conclude the conservation strategy and its basic design is still valid. In addition, we believe that the limited activities allowed in the Old-growth reserve standard and guidelines are consistent with the conservation strategy. Further, Chapter 6 of the Plan describes a monitoring plan for old growth that will ensure activities, over time, are consistent with the intent of this strategy.

Comment: There are a number of medium and large reserves throughout the Forest that fail to meet the minimum criteria in Appendix K for total acres and acres of productive old-growth habitat. Please identify all medium and large OGRs and display these criteria to identify the reserves that do not meet them. Then please give rationale as to why medium and large reserves not meeting these criteria were not adjusted.

Response: As stated in Appendix K of the Final Proposed Forest Plan, large and medium OGRs were designed based on the most restrictive requirements of species with large home ranges and for which there were viability and distribution concerns. They were designed to provide for source populations of species, specifically brown bear, marten, northern goshawk, and wolf, and to provide refugia for dispersing animals. These reserves received rigorous review during the development of the 1997 Forest Plan and, when considered within the context of the entire strategy, are likely adequate considering the logistics of where each reside within the overall strategy.

Comment: Section VII.A.3 of Appendix K of the Draft EIS appears to mean that in VCUs where any portion is designated as a very large, large, or medium old-growth reserve, these VCUs do not need to contain additional productive old-growth to meet the minimum requirements of small OGRs. This is difficult to interpret because the Draft EIS fails to provide a map depicting these reserves, and large and medium reserves are often identified not as Old-growth Habitat LUD but as one of several other Non-development LUDs.

Response: This interpretation of the criteria is correct. The rationale for not requiring a small old-growth reserve in a VCU which has a portion designated as a medium, large, or very large old-growth reserve is that it is assumed that these reserves in combination with old-growth retained by standards and guidelines will provide sufficient productive old-growth to ensure connectivity across the landscape through time. Old-growth Habitat LUDs are depicted on the Forest Plan maps.

Comment: How much is enough [adequate portion of each ecosystem type maintained in an unmanaged state]? Ten to 30 percent of a biogeographic region is the generally accepted minimum. Most expert landscape ecologists would suggest 30 to 40 percent.

Response: Targets for landscape level conservation features are partially defined as the percentage of a resource's overall distribution that is contained within a given area (Dunn et al. 1999), but also must take into account specific planning objectives as well as the identification of vulnerable habitat types and critical habitats for vulnerable species. There are no defined thresholds for how much old-growth should remain within a biogeographic province on the Tongass. The Final EIS displays the amount of old growth that is predicted to remain after 100 years for each biogeographic province and identifies the resulting effects to wildlife and biodiversity. Table 3.9-14 in the *Biodiversity* section shows that none of the biogeographic provinces would have less than 53 percent of its original POG remaining on NFS lands after 100+ years of implementation under any of the alternatives at the maximum level allowed. Even if all lands in Southeast Alaska are considered together, the minimum percent of original POG remaining on all lands among all provinces would be 44 percent (see Table 3.9-20)

Comment: The Draft EIS fails to disclose the opposition to, and uncertainty behind, the Conservation Strategy.

Response: Additional discussion of risk and uncertainty related to the conservation strategy and wildlife viability assessments has been added to the *Wildlife* section of the Final EIS and Appendix D has been added which addresses these topics in more detail.

Comment: Some respondents felt that the process for preparing the amendment was flawed. They believe that the results of the conservation strategy review were not incorporated and that

the conservation strategy review itself was flawed because not all key experts were invited, the observers were not allowed to participate, and some key issues were not brought up.

Response: The conservation strategy review was designed as an interagency review of the conservation strategy focusing on new information and knowledge developed since 1997. As a structured information assessment it was not intended to be an all encompassing review of all aspects of the conservation strategy or to involve special interest groups with other agendas. The review focused on new information relative to implementation and monitoring of components of the strategy, especially within the matrix part of the strategy where development activities will occur through time. The review involved numerous interagency meetings to develop the agenda, much preparation time by the speakers and a full week meeting in Ketchikan in April of 2006. Expanding the meeting to encompass all subjects and all interested parties would have made it even more time consuming.

The information was very useful in the Forest Plan Amendment process but there was never any intent that the Amendment would address all of the ideas brought forward in the review. As noted on the Conservation Strategy Review Website at the time of the review:

> "The new information and knowledge will be presented at a science-based technical workshop designed to rigorously explore the subjects and to develop a suite of potential actions and investments the Tongass and its interagency partners can consider related to new information needs or exploring changes in how the conservation strategy is designed, implemented or monitored. The suite of considerations could lead to conservation strategy-related adjustments to the Tongass Forest Plan as well."

The planning record shows the findings from the review and the plan for how each finding will be addressed over time.

Comment: Some respondents also believed the process was flawed because changes to the small OGRs were completed after the Draft EIS was published. They also stated that the comment period was not long enough.

Response: Alternatives in the Draft EIS included those small old-growth reserve adjustments that had been completed by the interagency team at a point prior to the time of publication. The Draft EIS solicited comments on these changes and the interagency process in general. All of the small old-growth reserve adjustments were completed and posted on the Website with over 30 days of the comment period remaining. The comment period was then extended for an additional 18 days, because of the weather and because we wanted to ensure that those interested had a chance to comment on these changes. Even after the comment period closed, the Website was quite clear that we would continue to welcome comments on the small old-growth reserve changes.

The formal comment period on the Draft EIS lasted for a total of 108 days. In addition, most of the proposed changes to the Forest Plan were on the Website months in advance of the comment period. The public had a considerable amount of time to consider the changes we were proposing.

Old-Growth Mapping

Comment: Several comments were received regarding the use of the size-density model (SDM) for vegetation versus the original Vol-Strata vegetation model in the deer habitat capability model. Some feel this is unimportant provided model results are only used to make a relative comparison among alternatives. Others feel this is a modest improvement but that condensing the model into only three categories masks the loss of the highest value deer winter habitat due to past and future timber harvest. These respondents supported the modification of the model to represent all seven SDM vegetation classes.

Response: The deer model provides a means for making relative comparisons among alternatives in terms of their effects to deer winter range. The existing model parameters are based on the three volume strata categories. In addition to this fact and the fact that sufficient information to accurately update the model to use all seven categories does not exist, the statistical precision of the SDM classification into the seven classes is low. New deer models are in development, but are not ready for use at the Forest planning scale.

Specific concerns regarding deer and the deer model are discussed in a following subsection of this appendix under the heading “Deer.”

Comment: Much of the biodiversity and wildlife analysis in the Draft EIS is too “productive old-growth (POG)-centric” and the Draft EIS has violated NEPA by not disclosing this shortcoming. Some respondents felt that the general reference to POG as a key indicator for effects to many wildlife species made in Chapter 2 is incorrect in that many species have more specialized habitat requirements (i.e., coarse canopy productive old-growth provides higher quality winter habitat for deer) and the Draft EIS should have disclosed effects to individual SDM categories, particularly those that represent high-value POG including “big-tree” POG (i.e., SD67, SD5N, and SD5S categories).

Response: The summary statement in Chapter 2 that POG is a key indicator of effects to many wildlife species on the Tongass is correct, as this is the primary resources affected by timber harvest. Where appropriate, the wildlife analysis does separate out effects to the most important SD7 model categories of POG. A full analysis has been added to the *Biodiversity* section of the Final EIS showing effects to high volume (SD5N, SD5S, SD67) vegetation categories and large-tree (SD67) vegetation category POG, both on NFS lands alone, and on all lands in Southeast Alaska combined (by biogeographic province).

Comment: The Draft EIS fails to disclose how the assumed harvest of vegetation categories SD4N, SD4S, SD5H, SD5N, SD5S, and SD67 prior to 1954 was distributed among these categories for the estimate of 1954 deer habitat capability, and therefore violates NEPA.

Response: To estimate 1954 or original POG, it was necessary to “grow back” previously harvested units. Previously harvested units identified in the vegetation layer (HS1, HS2, and HS3 categories in the SDM GIS coverage) were assumed to have been stands of POG. To estimate original high volume and SD67 POG, an estimate was made of the percentage of past harvest in these categories using timber type mapping from the mid-1980s. Based on this analysis, prior harvest on NFS lands was estimated to have been 29 percent SD67 and 64 percent high volume (see Appendix B) These estimates are higher than estimates made by Audubon Alaska and The Nature Conservancy (Albert and Schoen 2007).

Comment: Populations of some species (bear, goshawk, marten, and wolf) occur at viable levels in habitats containing substantially less old-growth and greater levels of development than the Tongass. This suggests that habitat associations of species considered in the Proposed Forest Plan are in some instances less linked to old-growth than assumed.

Response: On the Tongass all of the species listed above are considered old-growth associates, being most closely associated with this habitat type. However, as described in their respective subsections in the *Wildlife* section of the Draft EIS, these species are all wide-ranging and their home ranges may encompass a variety of habitat types. Species-specific standards and guidelines focus on protecting old-growth because this is the habitat type most affected by timber harvest activity. Where new science has indicated that certain species are more adaptable than once thought, information from pertinent peer-reviewed literature has been included in the Final EIS.

Comment: The focus on retention of high-volume timber stands in the Proposed Forest Plan is based on the assumption that past harvesting targeted these stands. However, for purposes of economical and operational efficiency, harvests prior to 1976 more typically involved entire

watersheds or portions of entire watersheds and the range of volumes associated with stands occurring there.

Response: This is true to some degree, but there is no doubt that the lower elevation stands, which generally have the highest volume and wildlife values, were harvested at a disproportionate rate (Table 3.9-7 in the *Biodiversity* section).

Comment: The Draft EIS does not disclose the continued effects of high-grading on the forest or the cumulative effects of continued high-grading on non-federal lands. The Final Proposed Forest Plan must address past high-grading of the most productive forest types on federal and non-federal lands. Some respondents contend that because past high-grading has reduced forest and habitat diversity, additional conservation measures need to be applied on the Tongass to minimize the loss of additional diversity; others expressed opposition to all high-grading. Others brought up timber harvest statistics suggesting that the Forest Service's estimate that only 8 percent of the timber harvested on the Tongass is cedar is actually closer to 20 to 40 percent, based on independent ground truthing, evidence that the Draft EIS and market demand analysis under represent the role cedar exports play in the Tongass timber program and the corresponding impact on the environment.

Response: Additional discussion of the historical disproportionate harvest on certain landforms and of certain forest types has been added to the *Biodiversity* section of the Final EIS and includes NFS and non-NFS lands. The *Biodiversity* section also includes an expanded discussion of old-growth representation within reserves and matrix lands for high-volume and large-tree POG and the effects of the alternatives on this representation, as well as an expanded cumulative effects analysis evaluating future disproportionate harvest on non-NFS lands. We assume that this comment actually refers to the statement in the Draft EIS that 8 percent of POG historically occurring on the Forest has been harvested, not yellow cedar. As noted on page 3-241 of the Draft EIS, our records indicate that hemlock and spruce account for 94 percent of trees harvested in most sales on the Tongass. Cedar occurs as a minor tree species in most stands. The comment that cedar represents up to 40 percent of the total past harvest is not supported by historical data.

Comment: Historically, the most productive forest types have been disproportionately targeted for logging. As an example, low elevation karst and valley-floor forests have been logged at 560 percent and 160 percent of their proportional availability, respectively.

Response: More information on the disproportionate nature of past timber harvest in Southeast Alaska has been added to the *Biodiversity* section of the Final EIS.

Comment: A number of comments were received regarding the protection of high-value or rare habitats (e.g., large-tree old-growth, karst lands, yellow cedar) and the natural range of environmental variability across the forest. Some respondents asked the Forest Service to protect these habitats, some suggested that new standards and guidelines need to be developed for remaining rare and large-tree forests and others suggested these elements be protected in each biogeographic province. Others commented that areas of intense logging seem to correspond with areas of concentrated wildlife use.

In their comments TNC and Audubon describe an analysis in which they used the protection of high-value habitats as a measure of the effectiveness of the conservation strategy and analyzed the existing protection afforded to focal species and ecosystems (large tree forests, deer, bear, salmon, and marbled murrelet) within existing reserves by biogeographic province. This analysis revealed that, in general, the provinces with the highest biological value are also those with the greatest vulnerability (i.e., least amount of high-value habitats protected). North Prince of Wales, East Chichagof, Revilla/Cleveland, Kupreanof/Mitkof, and others rank as the highest priorities for

additional conservation and restoration measures. The analysis also looked at cumulative ecological risk, recommending this as a tool to be used for adjusting the Tongass Conservation Strategy to prioritize conservation and restoration actions.

Response: Harvesting high-value stands, which has affected high-value habitats such as large-tree old-growth, karst lands, and cedar) is discussed in detail in the *Biodiversity* section of the Final EIS. The fact that some areas of high value to wildlife coincide with areas of high value for timber harvest is also discussed in the *Biodiversity* section. Of note is that while it is true that there is high biological value in areas where timber harvest is allowed, there are also many high biological value areas on the Tongass (as ranked by TNC and Audubon) that are fully protected (for example, Admiralty Island National Monument).

Comment: Page 3-120 in the Biodiversity section of the Draft EIS states that "Albert and Schoen (2006) estimate that region-wide approximately 29 percent of 242,211 acres harvested since 1986 occurred in large-tree (SD67) ecosystems, and approximately 72 percent of these forests remain intact." This statement occurred in an earlier report to ADF&G prior to completion of our conservation assessment. The statement was preliminary and needs additional clarification. In our final conservation assessment (Albert and Schoen 2007) we stated the following: "Region-wide only 12 percent of all productive old-growth has been harvested since 1954, but at least 28 percent of Southeast's large-tree forest types have been cut. It is important to recognize, however, that this percentage-derived from post-1986 selectivity coefficients-represents a significant underestimate of the original high-grading of the large-tree stands." This should be corrected in the Final EIS.

Response: Additional information from Albert and Schoen 2007 has been added to the *Biodiversity* section of the Final EIS. Our independent estimate of the percentage of past harvest of large-tree POG is higher than the percentage calculated by Albert and Schoen (2007). Using timber type mapping from the mid-1980s, we estimated that 29 percent of the large-tree POG on NFS lands and 37 percent of the large-tree POG on non-NFS lands was previously harvested, for a cumulative harvest rate of 32 percent (see Appendix B).

Comment: The Size-density Model should have been used throughout the Draft EIS analysis and tables in Section 3.9 and 3.13 should be revised to provide a summary by SDM class. The fact that the ecological sensitivity analysis of the Size-density Model was omitted from the biodiversity analysis of the Draft EIS is a major flaw and should be corrected in the Final EIS. It would also be useful if the Final EIS could also account for the SD7 class separately from the SD6 class because of their great rarity and value on the Forest.

Response: Tables showing the amount of POG, high-volume POG (SD5N, SD5S, SD 67), and large-tree POG (SD67) harvested and remaining, and a cumulative effects discussion on future harvest of POG, high volume POG, and large-tree POG, have been expanded in the *Biodiversity* section of the Final EIS. SD7 is not one of the types in the Size-Density model. It is assumed the commenter is referring to the old volume class 7, which is not statistically distinguishable from other types, based on existing mapping.

Comment: One respondent discussed the new tools that are available such as the Size Density Vegetation Model and the modeling work recently completed by The Nature Conservancy. They suggest that implementation not begin until these new tools have been incorporated.

Response: The Size Density model has been used throughout the analysis. The Nature Conservancy's work has been examined closely and has informed the analysis, especially in the areas of biodiversity and roadless area evaluation.

Legacy and Goshawk/Marten Standards and Guidelines

Comment: Some respondents supported Alternative 7 with some modifications. They felt that some of the Conservation Strategy Standards and Guidelines lacked a basis in science and should be removed from Alternative 7. These standards and guidelines include the 1000-foot beach buffer, OGRs, Class III stream buffers, the Legacy standard, and the Goshawk and Marten standards.

Response: Table 2-16, page 2-41 of the Draft EIS illustrates that Alternative 7 has none of these standards and guidelines except for the Class III riparian standard. Alternative 7 has been modified in the Final EIS and it no longer includes buffers on Class III stream. See Appendix D of the Final EIS for more information about the scientific rationale behind the conservation strategy.

Comment: The Draft EIS provides no supporting science for adopting the Forest Legacy standard and guideline as a replacement of the Marten Habitat and Goshawk Foraging Standards and Guidelines. Without this assessment there is no way to evaluate any benefits of the standard and guideline to wildlife. The Final EIS should include a qualitative and quantitative analysis of how the Marten Habitat and Goshawk Foraging Standards and Guidelines have been applied and the extent to which these requirements have impacted timber harvest activities.

Response: Appendix D of the Final EIS provides the rationale behind the development of the Forest Legacy standard and guideline as well as an assessment of how it compares to the existing Marten Habitat and Goshawk Foraging Standards and Guidelines.

Comment: Risk levels (i.e., low, medium, and high) of VCUs used to determine application of the Legacy Standards and Guidelines in the Final EIS and Final Proposed Forest Plan should incorporate timber harvest on all land ownerships.

Response: The Final Proposed Forest Plan specifies only higher-risk VCUs in the application of the Legacy standard and guideline; the harvest level for determining risk category does not include all land ownerships, though it is anticipated that harvest on these lands will continue into the future. The overall conservation strategy design accounts for cumulative effects on non-NFS lands, and therefore the analysis of VCUs for application of Legacy has considered only the NFS portion of VCUs.

Comment: Because natural openings in old-growth forest on the Tongass average 2 acres, the Legacy standard and guideline should be implemented in all harvest units greater than 2 acres, as required under the existing Goshawk Foraging and Marten Habitat Standards and Guidelines, versus the 20 acre requirement under the Legacy standard and guideline. The loss of legacy retention in units between 2 and 10 acres in High Risk VCUs would increase impacts of logging on the goshawk and other old-growth associated species in landscapes where they are already most at risk.

Response: The use of 20-acres for the minimum unit size where the Forest-wide Legacy standard and guideline applies was selected because it represents a typical logical logging system setting, based on analysis of the LSTA. In order to better balance wildlife conservation concerns and timber sale operability concerns, this unit size was selected. This change may not be as beneficial as the 1997 Plan Goshawk Foraging and Marten Habitat Standards and Guidelines for some species. For wildlife species sensitive to forest fragmentation, clearly smaller units would have less impact than larger units. However, there is no strong empirical evidence on what the maximum unit size is before a clearcut becomes a barrier. It is also important to consider that wildlife encounter a range of conditions and natural fragmentation on the Tongass. Opening sizes from natural wind events range up to 1,000 acres, but are typically less than 40 acres (Nowacki and Kramer 1998). While there could be openings up to 20 acres without retention of legacy, we anticipate that there would be a mix of openings in a typical timber sale layout because of the

OGRs in buffers, over-steepened slopes, and other protection measures associated with those units. Appendix D of the Final EIS provides additional discussion of the rationale behind the development of the Legacy standard and guideline.

Comment: The Forest Legacy standard and guideline could result in trees retained along the perimeter of a harvest unit, unlike the Marten Habitat and Goshawk Foraging Standards and Guidelines which require that trees be individually spaced or retained in clumps.

Response: The legacy standard and guideline is simpler and clearer than the goshawk and marten standards. The intent is similar – retain forest structure in units. The standard is clear that this structure is meant to be within the harvest units, not on the edge, though it does provide for exceptions when logging systems preclude this. Continued Forest Plan monitoring provides for continual monitoring of this to ensure that legacy retention within units is occurring. Adjustments can be made through adaptive management if it is determined that objectives are not being met. Additional technical information has been added to the Timber and Forest Health sections to discussions regarding legacy and other retention standards and guidelines and to Appendix D of the Final EIS.

Comment: Several comments were received requesting clarification as to what harvest units the Legacy Standards and Guidelines would apply. One respondent stated that neither the Proposed Forest Plan nor the Draft EIS provide a scientific rationale for the criteria for defining the maximum sizes of units that can be harvested and still retain legacy forest structure, and how much legacy forest structure should be maintained, because both the maximum size of openings allowed and the amount of forest structure to be left depend on the risk level within the VCU. Other respondents were opposed to applying the Legacy Standards and Guidelines to all harvest units (or altogether), suggesting this would hamper timber sale economics by distributing timber harvest and setting aside the most economic timber stands in areas that are managed for multiple use.

Response: Based on further analysis and public comment, the Legacy standard has been refined for the Final Proposed Forest Plan. The Legacy Standards and Guidelines are to be applied only in higher-risk VCUs where 33 percent or more of the POG has been harvested as of 2005, or VCUs where less than 33 percent has been harvested but more than 67 percent of the POG is projected to be harvested by the end of the Forest Plan planning horizon. Within these VCUs the only criterion related to unit size is that the standard is to be applied to the original planned harvest units of 20 acres or greater. Appendix D of the Final EIS provides information on the rationale behind the development of the Legacy standard and guideline.

Comment: Several respondents questioned whether a mechanism would be in place for ensuring that legacy retention is protected from future removal, be it salvage or commercial harvest, firewood collection or personal use. A suggestion was made to develop a legacy structure tracking system.

Response: Standard and guideline IV.B of the Final Proposed Forest Plan states that Legacy forest structure should remain indefinitely after harvest and shall be tracked through the life of the next stand. Salvage logging of legacy trees is generally prohibited unless the rationale is clearly documented and the effects are clearly neutral or an improvement.

Comment: The Forest Legacy standard and guideline is a cookie-cutter approach that is inappropriate for an island archipelago. This approach fails to account for island size, fragmentation, the uniqueness of the area, the presence of karst or other landscape features, or the presence of endemic mammals. It also fails to account for impacts on adjacent private lands.

Response: The design of the conservation strategy took into account a variety of factors, including biogeographic province differences (which incorporates the fact that the Tongass is an island archipelago), fragmentation, and endemics. The OGR system in the conservation strategy fundamentally is a 'coarse filter' approach to addressing wildlife viability and the conservation of biodiversity. In addition, a variety of other coarse filter standards and guidelines provided connectivity between the reserves. At the "fine filter" level, species-specific standards were fully considered in light of additional information such as conservation assessments, panel assessment results, etc. and appropriate standards and guidelines were incorporated for species that needed additional protection measures to assure their viability and well-distributed status. The design of Forest Legacy standard and guideline also took into account past and future harvest within a VCU.

Comment: The Reserve Tree/Cavity-nesting standard and guideline leaves unanswered the question of how many trees and what sizes.

Response: The generality of these standards and guidelines is intended to leave some flexibility in its implementation as the quantity and quality of available reserve trees will vary by project location. This standard and guideline has not changed since 1997.

Comment: There is no science behind the 100-acre goshawk nest buffers. It is likely that the nest buffers afforded bald eagles would be sufficient for goshawks (8 acres versus 100 acres).

Response: Much information, including peer reviewed science, related to goshawk nest sites and use areas exists. Such information was used to inform development of the standard and guideline requiring the nest buffer included in the Final Proposed Forest Plan.

Comment: Foresters have recently field-applied the proposed Legacy standard and guideline and have concluded that it only slightly improves the economics of timber sales over the current Forest Plan and only marginally offsets the impacts of the OGRs and other conservation strategy measures in place. The commenter indicated they would like to see the research called for in the May 1994 "Response to the peer review of: a proposed strategy for maintaining well-distributed viable populations wildlife associated with old-growth forest in Southeast Alaska" completed and a full NEPA analysis made prior to proposing implementation of this standard and guideline.

Response: The various peer reviews conducted for the 1997 Forest Plan Revision were incorporated as applicable into the associated analyses which lead to the 1997 Forest Plan. That information is available in the 1997 Forest Plan planning record. The conservation strategy included in the 1997 Forest Plan was reviewed in 2006 and the Forest Service concludes the conservation strategy is still sound and an appropriate approach for the Tongass National Forest. The Legacy Standard has been modified for the Final Proposed Forest Plan.

Population Viability

Comment: The rating for Alternative 4 needs to be corrected on page 2-51 of the Draft EIS.

Response: This has been corrected in the Final EIS.

Comment: Carrying over results of the 1997 expert panel risk assessments and associated "likelihood ratings" into the Draft EIS should be justified, particularly in the case of wolves and endemic species in light of recent scientific findings..

Response: Appendix D of the Final EIS contains a detailed description of the 1997 panel assessment process, results, rationale for carrying over applicable results into the Final EIS, and a discussion of where new science differs from information used by the panel to rate alternatives.

Comment: Several comments were received about the population levels managed for under the Proposed Forest Plan. Some felt that the standard for fish and wildlife population levels should be based on sustainability rather than viability because a sustainable population provides for both human use and biological survival whereas viability only guarantees survival in the absence of human use. These respondents noted that the standard of sustainability is consistent with the State of Alaska's constitution. Others felt that the conservation strategy should focus on "abundant or moderate," "abundant and useable," or "sustainable and normally distributed" populations because they are more likely to sustain moderate levels of human use or meet regional subsistence needs.

Response: The Forest Service is complying with direction under the NFMA to maintain viable wildlife populations. It is recognized that minimum viable populations for many species may not satisfy the public need for wildlife populations depended upon to meet subsistence and/or sport hunting uses. Lengthy discussion is found in the *Subsistence* and *Wildlife* sections of the Final EIS regarding such species.

Comment: **The characterization of Alternative 7 as having a moderate to low likelihood of maintaining viable and well-distributed wildlife populations across the Tongass because of the elimination of the old-growth reserve system is not founded in science. The fact that this alternative is the least protective does not automatically translate into a risk for a species.**

Response: This statement has been modified to indicate risk relative to Alternative 5 No Action, which is equivalent to Alternative 11 of the 1997 EIS that had been evaluated by a risk assessment panel using the best available science. Due to elimination of the old-growth reserve system under Alternative 7 and the increase in area of development LUDs, Alternative 7 would have a reduced likelihood of maintaining viable, well distributed populations relative to Alternative 5.

Comment: The Draft EIS does not adequately address the potential value of harvest regulations and access control, in combination with habitat management, in helping assure the viability of some wildlife species.

Response: While the Forest Service has a role in setting harvest regulations through the Federal Subsistence Board, the Forest Service, by itself, cannot set or manipulate wildlife harvest levels. Therefore, harvest regulations are not considered as a sole means to mitigate effects to wildlife. However, we do recognize our ability to work within the federal system and to work cooperatively with the State in considering harvest regulations if needed. This is discussed as a specific means for mitigating the effects of timber harvest on species that are sensitive to over harvest (legal and illegal) due to increased human access along roads (e.g., marten, wolves). Access control is discussed in the *Wildlife* section of the Final EIS where appropriate; however decisions to close or maintain open roads are made at a district or project level and therefore are described only generally in the Final EIS.

Comment: The Draft EIS fails to address the joint statements issued by the Peer Review Committee, a distinguished panel of 12 PhD scientists assembled by the PNW Research Station, in 1996 in response to the release of the Draft EIS of the 1997 Forest Plan, and in 1997 after the release of the Final EIS. The 1996 statement concluded that (1) the best available science indicated substantial risk to the viability of wildlife associated with old-growth forests of Southeast Alaska; (2) none of the action alternatives included measures which would ensure the continued viability of all old-growth associated species on the Tongass; (3) deferring adoption of an effective plan to ensure viability of wildlife populations entails serious risk to Tongass wildlife;

and (4) the Forest Service should address new alternatives that a full array of necessary conservation measures. The 1997 statement concluded that the final management plan did not incorporate any of the review committee's findings in fundamental ways and the plan would not protect viable, well-distributed populations of vertebrate species on the Tongass.

Response: The Tongass conservation strategy has been implemented for 10 years and has not resulted in the decreased viability or listing of any species. It continues to be one of the most detailed and comprehensive strategies among national forests. In addition, over the course of its implementation the level of harvest has been substantially less than that anticipated by the peer review committee during their review. The 2008 alternatives also consider the peer review committee recommendations. The conservation strategies of Alternatives 1, 2, 3, 5 and 6 include enhanced connectivity through maintaining the 1,000-foot beach fringe, Riparian Standards and Guidelines, and other standards and guidelines that together would protect at least 66 to 74 percent of the existing POG inside the matrix (development LUDs) after 100+ years of maximum Forest Plan implementation (harvesting at the maximum harvest level). Further, from 71 to 93 percent of all existing POG on the Tongass would be protected in reserves. These alternatives would also provide at least one very large reserve within each biogeographic province. Appendix D has more information about the conservation strategy and the science that led to its development.

Comment: Several respondents expressed confusion over the conclusions drawn in Table 2-17 of the Draft EIS regarding viability ratings for some of the species under consideration.

Response: Appendix D of the Final EIS provides detailed background information on the viability panel assessments convened prior to the 1997 Forest Plan, and their application to the 2008 Final EIS.

Comment: Much of the Proposed Forest Plan deals with the management of "buzz words." The terms biodiversity, old-growth, endemics, extinction, protection, and endangered are not concisely defined or clearly set in the context of forest management. Old-growth appears to refer to "forest that has not been previously harvested by humans." Local extinction can be at any scale and should be defined, as should the term protect, which appears it the context of the Forest Plan to be protection from timber harvest. The Final Proposed Forest Plan should also define at what level endemism is considered (population, subspecies, species); the plan is also contradictory in describing "well-distributed" populations of endemic mammals across the Forest" (i.e., if populations are not well-distributed they are not endemic).

Response: The Glossary, which is located in Chapter 7 of the Proposed Forest Plan, defines these terms. Biological diversity is defined as "The variety of life forms and processes, including the complexity of species, communities, gene pools, and ecological functions, within the area covered by a land management plan." Endemic is defined as "restricted to a particular locality, or occurring at low levels" giving the example of "a particular species or subspecies may occur on only one or a few islands." Extinction is defined as "any species of animal or plant that is in danger of extinction throughout all or a significant portion of its range," the definition given under the ESA. An endemic population may occur within a restricted range (i.e., island or group of islands), but can be widely-distributed within this range. Extinction, as described under the definition of Endangered, relates to all or a significant portion of a species range.

Management Indicator Species

Comment: Several respondents made suggestions for species that should be added to the list of MIS, including the marbled murrelet, Canada lynx, and wolverine. One respondent believed that recommendations made in 1999 by the Interagency Monitoring and Evaluation Group MIS subcommittee to reduce the current list of 13 species to 6 had been accepted and implemented on the ground for numerous timber sales. This respondent also felt that a discussion of changes to

the MIS list should have been disclosed in the Draft EIS. Another respondent felt that use of the MIS concept was appropriate only at very broad scales (i.e., indicators of old-growth) because but was not sufficient for finer levels of habitat selection such as specific features within old-growth forest (i.e., canopy openings, snags, or downed wood).

Response: An effort to re-evaluate the current list of MIS has been ongoing since 1999; however it is separate from this Forest Plan Amendment because any changes will depend, in part, on the selected alternative. Any changes to this list will be considered during this process. As noted in the Final EIS, there are currently 13 MIS wildlife species, each of which was addressed in the analysis. Each of these species was selected for different reasons. Some are representative of large tracts of old-growth habitat, however others were selected for their use of other habitat types, sensitivity to human disturbance, importance as subsistence/hunting resources, or use of specific features within old-growth forest (i.e., cavity nesters).

Comment: The Forest Service should not use MIS that are introduced on islands because they often do not adequately represent the responses of native fauna to habitat conversion and human disturbance. Red squirrels and marten are two examples of MIS that have been introduced to several islands in the archipelago and therefore should not be used as MIS in these locations.

Response: The MIS for the Tongass were selected so under the auspices of the 1982 Planning Regulations in which species of interest, whether native or non-native, could be considered as MIS. The list of MIS is currently under review and is likely to change in the future. This is based in part on evaluations of monitoring information since 1997 and associated analyses summarized in Chapter 3 of the Final EIS.

Wildlife Cumulative Effects

Comment: The cumulative loss of habitat value for deer, bear, large-tree forests, marbled murrelets, and salmon under Alternatives 4, 5, 6, and 7, when considered in combination with activities on adjacent non-NFS lands, represents greater than 45 percent of habitat forest-wide, and greater than 67 percent of habitat value in the North Prince of Wales and Kupreanof/Mitkof biogeographic provinces, as demonstrated by the Coastal Mountains and Forests Ecoregional Assessment (Albert and Schoen 2007).

Response: It is true that two of the most heavily developed provinces are North Prince of Wales and Kupreanof/Mitkof. The cumulative loss of old-growth habitat, taking all land-ownerships into account, is quantified and discussed in the *Wildlife* and *Biodiversity* sections of the Final EIS. Table 3.9-20 in the *Biodiversity* section indicates that the cumulative loss of POG after 100+ years of Forest Plan implementation at maximum levels would be 24 to 29 percent for all of Southeast Alaska under these four alternatives counting all ownerships. For the North Central Prince of Wales province the cumulative loss would be 49 to 56 percent and the cumulative loss would be 39 to 47 percent for the Kupreanof/Mitkof province..

Comment: Assumptions that non-federal lands have zero habitat capability and that there is a direct relationship between the amount of productive old-growth and the abundance of marbled murrelets and flying squirrels are incorrect.

Response: Substantial timber harvest has occurred on non-federal lands adjacent to the Tongass. Therefore the analysis in the *Wildlife* section takes a conservative approach by assuming that these lands provide little habitat value because continuing harvest activities are expected to occur in the future. The *Wildlife* section recognizes that relatively little is known about the terrestrial habitat relationships or population trends and abundance of marbled murrelets in Southeast Alaska, though nesting has been documented in old-growth. Therefore, the analysis focuses primarily on harvest of productive old-growth and because the scope of the analysis for this Forest Plan Amendment is related to timber demand. Harvest of productive old-growth is listed in the Final EIS as one of several possible causes of the estimated overall declines documented in the Alaska marbled murrelet population. Similarly, the Final EIS does not assume that flying squirrel abundance is solely dependent on old-growth but cites recent research that has documented their use of peatland-scrub-mixed conifer forests.

Comment: Table 3.4-3 of the Draft EIS suggests that Alternative 7 would reduce the productive old-growth by 31 percent. How is this possible when we will harvest less than 21 percent of the commercial timberland? Is the table referring to just the commercial old-growth outside of the congressional set-asides?

Response: Table 3.4-3 of the Draft EIS states that currently 88 percent of the POG existing in 1954 remains on the Tongass. Under Alternative 7, 69 percent of 1954 POG would remain long-term if percent Alternative 7 is selected and harvests at the highest rate modeled. The table also includes non-NFS harvests and the 31 percent refers to the reduction about 100 years from now relative to 1954 levels. In the Final EIS, this estimate has been refined to a 30 percent reduction relative to original POG levels.

Restoration and Young-Growth Management

Comment: Silvicultural treatments have been shown to be effective on the Tongass in increasing the amount of understory shrubs important as deer forage and as habitat for small mammals and shrub-nesting birds and should be recognized for their current and future contributions to habitat. Several respondents requested that the Final EIS acknowledge that there are many uncertainties related to the benefits and application of young-growth management as a tool for enhancing wildlife habitat given that some studies have documented correlations that indicate adverse effects (i.e., increased risk of black-tailed deer fawn mortality associated with pre-commercial thinning).

Response: A statement about the uncertainties related to young-growth management has been added to the text.

Comment: The Forest Service should shift priorities from timber harvest and road building to stream restoration and habitat enhancement.

Response: Stream restoration and habitat enhancement have been priorities on the Tongass for many years. The Final Proposed Forest Plan lists the maintenance and restoration of aquatic habitats as a forest-wide multiple use goal and lists designing and implementing structural and non-structural wildlife habitat improvement projects as a management objective (Forest Plan 2-3).

Comment: Please explain why you are adding "habitat restoration treatment" as a reason that programmed timber harvest can be done in the beach buffer. We fully support such restoration treatments, including commercial thinning, but this needs to be done with particular caution. The beach fringe should not be logged for commercial gain in anything other than a way that specifically benefits the beach fringe buffer values. When those interests overlap, then commercial timber harvest should be pursued.

Response: No programmed timber harvest would occur in the beach buffer; however, thinning or other treatments could occur if it is designed to improve wildlife habitat in dense young-growth stands. Timber cut for this purpose, if excess to down woody debris needs, could be sold, but this volume would not contribute to ASQ.

Comment: We recommend allowing selective harvest of second-growth timber in portions of the beach and estuary buffers that is more than 500 feet from the water, and in portions of riparian buffers that are more than 100 feet from rivers and streams; we do not support old-growth harvest in these buffers.

Response: The Final Proposed Forest Plan permits thinning dense young-growth stands in beach and riparian buffers to improve habitat.

Threatened, Endangered and Sensitive Species

Comment: Several suggestions were made to add species to the Regional Forester's Sensitive Species list as part of the Forest Plan Amendment. Several respondents suggested listing the marbled murrelet, given that the recent USGS status review indicates declines in the available habitat and the population in Southeast Alaska. Suggestions were also made to list *Martes caurina,* given its low numbers on Kuiu Island. Another respondent suggested adding endemic species.

Response: The Regional Forester's Sensitive Species list is currently undergoing review but this endeavor is separate from this Forest Plan Amendment and will occur on a separate time frame.

Comment: The U.S. Department of the Interior concluded that because the Kittlitz's murrelet, found in marine waters north of the Tongass, is most susceptible to recreation near tidal glaciers and high elevation land activities such as mining, changes reflected in the Proposed Forest Plan do not appear to pose a significant risk to this species.

Response: We concur with this conclusion, as indicated in the Final EIS.

Comment: No threatened or endangered species under the jurisdiction of the Fish and Wildlife Service exist within the project area. In response to the court-ordered remand the USFWS is currently evaluating the status of the Queen Charlotte goshawk and its habitat to determine if Vancouver Island is a significant portion of its range and, if so, whether listing under the ESA is warranted for all or part of the goshawk's range. In addition to the goshawk, the Alexander Archipelago wolf has previously been petitioned for listing; and the Kittlitz's murrelet is a candidate species. In addition there are numerous other endemic and sensitive species on the Tongass that will require continued collaboration between the Forest Service and USFWS in developing conservation provisions.

Response: The only federally listed species under the jurisdiction of the Fish and Wildlife Service determined in the past to occur on the Tongass National Forest is the peregrine falcon, which was delisted in 1999. An updated biological assessment has been prepared that addresses effects to this species. Information from the recent goshawk status review and 12-month finding has been incorporated into the Final EIS. Information regarding the Kittlitz's murrelet is also incorporated. We agree that there are many opportunities for collaboration with the Fish and Wildlife Service and are committed to continuing these endeavors.

Endemic Species

Comment: Standards and guidelines related to endemic mammals should emphasize climate change and connectivity between populations. Marten should be an emphasis of survey efforts.

Response: Standard and guideline VIII.A.2 of the Final Proposed Forest Plan relates to connectivity between populations of endemic mammals. Regarding species to survey, the species listed in standard and guidelines VIII.A.1.C of the Final Proposed Forest Plan are given as examples; it is inferred that marten are included in the medium-sized mammal category. Also see comments and responses in the Climate and Air section of this appendix.

Comment: The Draft EIS fails to adequately assess impacts to endemic mammals and the proposed plan fails to ensure viability of these species. The Draft EIS does not address impacts of the proposed plan on endemic mammals. It also fails to list specific islands or groups of islands with endemic fauna or recognize that a different management scheme may be warranted for such areas. Despite concerns about the inadequacy of the conservation strategy to protect endemic species expressed at the recent 2006 Conservation Strategy Review Workshop the Draft EIS fails to recognize these concerns.

Response: Additional information, much of which was presented at the 2006 Tongass Conservation Strategy Review workshop, has been added to the Final EIS text, including the opinion of some scientists that an island-centered management plan would be appropriate for the Tongass. Effects of the proposed plan on endemic mammals are discussed in the *Wildlife* section; additional discussion related to the ability of the conservation strategy to support viable endemic mammal populations is included in Appendix D.

Comment: Several comments were received regarding the project-level Forest Plan requirement for mammal surveys. Suggestions included requiring surveys for endemic mammals on all islands, not just those less than 50,000 acres; requiring surveys for all timber sales; requiring that surveys be conducted for rare and endemic birds, amphibians, and insects; and that the Final Proposed Forest Plan include considerations for adjusting timber harvest on islands as more information is gained on the habitat associations and population status of endemic species. Suggestions were also given for the intensity of surveys.

Related comments suggested that standards and guidelines basing the need for endemic mammal surveys on whether there is a "high likelihood" of the presence of an endemic mammal is too low a standard, given the lack of knowledge about endemics on the Forest.

Response: Surveys are required on all islands smaller than 50,000 acres and on islands larger than 50,000 acres if there is a high likelihood that endemic taxa are present and a high likelihood that these species would be affected by the proposed project (Wildlife Standards and Guidelines). Survey intensity will be decided on a project by project basis, depending on the size and type of project and level of anticipated disturbance, and information gained from these surveys (as well as from ongoing research) will be used to minimize the effects of forest management activities on endemic species. In addition, site-specific NEPA analysis generally consider the effects of the project on a wide range of wildlife species. Biologists use a combination of existing information, surveys and habitat assessment to determine effects. While having survey information is valuable, biologists generally assess the effects to species habitat if the species is suspected to be present, whether or not actual presence is verified.

The OGR system in the conservation strategy fundamentally is a 'coarse filter' approach to addressing wildlife viability and the conservation of biodiversity. In addition, a variety of other coarse filter standards and guidelines provided connectivity between the reserves. At the "fine filter" level, species-specific standards were fully considered in light of additional information such as conservation assessments, panel assessment results, etc. and appropriate standards and guidelines were incorporated for species that needed additional protection measures to assure their viability and well-distributed status.

The Wildlife Standards and Guidelines direct the Forest to conduct surveys when existing information on the distribution of endemic mammals is inadequate to assess project-level effects. It states that surveys should be conducted if there is a "high likelihood" that an endemic mammal could be affected by the proposed project, not if there is a high likelihood of its presence. Thus a proposed timber harvest in an area with little or no information on endemic mammals would require surveys.

As new information on endemics or other species is obtained, changes to the amended Forest Plan can be considered through the periodic Forest Plan review process, which occurs every 5 years, or at any time through an amendment.

Comment: Some respondents suggested that removing islands less than 1,000 acres from the timber base (to eliminate risk associated habitat loss or alteration) was sufficient to ensure viability of the 14 endemic mammals considered by the risk assessment panel and that other protective measures were unnecessary and costly, resulting in road construction and development in areas that would otherwise be untouched.

Response: Since 1997 a wealth of new information has been gained regarding endemic mammals on the Tongass which, in addition to expanding the knowledge base, has highlighted the substantial uncertainties that exist related to the population status and distribution of many species. Recent studies have also identified species in addition to the 14 species considered by the risk assessment panel and indicated that within Southeast Alaska the Prince of Wales Island complex is an endemism hot spot. Protective measures for endemic mammals include conducting surveys in areas where knowledge about the presence or distribution of endemic species is lacking and where projects could affect endemic species. Given the uncertainties that exist and the prevalence of endemism, these protective measures are appropriate for minimizing effects to endemic species. Moreover, conducting project-specific surveys for endemic mammals has no relation to the expansion of road construction and development in undeveloped areas.

Comment: Given that the insular landscape of the Alexander Archipelago has produced highly endemic populations, and is considered a hotspot for lineage diversity. The 2006 Conservation Strategy Review indicated that endemism was a "top priority" for the Tongass and that the Conservation Strategy fails to adequately address endemism on the Tongass. A new conservation paradigm should be developed for the Tongass under which each island is considered a unique biological unit until a better understanding of connectivity among these divergent populations is developed. Similar comments related to the lack of alternative conservation strategies considered in the Draft EIS.

Response: The general structure of the conservation strategy includes a system of OGRs and species-specific standards and guidelines that apply to matrix lands. Furthermore, the development of this strategy for the 1997 plan did take into account endemic species. Given that there are many uncertainties related to the effectiveness of the conservation strategy, each element of the conservation strategy requires consistent implementation across all islands. However, during project implementation, characteristics of individual islands are taken into account. All islands less than 1,000 acres are also fully protected. In addition, in a review of the conservation strategy, which has been incorporated into the Final EIS, Haufler (2007) indicated that a complete revision of the conservation strategy is not needed. Increasing our knowledge of endemic mammals continues to be a high priority for information needs on the Tongass (Appendix B of the Final Proposed Forest Plan) and as new information on endemics or other species is obtained, changes to the amended Forest Plan can be considered through the review process. See also related comments and responses above.

Comment: The location and status of endemic species is absent from the Draft EIS. The Forest Service is not incorporating scientific information on sensitive species into its management plans and not trying to locate this information. Arthropods, birds, and plants have not been surveyed as thoroughly as mammals, though there is a high likelihood that endemic forms will be found across these groups. Surveys should be required for non-mammalian rare and endemic species.

Response: Knowledge related to endemism on the Tongass (i.e., number of endemic species, distributions, and population status) is constantly expanding and being refined. The Final EIS addresses this by referencing some of the most recent peer-reviewed publications on this topic, but focusing the discussion of endemics on larger, Forest-level issues including landscape connectivity and fragmentation which relate to all endemics. We agree with the statement that survey efforts and existing scientific information are skewed toward endemic mammals but that there are likely many more non-mammalian endemic species on the Tongass. See also related comments and responses above.

Comment: The second definition for endemic in the Proposed Forest Plan glossary ("low occurrence of individual trees blowing over in a particular location") should be removed as this definition does not appear anywhere in the Proposed Forest Plan or Draft EIS.

Response: This term is used in the EIS. The definition in the glossary has been modified to better explain how it is used in the text.

Comment: The process for designating a subspecies is subjective and imprecise, and there are no quantitative criteria on which to base such designations. Therefore, it is inappropriate to uncritically accept designations such as the Queen Charlotte Goshawk and the Alexander Archipelago Wolf, which figure prominently in the Proposed Forest Plan.

Response: The Forest Service does not have legal authority to make determinations about the taxonomic status of a species. Subspecies addressed by forest planning documents are those currently recognized by the U.S. Fish and Wildlife Service.

Comment: The "Island Theory of Biodiversity" does not fit well with the Tongass. We have islands of development in a sea of old-growth. The short reaches of water between islands have proven not to be a barrier. Animals swim from island to island quite easily, which is why even very small islands have a diversity of wildlife. Differing areas traditionally have more or less of a particular species regardless of logging.

Response: It is true that some larger, more mobile species do swim between islands; however there are many smaller, less mobile species that are not capable of swimming and thus do not interact with subpopulations on other islands. It is likely that these less mobile animals populated the islands during periods when low sea levels created land connections.

Comment: Due to levels of past timber harvest, every timber sale on Prince of Wales Island should go through a rigorous scientifically designed inventory to assess impacts on endemic plants, birds, amphibians, and mammals.

Response: Endemic species were considered in the conservation strategy and some standards and guidelines, including Legacy, also take them into account. As noted in the *Wildlife* section of the Final EIS, there are likely many endemic non-mammalian species on the Tongass. However, current Forest Plan standards and guidelines focus on endemic mammals. Under the Forest Plan, surveys will be required for timber harvests on larger islands where there is a high likelihood that endemic taxa are present and a high likelihood that they would be affected by the proposed project. The extent and rigor of surveys will be commensurate with the degree of existing and proposed forest fragmentation, and potential risk to endemic mammals that may be present. See also related comments and responses above.

Birds—General

Comment: The selection of bald eagle nest sites in proximity to the shoreline makes it unlikely that a reduction in the beach buffer under Alternative 7 would result in risk to bald eagle

populations. Given the federal regulation for a 330-foot zone around bald eagle nests, a 330-foot beach buffer should be more than adequate.

Response: There is no statement in the analysis of effects to bald eagles that a reduction in the beach fringe under Alternative 7 would result in risk to the bald eagle population but rather it would reduce protection of nests located beyond 500 feet of shoreline to the 330-foot buffer surrounding them. Thus nesting habitat beyond 500 feet of the shoreline and outside of the nest buffers could be removed by timber harvest or road building. As stated in the Draft EIS, recent research indicates that nesting activity is reduced within 948 feet (300 m) of clearcuts, indicating that the 330-foot buffer may be inadequate to mitigate effects of harvest (Gende et al. 1998).

Comment: The local distribution of breeding birds may change but it is unlikely that any species will be at risk of major population declines. Timber harvest may create suitable habitat conditions for a number of species.

Response: It is true that timber harvest may adversely affect some species while benefiting others. A statement regarding the potential benefits of timber harvest to some bird species has been added to the Final EIS.

Comment: Surveys for raptors in proposed management areas should include forest owls, specifically western screech owls, barred owls, and northern saw-whet owls.

Response: The Wildlife standard and guideline for Heron and Raptor Nest Protection in the Final Proposed Forest Plan specifies that surveys required for raptor nesting habitat include the habitat of hawks and owls.

Comment: Classical fragmentation and effects of habitat loss (I.e., nest parasitism, loss of species, increased predation) are unlikely to be realized on the Tongass National Forest given the amount of remaining old-growth habitat, the rapid reestablishment of young forest on harvested sites, and the fact that some studies in western forests have not documented the same fragmentation/edge effects found in eastern forests.

Response: While studies of bird community response to timber harvest alternatives to clearcutting in Southeast Alaska indicate that creation of forest edge may increase nest predation rates, it is true that the actual response depends on a broad array of factors and is highly variable. This has been clarified in the Final EIS text.

Comment: Resident and migratory landbirds have been neglected in the planning process. Monitoring and habitat management considerations of cavity-nesters, other forest-associated species, and other species identified by state and national conservation plans as vulnerable (i.e., the olive sided flycatcher) should be incorporated into the Final Proposed Forest Plan.

Response: Maintenance of the biodiversity of all species was considered in the development of the conservation strategy. The Forest Service cooperates in the Alaska Landbird Monitoring System (ALMS) and other bird monitoring programs. Additional information needs by program area, including wildlife, will continue to be evaluated and prioritized using the framework described in Appendix B of the Final Proposed Forest Plan.

Marbled Murrelet

Comment: Respondents expressed opposing views on the status of marbled murrelet populations in Southeast Alaska. Some respondents were under the impression that the population was stable and did not appear to be in trouble, suggesting that the species was unlikely to be affected by levels of timber harvest proposed under the alternatives. Others cited the recent USGS status review (Piatt et al. 2007) which indicates that the population has declined substantially, as has suitable habitat. These respondents requested that this status review be referenced in the Final EIS and that additional species-specific standards and guidelines be added to the Final Proposed Forest Plan. One respondent commented that the analysis should consider effects of timber harvest on marbled murrelet habitat and should quantitatively evaluate how much marbled murrelet habitat is protected by OGRs and the effectiveness of this protection.

Response: Information on marbled murrelet ecology and status in Southeast Alaska published in 2007 has been added to the text. Effects of timber harvest on old-growth habitat are discussed under the marbled murrelet subsection of the wildlife analysis and tables indicating the distribution and protected status of this habitat are provided in the *Biodiversity* section.

Comment: Uneven-aged management should be specifically defined in relation to its use as mitigation for loss of marbled murrelet habitat and information on gap sizes and interspersion of individual trees or patches in cutting units should be provided to judge the effectiveness of this prescription.

Response: The definition and application of uneven-aged management is provided in the *Timber* section of the Final EIS. As noted in the *Timber* section, there is a lack of scientifically documented information on uneven-aged harvest in Southeast Alaska from which to document the effectiveness of this prescription. This has been the subject of retrospective study and is outside the scope of the Final EIS analysis. In terms of marbled murrelet habitat, uneven-aged management by definition reduces the loss of suitable habitat by maintaining mature forest within harvested units.

Comment: Providing 600-foot buffer zones around marbled murrelet nests provides no effective benefit because nests are difficult to detect. Respondents suggested eliminating this S&G and reinitiating marbled murrelet at-sea surveys. Other respondents voiced support for project-level surveys.

Response: A statement about the difficulty of detecting marbled murrelet nests has been added to the text. Given the current legal status of the marbled murrelet, it is unlikely that either at-sea or forest-wide nest surveys would be reinitiated or required. However, the Forest Service recognizes that declines in the population and available nesting habitat in Southeast Alaska have been documented. Information from the recent USGS status review (Piatt et al. 2007) has been added to the Final EIS text. The occurrence of marbled murrelets is assessed at the project level and surveys within suitable habitat could be conducted concurrently with other studies.

Comment: It is unclear what Forest Service supported marbled murrelet research is ongoing as stated in Appendix B.

Response: Appendix B of the Final Proposed Forest Plan has been modified to reflect the overall information needs program and acknowledges the many efforts to gain such information that is ongoing by state and federal agencies, academia, and many others. Specifics to marbled murrelet are not included in Appendix B now, but left to the appropriate entities that continue to study the species. Appendix B includes a greater intent to share and coordinate between those entities so all can benefit more readily when such information is available, as well as explore opportunities to share in the investments for new information.

Comment: For marbled murrelets, maintaining old-growth habitat for nesting is essential to the persistence of the species. When fully implemented the Tongass conservation strategy should provide adequate nesting habitat, therefore the old-growth reserve network should be maintained in the Final Proposed Forest Plan.

Response: The 1997 marbled murrelet panel assessment determined that the conservation strategy, including the old-growth reserve system, would have a high likelihood of maintaining well-distributed, viable populations in Southeast Alaska.

Comment: There is no science to support the conclusion that Alternative 7 would harm the viability of marbled murrelets.

Response: Additional information has been added to the *Wildlife* section of the Final EIS and Appendix D has been added which summarizes the 1997 marbled murrelet panel assessment.

Comment: The Draft EIS does not explicitly evaluate the cumulative effects of the alternatives on the long-term sustainability of marbled murrelets in Southeast Alaska.

Response: The effects analysis for marbled murrelets draws on the findings of the 1997 expert panel assessment. It is important to note that the conclusions drawn by the panel took into account the level of past and likely future harvest on non-NFS lands. Likelihood scores, which are described in more detail in Appendix D of the Final EIS, recognized this cumulative harvest. Therefore, the viability ratings represent a cumulative effects prediction for each alternative. The Biodiversity section quantifies the amounts of total POG, POG in reserves, POG in matrix, high-volume POG, large-tree POG, and other categories of POG at present and in the future under the alternatives.

Goshawk

Comment: Several respondents expressed concern that the existing and proposed Goshawk Nest Standards and Guidelines do not provide adequate protection. Reasons cited were that only a small number of nests have been found; proposed standards and guidelines potentially allow all the trees around a nest site be cut as long as there are 300 acres old-growth within a 0.75 mile radius (Threatened and Endangered Species II.K.1.e); and that a minimum no-harvest buffer of 500 acres surrounding active and alternate nests is needed to protect active goshawk nests from disturbance, preserve most alternate goshawk nests, and provide suitable goshawk post-fledging areas. Some respondents also requested that the Final Proposed Forest Plan retain the requirement for pre-project surveys using current protocols developed in cooperation with other agencies and that the Forest Service adopt an inventory and monitoring program for goshawk nests consistent with the guidance found in its recent publication on the topic (Woodbridge and Hargis 2006).

Response: Existing standards and guidelines require that a 100-acre no-harvest buffer be maintained around confirmed and probable active goshawk nest sites. The allowance for harvest in the future applies only to probable nest sites, not documented nest sites, and only if there is no evidence of occupancy in the future after two years. Though there is some risk that an occasional inactive nests may be affected by timber harvest, a majority of goshawk nests on the Tongass are protected by virtue of the fact that OGRs, beach and stream buffers and other standards and guidelines, and additional acreage removed from the timber base due to economic reasons protect over 90 percent of the existing POG over the life of the Forest under Alternatives 1, 2, 3, and 6. Additionally, on a forest stand level, most goshawk nests that have been found on the Tongass within timber sale project areas were included within the boundaries of small OGRs when districts were doing project level adjustments. This resulted in larger protection for most goshawk nests than just the nest stand. In regards to nest surveys, the Tongass will continue to do goshawk surveys for timber sale planning prior to NEPA decisions. Actual protocols will consider current research on goshawk inventory and monitoring, including Woodbridge and Hargis (2006). This requirement was mistakenly deleted from the Proposed Forest Plan, but has been added to the Final Proposed Forest Plan. Appendix D of the Final EIS provides additional discussion of the rationale behind the proposed changes to the Goshawk Standards and Guidelines.

Increasing nest buffers to greater than 100 acres was considered by USFWS in their November 2007 finding (Federal Register vol 72, no. 216 page 63123). While they acknowledge that larger buffers would likely enhance goshawk conservation by providing better habitat for fledglings in the immediate vicinity of the nest, they conclude that lack of larger buffers is not expected to reduce fecundity or survival to an unsustainable level because of the amount of nesting habitat that is retained in OGRs in non-development LUDs and other retained forest patches retained in the matrix. We concur with this and therefore, did not consider an increase in nest buffers.

Comment: Several respondents requested the inclusion of recent peer-reviewed literature on goshawk habitat requirements needs to be expanded to include annual and final Southeast Alaska specific reports produced by ADF&G (e.g., Flatten 2001), diet studies published by Lewis and colleagues (2006), and other published studies from the Pacific Northwest. Some respondents also requested the clarification that goshawks inhabit *western* forests rather than all forests in North America, and that the statement that the Queen Charlotte goshawk is a distinct subspecies be attributed to a primary reference rather than the 1996 status review (Iverson et al. 1996).

Response: Additional scientific information on goshawks, including that listed above, has been added to the Final EIS.

Comment: The Forest Service should consider using habitat associations of key goshawk prey species as a tool for sustaining goshawks on the Tongass.

Response: This comment stems from a consideration suggested during the 2006 Conservation Strategy Review Workshop. We believe that the conservation strategy coupled with application of site-specific nesting habitat standards and guidelines in the Proposed Forest Plan provide adequate protection to maintain sustainable goshawk populations. We have however, added the prey habitat relationship topic to Appendix B of the Final Proposed Forest Plan as one of the higher priority information need categories.

Comment: Several comments were received regarding the association of goshawks with old-growth forests. Some respondents felt that the statement in the Draft EIS regarding goshawks nesting in forest types other than old-growth (Draft EIS p 3-161 to 3-162) incorrectly implied that goshawk telemetry data from Southeast Alaska has produced similar results to those observed in the Southwestern United States which showed use of a greater range of forest types for nesting, clarifying that telemetry data from the Tongass still suggests a strong selection for old-growth. In contrast, other respondents felt that the relationship between goshawks and old-growth forest was overemphasized, given new research, citing a study (Flatten et al. 2001) on the east side of Douglas Island, which had been clearcut in the early 1900s.

Response: As noted in the *Wildlife* section of the Draft EIS, recent research indicated that goshawks use a greater variety of habitats than once thought and that there is some documented use of second-growth by nesting goshawks, though most goshawks in Southeast Alaska are associated with older forests. Goshawks can nest successfully in relatively young stands if adequate-sized trees are available to support a nest; however a majority of the second-growth on the Tongass is less than 50 years old and lacks these conditions. Flatten et al. (2001) documented higher nesting activity in the contiguous second-growth forests of northern Southeast Alaska (Douglas Island) compared to the more fragmented forests of southern Southeast, which they attributed to the fact that as second-growth stands mature they increase in contiguousness and thus in forest-dwelling prey and suitable hunting habitat. The authors noted that this trend may also reflect the lack of prey (squirrels and blue grouse) in southern Southeast

Alaska, though they emphasized that region-wide there is a lack of prey associated with open habitat, rendering fragmented forests less productive for goshawks.

Comment: The Draft EIS fails to discuss the scientific opposition to the current 100-year harvest rotation in relation to its effects on goshawks and is therefore in violation of NEPA. The Goshawk Conservation Assessment prepared for the 1997 EIS recognized a rotation of 300 years as adequate for regaining old-growth forest characteristics in harvest units; a 300-year rotation was also recommended by the Department of the Interior and by the 2002 Supplemental Wilderness Review.

Response: In the Goshawk Conservation Assessment, Iverson et al. (1996) differentiated two types of rotations: a 300-year "ecological" rotation applied to all old-growth as a means to express age class distribution over time, and a silvicultural rotation applied to suitable acres scheduled for timber harvest. Iverson et al. (1996) concluded that landscapes that maintained a forest age structure consistent with a 300-year ecological rotation would provide a high likelihood of sustaining goshawks. This composition would generally consist of one-third each of 0- to 100-year old stands, 100- to 200-year old stands, and 200-year old or older stands, categories with increasing value to goshawks, which can be accomplished by implementing a shorter harvest rotation. Notice that this is on a landscape scale like at the VCU scale or larger. Text has been added to the Final EIS to clarify this.

Marten

Comment: **The statement in the Draft EIS about the lack of clear correlation between marten population trends and habitat alteration is related to the lack of effort to study this dynamic or lack of data (i.e., no long-term datasets), rather than there being no relationship. Some respondents requested that marten harvest on Kuiu Island be separated out from the rest of harvest in GMU 3 for clarification because of low marten numbers on that island. The lack of information regarding the distribution of the endemic *M. caurina* marten subspecies on the Tongass needs to be emphasized in the EIS, particularly the fact that many unsampled islands could support endemic marten populations, and made a high priority issue. The EIS should devote larger attention to fragmentation of marten habitat.**

Response: These points have been clarified in the text in the Final EIS. Information on marten harvest on Kuiu Island has been added to the Final EIS text. A statement about the status of information on the distribution of endemic marten has been added to the Final EIS text. Additional discussion of fragmentation has been added to the marten subsection of the Final EIS.

Comment: Available data suggest old forest is important for marten, but they will also use other habitats including younger forest provided that structural features such as large downed logs are present. Plan alternatives with the highest level of timber harvest retain 76 percent of productive old-growth suggesting suitable marten habitat will continue to exist across the Tongass. A more apparent contribution to population levels is fur trapping which confounds interpretation of habitat need and which should be amenable to regulatory controls.

Response: We agree with the statements regarding marten use of younger forests and that plan alternatives will retain a substantial amount of marten habitat, as stated in the Draft EIS. It is true that trapping is one of many factors that affect marten population levels.

Comment: There is no science that suggests that marten require legacy trees.

Response: Additional information related to marten use of legacy structure has been added to the Final EIS text and in Appendix D.

Comment: Some respondents were concerned that the Draft EIS relied on the marten model to predict marten habitat capability due to various inadequacies.

Response: The marten habitat capability model was not specifically used in the Draft or Final EIS; however, the acreage of high-volume POG below 1,500 feet elevation was used as one measure of habitat.

Comment: Marten viability is only guaranteed by large, unfragmented areas of high volume old-growth that is not accessible to legal or illegal trapping. Rather than disclose or analyze this, the Draft EIS relies on the Proposed Forest Plan to adequately protect this species. The Draft EIS fails to analyze how various alternatives will affect marten survival across the landscape and particularly within islands such as Kuiu where concerns for this species have been documented by the scientific community.

Response: As stated in the Draft EIS, marten are wide ranging and require large tracts of contiguous habitat to move across the landscape. Further, the Draft EIS notes that although marten populations appear to be sensitive to habitat alteration, there is no clear correlation between population trends and habitat change. This is due to the lack of research on this dynamic and the absence of long-term population datasets, in addition to the many unknowns related to marten distributions on the Tongass. Therefore the effects analysis focuses on habitat alternation.

Maintaining viability and well distributed population of marten is dependent on many factors, including habitat, prey abundance and trapping mortality. Assuring viable marten populations through trapping regulations involves cooperation with the State and the Federal Subsistence Board. While the Forest Service has a role in setting harvest regulations through the Federal Subsistence Board, the Forest Service, by itself, cannot set or manipulate wildlife harvest levels.

Comment: Some respondents expressed concern over the Kuiu Island population of endemic marten because there are two approved timber sales (Crane Rowan and Threemile) and one planned timber sale (Kuiu Timber Project) proposed on a proportion of the island where this species is known to occur.

Response: The Final EIS discloses effects to marten and the likelihood of maintaining viable and well-distributed populations, based in a large part on the amount of land within the suitable timber base. Timber sales fall within the suitable land and therefore, viability concerns have already been addressed at the Forest Plan scale. The NEPA analysis for these timber sales considered site-specific issues, including marten habitat, documented in their EISs, and included mitigation to protect marten (i.e., Marten Standards and Guidelines). Individual timber sales are not the appropriate scale to address issues related to viability on a wide-ranging species such as marten.

Comment: Several comments were received regarding guidelines marten and road closures. One respondent felt that Marten standard and guideline XVIII. A.1.3 requiring road closures where roads are a significant factor in unsustainable mortality is important. In contrast, another respondent commented that it is unnecessary to perform specific road closures in areas of identified marten mortality due to trapping because ADF&G is capable of implementing appropriate enforceable regulations restricting trapping.

Response: The Final Proposed Forest Plan clarifies open and closed road density analysis requirements for consistency in helping to determine road influences on marten mortality that can be incorporated into Travel Management planning with the objective of reducing mortality risk using local knowledge of habitat conditions, spatial location of roads, and other factors rather than solely relying upon road densities. This analysis would be a collaborative effort between the Forest Service and ADF&G to assess the relationship between hunter/trapper marten harvest and human access. Note also that the open road density restrictions do not need to be applied without consideration of marten trapping harvest levels. Several thousand marten are trapped on a sustainable basis each year in Southeast Alaska.

Wolf

Comment: Some comments stated that the Draft EIS failed to consider the effects of climate change and other stochastic events on wolves and the predator-prey dynamic of wolves and deer. Wolves are depended on deer and the EIS needs to consider how declines in deer populations due to climate change will affect wolves.

Response: The exact effect of climate change on deer and wolves is uncertain; however, most researchers expect warmers winters. Current science supports that severe winters are the greatest threat to deer populations, as some comments state. Juday et al, (1998) predict that it is likely that there will be warmer winters and low snowfall in low elevation forests and this will lead to higher deer populations, which would increase prey for wolves. Conversely, Juday et al. also predict increased large-scale blow down from the increased in storm activity, though, as the Final EIS notes, this has not occurred even though the number of days with gale-force winds has doubled since 1950. Models cannot accurately predict whether snowfall will increase or decrease or whether blow down will increase or decrease in low-elevations; therefore, they cannot predict the effect on deer and wolves. This is why monitoring the effects of climate change on wildlife habitat was incorporated into Chapter 6 of the Proposed Forest Plan. One strategy the Forest is strongly considering is thinning dense young-growth stands in low-elevation areas, such as the beach fringe, to increase forage and to speed the development of mature forest structure. This may improve low-elevation winter habitat for deer, and therefore for wolves.

Comment: Some respondents questioned the statement in paragraph 2 on 3-170 of the Draft EIS that no clear link had been established between wolf population numbers and changes in habitat characteristics.

Response: This paragraph is referring to a direct link between project level habitat changes caused by forest management activities (e.g., timber harvest) and wolf population change on the Tongass. As noted, datasets available for monitoring wolves are insufficient for detecting all but very large changes in the wolf population and are not designed to track trends in the population resulting from changes in their habitat due to Forest Service actions. The Final EIS states that deer are the primary prey of wolves in Southeast Alaska, and the significance of predator/prey interactions indicates that wolf persistence is directly linked to deer habitat capability. That said, data on deer population trends across the Forest are also inadequate (i.e., consisting of limited pellet count data in heavily hunted GMUs) to enable a direct comparison between habitat changes associated with forest management activities and the Tongass deer population.

Comment: Respondents pointed out that a substantial decline in deer population could result in gaps in wolf distribution, particularly on islands, but a more likely outcome would be that wolf population density would be reduced as pack home range size increases. They also suggested that if deer numbers decline substantially wolves may experience increased harvest pressure from subsistence users in an effort to protect deer, which could ultimately further reduce wolf genetic diversity.

Response: Information on the potential response of the wolf population to changes in the deer population has been added to the Final EIS. This is speculative at best. If decreases in prey reduced wolf populations, density of wolves would also be reduced, decreasing opportunities to harvest wolves, despite potentially increasing pressure to harvest wolves. If over harvest of wolves were to become a concern, harvest regulations and closure of specific areas are tools the State and Federal Subsistence Board may use to limit that harvest.

Comment: Density-dependent population change in relation to habitat carrying capacity and the non-linear relationship between predation, carrying capacity, and deer population numbers should be discussed in relation to deer and wolves. Information from Person (2001) and Person and Bowyer (1997) regarding wolf population viability and the effects of the 1997 Forest Plan alternatives on the wolf population should be included in the Final EIS. New information presented at the Conservation Strategy Review regarding the ratio of recruitment to mortality in an unmanaged landscape should be included; respondents suggest using this ratio to compare OGRs in terms of their ability to support sources wolf populations.

Response: Additional discussion of density-dependence, predator suppression of declining deer populations, and other related information has been added to the Final EIS.

Comment: Several respondents noted that some of the new information presented at the 2006 Conservation Strategy Review workshop has not been incorporated into Wolf Standards and Guidelines. This includes information presented during the 2006 Conservation Strategy Review indicated that the den buffer standard and guideline needs revision.

Response: The Conservation Strategy Review workshop represents one step in the Forest Plan review process, with the purpose of identifying considerations to be addressed in the overall review of the Conservation Strategy. Subsequent steps will include an assessment of each consideration identified during the work shop based on workshop information, peer-reviewed scientific literature, the recent *Review of Conservation Science Produced Since 1997 and Its Relationship to the Tongass National Forest Land and Resources Management Plan* (Haufler 2006), as well as input from various state and federal agencies. These assessments will culminate in a determination of how each consideration will dealt with. Some considerations have been addressed in time for incorporation in the Final EIS however others, like the Wolf Standards and Guidelines, require additional interagency consultation, the formation of specialized workgroups, and more detailed development, and therefore will be implemented after the Final EIS. These long term considerations could lead to conservation strategy-related adjustments to the amended Forest Plan through additional amendments or may be identified as information needs.

Comment: The 2007 Proposed Forest Plan standards and guidelines for wolves specify an optimal deer density of 17 deer per square mile. This is incorrect and should be 18 deer per square mile, consistent with the Draft EIS and the science underlying the standard and guideline, however should not be confused with the 13 deer per square mile specified in the 1997 Forest Plan. The respondents note that there has been much confusion with these numbers, clarifying that the latter number represents population density, based on Person (1996), whereas the other numbers represent a habitat capability (18 deer per square mile being the accepted, correct number). The respondents request that the Final Proposed Forest Plan include specific guidance for computing the habitat capability deer density (using the deer multiplier to convert deer winter habitat capability models into deer densities) and clearly differentiate between the recommended actual deer density and habitat capability.

Response: The Forest Service primarily manages habitat and assesses effects to deer and wolves based on habitat capability rather than actual population numbers. The deer habitat capability density specified in the Wolf Standards and Guidelines has been corrected in the Final Proposed Forest Plan. Guidance for using the deer model is too detailed for inclusion in the Forest Plan, and may change as newer models are developed. Using the deer model is only one method of assessing effects to wolves and deer. The Final Proposed Forest Plan directs use of variety of methods, including the deer model, in assessing effects. This includes local knowledge of habitat conditions, spatial location of habitat, and other factors that need to be considered by the biologist rather than solely relying upon model outputs. In addition, the Plan allows for alternative tools to be developed as new information on assessing habitat for deer and wolves evolves.

Comment: The deer analysis is inadequate in that it does not quantitatively evaluate the risks under each of the alternatives associated with providing an adequate supply of deer for wolves and hunters and does show whether the alternatives meet the standard and guideline for maintaining a threshold habitat capability of 18 deer per square mile (as determined by the deer habitat capability model).

Response: Using a habitat capability of 18 deer/square mile is not a threshold. It is only one of several tools that can be used at the project scale to assess if sufficient deer habitat capability exists to maintain sustainable wolf populations. Other tools include local knowledge of habitat conditions and spatial location of habitat.. Other factors need to be considered by the biologist rather than solely relying upon model outputs. Habitat capability is also a tool to determine effects of a project on, human deer harvest demands. An analysis of the ability of the alternatives to meet the Wolf standard and guideline deer habitat capability has been added to the Final EIS text.

Comment: The Wolf standard and guideline for road density was based on the analyses described in Person et al. (1996) but has never been implemented in a manner consistent with Person et al. (1996). The 0.7 mile per square mile road density should account for all open, closed, and overgrown roads in areas below 370 meters elevation, not simply open roads. This is because it is hard to distinguish between open and closed roads (i.e., close roads may still be used by hikers and OHV users), and both may provide easier access for wolf hunting and trapping. Additionally, a majority of wolf activity occurs below 370 meters elevation (Person et al. 1996, 2001). The road density guideline should be applied at a scale equal to an average wolf pack home range (e.g., 300 km; Person et al. 1996). The incorrect use of this guideline has been brought up in interagency meetings since 1997, but has never been corrected in the Forest Plan. A respondent suggested that consideration should be given to peak road density.

In regards to the range or road densities, one respondent commented that an open road density requirement of 0.7 to 1.0 miles per square mile to reduce "human-caused mortality" of wolves is unnecessary because ADF&G is capable of applying and enforcing appropriate regulations to provide for abundant wolf populations. Conversely, another respondent felt that a less discretionary standard of 0.7 miles per square mile should be set.

Response: Specification of total road density for analysis purposes has been added to the Final Proposed Forest Plan to promote consistent interpretation and use. The misinterpretation of the guideline was described in the *Wildlife* section and, as stated, the analysis in the Final EIS accounts for lands below 1,200 feet in elevation, included both open and closed roads, evaluated road densities by WAA which are approximately equal in size to wolf pack home ranges in Southeast Alaska, and included all land ownerships. Because this EIS covers the entire Forest, all WAAs were included in the analysis. The wolf guideline of 0.7 miles per square mile road density is not a limit, but the lower end of a range of road densities (up to 1.0 miles per square mile) recommended if road access and associated human-caused mortality has been determined to be the significant contributing factor to unsustainable wolf mortality. Note that the 0.7 to 1.0 miles per square mile guideline does not need to be considered until that determination has been made and that consideration of wolf hunting and trapping harvest is also considered. In addition, local knowledge of habitat conditions, spatial location of roads, and other factors would also need to be considered by the biologist rather than solely relying upon road densities. As noted in the *Wildlife* section, the ADF&G currently enforces a harvest cap in GMU 2 to ensure that a viable wolf population is maintained, however there are other key components of wolf conservation, in addition to harvest regulations, including maintaining adequate deer habitat capability and minimally roaded core areas.

Comment: Transportation Standards and Guidelines need to implement the Wolf Standards and Guidelines for road density.

Response: Standards and guidelines in TRAN4.I.A requires the Forest Service to "perform route or site selection, location, geotechnical investigations, survey, and design to a technical level sufficient to meet the intended use and commensurate with both ecological objectives and the investment to be incurred" and to "ensure consistency with Forest-wide Standards & Guidelines and Best Management Practices." This includes the Wolf Standards and Guidelines.

Comment: The discussion of habitat use by wolves needs to summarize Person (2001) otherwise it is outdated.

Response: Information from Person et al. (2001) has been added the Final EIS text.

Comment: Wolf numbers are limited by prey availability, not social interactions. The discussion in the affected environment section should refer to and summarize the appropriate sections in Mech et al. (1998) and Fuller et al. (2003). The density limit of 10 wolves per square mile stated in the Draft EIS is incorrect. For example, Isle Royale has had densities of wolves that substantially exceed that limit.

Response: Information from Mech et al. (1998) and Fuller et al. (2003) has been added to the Final EIS text. In regards to wolf density, the Draft EIS actually states that "Due to social interactions, wolf densities do not exceed certain levels even when prey abundance is high. A density of one adult wolf per 10 square miles is considered high, and this density is often considered as a saturation point beyond which wolf populations would not expand. Wolves have large home ranges (about 100 square miles per pack), use a wide variety of habitats, and are very mobile." This information came from the Alexander Archipelago wolf conservation assessment (Person et al. 1996) which presented wolf densities for 9 study areas in Minnesota, Ontario, Quebec, Vancouver Island, and Prince of Wales/Kosciusko islands. Wolf densities reported from these study areas ranged from 1 to 1.7 wolves per 10 square miles (8 study areas had densities of 1 wolf per 10 square miles or less).

Comment: Units 2 and 3 support modest wolf densities compared to other areas where wolves prey on deer rather than moose, caribou, bison, or other large prey. While wolf densities are high in Units 2 and 3 compared to other parts of Alaska (where deer are absent), they are not high when compared to other areas where deer are the principle prey (i.e., northern Minnesota, southeastern Ontario, and British Columbia). More information on this is available in Person et al. (1996, 2001). The wolf population in Unit 2 is currently healthy but that does not imply it will be in the future when more of the landscape is in stem-exclusion forest. Current populations are not indicators of the future. Reference should be made to the concept of "succession debt" described by Person (2001).

Response: Information from Person et al. (2001) has been added to the Final EIS text.

Comment: Prince of Wales Island wolves seem to be a distinct population segment. However, the Draft EIS fails to disclose what those profound implications are or take them into account in the impact analysis. Weckworth et al. (2005) should be reviewed and cited in the Final EIS.

Response: Information from Weckworth et al (2005) regarding the distinct wolf population on Prince of Wales Island has been added to the Final EIS.

Comment: Factors affecting the Alexander Archipelago wolf are primarily density of black-tailed deer and road access for wolf hunters/trappers. A strong inverse relationship between wolf home range size and critical deer winter range was found. Wolves are highly mobile and move between islands in Southeast Alaska, some being separated by up to 2.5 miles. Between 1993 and 2000, 85 percent of radio-collared wolf mortality was due to trapping, with equal amounts of legal and

illegal harvest. The presence of roads has a significant effect on wolf harvest. Historically, the ADF&G allowed year-round no-limit wolf harvest.

Response: Deer populations and road access were identified in the Draft EIS as important components in wolf conservation. The Draft EIS also discussed harvest regulations in GMUs 2 and 3. The Forest Service, by itself, does not have the authority to regulate wolf harvest.

Comment: The Draft EIS and Proposed Forest Plan fail to adequately protect this wolves from human disturbance. In fact the proposed plan would weaken the protections already in place. The plan does not trigger action until road density is determined to be the <u>significant</u> <u>contributing factor</u> to unsustained wolf mortality. This is a very discretionary standard. The trigger should be when road density is determined <u>to contribute</u> to unsustained wolf mortality. The plan also lacks teeth in its remedial action to protect wolves when the road densities are exceeded; it should trigger road closures and road building prohibitions.

Response: If and when open roads contribute to unsustainable mortality, actions to reduce that factor can and will be considered. This would be guided by the appropriate Forest Plan standards and guidelines including the wolf mortality guideline. The extent of actions taken will be in consultation with other agencies and the affected publics as well.

Deer

Comment: Assumptions of the Tongass deer habitat capability model need to be evaluated and updated and model results should be ground-truthed.

Response: The 1997 deer model habitat capability model represents the most current tool available for evaluating deer winter range conditions on the Tongass. The habitat types included in the model are broad and general, and they are not based on any particular site-specific data which would enable ground-truthing. Given the large differences in deer habitat value between many of these broad classes of habitat, the model provides a useful and reasonable estimate of deer habitat value for large-scale analyses. Despite limitations to the existing model, which are discussed in the *Wildlife* section of the EIS, the model provides a relative estimate of deer habitat value which is appropriate for comparing management alternatives. Modifications to the model, such as refining coefficients due to changes in vegetation mapping on the Tongass, are forthcoming but will occur outside of the timeframe for the Forest Plan Amendment. Scientific research published after the 1997 has increased knowledge about deer-habitat relations in Southeast Alaska, but does not contain anything that would change the 1997 expert-based model significantly. However, a nutritional-based model has recently been developed that could provide the basis for completely re-evaluating our analysis of deer habitat. However, since, it is an entirely data-driven system, and its data requirements cannot be met with existing Forest data it will take additional time to fully implement this new analysis. See Appendix B of the Final EIS for additional information on the deer model.

Comment: Clearcuts have been assigned high value by the deer model but during severe winters these habitats provide little value to deer.

Response: This comment is incorrect in that the 1997 deer model, which is currently the only model available for conducting large-scale analyses of deer habitat on the Tongass, assigns the highest values to forests with closed canopy (based on volume class rather than canopy cover), maritime influence, south facing slopes, and low average snow depth. Recent clearcuts are assigned moderate values. See Appendix B of the Final EIS for additional information on the deer model.

Comment: Some respondents expressed concern that the cumulative loss of deer habitat will result in catastrophic population crashes, reflecting lost winter habitat, that may have cascading effects to wolves and bears, and that deer will be extirpated from some islands or will fall into predator pits. Related comments suggested that restoration of deer winter range is needed.

Response: The deer model presents a worst-case scenario by assuming that all suitable acres are harvested under each alternative. However, the current level of road construction and timber harvest on the Tongass is at a 5-decade low and the life of this Amendment is expected to be 10 to 15 years at most, at which time a Plan Revision will likely be undertaken. In addition, there will be a period of preparation prior to the implementation of any sale during which no harvest will occur, even if the timber industry responds rapidly. The management of second-growth stands on the Tongass has helped offset the cumulative loss of winter range by accelerating the stem exclusion phase of forest development, which occurs roughly 15 to 25 years following a major disturbance when the growing space is fully occupied, tree crowns are crowded, and forage is limited. The creation of new foraging habitat is not reflected by the current deer habitat capability model.

The analysis of effects to deer winter range provided in the *Wildlife* section takes into account past timber harvest and therefore serves as an assessment of cumulative effects. This assessment is conservative in that it assumes that non-NFS lands provide no habitat capability. Currently there is no defined threshold for loss of winter range with which to predict the likelihood of a population crash. We can only speculate that losses could be amplified during severe winters; however, one expected result of the current warming trend is warmer winters. Management of young-growth was discussed in the *Wildlife* section of the Draft EIS as a potential way to improve the quality of deer winter range.

Comment: The second paragraph under Deer in the description of the affected environment for wildlife in the Draft EIS, fourth sentence should read: "the quantity, quality, distribution, and arrangement of winter habitat are considered the most important limiting factors for deer."

Response: This sentence has been corrected in the Final EIS text.

Comment: Several respondents questioned the use of the 1997 deer habitat capability model in relation to the application of the deer multiplier (i.e., high HSI scores, whether 1.3 or rescaled to 1.0, should correspond to a deer habitat capability density of 100 deer per square mile).

Response: A re-occurring appeal point against the interagency deer model is the proper use of the deer density multiplier. The Final EIS uses the currently approved version of the model. In the Draft EIS the deer model was employed only to compare alternatives based on HSI scores rather than population numbers in the deer and wolf effects analyses. However, to compare the alternatives in terms of their ability to meet the Wolf standard and guideline for deer habitat capability (expressed in terms of the number of deer per square mile), an analysis using the deer multiplier has been added to the Final EIS.

Comment: One comment stated that the deer habitat capability model is not a valid risk assessment tool because it does not provide probabilities of risk with which to compare alternatives.

Response: The term "risk assessment" has been removed from this sentence in the Final EIS.

Comment: The Draft EIS only mentions the FRESH-Deer model as an alternative to the deer habitat capability model, however this model can not be expanded from a stand-level to a landscape-level analysis.

Response: This statement is not correct. The FRESH-Deer model consists of two levels of application: a web-based, stand-level module; and a GIS-based, landscape-level module. For more information on model specifics please see the FRESH-Deer model home page located at http://cervid.uaa.alaska.edu/Home.aspx.

Comment: Respondents clarified that black bears were primary predators of newborn black-tailed deer fawns on Prince of Wales Island, rather than Heceta Island.

Response: This statement has been corrected in the Final EIS.

Comment: The analysis of effects to deer is insufficient in that the use of POG as an indicator is an overly broad classification, there is no means provided to assess the implications of percentage changes in habitat because there is no established threshold beyond which reductions in habitat capability are deemed unacceptable, and relative rather than direct comparisons among alternatives is made. This type of comparison does not facilitate meaningful analysis of impacts to wolves or subsistence due to changes in deer population numbers. The Draft EIS should include a comparison among the alternatives based on their ability to provide the required 18 deer/square mile density standard and guideline.

Response: The deer analysis does not use POG as a means for comparing alternatives with respect to deer, rather the tables in the discussion of effects to deer present percentage changes in deer habitat capability, as quantified by the deer model. As described in the affected environment section under deer, the deer habitat capability model takes into account the value of individual SD7 model POG categories to deer. The tables provided in the deer section displays the existing percentage of remaining deer habitat capability relative to 1954 levels, indicative of baseline pre-large-scale timber harvest conditions, and percentages projected under each alternative. This enables a relative comparison among the alternatives in terms of how each alternative will directly affect baseline deer habitat capability. Additional information on the deer model, including how these numbers are derived, is provided in Appendix B of the Final EIS. As noted by the respondents, currently there is no threshold reduction in habitat capability that has been identified by science and therefore the effects of reductions in deer habitat capability are appropriately discussed in general terms. An analysis of changes to deer habitat capability expressed in terms of a deer density has been added to the analysis of effects to wolves.

Comment: The Draft EIS evaluates reductions in deer habitat capability on Tongass National Forest lands only and disregards substantial past and future anticipated losses on other land ownerships in the region.

Response: The Draft EIS states that for the deer habitat capability analysis lands under non-federal ownership have an assumed habitat capability of zero because these lands have been, or will be, developed for intensive timber production and are expected to have lower habitat capability over time.

Comment: The definition and analysis of "high value deer winter range" are inaccurate because by defining quartiles by equal land area what is considered high value may differ by WAA.

Response: There is natural variation among WAAs in what is considered high-value winter range. For example, maritime and interior WAAs naturally show differences in habitat capability due to differences in winter severity (i.e., snow levels during average winters are typically different). Consequently, high quality habitat within the home range from a deer's perspective may differ depending on the location of that home range within a particular WAA. Thus, defining high value winter range as the quartile of acreage within a WAA with the highest HSI scores allows a more accurate, and conservative, portrayal of lost habitat capability, given that there are WAAs where there is no habitat that falls within the upper quartile of possible HSI scores (i.e., scores above 75 on a scale of 0 to 100) yet they are inhabited by deer.

Comment: Critical deer winter habitat, especially in areas relied on for hunting, should be protected and not slated for logging under the amended Forest Plan.

Response: Effects to deer winter range are discussed in the *Wildlife* section of the Final EIS. The 2006-2007 Interagency Forest-wide Small Old-growth Reserve review considered deer winter range as a factor when evaluating the placement and configuration of small OGRs. Though this effort eliminates the need to conduct project level reviews for the most part, additional reviews that take place on the project level will follow a standardized protocol, developed as part of this forest-wide effort. This includes using the Tongass deer winter habitat capability model to identify high value deer winter range that warrants protection.

Comment: Winter range should be more clearly defined as it applies to the deer habitat capability model to incorporate severe, rather than average, winters. The Draft EIS fails to evaluate the effects of severe winters on deer, particularly in areas where there are no wolves.

Response: The Forest Service feels that the Draft EIS adequately addresses the subject of severe winters by noting that effects of reductions in carrying capacity for deer would be greatest during severe winters when resources are most limited. Severe winters are stochastic events that are highly variable. Heavy snowfall may occur with increased or decreased frequency or magnitude as a result of global climate change, there are many uncertainties and differences of opinion related to these predictions. Information on these uncertainties has been added to the Final EIS. As the Climate and Air section of the Draft EIS states, models available for estimating climate change are designed to predict changes on a regional level and are not detailed enough to predict changes to the Tongass. Consequently, they do not agree on how global warming will affect Southeast Alaska. Thus, it is impossible to accurately predict the frequency or magnitude of severe winters, much less the effects of severe winters on deer under each of the management alternatives.

Comment: It should be noted that the forage production in recent clearcuts is of lower nutritional quality than the same forage types found in old-growth.

Response: This statement has been added to the Final EIS text.

Comment: Deer and bear are abundant on Native Corporation lands where silvicultural management of harvest units provides forage and cover for these species, compensating for lost habitat capability.

Response: We agree that young-growth management can potentially benefit wildlife; however, there are many uncertainties related to appropriate young-growth treatment designs, specific beneficial effects of such treatments, and implications for deer and other wildlife species. In addition, some studies have shown the opposite results. Additional discussion of uncertainties related to young-growth management has been added to the *Wildlife* section of the Final EIS text.

Comment: The likelihood of long-lasting declines in deer population under all alternatives appears to be low; the potential for stand treatments to improve forage conditions in young stands is high.

Response: We concur that the effects of the alternatives are unlikely to result in long-term population declines. A discussion of young-growth management was included in the *Timber* and *Wildlife* sections.

Comment: Several comments were received regarding timber harvest and road construction in specific areas. On respondent stated that targeting important deer areas like Tenakee Inlet will

have long-lasting impacts on deer populations and subsistence. Another respondent stated that timber harvest and road building in the Bostwick Inlet/Gravina Island area could jeopardize subsistence and hunting resources. Another respondent expressed concern over effects to eagles in the 11 Mile area.

Response: Any timber harvest planned for the Tenakee Inlet (or any other part of the Tongass) will require a site-specific environmental analysis which will consider effects on deer and subsistence resources.

Comment: Forest Service planning assumes a static average deer density needed to support hunter demand and proposes restricting federally ineligible hunters when habitat impacts from the Forest Plan result in a density below levels needed for local subsistence. This is a false trade-off because hunting and habitat loss due to clearcut logging affect deer populations in different ways; hunting tends to stabilize deer populations in areas with few predators whereas logging winter range is a destabilizing force. Restricting non-local hunting effort will not maintain deer for subsistence but will amplify deer population cycles ultimately reducing the number of deer available to subsistence hunters during population lows.

Response: The Forest Service does not assume static deer densities, but recognizes cycles. Hunting may need to be regulated in some areas if deer numbers decline and that could include restrictions to non-federally qualified hunters.

Comment: Some young-growth stands, particularly those located on hillsides where sunlight can reach the forest floor, and noncommercial forests provide forage for deer. Thus, the deer model is conservative.

Response: It is true that habitats other than productive old-growth provide habitat for deer. The conservative nature of the deer model analysis was noted in the *Wildlife* section of the Draft EIS.

Comment: The statement in the Draft EIS that the deer populations in GMU 2 are at moderate levels and expected to decline is incorrect because an article in the Ketchikan Daily News (2006) states that Prince of Wales deer populations are sky-rocketing.

Response: The statement in the Draft EIS refers to long-term population trends and is correct. The 2005 ADF&G harvest summary for deer in GMU 2 (Porter 2005) states "as clearcut logging continues to reduce old-growth habitat in GMU 2, deer populations are expected to decline." This report also states that based on deer pellet-group counts, Unit 2 pellet-group densities represent low to moderate population levels relative to high pellet-group densities documented in Unit 4; they attributed this disparity to the presence of wolves in Unit 2 and their absence from Unit 4.

Comment: Every acre of high-quality old-growth cut greatly reduces the chance of survival of deer in hard winters. In areas that are clearcut deer are dying by the thousands and if the proposed alternative is implemented, that situation will only be made worse when we get another severe winter.

Response: The fact that effects to deer due to the loss of critical winter habitat would be of greatest concern during severe winters was noted in the Draft EIS. Individual timber sales will undergo appropriate environmental analysis and will address deer winter range at the project level.

Comment: The Proposed Forest Plan fails to adequately protect black-tailed deer; there is no definition of "critical winter range" and there is no means to ensure that an adequate number of

deer are maintained for wolves and subsistence use; standards and guidelines focus on assessing impacts to winter range as part of project-level analysis but do not require that an adequate amount of quality habitat be maintained. No mention of the Forest Service deer habitat capability model is made.

Response: The conservation strategy was designed to adequately maintain populations of wildlife, including deer. However, the Final EIS acknowledges that there may be impacts to deer in specific geographic areas due to timber harvest. The Proposed Forest Plan sets broad direction for project-level actions due to the variability in site-specific conditions. No definition is given for "critical" deer winter range because its identification will occur during project-level analysis and will involve local knowledge of habitat conditions, spatial locations of habitat, and other factors, in addition to outputs of the deer winter habitat capability model. Wolf standard and guideline XII.A.2 2 of the Final Proposed Forest Plan directs the Forest to provide for sufficient deer habitat capability to first maintain sustainable wolf populations and then to consider meeting estimated human deer harvest demands. It also requires use of the most recent deer habitat capability model along with field verification to estimate deer habitat capability in biogeographic provinces where there are wolves.

Comment: One comment noted that Southeast Alaska communities could face significant restriction to their deer hunting as a result of past and anticipated clearcutting and road building. The comment stated that the Forest should not log areas that provide corridors for deer and areas that are critically over-logged should be restored. They also note that thinning projects could provide valuable employment to residents in rural communities.

Response: Effects to subsistence and deer harvest in rural communities are discussed in the *Subregional Overview and Communities* section. Forest Plan Wildlife Habitat Planning (WILD1) standard and guideline VI directs the Forest to maintain landscape connectivity and standard and guideline VI.C requires the Forest to consider black-tailed deer habitat needs before or as part of project analysis. Forest Plan Wildlife Habitat Improvement Standards and Guidelines (WILD2) describe wildlife habitat improvement projects.

Comment: One comment noted that when Ketchikan Pulp was logging in the Thorne Bay area it was common to see deer with twins or triplets, probably due to good forage quality, but today, singles are more common. This, they conclude, suggests that timber harvest and deer exist well together. Another comment stated that more deer and more diverse wildlife habitat occurs forest edges and therefore timber harvest creates more wildlife habitat.

Response: There are numerous factors that can affect deer reproductive success, forage quantity and quality being one of them. Although timber harvest temporarily increases forage production in recently cut areas by increasing the amount of sunlight that reaches the forest floor, timber harvest also reduces other habitat elements that are important to deer, such as hiding cover and overstory cover for intercepting snow, and increases habitat fragmentation.

It is true that deer prefer to live on the forest edge adjacent to open habitat types where many resources (e.g., forage and cover) are available in proximity to each other. Though timber harvest does create more edge habitat, it also increases habitat fragmentation, resulting in remaining forested patches becoming smaller, more isolated, and less functional and therefore should always be considered in a landscape context. In addition, it is well known that old-growth forest provides important deer winter habitat.

Comment: The deer model is biased toward old-growth and over states the impact of timber harvest on deer habitat capability.

Response: The conservative nature of the deer model analysis is noted in the description of the affected environment under Deer in the *Wildlife* section of the Final EIS.

Comment: Important deer winter range should be displayed by development and non-development LUDs for each VCU to determine how much is fully protected under the reserve system and how much is partially protected in the matrix.

Response: Important deer winter range is identified by ground-truthing deer habitat capability model results and incorporating deer use levels, when available. This is required as part of the project planning process under the Forest Plan.

Comment: The standards and guidelines for deer, wolves, and subsistence are interrelated and all fail to define objectives in one or more of their sections; there is a lack of logic in how deer issues are distributed among the three broad standard and guideline topics. Some respondents felt that there needed to be a stated purpose or objective for protecting deer populations. Others commented that the focus was on assessing habitat rather than assuring an adequate amount or quality of habitat.

Response: It is true that deer, wolf, and subsistence issues are related, as discussed in the *Wildlife* section of the EIS. Standards and guidelines are included for species that were felt to be at risk or needed extra consideration at the project level. The extra consideration at the project level for deer that is provided under the Deer Habitat Standards and Guidelines is believed to be adequate.

Comment: Mitkof Island has some of the most restrictive deer seasons in all of Southeast Alaska due to the inability of the deer population to recover from several consecutive severe winters coupled with the effects of timber harvest, road construction, and habitat fragmentation.

Response: It is true that there are many factors at play in the status of Southeast Alaska deer populations and that the ADF&G takes these factors into account when setting harvest levels.

Comment: During severe winters, deer prefer southerly aspects below 500 feet elevation within 1,000 feet of the shoreline, medium- and high-volume stands, and forest edges; they avoid unforested and noncommercial habitats, predominantly north-facing gap phase old-growth and sheltered areas above 1,500 feet elevation. During summer and low-snow winters deer are habitat generalists and occupy a variety of habitats.

Response: Deer habitat relationships are described in the description of the affected environment of the *Wildlife* section of the Final EIS.

Comment: Past clearcutting, which has targeted high value deer winter habitat, has increased the likelihood of deer collapses during severe winters, and decreased the recovery potential when recoveries do happen. The occurrence of severe winters will remain a fact of life in Southeast Alaska in spite of climate change and this is beyond the control of the Forest Service. What is not beyond the control of the Forest Service is to limit the cutting of additional high quality deer habitat, and to not allow clearcutting where correct application of the deer model indicates that there is not sufficient habitat capacity to sustain sufficient deer numbers to provide for wolf needs and human consumption.

Response: As part of timber sale planning, Forest Plan standards and guidelines are applied to assure that sufficient deer habitat capability is maintained to provide for wolves and human consumption.

Elk

Comment: Although a radio-collared elk was located on Farm Island, at the mouth of the Stikine River, there is no evidence the elk have migrated up the river drainage.

Response: This statement has been corrected in the Final EIS text.

Brown Bear and Black Bear

Comment: Brown bears do not occur on all islands north of Frederick Sound.

Response: The description of the distribution of brown bears in the Final EIS has been modified to reflect this.

Comment: Some respondents requested clarification that hunting of brown bears is allowed throughout other parts of Southeast Alaska, outside of GMU 4, and a statement about outfitter uses of brown bears and available viewing areas.

Response: The statement about brown bear harvest has been clarified in the Final EIS. Outfitter and viewing uses have been noted in the text.

Comment: There is a lack of references provided for statements about the late-summer season being the most critical time for brown bears.

Response: Additional references for this information have been added to the Final EIS.

Comment: Black bears den in both harvested and unharvested forest stands. Because some dens on the Tongass have been documented in clearcuts it seems likely that black-bears prefer denning in clearcuts.

Response: It is true that black bears are habitat generalists and will use both early- (clearcuts and young growth) and late-seral (old-growth) forests. This was noted in the Draft EIS, though the focus of the analysis was road construction given that this species is sensitive to overhunting which can result from increased road access.

Comment: **One respondent commented that he would like to see commercial black-bear hunting on Prince of Wales Island abolished.**

Response: Sport hunting regulations are under the jurisdiction of ADF&G, and therefore not an issue that can be addressed by the Forest Plan Amendment process.

Comment: Several respondents cited information presented in Flynn (2007) regarding brown bear use of riparian areas along streams in two drainages, one intact and one heavily logged, requesting that it be incorporated into the Wildlife section of the Final EIS. They also requested that the recommendations provided by the authors for maintaining 500-foot no-cut buffers along all salmon streams in landscapes used by brown bears, and 1000-foot buffers along all streams (or complete watershed protection) in areas where bear management objectives are to maintain abundant healthy brown bear populations, be incorporated into the Final Proposed Forest Plan. Respondents noted that there are substantial risks to maintaining viable and well-distributed brown bear and black bear populations in some biogeographic provinces, particularly those where there is a low proportion of watershed-scale habitat protection, and that these areas may

warrant additional protective measures that maintain adequate habitat, minimize road densities, and maintain roadless areas.

Response: Information from Flynn (2007), which was also discussed at the 2006 Tongass Conservation Strategy Review workshop, was included in the Draft EIS. The recommendation for applying no-cut buffers to all salmon streams was initially made during the 2006 workshop, along with a number of other suggested items to be considered by the Forest Service. Some items were addressed in time for incorporation in the Final EIS, whereas others, such as the no-cut buffers, which might require additional interagency consultation, the formation of specialized workgroups, and more detailed development, may be considered after the Final EIS. These long term considerations could lead to conservation strategy-related adjustments to the amended Forest Plan through additional amendments or identified as information needs. The Final Proposed Forest Plan includes 500-foot buffers on important brown bear feeding streams. A discussion regarding brown bears can be found in Appendix D of the Final EIS.

Comment: The ADF&G allows a relatively substantial annual harvest of brown bears on northeast Chichagof Island, where one of the highest densities of this species occurs in Southeast Alaska; the area also experienced a high level of road building and timber harvest in the 1970s and 1980s. This brings the need for Brown Bear Standards and Guidelines into question.

Response: Species-specific standards and guidelines form the fine filter component of the Tongass conservation strategy. They are designed to ensure that the Forest's multiple use objectives are met, as directed by the National Forest Management Act, which include enabling continued subsistence and recreational uses (consumptive and non-consumptive) of wildlife resources. Therefore, the brown bear standards and guidelines, which work to minimize the effects of timber harvest on brown bears and reduce human-brown bear conflicts, contribute to the maintenance of sustainable brown bear populations and continue to let the ADF&G allow brown bear harvest on northeast Chichagof Island. A discussion regarding brown bears can be found in Appendix D of the Final EIS.

Comment: Several respondents commented on brown bear use of second-growth forest, some suggesting that brown bears do well in young-growth areas, and others stating that old-growth forests provide the only suitable habitat for brown bears. Respondents with the latter view suggested that the Forest maintain roadless areas to prevent clear-cut logging and attributed more restrictive regulations on outfitters and hunters to the loss of old-growth forest.

Response: Brown bears are habitat generalists in that they use a variety of habitats including young-growth. However, mature and old-growth forest, particularly in the form of riparian habitat along salmon streams, plays an essential role in brown bear population viability, both in terms of the maintaining adequate vegetative cover to support anadromous fish production (i.e., regulate stream temperature) and providing visual obscurity of bears from humans and other bears. The reserve system, including OGRs and other non-development LUDs, protects approximately 57 to 93 percent of the productive old-growth existing in 1954 on the Tongass, much of which is roadless, depending on the alternative.

Comment: The Draft EIS fails to adequately analyze direct, indirect, and cumulative impacts to brown bears and black bears, especially increased hunter access to bears (direct take, reduction in prey base, and human presence).

Response: The potential for increased human access under each of the alternatives was discussed in detail in the Draft EIS analysis of effects to both black and brown bears (pages 3-203; 3-205 to 3-207). The discussions focused on direct take, or other mortality associated with human-bear interactions, and the effects of human disturbance. The ability of each alternative to maintain important roadless refugia was highlighted for brown bears. Reductions in the prey base for each species was not discussed as neither species is a predator that specializes in one type of prey whose population has the potential to be affected by increased human access.

Comment: One respondent stated that she was quite appalled to discover that the Forest Service's Proposed Action would "essentially render the Tongass uninhabitable by grizzly bears."

Response: The analysis does not indicate that any of the alternatives would render the Tongass uninhabitable by grizzly bears, known as brown bears in Southeast Alaska. Even Alternatives 4 and 7 which propose the highest levels of harvest and reduce or eliminate the reserve system, respectively, rank as having moderately high likelihoods of maintaining well-distributed, viable brown bear populations. Alternatives 1, 2, 3, 5, and 6 rank as having a high likelihood of maintaining well-distributed, viable brown bear populations.

Comment: Standards and guidelines IX.A, C, D in the Proposed Forest Plan regarding management of human-bear encounters should be effectively incorporated into road management and timber harvest planning at the project level.

Response: Forest Plan standards and guidelines are incorporated into road management and timber harvest plans.

Comment: Standard and Guideline IX.D, of the Proposed Forest Plan regarding roads, should be strengthened by closing more roads because roads are correlated with bear mortality.

Response: Site-specific needs to minimize human/bear conflicts will be taken into account at project level planning including assess and travel management planning with regard to road management.

Comment: There is no science to suggest that brown bears require a 500-foot buffer for foraging. For areas where human bear encounters are predicted (i.e., Anan Creek, Pack Creek, Salmon River) this may be appropriate but otherwise is not needed, considering that the highest concentration of brown bears in Southeast Alaska occurs in an area with substantial past timber harvest and road building and harvest of brown bears is permitted on the Admiralty, Baranof, and Chichagof islands.

Response: As stated in the *Wildlife* section of the Draft EIS, cover for visual obscurity, provided by riparian buffers, is important for minimizing interactions among bears and between humans and bears. During the salmon spawning season bears concentrate their use within 500 feet of salmon spawning streams (Schoen and Beier 1990, Titus and Beier 1999), though will make greater use of upland areas in watersheds with greater development. The 500-foot buffers required by the Final Proposed Forest Plan are intended to provide visual cover in the areas that receive the greatest use.

Comment: One comment requested that the Forest Service adopt the Flynn et al. (2007) recommendations for bear buffers of 500 feet along each side of all salmon streams that are used by brown bears, and a buffer of 1,000 feet along each side in areas where ADF&G management objectives are for a brown bear population that exceeds the level of minimum viability.

Response: Standard and Guideline WILD1 IX.B, (Bear Habitat Management) in the *Wildlife* section of Chapter 4 of the Final Proposed Forest Plan requires consultation with ADF&G to determine the best application of needed buffers. Some sites might warrant these types of buffers, but this is best determined at the project level.

Plants

Comment: The Forest Service and the Tribes must work together to address the issues of noxious or invasive animal and plant species.

Response: The Forest Service works with the Tribes, as well as with other agencies and organizations, on issues related to noxious and invasive species.

Comment: One comment noted that the Proposed Forest Plan does little to prevent the spread of invasive plants.

Response: The Final Proposed Forest Plan has been modified to include a section on invasive plants. The standards and guidelines reference the direction in the recently completed (November 2007) Region 10 supplement to Forest Service Handbook 2000, Noxious Weed Management, Chapter 2080. Standards and guidelines in the Final Proposed Forest Plan implement direction in this Regional Supplement.

Comment: One comment asked how many of the 46 species classified as invasive plants present on the Tongass are the result of logging operations.

Response: It is likely that many of these plants were spread by logging operations, especially prior to the Forest implementing measures to halt their spread. However, invasive plants are also spread by recreational traffic and by natural means. The Forest Service has recently completed a regional supplement to Forest Service Handbook 2000 Noxious Weed Management, Chapter 2080. Standards and guidelines in the Final Proposed Forest Plan implement the direction from this Regional Supplement.

Comment: **One comment requested that the Final Proposed Forest Plan protect orchids and goldenthreads.**

Response: Bog orchid is listed on the Regional Forester's sensitive plant list. The Final Proposed Forest Plan contains standards and guidelines to protect sensitive species, as identified in the effects analysis in the Final EIS. There are two species of goldenthread on the forest. One is found in bogs and is not likely to be disturbed by harvest operations. The other is found in moist forests where some populations may be disturbed by logging. Neither species is listed as sensitive, threatened or endangered because neither is uncommon.

Specific Geographic Area Comments

The following section presents comment summaries and responses that address specific geographic areas. These comment summaries are organized into two sections. The first section presents comments that requested information or suggested management direction for specific places. The second section lists and discusses specific places that were more generally identified for protection from timber harvest and road construction.

Specific Geographic Area Comments and Responses

Comment: Several comments expressed concern about the recommendation that the existing Young Bay Experimental Forest be declassified as an Experimental Forest and assigned to the Remote Recreation LUD under management of the Juneau Ranger District. These comments argued that the Young Bay should become part of the adjoining Kootznoowoo Wilderness and Admiralty National Monument. Respondents stated that this would be inconsistent with President Carter's Proclamation 4611 and ignores ANILCA. One comment encouraged the Forest Service to

consult with the Kootznoowoo to determine the potential impacts of this designation on the unique coastal island ecosystem. Another comment emphasized the value of Young Bay to the public and as a "crucial wildlife linkage" between Mansfield Peninsula and the rest of Admiralty Island. This comment recommended that the mineral entry withdrawal for this area remain in effect.

Response: The recommended declassification of the Young Bay Experimental Forest will be addressed in a separate decision outside of this Forest Plan Amendment effort. The above concerns are noted and will be considered in that decision process. However, it is important to note that adding this area to the Kootznoowoo Wilderness would require Congressional action.

Comment: One comment requested that Corner Bay on Chichagof Island be classified as a new Experimental Forest, not the Cowee Creek-Davies Creek area, which is recommended for this designation in the Proposed Forest Plan. The comment author would prefer the Forest Plan recommend Corner Bay because it has an established road system and has been logged in the past.

Response: The Corner Bay area was examined as a potential Experimental Forest location, but the PNW Research Station recommended that the Cowee-Davis area be classified as an Experimental Forest. Their preference is reflected in the recommendation in the Final Proposed Forest Plan. A final decision on changes to the Experimental Forest will be made outside of this Forest Plan Amendment effort.

Comment: Some respondents want the name of Admiralty Island National Monument Wilderness changed to the Kootznoowoo Wilderness with appropriate legal boundaries identified in the Final Proposed Forest Plan and supporting maps. Others asked that the name Kootznoowoo be spelled with an "X" as they felt that was more traditional. Another comment pointed out that Angoon elders maintain that "Young Bay" should in fact be "Young's Bay" and requested that the Forest Service make the applicable changes as soon as possible

Response: The alternative maps in the Draft and Final EIS documents clearly show both Admiralty Island National Monument and Kootznoowoo Wilderness. Text in the Final EIS refers to Kootznoowoo Wilderness. The boundaries of the wilderness were legislated by Congress, as was the name and spelling. Changing the name of the area is beyond the scope of this Forest Plan Amendment. This is also the case with the suggested change from Young Bay to Young's Bay.

Comment: A number of respondents from the community of Angoon expressed concern about a proposal by the Borough of Juneau to extend the Borough boundaries to include Admiralty Island. They asked that the Forest Service stop this effort.

Response: Annexation proposals by the Borough of Juneau are outside the scope of this Forest Plan Amendment.

Comment: One comment requested that the Final Proposed Forest Plan clearly identify the following areas of subsistence-related concern in the text and also depict them graphically: Chatham Strait Sockeye returns, voluntary closures, and migratory maps; Mitchell Bay Coho returns and existing commercial fishing areas; Southeast Herring Stocks, returns and commercial fishing harvest areas; and all areas within the Kootznoowoo Wilderness currently open to commercial fishing.

Response: The Forest Plan guides natural resource management activities on the Tongass. Subsistence fisheries management issues and mapping are outside the scope of the Forest Plan.

Comment: Some respondents stated that the navigable waters in the Angoon area such as Kootznoowoo Inlet, Favorite Bay, Mitchell Bay and Kanalku belong to the Kootznoowoo.

Response: This issue is beyond the scope of decisions made in this Forest Plan Amendment.

Comment: Some respondents felt that Admiralty Island should either be removed from the Tongass or at least put into a different category that would foster more attention to this island and the people that live there. They also suggest that an integrated management plan needs to be developed with Kootznoowoo. Several respondents felt that the Admiralty Island District office should be in Angoon rather than in Juneau.

Response: The Final Proposed Forest Plan provides broad strategic direction for the Forest as a whole, but it also recognizes the differences between areas and allocates areas to different LUDs for management purposes. Most of Admiralty Island is a National Monument and a Congressionally designated Wilderness, and this is reflected in the LUD designations and the management direction associated with them.

Location of Forest Service offices is an administrative decision and beyond the scope of this Forest Plan Amendment.

Comment: One comment asked for a detailed analysis of Goldbelt Corporation's proposed tourism activities in Hobart Bay.

Response: This Final EIS is a programmatic forest-wide analysis appropriate for a strategic Forest Plan Amendment. Site-specific projects or activities are best examined locally during the decision making process as appropriate for that action. Tourism and recreation developments are considered in cumulative effects analysis.

Comment: One comment recommended the LUD boundaries of the Greater Situk Watershed be moved to protect an important fisheries resource.

Response: The alternatives in the Final EIS are designed to show varying levels of development in this watershed, including Alternative 1, which would have no development LUDs. The Forest Service will consider the importance of the resources and potential level of effects if a timber sale is proposed in this area in the future.

Comment: One comment recommended that the Forest Service increase stream buffers from 200 to 500 feet in the Yakutat Ranger District for some streams. This request was based on a recommendation for this size buffer in a 1996 Forest Service document.

Response: All of the past information, including the Panel Assessments (referenced in the comment), was considered when developing the standards and guidelines for stream buffers. There is leeway in the guidelines to increase buffers on a case-by-case basis if on-site evaluations determine that greater buffers are need to protect the function of the system. This is a Forest-wide programmatic amendment; therefore, site-specific buffer requirements for individual areas are not included.

Comment: One comment recommended that small patch cuts and selective harvest be used in the Yakutat area.

Response: These prescriptions are available for consideration by Interdisciplinary Teams planning harvests in the Yakutat Ranger District, and elsewhere on the Forest. Additional information on selective harvest has been added to the *Timber* section of Final EIS

Comment: Some respondents requested adjustments to the proposed LUD boundaries and placement in the Niblack and Hyder areas where minerals activity is high or has the potential to increase in the future. A number of comments were opposed to the Wild and Scenic River and Old Growth LUDs in the NIblack area and wanted to see the Minerals LUD overlay extended.

Response: The alternatives include a range of levels of development LUDs in these two areas. It is possible in the future also, to make a LUD change if and when specific mining operations are proposed and approved.. Extension of the Minerals LUD overlay in these two areas is evaluated in the action alternatives of the Final EIS. These changes were made to recognize the valid existing rights in these areas along with the potential for additional minerals activity in these areas because of their minerals potential.

Comment: One comment proposed that all non-Wilderness lands in the Petersburg Creek watershed be designated Wilderness, with the remaining lands within the "Petersburg Creek Land Acquisition" designated Remote Recreation.

Response: No additional areas are considered for wilderness under this Forest Plan Amendment. Wilderness recommendations were considered in detail in the 2003 SEIS. The area would be allocated to Semi-remote Recreation under Alternatives 1, 2, 3, 5, and 6. It would be allocated to a mixture of Semi-remote Recreation and Timber Production under Alternatives 4 and 7.

Specific Places Identified for Protection

Many respondents wrote to urge protection of specific places from timber harvest and road construction. The importance of subsistence in these areas was often the main rationale, as was recreation use. In other cases the identified areas were viewed has having unique values. Legislative protection of some sort was often requested.

Each alternative was designed to include these areas needed to achieve the timber harvest levels established for that alternative. So Alternative 1, with the lowest harvest level, excludes most of the areas mentioned from development. On the other hand, Alternative 7, with the highest harvest level, has the potential to impact many of the identified areas.

This section identifies many of the areas identified for protection and discusses the LUDs allocated to these areas under each alternative. The list of places presented in Table H-2 includes the majority of the areas that were identified by more than one respondent, but is not intended to be fully inclusive. Readers concerned about specific places not included in this section can find the same type of information by reviewing the large alternative maps that accompany this EIS.

The places identified in Table H-2 are organized by Ranger District. In many cases, identified areas were located in proximity to one another. These areas are grouped by general area in Table H-2 and the following discussion. The text discusses these places by Ranger District and geographic area.

Table H-2
Specific Places by Ranger District

Ranger District	Geographic Area	Specific Place
Yakutat	Situk Watershed	Situk Watershed
Hoonah	Elfin Cove	Elfin Cove
	Chicken Creek	Chicken Creek

Yakutat Ranger District

Situk Watershed: This area is not available for timber management under Alternative 1. Portions of the upper watershed would be available for timber management under all other alternatives. All alternatives except 4 and 7 include a small old-growth reserve in the upper watershed. OGRs are withdrawn from timber management.

Hoonah Ranger District

Elfin Cove: This area is allocated to LUDs that do not allow timber management under all alternatives.

Chicken Creek: This creek is within an old-growth reserve under all alternatives except Alternatives 4 and 7. The area would be available for timber management under these two alternatives.

Sitka Ranger District

Tenakee Inlet: The southeast side of Tenakee Inlet includes Long Bay, Saltery Bay, Seal Bay, and Crab Bay. These areas would not be available for timber management under Alternative 1 and only small portions would be available under Alternatives 2 and 3. Nearly all of these areas are allocated to development LUDs under Alternatives 4 and 7. While most of these areas are within development LUDs under Alternatives 5 and 6, key portions are allocated to old-growth reserve, especially under Alternative 6. The Kadashan Watershed is allocated to LUD II under all alternatives. LUD II is withdrawn for timber management.

Neka Bay: The area around the bay would be entirely allocated to non-development LUDs under Alternative 1 and primarily to non-developement LUDs under Alternatives 2, 3, 5, and 6. This area would be allocated to a development LUD under Alternatives 4 and 7.

Peril Strait: Ushk Bay and Poison Cove are allocated to LUDs that do not allow timber management under Alternatives 1, 2, and 3 and to a mix of development and non-development LUDs under Alternatives 5 and 6. These areas would be allocated to development LUDs under Alternatives 4 and 7. Saook Bay would be allocated to a non-development LUD under Alternative 1 and primarily to non-development LUDs under Alternatives 2 and 3. The area would be allocated to development LUDs under Alternatives 4, 5 and 7 and to a mix of development and non-development LUDs under Alternative 7. Deep Bay would primarily be within an old-growth reserve under all alternatives except 4 and 7, which would allocate the area to development LUDs. Upper Peril Strait would remain LUD II under all alternatives. The Broad Finger or Broad Creek area to the southeast of the Pelican LUD II area would be an old-growth reserve under all alternatives except Alternatives 4 and 7. It would be available for timber harvest under those two alternatives.

Redoubt Lake: This area would not be available for timber management under any alternative.

Sitka North: This area, which includes Starrigavan Bay, Katlian Bay, and Nakwasina Sound, would not be available for timber management under any alternative, except for the area north of Nakwasina Sound which would be allocated to development LUDs under Alternatives 4 and 7.

Silver Bay: The area along Silver Bay would be allocated to LUDs that do not allow timber management under Alternative 1 and primarily to non-development LUDs under Alternatives 3, 4, 5, and 6. Most of the area would be allocated to development LUDs under Alternatives 4 and 7.

Kruzof Island: This island would not be available for timber management under Alternative 1. All other alternatives would allocate the island to a mix of development and non-development LUDs. The southern third of the island would be a special interest area under all alternatives. The northern portion of the island, including Kalinin Bay, would be an old-growth reserve under all alternatives except Alternatives 4 and 7. This portion of the island would have a development LUD under these two alternatives. Portofshikof Island to the east would be allocated to a non development LUD under all alternatives except Alternatives 4 and 7.

Juneau Ranger District

Homeshore: This area would be allocated to a non-development LUD under Alternative 1 and to development LUDs under all other alternatives.

Taku Inlet: Rhine Creek and Slocum Inlet near the entrance to Taku Inlet would be allocated to non-development LUDs under Alternatives 1, 2, and 3 and to LUDs that permit timber management under all other alternatives. Taku River would be allocated to non-development LUDs under all alternatives. There would be a Transportation and Utility LUD on the south side of the river under all alternatives.

Sweetheart: Both Sweetheart Creek and Sweetheart Lake would be allocated to non-development LUDs under all alternatives.

Port Houghton: The Windham Bay, Hobart Bay, and Port Houghton area would not be available for timber management under Alternative 1. Alternative 3 would allow some timber harvest near Port Houghton, while remaining areas would be allocated to non-development LUDs. Most of these areas would be allocated to development LUDs under Alternatives 4, 5, 6, and 7. The Sanborn Canal area would be within an old-growth reserve under all alternatives except Alternatives 4 and 7. The area would be allocated to development LUDs under those two alternatives.

Petersburg Ranger District

Farragut Bay: The Cape Fanshaw and Farragut Bay area would not be available for timber management under Alternative 1. Only a small area near Farragut Bay would be allocated to LUDs that allow timber management under Alternative 2. Alternative 3 would allow some timber harvest near Farragut Bay, while the Cape Fanshaw area would be allocated to non-development LUDs. These areas would be allocated to a mix of development and non-development LUDs under Alternatives 4, 5, 6, and 7, with Alternatives 4 and 7 allowing the most timber management.

North Kuiu Island: This area includes Port Camden, Security Bay, Saginaw Bay, Kadake Creek, Rowan Bay, and Three Mile Arm (Table H-2). These areas would not be available for timber management under Alternative 1. Most of North Kuiu Island would be allocated to development LUDs under the remaining alternatives. The west side of Security Bay would have a non-development LUD under all alternatives. The north side of Rowan Bay would be allocated to a non-development LUD under Alternative 1; to a mixture of development and non-development LUDs under Alternatives 2, 3, 5, and 6; and to development LUDs under Alternatives 4 and 7.

South Kuiu Island: This area includes Reid Bay and No Name Bay. No timber management would be permitted in these areas under Alternatives 1, 2, and 3. Both areas would be allocated to development LUDs under the other alternatives. Only Alternatives 4 and 7 would permit timber management in the Roadless Area south of the Kuiu Wilderness.

Duncan Canal: The west side of Duncan Canal, which includes Kah Sheets Creek and Castle River, would be allocated to non-development LUDs under Alternatives 1, 2, and 3 and to a mix of development and non-development LUDs under the other alternatives. The east side of Duncan Canal would have a mix of development and non-development LUDs under all alternatives, with Alternatives 4 and 7 allowing the most timber management.

Wrangell Narrows: The area along the Narrows would be allocated primarily to a mix of development and non-development LUDs under all alternatives, with Alternatives 4 and 7 allowing the most timber management and Alternative 1 the least.

Kushneahim Creek: The southwest corner of Kupeanof Island would be allocated to non-development LUDs under Alternatives 1, 2, and 3 and primarily to development LUDs under Alternatives 4, 5, 6, and 7. However, Alternatives 5 and 6 would include three OGRs in southwest Kupreanof Island, while Alternatives 4 and 7 would not.

South Mitkof Island: This area would have a mix of development and non-development LUDs under all alternatives, with Alternatives 4 and 7 allowing the most timber management and Alternative 1 the least.

Wrangell Ranger District

Madan Bay: The Madan area would be allocated to non-development LUDs under Alternatives 1 and 2 and to a mix of development and non-development LUDs under the other alternatives. Most of Madan Bay borders an old-growth reserve under all alternatives except Alternatives 4 and 7.

Bradfield Canal: The Bradfield Canal area would be allocated to non-development LUDs under Alternatives 1 and 2 and to a mix of development and non-development LUDs under the other alternatives.

Navy Lake: This area would be allocated to development LUDs under all alternatives except Alternative 1.

Anan Creek: The Anan Creek area is allocated to LUD II under all alternatives.

Ketchikan Ranger District

Cleveland Peninsula: The peninsula southwest of Yes Bay would be allocated to non-development LUDs under Alternatives 1 and 2. The area southwest of Spacious Bay would be allocated to non-development LUDs under Alternative 3 while the area to the north would be a mix of development and non-development LUDs. The area southwest of Meyers Chuck/Helm Bay would be allocated to non-development LUDs under Alternatives 4, 5, and 6, while the remainder of the peninsula would have a mix of development and non-development LUDs. Nearly all of the peninsula would be allocated to development LUDs under Alternative 7.

Gravina Island: All but a very small portion of the island would be allocated to non-development LUDs under Alternative 1. The small area of development LUD is not near Bostwick Inlet. Most of the island would have non-development LUDs under Alternatives 2, 3, 4, 5, and 6, with a development LUD extending north from Bostwick Inlet to California Ridge. Most of the island would be allocated to development LUDs under Alternative 7.

Cat Island/Duke Island: Both islands would be contained in the Duke Island Zoological Special Interest Areas under all alternatives. This area was designated because of its abundant wildlife, especially waterfowl.

Thorne Bay Ranger District

Honker Divide: This area would be allocated to non-development LUDs under all alternatives except Alternative 7, which would allocate the area to development LUDs, except for the Recreational and Scenic River corridor along the Thorne River/Hatchery Creek.

Calder Halbrook: The Mt. Calder/Mt. Halbrook area is allocated to LUD II under all alternatives. The area immediately to the northeast of the LUD II area would be allocated to development LUDs under all alternatives.

20 Road: The area along the 20 Road would be allocated to a mix of development and non-development LUDs under all alternatives.

Eleven Mile: The Eleven Mile Watershed would be allocated non-development LUDs under Alternatives 1 and 2; to a mix of development and non-development LUDs under Alternatives 3, 5, and 6; and to development LUDs under the Alternatives 4 and 7.

Craig Ranger District

Salmon Bay Lake: This area is allocated to LUD II under all alternatives. The area to the east would have development LUDs under all alternatives except Alternative 1. The area to the west would be allocated to non-development LUDs under all alternatives except Alternative 7.

Salmon Lake: This area is allocated to LUD II under all alternatives. Adjacent areas would have varying levels of development LUDs depending on the alternative.

Sea Otter Sound: Most of the area along Sea Otter Sound would be allocated to development LUDs under all alternatives.

Dall Island: NFS land on the island south of Diver Bay (which is on the north end of the island) would be allocated to non-development LUDs under all alternatives. The area north of Diver bay would be allocated to non-development LUDs under Alternatives 1, 2, and 3 and development LUDs under the other alternatives. The island would have several Special Interest Areas under all alternatives.

Outside Islands: With the exception of San Juan Bautista Island, all the islands west of Craig would be allocated to Wilderness, LUD II, or other non-development LUDs under all alternatives. San Juan Bautista Island would be allocated primarily to a development LUD under Alternatives 4, 5, 6, and 7 and to a non-development LUD under Alternatives 1, 2, and 3.

South Prince of Wales Island: Nine specific places were identified on south Prince of Wales Island were identified for protection (Table H-2). The south half of the island includes Keete Inlet, Mabel Bay, Kassa Inlet, Sunny Cove, Niblack, Clover Bay, and Moria Sound. These areas would be allocated to non-development LUDs under Alternative 1. Under Alternative 2, most of south Prince of Wales Island would be allocated to non-development LUDs except for the Cholmondeley Sound area, which includes Sunny Cove. This area would be allocated to development LUDs. Keete Inlet, Mabel Bay, Kassa Inlet, Sunny Cove, Niblack, and Moria Sound would primarily be allocated to development LUDs under Alternatives 4, 5, 6, and 7. As noted in the preceding section, the Minerals LUD overlay was extended in the Niblack area under all of the action alternatives.

The south side of Clover Bay would be allocated to a non-development LUD under all alternatives but the north side of the bay, and the Monie Lake area, would be allocated to development LUDs under all alternatives except 1 and 2. Trollers Cove would be allocated to non-development LUDs under all Alternatives 1 and 2 and to a mix of development and non-development LUDs under all other alternatives. The west side of south Prince of Wales Island would be allocated to non-development LUDs under Alternative 3, while most of the east side would be allocated to LUDs that permit timber management.

RE: Tongass Land Management Plan Amendment, DEIS

Dear Mr. Bschor:

The National Marine Fisheries Service (NMFS) reviewed the Tongass Land Management Plan (TLMP) Amendment Draft Environmental Impact Statement (DEIS). Our specific comments are enclosed and our general summarized comments follow below.

Overall Comments

The revised TLMP provides an opportunity to restore fish habitat and improve fish passage in areas that have been degraded as a result of past management practices. Below and in the enclosure we recommend several changes for the Final EIS and TLMP Amendment to ensure that future timber sales and forest management decisions incorporate measures to restore access to fish habitat blocked by inadequate culverts, restore fish habitat, and minimize further impacts to anadromous fish.

The proposed plan makes some changes in the Soil and Water, Riparian, and Transportation Standards and Guidelines (S&Gs) which improve the S&Gs from a fish habitat perspective. In particular, the Transportation S&Gs now include road storage and decommissioning, providing greater specificity as to what to consider and how to conduct road closure activities.

The Final EIS should provide additional clarity and information in the following areas:

Effects of Roads on Fish

NMFS recommends the environment and effects fish section include an analysis of the number of culverts on the forest that do not fully meet the criteria for passing fish (red and gray culverts). The analysis should include the potential cumulative effect of constructing additional roads with culverts that may not meet fish passage criteria. NMFS recommends that the products of the Fish Passage Working Group (decision information matrix and biological significance model) be incorporated into the EIS and into the proposed plan.

Restoring fish passage through red culverts should be a high priority in the Forest Plan. In addition to disclosing the number and location of problem culverts the Final EIS should include plans or opportunities for remedies in future timber sales pursuant to the revised TLMP.

Road Density

The density that is displayed by alternative is the average road density in all value comparison units (VCUs) including VCUs with no development. NMFS recommends that the average road density in VCUs with past and or proposed harvest be displayed and discussed for all alternatives. Such information would give a better idea of the density of roads in developed VCUs where impacts are most likely to occur.

Riparian Management Objectives and Riparian Standards and Guidelines

NMFS supports the continuation of riparian buffers along Class III streams. NMFS is aware of some discussions to eliminate riparian buffers along Class III streams. We are glad this was not a proposed change in the DEIS. As documented in a March 10, 2006, paper titled "Evaluation of Concern 04-25, Class III Stream Management" by Steve Paustian, Colleen Grundy, Dennis Landwehr and other Forest Service staff there is compelling scientific rationale to continue buffers along Class III streams . Recommendations made by this group include the following: *The literature review indicates that the Riparian Management Objectives and Standards and Guidelines in the forest plan are appropriate. Class III streams need large woody debris to function properly and that woody debris inputs need to be understood at the scale of decades or centuries. The literature indicates that forest plan objectives could be broadened to include invertebrate production, the majority of streamflow within a watershed, and contributions to primary productivity. Cumulatively Class III and IV streams may account for 60 to 80 percent of the runoff volume in Tongass Watersheds. Headwater streams need to be understood on decadal scale or centuries scale.*

Watershed Restoration

NMFS recommends that the Forest Plan place a greater emphasis on watershed restoration as a means of reversing the negative consequences of past forest management activities on watershed health, especially timber harvest and road building impacts. Restoration of aquatic habitat and ecological processes should have priority over mitigation (so-called watershed improvement projects).

NMFS Recommendations for a Preferred Alternative

Fish and the aquatic resources on the Tongass National Forest support major subsistence, commercial, and sport fisheries, as well as traditional and cultural values. Road building and timber harvest can negatively impact fish resources. Adverse effects can be minimized with best management practices but not eliminated. Alternatives 1, 2 and 3 provide for a range of timber harvest and have less potential effects on fish than alternatives 4, 5, 6, and 7 with higher allowable sale quantity (ASQ). NMFS recommends that the Forest Service preferred alternative be Alternative 1, 2, or 3. This alternative range allows for harvest at the present rate and higher and will satisfy a medium integrated-industry level of timber demand according to the Brackley study cited in the DEIS. These alternatives minimize entry into roadless areas which would leave most roadless watersheds in the forest intact. These alternatives provide a mix of National Forest uses and activities and allow up to an ASQ of 204 million board feet which significantly exceeds current demand.

If you have questions regarding our comments contact Cindy Hartmann at (907) 586-7585 or John Hudson at (907) 586-7639.

Sincerely,

Robert D. Mecum

National Marine Fisheries Service (NMFS) Comments on TLMP Amendment - Enclosure

Comments Specific to the: Tongass Land and Resource Management Plan, Draft Environmental Impact Statement (EIS), Plan Amendment, January, 2007.

Page 3-57 to 3-58, Environment and Effects, Fish, Essential Fish Habitat (EFH)
The EIS states "Habitat areas of particular concern are identified as living marine substrates in shallow and deep waters, and freshwater habitats used by anadromous fish (NMFS 2003)." This definition is no longer valid. An August 8, 2005, record of decision (ROD) selected Alternative 3 of the April 2005 Final Environmental Impact Statement (FEIS) for Essential Fish Habitat Identification and Conservation in Alaska (EFH EIS) for the identification of habitat areas of particular concern (HAPCs). Under this alternative the previous HAPC identifications (living marine substrates in shallow and deep waters, and freshwater habitats used by anadromous fish) were rescinded. Existing HAPCs in the vicinity of the Tongass are offshore on the Fairweather Grounds and near Cape Omnaney.

The descriptions of EFH for Pacific salmon were also modified per the August 2005 EFH EIS ROD. NMFS refers you to Appendix D pages D-77 to D- 82 (EFH descriptions for Alternative 3) of the EFH FEIS found at
http://www.fakr.noaa.gov/habitat/seis/efheis.htm.

Page 3-59, Environment and Effects, Fish, Invasive Aquatic Species
NMFS recommends that the Forest Service make changes to this section as noted below (additions are underlined and deletions are lined through). The recommended additional citation follows the paragraph on invasive aquatic species.

Invasive aquatic species can affect native species by eating them, competing with them, hybridizing with them, disrupting or destroying their habitat, or introducing pathogens or parasites that sicken or kill them (Schrader and Hennon 2005).
In addition to natural range extension, several potential pathways exist for introduction of invasive aquatic species. These pathways included fish farms, international and local movement of bait and game fish, trade in live seafood, aquaculture, and contaminated sport angle gear brought into Alaska, as well as ballast discharge from international vessels (Fay 2002, Schrader and Hennon 2005). Several aquatic species have been noted as potential threats to Alaska, including fish (northern pike, Atlantic salmon, yellow perch, ornamental aquarium fish), invertebrates (green crab, New Zealand mudsnail, Chinese mitten crab, zebra mussel, signal crayfish, spiny water flea), plants (cordgrass) and several additional other miscellaneous taxa (Fay 2002, Schrader and Hennon 2005). Additionally, eastern brook trout (non-native) and non-endemic rainbow trout have been stocked in many areas where they were not native and compete or hybridize with native trout (Schrader and Hennon 2005). Of these fish, transplanted northern pike and Atlantic salmon are the two fish species of greatest concern (Fay 2002). The invertebrates Chinese mitten crab, green crab, and New Zealand mudsnail, even though they have not been found in Alaska, are of major concern because of their potential to do serious damage to

~~the~~ Alaskan ecosystems (Hines et al. 2004; Schrader and Hennon 2005). Atlantic salmon that have escaped from fish farms pose a threat to native salmon by competing for habitat and introducing diseases and parasites. This species has already been observed in Southeast Alaska marine waters and rarely in streams (Fay 2002). Also, northern pike, which has not appeared in Southeast Alaska (with the exception of a native stock in Yakutat), have caused widespread damage to resident trout where they have been introduced, and could potentially affect coho salmon through predation. Northern pike have the potential to cause serious environmental and economic damage to highly productive salmon streams in Southeast Alaska (Fay 2002). In the Tongass there is a risk that these and possibly other non-native sport fish may be introduced into lakes and rivers by individuals seeking to increase sport fishing opportunities. As the road network is extended into more areas of Southeast Alaska, this risk increases.

Page 3-61, Environment and Effects, Fish, General Effects, Roads
A previous section on fish habitat enhancement (page 3-55) had a paragraph on restoration of habitat access to streams through replacement of culverts that did not meet current fish passage design criteria. It stated that approximately 240 culverts have been replaced through 2006. It also stated, "The culvert replacement program declined in 2006 due to funding reductions and is projected to continue to decline in future years." The roads effects section should include a discussion on the number of culverts that do not meet current fish passage design criteria. Culverts that do not meet current fish passage design criteria (Q2-2day duration design flow or the stream flow that exists two days before and two days after a peak flow) have been classified as RED culverts, GRAY culverts require more analysis to determine their juvenile passage ability, GREEN culverts have a high certainty of meeting juvenile fish passage at all desired stream flows. There are currently approximately 2000 red culverts on the Tongass National Forest. Because of changes in standards and guidelines, better engineering ability, and implementation monitoring the number of red culverts from past road construction may not be predictive of future fish passage problems. However, fish passage through culverts is an important issue that needs further discussion in the general effects/cumulative effects section. The number of red and gray culverts should be identified and their impacts discussed in the EIS. Restoring fish passage through culverts should be a high priority in the Forest Plan.

NMFS participated in an interagency Fish Passage Working Group regarding red and gray culverts. The working group completed a number of products that could be used to further efforts to remediate red culverts. These products included a decision information matrix and a biological significance model. These products are tools that could be used in a process or decision framework designed to identify which red culverts to fix, and which culverts to submit for Clean Water Act 404 permitting (compensatory mitigation) instead of fix. The products were tested on the North Thorne Watershed stream and culvert replacement data set. The results of this test are documented in a January 27, 2006, paper titled "Test of a Process to Assign Fish Passage Remediation to Culverts in the North Thorne Watershed." The January 27 paper identified three components of the overall process that needed to be completed before expansion to the entire Tongass. Automating data acquisition was one component which included completing a stream crossing layer in the Forest Service GIS that contains all the attributes to run the biological significance model. NMFS hoped that these components would have been completed in time for this process to be incorporated into the Forest Plan Amendment and EIS. We recommend that the Forest Service make completing these components a high priority. At a minimum the data acquisition component should be automated and data gaps filled so the number of red culverts can be included in the EIS as well as the costs of fixing them. Our preference is for the full modeling and decision process to be incorporated into the Forest Plan Amendment.

Given funding reductions in the culvert replacement program, it is unlikely sufficient funding will be available to remediate the fish passage problem at one time Tongass-wide. Until such time, NMFS recommends that an analysis of the red and gray culverts within a timber sale area be incorporated into the timber sale NEPA process. Opportunities to fix red culverts should be expanded from the road maintenance planning process and the capital investment program to timber sale planning.

References that emphasize the importance of the potential effects of roads on fish include the following two references:

"Numerous studies show that watersheds with fewer roads are often associated with healthier fish populations, and roads may have unavoidable effects on streams, regardless of how well they are located, designed, or maintained (USDA Forest Service and USDI Bureau of Land Management 1995).

Citation: USDA, Forest Service and USDI, Bureau of Land Management. 1995. Decision Notice/Decision Record, Finding of No Significant Impact, and Environmental Assessment for the Interim Strategies for Managing Anadromous Fish-Producing Watersheds in Eastern Oregon and Washington, Idaho, and Portions of California. Washington, DC. 206 pp.

And from "Fisheries", Vol. 30, No. 1

".........the Alaska Department of Fish and Game reported that 66% of the culverts in salmon streams in the Tongass National Forest may be inadequate for fish passage, and 85% of the culverts across trout streams may be likewise (Flanders and Cariello 2000). A briefing document by Trout Unlimited (J. Konigsberg, Trout Unlimited, Anchorage, Alaska, pers. comm.) reported that one of the more significant threats to Alaska's wild

salmon was barriers created by culverts, causing loss of spawning and rearing habitats upstream."

Page 3-62, Environment and Effects, Fish, General Effects, Roads
The EIS states: "Currently the average road density in all VCUs is 0.19 mile per square mile, while the average road density in only VCUs with some past harvest is approximately 0.46 mile per square miles." "After more than 100 years of Forest Plan Implementation, the estimated overall road density on NFS lands would range from 0.26 under Alternative 1 to 0.43 mile per square mile for Alternative 7." NMFS interprets your use of "overall road density" to be the average road density in all VCUs. Since many VCUs are designated wilderness, national monument, remote recreation or LUD II (congressionally-designated unroaded areas) displaying only the average road density in all VCUs by alternative does not provide a true picture of road density in VCUs with moderate and intensive development. Since roads pose the greatest risk to fish resources on the Tongass (page 3-61) NMFS recommends adding a line to Table 3.6-2 which has the average road density by alternative for VCUs with timber harvest (past and/or future harvest) and adding a table and/or graph showing the distribution of road densities among all VCUs. These numbers then need to be fully discussed in the effects section.

Page 3-69, Environment and Effects, Fish, Essential Fish Habitat Assessment
NMFS offers the following clarification: Section 305(b)(2) of the Magnuson-Stevens Act requires all Federal agencies to consult with the Secretary on all actions or proposed actions authorized, funded, or undertaken by the agency that may adversely affect EFH.

Comments Specific to the: Tongass National Forest, Proposed Land and Resource Management Plan with EIS Appendices, January, 2007.

Pages 2-4 and 2-5, Chapter 2 - Goals and Objectives, Soil and Water Resources
Under Soil and Water Resources two objectives (see below) related to watershed restoration were deleted from the DEIS.

Deleted: Perform watershed restoration projects in at least two large watersheds (over a ten-year period). **Replaced with:** Complete Hydrologic Condition Assessments and Restoration Plans for priority watersheds.

Deleted: Perform an average of 3 single-year-type watershed improvement projects annually across the Forest. **Replaced with:** Complete watershed restoration projects in conjunction with Integrated Resource Program (see Appendix C).

These objectives were replaced with statements that lack the narrowly defined, precise, and measurable quality of an objective. The deleted objectives should be retained in the Final EIS because they provide a better means of gauging progress towards the stated goals of protecting and restoring watershed integrity. Many of the other objectives in this chapter are rather vague "general intentions" lacking the details required to properly evaluate progress towards achieving goals. All objectives should be reviewed and, if necessary, re-written as narrowly defined, precise, and measurable statements.

Page 4-4, Chapter 4 – Forest-wide Standards and Guidelines, Beach and Estuary Fringe, I. C. 1.
The proposed plan states: "The estuary fringe is an area of approximately 1,000 feet slope distance around all identified estuaries." If available, this definition should include reference to the source or sources that give the location of estuaries on the Forest.

Pages 4-8 to 4-12, Chapter 4- Forest-wide Standards and Guidelines, Fish Habitat Planning: FISH112
Past forest management practices that failed to consider the impacts of certain logging and road construction practices on watershed health have resulted in degraded fish habitat and productivity in many watersheds on the Forest. NMFS appreciates and supports the numerous references to restoration in the Fish Habitat Planning (FISH112) Standards and Guidelines. Fish habitat restoration should be a critical component of the Forest Plan. In the current draft, guidelines for fish habitat restoration are found in section IV under the Fish Habitat Planning heading (pages 4-9 and 4-10). NMFS would like to see fish habitat restoration elevated to a higher level within the Forest-wide Standards and Guidelines for Fish. To that end, NMFS recommends the addition of a "Fish Habitat Restoration" section to the Standards and Guidelines for Fish.

Page 4-8, Fish Habitat Planning, III. Fish stream value classification, B. 2. Class II
In defining Class II streams the phrase "have limited fisheries values" is used. Does "fisheries values" refer to the economic value of a fish population to a fishery? If so, why should the economic value of a fish population determine the classification of a stream channel? Fish populations can exhibit a wide variety of values - ecological, genetic, and economic among others. NMFS recommends that term "fisheries values" be defined and, if necessary, quantified and include the genetic and ecological benefits of a fish population.

Page 4-8 and 4-9, Fish Habitat Planning, III. Fish stream value classification, B. 3. Class III
The definition for Class III streams should describe the objective and measurable characteristics of a stream reach that result in an "immediate" influence on downstream water quality and fish habitat. How does one quantify whether a stream reach has an immediate or delayed or gradual influence on downstream reaches? Would a perennial or intermittent stream that is not flowing at the time of a survey be misclassified because it does not influence downstream water quality and fish habitat? The Forest Plan should clarify what immediate means. Also, NMFS recommends retaining the following statement from the current forest plan in the definition of a Class III stream: "in channels

with less than 30 percent gradient, special care is needed to determine if resident fish are present."

Page 4-9, Fish Habitat Planning, IV. Objectives/guidelines for management affecting fish habitat, A. 1.
Modify guideline number 1 to read:
1. Width-to-Depth Ratio. Relationship between <u>average</u> bankfull width and average bankfull depth, expressed as average bankfull width / average bankfull depth.

Page 4-12, Fish Habitat Improvement: FISH22
NMFS recommends that the Forest Plan distinguish between the terms "improvement" and "restoration" as applied to watershed and fish populations and habitat. This distinction would help to avoid confusion over projects that may have similar goals yet are achieved by very different means and with different ecological effects (e.g. stocking hatchery fish versus adding large woody debris to a stream. While both enhance fish populations, the former enhances an existing population – for example, with hatchery fish - while the latter allows an existing population to expand in numbers by increasing the quality and quantity of habitat). Although not explicitly defined in the Forest Plan, watershed and fish habitat improvement projects appear to be those projects which seek to enhance existing populations or create new populations such as through the construction of fish ladders, stocking programs, or lake fertilization. These types of projects are often promoted as mitigation for unavoidable impacts to fish habitat from timber management activities. Improvement projects can be quite costly (e.g. fish ladders) and certain improvement projects (e.g. lake fertilization) require continual expenditures and oversight to ensure long-term success. Despite careful planning and design, many improvement projects do not meet their target goals. In the case of fish ladders and stocking projects, the resulting enhanced fish production may come at the expense of resident fish populations through competition, predation, or interbreeding. In contrast, restoration projects seek to restore the original functionality and productivity of a watershed and associated fish population to its pre-managed condition. Watershed restoration projects may include road obliteration, enhanced fish passage (i.e. culvert replacement), tree thinning, and fish habitat creation. Although up-front costs for restoration can be quite high, restoration projects are typically self-sustaining because they re-establish ecosystem components and processes that sustain fish production without management intervention. As written, the Forest Plan focuses on watershed and fish habitat improvements. NMFS would like to see the Forest Plan address improvement and restoration separately with restoration being a priority. For example, under Section VIII Projects in the Fish Standards and Guidelines, the highest priority for fish habitat project work should be restoration/rehabilitation, followed by mitigation and enhancement (a.k.a. improvements).

Page 4-92 to 4-93, Watershed Resources Improvements: S&W2, I. Soil and Water Quality Protection and Improvement
Management activities have negatively impacted watershed health and fish habitat in numerous watersheds throughout the Forest. To date, restoration efforts have occurred in

only a small percentage of these watersheds. Watershed restoration must be a major component of a new forest management plan. Use of the term "improvement" in the Soil and Water standards and guidelines fails to recognize the current impaired status of many watersheds. Restoring watersheds to their pre-impact condition should be the goal of a new forest plan, not merely implementing improvement projects. NMFS recommends modifying the Soil and Water Standards and Guidelines as follows (additions are underlined and deletions are lined through):

Watershed ~~Resources Improvements~~ Restoration: S&W2

I. Soil and Water Quality Protection and ~~Improvement~~ Restoration

A. Protect or ~~improve~~ restore water quality and sustain soil productivity.

1. Conduct Watershed Condition Surveys and develop Watershed Restoration Plans to determine treatment priorities and needs. Consideration of treatment needs should include evaluating changed fish habitat and population levels, riparian vegetation community structure and function, and hydrology as measured against natural conditions predicted by baseline ~~fish habitat~~ objectives (see Fish Forest-wide Standards & Guidelines). Identify and prioritize needs in the NRIS Watershed Improvement Tracking (WIT) database. Complete watershed restoration project plans and coordinate with fish habitat ~~improvement~~ restoration projects. Include projects in Sale Area Improvement Plans and use K-V funds as appropriate. (Consult FSM 2510 and 2520.)
2. Give priority to cost-effective watershed ~~improvement~~ restoration projects in watersheds with the most erodible conditions directly affecting the beneficial uses of water.
3. For revegetation of disturbed sites, erosion control, fire rehabilitation, riparian restoration, forage enhancement, and other revegetation projects, consider natural revegetation as an alternative to seeding or planting. Encourage natural revegetation where seed source and soil conditions are favorable. Use native species of seeds and plant in revegetation projects where seeding or planting is appropriate. Native plant material sources include commercial nurseries, agency native seed programs, and local seed collection.
4. Inspect all watershed ~~improvements~~ restorations until the final evaluation indicates that maintenance is no longer needed.
5. Road decommissioning and storage projects to ~~improve~~ restore watershed conditions should pay special attention to fish passage, channel stability and water quality issues (Consult *Tran 24* guidance, and Soil and Water Conservation Handbook, FSH 2509.22).

Page B-2, Appendix B – Information Needs, II. Priority Research Needs

NMFS strongly supports research need #8: "Assess the effectiveness of restoration efforts in increasing fish habitat and fish production."

Page B-9, Appendix B, N. Soil and Water

Change Information Need number 20 from "Classify and develop a cost effective mapping scheme to map wetlands on the forest" to "Develop a cost effective mapping scheme to classify and map wetlands on the forest."

Page G-4), Appendix G - Log Transfer Facility Guidelines, S7. Sensitive Habitats, Discussion

The discussion concerning impacts of bark deposition on benthic water quality and biota tends to understate the biological impacts of bark accumulations. This section should be modified as noted (additions are underlined). The recommended additional citation follows the discussion on woody debris.

Woody debris from log transfer and water storage can be carried by currents and deposited on these plant and animal communities. Debris may cover the area and physically smother plants and animals. There is a concern that debris accumulation may reduce dissolved oxygen concentration in the water below the minimum level required by fish and other aquatic life. Bark debris is expected to reduce dissolved oxygen concentration in the bark interstices. High oxygen demand can lead to an anaerobic zone within the bark pile where toxic sulfide compounds are generated, particularly in brackish and marine waters. Reduced oxygen levels, anaerobic conditions, and the presence of toxic sulfide compounds can result in reduced localized habitat value for groundfish species and their forage base (National Marine Fisheries Service 2005). One study found that the dissolved oxygen, pH, oxidation reduction potential, and concentration of toxic products of decomposition in the water column at 30 centimeters (12 inches) above the bark were not significantly different than at the control sites. Reductions in dissolved oxygen below Water Quality Standards have not been documented.

Congress of the United States

Washington, DC 20515

April 30, 2007

Chief Abigail Kimbell
USDA Forest Service
1400 Independence Ave., SW
Washington, DC 20250-0003

Dear Chief Kimbell:

We are writing to express our concern about the proposed action for the January 2007 Draft Land and Resource Management Plan for the Tongass National Forest. Under the revised plan, the timber sale program would continue to require annual federal subsidies of $40-50 million

Since 1982, the Forest Service has lost nearly a billion dollars subsidizing timber sales on the Tongass. During this time, timber employment has significantly decreased due to declining demand for Tongass timber products, however; program costs remains high. As a result, fewer than 300 jobs are now attributable to the Tongass timber sale program. The cost to federal taxpayers is over $150,000 per job per year.

The high cost of the Tongass timber sale program is based on past economic conditions in southeast Alaska. The new Forest Service plan fails to address these changes. The agency continues to plan timber sales at volumes far exceeding the demand.

Most timber sales continue to be planned in remote areas requiring expensive road construction, and resulting in significant adverse effects on wildlife, tourism, subsistence, and recreation. The Tongass National Forest contains the largest remaining tracts of old-growth temperate rainforest in the world, including many roadless watersheds with native species such as bald eagles, brown bears, wolves, black-tail deer and salmon. Given that almost four percent of the Tongass is made up of the large old growth that is vital to fish and wildlife, this habitat is a valued treasure. Already, more than half this rare and valuable old-growth in the Tongass has been clearcut.

The Tongass forest planning process now underway presents an opportunity for change. However; the proposed action does not make any substantial changes to the current plan. The annual allowable timber sale quantity would remain at 267 million board-feet; the total volume logged on the Tongass in the last six years combined. Like the existing plan, the proposed action leaves 2.4 million acres of roadless areas open to road construction, with most of the timber coming from these costly-to-access sections. The new plan should reduce costs to the federal taxpayers by decreasing the planned timber sale volume and eliminating new logging roads. Continuing without change is not sustainable and is a disservice to the American people and the residents of southeast Alaska.

We strongly encourage the USDA to reject the proposed action for the Tongass plan and adopt a balanced solution which meets the true needs of Southeast Alaska's communities and economy.

Thank you for your attention to this matter. We look forward to your response.

April 30, 2007

Mr. Forrest Cole, Forest Supervisor
Tongass National Forest
648 Mission Street
Ketchikan, Alaska 99901

Dear Mr. Cole:

The U.S. Department of the Interior has reviewed the Draft Tongass National Forest Proposed Land and Resource Management Plan Amendment (Proposed Forest Plan) and Draft Environmental Impact Statement (Draft EIS). The Draft EIS evaluates seven alternatives for managing the 17 million-acre Tongass National Forest. We believe the information included in this letter needs to be taken into account in the Final EIS and in the Final Forest Plan. These comments are submitted in accordance with the Fish and Wildlife Coordination Act, the Multiple Use-Sustained Yield Act, the National Forest Management Act, the Alaska National Interest Land Conservation Act, the National Environmental Policy Act, and the Council on Environmental Quality guidance for providing special technical expertise on water, biological, and geological resources.

We support the Proposed Forest Plan goal of maintaining viable and well-distributed fish and wildlife populations across the Tongass. We appreciate the long history of the U.S. Forest Service (USFS), the Fish and Wildlife Service (FWS), and the Alaska Department of Fish and Game working together to develop and implement conservation measures to address this goal. As you know, the 1997 Tongass National Forest Land and Resource Management Plan addressed this goal through implementation of the Tongass Conservation Strategy, a landscape conservation approach with special emphasis on species and habitats associated with old-growth forests. The strategy helps reduce risks to rare and endemic species, and therefore helps minimize, and/or avoid, wildlife species' numbers declining to the point of requiring protection under the Endangered Species Act (ESA).

The USFS is evaluating potential changes to the Tongass Conservation Strategy as part of this Proposed Forest Plan revision. Elements of the Tongass Conservation Strategy essential to Queen Charlotte goshawks and their prey include Old-Growth Reserves (OGRs), nest buffers, beach and estuary fringe, and tree retention under the Goshawk Foraging Habitat Standards and Guidelines and the American Marten Standards and Guidelines. Key Tongass Conservation Strategy elements for the Alexander Archipelago wolf and its prey include OGRs for habitat, and beach and riparian buffers for connectivity between habitats. Landscape pinch points are also important to wolf movement and dispersal across the landscape. Therefore, some of our key recommendations include: (1) eliminating, in the Final EIS, further consideration of Alternatives 4 and 7; (2) maintaining the Tongass Conservation Strategy in any alternative selected in the Final EIS, and implementing in the Final EIS and the Final Forest Plan, biological locations for Small and selected Medium OGRs as recommended by the Interagency Small OGR Work Group; (3) retaining in the Final EIS and the Final Forest Plan, the existing Goshawk Foraging Habitat Standards and Guidelines; and (4) improving in the Final EIS, the USFS proposed alternative 6 by adopting the Interagency Small OGR Work Group preferred biological locations for 48 additional Small OGRs and by retaining the existing Goshawk Foraging Habitat Standards and Guidelines, so as to help prevent the need to list the goshawk under the ESA. For more detailed information regarding these and other recommendations, see Attachments A, B, and C.

No threatened or endangered species under the jurisdiction of the FWS are currently known to exist in the project area. In response to a court-ordered remand, the FWS is currently evaluating the status of the Queen Charlotte goshawk and its habitat to determine if Vancouver Island is a significant portion of the goshawk's range and, if so, whether listing under the ESA is warranted in all, or part of, the goshawk's range. In addition to the goshawk, the Alexander Archipelago wolf has previously been petitioned for listing; and Kittlitz's murrelet is a candidate species. In addition, there are numerous other endemic and sensitive species on the Tongass that will require our continued collaboration in developing conservation provisions. More detailed information on specific Proposed Forest Plan revisions that may affect those species is included in Attachments A, B, and C.

If you have questions concerning our comments, or if we may be of further assistance with regard to fish and wildlife resource information, please contact Mr. Bruce Halstead, Juneau Fish and Wildlife Field Office, at 907-780-1161.

Sincerely,

Pamela Bergmann

ATTACHMENT A

GENERAL COMMENTS

Tongass Conservation Strategy

We support the retention of the "Desired Condition and Goal" of maintaining viable, well-distributed fish and wildlife populations throughout the Tongass as outlined in the Draft Tongass National Forest Proposed Land and Resource Management Plan Amendment (Proposed Forest Plan) (Proposed Forest Plan, Pages 2-1 to 2-6). The Tongass National Forest Land and Resource Management Plan (1997 Forest Plan) addressed this goal through implementation of the Tongass Conservation Strategy, a landscape conservation approach with special emphasis on species and habitats associated with old-growth forests. These habitats are most at risk from timber harvest and road construction. The Tongass Conservation Strategy helps reduce risks to rare and endemic species in this naturally-fragmented landscape of islands, which are isolated from the rest of North America by coastal mountains, ice fields, and the Gulf of Alaska.

The Tongass Conservation Strategy is based on scientific information and assessments that specifically addressed species viability on the Tongass (Suring et al. 1993; Kiester and Eckert 1994; Suring et al. 1994). In April 2006, the U.S. Forest Service (USFS) convened a Tongass Conservation Strategy Workshop to review applicable scientific work completed since 1997. An expert panel including representatives of the USFS, U.S. Fish and Wildlife Service (FWS), and Alaska Department of Fish and Game (ADF&G) reconfirmed that the overall architecture of the Tongass Conservation Strategy continues to represent the best available science; and compiled more than 100 considerations for updating the Tongass Conservation Strategy and addressing scientific work published since 1997 (USFS 2006).

We believe it is important to retain the Tongass Conservation Strategy in its entirety throughout the Tongass, particularly the network of Old-Growth Reserves (OGRs), the 1,000-foot Beach and Estuary Fringe Standards and Guidelines, and the Goshawk Foraging Habitat Standards and Guidelines (Goshawk Standards and Guidelines). We also believe the Tongass Conservation Strategy represents the best management approach to help minimize, and/or avoid, wildlife species' numbers declining to the point of requiring protection under the Endangered Species Act (ESA). It is important to note that in 1997, the FWS found the revised 1997 Forest Plan and its Tongass Conservation Strategy adequate to sustain the Queen Charlotte goshawk (goshawk) and Alexander Archipelago wolf (wolf) in Southeast Alaska; therefore, concluding that ESA listings for those species were not warranted. Therefore, we recommend the Final Environmental Impact Statement (EIS) and Final Forest Plan retain the Tongass Conservation Strategy in its entirety throughout the Tongass, particularly the network of OGRs, the 1,000-foot Beach and Estuary Fringe Standards and Guidelines, and the Goshawk Standards and Guidelines.

Management of natural resources during climate change requires increased emphasis on building ecosystem resilience (WWF 2003). One of the most effective ways to help ensure ecosystem resilience is to eliminate or limit additional stresses through a system of OGRs and buffer zones (Noss 2001). We believe that retaining the Tongass Conservation Strategy in its entirety throughout the Tongass will provide the USFS with an important management tool for dealing with these changing conditions.

Old Growth Reserves

OGRs contain large blocks of old-growth forest set aside from timber harvest and most road construction to provide habitat for a wide array of old-growth associated species. Very Large, Large, and Medium OGRs are important for helping ensure the viability of wolves and goshawks, and for providing benefits for a wide array of endemic and other species. Small OGRs provide a system of "stepping stones" between the larger OGRs and help ensure that habitat is protected in each watershed. Small OGRs emphasize habitats important to birds (e.g., marbled murrelet and goshawk [e.g., known goshawk nests], small mammals (e.g., flying squirrel and marten), and deer [e.g., deer winter range]) (USFS 1997b, Appendix K; USFS 1997a, Appendix N).

It should be noted that implementation of OGRs across the entire Tongass was the most important factor in the 1997 ESA Finding that the goshawk did not warrant listing as a threatened or endangered species (FWS 1997b). It was also an essential factor in the "not-warranted Finding" for the wolf in 1997 (FWS 1997a). Appendix K of the 1997 Forest Plan (Appendix K) and various Tongass Plan Implementation Team (TPIT) clarifications (as identified in TPIT 1998) provide guidance for locating OGRs, including acreage requirements and other considerations pertaining to species of concern (e.g., marbled murrelet, black-tailed deer, marten, and goshawk) and special habitats (e.g., large blocks of productive old-growth, rare plants, highest volume stands, and deer winter range).

Small Old Growth Reserves

Biological Locations for OGRs. We believe that Alternatives 1, 2, 3, and 6 include better biological locations for Small OGRs than Alternative 5, the no-action alternative. Alternative 4 eliminates Small and Medium OGRs in 17 of 21 biogeographic provinces, effectively negating the overall Tongass Conservation Strategy. Alternative 7 eliminates all OGRs regardless of size and location. Therefore, we recommend that the Final EIS adopt an alternative (such as Alternative 1, 2, 3, or 6) that implements better biological locations for Small OGRs.

We believe it is important that the revised locations for Small OGRs, which fully meet the criteria specified in Appendix K and either fully implement, or implement, the intent of the Tongass Conservation Strategy, are adopted in the Final EIS and the Final Forest Plan. It is important to note that the proposed locations of 191 Small OGRs (see Attachment B, Tables 1 and 2) fully meet Appendix K criteria and either fully implement, or implement, the Tongass Conservation Strategy. Of those, 133 Small OGRs (see Attachment B, Table 1) implement the preferred biological locations. An additional 58 Small OGRs (see Attachment B, Table 2) implement acceptable (although not preferred biological) locations, thereby fully meeting Appendix K criteria, while implementing the Tongass Conservation Strategy and accommodating timber harvest, road construction, and/or other development activities. Therefore, we recommend that the Final EIS and the Final Forest Plan adopt the revised locations for Small OGRs that fully meet Appendix K criteria and either fully implement, or implement, the Tongass Conservation Strategy.

Revised Locations for Small OGRs. The 1997 Forest Plan identified draft locations for Small OGRs, and established an interagency process to identify the preferred biological location for each OGR (USFS 1997b, TPIT 1998). In accordance with that process, in 2006 and 2007, the Interagency Small OGR Work Group (which was comprised of USFS, ADF&G and FWS biologists and lead by the USFS) reviewed each of the draft locations for the 239 Small OGRs and recommended the preferred biological location for each Small OGR. The Interagency Small OGR Work Group then met with each of the USFS District Rangers and their respective foresters, engineers, and biologists, with the goal of reaching joint recommendations, through a collaborative process, that resolved potential conflicts between preferred biological locations and areas for proposed timber harvest and road construction. The results of that work were provided to the Forest Supervisor, who then reviewed and accepted 133 (see Attachment B, Table 1) of the joint recommendations as proposed locations. In addition, the Forest Supervisor proposed, in March 2007, additional changes to 48 Small OGRs (see Attachment B, Table 3) and 49 Medium OGRs (see Attachment B, Tables 4 and 5). It is important to note that the 48 Small OGRs listed in Attachment B, Table 3 do not fully meet the Appendix K criteria or fully implement the Tongass Conservation Strategy. Recommended changes for each Small and Medium OGR will be documented in the Interagency Small OGR Work Group's final report, which we anticipate will be completed by June 2007 and presented to the Forest Supervisor for additional consideration.

Small OGR Resolution. While it is our understanding that the USFS plans to modify the 48 Small OGRs to ensure that each of these Small OGRs meet the acre criteria in Appendix K, we believe additional changes are necessary in order for each Small OGR to fully meet Appendix K's other criteria and to fully implement the Tongass Conservation Strategy. We recommend that these changes be completed for as many of these Small OGRs as possible, so the resulting appropriately-modified Small OGRs may be included in the Final EIS and the Final Forest Plan. We believe this will result in more predictability, less uncertainty, and a reduced potential for conflict for the USFS and its Tongass stakeholders regarding these Small OGRs. Including this information in the Final EIS and the Final Forest Plan will also eliminate the need for time-consuming individual project (e.g., timber sale) reviews. If it is not possible for the necessary additional interagency review and analysis for the 48 Small OGRs to be completed and included in the Final EIS and the Final Forest Plan, we recommend that the Final EIS and the Final Forest Plan adopt the preferred biological locations as recommended by the Interagency Small OGR Work Group.

Interagency Small OGR Work Group Procedural Changes. As noted above, in the event there are Small OGRs remaining that do not fully meet the criteria in Appendix K or fully implement the Tongass Conservation Strategy, those Small OGRs will need to be addressed during individual project reviews. The process for the interagency review and analysis is delineated in Appendix K and various TPIT clarifications, as identified in TPIT 1998. We recommend that from this point forward, all interagency reviews and analyses of any OGRs include the following additions, which were identified and used in 2006 and 2007 by the Interagency Small OGR Work Group (Hanson et al. 2006):

- Development of a consistent protocol for incorporating interagency recommendations into the Forest Plan and individual National Environmental Policy Act projects.

- Documentation of the Appendix K criteria for each OGR, and periodic updating of that information.
- Assessment of the effects of roads in, and adjacent to, OGRs.
- Implementation of the TPIT clarification entitled "Conveyance on Overselected Lands and the Old-Growth Habitat Land Use Designation."

We further recommend that these additions to the interagency review and analysis identified above and TPIT clarifications as identified in TPIT 1998 be included in Appendix K in the Final Forest Plan.

[See Alexander Archipelago Wolf section below for information on the importance of adopting the Interagency Small OGR Work Group-recommended Small OGR for Value Comparison Unit (VCU) 5960 for the Rio Roberts watershed on Prince of Wales Island to address connectivity issues related to the wolf.]

Medium Old Growth Reserves

Out of a total of 130 Medium OGRs on the Tongass, as noted above in the Small OGR section, the USFS proposed in March 2007, changes to 49 Medium OGRs (see Appendix A, Tables 4 and 5). The proposed changes include relocations, addition and deletion of acreage, and replacement of some Small OGRs by adjustments to Medium OGRs. These changes, which were proposed primarily to facilitate potential timber harvest and road construction, have not undergone interagency review and analysis to fully consider the effects of these activities on the OGR system, to determine whether Appendix K criteria have been fully met, and/or whether the Tongass Conservation Strategy has been fully implemented.

While the remaining 81 Medium OGRs throughout the Tongass have not been reviewed, we believe such a review also needs to be undertaken for those Medium OGRs. As stated above, since 1997, land selections and transfers have affected, and in some cases, eliminated Medium OGRs. It is anticipated that this will continue to be the case in the future. For example, the Interagency Small OGR Work Group identified a small number of Medium OGR adjustments that need to be made to meet the 10,000 acres minimum size and the high-volume productive old-growth acres criteria required by Appendix K for Medium OGRs. We believe that Medium OGRs need to be considered in their overall landscape context, not only in relation to individual projects and/or OGRs, but also with respect to potential consequences to the Tongass Conservation Strategy.

We also believe a review and adjustment of Medium OGRs is warranted: (1) if any of the Medium OGRs fail to meet the Total Acreage, Productive Old-growth Acreage, and High Volume Acreage Standards described in Appendix K; (2) if any of the Medium OGRs have been compromised by land selections made by, and/or land transfers to, the State of Alaska and/or Native Corporations; and/or (3) if any of the Medium OGRs no longer fully meet Appendix K criteria and/or fully implement the Tongass Conservation Strategy. As shown in Attachment B, Table 5, at least 28 of the 49 Medium OGRs proposed for changes do not meet Appendix K acreage criteria.

In summary, we recommend that the USFS defer changes to Medium OGRs (see Tables 4 and 5) until a comprehensive interagency review and analysis of all Medium OGRs has been completed to determine whether these Medium OGRs continue to fully meet Appendix K criteria and fully implement the Tongass Conservation Strategy. As stated above under the Small OGR section, we further recommend that any comprehensive interagency review and analysis of Medium OGRs also include the additions to that process, which were identified in 2006 and 2007 by the Interagency Small OGR Work Group (Hanson et al. 2006), and the TPIT clarifications, as identified in TPIT 1998.

Beach and Estuary Fringe Standards and Guidelines

We believe retaining Beach and Estuary Fringe Standards and Guidelines of at least 1,000 feet will help support viable, well-distributed wildlife populations. Beach and estuary fringes, along with riparian management areas, are the primary landscape linkage between OGRs. Beach fringes protect long-term bald eagle habitat capability (Gende et al. 1998); help sustain habitat for goshawks and their prey; buffer the primary beach and estuary fringe from windthrow; and provide critical winter habitat for black-tailed deer, which are the primary prey of wolves and an importance species for subsistence users (USFS 1997a, Page 3-21).

Results from recent research conducted in Southeast Alaska support the retention of beach and estuary fringes at least 1,000 feet in width to mitigate loss of habitat for most forest-dwelling birds, such as the pacific-slope flycatcher and red-breasted sapsucker (Kissling and Garton in Review). Several species of thrushes had higher reproductive success in large (e.g., >1,000 foot) buffers (Sperry 2006). Some species (e.g., Townsend's warbler, brown creeper, and hairy woodpecker) are sensitive to small amounts of fragmentation on the landscape and require a minimum beach and estuary fringe of 1,000 feet in order to help maintain viable populations (see Kissling and Garton for details). Some goshawks preferentially use (presumably for foraging) areas close to the shoreline (Iverson et al. 1996). Birds constitute more than 70 percent of prey deliveries made to goshawk nests (Lewis et al. 2006). Thrushes are particularly important prey for goshawks early in the nesting period, and healthy beach and estuary fringe forests are critical to robust thrush populations. Therefore, we recommend that the Final EIS and the Final Forest Plan retain a Beach and Estuary Fringe Standards and Guidelines of at least 1,000 feet to help support viable, well-distributed wildlife populations.

Pinch Points

We believe it is important that the Final EIS and the Final Forest Plan (1) retain protection for pinch points, including those identified in the 1997 Forest Plan (USFS 1997b, Page 4-123) and the Proposed Forest Plan (Page 3-157); and (2) add protection for pinch points identified during the Small OGR review. The Draft EIS recognizes the importance of landscape pinch points to endemic species and other wildlife. Those pinch points serve as critical links between larger land units where future alterations in habitat could significantly reduce natural connectivity and limit the ability of land-based species to disperse or migrate (Draft EIS, Page 3-157; Kiester and Eckhardt, 1994). Four pinch points were included in the 1997 Final EIS and 1997 Forest Plan, and two more were added in the Proposed Forest Plan. We believe that pinch points are adequately addressed in Alternatives 1, 2, 3, 5, and 6. That is not the case, however, for Alternatives 4 and 7, since Alternative 4 only protects 1 pinch point and no pinch points are protected in Alternative 7 (Draft EIS, Table 2-17). It is important to note that none of the alternatives or proposed changes to Small OGR protect pinch points at Anita Bay on Etolin Island or at Rio Roberts on Prince of Wales Island (see also the Alexander Archipelago Wolf section below). Therefore, we recommend that the Final EIS and the Final Forest Plan (1) retain protection for pinch points identified in the 1997 Forest Plan and the Proposed Forest Plan, and (2) add protection for pinch points identified during the Small OGR review, including pinch points at Anita Bay on Etolin Island and at Rio Roberts on Prince of Wales Island.

Connectivity

We believe it is important that corridors and connectivity meet the Viable Population Strategy described by Suring et al. 1993. The 1997 Forest Plan requires Tongass District Rangers to analyze connectivity during project reviews (USFS 1997b, Page 4-118). In addition, the TPIT identified a number of key areas requiring additional connectivity analysis (TPIT 1998). It is unclear, however, to what extent this has been accomplished. Therefore, we recommend that the Final EIS and the Final Forest Plan require the development of a standardized protocol for conducting connectivity analyses as directed in the Proposed Forest Plan (Page 4-123).

Legacy Forest Structure

Standards and Guidelines

The Proposed Forest Plan proposes replacing the American Marten Standards and Guidelines (Marten Standards and Guidelines), the Goshawk Standards and Guidelines, and Reserve Tree/Cavity-Nesting Habitat Standards and Guidelines (Cavity-Nesting Standards and Guidelines) with a Legacy Forest Structure Standards and Guidelines (Legacy Standards and Guidelines). The proposed Legacy Standards and Guidelines would require retention of forest structure within harvest units throughout the Tongass, depending on the amount of harvesting in the surrounding landscape and the size of the harvest units. We agree that retaining legacy forest structure (e.g., residual trees and snags and clumps of trees remaining in timber harvest units) throughout the Tongass provides important wildlife benefits. Along with the Marten and Goshawk standards and guidelines, the 1997 Forest Plan addressed the need for residual forest structure in harvest units through a combination of the Cavity-Nesting Standards and Guidelines and two-aged forest management, which were intended to benefit red-breasted sapsucker, brown creeper, hairy woodpecker, and red squirrel (USFS 1997a, Page 3-364).

While we understand that the Legacy Standards and Guidelines are intended to provide similar benefits, it is not clear that it does so. For example, while the Legacy Standards and Guidelines would encourage retention of trees in harvest units across the entire Tongass; it would reduce retention of trees in the most heavily harvested biogeographic provinces where goshawks are most at risk. Furthermore, the Draft EIS provides no scientific assessment to support the general or specific changes included in the proposed Legacy Standards and Guidelines. If the Legacy Standards and Guidelines are adopted, we believe the changes would reduce the existing conservation standards for the goshawk. As always, the FWS is ready to work with the USFS and ADF&G to identify ways to modify the existing Goshawk Standards and Guidelines to address wildlife values, while helping ensure timber harvesting operational feasibility. In the meantime, however, we recommend that the Final EIS and the Final Forest Plan retain the existing Goshawk Standards and Guidelines.

We believe it is important for the USFS to analyze the effects of replacing Marten, Goshawk, and Cavity-Nesting standards and guidelines with the Legacy Standards and Guidelines, since the Marten, Goshawk, and Cavity-Nesting standards and guidelines were each designed to reduce risks to species identified during panel assessments (USFS 1997a ROD, Page 33-35, USFS 1997a, Appendix N). We further believe that the analysis needs to compare the number of harvest units to which each of the Marten, Goshawk, and Cavity-Nesting standards and guidelines would apply and the total acreage protected under each; and that this needs to be analyzed for biogeographic provinces as well as other logical landscape units for each species.

Risk Levels of Value Comparison Units

We believe that "Risk" levels of VCUs – which are landscape units designated on the Tongass that generally compare to small watersheds – need to reflect the cumulative effects of harvesting both throughout the Tongass and on adjacent, non-Tongass lands, since forest-dependent wildlife respond to the availability of habitat across the landscape. Some watersheds have been heavily harvested by USFS contractors and by operators on adjacent land owned by non-Tongass entities (e.g., private, local government, and State of Alaska entities). We believe that Risk levels (i.e., "High," "Moderate," and "Lower") of VCUs need to be defined to include all ownerships within each VCU. Therefore, we recommend that the "High", "Moderate", and "Lower" Risk levels of VCUs include, in the Final EIS and the Final Forest Plan, cumulative effects of timber harvesting on both Tongass and adjacent, non-Tongass lands.

High-Risk Value Comparison Units

We believe it is important in High-Risk VCUs, to retain the legacy forest structure in all units larger than 2 acres. Current Goshawk and Marten standards and guidelines require uniform distribution of at least 30 percent canopy cover in harvest units larger than 2 acres in High-Risk (i.e., heavily harvested) VCUs. The Goshawk and Marten standards and guidelines were designed to retain key elements of legacy forest structure similar to old-growth forest. The key features of old-growth forest were derived from scientific literature (C. Iverson, USFS, personal communication, 2006). Natural openings in old-growth forest on the Tongass average less than 2 acres (Nowacki and Kramer 1998). We believe the loss of legacy retention in harvest units between 2 and 10 acres in High Risk VCUs would increase impacts of logging on the goshawk and other old-growth dependent species in landscapes where they are already most at risk. Therefore, we recommend that the Final EIS and the Final Forest Plan retain in High-Risk VCUs, legacy forest structure in all units larger than 2 acres.

Horizontal and Vertical Structure in Harvest Units

To accomplish the objectives stated in the Proposed Forest Plan for the Legacy Standards and Guidelines, legacy forest structure needs to penetrate into created openings. Uniform distribution of retained legacy forest structure throughout a harvest unit, as required by the Goshawk and Marten standards and guidelines, is less important than attaining both vertical and horizontal diversity within the harvested area (Franklin et al. 2002). Retention of windfirm patches and clumps can effectively accomplish this, if the windfirm and patches and clumps are distributed within, rather than around the edges of, harvest units. Since the intent of the Goshawk, Marten, and Legacy standards and guidelines is to provide horizontal and vertical structure in harvest units, we recommend that the Final EIS and the Final Forest Plan retain legacy forest structure within harvest units, rather than along the perimeter of the units.

Maximizing Unit Size for Harvest Criteria

As currently written, neither the Proposed Forest Plan nor the Draft EIS provide a scientific rationale for the criteria for defining the maximum sizes of units that can be harvested and still retain legacy forest structure, and how much legacy forest structure must be maintained. This information needs to be included in the Final EIS and the Final Forest Plan, since both the maximum size of openings allowed without retention (i.e., 10, 20, or 30 acres) and the amount of legacy forest structure to be left (i.e., 10, 20, or 30 percent) depend on the risk level (i.e., amount of harvest) within VCUs. Therefore, we recommend that criteria (based on the best available science) that define the maximum sizes of units that can be harvested and still retain legacy forest structure, and how much structure must be maintained, be included in the Final EIS and the Final Forest Plan.

Since dead and downed trees are important habitat features, we believe retained legacy forest structure needs to be protected from firewood cutting and salvage logging, even if the trees die or blow down. Therefore, we recommend that the Final EIS and the Final Forest Plan retain legacy forest structure until the surrounding stand provides mature or old-growth structure. In addition, we recommend that the Final EIS and the Final Forest Plan include a system for tracking legacy forest structure and retention.

<u>Threatened and Endangered Species and Species of Concern</u>

Queen Charlotte Goshawk

OGR System and Beach and Estuary Fringe Standards and Guidelines. We believe it is important to retain the OGR system and 1,000-foot Beach and Estuary Fringe Standards and Guidelines throughout the Tongass to help protect key goshawk habitats. In 1994, the FWS was petitioned to list the goshawk as endangered under the ESA. Goshawks nest and forage in mature and old-growth forests and, therefore, are sensitive to habitat loss caused by logging. The FWS found the 1979 (amended 1991) Forest Plan to be inadequate to sustain goshawks in Southeast Alaska (FWS 1995). It should be noted that the 1979 (amended 1991) Forest Plan was similar to Alternative 7 and much of Alternative 4 in the Draft EIS. Subsequently, the FWS determined the revised 1997 Forest Plan and its Tongass Conservation Strategy were adequate to sustain goshawks in Southeast Alaska, concluding that listing was not warranted (FWS 1997b). That conclusion was subsequently challenged in court; and litigation is ongoing. The FWS is currently re-evaluating the status of the goshawk and its habitat to comply with a court remand.

OGRs and other non-development Land Use Designations (LUDs), linked by beach, estuary and riparian buffers and other habitat corridors, help maintain key prey species, and provide nesting and foraging habitat. Goshawk nesting territories tend to be evenly spaced across the landscape, where habitat is suitable. We believe elimination of OGRs would likely result in loss of viable nest territories in harvested landscapes, as adjacent unharvested areas are likely to be occupied by resident pairs. OGRs also help support local prey populations, which are largely dependent

on mature and old-growth forest in Southeast Alaska. Beach fringes similarly provide important breeding habitat for goshawk prey species and foraging habitat for goshawks. Information presented at the Tongass Conservation Strategy Workshop confirmed that many species of birds preyed on by goshawks rely on both OGRs and beach buffers for nesting habitat, and that beach and estuary fringes should be at least 300 meters (1,000 feet) wide to provide adequate nesting habitat (DeSanto et al. 2006). Therefore, we recommend that the Final EIS and the Final Forest Plan adopt an alternative that (1) retains the Tongass Conservation Strategy in its entirety throughout the Tongass, since it contributed to an ESA Finding of "not warranted", and (2) offers protections at least equivalent to the 1997 Forest Plan. We further recommend retaining the OGR system and 1,000-foot Beach and Estuary Fringe Standards and Guidelines throughout the Tongass to help protect key goshawk habitats.

Nest Buffers. We believe it is important for goshawk nest buffers to be increased to 500 acres of productive old-growth to protect active and alternate nest sites and post-fledging habitat. Nest buffers protect known nests from disturbance and offer long-term protection to habitat features selected by goshawks in locations consistent with natural spacing between adjacent resident pairs. Existing Goshawk Standards and Guidelines require the retention of at least 100 acres of productive old-growth around known and suspected goshawk nests. Alternate nests are often clustered near an active nest, but may be up to several miles away. Circular nest buffers of 100 acres protected 54 percent of alternate nests used in subsequent years in 24 active territories studied on the Tongass. Alternatively, 775 acre buffers (1 km radius) would have protected 80 percent of the subsequent-year nests (Flatten and Lowell 2001; Titus et al. 2006), although the entire circular buffer would not be productive old-growth (or nesting habitat) in most cases. For this reason, although they did not specify a particular size, Flatten and Lowell (2001) recommended expanding nest buffers beyond 100 acres.

Goshawk fledglings learn to fly and hunt in the mature and old-growth forest surrounding their nest. This area is known as the post-fledging area and is important to the survival of fledglings. While the size of post-fledging areas has not been measured in Southeast Alaska, studies of goshawks elsewhere have documented post-fledging areas of approximately 500 acres (Reynolds et al. 1992, Kennedy et al. 1994, McClaren et al. 2005). The British Columbia study by McClaren et al. (2005) documented post-fledging areas for Queen Charlotte goshawks. Although the studies by Reynolds et al. (1992), and Kennedy et al. (1994) documented post fledging areas of the northern goshawk, which is the more common subspecies of goshawk, the nesting and post fledging requirements of all goshawks are similar enough to believe that the 500-acre buffer recommended for the Queen Charlotte subspecies is justified.

Currently, almost all known goshawk nests on the Tongass are located in old growth reserves or other non-development LUDs. Therefore, no goshawk nest buffers have been established to date (P. O'Conner, USFS, personal communication, 2006). As new nests are discovered during project development, monitoring programs, and/or other activities on the Tongass, OGR delineations will need be adjusted to encompass the goshawk nest and 500-acre buffer. If it is not feasible to enclose the goshawk nest and buffer within an OGR, then we recommend that a nest buffer of 500 acres of productive old growth be established around the active nest.

In summary, we believe buffers of 500 acres would protect active goshawk nests from disturbance; preserve most alternate goshawk nests; and provide suitable goshawk post-fledging habitat. Therefore, to protect active and alternate nest sites and post-fledging habitat, we recommend that the Final EIS and the Final Forest Plan include goshawk nest buffers that are increased to 500 acres of productive old-growth.

Partial Canopy Retention. We believe it is important to retain partial canopy of legacy forest structure in all harvest units larger than 2 acres throughout the Tongass, including High-Risk VCUs. Forest legacy structure helps reduce impacts for many species, including goshawks and their prey. Because goshawks hunt primarily from perches, we believe leaving forest legacy structure in harvest units is likely to improve foraging habitat by providing perches and hiding cover. Kenward (1978, Page 458) reported that goshawks in Britain captured over 90 percent of their prey within 50 meters (164 feet) of cover, unless newly-fledged or starving prey were present, since newly-fledged or starving prey could be overtaken by goshawks on longer pursuits. Because a circular 2-acre opening has a radius of about 50 meters, larger openings are likely to have areas beyond the effective striking range of goshawks. We further believe that retention of forest legacy structure in High-Risk VCUs is likely to help reduce impacts on goshawks.

While the existing Goshawk Standards and Guidelines apply only to heavily harvested VCUs on Prince of Wales Island, the proposed Legacy Standards and Guidelines would be expanded to apply throughout the Tongass. We believe that if the proposed Legacy Standards and Guidelines require residual structure within, rather than along the perimeter, of harvested units, goshawks throughout the Tongass are likely to benefit. Therefore, we recommend that the Final EIS and the Final Forest Plan adopt partial canopy retention of legacy forest structure in all harvest units larger than 2 acres throughout the Tongass, including in High-Risk VCUs. (See the Legacy Forest Structure section for additional consideration.)

Nest Surveys. Effective management of goshawk nest sites depends on knowledge of nest locations. The Proposed Forest Plan eliminates the requirement for pre-project inventories. We recommend that the Final Forest Plan retain the requirement for pre-project (e.g., timber sale) surveys to locate goshawk nests as required under the 1997 Forest Plan (USFS 1997, Page 4-90). We further recommend that the Final Forest Plan include a requirement that the USFS adopt a goshawk inventory and monitoring program consistent with the guidance found in the USFS's recent publication on this topic (Woodbridge and Hargis 2006).

Investigation of Goshawk Biology. The Proposed Forest Plan eliminates the Goshawk Standards and Guidelines for cooperative investigation of goshawk biology. Much remains unknown about the goshawk and its responses to forest management. For example, the effects of increasing proportions of second-growth forest on survival and reproduction of both goshawks and their prey are not well understood. Despite considerable effort, we still do not have a good understanding of nesting densities or population size for goshawks throughout the Tongass. We believe these and similar unanswered questions are best investigated through cooperative, interagency research and monitoring. Therefore, we recommend that the Final Forest Plan retain the Goshawk Standards and Guidelines requirement for cooperative investigation of goshawk biology.

Alexander Archipelago Wolf

We believe it is important to retain the OGR system and 1,000-foot Beach and Estuary Fringe Standards and Guidelines throughout the Tongass to help protect key wolf habitats. The FWS

was petitioned in 1993 to list the wolf, an endemic subspecies confined to Southeast Alaska, as a threatened species under the ESA. Following adoption of the 1997 Forest Plan and Tongass Conservation Strategy, the FWS concluded that listing the wolf was not warranted (FWS 1997a), assuming full implementation of the 1997 Forest Plan.

Person (2006a) reviewed scientific information and submitted considerations concerning viability of the wolf during the 2006 Tongass Conservation Strategy Workshop. Person concluded that maintaining well distributed, viable wolf populations depends on retaining the Tongass Conservation Strategy in its entirety throughout the Tongass, including fully-functioning, well-distributed OGRs. It was also noted that even with the existing Tongass Conservation Strategy and 1997 Forest Plan, it is likely that wolf and deer populations will be lower in the future. Since OGRs and other non-development lands serve as population sources for wolves (and possibly deer), we believe that eliminating or degrading OGRs and other non-development lands would increase the likelihood that wolf populations will decline. Therefore, we recommend that the Final EIS and the Final Forest Plan retain the OGR system and the 1,000-foot Beach and Estuary Fringe Standards and Guidelines throughout the Tongass to protect key wolf habitats.

Landscape pinch points are important to wolf movement and dispersal across the landscape. The largest and most complex system of OGRs is associated with Honker Divide on Prince of Wales Island. These OGRs provide refugia in which wolves produce enough offspring to supplement areas with higher risk and less stable populations (Person et al. 1996). The Rio Roberts watershed is an important denning area and provides for dispersal through a pinch point created by timber harvest from the Honker Divide area to the southern half of Prince of Wales Island, as confirmed by ADF&G telemetry studies from 1998 to 2002 (D. Person, ADF&G, Personal Communication, 2006). Therefore, we recommend that the Final EIS and the Final Forest Plan adopt the Interagency Small OGR Work Group-recommended Small OGR for VCU 5960 (see Attachment B, Table 3) to protect the Rio Roberts watershed.

Murrelets

Kittlitz's murrelet, a candidate species for ESA listing, is found in marine waters adjacent to the northern Tongass. This species is likely to be most susceptible to increased recreation near tidal glaciers and high-elevation land activities such as mining. Therefore, we believe that proposed changes in the Proposed Forest Plan do not appear to pose a significant risk to Kittlitz's murrelets.

Since 1993, the marbled murrelet has been listed in the Lower 48 States as threatened under the ESA. Marbled murrelet populations in Alaska have declined by about 70 percent during the past 25 years (Piatt et al. 2007). While it is unlikely that the decline is attributable to timber harvest alone, we believe that maintaining old-growth habitat for nesting is essential to the persistence of the species. When fully implemented, we believe the existing Tongass Conservation Strategy should provide adequate nesting habitat for the marbled murrelet, while the factors that are leading to the population decline are identified and addressed, where possible. Therefore, in order to continue providing marbled murrelet nesting habitat, we recommend that the Final EIS and the Final Forest Plan retain the OGR system throughout the Tongass.

Subsistence

The Draft EIS states that "deer habitat capabilities in portions of the Tongass may not b adequate to sustain current/future harvest levels under any of the alternatives" (Draft EIS, Tabl 2-18, Page 2-57). Therefore, to help minimize, or prevent, restrictions on subsistence an competition with other users (including the wolf), we recommend that the USFS maximiz protection of important deer winter range, which is the primary limiting factor for dee populations (Person 2006b). To that end, we further recommend retaining the Tongas Conservation Strategy in its entirety throughout the Tongass, including OGRs and the 1,000-foo beach and estuary fringe.

Areas with High Wildlife Values

In 2003, the USFS revised the 1997 Forest Plan to address inventoried roadless areas (USF 2003). In reviewing this revision, FWS biologists conducted on-the-ground and/or aerial visit to each area, and then ranked the quality and importance of each area's habitat. As a result o this work, 13 inventoried roadless areas with outstanding fish and wildlife values and 2 inventoried roadless areas that contain important fish and wildlife habitats and populations wer identified (DOI 2002). We recommend that the alternative selected by the USFS in the Final EI include the 36 areas listed in Attachment C for their habitat value and their importan contribution to maintaining viable, well-distributed fish and wildlife populations throughout th Tongass.

Conservation Principles and Priorities

As in comments previously made by the U.S. Department of the Interior, (DOI 1996), w continue to support the USFS using the best available scientific information for planning an forest management activities related to the Tongass. Scientific assessments and risk assessmen panels ensured that the Tongass Conservation Strategy and 1997 Forest Plan were based on strong scientific foundation. We believe proposed changes to the Tongass Conservation Strateg and the 1997 Forest Plan need to be based on an equivalent level of science. Therefore, w recommend that the Final EIS provide the scientific rationale for any changes to the Tongas Conservation Strategy and 1997 Forest Plan as well as a comparison of the effects between th existing and proposed plan components.

Alternatives

In developing the Draft EIS for the Proposed Forest Plan, the USFS developed 7 alternatives tha are fundamentally the same as alternatives in the 1997 Final EIS (Draft EIS, Page 2-50). Th USFS adopted this approach so the panel assessments from the 1997 Final EIS may be applied t the 7 alternatives included in the Proposed Forest Plan. The panel assessments rated th likelihood that each of the alternatives would ensure viable, well-distributed populations o wildlife species throughout the Tongass. Alternatives 4 and 7 of the Draft EIS are designed to b essentially the same as Alternatives 2 and 6 in the 1997 Final EIS.

Alternatives 4 and 7

We believe the adoption of Alternative 4 or Alternative 7 would eliminate or undermine the Tongass Conservation Strategy, which, in turn, would fail to ensure that viable, well-distributed populations of goshawk, wolf, endemic mammals, and other species, would be maintained (Draft EIS, Table 2-17, Page 44). It is important to note that alternatives similar to Alternatives 4 and 7 were removed from final consideration during the 1997 Forest Plan revision process because those alternatives would not provide a "relatively high assurance that the habitat needed for long-term viability of all wildlife species would be maintained and commercial, sport and subsistence use sustained" (TLMP 1997 Record of Decision (ROD), Page 15). The Draft EIS identifies the "distribution of high quality old-growth blocks" as the key indicator of "protection of the wildlife habitat and biodiversity" across the Tongass (Draft EIS, Page 1-8), and concludes that Alternatives 4 and 7 would provide only "poor" distribution of high quality old-growth blocks across most or all of the Tongass (Draft EIS, Page 2-50). The 1997 Record of Decision stated that a "relatively low level of risk" to these resources was considered essential in order to meet stated goals of the 1997 Forest Plan, which included a biodiversity goal to "maintain healthy forest ecosystems [and] maintain a mix of habitats at different spatial scales (i.e., site, watershed, island, province and forest) capable of supporting the full range of naturally occurring flora, fauna, and ecological processes native to Southeast Alaska." (USFS 1997b, Page 2-2). The goal identified in the Proposed Forest Plan (Draft EIS, Page 2-7) has not appreciably changed over the goal included in the 1997 Forest Plan. Therefore, we recommend that in the Final EIS, Alternatives 4 and 7 be eliminated from further consideration.

Alternatives 1, 2, 3, 5, and 6

We believe Alternatives 1, 2, 3, 5, and 6 retain the Tongass Conservation Strategy in its entirety throughout the Tongass and provide reasonable assurance that viable, well-distributed wildlife populations will be maintained. For example, Alternatives 1, 2, and 3 are rated "high" to "very high" for all species except endemic mammals, which are rated as "moderate" to "high". Alternatives 5 and 6 are rated "moderately high" to "very high" for the goshawk, wolf, and brown bear, and "moderate" for endemic mammals and marten (Draft EIS, Table 2-17, Page 44). Therefore, we recommend adoption of an alternative in the Final EIS that retains the Tongass Conservation Strategy in its entirety throughout the Tongass and provides reasonable assurance that viable, well-distributed wildlife populations will be maintained.

Alternative 6

With respect to Alternative 6, the USFS proposed alternative, we note that it retains the Tongass Conservation Strategy; implements improved locations for 191 Small and 21 Medium OGRs; and retains the 1,000-foot beach buffer. However, we believe that Alternative 6 could be improved if it (1) included the Interagency Small OGR Work Group preferred biological locations for 48 additional Small OGRs; and (2) retained the existing Goshawk Standards and Guidelines. To help prevent the need to list the goshawk under the ESA, we recommend that in the Final EIS, Alternative 6 be amended to include the preferred biological locations for 48 additional Small OGRs (see Attachment B, Table 3) and to retain the existing Goshawk Standards and Guidelines.

SPECIFIC COMMENTS

Proposed Forest Plan, Page 2-51: The description of Alternative 4 needs to be corrected in the Final Forest Plan to match the ratings in Table 2-17 (Page 2-44) from which it is drawn. As currently written, the narrative incorrectly uses the ratings from Alternative 3.

Proposed Forest Plan, Page 3-5: In recognition of its high fish, wildlife, and subsistence values, we recommend that in the Final Forest Plan, the area currently designated "Young Bay Research Natural Area (RNA)" revert to the same LUD as Admiralty National Monument. The Young Bay RNA on Admiralty Island is proposed to be released and a new RNA is proposed for establishment in the Cowee Creek watershed near Juneau. As written, the Draft Forest Plan leaves the new LUD for Young Bay unspecified.

Proposed Forest Plan, Page 4-126: Forest owls, specifically western screech-owls, barred owls, and northern saw-whet owls need to be included in the Final Forest Plan in the list of nesting raptors to be surveyed in proposed management areas.

Proposed Forest Plan, Page 4-128: We believe the "Endemic Terrestrial Mammals Standards and Guidelines" need to be re-titled, in the Final Forest Plan, as "Endemic Terrestrial Wildlife Standards and Guidelines". We also believe the Endemic Terrestrial Wildlife Standards and Guidelines need to be: (1) revised to include surveys for rare and endemic mammals, birds, amphibians, and insects, which may represent populations that are unique and/or which have restricted ranges; and (2) subsequently included in the Final Forest Plan.

Draft EIS, Page 3-173: The population decline estimates and discussion for the marbled murrelet need to be updated in the Final EIS, using the recent U.S. Geological Survey status review (Piatt et al. 2007).

Draft EIS: Since Appendix N of the 1997 Forest Plan, "Additional Evaluation of Wildlife Habitat Conservation Measures," (USFS 1997a, pp. N1 - N50) provides essential background information related to the Tongass Conservation Strategy and provides an important reference for understanding the rationale for specific components of the strategy, we believe Appendix N needs to be revised to include updated information and then included in the Final EIS.

Forrest Cole, Forest Supervisor
USDA Forest Service
Alaska Region, Tongass National Forest
648 Mission Street
Ketchikan, Alaska 99901

Dear Mr. Cole:

The U.S. Environmental Protection Agency (EPA) has reviewed the **Draft Environmental Impact Statement (DEIS) and Proposed Tongass Land and Resource Management Plan (TLMP) Amendment** for the Tongass National Forest in southeast Alaska (CEQ No. 070003). Our review has been conducted in accordance with our responsibilities under the National Environmental Policy Act (NEPA) and Section 309 of the Clean Air Act. Section 309 specifically directs the EPA to review and comment in writing on the environmental impacts associated with all major federal actions. Under our Section 309 authority, our review of the DEIS will consider the expected environmental impacts, and the adequacy of the EIS in meeting procedural and public disclosure requirements of NEPA.

The 16.8 million acre Tongass National Forest is the largest forest in the National Forest System. Management of this forest is guided by the Tongass Land Use Management Plan (Forest Plan). The current Forest Plan was revised in 1997, and was intensively reviewed in 2005 (5-Year Review). Since 1997, the Forest Service (FS) has been responding to a variety of appeals and litigation on the processes that were used to create the 1997 Plan. In August 2005, the U.S. Court of Appeals for the Ninth Circuit issued a decision that found deficiencies in the process used to develop the 1997 Forest Plan revision. Specifically, the Court found inadequacies related to timber demand, the range of alternatives considered relative to timber demand and potential effects on roadless areas, and cumulative effects from activities conducted on non-National Forest System lands.

The current DEIS is intended to address these deficiencies, and to incorporate opportunities identified through the 5-Year Review into the Plan. The DEIS considers projections of timber products output and timber harvest over the next 20 years under four different timber demand scenarios (low to high). The DEIS evaluates seven alternatives that encompass all of these demand scenarios in a variety of ways, while addressing three key issues. Those key issues are identified as:

- Key Issue 1 – Protection of high value roadless areas from road development and timber harvest activity on the Tongass National Forest is of local and national importance, particularly for wildlife and biodiversity, recreation, and tourism.

- Key Issue 2 – The Tongass National Forest needs to provide a sufficient timber supply t meet the market demand and help maintain a vibrant economy in Southeast Alaska.
- Key Issue 3 – Protection of the wildlife habitat and biodiversity of the Tongass National Forest is of local and national significance and is affected by road development and timber harvest activities.

The alternatives differ principally in the amount of land designated for development (in development land use designations or LUDs), and the amount of timber harvest propose

- **Alternative 1** would place 1.2 million acres in Development LUDs, and 15.6 million acres in Non-development LUDs. The estimated suitable forest land base (harvestable land base) would be .43 million acres, and the allowable sale quantity (ASQ) would be 5 million board feet (MMBF).
- **Alternative 2** would place 2.0 million acres in Development LUDs, and 14.8 million acres in Non-development LUDs. The estimated suitable forest land base would be .54 million acres, and the ASQ would be 152 MMBF.
- **Alternative 3** would place 3.0 million acres in Development LUDs, and 13.8 million acres in Non-development LUDs. The estimated suitable forest land base would be .68 million acres, and the ASQ would be 204 MMBF.
- **Alternative 4** would place 4.7 million acres in Development LUDs, and 12 million acre in Non-development LUDs. The estimated suitable forest land base would be 1.01 million acres, and the ASQ would be 360 MMBF. In addition, Alternative 4 uses a different strategy to provide old-growth habitat.
- **Alternative 5** is the no action alternative. This alternative would maintain 3.6 million acres in Development LUDs, and 13.2 million acres in Non-development LUDs. The estimated suitable forest land base would be kept at .76 million acres, and the ASQ woul remain 267 MMBF.
- **Alternative 6** is the proposed action alternative. This alternative is similar to Alternativ 5 (3.6 million acres in Development LUDs, and 13.2 million acres in Non-development LUDs), however, it includes refinements to the boundaries of a number of small old growth reserves and other refinements. The estimated suitable forest land base would b .79 million acres, and the ASQ would be 267 MMBF.
- **Alternative 7** would place 5.1 million acres in Development LUDs, and 11.7 million acres in Non-development LUDs. The estimated suitable forest land base would be 1.15 million acres, and the ASQ would be 421 MMBF. In addition, Alternative 7 would hav the least restriction on harvest in old-growth forest. It does not include old-growth reserves or have minimum old-growth retention requirements.

The EPA appreciates the efforts of the Tongass National Forest in preparing this DEIS and i developing an innovative website and CD to help agencies and the public analyze impacts associated with the proposed alternatives. We have assigned a rating of EC-2 (Environmental Concerns – Insufficient Information) to the DEIS. This rating and a summary of our comments will be published in the Federal Register. A summary of the rating system we used in conducting our review of the DEIS can be viewed at http://www.epa.gov/compliance/nepa/ comments/ratings.html. The FS did not identify a preferred alternative, therefore we focused our review on the full suite of alternatives within the context of the three key issues identified in the document.

Based on this review, we find alternatives 1, 2 and 3 to be environmentally preferable. These alternatives provide significant protection of water quality and a connected network of aquatic and terrestrial habitats, afford extensive protection of old growth, minimize road development and associated impacts, and provide a sustainable supply of timber consistent with current and recent timber harvest levels. The conservation emphasis under these alternatives is less sensitive to agency budget levels and less dependant on active management. Our environmental concerns with Alternatives 5 and 6 primarily relate to high and moderate intensity land use designations, increased road development, and associated impacts to aquatic and terrestrial habitats and water quality. Additional information on how these impacts will be minimized and on monitoring and adaptive management strategies should be provided in the FEIS. We believe that as currently proposed, Alternatives 4 and 7 do not address key issues 1 and 3, and hence, are not viable. EPA would have serious objections to the selection of Alternative 4 or 7 as the Preferred Alternative in the Final EIS/Record of Decision.

In general, we recommend that the FS select an Alternative in the Final EIS and Record of Decision that:

- Minimizes the acreage of forest designated for Intensive or Moderate Development;
- Protects high value roadless areas for wildlife and biodiversity, recreation and tourism, thus supporting local and regional economic viability and subsistence activities;
- Accurately reflects the most recent timber industry market trends; and
- Clearly identifies monitoring plans and adaptive management strategies to be employed for the next planning cycle.

Thank you for the opportunity to comment on this draft EIS. If you would like to discuss our response further, please contact Jennifer Curtis, at (907) 271-6324 or me at (206) 553-1601.

Sincerely,

Christine B Reichgott

Christine Reichgott, Manager
NEPA Review Unit

EPA Region 10 Detailed Comments
Tongass Land and Resource Management Plan Amendment
Draft Environmental Impact Statement

As noted above, the FS identified three key issues to frame each of the alternatives. EPA appreciates this strategic and focused approach to the Plan amendment. We have accordingly structured our own detailed comments around the identified key issues.

Key Issue 1 - Protection of high value roadless areas from new roads and timber harvest is locally and nationally significant for wildlife and biodiversity, recreation, and tourism.

EPA agrees with the identification of high value roadless areas as a key issue, and we commend the FS for establishing this as a standard of review. The Tongass is the earth's largest, intact temperate rainforest, and contains some of the largest, intact blocks of forest in North America. Each of the 21 distinct bio-geographic provinces within the Tongass contributes to the biodiversity of the national forest system, making the Tongass rich with endemic species. The Tongass also contains nearly 5,000 salmon-supporting streams (Halupka et al. 2000). These streams provide the spawning and rearing habitat for more than 90 percent of the salmon commercially caught in southeast Alaska.

As recognized in the document, those alternatives that place emphasis on maintaining inventoried roadless areas (IRA), protecting productive old growth (POG), and limiting road construction and the amount of acreage placed in Development LUDs, pose a lower risk of direct and indirect effects to focal resources. Alternatives 1 and 2 perform well against this measure. As noted on page 2-41, none of the 21 biogeographic provinces would contain less than 50 percent of their areas in Non-development under these alternatives. Alternatives 3, 5, and 6 represent higher harvest levels and additional road building, but would retain good to very good spacing of old growth reserves and other Non-development LUDs. These alternatives are less protective than Alternatives 1 and 2 but, when taken together with site-specific analyses and interagency monitoring, continue to address Key Issue 1. Alternatives 4 and 7 would each result in five biogeographic provinces with less than 50 percent in Non-development LUDs, and do not appear to be as responsive to Key Issue 1.

We are particularly concerned about the number of roads that would be constructed under Alternatives 4 and 7. At present, there are 4,942 miles of road on the Forest. The Tongass Road Condition Survey Report (ADFG, 2000) looked at approximately 40 percent of these roads (2,153 miles). The report documents numerous instances of ditch plugging, ditch erosion, cut-slope and fill-slope erosion, road surface erosion, catch basin failure, ditch blockage, culvert inlet and outlet erosion, and other system failures. These are the very kinds of failures that resulted in the listing of Katlian River and Nakwasina River on the CWA 303(d) list for sediment and turbidity. In addition, the Road Condition Survey indicates that 66 percent of the culverts across anadromous streams (Class I streams) are assumed not to be adequate for fish passage, and eighty-five percent of the culverts across resident fish streams (Class II streams) are assumed not to be adequate for fish passage. EPA acknowledges that the FS has used the results of this report to help target restoration work, and to acquire additional road maintenance funding. We also note, however, that the 2003 Forest Level Roads Analysis for the Tongass (p. 75) indicates that deferred costs for solving all passage problems at maintenance level 3, 4, and 5 road-stream crossings could be as high as $30 million. Given current budget shortfalls and anticipated

reduction in staff, we question the ability of the FS to maintain the existing road network, address fish passage and other road-related issues (such as drainage and road stability), while at the same time undertaking to construct over 5,000 miles of new road. We recommend that the document give discussion to how the FS will meet the proposed construction, maintenance and decommissioning goals while continuing to address the deferred maintenance backlog. A recent letter from the Wrangell District Ranger, Mark Hummel, regarding the decision to select an alternative for the Wrangell District Road Analysis and Access and Travel Management Plan stated the following: "This alternative will reduce the potential for resource damage more than any other alternative by removing the most miles of risk from culvert failure, loss of fish passage, erosion, and sedimentation. The sooner the District acts to close roads it can no longer maintain, the more likely that funding is available to close them. Funding is currently anticipated for the next few years. After that, the likelihood is greatly reduced." This statement recognizes that budget shortfalls will continue into the future.

In addition, we note that many of the transportation corridors authorized under Public Law 109-59 would cross the Tongass, as would a number of power transmission lines currently proposed by the State of Alaska. Given that Transportation and Utility LUDs would be given priority over all underlying LUDs, including LUDs that do not normally allow road construction, it is critically important to fully analyze road-related cumulative impacts. We recommend that the document more fully address the cumulative impacts of existing roads, the proposed increase in roads under the various alternatives, road activity on non-NFS land, and the proposed road and energy infrastructure under Public Law 109-59.

Lastly, we note that the DEIS states that, "[p]rotection for riparian areas would be the same under all alternatives" (p. 3-40). Regardless of which alternative or combination of alternatives the FS selects, EPA recommends that the Forest Plan Amendment include the riparian standards and guidelines as shown in the Proposed Land and Resource Management Plan (p. 6-41).

Key Issue 2 – The Tongass National Forest needs to provide a sufficient timber supply to meet the market demand and help maintain a vibrant economy in Southeast Alaska.

EPA agrees with the identification of sufficient timber supply as a key issue. As noted in the document (page 3-424), the Tongass Timber Reform Act (TTRA) of 1990 states that "…the Secretary shall, to the extent consistent with providing for the multiple use and sustained yield of all renewable forest resources, seek to provide a supply of timber from the Tongass National Forest which (1) meets the annual market demand for timber and (2) meets the market demand for each planning cycle." Additionally, we recognize that there is a particular need in southeast Alaska for year-round, family wage employment, as well as a need to strengthen and diversify the regional economy.

The Alternatives proposed in the DEIS roughly correspond with four timber demand scenarios developed by Brackley et al. (2006): (1) Limited Timber Production (under this scenario, total derived demand is projected to be 65 MMBF in 2020); 2) Expanded Lumber Production (163 MMBF in 2020); 3) Medium Integrated Industry (204 MMBF in 2020); and 4) High Integrated Industry (325 MMBF in 2020).

The document gives discussion on page 3-441 to the ability of the various alternatives to meet these demand scenarios. In general, Alternatives 1 and 2 would be sufficient to meet limited timber production. Alternatives 3, 5 and 6 would provide volume sufficient to meet scenarios 1 thru 3 (up to the medium integrated industry scenario). Only Alternatives 4 and 7 would provide volume sufficient to meet scenario 4 (high integrated industry). We do not disagree with the premise that sufficient "shelf volume" is needed in order for the timber economy to fully realize market demand and stimulate investment (thereby addressing key issue 2) but we do question the attainability of the highest volume scenario (scenario 4 - high integrated industry).

The model developed by Brackley et al. considers a number of drivers affecting timber demand (timber statistics, trade data, etc.), but is unable to account for other factors potentially affecting timber demand, such as competition, fuel costs, labor costs, complicated shipping logistics, litigation and Congressional action. The study in fact notes (p. 34) that changing conditions in Alaska and world markets are rapidly making the existing model and approach obsolete, and that future attempts to project demand for National Forest timber in Alaska will require new methods and additional information.

We also note that the Forest has not harvested over 50 MMBF annually since 2000, and that the wood products industry accounted for only 1 percent of total regional employment in 2004 (p. 3-413). Notably, this is under the current ASQ of 267 MMBF, which according to the study is enough to support medium integrated industry. The lack of investor response to date would seem to indicate that there are variables outside the realm of FS influence (and available ASQ) that are limiting investment into wood products in the Tongass region.

Additionally, we question some of the assumptions in the DEIS related to projected employment. Page 3-449 indicates that projected timber industry employment figures were calculated assuming a linear relationship between harvest and employment levels (a one percent change in harvest resulting in a one percent change in employment). We are concerned that not only will changes in employment will lag changes in harvest, but that given current trends in automation, there is not a direct linear relationship between harvest and employment. This could lead to an overestimation of the amount of employment generated by the higher timber output scenarios. An examination of the timber market in Oregon concluded that even if harvest levels could be maintained, increased productivity would result in a 1.2% drop in employment over a 7-year period (Conway and Wells 1994).

In summary, Alternative 1 would maintain current harvest levels. As noted by the Brackley study, this may be the "most probable outcome" (p. 32), but it also falls short of fully satisfying key issue 2. Alternatives 2, 3, 5 and 6 would provide for a timber economy that is expanded from present levels. It is likely that each of these alternatives would, to varying degrees, satisfy key issue 2. Alternatives 4 and 7 would clearly provide ASQ levels sufficient to meet any potential timber demand, but, given the noted uncertainties surrounding the timber economy in Alaska, we question the whether these sale quantities are in fact attainable.

Key Issue 3 – Protection of the wildlife habitat and biodiversity of the Tongass National Forest is of local and national significance and is affected by road development and timber harvest activities.

EPA agrees with the identification of wildlife habitat and biodiversity as a key issue. The Tongass is naturally fragmented by islands and coastal ice fields and many of the islands have

distinct climatic, floral, and faunal differences. This presents a challenge for conservation of biodiversity and highlights the need to manage for intact habitats as a priority.

Impacts to habitat and biodiversity vary under the alternatives according to the amount of road construction and timber harvest proposed. Because ecosystems in naturally fragmented landscapes are less resilient to further fragmentation, logging additional unroaded areas poses a higher risk to species existence and persistence.

Chapter 3 of the DEIS provides an excellent discussion of the effects of the alternatives on landscape connectivity and biodiversity, noting the importance of an intact Old Growth Reserve (OGR) strategy in terms of ensuring long-term habitat viability. The reduction of OGR protections under Alternative 4, and the elimination of OGR protection under alternative 7, would effectively eliminate old-growth connectivity across numerous ecological "pinch-points" (3-187) and reduce the functional connectivity of the old-growth ecosystem (3-188).

Based on the information provided, we concur that Alternatives 4 and 7 could have a low likelihood of maintaining viable, well-distributed populations (3-186), and that Alternative 7, in particular, would result in the greatest loss of biodiversity among the alternatives (3-143). Based on the analysis, it seems clear that Alternatives 1 and 2 would result in good distribution of high quality old-growth over the long term, Alternatives 3, 5 and 6 would likewise continue to provide good habitat distribution, though to a lesser degree (affecting one ecological "pinch-point") and Alternatives 4 and 7 do not meet key issue 3.

In addition to old-growth as a habitat component, we are concerned about affects to wetland structure and function due to timber harvest and road construction. As noted on page 3-47, wetlands provide important physical, biological, and chemical functions that contribute to the overall functioning within a watershed and landscape. These functions are particularly critical to maintaining stream health. Page 3-45 indicates that 22 percent of existing road miles are in wetland areas. New road miles under the various alternatives range from 434 miles under alternative 1 to 2,043 under Alternative 7. As noted above, road impacts have resulted in the listing of two Tongass streams on the state 303(d) list. We are concerned that opening new wetland areas to road construction and harvest could increase sediment yield to streams within the Tongass and, subsequently, add more miles of streams to the 303(d) list. Site specific analysis and the TLMP riparian conservation strategy will help to mitigate some of these impacts, but as the FS has recognized, road construction can have significant unavoidable adverse impacts to water quality, regardless of how well the roads are designed constructed or maintained (USFS, 2001). Given the potential adverse effects of roads on aquatic life, we feel that in order to be consistent with key issue 3, the FS should pursue an alternative that minimizes road construction, particularly in wetland areas.

EPA Recommendation for a Preferred Alternative

Alternatives 1, 2, and 3 place the most emphasis on maintaining inventoried roadless areas (IRA), protecting productive old growth (POG), and limiting road construction and the amount of acreage placed in Development LUDs. These alternatives are environmentally preferable from a water quality, habitat, and roadless value perspective. Alternatives 5 and 6 are more responsive to key issue 2, and seek to strike a balance on habitat and roadless values, but result in significantly greater impacts. Given site-specific analysis and interagency monitoring, it is likely that Alternatives 5 and 6, together with the robust TLMP aquatic and riparian strategy, would continue to address key issues 1 and 3. Alternatives 4 and 7 appear designed to respond principally to key issue 2, and in fact go beyond the ASQ deemed necessary for a highly integrated industry. We are concerned not only with the assumptions driving this high ASQ, but also with the lack of responsiveness these alternatives demonstrate to key issues 1 and 3.

Regardless of which alternative is selected in the Final EIS and Record of Decision, we cannot stress enough the importance of continuing to engage Federal and non-Federal partners in the monitoring and assessment of the Land Management Plan (including POG designation). The Forest's use of the 1984 planning rule to pursue this amendment is testament to the Forest's commitment to broad collaboration. We commend you for making this a priority, and encourage you to maintain that focus as the plan moves once again into implementation. Specifically we request that the Interagency Monitoring Group be engaged in the 5-Year Review process, in addition to the involvement it has in the annual assessment report.

Comments Specific to the Tongass National Forest, Proposed Land and Resource Management Plan with EIS Appendices, January, 2007

Page 4-92 to 4-93, Watershed Resources Improvements: S&W2, I. Soil and Water Quality Protection and Improvement

Past road building and timber harvest activities, in combination with extensive harvest on adjacent private lands, have negatively impacted water quality and watershed health. This is particularly true for those biogeographic provinces with a history of intensive timber harvest (such as Kupreanof-Mitkof islands). Watershed restoration should be a major focus of the Forest Plan for these areas in order to ensure that they do not lose their ecological integrity.

The Soil and Water standards and guidelines talk of the need to "improve" these areas. This terminology does not adequately convey the current impaired status of these watersheds. Furthermore, when speaking of water quality protection, the wording in the Plan should be consistent with wording in the Clean Water Act. That Act mandates *restoring* and *maintaining* the chemical, physical and biological integrity of the nation's waters. We recommend amending S&W2 to remove the words "improve" or "improvement" and insert the words "restore" or "restoration."

Page G-2, Appendix G – Log Transfer Facility Guidelines, S7. Siting Guidelines

Impacts of Log Transfer Facilities (LTFs) typically include: 1) disruption of biota during log transfer and storage; 2) leaching of soluble materials that may be toxic; and 3) loss of bark and resultant effects on the benthos (Jackson, 1986). In order to avoid cumulative effects on sensitive marine environments, an examination of past and current LTF impacts should be made prior to siting. We recommend that the Siting Guidelines require a cumulative impact assessment prior to siting that references the following parameters: 1) measurements of bark and organic accumulation; 2) measurements of the concentration of organic log leachates, biological oxygen demand, dissolved oxygen, and hydrogen sulfides; and 3) a comparative survey of the kinds and relative abundances of benthic organisms.

Page 4-20, Invasive Species Protection

Invasive species can aggressively spread into areas altered by road construction and harvest activities. Nationally, as well as in Alaska, the establishment of invasive nuisance species has rapidly become an issue of extreme environmental and economic significance. EPA commends the FS for incorporating invasive species standards and guidelines into the Plan. We recommend that the new section be expanded upon to include discussion of Integrated Pest Management (IPM). EPA promotes IPM because it represents a prudent approach to understanding and dealing with environmental concerns. IPM promotes a thoughtful awareness of the pest management inherent in natural systems through an understanding of pest life cycles and through the use of beneficial organisms, cultural modifications, physical barriers and other mechanical controls. It does not rule out the use of pesticides, but requires that their use be thoughtfully considered.

We also recommend that the Invasive Species section discuss compliance with Executive Order (EO 13112) on invasive species. This Order emphasizes the need to address invasive species in the context of NEPA, and mentions six key categories of issues federal agencies should consider. Specifically, the Order states: "Each Federal agency whose actions may affect the status of invasive species shall, to the extent practicable and permitted by law:

> (1) identify such actions. [and]
>
> (2) use relevant authorities to: (i) prevent the introduction of invasive species, (ii) detect and respond rapidly to and control populations of such species..., (iii) monitor invasive species populations reliably and accurately, (iv) provide for restoration of native species and habitat conditions in ecosystems that have been invaded; (v) conduct research on invasive species and develop the technologies to prevent introduction and provide for environmentally sound control of invasive species and (vi) promote public education on invasive species..., and
>
> (3) not authorize, fund or carry out actions that it believes are likely to cause or promote the spread of invasive species in the U.S. or elsewhere unless...benefits of such actions clearly outweigh the potential harm caused....".

Page 6-3, Monitoring and Evaluation

EPA continues to view the Monitoring and Evaluation Plan in Chapter 6 as a critically important element of the proposed Plan, especially with the FS's application of an adaptive management strategy to forest planning activities on the Tongass. An interagency monitoring and evaluation program designed to provide the necessary feedback on the successes (and failures) of management practices specified in the Plan and implemented on-the-ground is the cornerstone of a successful adaptive management strategy. EPA's support of the current Plan continues to be predicated on the full implementation of a successful interagency monitoring and evaluation program. In light of budget shortfalls, we are encouraged that the FS is continuing to place a high level of emphasis on monitoring in the Plan. We ask that you continue to work in close collaboration with other Federal and non-Federal partners as you move forward with this program.

Re: State of Alaska Comments on the Tongass Land and Resource Management Plan Amendment and Draft Environmental Impact Statement

Dear Mr. Cole:

The State of Alaska (State) appreciates the opportunity to work with the USDA Forest Service (USFS) as a Cooperating Agency under the 2006 Memorandum of Understanding to amend the Tongass Land and Resource Management Plan (TLMP). A Management Plan that will minimize legal challenges and stabilize the supply of resources to the economic enterprises of Southeast Alaska is essential to the well-being of the entire region. Our comments describe our goals and principles for the plan amendment and Draft Environmental Impact Statement (DEIS). These comments focus on timber management in the context of wildlife conservation. Overall, we seek to balance protection of fish and wildlife resources, recreation and tourism activities, and development of timber and minerals within the Tongass National Forest (TNF). This letter summarizes our general comments, with more detailed information in the following pages and appendices.

I understand that this plan amendment is primarily in response to timber issues, and our comments are accordingly focused. However, I must emphasize that the State of Alaska acknowledges that the Tongass National Forest has many other uses and benefits to the local residents, the State of Alaska, and the Nation. However we decide to manage the timber resources of the TNF, we must always consider these non-timber uses in our decision making.

Timber industry. The State of Alaska supports a sustainable timber industry in Southeast Alaska as part of a diversified regional economy. A sustainable timber industry is one which operates efficiently and supports reinvestment in capital infrastructure. Sufficient timber must be available from federal land to allow the

existing industry to operate efficiently and sustainably. This will require annual timber sales of at least 167.5 million board feet of economically feasible timber (see Appendix A). Historically, the volume of economically feasible timber offered has been significantly different than the gross Allowable Sale Quantity (ASQ) figure. The focus should be on the volume of economically feasible timber offered, not the ASQ. More detailed comments on this topic follow in the section on specific issues (see page one of our detailed comments).

Transitioning to a sustainable industry supported by second-growth timber is a key objective. However, given current timber stand ages, fully transitioning to second-growth harvests will take at least 50 years. Reaching this goal will require considerable investment, and intensive management of second-growth stands. We are committed to working with the USFS, the timber industry, and the full range of interests in Southeast Alaska to develop a strategy for this transition.

In the interim, it is critical that the USFS provide a sufficient, predictable supply of old-growth timber that sustains the existing industry and has the flexibility to incrementally increase timber supply as the industry expands. This will best be achieved by concentrating timber harvest in areas that are intensively managed. This will reduce the area affected by harvesting, improve timber sale economics, and increase the undisturbed area for wildlife, recreation, subsistence, and other uses. Within intensively managed harvest areas, it is appropriate to relax some Standards & Guidelines (S&Gs), in exchange for more stringent S&Gs in other areas.

Conservation Strategy. The timber goals must be balanced with a sound, science-based, conservation strategy. Conservation values and economic values are not mutually exclusive – both are needed for a healthy economy and a healthy environment. Regardless of land status, the State is obligated to manage all renewable resources on a sustainable basis, including habitat for fish and wildlife, public access, and wilderness values.

These resources should be managed on the basis of the most recent, credible, scientific studies available, including information compiled by the 2006 Conservation Strategy Review. We request that the USFS complete a synthesis of key findings from the review so that the information can be used to identify and address proposed or anticipated modifications to the S&Gs. To the extent possible, implementation of conservation measures should be flexible enough to enable tailoring them to site-specific conditions and facilitate design of economically feasible timber sales. Measures may vary from area to area to reflect different species concentrations and sensitivities, and to concentrate timber harvesting in intensively managed areas rather than dispersing harvesting throughout the forest. Intensive timber management which minimizes the areas affected by harvesting will have the least impact on conservation values and the best chance of broad public support.

The system of small, medium, and large old-growth reserves (OGRs), along with beach and riparian buffers, must remain the cornerstone of the wildlife conservation strategy. The system of buffers and reserves provides a safety net for the conservation of viable fish and wildlife populations. Combined with the other protected areas in Southeast Alaska (e.g., wilderness areas) and prudent management of the lands where timber harvest is allowed (matrix lands), the overall strategy provides habitats sufficient for providing sustainable and usable fish and wildlife populations.

Tongass Futures Roundtable. We strongly support the efforts of the Tongass Futures Roundtable (TFR) to find common ground among the many entities with deep interest in the Tongass National Forest. The TFR is striving to build consensus on a plan to convert to an industry based on second-growth and to identify areas where more intensive timber management can occur with minimal impacts on fish and wildlife conservation. We are committed to active participation in these efforts. We believe that building consensus offers the best chance to alter the pattern of litigation over Tongass management. The TLMP amendment must retain flexibility to implement consensus recommendations developed by the TFR, without compromising adoption of the amended plan this fall.

IMPLEMENTATION STRATEGY

The State recommends that the USFS employ a phased strategy to implement the plan quickly, stabilize timber supply, protect fish and wildlife resources, and provide time for the TFR to develop consensus recommendations. Throughout implementation of this strategy, we also support development of other commercial and personal uses of the forest such as recreation, tourism, subsistence, commercial fishing, and mining. The following outline describes this strategy.

Phase 1 - Short-term - Support the existing timber industry and continue to apply the existing Conservation Strategy.

- Offer at least 167.5 million board feet of economically feasible timber annually to support the existing timber industry at an efficient level and allow for a facility that can utilize low value timber. Focus harvests on roaded areas. Limit incursions into unroaded areas to the level necessary to provide economically feasible timber during the transition to a second-growth industry. Due to the young age of most existing

stands, timber harvest would continue to be predominantly old-growth in this phase. Monitor timber demand and encourage local, value-added timber uses.
- Maintain the existing Conservation Strategy, including the old-growth reserve system, beach and riparian buffers, and Standards and Guidelines. Monitor the effectiveness of the Strategy.
- Continue TFR efforts to plan for conversion to a timber industry based on second-growth, identify areas for intensive timber management and flexible implementation of S&Gs, and assess opportunities for flexible implementation of the S&Gs that would improve operability for timber harvesting without compromising fish and wildlife conservation.
- Prepare for the conversion to second-growth harvesting by:
    - Developing a coalition to work with Congress to revise the National Forest Management Act (NFMA) requirement for use of Culmination of Mean Annual Increment to determine rotation age. The NFMA should be revised to allow shorter rotations for second-growth;
    - Considering appropriate means to reduce the rotation age for second growth stands through intensive management; and
    - Working with recreation, tourism, timber, and conservation interests to review portions of Modified Landscape and Scenic Viewshed LUDs that are outside areas protected under the Conservation Strategy, for potential inclusion in Timber Production LUDs.

Phase 2 - Mid-term - Expand timber harvest based on industry growth, demand, and demonstrated success of the Conservation Strategy with a goal of developing an integrated timber industry.

- Review results of monitoring on timber demand and conservation effectiveness.
- Update the Conservation Strategy based on consideration of research (including the 2006 Conservation Strategy Review), monitoring results, and TFR recommendations on flexible implementation of S&Gs in intensively managed areas.
- As the timber industry grows and demand increases, increase the volume of economically feasible timber offered for sale.
    - Most harvests would continue to be old-growth due to the young age of most second-growth stands; harvests would include second-growth where suitable stands exist.
    - Concentrate timber harvests in intensive management areas and incorporate TFR recommendations on the location of these areas.

Phase 3 - Long-term - Convert to a timber industry focused on second-growth harvests.

- Offer economically feasible timber sales in second-growth based on demand. Given the distribution of stand ages in the forest, full conversion to a second-growth harvesting will not be feasible until at least 2057. Intensively manage second-growth to maximize the available timber volume and minimize the area needed to support the timber industry. If intensively managed, we expect second-growth stands to produce a greater volume of timber per acre and provide more flexibility in management.

- Review the Conservation Strategy and modify it as necessary to tailor it to conditions of second-growth harvesting, address slash management, and incorporate restoration activities. The review should include information developed in the Tongass-Wide Young Growth Study (TWYGS) and other research.

Under all three phases,

- Continue restoration management work, including commercial thinning in second-growth, stream habitat restoration, road removal and fish passage improvements.
- Support development of other economic activities that utilize the forest for recreation, tourism, mining, commercial fishing, and subsistence activities at a variety of scales and from commercial to personal in scope.

ANILCA AND FEDERAL LAND MANAGEMENT ISSUES

The proposed plan amendment is inconsistent with several provisions of the Alaska National Interest Lands Conservation Act (ANILCA) and other federal-state laws and policies. In particular, there are issues with restriction of off-highway vehicle use for subsistence activities, application of required zoning for public recreation and encounter rates to limit public uses on Forest Service lands, and allowance for fish and wildlife management activities and facilities in Wild and Scenic River Corridors, Research Natural Areas, and Experimental Forests. We request that the Final EIS and plan amendment be consistent with ANILCA and other federal-state agreements on these issues.

The State of Alaska supports completion of Alaska Natives Claims Settlement Act (ANCSA) land conveyances for Sealaska Corporation. The lands to be conveyed to Sealaska must be of a nature and character to fulfill the promise of ANCSA. This can only be achieved by the conveyance of lands suitable to meet Alaska Native cultural, traditional, and economic needs.

AGENCY STATUS AND PLAN IMPLEMENTATION

The State urges the USFS to implement the TLMP amendment in a timely fashion. While the recent legal settlement allows Tongass timber to make it into the "pipeline" and provides short-term relief to the timber industry, final plan approval

and implementation is critical to the industry and economy of Southeast Alaska. Until the timber supply is stabilized, there is no assurance that the industry can survive.

Under the 2006 MOU between the State and USFS, the State is a cooperating agency for TLMP amendments and revisions through 2013. We are committed to working with you throughout the remaining process. We strongly believe that an interagency effort that includes expertise in timber management, economics, and fish and wildlife science and management has the greatest chance of success.

In addition to the overview of our goals and policies above, specific comments on the DEIS and Proposed Amendment follow.

We look forward to working with you during the completion of the TLMP amendment process and implementation of the plan. I am confident that our collective efforts will result in a viable and widely supported plan amendment.

Sincerely,

Sarah Palin
Governor

DETAILED COMMENTS

Timber Issues

Timber Sale Thresholds. In this document, the State refers to three harvest levels that represent different thresholds for the timber industry.

- First, a volume of 83.5 million board feet (MMBF) is the bare minimum needed to keep existing Southeast Alaska mills in operation over the next one to two years while the supply of timber from the Tongass National Forest is increased. With this amount of timber, the existing mills could operate only a single shift daily and could not stay in business long-term.
- Second, 167.5 MMBF are needed to 1) allow the existing mills to operate two shifts daily, and 2) provide 30 MMBF per year for development of a new facility that utilizes low-value timber. This level of volume is necessary for efficient mill operation over the longer term, and for development of an integrated timber industry. This is the level of sales that must be achieved to support a sustainable timber industry in Southeast Alaska.
- Lastly, 231.7 MMBF would be required for the existing mills to operate at full capacity (three shifts daily) while still providing 30 MMBF for a facility to utilize low-value timber.

These volumes refer to the volume of economically feasible timber that is required annually, not the Allowable Sale Quantity (ASQ). See the section on Timber Sales and ASQ on page 8 for a more detailed discussion of this topic.

Timber volume. A stable, moderate-sized, integrated timber industry is an important component of a vibrant economy in Southeast Alaska, and is a feasible objective. To make this a reality, TLMP must provide a sufficient, stable supply of timber from the Tongass National Forest. Timber industry survival depends on a sufficient supply of economically feasible timber. This requires that at least 167.5 million board feet be offered annually, and that all timber sales be economically feasible for the purchasers. Economic considerations and expertise in timber harvesting must be included from the very beginning of timber sale design.

Timber supply and demand. The new analysis of the demand for Tongass timber prepared by Brackley et al. (2006), and released by the Pacific Northwest Research Station (PNW) is a significant improvement over the demand analysis prepared by Brooks and Haynes (1997), which was used in the 1996 Supplement to the DEIS and the 1997 Record of Decision. Specifically, Brackley et al. (2006) includes results from other analyses since 1996, describing the potential markets for Tongass timber if sufficient supply is made available (*e.g.*, McDowell 1999 and McDowell 2004). We disagree, however, with some of the assumptions that were made in the timber demand study by Brackley et al. (2006), and note that it did not consider several important factors affecting timber sale purchases.

First, the study failed to acknowledge the influence of timber supply on timber demand. Until a few years ago, the Southeast Alaska timber industry was set up to process all of the components of a timber sale, with the possible exception of some of the utility volume. Utility logs are

defined as cull logs with 50% chip volume. Low value and small diameter logs were being processed by Viking Lumber and Pacific Log and Lumber. Both mills also chipped the better quality utility logs for sale to the Pacific Northwest. They were also ready to provide the Ketchikan veneer mill with veneer quality logs. Shake and shingle mills were operating on Prince of Wales Island. The reason this partially integrated industry did not persist was the lack of a sufficient, long term supply of economic timber. Without a reasonable assurance of sufficient supply, the veneer mill could not continue to operate, forcing the existing mills to process this volume. The lack of a consistent supply also affected the existing mills' ability to fill the market requests for their products. The supply of timber was not enough to meet the market demands, and the mills lost part of their market share. At reduced production levels, the mills' costs per unit increased. Current mills are operating at just a third of their capacity or less. At this level of production, they must focus solely on high quality logs. If the existing mills (including the veneer mill) had a sufficient supply of timber to operate at full capacity, we would expect to have an integrated industry. Supply greatly affects the level of demand!

Second, high logging costs that result from poorly designed sales also affect the mills' ability to process all of the volume from the timber sales. Higher logging costs increase the delivered cost of logs to the mills, negating the mills' ability to process low quality and small diameter logs. Reducing the logging costs by providing economic sales would allow the mills to process all the volume from these sales, as they did in the past.

The quality of the timber in the timber sales is the third factor. Areas of non-merchantable timber should be excluded from timber sales. Tongass timber sales contain more and more non-merchantable timber. This strongly affects the economic viability of the sale and forces the purchaser to deal with unusable volume.

Finally, re-establishing an integrated timber industry in Southeast Alaska will require a means to fully utilize lower grades of logs. When the pulp mills ceased operation, there was no longer a market for low grade logs. This contributed substantially to the problem of uneconomic timber offerings in the Tongass. Efforts made by the USFS to address this problem in the short term have included offering some sales with the option of leaving utility volume in the woods, and granting more export permits for low grade hemlock. These measures have not been entirely satisfactory in addressing harvest economics, and the challenge of finding an economically viable means of utilizing the low grade timber remains. The timber industry should be given an opportunity to redevelop itself so that the full range of Tongass timber resources can be utilized and processed efficiently in the mid-term and long-term scenarios. The USFS should continue to support efforts to identify new products and markets for low-grade timber, and ensure that the Plan allows a harvest level that can support new operations that can use low-grade timber.

Timber Sale Design. As noted above, the timber sale planning process often fails to adequately incorporate timber sale economics into sale design decisions. Many proposed sales are not economically feasible, which defeats the purpose of the sale and wastes agency resources. Sales must be designed so that they still include sufficient economically feasible timber after meeting the requirements of the Conservation Strategy.

We request that the plan amendment and DEIS recognize that providing economically viable timber is the primary consideration for timber sale design within the sale boundary. Timber sales can be designed within the constraints of the existing Conservation Strategy, but only if economic feasibility is the clear goal throughout the design process. Except for site-specific concerns about endemic species of fish and wildlife[1], conservation requirements beyond those required by the Conservation Strategy should not be instituted for individual sales during the sale design process. A standard requiring economic timber sale design should be included in the section on Standards and Guidelines.

We also request that the USFS include personnel with experience and expertise in timber economics in all stages of the timber sale design process. The process should include people with a thorough knowledge of timber value, road construction and harvest costs, harvest methods, and access construction in Southeast Alaska. We look forward to working with you to accomplish this through the Economic Timber MOU between the State and the Tongass National Forest.

Timber sales and ASQ. Timber offered for sale must be economically feasible to have any value to the timber industry. Several factors result in a significant falldown between the ASQ set for the Tongass and the amount of economically feasible timber that is purchased and processed locally. Factors contributing to falldown include:

- In the sale design process, standards and guidelines established to protect non-timber values decreases the amount of timber available for harvest in a unit. This increases the cost of road access and the cost of harvesting the timber.
  - The Interdisciplinary Team (IDT) process used to design timber sales often fails to adequately incorporate timber sale economics into design decisions for individual harvest units and for total sales. Many proposed sales are not economically feasible, and are pulled from offerings prior to sale or are not purchased when offered.
    - Timber sales that are economically feasible are commonly subject to court challenges that delay or eliminate the sale.
      - Export is allowed on up to 50% of the timber in USFS sales. This improves the sale economics but decreases the volume that goes to support local mills.

As a result, the current timber supply to support local mills is actually far smaller than the ASQ volume. Based on work prepared for the bridge timber committee of the Tongass Futures Roundtable[2], 167.5 MMBF per year is required for the existing mills to operate efficiently (i.e., at two shifts per day) and allow for a facility to use low-value wood (see Appendix A). The existing mills need this volume to stay in business. Operating at full three-shift capacity would require 237.1 MMBF (see Appendix A).

---

[1] Endemic species are those that are prevalent in or peculiar to particular isolated localities.

[2] It should be noted that the TFR never adopted the bridge timber committee report. This work was done at the committee level and presented at a work session in Juneau on July 12-13, 2006. Some TFR members do not agree with the report's finding concerning mill capacity, which is a controversial subject. The mention of the TFR is not meant to imply an endorsement of this statement, but rather cites the source for where the work was accomplished.

Timber supply timing. If the amendment and implementation of TLMP fails to promptly provide sufficient economically feasible timber, the remaining family-owned companies that depend on Tongass timber will go out of business in the next few years. Even if the plan amendment is adopted and implemented quickly, there will be a lag between the current situation and a significant increase in timber sales. The federal timber pipeline is constricted at the top and has a weak outflow that may produce less then 25 MMBF of timber for purchase in the next year. At least 83.5 MMBF is needed to run a single shift at the existing mills – this volume could keep the mills in operation temporarily while timber flow increases, but it is not sufficient to support long-term operations (see Appendix A).

The year 2010-2011 is a crux year for timber supply. The old timber pipeline is not producing sufficient economic volume, a new pipeline under the TLMP amendment will not be flowing, and state bridge timber efforts will be nearing completion. Over the past three years the state stepped up its timber sale program in Southeast Alaska to supply some critically needed volume to the industry. However, this effort can continue for only 1-2 more years before reaching the cap on what the state can offer within its sustained yield capability of 12.8 MMBF per year. Federal timber sale volume for 2009 and 2010 is primarily in roadless areas where timber sales have been subject to litigation from the environmental community. Based on the USFS sale projections for the next five years, there is only enough volume in the pipeline to supply timber for Alternatives 1, 2, and 3, and that is only possible if there are no roadless issues. If appeals and litigation over roadless areas impede the timber sale process, there will only be enough volume for Alternative 1. The roadless issue must be resolved promptly to provide enough volume to keep the mills open even to 2010.

The state requests that the USFS promptly adopt and implement the TLMP amendment, and continue efforts with the TFR to find innovative and collaborative ways to keep timber volume flowing to the mills while a long-term management solution is crafted.

Second-growth and old-growth. The State strongly supports efforts to convert the current industry from old-growth timber to second-growth timber. However, it will take at least 50 years to reach the point where sufficient second-growth volume could be available to fully support the local industry. Continued harvest of old-growth timber will be necessary during the conversion period and may need to continue on a limited basis after that to provide sufficient economically feasible timber to meet demand.

Based on USFS studies on second-growth stands, the rotation age for second-growth stands should be at 90 years, not 160 years. Maintaining a 160-year rotation on second-growth stands will produce only enough volume for Alternative 1.

Converting the industry to second-growth manufacturing should result in intensive management and harvest of these second-growth stands. Changing just the rotation age will only provide enough volume for Alternatives 1, 2, and 3. Providing additional volume may require relaxation of current Standards and Guidelines (S&Gs) within second-growth areas. Some of the S&Gs established to protect wildlife in old-growth harvest areas do not reflect second-growth conditions, and may need to be applied differently in those areas. For example, we recommend allowing selective second-growth harvesting in the portion of beach and estuarine buffers that is more that 500' from the water, as well as within the portion of second growth riparian buffers that is more than 100' from rivers or streams. We anticipate this requiring project level review to define appropriate amounts and layouts for such harvests. Other guidelines that should be reviewed for possible revision in intensively managed second-growth areas include the S&Gs for marten and goshawks.

We recommend that the USFS emphasize pre-commercial thinning in second-growth stands that are available for harvest. The goal of the pre-commercial thinning is to shorten the rotation age from 160 years to 90 years, which will greatly increase the second-growth volume that is available for harvest. Pre-commercial thinning also creates openings in dense second-growth stands which have short-term benefits for wildlife. By contrast, commercial thinning is aimed at producing large, high quality logs. Mills designed to process second-growth are not likely to be able to handle large (>32" DBH) logs.

Conversion to a second-growth industry will be expensive. Existing mills must be replaced with new mills capable of efficiently processing smaller trees, and second-growth stands must be managed more intensively than old-growth stands. A second-growth industry uses mechanized harvesting equipment and manufacturing equipment specifically designed for smaller logs. After businesses convert to the new equipment, their ability to harvest and manufacture large logs will be severely limited. Sufficient second-growth volume must be provided to justify the capital investment. Much of the initial supply of second-growth is on outer islands where handling and transportation of small timber will be costly. Log transfer facilities (LTFs) will have to be secured and roads maintained to facilitate harvesting in second-growth areas. Finally, to be profitable, second-growth mills will have to process a larger volume of timber than existing mills, to offset the increased costs of handling more, smaller pieces of wood to produce a given volume. On the positive side, intensively managed second-growth stands should produce more volume per acre than typical old-growth stands.

Concentrated vs. dispersed timber harvest areas. Concentrating timber harvesting may benefit both the timber industry and wildlife conservation, and is an approach suggested previously by the State. Allowing more intensive harvest of timber within certain areas -- especially in areas that are already roaded -- may reduce the need for roads into new areas. Reducing the footprint of logging on the landscape would likely reduce the cost of logging operations and decrease the area affected by new timber harvesting. Human access, ATV use, hunting, trapping, and fishing typically increase along new roads, even if they are closed to vehicular use after logging. Potential benefits could accrue to wildlife if concentrating harvest areas allows conservation of more high-value old-growth. Timber management strategies that minimize road development are generally better for certain wildlife species and should be considered whenever possible. Roads pose one of the greatest risks to fish habitat on the Tongass, and minimizing road development often benefits fish as well.

Existing S&Gs apply throughout the Tongass. S&Gs contribute to the high cost of harvesting timber in the Tongass and reduce the available timber. The plan should strive to identify areas where harvesting would have relatively low impacts on other resources and focus harvesting on these areas. Within these areas, timber should be managed intensively to improve economic feasibility and timber volume output. The goal for these areas would be continued second-

growth production and harvest rather than a return to old-growth conditions. Concentrating harvest areas to reduce impacts may require conscious tradeoffs in the application of S&Gs between intensively harvested areas and other more sensitive lands. In intensively managed areas, S&Gs might be loosened in exchange for applying more stringent requirements in other areas.

This approach assumes that more impacts occur to wildlife if logging activity is dispersed. This assumption should be tested through studies to confirm whether it is correct and assess the benefits and impacts of concentrating harvests in intensively managed areas.

Fish and Wildlife Issues

Best available data. Use the best available information for evaluating impacts to fish and wildlife and establishing the Conservation Strategy. At a minimum, the amendment should include a synthesis of key findings from the 2006 Conservation Strategy Review workshop, incorporate the findings into the Final EIS where possible, and identify when and how other study results will be addressed subsequent to adoption of the amendment. Appendix C of our comments includes a summary of new information from the workshop that is relevant to the Conservation Strategy. This includes information presented by State staff on specific species (e.g., goshawks, forest birds, wolves, deer, marbled murrelets, and brown bears). Appendix D of our comments includes a list of associated references and cited literature.

Sustainability. The Plan protects habitats capable of providing for viable, well-distributed populations of fish, wildlife, and other resources, but also recognizes a need to provide for a variety of uses, including subsistence harvests, big-game guiding, fishing charters, and wildlife viewing programs. The standard for fish and wildlife population levels should be based on sustainability rather than viability. A sustainable population provides for both human use and biological survival; viability only guarantees survival in the absence of human use. A standard of sustainability is consistent with the State of Alaska's constitution.

Conservation Strategy

Old-growth reserves. The system of small, medium, and large old-growth reserves (OGRs) is, and must remain, the cornerstone of the wildlife conservation strategy. The reserve system provides a safety net for the conservation of habitat for minimum viable populations. It was not designed to ensure habitats necessary to provide for the sustained yield use of key fish and wildlife populations in the locations where the public has a history of subsistence or recreational harvest. For the reserve system to ensure sustainable populations of wildlife, it must include plant communities whose structure and composition are representative of the forest types. Reserves should be established in proportion to their occurrence and abundance across the Forest before widespread logging. The reserves also need connectivity to allow for animal movements. Finally, they must be well-distributed across biogeographic provinces and larger islands, as well as across the range of elevations and aspects. Failure to adhere to these design principles will jeopardize sustained yield and increase risks of extirpation for some wildlife species on the forest. Insights on this are offered by Cushman et al. (2006; see Appendix D).

Some of the timber management options under consideration in this plan revision would require modifications or reductions to the existing OGR system. While the state recommends assessing possible flexibilities within the Conservation Strategy, any relaxation of existing requirements must not unduly compromise the conservation of fish and wildlife habitats. Changes that reduce the OGR system will increase the risks associated with maintaining viable populations of some wildlife species and eventually could lead to consideration of listing species, subspecies, stocks, or endemic populations under the Endangered Species Act. Recent wildlife surveys have shown significant levels of mammalian endemism on some islands within the forest. In these isolated areas, current reserves may not be adequate to maintain an acceptable level of risk for population viability. We encourage the USFS to work with other agencies to assess such risks and consider alternative conservation measures.

Small OGRs: Specifications and design requirements for establishing small OGRs were included in the 1997 TLMP; however, many small OGRs were never finalized, some were subsequently relocated, and several have been blamed for creating issues for timber sale reviews and analyses. As a result, the USFS, Fish and Wildlife Service (USFWS) and ADF&G reviewed all small OGRs to resolve remaining issues of size and location, and map the final small OGRs in the TLMP amendment. We supported this goal and contributed significant amounts of staff time and expertise to the process. USFS district staff reviewed the recommendations from the interagency group, and with few exceptions agreement was reached on their final configuration and placement. The Forest Supervisor subsequently reviewed all the small OGR decisions and changed roughly 40% of the agreed upon locations. The interagency group reconvened to assess and comment on these changes.

At the time of this review, the group expressed discomfort with some of the placements and agreed to place the reviewed small OGRs into one of three categories: (1) those that were considered biologically preferred (IOGR), (2) those that were not considered biologically preferred, but could be accepted (FPOGR), and (3) those that were not considered to be acceptable and should be further evaluated as part of project level reviews (PROGR).[3] The group also identified 13 small OGRs that raised especially high levels of concern for wildlife. These were later reviewed cooperatively by the group and Forest Supervisor, and resulted in 4 being classified as IOGR, 6 as FPOGR, and 3 as PROGR. Overall, of the 238 small OGRs identified on the Tongass, it is our understanding that 133 (56%) are now classified as IOGRs, 58 (24%) are classified as FPOGRs, and 47 (20%) are classified as PROGRs. We encourage the USFS to review future PROGRs with an eye to timber operability and economics as well as fish and wildlife conservation. Overall, we conclude that the newly proposed sizes and locations for the small OGRs are better than they were previously.

Since the adoption of the 1997 Forest Plan, small OGRs have been examined and adjusted during project level reviews. In most cases, the result has been growth in the gross acreages included in OGRs and a reduction in available timber. Appendix B shows the resulting reduction in suitable and available acres by project over the past 10 years. Of particular concern is that project-level reviews removed more than 5,100 acres of Productive Old Growth (POG) from the suitable land base during 1998 – 2005 (USDA, unpublished 2005 monitoring report found at http://www.fs.fed.us/r10/tongass/projects/tlmp/2005_monitoring_report/#1).

[3] IOGR = Interagency OGR; FPOGR = Forest Plan OGR; PROGR = Project Review.

This steady erosion of the timber base presents a significant obstacle to maintaining a viable timber industry in Southeast Alaska. Therefore, we appreciate the joint effort under way to map final locations of small OGRs across the Tongass. We urge that this cooperation continue beyond the current planning effort and further urge that transfer of POG from the suitable land base into small OGRs be kept to the minimum necessary to achieve the stated wildlife goals and to satisfy the criteria in Appendix K of TLMP.

Medium OGRs: The interagency OGR group only reviewed small OGRs. The USFS has modified some medium OGRs, and some of the existing medium OGRs do not meet the minimum requirements specified in Appendix K of TLMP. We do not know how these changes and conditions will affect the Conservation Strategy, and we urge the USFS to undertake an interagency assessment of medium OGRs. This process should include state and federal expertise on both wildlife conservation and timber management. We further urge the USFS to do this as soon as possible in order to avoid limiting or eliminating suitable options to meet requirements for the size, placement, and composition of medium OGRs.

Beach and Riparian Buffers. In 1997, forested beach buffers were extended from 500 to 1,000 feet. This extension reflected the value of this habitat to a host of wildlife species, including river otters, mink, bears, wolves, Sitka black-tailed deer, bald eagles, goshawks, and others. Beach buffers are a key component of the Conservation Strategy and must be retained. At the same time, we recognize the utility of allowing some selective timber harvesting of second-growth within beach buffers, to the extent that it accelerates a return to characteristics of the old-growth condition and is a benefit to wildlife. For this reason, we recommend allowing selective harvesting of second-growth timber in the portion of beach and estuarine buffers that is more than 500' from the water, and within the portion of riparian buffers that is more than 100' from rivers and streams. We do not support the use of beach buffer or riparian buffer areas for old-growth harvesting.

Forested buffers along all Class I and II streams are critical elements of the Conservation Strategy. Class I and II streams provide valuable spawning and rearing habitat for species of Pacific salmon, trout, and char, and forested riparian buffers along Class I, II, and III streams provide protection from erosion, sedimentation, and temperature increases.

Class III streams are also a component of the Conservation Strategy and are important sources of water, energy, nutrients and organic matter for downstream reaches. Land uses along headwater streams influence this linkage with downstream areas (Wipfli 2005). At the same time, we appreciate that implementation of Class III stream buffers can reduce the timber base and create difficulties for timber economics. This issue is further complicated by mis-classification of some Class III streams. Field verifications of Class III streams often occur during the drier summer months, when fish typically are not present. As a result, some streams classified as Class III may actually provide fish habitat and have fish present at some time during the year and should be reclassified as Class I or II streams. In other cases, some streams classified as Class III streams may be more accurately classified as Class IV.

We recommend that the USFS in consultation with the State, develop objective criteria and protocols to use for stream classifications, and train USFS staff in application of the classification criteria. We also urge the USFS to use existing flexibility in the Class III guidelines to protect water quality and downstream fish habitat in a manner that is practical for timber harvesting. Lastly, we would like to discuss with the USFS, industry, and other agencies and groups flexibilities within the existing Class III S&Gs, and would be willing to discuss possible alternatives to existing stream buffer requirements for Class III streams, provided that they assure conservation of habitats for fish and wildlife.

Riparian buffers are important to wildlife, including river otters, which are known to use cavities adjacent to inland streams as natal dens (Woolington 1984), and to brown bears, which strongly select for these areas during the salmon spawning season (Schoen and Beier 1990, Titus et al. 1999, Flynn et al. 2007). They also provide critical connectivity between old-growth reserves and are important for maintaining the ecological function of small OGRs.

Marten & Goshawk / Legacy Forest Structure Standard and Guideline. Under the amended plan, a new "Legacy Forest Structure" (legacy) S&G is proposed as a substitute for the existing "Marten and Goshawk" S&G. We understand this change is being proposed because: (1) the existing S&G is not particularly effective for conservation of marten and goshawks, and (2) the marten and goshawk S&G creates significant difficulties from a timber harvesting standpoint (feasibility, safety, and cost).

The proposed legacy S&G would apply when the harvest levels in various planning units exceed set thresholds, much as it does under the existing marten and goshawk S&G. However, unlike the requirement for trees to be individually dispersed or clumped under the marten and goshawk S&G, the legacy S&G could result in trees being retained primarily along the back edges of cutting units. Following are our observations and uncertainties associated with replacing the existing marten and goshawk S&G with the proposed legacy S&G. These are follow-ups to two letters sent by ADF&G to the USFS on this subject during September, 2006.

1. To the best of our knowledge, there is no supporting science for adopting the legacy S&G. At the same time, it is our understanding that the proposed legacy S&G does not significantly benefit the timber industry. To better understand this, we encourage the USFS to include in the FEIS a scientific assessment for the proposed legacy alternative. Without that assessment, we have no information with which to assess any benefits of the S&G to marten or other wildlife populations. At the same time, because the legacy S&G provides less habitat value for martens, it cannot be considered a replacement that would maintain the same level of risk. We also encourage the USFS to include a quantitative analysis of how the marten and goshawk S&G has been applied, and the extent to which the existing S&G has impacted timber harvesting activities. Included in the analysis should be the number of units that have been harvested in a manner that results in retention of "individual trees" versus retention of "clumps" of trees; the average size of retained trees; the amount of retained timber that has been suitable and merchantable versus non-developable or non-merchantable; and how the implementation of the S&G has affected the design of safe and economically feasible timber sales. Also, we would appreciate clarification of the proposed legacy S&G relative to the amount of timber harvesting that would be allowed. As presented, it appears that there is no upper limit to the amount of harvesting that could occur within areas where this S&G would be applied. It seems to us that leaving 1/3 of the old-growth with each successive entry could result, in the extreme, in having only 3 trees left in a given area and still being able to harvest 2 of them. There should be a lower threshold for remaining old-growth within areas below which no more timber harvesting is allowed.

2. It is our understanding that the current marten and goshawk S&G includes flexibility to locate retention trees in ways that facilitate safe and economically feasible timber sales. For example, retention trees may be clumped to avoid conflicts with logical cable settings. We would appreciate affirmation or correction of this understanding. Additionally, we encourage the USFS to ensure that training and policy direction for unit lay-outs are clear and well understood so that available flexibilities can be used to better provide economically feasible timber sales.

3. The possibility of intensifying timber harvesting in some areas while avoiding or minimizing harvesting in other areas may require some level of flexibility within existing or newly-developed S&Gs. These flexibilities should be explored as a way to better provide economically feasible timber harvesting while also providing conservation of fish and wildlife habitats. We suggest that an interagency assessment of the implications of such action on marten, goshawk, and other wildlife be undertaken as part of this effort. This cooperative assessment should also include an effort to identify areas where concentrated timber harvesting may occur.

4. Regardless of what S&Gs are ultimately adopted, there should be an assurance that trees retained for wildlife should not be logged commercially or for personal use over the life of the rotation. With each new forest plan revision, the need for and amount of wildlife habitat retention should be re-evaluated. Moreover, efforts should be made to locate old-growth retention in places where it is not susceptible to catastrophic blow-down. Where feasible, in instances where blowdown, landslides, or disease kills >75% of retention trees, we suggest harvesting the downed trees and designating an equivalent amount of old-growth for retention elsewhere in

Endemic Species. [4] A considerable amount of new information about island endemic animal species, including new wildlife taxa and distribution information, was presented during the April 2006 CSR Workshop. This information has significant management implications for maintaining sustainable populations of wildlife and should be summarized and included in the TLMP amendment. The plan should include considerations for adjusting timber harvest on islands as more information becomes available about the habitat associations and population status of endemic species.

Fish passage. The DEIS states that the culvert replacement program declined in 2006 due to funding reductions and is projected to continue to decline in future years (DEIS, page 3 –55). This is a concern to us and we suggest that the culvert replacement program be given a higher priority to increase the possibility of funding. Culvert replacement and maintenance will only

[4] Endemic species are those that are prevalent in or peculiar to particular isolated localities.

become a greater issue in the future as more culverts are put in place and existing culverts continue to age and deteriorate, thereby further restricting fish passage.

Fish and Wildlife Management in Research Natural Areas and Experimental Forests. We request that the final plan amendment clarify that Research Natural Areas and Experimental Forests will not preclude the State's management responsibilities for fish and wildlife, including use of various facilities, such as weirs or radio towers, necessary for state wildlife or fisheries management purposes. ADF&G is the primary manager of fish and resident wildlife in Alaska, regardless of land ownership. Approval from the Director of the Pacific Northwest Research Station should not be required to conduct routine management responsibilities in these areas. The USFS has recognized the State's authorities regarding fish and wildlife through the USFS-ADF&G Master Memorandum of Understanding (MOU), which was re-signed in 2004. In addition, a national-level MOU between the Association of Fish and Wildlife Agencies and the Forest Service/Bureau of Land Management spells out respective responsibilities for fish and wildlife management in designated Wilderness

Fish management in Wild, Scenic, and Recreational Rivers. In Alaska, USFS management of potential wild, scenic, and recreational river corridors applies only to uplands. Restrictions on public use are subject to the Alaska National Interest Lands Conservation Act (ANILCA), including Section 1110(a). However, the proposed management prescriptions for scenic and recreational rivers contain language that appears to restrict activities below the ordinary high water mark. For example, we question language in the management prescriptions discouraging weirs from potential scenic and recreational rivers. Most weirs do not impede stream flow or river traffic and are temporary structures that are removed at the end of the project or season. Nothing in ANILCA or the National Wild and Scenic Rivers Act prevents use of temporary structures in designated or potential wild and scenic river corridors. For potential wild and scenic rivers in designated Wilderness, Section 1315(b) of ANILCA allows for improvements and facilities such as fish weirs and other structures to restore or maintain fish production on national forests.

In November 1982, the Alaska Land Use Council approved "A Synopsis for Guiding Management of Wild, Scenic, and Recreational Rivers in Alaska" (Appendix 1). The Department of Agriculture, along with the State of Alaska and the Department of the Interior approved the guidelines. We suggest reviewing these guidelines and revising the "Management Prescriptions for Wild, Scenic, and Recreational Rivers" section, as appropriate, to ensure management prescriptions are consistent with these approved guidelines.

Off-highway Vehicle Access for Subsistence. The proposed plan amendment is not consistent with ANILCA provisions for off-highway vehicle (OHV) access. Under the plan, trails and routes for off-highway vehicle use will be "closed unless opened" through a District access and transportation plan. Additionally, in some land use areas, OHV trails may only be designated where documented local traditional use has occurred and the route is compatible with the land use designation objectives.

ANILCA provisions require that subsistence and other ANILCA protected access "shall" be allowed, subject to "reasonable regulation." This "open until closed" approach is a cornerstone

of ANILCA and the USFS cannot supersede this legislative intent by a national policy document. The Department of the Interior adopted regulations at 43 CFR Part 36 that outline a specific closure process that includes public notice and hearings. The State of Alaska advocates that the USFS adopt parallel regulations for ANILCA-protected access and address the discrepancies between the national policy and ANILCA. We remain available to assist the USFS in this effort.

Section 811 of ANILCA ensures that rural residents engaged in subsistence uses "shall" have reasonable access to subsistence resources on all federal public lands in Alaska by use of snowmobiles, motorboats, and other means of surface transportation traditionally employed for subsistence purposes. Such access includes off-highway vehicles where such methods were used generally in the area prior to ANILCA.

We urge the USFS to work with the State of Alaska and affected subsistence users in all districts on the Tongass National Forest to identify trails, routes, and areas where subsistence off-highway vehicle access occurs to ensure subsistence access is not inappropriately closed. Any closure or restriction of OHV use for subsistence purposes must use a regulatory process as addressed in Section 811(b). Please note that our comments should not be construed as categorical opposition to all OHV closures. We know there are several compelling reasons to seek OHV closures, such as public safety or to protect resources. This does not absolve the USFS from adhering to the required processes under ANILCA.

Status of Appendices. Our understanding is that sections of the 1997 TLMP that are not specifically revised by this amendment remain in effect, including Appendix K (Old-growth Habitat Reserve Criteria) and Appendix N (Additional Evaluation of Wildlife Habitat Conservation Measures). These appendices contain procedures that are integral to implementation of the Conservation Strategy. We request that they be retained in the FEIS and plan amendment except where explicitly changed during the amendment process. Please clarify the status of these appendices.

Information needs for the Conservation Strategy were addressed in Appendix B of the 1997 TLMP. The limitation of this appendix is that it was created as a static list of studies that were priorities at the time the Plan was developed. Funding for research and monitoring is limited and we need a dynamic, well-defined process to identify and prioritize information needs, and compare results against original hypotheses. ADF&G is working with the USFS and USFWS to develop such a process. When complete, this process should be included in Appendix B of the Plan amendment and FEIS. The new process will be more practical and achievable than the past focus on just Management Indicator Species (MIS), although future monitoring will continue to address at least some of the existing MIS. With new DNA (Taberlet and Luikart 1999; Mills et al. 2000; Lukacs and Burnham 2005) and modeling (MacKenzie et al. 2006) techniques and capabilities, wildlife monitoring can now more efficiently and cost-effectively provide useful information about population sizes and trends. We recommend these alternative approaches to monitoring be incorporated into future interagency discussions and funding allocations.

Scenery and recreation guidelines

Scenic Designations. Restrictions on harvest (such as requiring helicopter yarding, tree selection harvests and other partial cutting prescriptions) in the Scenic Viewshed and Modified Landscape LUDs greatly reduce the volume of economic timber that can be produced from areas so designated. In fact, it is often questionable whether a timber sale in these LUDs will be capable of meeting a reasonable economic test. Therefore, the State is concerned about how much economic timber these areas can actually contribute to a sustainable timber industry. The State therefore urges the USFS to immediately convene a joint federal-state process to identify areas that can be re-designated from Scenic Viewshed and Modified Landscape to Timber Production. This process should incorporate information from affected parties, such as the cruise industry and other recreation businesses. The State's expectation would be that underlying requirements of the Conservation Strategy, that restrict or prevent timber harvesting (such as OGRs) would remain intact in these areas.

Karst and Cave resources. The proposed plan allows "limited recreation development" on sites that have been identified as "highly-vulnerable karst lands." Recreation development should not be allowed on highly-vulnerable karst land.

Funds for pre-commercial thinning are limited. The USFS should prioritize thinning on second-growth areas that will be available for future harvesting and can benefit wildlife, rather than on karst areas where timber harvest is not allowed.

Recreation and Tourism. The most significant growth in tourism and recreation activities within the Tongass National Forest over the past decade has been in the volume of cruise passengers. Shore-side tours and recreation activities have grown in abundance and focus in several communities, most notably Hoonah. Commercial sport fishing ventures continue to be a substantial part of the local economy in many Southeast Alaska communities.

None of the proposed alternatives is likely to have a significant impact on tourism and recreation activities over the life of the Plan. The niche market for eco-tourism is likely to remain unaffected, since Wilderness and LUD II designations remain unchanged and the Plan, in all its alternatives, would continue to set aside vast acreages for remote and semi-remote recreation.

Only road-based recreation opportunities are constrained by the proposed amendment of the Forest Plan in any of its iterations. These opportunities could be expanded under Alternatives 4, 5, 6, and 7. Contrarily, Alternatives 1, 2 and 3 would likely not provide for significantly expanded road-based recreation opportunities.

Recreation Opportunity Spectrum and Encounter Rates. It is unclear whether encounter rates set out under the proposed forest plan are a hard-line indicator of public use, where management action would be taken to reduce use if rates are exceeded, or if they are meant as guidelines for visitor expectations within a given land designation. We encourage the USFS to use encounters as guidelines for public expectations and not as firm indicators for measuring the satisfaction of recreation experiences.

Land management agencies often use encounter rates to measure solitude and visitor satisfaction. However, in many cases, solitude is not an important factor in determining satisfaction. Instead, surveyed users often cite other factors such as the weather or mosquitoes as more important factors in visitor studies. In addition, blanket encounter rates often do not take into account variability of terrain and vegetation. In areas of dense undergrowth, an encounter rate of three groups per day may cause a greater negative reaction from some users than in open terrain areas.

Economic diversity

Mining. Some alternatives would have a direct negative effect on future mineral development opportunities within Southeast Alaska. We note the following specifics gleaned from the DEIS pages 3-269 – 280.

1. Fifty-two areas totaling 589,000 acres within the Tongass contain identified mineral resources. Of these, 25% are in areas withdrawn from entry. Under the current Plan, 29% of the open areas are in Land Use Designations (LUDs) that result in higher cost of entry if these resources were to be developed. Under Alternatives 1-3 this percentage increases, with Alternative 1 being the highest at 41%; under Alternative 6 it would remain the same; and under Alternatives 4 and 7 it would decrease to 23% and 22%, respectively.

2. Of the identified mineral tracts, 377,000 acres are considered Rank 1, having a "high potential" for being developed. Fifteen percent of the area in Rank 1 tracts is withdrawn from entry. Of the acres open to mineral entry, the current Plan places 30% in LUDs that result in higher cost of entry. Under Alternatives 1-3 and 6, this percentage would increase. Under Alternative 4, it would decrease to 24%, and under Alternative 7 it would decrease to 22%.

3. There are 6.6 million acres of potential, but undiscovered mineral resources within the Tongass. Of these, 989,000 acres are estimated to have a high or moderate likelihood of yielding a mineral resource that could be developed. Thirty-eight percent of this acreage is withdrawn from entry. Of the lands that are open to entry, the current Plan allocates 39% to LUDs that result in higher cost of entry. Only Alternatives 4 and 7 would reduce the percentage significantly (to 28% and 26%, respectively), while Alternative 6 would reduce it slightly (to 38%). Under Alternative 3 it would remain unchanged from the current Plan, under Alternative 1 it would increase to 51%, and under Alternative 2 it would increase to 46%.

Some of these changes are likely to prove to be a disincentive for companies considering new mineral exploration and development investments in Alaska and are therefore of concern to the State of Alaska. Mineral exploration, development, and production can be a critical component of a vibrant economy in Southeast Alaska, as it is in other parts of the State. Mineral activity can also be done in an environmentally sound manner, as is the case at Greens Creek and in other parts of the State. The TLMP should encourage responsible mineral investment in Southeast, and the final alternative should minimize the amount of land with a higher cost of entry.

Community impacts. The DEIS section in Chapter 3 that covers effects on each community fails to mention the Icy Straits Lumber Company sawmill and its role in the economy of Hoonah (pp. 3-520 to 3-524). Please add this to the FEIS.

Impacts to state land

The State believes that the impacts to State lands under all of the alternatives have been adequately addressed in the DEIS. In addition, the State believes that the potential cumulative impacts to State lands have been adequately identified and discussed in the draft DEIS.

Sealaska Entitlement

The DEIS, particularly in Appendix C but reflected in several other sections, misrepresents Sealaska's ANCSA land entitlement and out of withdrawal selection proposal by exaggerating potential negative effects of the proposal and largely ignoring the benefits. The State believes that fulfilling the entitlement will yield overall net benefits for the Southeast economy, environment, and culture, and the potential adverse effects are not significant.

The State believes that Appendix C should recognize that completing conveyances of land to Sealaska in a sustainable configuration is an entitlement under ANCSA and a priority for stabilizing Tongass National Forest management as well as the broader Southeast Alaska economy. The Appendix should not treat Sealaska's land entitlement and adjustment proposal as a negative encumbrance on the USFS or the public interest.

APPENDICES

Appendix C - Species-specific comments on wildlife
Appendix D – Citations

Appendix A -- Industry Needs for Bridge Timber

This table was prepared by the Bridge Timber Committee of the Tongass Futures Roundtable. The TFR never adopted the Bridge Timber Committee report. This work was done at the committee level and presented at a work session in Juneau on July 12-13, 2006. Some Roundtable members do not agree with the report's finding concerning mill capacity, which is a controversial subject. The mention of the TFR is not meant to imply an endorsement of this statement, but rather cites the source that accomplished the work.

Sawmills	Total Volume Needs (MMBF) for bridge timber at 66% of mill capacity 1/	Total Volume Needs (MMBF) for bridge timber at full mill capacity 1/	Survival Volume Needs 3/ (MMBF)
Viking Lumber Company	53.0	80.0	25.0
Pacific Log and Lumber	22.0	33.6	22.0
Silver Bay Logging Company	43.0	65.0	25.0
Icy Strait Lumber Company	13.0	20.0	5.0
Small Sales	5.0	7.0	5.0
Micro Sales	1.5	1.5	1.5
Veneer Mill			
Ketchikan Veneer Mill 2/	30.0	30.0	25.0
Total	167.5	237.1	108.5

1/ Mill capacity needs from Juneau Economic Development Council (Dan Parrent).
See chart on following page.

2/ Estimate of need. Gateway Forest Products did not operate sufficiently to establish capacity.
3/ Milll survival capacity needs from phone conversations with mill owners 8/06 (C. Maisch)

Existing mills in operation can operate on a yearly flow of volume noted. Mills like Silver Bay (currently being considered for sale with no USFS timber under contract) and the Ketchikan Veneer Mill will need to acquire volume under contract prior to start-up operations. This volume is critical in order to obtain operating capital from lending institutions. Without volume under contract, mills will not be sold and can be expected to be dismantled to recoup some of current mill owner investment.

8/06 Notes: Volume for mills must be economical volume and is not considered the most efficient operating level by mill owners. For example, Viking Lumber would operate at a two shift level if volume was available and the veneer mill would run two shifts. Veneer mill would add a second shift approximately 3 months after resuming operations. The most efficient operating level for all mills is a 2 shift or higher basis.

[5] Prepared by Dept. of Commerce, Community, and Economic Development based on information provided by the USFS, including published accounts in project-level decision documents.

[6] The Cholmondeley project modified both a small and a medium OGR. All other changes affected small OGRs only.

Appendix C – Species-Specific Comments on Wildlife

Queen Charlotte Goshawk

Environment & Effect: We suggest that the USFS revise some of the background information, as portions of the species summary are inaccurate (DEIS, page 3-161). As currently portrayed in the proposed Plan, the understanding of the relationship between goshawk habitat and forest management is less now than when the 1997 plan was developed. However, the opposite is true. Both in Southeast Alaska and across their range, knowledge of goshawks and forest management has increased. The use of available literature in the DEIS, both unpublished and in journals, is poor or missing. None of the annual or final Southeast Alaska specific reports produced by ADF&G are referenced (e.g., Flatten et al. 2001) and none of the diet studies published by Lewis and colleagues (2006) are referenced. It is also unfortunate that none of the numerous and relevant goshawk studies published over the past decade were used in the plan amendment, particularly those from the Pacific Northwest.

Examples of mis-portrayed information include statements such as: "The northern goshawk inhabits forested lands throughout North America . . ." This statement is not accurate as many eastern forested lands do not have goshawks. In the next sentence, the background information notes that the Queen Charlotte goshawk is a distinct subspecies and cites Iverson et al. (1996) as the reference. Rather than citing Iverson et al. (1996), the document should list the primary references where the subspecies is described or its taxonomy is accepted (e.g., Taverner1940, AOU 1957, Whaley and White 1994).

The USFS should consider the habitat associations of key goshawk prey as a tool for sustaining goshawks (Reynolds et al. 1992, Reynolds et al. 2006). The first step in this process should be to use diet data from Lewis et al. (2006) and determine the habitat associations of key prey (for examples, see Reynolds et al. 1992, and Drennan 2006).

While some available information suggests that important goshawk prey species (e.g., grouse, red squirrels) can be negatively impacted by even-aged silvicultural practices (Doerr et al. 1984, Carey 1995, Russell 1999), there is a lack of information on how these practices specifically affect sooty (formerly known as blue) and spruce grouse, red squirrels, medium to large forest passerines (e.g., varied thrushes, Steller's jays), and woodpeckers. We recommend that studies of these prey species in Southeast Alaska focus on how alteration of forest structure and landscape patterns specifically affect their abundance and availability to goshawks. For goshawks, management should focus on their habitat needs and accompanying prey base for long-term viability and sustainability on the Tongass.

The paragraph starting on page 3-161 and ending on page 3-162 of the DEIS implies that findings from the analysis of goshawk telemetry data in Southeast Alaska produced similar results to those observed in the southwestern United States (Boyce et al. 2006, Reynolds et al. 2006). It is specifically stated that when mature forest habitats are not available, goshawks will nest in younger forests or in smaller patches of trees and forage in young forests as well as along edges and in openings (Boyce et al. 2006, Reynolds et al. 2006). However, this has not been observed with great frequency in Southeast Alaska. A few nests have been found in older

second-growth (~80-100 year old stands) and use of this type of habitat is known to have occurred in other areas (Squires and Kennedy 2006). Telemetry data from radio-tagged birds has been analyzed a number of times and consistently suggests strong selection for old-growth forest habitat. Past interagency attempts to evaluate habitat selection relative to edge have resulted in no detectable patterns, noting that the Tongass GIS layers are probably not well suited for such an analysis for goshawks.

Based on research conducted on the Tongass and multiple peer reviews related to the 1997 forest plan, we believe that conversion of mature forests to even-aged second-growth will negatively affect goshawks. Not only do dense second-growth habitats keep goshawks from entering them to hunt (affecting availability of prey to goshawks), but they likely affect the abundance of goshawk prey as well. For example, there is no information about goshawk numbers on Prince of Wales Island prior to the large-scale logging that took place in the last half of the 20th century; however, very few goshawks are now found on that island and nest failure has been documented there. This is likely due to an inability of goshawk pairs to capture and deliver sufficient food to their young (Lewis et al. 2006).

The USFWS is soon to rule on the remand of their decision not to list the Queen Charlotte Goshawk, and will be issuing a new 12-month finding. The goshawk is also listed as a threatened species in British Columbia. Given these conditions, the USFS should consider retaining all conservation guidelines for goshawks in the final TLMP amendment. The initial decision to not list the Queen Charlotte Goshawk was based on the conservation measures included for goshawks in the existing TLMP. ADF&G has consistently noted over the past decade that the science does not support listing the goshawk in Southeast Alaska. If the conservation measures are changed, it leaves open the possibility that any decision by the USFWS could again be remanded. Reference could be made to the results of the genetic study of goshawk relatedness in the west-coastal region of North America (Talbot 2006).

Standards and Guidelines: Most of our comments below suffer from not having a draft appendix to evaluate the context of the proposed S&G changes. We request that the USFS complete such a science-based management document for the proposed goshawk changes. All proposed S&G changes for goshawks have been discussed in an interagency context for at least the past three to four years.

K. 1. b. page 4-98 It is unclear why "alternate" is added and "inactive" is deleted. By definition, a nest that is an alternate in any given year, is an inactive nest. We have information from the Tongass and elsewhere indicating that some alternate nests are used in subsequent years.

K. Deletion of monitoring requirement. We support removal of the need to "monitor" known goshawk nests because of the extensive time and money needed to do so. However, the effect of this is confusing because of the word change from "alternate" to "inactive" as described above. We suggest the continuation of USFS inventories to determine the presence of nesting goshawks in proposed project areas unless and until an alternative approach is developed and described. We further suggest using the most current inventory protocols developed in cooperation with the appropriate State and Federal agencies (Woodbridge and Hargis 2006). We encourage the USFS to describe their approach for monitoring goshawks in the FEIS.

K. 1. d. page 4-98 The Goshawk S&G regarding nesting sites appears to be based on the USFS's need to incorporate flexibility into the S&Gs for goshawk nest sites. We agree that flexibility is useful for land managers; however, moving the decisions to a landscape assessment or some other mid-scale analysis process is vague. As mentioned above, the operating rules for this flexibility and the science behind the decisions and alternatives need to be defined in an appendix to the FEIS, rather than as part of a future planning effort. This appendix should include the variety of conditions that would bring about the "alternate management" of goshawk nest sites.

K. 1. e. As mentioned above, we request the inclusion of an appendix where these science-based management details are described. We recognize that flexibility regarding goshawk nests located in contracted timber sale areas is warranted. The loss of such nest areas is probably not critical to goshawk viability, depending on how many times this situation occurs. Unfortunately, the plan does not mention the fact that as monitoring declines, there is an ever increasing probability that active and inactive goshawk nest trees will be harvested. Even when pre-timber sale monitoring occurs, there is a high likelihood that active goshawks nesting areas will be missed. Therefore, finding goshawk nests in areas already under sale or contract, or proposed for sale, will decrease as monitoring decreases.

Forest Birds

The S&G entitled "Endemic Terrestrial Mammals" (TLMP, page 4-129) should be expanded and re-titled "Endemic Terrestrial Wildlife." It should include surveys for rare and endemic birds, as well as amphibians and insects that may represent unique populations with restricted ranges.

Surveys for other nesting raptors in proposed management areas should include forest owls, specifically western screech-owls, barred owls, and northern saw-whet owls.

Deer and Wolves (General Comments)

The TLMP amendment DEIS does not take into account scientific findings available after 1997. We request that it be revised to incorporate recent research based on a thorough literature review.

The deer Habitat Suitability Index (HSI) model presented on page 3-165 purports to estimate carrying capacity for deer during an average snow winter. However, this does not provide protection in the event of severe snow conditions. Severe winters may drive deer and predator-prey dynamics long after an event has occurred. For example, in Game Management Unit (Unit) 3 (i.e., Mitkof, Kupreanof, Etolin and Zarembo islands), the severe winters of 1969 and 1971 resulted in a major crash in the deer population. It has taken over 30 years for that population to recover, largely because predation retarded recovery long after the severe winters. Planning for severe winter events is the best policy when considering protection of winter habitat for deer. The deer HSI model fails to do this. Further, climate change predictions for Southeast Alaska indicate the likelihood of extremes of warm and cold during future winters, along with much greater precipitation. That may mean occasional extreme snowfalls, not unlike what was experienced during the 2006-2007 winter. It would be wise, therefore, to emphasize the need to

retain winter habitat for deer and calculate HSI under the assumption that all areas are at risk of deep snow. This would result in more scientifically credible evaluations.

Wolves (specific comments)

Page 3-169, first paragraph: The discussion of habitat use by wolves needs to refer to and summarize Person (2001), otherwise it is out of date.

Page 3-169, second paragraph: This information is incorrect and needs to be updated. Wolf numbers are limited by prey availability, not social interactions. This section should refer to and summarize the appropriate sections in Mech et al. (1998) and Fuller et al. (2003). The density limit of 10 wolves/ mi^2 is incorrect. For example, Isle Royale has had densities of wolves that substantially exceeded that limit.

Page 3-169, fourth paragraph: Units 2 and 3 support modest wolf densities compared to other areas where wolves prey on deer rather than moose, caribou, bison, and other larger prey. While wolf densities are high in Units 2 and 3 compared to the rest of Alaska (where deer are absent), they are not high when compared to other areas where deer are the principle prey (i.e., northern Minnesota, southeastern Ontario, and coastal British Columbia). More information on this is available in Person et al. (1996, 2001). The wolf population in Unit 2 is currently healthy but that does not imply it will be in the future when more of the landscape is in stem-exclusion forest. Current populations are not indicators of the future. Reference should be made to the concept of "succession debt," described by Person (2001).

The statement referring to a harvest objective of 39 wolves in Unit 2 is incorrect, and should actually be about 90 wolves, depending on available population estimates.

Page 3-170, first paragraph: The road density guideline in the TLMP amendment was purported to be based on analyses described in Person et al. (1996); however, the guideline has never been implemented in a manner consistent with Person et al. (1996). The 0.7 mi/mi^2 is to account for all open, closed, or overgrown roads in areas below 370 meters elevation, not simply open roads. This approach has been used because we have found it impossible to distinguish between open and closed roads, and further, the definition of what constitutes "open" versus "closed" roads is vague (i.e., some roads may be passable with snowmachines or ORVs). Even roads that are overgrown are used as hiking trails, providing easier access for wolf trapping and snaring. Additionally, the denominator should be land area below 370 meters because the vast majority of wolf activity occurs in this area (Person et al. 1996, Person 2001). The road density guideline should be applied at a scale equal to an average wolf pack home range (300 km^2) (Person et al. 1996). The incorrect use of the guideline has been brought up in numerous interagency meetings since 1997, but has never been corrected. We again recommend using the guideline described by Person et al. (1996).

The den buffer guideline has not been supported by scientific data. Information presented during the CSR Workshop indicated that the guideline needs revision. The guideline for roads is the most important because roads facilitate chronic disturbances long after timber harvesting activities are completed. Suitable areas for dens would only have a 45% probability of selection by wolves if a road was within 600 feet of the den (Person in prep, Conservation Strategy

Review Workshop). Moreover, as presented during the CSR Workshop, dens may be unused for up to 5 years before being used again.

Page 3-170, second paragraph: This paragraph implies that there is no established link between habitat changes and wolf populations. This is incorrect based on research findings (Person and Bowyer 1997, Person 2001, Mech et al. 1998, Fuller et al. 2003, and Fuller 1989). Wolf populations will increase and decline in response to changes in prey populations, and any habitat changes that affect prey will affect wolves. This has been modeled and presented in Person (2001) and Person and Bowyer (1997), along with projected effects of habitat change on wolves and deer in Unit 2. Additionally, Farmer et al. (2006) provide information on habitat features that influence predation. We recommend revising this paragraph to include information from the published literature identified in our list of references (see Appendix D).

Page 3-207, first paragraph under Alexander Archipelago wolf: Deer are not required for wolf persistence if other ungulate prey are present (i.e., moose, goats, or sheep). However, their densities will be much lower and home ranges much larger. Details on this are presented in Person et al. (2001) and other works such as Mech et al. (1998), Fuller et al. (2003), and Fuller (1989). Gaps in wolf distribution may occur, particularly on islands where deer numbers decline substantially, but the likelihood is that home ranges will get larger and wolf densities lower rather than experiencing local extirpations. That said, as deer numbers decline, there will likely be increased pressure from subsistence users to reduce wolves in an effort to protect deer. Under that circumstance, poorly managed hunting and trapping seasons and illegal killing could result in local extirpations. The implications of this are compounded because wolves in Southeast Alaska have low genetic diversity (e.g., the population in Unit 2 shares 1 mtDNA haplotype (Weckworth et al. 2005)). Lowering densities may therefore result in further reductions to genetic diversity. This would be especially true in small populations that are isolated on islands.

Page 3-207, second paragraph under Alexander Archipelago wolves: This section should be revised after referring to Person (2001). Specifically, reference should be made to the consequences of the non-linear density-dependent shape of change in deer populations in relation to carrying capacity (K) and how predation will affect deer numbers as K is reduced due to timber harvesting. This will lead to a better understanding and appreciation for how habitat changes will likely affect predator-prey dynamics. This is published in Bowyer et al. (2005), Person (2001), and Person et al. (1997), and much of it was presented during the CSR Workshop.

Pages 3-207 and 3-208: No mention is made of results from Person (2001) or Person and Bowyer (1997) concerning population viability and TLMP alternatives. That work provides insight concerning how the new alternatives might affect wolf-deer predator-prey dynamics. Results from wolf Population Viability Analysis (PVA) for Prince of Wales (POW) Island indicated that a substantial reduction of wolves and deer is likely under the current forest plan (Person 2001, Person et al. 1997). Any alternative that increases road development or logging from the current plan is likely to reduce the wolf population to very low levels. Add to that the higher risk of hunting and trapping mortality (legal and illegal) due to the perception that wolves are competing with hunters for deer, and the viability of wolf populations on POW could be compromised. Further, there is no mention of information provided at the CSR Workshop showing the relationship of undeveloped land with the ratio of recruitment to mortality of

wolves. Information presented during the workshop indicated that the ratio of recruitment to mortality approaches 1 for wolf packs occupying home ranges with < 44,000 undeveloped acres. That finding should be compared with existing OGRs to see how many may actually have a high probability of supporting source populations of wolves.

Page 4-127, TLMP: The new information provided at the CSR Workshop, along with findings published since 1997 have not been included in the S&Gs. The road guideline is still implemented incorrectly and the denning guideline is not consistent with available information. Given the noted disparity between the existing S&Gs and existing supporting scientific materials, we encourage the USFS, in consultation with the State, to consider revising the S&Gs in the Plan amendment or future Plan revisions.

Deer (specific comments)

Page 3-164, second paragraph under deer, fourth sentence: This sentence should read "The quantity, quality, distribution, and arrangement of winter habitat are considered the most important limiting factors for deer."

Page 3-165, first paragraph: It is unclear whether the USFS is using the deer HSI model correctly. The 1997 description of the model and its application was incorrect with respect to the deer multiplier. The highest HSI value (whether it is scaled to 1.0 or 1.3) should correspond to a density of 100 deer/mi^2.

Page 3-165, second paragraph: The first sentence states that the deer HSI model provides a tool for risk assessment. This is not true. There are no probabilities associated with the HSI index so it cannot be used to assess relative risk, only relative HSI values. For example, we do not know how much risk is associated with a difference in an HSI of 0.1. Further, as Bowyer et al. (2005), Person (2001), and Person et al. (1997) showed, an increment change in deer carrying capacity (which is what HSI supposedly represents) could lead to a much larger increment change in deer numbers due to the non-linear dynamics associated with predation. Therefore, there is no quantifiable risk associated with HSI values.

The paragraph describes the "FRESH" deer model but fails to include any mention of the other deer models presented at the CSR Workshop. The FRESH model cannot be extended from a stand level analysis to a landscape scale. It does not predict availability to deer due to patch size, location on the landscape, risk of predation, fragmentation, or connectivity. All of those features have a significant, if not primary, role in predicting habitat quality for deer (see Farmer et al. 2006, Kie et al. 2002). By itself, the FRESH model will be of very limited value as a replacement for the current deer HSI model.

Page 3-165, third paragraph: The statement on sources of predation should be clarified. Neonate fawns were not captured on Mitkof Island and bears were therefore not identified as a significant source of mortality to study animals. If neonates had been collared, the results would likely have shown substantial predation by black bears. Given their paucity on Heceta Island, black bears are not a major predator on fawns. However, on POW Island, where black bears are abundant, we observed significant black bear predation on neonate study animals (ADF&G, unpub. data).

We suggest deleting the last sentence in the paragraph because of its inaccurate context. That is, citing statistics for the Tongass as a whole (a forest of islands) is misleading given local differences in impacts. The amount of old-growth habitat remaining on POW Island, for example, will be substantially less than elsewhere on the forest and will thereby have more severe localized implications for wildlife and associated users.

Page 3-192, first paragraph under Sitka Black-Tailed Deer: It is inaccurate to say that the difference in magnitude of the HSI values when using the size-density forest classification versus the original classification is unimportant because only relative values are compared between alternatives. That is true only when the model is used to compare changes in HSI between alternatives. It is not true when applying the deer guidelines for wolves and subsistence. In those applications the magnitude of deer habitat capability is very important.

Page 3-194, third paragraph: This paragraph should discuss the effect of lowering K on deer populations exposed to wolf predation. Deer numbers likely will be reduced much more than predicted by changes in HSI because of the non-linear relation between K, deer recruitment, and predation. Please refer to Bowyer et al. (2005), Person (2001), and Person et al. (1997).

Page 3-194, last paragraph: The first sentence in this paragraph should note that there is great uncertainty about the effects of second-growth management on the availability of forage to deer. The value of treatments, the scale of treatment effects, and the potential of treatments to be implemented at scales meaningful to deer populations is unknown at this time. This paragraph makes no mention of Farmer et al. (2006). In that study, a positive relation was observed between risk of death of fawns and pre-commercial thinning. Also, Farmer et al. (2006) demonstrated that landscape level features play a large role in determining risks of death for deer. TWYGS and other studies do not address the scale, distribution, and arrangement of treatments on the landscape. Those factors will be as or more important than the amount of forage produced.

Elk

Page 3-179, fourth paragraph: Although a radio collared cow elk was located on Farm Island, at the mouth of the Stikine River, there is no evidence of any collared elk migrating up the Stikine River drainage (ADF&G, unpub. data).

Marbled Murrelets

The marbled murrelet should be identified as a Sensitive Species on the Tongass. We believe that the USFS would be remiss in not listing this species as part of the TLMP amendment given that they are known to be old-growth dependent for their nesting. Sensitive Species are defined as "those plant and animal species for which population viability is a concern on National Forest System (NFS) lands within the region. Either a significant current or predicted downward trend in population numbers or density, or a significant current or predicted downward trend in habitat capability that would reduce a species' existing distribution indicates a viability concern." The best available information suggests that marbled murrelets have declined by nearly 80% in Southeast Alaska since the early 1990s (Piatt et al. 2007).

The referenced literature on marbled murrelet ecology in Southeast Alaska should be updated. Cotter and Kirchhoff (2007) and Piatt et al. (2007) summarize existing data on marbled murrelets in Southeast Alaska, including new information on population status and trends, distribution, and habitat relationships.

The TLMP amendment should display the effects logging will have on marbled murrelet habitat under each of the alternatives. Preferred nesting habitat for marbled murrelets includes older trees, larger trees, and trees on steeper slopes (Schoen and Dovichin 2007, Appendix B). Habitat capability for marbled murrelets has declined significantly from past logging (Piatt et al. 2007), and will decrease further under the new Plan. These effects should be displayed in the FEIS.

Page 3-174: The Plan should show how much marbled murrelet habitat is protected by the OGR system. The Plan references the forest-wide system of OGRs as helping meet the conservation needs for marbled murrelets. Although any retention of old-age trees helps, a quantitative assessment of how effective these old-growth reserves might be is needed.

Page 3-174: "Uneven-aged management" should be specifically defined. Uneven-aged management "in many areas" is cited as mitigation for loss of marbled murrelet nesting habitat, yet the term is not specifically defined. To judge the effectiveness of this prescription for marbled murrelets, information on gap sizes and interspersion of individual trees or patches in the cutting units should be provided.

Page 4-128: Providing 600' buffer zones around discovered marbled murrelet nests (XVI. B.) provides no effective benefit. Marbled murrelet nests are extremely difficult to find because most are high up in old-growth trees, the birds are quiet on the nest, and they travel to and from nests in the dark. The fact that it was the last species in North America to have its nest discovered underscores the futility of an S&G that requires finding nests. We suggest dropping this S&G and re-establishing past murrelet surveys.

It is unclear what USFS supported marbled murrelet research and monitoring is ongoing. Appendix B (page B-11) lists a number of information needs for marbled murrelets (items 8, 13, and 15), and indicates the USFS is currently funding marbled murrelet studies. ADF&G has signed a cooperative agreement with the Juneau Ranger District to work together as opportunities present themselves. Beyond this, however, we are unaware of any USFS related marbled murrelet studies on the Tongass.

The USFS commitment to doing marbled murrelet surveys is unclear. In the early 1990s, the Ranger Districts across the Tongass embarked on rigorous training for doing at-sea surveys, and established numerous transect routes across the region (Piatt et al. 2007, Appendix M). Unfortunately, the surveys were not continued. This represents a big loss because it now appears from limited data that marbled murrelets are in serious decline. It is not clear whether identifying this as an "information need" in Appendix B constitutes a commitment to resume the surveys or not. We request that surveys be reinstated.

Martens

New information presented at the CSR Workshop indicated that two genetic lineages of martens occur on the Tongass NF (Cook et al. 2006). Based on genetic research, these authors suspect that the two lineages of marten found in Southeast Alaska actually represent two distinct species; *Martes americana* and *M. caurina*. If so, *M. caurina* has an extremely limited distribution in Southeast Alaska (Kuiu and Admiralty islands only) and globally (from northern California to Admiralty Island). Because of the limited distribution of *M. caurina*, these populations should be given special management consideration. Furthermore, given Flynn et al.'s (2004) finding of low marten populations on Kuiu Island, we encourage further research of marten on that island to better assess implications of forest practices and possible management measures (i.e., state and federal trapping seasons, federal habitat management).

Page 3-167. We suggest adding text (underlined) to the statement about marten habitat: The <u>larger-sized</u>, old-growth forest habitats have the highest value for marten.

In order to clarify the marten harvest for Kuiu Island, that island's harvest should be separated from harvests for the rest of Unit 3.

Page 3-168, last sentence. This statement needs clarification. We contend that the lack of any "clear correlation" between marten population trends and habitat changes reflects a lack of effort to study this dynamic rather than indicating no relationship. Determinations of population trends require long-term data sets, and these have not been collected. Consequently, modeling habitat changes is the best that can be done at this time.

Brown Bears

Substantial new information is available on the importance of riparian habitats for maintaining sustainable and high brown bear populations (Flynn et al. 2007). This new information is consistent with and further supports maintaining no-cut buffers along salmon spawning streams. The implementation of the current brown bear buffer was left to field reviews without easily measurable criteria. Recent research results indicate that field evaluations for identifying important brown bear feeding areas may be difficult to complete and will yield ambiguous results. Given the lack of mapping for lands buffered for brown bear foraging, it is difficult to evaluate the effects of implementing the current S&G.

Based on current information, the following recommendations are made regarding no-cut, riparian buffers for brown bears:

Page 4-124, TLMP, IX Bear Habitat Management: We suggest modifying the brown bear S&G to provide for no-cut buffers along all salmon spawning streams based on work conducted by Flynn et al. (2007) and presented at the CSR Workshop. This could be incorporated into section IX. B., as follows (replacement text is underlined):

> <u>B. Provide for</u> additional protection of important brown bear foraging sites in addition to the buffers already provided by the Riparian and Beach & Estuary Fringe Forest-wide Standards and Guidelines, and the old-growth Habitat and other natural setting Land Use Designations. Establish no-cut forested buffers, where available, of <u>at least</u> 500 feet from the stream at sites where additional protective measures are needed to provide cover among brown bears while feeding, or between brown bears and humans. This no-cut buffer should be applied more broadly than the current S&G which is unclear in application. In high density brown bear areas (e.g., ABC islands), all segments that support spawning salmon are important for foraging during the late summer and these need careful evaluation for protection. On the mainland, where brown bear numbers are lower and patchy in distribution, the no-cut buffers may be particularly important.

Page 3-168. We suggest revising this section to more accurately describe the distribution of brown bears north of Frederick Sound. For example, while it is true that brown bears occur on islands north of Frederick Sound, this is not all-inclusive (i.e., Douglas, Lincoln, Shelter islands do not currently support brown bears).

Reference is made to brown bear hunting being allowed in Unit 4. However, this statement needs to be expanded to reflect the fact that brown bear hunting is allowed throughout other parts of Southeast Alaska. Additionally, we suggest adding a statement or two about guide/outfitter uses of brown bears on the Tongass as well as available viewing opportunities (i.e., Pack Creek, Anan Creek).

The section suggests that the late summer season is the most critical time period for brown bears. No references are provided despite many available publications by ADF&G (i.e., Titus, Flynn, others), USFS researchers (i.e., Gende) and others (i.e., Ben-David). Some of these publications along with recent ADF&G experience suggest that spring is also a critical time for brown bears across Southeast Alaska. The estuarine beach and certain riparian habitats are key for providing certain sedges and grasses as the first food of the season for bears. Therefore, conservation of the beach buffer remains an important attribute of the forest plan for this species.

Preliminary results from an interagency, cooperative mainland brown bear study suggest differences between brown bear ecology on the mainland (e.g., Misty Fjords, Bradfield Canal) versus the very high density populations that have been well-studied in Admiralty and Chichagof islands. We suggest that the less abundant and patchy distribution of estuarine and salmon spawning habitat in the mainland may be very important for maintaining sustainable brown bear populations in these areas. ADF&G staff will work with USFS staff to help interpret results from this ongoing work for better, long-term management of mainland brown bears.

Fish

Page 3-56: The information used to characterize sport fisheries and the data used to describe fishing effort and demand appears to be rather dated. We recommend that the most recent information available from the ADF&G Statewide Harvest Survey (SWHS) be used.

Page 3-52: The table of fish species important for sport, subsistence, and commercial fisheries does not include Dolly Varden char and cutthroat trout as being important for subsistence (Table 3.6-1). These should be included here.

March 26, 2007

Forrest Cole
Forest Supervisor
Tongass National Forest
Attn: Forest Plan Adjustment
648 Mission Street
Ketchikan, AK 99901

Dear Mr. Cole,

The 1997 TLMP Revision is hurting the communities of Southeast Alaska. Since the revision, Wrangell, my hometown, has suffered a 20 percent decline in population due to the suppression the timber industry has faced. The residents who have chosen to stay in Wrangell have faced layoffs and serious financial hardship because the resource that they have depended upon for their livelihood has been taken away from them.

The industry decline is due primarily to the drastic restriction of the timber supply from the Tongass. The markets for lumber have been very good over most of the last decade, and the timber production has never once exceeded the market demand.

The timber supply constraints take two forms:

1. Not enough timber volume is planned and prepared and,
2. Most of the timber sale volume that has been prepared is too costly to be profitable despite the good markets the industry has experienced.

The industry has studied their timber volume needs and reaffirmed those estimates with independent economists. The consensus is that about 360 million board feet of timber is needed from the Tongass to support a sustainable, fully-integrated manufacturing industry.

I have discovered four elements of the 1997 TLMP conservation strategy that are causing most of the high cost:

1. The old-growth reserve strategy, which sets-aside the lowest cost, highest value timber in every harvest area

June-Dec, Wrangell: PO Box 109 • Wrangell, AK 99929 • *ph:* (907) 874-3088 • *fax:* (907) 874-3055
Rep.Peggy.Wilson@legis.state.ak.us • http://www.akrepublicans.org/wilson/ • 1-800-686-3824

2. The marten and goshawk Standard and Guidelines which require that we leave 30% to 50% of the timber standing in every harvest unit in most of the previously developed areas
3. The beach-fringe buffers which were increased from 500-feet to 1,000-feet in 1997
4. The blanket application of class-3 (non-fish) stream buffers

Alternative 7 for the TLMP Amendment is the option that makes the most sense, and I urge you to adopt it. It is the only option that supplies the necessary volume and incorporates a conservation strategy that does not have the devastating economic consequences of the 1997 conservation strategy.

Sincerely,

Peggy Wilson

Tongass National Forest
Attention: Forest Plan Adjustment
648 Mission Street
Ketchikan, AK 99901

I am writing to express my concerns and provide comment on the Tongass Land Management Plan Amendment Draft EIS. There are several issues regarding the Tongass National Forest that are important to Alaska and her citizens that I wish to address in the following comments.

The timber industry was once a vital economic engine for the State of Alaska and Southeast Alaska in particular. It is no longer the predominant factor it once was, but due to a variety of circumstances, it is our concern in the Alaska Legislature that we explore all possible avenues as we move forward with our efforts to diversify Alaska's economy. A rejuvenated forest products industry in Southeast Alaska could play a significant role in our efforts along those lines.

In searching for a meaningful proposal to invigorate the timber industry within the Tongass, it is important to note that we do not endorse any reduction in the effort to maintain a viable and healthy forest for the many other uses engaged in by the citizens of Alaska, or of the rest of the nation. We encourage the Forest Service to continue important protections for fish and wildlife habitat, as well as the recreational opportunities those resources supply.

With the above general thoughts and points in mind, I would like to highlight a few more specific, salient points that I believe should be considered as this process moves forward. First, I would like to say that the Tongass Futures Roundtable discussions hosted by the Nature Conservancy and the National Forest Foundation should be allowed to move forward with some assurance that the solutions they are able to conceive may be incorporated into this plan. Although the comment period is ending it seems that a stipulation allowing for further adjustments would be in order considering the level of community participation in the Roundtable.

The current allowable sales quantity (ASQ) appears to be sufficient considering the amount being accessed by existing timber operations. However, it would seem prudent to build some flexibility into the plan. It should be imperative to provide an alternative that has the greatest opportunity for the Forest Service to react to changing conditions. It may be for the time being that an ASQ of 200 to 300 mmbf is adequate, but if market conditions are such that a greater volume is necessary, then the plan ought to be open to increases in market demands.

Careful consideration must also accompany strategies that are based on less than sound science. If there is incontrovertible evidence that conservation imperatives are necessary to sustain species within the forest then accommodations should be made for those strategies that will provide viable options for sustaining and recovering such species. However, the Forest Service and the Congress should seek legislative and regulatory parameters that bar the use of strategies that hamper sound economic and recreational uses by those who oppose multiple uses of our forest for philosophical reasons.

It appears there are recognized conservation needs resulting from some uses practiced in the past. It is my understanding that there may be cases where corrective measures to restore habitat to functionally productive states provides alternative economic opportunities for contractors. If that is the case, the plan should make use of those companies that are actively engaged in the forest products industry to provide man power and machinery to such recovery efforts. Such a strategy would enhance the economic viability of our existing logging companies.

I realize this is a major planning process with many intricate relationships between the forest itself and the various user groups among the public. That being the case, it seems the best interests of most people would be accommodated with a plan that supplied an adequate supply of timber to maintain current operations while holding the door open for changing market demands which may increase or decrease. The plan should carefully structure any use or activity so as to provide the best options to sustain the forest habitat and associated fish and wildlife populations. Last of all, the plan should accommodate reasonable economic and recreational activities as closely as possible to a multiple use framework.

I would like to thank the Forest Service for this opportunity to express my views on this important subject to Alaska. I hope my comments offer some constructive views as you work toward formulating an acceptable working plan for the Tongass. If you have any questions or would like to discuss further any of the comments reflected in this letter, please do not hesitate to contact my office.

Sincerely,

John Harris
Speaker of the House

SENATOR BERT K. STEDMAN

April 30, 2007

Mr. Forrest Cole
Forest Supervisor
Tongass National Forest
Federal Building
Ketchikan, AK 99901

Dear Supervisor Cole:

I appreciate the opportunity to comment on the draft Tongass National Forest Plan Adjustment.

It's obvious that your team put a great deal of work into this adjustment to bring it into compliance with recent court orders. I have comments I would like you to consider in finalizing the plan.

For over a century, the United States Forest Service has managed our national forests and grasslands to provide for multiple uses. The Tongass National Forest provides recreational, mining, logging, hunting, and tourism opportunities, as well as providing the spawning grounds for one of the best fisheries in the country. It is important that all of these uses receive equal consideration under the new management plan.

In recent years, timber has not received this equal consideration. Since long before statehood, timber has been a mainstay of the Southeast economy, providing steady, well-paying and, most importantly, year-round jobs to many residents. In addition to the good jobs, communities benefited from the shared revenue generated by timber sales.

There are a dozen sawmills operating in Southeast employing over 150 residents and providing significant stimulus to the region's economy.

DISTRICT A
Ketchikan • Sitka • Petersburg • Wrangell
Pelican • Elfin Cove • Port Alexander • Saxman • Myers Chuck • Thorne Bay • Coffman Cove • Hollis

April 5, 2007
Page 2

However, they are woefully under capacity. In order for these mills to survive and compete effectively on the world market, a stable and sufficient timber supply is vital.

I realize that you must balance many interests as you move carefully towards an acceptable management plan. I firmly believe that timber harvesting can coexist with other activities in the Tongass and ask that you recognize the great benefits of a healthy wood products industry in Southeast when setting the final timber harvest levels.

Best regards,

Bert K. Stedman

RE: Corridor Omissions from the Tongass Land and Resource Management Plan

Dear Plan Preparers,

The Draft Environmental Impact Statement for the Tongass Land and Resource Management Plan is incomplete. It does not include eight Essential State Transportation and Utility Corridors listed in the Southeast Alaska Transportation Plan. Omitting these corridors is not an acceptable outcome to the State of Alaska.

Background

In 2004, the Southeast Alaska Transportation Plan was adopted as a component of the Alaska Statewide Transportation Plan. It identifies a total of 34 Essential Transportation and Utility Corridors that must be reserved and protected to meet future transportation needs. The Executive Summary of the plan specifically requests that the Forest Service incorporate each corridor into the Tongass Land and Resource Management Plan.

Affected Environment discussion

The text of pages 3-229 and 3-230 fails to explain how only a subset of the 34 corridors were incorporated into the Tongass Land and Resource Management Plan. Apparently, the Forest Service is confused because a subsequent Memorandum of Understanding did not include all 34 corridors.

Remedy

Revise the Tongass Land and Resource Management Plan so that the management prescription includes the Transportation and Utility overlay for each of the 34 corridors. Depict all 34 corridors on alternative maps. Revise the discussion of Affected

25A-T34LH

Environment to specify the preeminence of the entire set of 34 corridors with respect to the subsequent Memorandum of Understanding.

In conclusion, please revise the Tongass Land and Resource Management Plan per the above.

Thank you for the opportunity to comment.

Sincerely,
DOT&PF Southeast Region

Malcolm A. Menzies, P.E., L.S.
Regional Director

cc: Andy Hughes, Regional Planning Chief

APPENDIX A. ESSENTIAL STATE TRANSPORTATION AND UTILITY CORRIDORS

Essential Transportation and Utility Corridors

The Southeast Alaska Transportation Plan (SATP) identifies 34 essential highway and utility corridors to be reserved and protected to meet future transportation needs. These corridors are required to connect communities to the regional transportation system and to establish a regional power grid. The state requests that the Forest Service incorporate all of these highway and utility corridors into the Tongass Land Management Plan and reserve and protect these corridors for these purposes. Adoption of this plan is an official expression of state policy that no other action by any other party should be taken (such as designations of wilderness areas) that would interfere with public use of any of the mapped corridors. In addition, the state requests that the Forest Service contribute to state efforts by improving and connecting forest roads that are located within essential road corridors identified by the state. Corridors of particular interest are Kake - Petersburg, Kake - Totem Bay, and North Prince of Wales Island Road - Red Bay.

In a region as rugged as Southeast Alaska, valleys and mountain passes represent invaluable corridors for highway routes and utility transmission lines. Maps 16 to 23 identify the transportation and utility corridors considered essential to the state. These corridors are identified below.

Corridor Descriptions

Lynn Canal Corridors — Juneau to Haines and Skagway

1. From Echo Cove northerly along the shore of Berners Bay and Lynn Canal to Skagway with a ferry terminal near the mouth of the Katzhin River.

2. From Skagway southerly along Taiya Inlet to Taiya Point, then northwesterly along Lutak Inlet to Haines.

3. From Haines across the Chilkat River/Inlet at or above Pyramid Island, then southerly along the west shore of Lynn Canal to a suitable ferry terminal site on William Henry Bay.

Taku River Corridors

4. From Thane Road southeasterly along Gastineau Channel to Bishop Point, then northeasterly along Taku Inlet to a suitable bridge crossing at Grizzly Bar.

5. From Jaw Point northeasterly along the southeast shore of Taku Inlet and River to the Canada border to provide ferry crossing options.

Mansfield Peninsula Crossing, Admiralty Island, Corridor

6. From Young Bay to Greens Creek, Hawk Inlet.

Chichagof Island Corridors

7. From a suitable ferry terminal site on Whitestone Harbor to Hoonah.

8. From Hoonah to a suitable ferry terminal site on Tenakee Inlet.

9. Pelican cut-off road from Tenakee Inlet Road to Pelican.

10. Kadashan Road from a suitable ferry terminal site on Tenakee Inlet southeasterly along the Kadashan River to a suitable ferry terminal site on the north shore of Peril Strait across from Rodman Bay.

Baranof Island Corridors

11. From the end of Halibut Point Road to a suitable ferry terminal site on Rodman Bay.

12. From the end of Sawmill Creek Road to a suitable ferry terminal site on Warm Springs Bay.

Kuiu Island Corridor

13. From a suitable ferry terminal site on Security Bay to a suitable ferry terminal site on Reid Bay for crossing Sumner Strait to Labouchere Bay on Prince of Wales Island.

Kupreanof Island Corridors

14. From Kake to a suitable ferry terminal site in Kupreanof for crossing the Wrangell Narrows.

15. From Kake to a suitable ferry terminal site in Totem Bay for crossing Sumner Strait to Red Bay on Prince of Wales Island.

Prince of Wales Island Corridors

16. North Prince of Wales Island Road from the intersection with Coffman Cove Road to a suitable ferry terminal site in the vicinity of Red Bay on Sumner Strait.

17. Neck Lake Road from North Prince of Wales Island Road easterly along Neck Lake to Wale Pass.

18. Cavern Lake Road from Wale Pass westerly to North Prince of Wales Island Road.

19. Caulder Road from North Prince of Wales Island Road near El Capitan northwesterly to a suitable ferry terminal site on Labouchere Bay.

20. North Prince of Wales Island Road north, then west from Cavern Lake Road to a suitable ferry terminal location on Labouchere Bay.

21. Sandy Beach Road from Thorne Bay north to Ratz Harbor, then along the east shore of Prince of Wales Island to Coffman Cove.

Mid-Region Access Corridors

22. Stikine Delta Causeway to South Mitkof Island to Rynda Island to Kadin Island to mainland, near Green Point, then along the eastern side of Eastern Passage to a bridge crossing point at "the Narrows."

23. Stikine River Corridor (according to the Alaska National Interest Lands Conservation Act [ANILCA], Section 1113).

24. A bridge crossing Eastern Passage at the Narrows between Wrangell Island and the mainland.

25. East side of Eastern Passage from the Narrows south to Bradfield Canal, then east along the north side of Bradfield Canal to the Bradfield River at the head of the Bradfield Canal.

26. Bradfield Road from the head of the Bradfield Canal along the North Fork of the Bradfield River to the Canada border at the Craig River.

27. From the head of Bradfield Canal along the south side of the Bradfield Canal west to Duck Point (or other suitable ferry terminal site on the Bradfield Canal).

Wrangell Island Corridors

28. From Zimovia Highway easterly along McCormack Creek, to Eastern Passage, then southerly to a suitable ferry terminal site on Fools Inlet.

29. From Zimovia Highway easterly along McCormack Creek to Eastern Passage, then to the Narrows bridge crossing site.

Cleveland Peninsula Corridors

30. Upper Cleveland Peninsula crossing from Bradfield Canal southeasterly along Eagle River to Point Lees to a suitable ferry terminal on the Behm Canal.

H-A52

Lower Cleveland Peninsula crossings:

31. From a suitable ferry terminal site on Santa Anna Bay southeasterly to a suitable ferry terminal site on Spacious Bay.

32. From a suitable ferry terminal site on Frosty Bay south to Santa Anna Bay, then southeasterly to Spacious Bay, then south to Port Stewart and along the southwest shore of Port Stewart to a suitable ferry terminal site on Helm Bay.

Revillagigedo Island Corridors

33. From a suitable ferry terminal site at or near Claude Point, then southwesterly via Benrer and Klam creeks to Shrimp Bay, then easterly to Cedar Lake and Orchard Creek, then southeasterly along Orchard Creek to a south branch extending toward Carroll Creek, then south to Carroll Inlet, then south along the west shore of Carroll Inlet to Shelter Cove, then westerly to the head of George Inlet to Ward Lake Road.

34. From the head of George Inlet south along the west shore of George Inlet to the end of South Tongass Highway.

TONGASS NATIONAL FOREST
2007 DRAFT ENVIRONMENTAL IMPACT STATEMENT
AND
TONGASS LAND AND RESOURCE MANAGEMENT PLAN AMENDMENT

COMMENTS SUBMITTED BY ALASKA ENERGY AUTHORITY

1. INTRODUCTION

A Ninth Circuit Court ruling in 2005 and the January 2005 "5 Year Plan Review" set the stage for the amendment to the 1997 Tongass National Forest Land and Resource Management Plan. The Draft Environmental Impact Statement (DEIS) responds to the 2005 Court decision[1] and adjustments recommended during the recent 5-Year Review of the Forest Plan. A companion document, Proposed Land and Resource Management Plan represents the complete Forest Plan including all proposed amendments. Land and Resource Management Plans are required by the National Forest Management Act (NFMA) of 1976.

The Alaska Energy Authority (AEA) is pleased to provide comments on the DEIS and Proposed Tongass Land and Resource Management Plan (Tongass Land Management Plan or TLMP) dated January 2007.

The AEA, created by in 1976 by the Alaska Legislature, is a public corporation of the state of Alaska with a separate and independent legal existence. The agency is responsible for the administration of various state power projects and programs.

AEA Mission: Reduce the cost of energy in Alaska.

"AEA projects and programs support its mission by 1) providing for the operation and maintenance of existing Authority-owned projects with maximum utility control, 2) assisting in the development of safe, reliable, and efficient energy systems throughout Alaska, which are sustainable and environmentally sound, 3) reducing the cost of electricity for residential customers and community facilities in rural Alaska, and 4) responding quickly and effectively to electrical emergencies." (Emphasis added)

AEA Interest in the DEIS and Tongass Land Management Plan

The 16.8-million acre Tongass National Forest is the largest forest in the National Forest System (NFS) and remains for the most part wild and undeveloped. Approximately 71,000 people live in 32 communities and other areas located on islands or on the mainland coast. Developed areas cover about 1.50 million acres, or about 9% of the Forest. Only 8 of the 32 communities have populations greater than 1,000 persons. The economies of SE Alaskan communities rely on the Tongass National Forest to provide natural resources to support local sustainable economies: fishing, timber harvesting, recreation, tourism, mining, and subsistence activities.

[1] Ninth Circuit Court's decision in *Natural Resources Defense Council vs. U.S. Forest Service* (421 F.3d 797, August 5, 2005)

Most of the communities in Southeast (SE) Alaska are dependent on isolated sources of electricity; only Haines and Skagway, Petersburg and Wrangell, and several communities on Prince of Wales Island enjoy electric transmission interconnections.

Most existing and proposed transmission lines in SE Alaska are and/or would be located on lands within the Tongass National Forest, thereby requiring federal approval to site, construct, and operate proposed facilities. Exceptions include line segments located in the Metlakatla Indian Community on Annette Island, a federal reservation, and certain lands that have been conveyed to the state of Alaska and Native Alaska Corporations.

Since July 2006 AEA is participating actively with communities and electric utilities in SE Alaska through the AK-BC Intertie Steering Committee, Work Group, and Technical Group (AK-BC Intertie Committee/Groups) to conduct investigations and develop information in support of the proposed southern SE Alaska Intertie Plan, including the export line to British Columbia. An overarching goal of the interconnected electric transmission system is to provide least cost alternatives to diesel-generated electricity and to allow communities to remain economically sustainable, resulting in jobs for Alaskans.

In November 2006 AEA contracted with Hatch Acres Corporation to evaluate engineering, economic and political factors for development of a transmission interconnection from SE Alaska to British Columbia (AK-BC Intertie).

Several meetings were held in Ketchikan, Anchorage, and Juneau with the AK-BC Intertie Work Committee/Groups for the purpose of discussing potential future scenarios for an interconnected system within southern SE Alaska and the viability of the proposed AK-BC Intertie. Consultations have been ongoing with the Forest Service during development of the proposed system and AEA expresses its appreciation for the information provided by Forest Service staff throughout preparation of reports.

On April 6, 2007, AEA issued the Draft Final Report of the Alaska-British Columbia (AK-BC) Feasibility Study prepared by Hatch Acres Corporation under contract to AEA (2007 AK-BC Intertie Draft Final Report). AEA expects to issue the final report in June 2007.

The purpose of the AK-BC Intertie Project is twofold:

- To facilitate the development of the Southeast Alaska Electrical Intertie System[2] to interconnect communities, encourage development of new renewable electricity generating facilities, and through interconnections reduce the current level of diesel generation and reduce emissions that affect air quality and contribute to climate change. Providing access to low-cost renewable electric power to currently isolated communities solely reliant on diesel generated power will reduce emissions and allow communities to remain economically sustainable.
- To facilitate development of the AK-BC Intertie and encourage new renewable electricity generation facilities for energy export. The proposed interconnection

[2] The concept of the Southeast Alaska Electrical Intertie System is set forth in Report #97-01 prepared by Acres International Corporation for the Southeast Conference. This Report is incorporated by reference in these comments on the DEIS and Proposed Land and Resource Management Plan.

with British Columbia will provide enhanced reliability to the Southeast Alaska Electrical Intertie System and provide additional revenue to SE Alaska through sales of Alaskan-generated power.

Currently several communities are served with clean renewable energy from existing hydro projects. In addition to encouraging new projects, the completion of an interconnected electric transmission system within SE Alaska would encourage upgrades to existing hydro facilities.

Energy export could lead to the development of a number of new renewable[3] electricity generating facilities in Southeast Alaska meeting domestic power needs and providing a surplus for export.

AEA requests that transmission corridors identified in the ongoing AK-BC Intertie Feasibility Study and corridors identified in an earlier comprehensive evaluation of an interconnected system for SE Alaska, the Southeast Alaska Electrical Intertie System Plan, Report #97-01, prepared by Acres International Corporation for the Southeast Conference dated January 1998 (1998 SE Alaska Intertie System Plan), be included on maps included in the DEIS and the Tongass Land Management Plan.

AEA requests the Forest Service to incorporate by reference the 2007 AK-BC Intertie Draft Final Report and a companion report, 1998 SE Alaska Intertie Plan. These reports are available on the AEA website www.akenergyauthority.org/AlcanProjectPage.

AEA has reviewed the DEIS and Tongass Land Management Plan and understands that the Proposed Action alternative (Alternative 6) and related management prescriptions appear to allow implementation of the proposed electric transmission interconnections as included in the 2007 AK-BC Intertie Draft Final Report and the 1998 SE Alaska Intertie Plan. The following sections of AEA's comments provide detailed information regarding AEA's interests in assuring that these essential electric connections among communities in SE Alaska are considered in the DEIS and the Tongass Land Management Plan.

AEA has reviewed the map included in Alternative 6 Draft EIS and notes that two proposed segments are not currently identified: a line from Coffman Cove to the Four Dam Pool Power Agency (FDPPA) transmission line between the Tyee Lake Project and Wrangell/Petersburg. These line segments are shown on Figure 1 Additional Transmission Line Segments is provided in Section 6 of these comments.

[3] Renewable electricity generating facilities includes hydro, tidal energy, geothermal, and wind.

2. STATE OF ALASKA EXPLANATORY STATEMENT

2.1 Importance of Utility System Corridors

Electricity is the universal energy form. Virtually every home, institution, office, business, and industry in the nation use electricity and all are directly affected by its price and availability. Utility rates and services affect the quality of life for residents, influence economic development in communities within the study area, and shape future opportunities in all sectors of the economy. Significant disparities in the cost of power for SE Alaska communities exist today.

Most electric systems in SE Alaska are community-based and serve isolated load centers. With the exception of the below-listed existing transmission lines, there are no interconnections to import or export power among the communities and electric utilities.

- Haines to Skagway - transmits hydropower generated near Skagway – Alaska Power & Telephone (AP&T)
- Tyee to Petersburg and Wrangell - Four Dam Pool Power Agency (FDPPA) line delivers power from the Tyee Lake Hydroelectric Plant
- Line linking several communities on Prince of Wales Island (POW) to the Black Bear Lake and South Forks Hydroelectric projects – AP&T

Lacking transmission interconnections to other electric systems, each utility must plan independently to provide full power requirements to meet customer needs. This results in many communities reliance on higher cost diesel-generated power and related emissions adversely affecting ambient air quality and contributing to global warming in SE Alaska. As noted above, with few exceptions, most existing and proposed new transmission lines are/would be constructed on lands within the Tongass National Forest.

AEA notes that the Forest Service includes "the social and economic well-being of the communities of Southeast Alaska" as one of the public issues considered in the 2003 Supplemental EIS. AEA does not see this concern brought forward as one of "The Three Focus Issues" in the 2007 DEIS. However, AEA notes that the social and economic well being in SE Alaska is woven into some of the discussion in the DEIS.

AEA notes that Land Use Designations (LUDs) specify ways of managing areas and resources within the forest. LUD's are assigned, or allocated, to specific areas of land and given areas have one LUD assigned. Transportation and Utility System LUDs are defined as "overlay LUDs and can apply to a given piece of ground when and if…transportation/utility systems are to be developed on that piece of ground." With certain exceptions, transportation and utility systems are allowed throughout the Tongass as directed by Title XI of the Alaska National Interest Lands Conservation Act of 1980 (ANILCA).

AEA notes that the Draft Proposed Tongass Forest Plan at Section 4 Standards & Guidelines does not include a section on Utility Systems. See specific comments and recommendations at sections 4 and 5 of these comments.

The following proposed transmission segments would fall within the definition of Transportation and Utility System LUDs. Many of the line segments currently under consideration are included in the list of Power Transmission Lines in the DEIS (page 3-233). The following list presents the complete list of line segments under consideration. These line segments are also depicted on the Maps at Section 6 within these comments.
Proposed Transmission Segments within SE Alaska

Proposed connections in process at this date include:

- Juneau to Hoonah (the Juneau to Greens Creek portion is completed) - Kwaan Electric Transmission Intertie Cooperative, Inc. (KWETICO)
- Swan-Tyee Intertie (STI) that would interconnect Petersburg/Wrangell with Ketchikan and serve Ketchikan with current excess available energy at the Tyee Lake Hydroelectric Plant. – FDPPA
- Thayer Creek to Angoon - Kootzoowoo Inc., a Native village cooperative, proposed line from a new hydro project

Future proposed transmission segments and connections include:

- Juneau to Skagway
- Lake Dorothy to Juneau (AEL&P)
- Otter Creek to Skagway (AP&T)
- Hoonah to Tenakee Springs
- Tenakee Springs to Angoon
- Angoon to Sitka
- Takatz Lake to Kake
- Kake-Petersburg Transmission Intertie (KPTI)
- Sunrise Lake to Wrangell
- Metlakatla to Ketchikan – Metlakatla Power & Light Prince of Wales (POW) Island – segment to connect Coffman Cove and Naukati to southern POW communities. (not included in the list on page 3-223)
- Prince of Wales Island to FDPPA line near Wrangell – AP&T (not included in the list on page 3-233. This is an alternative to the line between Thorne Bay and Ketchikan included on the list)
- Thomas Bay to FDPPA line near Petersburg (not included in the list on page 3-233)

Proposed International Interconnection

- AK-BC Intertie

2.2 Benefits to the State and to Southeast Alaska

SE Alaska decision-makers have an opportunity to engage in joint planning to develop an interconnected electric transmission system within SE Alaska and the potential to expand that concept to include an interconnection with BC. AEA requests that the Forest Service include the identified transmission segments in the DEIS and Tongass Land Management Plan (see Map – Figure 1 Additional Transmission Line Segments in Section 6 of these comments)

Implementation of joint planning and system operation are proposed in the AK-BC Intertie Draft Final Report and the 1998 Southeast Alaska Electric Intertie System Plan and will facilitate open access to regional system facilities at just and reasonable non-discriminatory rates. An interconnected electric transmission system will facilitate joint planning and shared use of existing and proposed new renewable electric generation projects.

Significant disparities in cost of power in SE exist today, in part related to availability of low-cost hydropower. Many isolated load centers are currently served by diesel generation.

SE Alaska communities have experienced slow population growth for decades. The economy is in transition from a commodity resource-based economy to one where the economy is mixed, with increasing development in service-oriented businesses including government services, recreation and tourism.

Completion of the STI and development of proposed transmission lines to interconnect submarkets, and a future interconnection with BC, will encourage new sustainable economic development in currently isolated load centers and improve quality of life for residents currently encumbered with high cost energy from diesel generation.

2.3 Benefits to the Tongass National Forest

Completion of an interconnected electric transmission system will reduce reliance on diesel generation in SE Alaska and facilitate switching from fuel oil to electric heat for residential, government, and commercial customers. Reduced diesel generation and fuel oil use in SE Alaska will result in reduced adverse environmental effects that occur with transport, storage, and end-use of diesel and fuel oil.

AEA presents in the following section detailed information regarding avoided emissions that could result when individual load centers and systems are interconnected in southern SE Alaska, including completion of the Swan-Tyee Intertie and connections between Kake and Petersburg and Metlakatla and Ketchikan. Similar results can be anticipated in other areas throughout SE Alaska as transmission line segments are completed.

The United States Environmental Protection Agency (EPA) is mainly concerned with emissions which are or could be harmful to people. EPA calls this set of principal air pollutants, criteria pollutants. The criteria pollutants are carbon monoxide (CO), lead (Pb), nitrogen dioxide(NO_2), ozone (O_3), particulate matter (PM), and sulfur dioxide (SO_2).

Four of the criteria pollutants related to diesel generation and household oil-fired furnaces with/without interconnections were examined in this analysis – CO2, SOx, CO, and NOx.

With completion of the STI in 2010, conversion of a portion of oil fired furnace load could reduce CO2 and SOx emissions by 795,155 and 5,074 tons or some 47.7% and 45.5% respectively over the period from 2007 to 2046 or 485,996 and 3,150 tons or some

53.3% and 51.5% respectively over the period from 2007 to 2031 when compared with the isolated case without conversion. Over the period from 2007 to 2046, emissions of CO and NOx would be increased by 348 and 1673 tons or about 9.2% and 10.2% respectively due to the corresponding high emission factors of diesel engines.

Detailed information is presented in the following section in response to the DEIS.

3. SPECIFIC COMMENTS - DEIS

3.1 Climate and Air (pages 3-11 – 3-15

One of the goals common to all alternatives stated in the DEIS is: "Air. Maintain the current air resource condition to protect the Forest's ecosystems from on- and off- Forest air emission sources." (Page 2-7 DEIS)

Section 3 of the DEIS includes a description of the affected environment and related environmental effects. AEA notes several references to diesel power plants as a source of air pollution. The proposed interconnected electric transmission system presented in the recently issued AK-BC Intertie Feasibility Study Draft Final Report would result in decreased diesel generation in southern SE Alaska and would facilitate switching from fuel oil to electric heat in several communities.

AEA requested Hatch Energy to perform an analysis of avoided emissions that could result when individual load centers and systems are interconnected in southern SE Alaska. The following section "Estimated Avoided Emissions" of AEA's comments presents the results of that analysis as it would relate to the goal staed in Chapter 2 of the Draft Proposed Tongass Forest Plan: *"Maintain the current air resource condition to protect the Forest's ecosystems from on- and off- Forest air emission sources."* And the related objective: *"Attain national and state-ambient air quality standards forest-wide."*

ESTIMATED AVOIDED EMISSIONS

Two load growth scenarios were investigated:

- Include conversion of a portion of heating supplied by oil fired heating furnaces to loads supplied by electrical heaters (case with conversion)
- Consider that heating would continue to be supplied by oil fired heating furnaces (case without or no conversion).

In the case with conversion of oil fired heating furnaces, the annual expected displaced oil consumption of these furnaces was estimated and the expected amount is discussed in this section.

For each of the two load growth scenarios, the generation for three system development cases was determined in order to calculate the avoided emissions. These cases are::

1) Isolated -- Swan-Tyee Intertie is not implemented and both Kake and Metlakatla remain isolated;
2) Isolated With STI -- Swan-Tyee Intertie is commissioned in 2010 but both Kate and Metlakatla remain isolated;
3) Interconnected With STI -- Swan-Tyee Intertie is commissioned in 2010, Kate is interconnected with Petersburg and Metlakatla is interconnected with Ketchikan.

Emission Factors

Four emission pollutants - CO2, SOx, CO and NOx - were examined in this study. The emission factors used were obtained from AP 42, Volume I, Fifth Edition published by the Environmental Protection Agency (EPA) of the USA in 1995. These factors are summarized as follows:

Pollutant	Diesel Engine	Furnace
Emission Factors in Pounds Per Horsepower-Hour (lb/hp-hr)		
CO2	1.16	
SOx	0.00809	
CO	0.0055	
NOx	0.024	
Emission Factors in Pounds Per Thousand Gallons of Fuel (lb/1000-gal)		
CO2	22,548	22,300
SOx	157	144
CO	107	5
NOx	467	18

It is important to note that the emission factors in lb/hp-hr for diesel engines shown in the table above are the average values for large diesel engines (greater than 600 hp). The factors in lb/1000-gal for the diesel engines are calculated based on the values in lb/hp-hr, heat rate of 7,000 Btu/hp-hr, diesel heating value of 19,300 Btu/lb and diesel density 7.05 lb/gal. It is also assumed that the diesel used contains 1% of sulfur.

It can be seen from these emission factors that for the same amount of liquid fuel consumed by the diesel engines and furnaces, the two types of facilities emit similar amounts of CO2 and SOx but diesel engines emit much more CO and NOx than furnaces. CO and NOx emissions from diesel engines are about 21 times and 26 times of those from furnaces.

2 Electricity Required for Conversion of Oil Fired Heating Furnaces

In this analysis, five load centers were considered - Ketchikan, Metlakatla, Wrangell, Petersburg and Kake. The estimated additional annual electrical energy required to supply the loads that would be converted from oil fired heating furnaces assumed as well as the displaced oil consumption in the case with conversion are summarized as follows:

Year	Additional Electricity Required (MWh)	Displaced Oil Consumption (US Gallon)
2007	2,759	108,375
2008	5,433	213,377
2009	8,016	314,846
2010	11,728	453,163
2011	18,962	707,095
2012	28,600	1,039,909
2013	30,889	1,129,792
2014	39,194	1,417,705
2015	41,449	1,506,298
2016	43,641	1,592,398
2017	45,765	1,675,796
2018	47,841	1,757,324
2019	49,874	1,837,193
2020	51,891	1,916,396
2021	53,860	1,993,728
2022	55,781	2,069,190
2023	57,660	2,142,990
2024	59,492	2,214,920
2025	61,286	2,285,395
2026	63,058	2,354,991
2027	64,793	2,423,133
2028	66,496	2,490,028
2029	68,168	2,555,676
2030	69,802	2,619,869
2031	71,425	2,683,600
Total	**1,117,863**	**41,503,183**

With conversion of each MWh of furnace load to electrical load, about 37 gallons of heating oil can be displaced. Based on a heat rate 7,000 Btu/hp-hr, a heating value of 19,300 Btu/lb and a density of 7.05 lb/gal as mentioned earlier, diesel engines would use about 69 gallons of diesel to generate one MWh. This implies that diesel engines have lower efficiency than heating furnaces. If the additional load for heating was produced by diesel engines, there would be more oil consumption and more pollution than in the case of supply from heating furnaces. I important to note that most of the additional or displaced heating furnace load is expected to be produced by unused hydro generation.

3 Estimated Avoided Emissions

The following tables present total and avoided emissions over the periods from 2007 to 2041 and from 2007 to 2031. Tables showing detailed information from which these summary tables were developed is attached at the end of this section of the comments.

Summary Table - Total Emissions

Theme	Case	CO2 (ton)	SOx (ton)	CO (ton)	NOx (ton)
		2007-2046			
No-Conversion	Isolated	1,667,754	11,160	3,790	16,381
	Isolated-STI	1,485,993	9,892	2,928	12,620
	IC-STI	1,383,714	9,179	2,443	10,504
Conversion	Isolated	1,424,535	9,935	6,754	29,473
	Isolated-STI	956,242	6,669	4,534	19,784
	IC-STI	872,599	6,086	4,137	18,054
		2007-2031			
No-Conversion	Isolated	912,198	6,123	2,235	9,672
	Isolated-STI	829,041	5,543	1,840	7,952
	IC-STI	770,639	5,135	1,564	6,743
Conversion	Isolated	754,157	5,260	3,576	15,603
	Isolated-STI	471,672	3,290	2,236	9,759
	IC-STI	426,202	2,972	2,021	8,818

It can be seen from the above table that in the interconnected case with the Swan-Tyee interconnection commissioned in 2010, conversion of a portion of oil fired furnace load could reduce CO2 and SOx emissions by 795,155 and 5,074 tons or some 47.7% and 45.5% respectively over the period from 2007 to 2046 or 485,996 and 3,150 tons or some 53.3% and 51.5% respectively over the period from 2007 to 2031 when compared with the isolated case without conversion. Over the period from 2007 to 2046, emissions of CO and NOx would be increased by 348 and 1673 tons or about 9.2% and 10.2% respectively and this is due to the corresponding high emission factors of diesel engines.

Summary Table - Avoided Emissions

Theme	Case	CO2 (ton)	SOx (ton)	CO (ton)	NOx (ton)
		2007-2046			
No-Conversion	Isolated	--	--	--	--
	Isolated-STI	181,762	1,268	862	3,761
	IC-STI	284,040	1,981	1,347	5,877
Conversion	Isolated	243,219	1,225	-2,965	-13,093
	Isolated-STI	711,513	4,491	-744	-3,404
	IC-STI	795,155	5,074	-348	-1,673
		2007-2031			
No-Conversion	Isolated	--	--	--	--
	Isolated-STI	83,156	580	394	1,720
	IC-STI	141,559	987	671	2,929
Conversion	Isolated	158,041	863	-1,341	-5,931
	Isolated-STI	440,525	2,833	-2	-87
	IC-STI	485,996	3,150	214	854

The following Tables 1 and 2 present detailed information regarding the estimated annual emissions in short tons (2000lb/short ton) for each of the two load growths studied.

Table 1: Estimated Emissions for Cases Without Conversion of Oil Fired Heating Furnaces

Isolated Case					Isolated Case With STI					Interconnected Case With STI

3.2 Human Uses and Land Management (pages 3-219 – 3-403

Transportation and Utilities

Power Transmission Lines

Page 3-233 – paragraph should include the following segments:

Proposed Transmission Segments within SE Alaska

Proposed connections in process at this date include:

- Juneau to Hoonah (the Juneau to Greens Creek portion is completed) - Kwaan Electric Transmission Intertie Cooperative, Inc. (KWETICO)
- Swan-Tyee Intertie (STI) that would interconnect Petersburg/Wrangell with Ketchikan and serve Ketchikan with current excess available energy at the Tyee Lake Hydroelectric Plant. – FDPPA
- Thayer Creek to Angoon - Kootzoowoo Inc., a Native village cooperative, proposed line from a new hydro project

Future proposed transmission segments and connections include:

- Juneau to Skagway
- Lake Dorothy to Juneau (AEL&P)
- Otter Creek to Skagway (AP&T)
- Hoonah to Tenakee Springs
- Tenakee Springs to Angoon
- Angoon to Sitka
- Takatz Lake to Kake
- Kake-Petersburg Transmission Intertie (KPTI)
- Sunrise Lake to Wrangell
- Metlakatla to Ketchikan – Metlakatla Power & Light (not included in the list on page 3-223
- Prince of Wales (POW) Island – segment to connect Coffman Cove and Naukati to southern POW communities. (not included in the list on page 3-223)
- Prince of Wales Island to FDPPA line near Wrangell – AP&T (not included in the list on page 3-233. This is an alternative to the line between Thorne Bay and Ketchikan included on the list)
- Thomas Bay to FDPPA line near Petersburg (not included in the list on page 3-233)

Proposed International Interconnection

- AK-BC Intertie

Economic and Social Environment

Introduction (page 3-403)

Note that the Tongass National Forest is the primary land-owner in SE Alaska. DEIS states that "Appropriate management of the Tongass' natural resources, is, therefore, extremely important for local communities and the overall regional economy."

Adequate infrastructure is an essential element of a healthy economic and social environment. As noted earlier in these comments, electricity is an essential service and electric transmission infrastructure is the delivery system. The introduction section should recognize the importance of this element.

Cumulative Effects (page 3-470)

"Other reasonably foreseeable actions include transportation and utility developments." While paragraph includes "utility developments", text solely relates to roads. Section should include reference to electric transmission line segments identified above under "Power Transmission Lines."

H-A61

4. SPECIFIC COMMENTS – Proposed Land and Resource Management Plan

Chapter 2 Goals and Objectives

Forest-wide Multiple-use Goals and Objectives (pages 2-2 through2-5)

Resource	Goal Statement from Plan	Objective Statement from Plan	AEA Comments
Air	*"Maintain the current air resource condition to protect the Forest's ecosystems from on- and off- Forest air emission sources."*	*"Attain national and state-ambient air quality standards forest-wide."*	Implementation of the proposed SE Alaska Electrical Intertie System will reduce current levels of emissions associated with diesel-generation (transportation & delivery, storage, end-use) and potential for spill. Reduction of current level of heating oil and associated emissions and potential for spill will occur as conversion to electric heat becomes an option.
Local and Regional Economies	*"Provide a diversity of opportunities for resource uses that contribute to the local and regional economies of Southeast Alaska."*	*"Work with local communities to identify rural community assistance opportunities and provide technical assistance in their implementation. Support a wide range of natural-resource employment opportunities within Southeast Alaska's communities."*	Implementation of the proposed SE Alaska Electrical Intertie System will provide access to lower cost electricity from renewable electricity generating facilities to currently isolated communities solely dependent on diesel-generated electricity. Access to lower cost power will enhance the ability of communities to attain economic sustainability and increase employment opportunities in isolated rural communities.
Transportation	*"Develop and manage roads and utility systems to support resource management activities; recognize the potential for future development of major Transportation ~~and Utility Systems~~."*	*"Provide access for forest users. In support of forest resource management activities, design and construct up to an average of 61 miles of roads annually. Manage and maintain roads to protect water, soil, fish, and wildlife resources."*	AEA notes that this section includes Utility Systems, however the Objectives solely relate to Transportation. AEA recommends a separate section "Utility Systems" be included in the Final TLMP Plan at page 2-5. See next section of this table.
Utility Systems (new resource category)	AEA recommended goal: "Develop and manage utility systems to support resource management activities; recognize the potential for future development of Utility Systems, including the proposed SE Alaska Electrical Intertie System."	AEA recommended objectives: "Provide access to the Forest for purposes of constructing and operating electric transmission lines and related facilities to reduce current levels of air emissions associated with diesel generation and provide communities with access to low-cost power to facilitate economically sustainable communities."	AEA recommendation for addition to current list of Resources and related Goals and Objectives. Page 2-5 Draft TLMP Plan.

Management Prescriptions 3

Transportation and Utility System
Land Use Designation TUS

See page 3-144: AEA requests that the Table "Transportation and Utility Systems Land Use Designation add a row below Transportation to include "Utility Systems" and that the Forest-wide Standards & Guidelines in Chapter 4 be expanded to include "Utility Systems."

See page 3-148: AEA requests that the list of LUD Standards and Guidelines include reference to "Utility Systems." Currently the text refers to Utility Systems, however the title is restricted to "TRANSPORTATION Transportation Operations: TRAN1.

Standards & Guidelines 4

LANDS
Forest-wide Standards & Guidelines

See page 4-32: VII. Right-of-Way Grants, D. States applicability of standards and guidelines to Transportation and Utility Systems. Note that powerlines may be installed to operate above 66kV, but in some instances are initially operated at 34.5kV. Some line segments (e.g. line from Metlakatla to Ketchikan) will be constructed at 34.5kV. These line segments play an important role in the overall plan to electrically interconnect SE Alaska and should be included within eligible facilities in the Transportation and Utility System (TUS) Land Designation (LUD).

See pages 4-110 through 4-117 TRANSPORTATION Forest-wide Standards and Guidelines. AEA notes that this section is referred to as the Forest-wide Standards and Guidelines for Transmission and Utility Systems. However, the current Draft Proposed Tongass Forest Plan does not include Standards and Guidelines applicable to Utility Systems.

5. RECOMMENDATIONS

This section of AEA's comments provides recommendations for the Final EIS and Final Proposed Tongass Forest Plan. These recommendations are discussed in the preceding sections of these comments and are compiled within this section 5 to facilitate Forest Service consideration and response in the Final EIS and Final Proposed Tongass Forest Plan. The above sections of these comments provide the background and basis for these recommendations.

5.1 DRAFT EIS

1. Purpose and Need

Add the social and economic well-being of the communities of Southeast Alaska as a Key Issue in the Final EIS. (Page 1-6 The Three Focus Issues – Key Issues) Presently the social and economic well-being relates solely to timber management. AEA notes that the electric transmission infrastructure that will occupy National Forest lands is a critical element to future social and economic well-being in the region.

3. Environment and Effects

Transportation and Utilities

Power Transmission Lines (Page 3-233)
Power Transmission Lines

Page 3-233 – paragraph should include the following segments:

Proposed Transmission Segments within SE Alaska

Proposed connections in process at this date include:

- Juneau to Hoonah (the Juneau to Greens Creek portion is completed) - Kwaan Electric Transmission Intertie Cooperative, Inc. (KWETICO)
- Swan-Tyee Intertie (STI) that would interconnect Petersburg/Wrangell with Ketchikan and serve Ketchikan with current excess available energy at the Tyee Lake Hydroelectric Plant. – FDPPA
- Thayer Creek to Angoon - Kootzoowoo Inc., a Native village cooperative, proposed line from a new hydro project

Future proposed transmission segments and connections include:

Proposed International Interconnection

- AK-BC Intertie

Economic and Social Environment

Introduction (page 3-403)

Note that the Tongass National Forest is the primary land-owner in SE Alaska. DEIS states that "Appropriate management of the Tongass' natural resources, is, therefore, extremely important for local communities and the overall regional economy."

Adequate infrastructure is an essential element of a healthy economic and social environment. As noted earlier in these comments, electricity is an essential service and electric transmission infrastructure is the delivery system. The introduction section should recognize the importance of this element.

Cumulative Effects (page 3-470)

"Other reasonably foreseeable actions include transportation and utility developments." While paragraph includes "utility developments", text solely relates to roads. Section should include reference to electric transmission line segments identified above under "Power Transmission Lines."

Alternative 6 Draft EIS Map

Add the following segments:

- Prince of Wales Island to FDPPA line near Wrangell – AP&T (not included in the list on page 3-233. This is an alternative to the line between Thorne Bay and Ketchikan included on the list)
- Thomas Bay to FDPPA line near Petersburg (not included in the list on page 3-233)

Map showing location of these segments is included in Section 6. Maps of these comments.

5.2 Draft Proposed Tongass Forest Plan

Chapter 2 Goals and Objectives

Table - Forest-wide Multiple-use Goals and Objectives (pages 2-2 through 2-5)

Resource category "Transportation" includes reference to utility systems in the goal statement, however the objectives relate solely to roads.

AEA recommends that the table include a new resource category "Utility Systems":

Resource	Goal Statement from Plan	Objective Statement from Plan	AEA recommendation
Utility Systems (new resource category)	AEA recommended goal: "Develop and manage utility systems to support resource management activities; recognize the potential for future development of Utility Systems, including the proposed SE Alaska Electrical Intertie System."	AEA recommended objectives: "Provide access to the Forest for purposes of constructing and operating electric transmission lines and related facilities to reduce current levels of air emissions associated with diesel generation and provide communities with access to low-cost power to facilitate economically sustainable communities."	AEA recommendation for addition to current list of Resources and related Goals and Objectives. Page 2-5 Draft TLMP Plan.

Management Prescriptions 3

Transportation and Utility System Land Use Designation TUS

See page 3-144: AEA requests that the Table "Transportation and Utility Systems Land Use Designation add a row below Transportation to include "Utility Systems" and that the Forest-wide Standards & Guidelines in Chapter 4 be expanded to include "Utility Systems."

See page 3-148: AEA requests that the list of LUD Standards and Guidelines include reference to "Utility Systems." Currently the text refers to Utility Systems, however the title is restricted to "TRANSPORTATION Transportation Operations: TRAN1.

Standards & Guidelines 4

LANDS
Forest-wide Standards & Guidelines

See page 4-32: VII. Right-of-Way Grants, D. States applicability of standards and guidelines to Transportation and Utility Systems. Note that powerlines may be installed to operate above 66kV, but in some instances are initially operated at 34.5kV. Some line

segments (e.g. line from Metlakatla to Ketchikan) will be constructed at 34.5kV. These line segments play an important role in the overall plan to electrically interconnect SE Alaska and should be included within eligible facilities in the Transportation and Utility System (TUS) Land Designation (LUD).

See pages 4-110 through 4-117 TRANSPORTATION Forest-wide Standards and Guidelines. AEA notes that this section is referred to as the Forest-wide Standards and Guidelines for Transmission and Utility Systems. However, the current Draft Proposed Tongass Forest Plan does not include Standards and Guidelines applicable to Utility Systems. AEA recommends that an additional category UTILITY SYSTEMS be prepared and provided in the Final Proposed Tongass Forest Plan.

This new section could contain information relating to the coordination of federal agency approvals for electric transmission established in the August 8, 2006 "Memorandum of Understanding on Early Coordination of Federal Authorizations and Related Environmental Reviews Required in Order to Site Electric Transmission Facilities" (MOU)[4] signed. by the departments of Energy (DOE), Agriculture (USDA – includes the Forest Service), Defense (DOD – includes the Corps of Engineers (COE)), Interior (DOI – includes the Fish and Wildlife Service (FWS)), Commerce (includes the National Marine Fisheries Service (NMFS)); and the Federal Energy Regulatory Commission (FERC), the Environmental Protection Agency (EPA), the Council on Environmental Quality (CEQ), and the Advisory Council of Historic Preservation with the commitment to work together to meet each Agency's obligations. The purpose of the MOU is to establish a framework for early cooperation and participation that will enhance coordination of all applicable land use authorizations, related environmental, cultural, and historic preservation reviews, and any other approvals that may be required under Federal law in order to site an electric transmission facility. Central to this MOU is compliance with NEPA and preparation of related environmental documents, including the EA or EIS.

[4] The MOU was developed in response to requirements of the Energy Policy Act of 2005 that amended the Federal Power Act; codified at USC 824p.

RECEIVED
APR 30 2007
RAP 4-30-07

Forrest Cole, Supervisor
Tongass National Forest
648 Mission Street
Ketchikan, AK 99901

Dear Mr. Cole,

On behalf of Central Council Tlingit & Haida Indian Tribes of Alaska (CCTHITA) and our 26,000 members worldwide, we are submitting the following comments on the Tongass Land Management Plan (TLMP) Amendment Draft Environmental Impact Statement (DEIS) 2007.

Our stewardship concerns are for our entire tribal membership but more specifically for those 13,500 living in direct proximity to the Tongass National Forest in Southeast Alaska. As part of the responsibility to our members, we are compelled to address the issues regarding the forest. The interests of tribal members and governments extend beyond mere use of forest resources. We have additional responsibilities as *stewards of the air, land, and sea* to ensure a balance is maintained in the use of natural resources.

After much deliberation on defining the balance between sustainable use and conservation of available resources we support, in principle, **Alternative 5** as proposed by the US Forest Service. Through our participation in groups (Tongass Futures Roundtable and Southeast Conference) working on the same forest related issues in the Tongass, we have come to the conclusion that <u>prudent use as well as prudent conservation of forest resources is necessary even in economically challenging times. Short-term gain at the expense of long-term stability is careless choice.</u>

It is for this reason that we support Alternative 5 with the inclusion of our concerns that any development of forest resources take into account: 1) Protection of Native Sacred Sites within the forest, 2) Protection of intact watersheds of importance to habitat, fisheries, and subsistence, 3) Promotion and funding of a forest and riparian restoration program, 4) Provision of sufficient forest resources to support a sustainable level of economic activity in forest related industries, 5) Slow and controlled transition from old growth to second growth in limited areas.

In addressing the conditional support of Alternative 5, the protection of Native Sacred Sites should be paramount in any decision about the development of Tongass resources.

TEL. 907/586-1432 www.tlingit-haida.org FAX 907/586-8...

Native Alaskan peoples have been in the forest for longer than recorded history. The preservation of sacred sites is essential. The disruption or destruction of any of these sites without explicit approval of proper tribal authorities is not acceptable.

Concern two in our support of Alternative 5 reflects the importance of the whole ecosystem to Native Alaskans. The very existence of many tribal members depends on the quality, quantity, and distribution of wildlife and fishery resources. Subsistence resources are of extreme importance to our culture and well being. Disruption, destruction, and/or contamination of these resources are of intense concern to us in any changes to the forest ecosystem. All proposed changes in areas, methods, and levels of resource development should reflect this concern.

Concern number three is a need for a substantive program put in place to promote, support, and fund a riparian and forest restoration program. Resource development in Tongass ecosystem over the past decades has had noticeable impact. Past and future development can be ameliorated through such a program. This program will be most successful with a dedicated funding source such as a federal trust fund. A program without a dedicated funding source is too unreliable.

Concern four addresses the actual use of Tongass Forest resources. Forest resources should be viewed in light of sustaining and preserving not stripping and abandoning. As stewards of the forest, we believe in the thoughtful use of its resources. The balancing of sustaining the forest and economic development is a tentative but essential one. A long term plan for value-added use of forest resources is much preferred to one on stripping and selling the resource at its lowest value point. In other words, use of forest resources should be vertically integrated on a local level in Southeast Alaska as to provide the largest positive economic impact for the resource being used. Federal policies dedicated toward these ends should be pursued. These policies allow for sufficient access to renewable forest resources to sustain local vertically integrated value added forest product industries. Access to non-renewable forest resources should be limited and closely controlled.

And finally, concern number five, transition from old growth to new growth is a natural cycle of life. To the best ability of the forest management team, this transition should take place in an orderly least disruptive process. Destruction of entire portions of the Tongass ecosystem as a method of harvesting should be considered a last resort not a preferred practice. Forest stewardship should be based on sustainable forestry practices and not extractive resource practices. The environmental and lost opportunity costs should be included in the overall economic feasibility evaluations of opening any new areas to resource development.

In conclusion, we understand that the review process for the TLMP is a long and sometimes contentious time for Southeast Alaska. At CCTHITA, we choose the path of sharing our concerns and support with you as your review process comes to another milestone. We felt it was more valuable to share with you our reasons based in our traditional values. If there is anything we can do to support your efforts as they address our concerns, please feel free to call on us.

Best regards,

William E. Martin

Dear Mr. Bschor,

Enclosed, please find a copy of the comments submitted by Central Council Tlingit & Haida Indian Tribes of Alaska as part of the Tongass Land Management Plan review.

The policy statement was developed as a cooperative effort of our Business & Economic Development and Native Lands & Resources Departments. Our efforts are in support of a policy of sustainable development of one of the most valuable cultural and economic assets in the United States. We believe ours is a sound and sensible approach to preservation and development of this resource for all citizens.

Thank you for your efforts on behalf of the residents of Alaska.

Forrest Cole, Supervisor
Tongass National Forest
648 Mission Street
Ketchikan, AK 99901

Dear Mr. Cole,

On behalf of Central Council Tlingit & Haida Indian Tribes of Alaska (CCTHITA) an our 26,000 members worldwide, we are submitting the following comments on th Tongass Land Management Plan (TLMP) Amendment Draft Environmental Impa Statement (DEIS) 2007.

Our stewardship concerns are for our entire tribal membership but more specifically fo those 13,500 living in direct proximity to the Tongass National Forest in Southea Alaska. As part of the responsibility to our members, we are compelled to address th issues regarding the forest. The interests of tribal members and governments exten beyond mere use of forest resources. We have additional responsibilities as *stewards o the air, land, and sea* to ensure a balance is maintained in the use of natural resources.

After much deliberation on defining the balance between sustainable use an conservation of available resources we support, in principle, **Alternative 5** as propose by the US Forest Service. Through our participation in groups (Tongass Future Roundtable and Southeast Conference) working on the same forest related issues in th Tongass, we have come to the conclusion that prudent use as well as pruden conservation of forest resources is necessary even in economically challenging times Short-term gain at the expense of long-term stability is careless choice.

It is for this reason that we support Alternative 5 with the inclusion of our concerns tha any development of forest resources take into account: 1) Protection of Native Sacre Sites within the forest, 2) Protection of intact watersheds of importance to habitat fisheries, and subsistence, 3) Promotion and funding of a forest and riparian restoratio program, 4) Provision of sufficient forest resources to support a sustainable level o economic activity in forest related industries, 5) Slow and controlled transition from ol growth to second growth in limited areas.

In addressing the conditional support of Alternative 5, the protection of Native Sacre Sites should be paramount in any decision about the development of Tongass resources

TEL. 907/586-1432 www.tlingit-haida.org FAX 9...

Native Alaskan peoples have been in the forest for longer than recorded history. The preservation of sacred sites is essential. The disruption or destruction of any of these sites without explicit approval of proper tribal authorities is not acceptable.

Concern two in our support of Alternative 5 reflects the importance of the whole ecosystem to Native Alaskans. The very existence of many tribal members depends on the quality, quantity, and distribution of wildlife and fishery resources. Subsistence resources are of extreme importance to our culture and well being. Disruption, destruction, and/or contamination of these resources are of intense concern to us in any changes to the forest ecosystem. All proposed changes in areas, methods, and levels of resource development should reflect this concern.

Concern number three is a need for a substantive program put in place to promote, support, and fund a riparian and forest restoration program. Resource development in Tongass ecosystem over the past decades has had noticeable impact. Past and future development can be ameliorated through such a program. This program will be most successful with a dedicated funding source such as a federal trust fund. A program without a dedicated funding source is too unreliable.

Concern four addresses the actual use of Tongass Forest resources. Forest resources should be viewed in light of sustaining and preserving not stripping and abandoning. As stewards of the forest, we believe in the thoughtful use of its resources. The balancing of sustaining the forest and economic development is a tentative but essential one. A long term plan for value-added use of forest resources is much preferred to one on stripping and selling the resource at its lowest value point. In other words, use of forest resources should be vertically integrated on a local level in Southeast Alaska as to provide the largest positive economic impact for the resource being used. Federal policies dedicated toward these ends should be pursued. These policies allow for sufficient access to renewable forest resources to sustain local vertically integrated value added forest product industries. Access to non-renewable forest resources should be limited and closely controlled.

And finally, concern number five, transition from old growth to new growth is a natural cycle of life. To the best ability of the forest management team, this transition should take place in an orderly least disruptive process. Destruction of entire portions of the Tongass ecosystem as a method of harvesting should be considered a last resort not a preferred practice. Forest stewardship should be based on sustainable forestry practices and not extractive resource practices. The environmental and lost opportunity costs should be included in the overall economic feasibility evaluations of opening any new areas to resource development.

In conclusion, we understand that the review process for the TLMP is a long and sometimes contentious time for Southeast Alaska. At CCTHITA, we choose the path of sharing our concerns and support with you as your review process comes to another milestone. We felt it was more valuable to share with you our reasons based in our traditional values. To Whom It May Concern,
We would like to thank Peter Griffin, Juneau Ranger District for taking the time to meet with Douglas Indian Association staff members Scott Sloane and myself to discuss the 7 Alternatives of the Draft Tongass land and Resource Management Plan (Forest Plans) as they pertained to the Douglas Indian Association and its Tribal members Traditional Lands.

Douglas Indian Association is a federally recognized tribal government established under the authority of the Indian Reorganization Act (IRA) of 1934 and we have a government to government relationship with all federal agencies of the United States of America. As a federally recognized tribal government it is very important that we relay to you our concerns about the 7 Alternatives and their impacts to our people and their Traditional lands.

It is very important to understand that we are always strongly advocating for the protection of the fisheries and game and the land for both commercial and subsistence use and that we request that our comments be seriously considered when it comes to any impacts that will occur to these resources as your organization continues to manage land usage within the Tongass National Forest. We have concerns for impacts to fish habitat, wildlife habitat, subsistence, timber harvests near fish and wildlife habitat and the need to be able to sustain jobs while not harming the environment which we depend on daily to sustain ourselves and our way of life.

We recognize that when addressing impacts to the Tongass National Forest we are also addressing the Economic well-being of our Southeast Alaskan communities, us included and we do so responsibly and respectfully.

The TLUMP Amendment overview that was provided showed, when speaking of the Traditional lands of the Douglas Indian Association members, that the impacts that were going to occur under;

Alternatives 1 thru 3: Represent basically a status quo usage of the land and waters around Juneau, from the northern shores of Berners Bay south to Snettisham and the Admiralty Island National Monument lands eastern shores from Young Bay to Point Gardner.

2

Alternative 4: We have a concern that there is a more “moderate” to “intense” approach to timber harvesting in the area north and south of the Taku River an along the southeastern shores of Stephens Passage toward Snettisham plus th southwestern shores of Douglas Island. We request as this process evolves th our government to government consultations occur and that we be kept inform as your organization develops these programs.

Alternative 5: The plan is that this is a No-Action alternative, representing a continuation of the current forest plan and would result in a mix of national fore uses and activities.

Alternative 6: Indications are that timber harvest is no longer shown on the southwestern shores of Douglas Island and that more “moderate” to “intense” timber harvest are to occur from The Taku River to Snettisham we request that our government to government consultation to occur and that we be kept informed as your organization develops these programs.

Alternative 7: Indications are that a “moderate” approach to timber harvest is to occur on the Southwestern shore of Douglas Island and that a “moderate” to “intense” approach to timber harvest will occur from the Take River to Snettish and we request as this process evolves that our government to government consultation to occur and that we be kept informed as your organization develo these programs.

We also note that there are no telecommunication systems site plans listed for the Tongass National Forest, are there any proposed?

On behalf of Douglas Indian Association thank you for considering our comme on the TLUMP Amendment and we do look forward to your response.

Respectfully,

Floyd M. Kookesh

RE: Comments on the Tongass Land and Resource Management Plan Amendment Draft EIS

To Whom It May Concern:

The Hydaburg Cooperative Association (IRA) is a federally recognized tribe organized pursuant to the authority of Section 16 of the Act of Congress June 18, 1934 (48 Statute 984) as amended by act of Congress, May 1, 1936. Hydaburg Cooperative Association Tribal Council is the governing body of the Hydaburg Tribe in accordance with its Constitution, and by-laws, including “the protection of the Haida Nation membership.

The Hydaburg Cooperative Association has the authority to consult on behalf of its membership with the Federal Government for the well being of the tribe.

The commonality of the customary and traditional use of land, sea, and natural resources is what binds the Haida Nation together. The customary and traditional use of each Village is inseparable from the language, tradition, and ceremonies of the Haida People. This dependency on the surrounding resources is what drives our tribe to protect the resources that surround us.

The Hydaburg Cooperative Association Tribal Council passed Resolution 2007-20 that speaks to the areas of importance and their cultural significance to the Haida people.

The HCA is very concerned about certain alternatives within the TLMP Draft revision document. Specifically, Alternative 4, 5, 6, and 7 propose large scale logging activities within a 15 mile radius of the community of Hydaburg. Key subsistence watersheds will be drastically impacted. Couple these alternatives with the current private timber harvest activities in the same area, we will be faced with a decimated landscape as well as lasting impacts to our most crucial subsistence resources (the natural inhabitants of healthy watersheds and their estuaries).

Most of the areas(Sukkwaan Island, Keete Inlet , Kassa Inlet, and Mable Bay) proposed in Alt. 4 thru 7 are currently road-less. We would like them to maintain the protections from road building and large scale timber harvest. The areas are adjacent to a current LUD II and a Wilderness area. Keeping this area in tact would serve to protect the biodiversity of Cordova Bay for future generations to enjoy. The area is also one of the last untouched surfaces in our traditional territories that we can access for subsistence uses.

Lastly, the cultural significance of the timber itself (namely western red cedar) is of high concern to the Haida People. The Haida people have always had a direct reliance on red cedar to maintain its cultural identity. The current timber market is focused on this specific resource, of which is only available in high quantities in our traditional areas. We are concerned that this critical resource will be targeted and depleted under Alternates 4 thru 7. We see no protections that certify future generations will be afforded the inherent rights to utilize old growth western red cedar to perpetuate our culture into the future.

Thank you for your consideration of our comments and Resolution 2007-20

Respectfully;

Anthony Christianson
Environmental Planner

Attachment:
Resolution 2007-20 Resolution to Protect Important Areas According to the Customary and Traditional Uses of the Haida People

HYDABURG COOPERATIVE ASSOCIATION

Resolution No. 2007- 20

A RESOLUTION TO PROTECT IMPORTANT AREAS ACCORDING TO THE TRADITIONAL AND CUSTOMARY USES OF THE HAIDA PEOPLE

WHEREAS, the Hydaburg Cooperative Association (IRA) is a federally recognized tribe organized pursuant to the authority of Section 16 of the Act of Congress June 18, 1934 (48 Statute 984) as amended by act of Congress, May 1, 1936; and,

WHEREAS the Hydaburg Cooperative Association Tribal Council is the governing body of the Hydaburg Tribe in accordance with its Constitution, and by-laws, including "the protection of the Haida Nation membership; and,

WHEREAS, The Hydaburg Cooperative Association has the authority to establish and enter into contract for the well being of the tribe; and,

WHEREAS, the commonality of the customary and traditional use of land, sea, and natural resources is what binds the Haida Nation together, and the customary and traditional use of each Village is inseparable from the language, tradition, ceremony of the Haida People; and,

WHEREAS, we hold these truths to be self-evident since time immemorial; and,

WHEREAS, the Forest Service is legally obligated to meaningfully consult and collaborate with tribal governments in the development of Federal policies that have tribal implications, as directed by Executive Order 13175; and,

WHEREAS, the Proposed Action of the 1997 Tongass Land Management Plan will have far reaching and profound impacts on tribal communities throughout Southeast Alaska; and,

WHEREAS, the Proposed Action chosen by the Forest fails to adequately protect or respect the customary and traditional uses of Haida traditional use areas. The Proposed Alternatives plan intensive logging activities in some of the last remaining customary and traditional use areas such as Kassa, Keete, Moira, and Mabel Bay, and the 90 documented Haida traditional use sites (and there are more); and,

Hydaburg Cooperative Association
Resolution No. 2007 - 20

WHEREAS, the Forest Service's Proposed Action fails to adequately recognize the value of providing lasting protection to important customary and traditional use areas of the Tongass, the history of previous protections, including the 1999 Tongass Land Management Plan Record of Decision, and the 1989 House passed version of the Tongass Timber Reform Act, and community concerns; and,

WHEREAS, the Proposed Action fails to restore important salmon and deer habitat in traditional and community use areas of the people of Hydaburg; and,

WHEREAS, the Forest Service states that "roads pose the greatest threat to fish resources," and that the Haida people have depended on salmon since time immemorial, the Proposed Action almost doubles the number of roads within the Tongass; and,

WHEREAS, areas including Hydaburg, Long Island, Northwest Dall Island, Sukkwaan, Keete, Kassa, Mable Bay, Moira Sound, and other areas that are traditional use areas of the Haida People of Southeast Alaska contain highly valuable watersheds important for subsistence, tourism, fish and wildlife habitat;

NOW, THEREFORE, BE IT RESOLVED, that the Hydaburg Cooperative Association request that the customary and traditional areas Sukkwaan, Dall Island, Keete, Kassa, Mabel Bay, Moira Sound, and other areas within Haida country be removed from the timber base in order to best protect the customary and traditional activities of the Haida People; and,

BE IT FURTHER RESOLVED, that the Hydaburg Cooperative Association urges the Forest Service to heed the request of communities, tribes, and individuals to protect important traditional and customary areas for the good of future generations.

This resolution was duly adopted at the Tribal Council of the Hydaburg Cooperative Association at their regular or special meeting held on this 24th day of April 2007 by a quorum of 5 Yes and 0 No and 0 Abstentions.

President

Forrest Cole, Forest Supervisor
2007 Tongass Forest Plan
Tongass National Forest
Federal Building
648 Mission Street
Ketchikan, AK 99901

Fax: 907-228-6215

Dear Mr. Cole:

The Organized Village of Kake (OVK) is a duly constituted Indian Tribe organized pursuant to the authority of the Federal Indian Reorganization Acts of 1934 & 1936 with the IRA Council as the duly elected governing body formed under its Constitution & By-Laws. OVK functions as a Federally recognized tribal government to provide services to its membership and, by its Constitution, which includes…"the protection of the tribal membership." The OVK membership has in the ancient past, present and future, used Kuiu Island, Kupreanof Island, parts of Admiralty and Baranof Islands for the customary and traditional use of the plants, animal, fish, land, water and air. The customary and traditional uses of these areas are inseparable from the language, tradition and ceremonies of the OVK Tribe. Kake is located on Kupreanof Island in the Tongass National Forest is home to an annual population of 600 people, with OVK's tribal enrollment comprising approximately 65% of the community.

This letter serves as our Tribe's comment on the updated Tongass Forest Plan. The seven alternatives presented in the Draft Environmental Impact Statement (DEIS) call for annual logging amounts ranging from current levels of approximately 52 million board feet in Alternative 1 to a five-fold increase in Alternative 6, the Proposed Action, to even more in Alternative 7. This Tongass Forest Plan amendment gives the Forest Service the opportunity to respond to changing demands for forest resources. Your decision will impact commercial fisheries from Metlakatla to Yakutat.

The Organized Village of Kake would like to select Alternative One as our preferred Alternative. OVK would suggest the US Forest Service take it's planned dollars that will be used to subsidize road building and logging and redirect it to rural villages that have been affected by the two large 50-year contracts for the Sitka and Ketchikan Pulp Mills and the Ketchikan and Wrangell Saw Mills. The USFS can redirect most of its time and money to work with the Southeast Alaska Hydro-electric Intertie to provide cheaper power to rural communities.

Other issues we want to point out:

?? Customary and Traditional Gathering by OVK Tribal Membership: The salmon-producing watersheds on Kuiu, Kupreanof, Baranof and Admiralty are vital to Kake's livelihood and customary and traditional gathering (aka, subsistence use). We support long-term funding for salmon habitat restoration and enhancement projects.

?? We support the development of a forest-wide restoration strategy for degraded watersheds that include salmon habitat restoration and forestry enhancement projects such as tree thinning and tree planting.

Organized Village of Kake
TLMP Letter to the U.S. Forest Service
Page 2

- ?? Because of past and anticipated clearcutting and road building in the region, 75% of Southeast Alaska communities could face a significant restriction to their deer hunting. Some community use areas could lose 50% or more of critical deer winter habitat, depending on which alternative the Forest Service selects. We propose that the USFS not log the areas that provide corridors for the deer. Areas that are critically over-logged need to be restored. Thinning projects could provide valuable employment to residents in rural communities.
- ?? We support no logging roads in undeveloped salmon-producing watersheds on these areas. Roughly 72 percent of all salmon in Southeast Alaska come from unroaded watersheds. The draft Forest Plan states that roads "pose the greatest risk to fish resources." Despite the risks, all alternatives increase road miles on the Tongass between 37 to 127 percent. Instead of fixing the 1,322 culverts that block fish passage on existing roads, the Forest Service wants to spend even more tax-dollars to build more roads. The USFS needs to fix existing problems before you go on to create even more.
- ?? We request that the Forest Service evaluate human disturbances to watersheds at the *very* beginning of timber sale planning by completing a comprehensive watershed analysis.

The USFS needs to re-prioritize for the 21st century. For decades, the Forest Service spent tens of millions of our tax-dollars every year subsidizing logging and building roads on the Tongass. Industries such as recreation, tourism, commercial and sport fishing, and hunting bring in millions of dollars annually to the regional economy. These industries provide more jobs than the Tongass timber industry—without massive taxpayer subsidies. In Kake, Customary and Traditional Gathering is not just important spiritually and culturally, it is an important economic factor. We do not have the luxury of shopping at a Fred Meyer's or similar grocery stores. Our 'bread basket' includes the streams and watersheds that provide homes to the sea life and wild life that we gather.

Thank you for the opportunity to comment on the 2007 Tongass Forest Plan. Please call, write or email our OVK staff, Mike Jackson, Edna Jackson or Teresa Gaudette if you need more information.

RESOLUTION NO. 07-32

TITLE: A Resolution To Protect Important Areas According To The Traditional And Customary Uses Of TheKlawock People.

WHEREAS: The Klawock Cooperative Association, (hereafter "Tribe"), is a duly constituted Indian Tribe organized pursuant to the authority of Section 16 of the Act of Congress of June 18, 1934 (48 Stat. 984), amended May 1, 1936 (49 Stat. 1250), and

WHEREAS: The Klawock Cooperative Association Tribal Council is a duly elected governing body of the Tribe, authorized to act by and on behalf of its members, and

WHEREAS: The commonality of the customary and traditional use of land, sea, and natural resources is what binds the Tlingit Nation together, and the customary and traditional use of each village is inseparable from the language, tradition, ceremony of the KCA Tribal Members, and

WHEREAS: We hold these truths to be self-evident since time immemorial, and

WHEREAS: The Forest Service is legally obligated to meaningfully consult and collaborate with tribal governments in the development of Federal policies that have tribal implications, as directed by Executive Order 13175, and

WHEREAS: The Proposed Action of the 1997 Tongass Land Management Plan will have far reaching and profound impacts on tribal communities throughout Southeast Alaska, and

WHEREAS: The Proposed Action chosen by the forest fails to adequately protect or respect the customary and traditional use of Tlingit traditional use areas. The Proposed Alternative plans intensive logging activities in some of the last remaining customary and traditional use areas such as Port Estrella, Port Dolores, Port Santa Cruz - Sumez, San Juan Batista – St. Johns, Point Amargura – Fern Pt. – San Fernando Is. And Fish Egg Island, and

WHEREAS: The Forest Service's Proposed Action fails to adequately recognize the value of providing lasting protection to important customary and traditional use areas of the Tongass, the history of previous protection, including the 1999 Tongass Land Management Plan Record of Decision, and the 1989 House passed version of the Tongass Timber Reform Act, and community concerns, and

WHEREAS: The Proposed Action fails to restore important salmon and deer habitat in traditional and community use areas of the people of Klawock, and

WHEREAS: The Forest Service states that "roads pose the greatest threat to fish resources," and that the Tlingit people have depended on salmon since time immemorial, the Proposed Action almost doubles the number of roads within the Tongass, and

WHEREAS: Areas including Klawock, Port Estrella, Port Dolores, Port Santa Cruz – Sumez, San Juan Batista – St. Johns, Point Amargura – Fern Pt. – San Fernando Is., and Fish Egg Is., and other areas that are traditional use areas of the Tlingit People of Southeast Alaska contain highly valuable watersheds important for subsistence, fish and wildlife habitat, and

THEREFORE, LET IT BE RESOLVED: That Klawock Cooperative Association Tribal Council request that the customary and traditional areas Port Estrella, Port Dolores, Port Santa Cruz – Sumez, San Juan Batista – St. Johns, Point Amargura – Fern Pt. – San Fernando Is., and Fish Egg Is., and other areas within Tlingit Country be removed from the timber base in order to best protect the customary and traditional activities of the Tlingit People, and

NOW THEREFORE, BE IT RESOLVED: That the Klawock Cooperative Association Tribal Council urges the Forest Service to heed the request of communities, tribes, and individuals to protect important traditional and customary areas for the good of future generations.

Notice of Flawed Process of the Office of Subsistence Management
Notice of Deficiencies and Violations of Tribal Law
Notice of Violations of International Law

Re: **Rural Review Process Office of Subsistence Management**
Date: ~~**September 25, 2006**~~ march 13, 2007
Location: **Saxman Village**

Jurisdiction

The Office of Subsistence Management purports to manage access to the traditional lands, waters and resources of Alaska's First Peoples. It wrongfully assumes a management responsibility for resources integral to the continuation of the Indigenous Peoples. When the Thlingit Peoples first arrived in South East Alaska there were no people here before us. The Thlingits displaced no one! We are the First People. We enjoy our Inherent Rights and Status.

The Federal government, the state of Alaska, and the Office of Subsistence Management do not exercise jurisdiction over the Indigenous Nations and Indigenous Peoples resident in region of Alaska, and have no power to deny us our traditional lifestyle, customary use and trade and traditional way of making a living and culture and a way of life that has been labeled by the newcomers as "subsistence" – an arrogant and demeaning term.

As Sovereigns, Indigenous Peoples have equal status to other nations of the world including the United States. Tribal identity must be preserved and the continuation of the First Peoples of the Americas must be insured. The United States has ratified the Covenant on Civil and Political Rights of the United Nations.

The Kuiu Thlingit Nation (aka the Kuye'di Tribe and Kuiu Kwáan) has existed since time immemorial. Its citizens are a permanent population sharing a specific history and territory; a common ancestry and lineage, tribal and ethnic background; religious, linguistic and cultural tradition. The Kuius have never relinquished rights, lands, waters, resources or liberties of any kind to any foreign power. The governing council safeguards the International Statehood and authority of the Nation and implements tribal law as sovereign. Tribal members are entitled to all ancestral rights and titles including those existing prior to contact with any Foreign Peoples including Tsarist Russia, Spain or the United States of America.

Deficiencies of the Current and Proposed Plan

Special Measures:

The current "plan" is deficient in that it contains no Special Measures recognizing or making provision for the special rights of tribes as indigenous peoples – rights that are mandated by international law, and United Nations covenants, agreements and accords and certain laws of th United States of America.

Dr. Y.N. Kly, Director of the International Human Rights Association of American Minorities (IHRAAM) Specialist in International Human Rights Law, states, "failure to provide priority rights or what is called Special Measures in International Law to the Indian Nations, leading to their extinction would be a grave violation of International Criminal Law, particularly as it relates to the Genocide Convention, to which the US is also a party. On all occasions the majority decision called for non-discrimination to include the requirement of special measures, special rights and self-determination in situations where they were warranted." The right to remedy under law is well established.

The actions of the Office of Subsistence Management and its parent governments and agencies are in violation of the Human Rights of the Indigenous Peoples. Those actions are illegitimate and actionable especially with regard to the state-wide corruption that has resulted in the theft o enormous amounts of resources.

ANCSA is supposed to add, not take away from, what we own. ANCSA, as great as it seems, is less than a meek offer by the United States and is actually a tear drop in the ocean of our huge assets we already have. ANCSA was written without our input regarding lands, waters, and resources, which cannot be taken away unless we give our consent.

Subsistence Award to Non-Natives:

By awarding subsistence to non-natives in Alaska, the state of Alaska has attempted to lump all persons, Indigenous and non-Indigenous alike into the same category, denying Indigenous Nations and Peoples their proper sovereign political status. This action has caused devastating impact on small streams and rivers, which have sustained Indigenous villages for thousands of years. Although the criteria utilized by the Office of Subsistence Management in assigning persons subsistence may be appropriate for non-Indigenous persons, it should be brought before the proper tribal authorities for approval and disposition on a Tribe by Tribe basis. The representatives of the federal and state agencies must come to a realization that each Tribe is properly and legally represented by their respective Traditional Tribal Elders and/or Village Councils. Corporations and entities created and funded by the various federal agencies, ostensibly for Indigenous benefit, are merely extensions of the federal agencies. An award of subsistence should in no way diminish tribal sovereignty or tribal rights or be utilized as a tool t exclude a portion of Indigenous peoples from their rights and titles based upon residence or oth irrelevant criteria.

Rural/Nonrural Designations not Applicable to Indigenous Peoples:

The criteria utilized for award of "subsistence" ignores the Indigenous Nations and Peoples of Alaska and their unique political status under International Law, the Constitution of the United States of America, and even the Alaska statehood Act and the Alaska State Constitution.

It is criminal to deny any First Peoples, due to physical residence, access to the resources that insure their health, ability to practice their culture and spirituality, and that guarantee their continuation as a distinct people. As noted to the Office of Subsistence Management in previous communications, our tribal members continue to practice their culture and way of life wherever they may reside.

"Subsistence" as defined by the Plan Not Applicable to Indigenous Peoples:

We prefer to use the words "traditional lifestyle" as "subsistence" is a non-Indigenous designation that we view as demeaning and arrogant.

Far more than simply supporting life, our traditional lifestyle speaks to the very heart and soul of the Thlingit Peoples. It speaks of respect for and our deep, spiritual ties to Mother Earth and our animal brothers and sisters. It speaks of Thlingits as caretakers, curators and protectors of all the resources of our Great Land.

The Traditional Lifestyle has always been and remains directly related to the spiritual, cultural and historical aspects of the Thlingit Peoples. Traditional foods and materials provide a bond and continuity to our forefathers. We are tied, in the form of respect, to the lands, waters, animals, fishes and fowl.

An Elder once compared the relationship between the Thlingit and our world to the closely interwoven fibers of the Chilkat blankets. Together they are durable and strong. Separating one from the other means the destruction of all. Indeed, the People cannot be true Thlingit unless we adhere to and practice our Traditional Thlingit Subsistence Lifestyle. Subsistence does not mean a tiny measured taste of traditional foods or only what we can carry away in our bellies. It means much more than supplying only immediate requirements. Products from the lands, waters and skies are employed for innumerable uses, such as providing foods, medicines, materials for shelter, waterborne vessels of transportation, clothing, furniture, and ceremonial and ornamental objects of art and providing and generating revenue.

Large quantities of natural resources from our region were utilized on a sustained yield basis. They were traditionally harvested, processed and stored. Portions of the harvest were commercially bartered, traded or sold to gather and accumulate wealth for days when families, Clans or Tribes would be required to assist in times of want or tragedy. When a Clan laid up goods, those goods served as a form of insurance for retirement and old age. A large portion of the first harvest was traditionally given to the elderly or incapacitated. The People commercially sold and bartered any or all of these items to secure by trade or purchase other goods that we di not manufacture or produce by our own efforts.

Our traditional lifestyle means the right to full, unrestricted utilization of the elements of our environment within the spiritual traditions, cultural traditions and customs of the Kwáan. These resources include:

Fishing. The Kuiu Kwáan have always utilized all resources located in both the fresh water and salt water systems for home and Tribal use, for barter and trade, or selling commercially whatever we chose, and what is available.

These water resources include, but are not limited to, all species of salmon that travel or pasture in our waters, bottom fish, trout, herring roe on kelp, all shellfish and crustaceans, various land, seabed vegetation and plants, and whatever is touched by the salt and freshwater systems.

Hunting. Traditional Subsistence has also includes utilizing all land mammals such as deer, moose, mountain goat, Mountain Sheep, brown bear, black bear, wolves, all fur-bearing mammals and virtually every animal that inhabits the region of the Kuiu Kwáan. All birds are utilized for food or ornamental use.

Forest and Land Products: All species of trees and vegetation are utilized for medicines, clothin shelter and to enhance the quality of Subsistence Lifestyle.
Spirituality, Happiness and Well-being: The Thlingit People cannot be Thlingit without access the lands, waters and resources that have been available to them from Tribal Lands for thousan of years.[1]

Traditional Economic Systems:

Traditional Economic Systems refers to the organized production and distribution of goods and services of a People, which enables them to live, subsist and continue as a people off the resources available to them. These systems include all the goods and services necessary to maintain all aspects of the culture to increase the survivability potential of the human being anc his family, Clan and Kwáan.

In Southeast Alaska, Subsistence Economic Systems have their basis with the Traditional Thlingit Kwáans that hold allodial title to their bioregional, kinship related regions. They are dependent upon distribution within Tribal systems that are based upon cooperation and need (rather than competition and greed).

This requires an inventory of the resources available within the Kwáan or Village structure, prioritizing these resources by their relative importance and abundance, and designation of the surplus resources to be used in the transfer or trade to other individuals, groups or nations.

The Kwáan Council (The Government of the Kuye'di) protects the Tribal Member's human rights and economic rights to resources. All Kwáan Members have a Trust Responsibility to respect, protect and nurture the resources. To do otherwise is *Thlickaws*. *Thlickaws* is an act of disrespect and ignorance or an act that breaks the Great Treaty. The perpetrators of such acts unleash negative forces upon themselves and their People. It is the same as asking for bad luck. It can result in grave consequences such as resources no longer being available.

Finally, The Indigenous Peoples, Tribes and Nations, have first priority to utilize all the resources of their respective regions. The immigrant peoples with their various entities, corporations and structures, may then utilize, only with agreement with each Tribe, the surplus as identified by the Indigenous Leadership.

Resolution No. 07-11

BY THE COUNCIL ANNETTE ISLANDS RESERVE

METLAKATLA INDIAN COMMUNITY

WHEREAS, *the Metlakatla Indian Community Council is the governing body of the Metlakatla Indian Community, Annette Islands Reserve, Alaska by the authority of the Constitution and By-laws of the Metlakatla Indian Community as approved on August 23, 1944 by the Secretary of the Interior; and*

WHEREAS, *the Metlakatla Indian Community is an Indian Tribe organized under the provisions of Section 16 of the Indian Reorganization Act. 25, U.S.C. Section 476; and*

WHEREAS, *the Metlakatla Indian Community, for centuries, has utilized all the natural resources of the land and waters in its traditional homeland for cultural activities, subsistence, gathering and general wellbeing, which lands include much of what is now the Tongass National Forest that are subject to the jurisdiction of the United States Forest Service; and*

WHEREAS, *the Metlakatla Indian Community, also has enjoyed the benefits of commercial logging and the sales of lumber products for its economic wellbeing and has opposed the shutdown of the Tongass National Forest as a source of raw materials for the Community's timber related industries; and*

WHEREAS, *the Metlakatla Indian Community, as a result of its multiple uses of the lands and waters within its homeland for cultural, subsistence and economic wellbeing, recognizes the need to balance the commercial use of resources from the forests with the need to protect vital fish and wildlife habitat, subsistence hunting and gathering areas and cultural sites; and*

WHEREAS, *the Metlakatla Indian Community, has carefully considered the foregoing balance regarding the uses of Gravina Island and recognizes that the island is far more valuable as a place where traditional uses are promoted, wilderness values preserved and wildlife habitat protected rather than as a place for commercial activities.*

NOW THEREFORE BE IT RESOLVED, *the Metlakatla Indian Community Council hereby request that, in its efforts to modify the Tongass Land Management Plan to comply with law, the Forest Service designates all federal land on Gravina Island to be wilderness or wilderness monuments or such other designation that will ensure that no further development takes place on the island and that it is preserved as a place where traditional cultural and subsistence activities can be pursued for all generation to come.*

Signed and dated this 6th day of March 2007 at Metlakatla, Alaska

RESOLUTION # 02-02-01

A RESOLUTION BY THE SAXMAN IRA COUNCIL, WHO IS THE TRIBAL GOVERNING BODY OF THE ORGANIZED VILLAGE OF SAXMAN OBJECTS TO ANY TIMBER CUTTING ON GRAVINA ISLAND.

WHEREAS, The Organized Village of Saxman (O.V.S.) is a duly constituted Indian Tribe, organized pursuant to the authority of Congress by the Indian Reorganization Act and such Legislation of June 18, 1934 and May 1936; and

WHEREAS, The Saxman IRA Council is authorized by the Organized Village of Saxman Constitution and By-laws approved on October 18, 1940 by the Secretary of Interior, and ratified on January 14, 1994 as the Tribe's governing body; and

WHEREAS, The Organized Village of Saxman is the Federally Recognized Tribe, governed by the Saxman IRA Council, who has the authority to represent and act in all matters that concern the health, education, and welfare of the Native people who reside in the Village of Saxman; and

WHEREAS, The United States Forest Service is proposing a timber cut on Gravina Island which has been our Tribal members food locker for hundreds of years; and

WHEREAS, Gravina Island is within the Tongass National Forest and is within the Timber Land Management Plan, and

WHEREAS, The Organized Village of Saxman has not participated in the development of the Timber Land Management Plan; and

WHEREAS, It is the opinion of the Organized Village of Saxman that TLMP is obsolete for today's plan because of many things that has happened since the plan has been approved without Tribal consent or input; and

WHEREAS, Gravina Island has been feeding our Tribal Members by way of hunting of the deer, and many different kinds of sea food, and the gathering of berries which provides for our food pantry for the Village of Saxman; and

WHEREAS, It is the Organized Village of Saxman belief that once cutting of timber on Gravina Island it will be easier to do in the future; and

WHEREAS, the cutting of timber will disrupt the food supply that has been feeding our Tribal Members for hundreds of years, and

WHEREAS, The Organized Village of Saxman has met with officials from the Forest Service on number of occasions and relayed this message, No Timber Cutting on Gravina Island, and

NOW THEREFORE BE IT RESOLVED the Organized Village of Saxman objects to any timber cutting on Gravina Island

CERTIFICATION:
Passed and Approved by a duly constituted quorum of the Saxman IRA Council.

RESOLUTION #07-06-94

A RESOLUTION FOR THE ORGANIZED VILLAGE OF SAXMAN BY THE SAXMAN I.R.A. COUNCIL TO STRONGLY REQUEST THE U.S. FOREST SERVICE TO PROTECT AND PRESERVE ALL WATER SHEDS THAT FEED INTO BOSTWICK INLET, AND TO REASSIGN THE U.S. FOREST SERVICE LAND USE DESIGNATION VALUE COMPARISON UNIT (VCU) 7630 FROM TIMBER PRODUCTION TO SEMI-REMOTE RECREATION.

WHEREAS, The Organized Village of Saxman is a duly constituted Indian Tribe organized pursuant to the authority of the United States Congress by the Indian Reorganization Act, and such legislation of June 8, 1934; and

WHEREAS, the Saxman I.R.A. Council is authorized by the Organized Village of Saxman Constitution and Bylaws approved on October 18, 1940 by the Secretary of Interior, and ratified on January 14, 1941, as the Organized Village of Saxman governing body; and

WHEREAS, the Organized Village of Saxman is the federally recognized tribe governed by the Saxman I.R.A. Council, who has the authority to represent and act in all matters that concern the health, education, and welfare of the Native people who reside in the Village of Saxman; and

WHEREAS, the Organized Village of Saxman is a federally recognized Tribe with all powers and responsibilities inherent in a sovereign government; and

WHEREAS, since time immemorial the economy, culture, spiritual tradition, and way of life of tribal citizens has been centered around fishing, hunting, and gathering natural resources, and the lands and waters in and around Bostwick Inlet are a natural food pantry ensuring a manner to sustain ourselves, for our grandchildren, and for seven generations and beyond; and

WHEREAS, all natural resources will suffer greatly if timber production occurs during any years to any water sheds feeding into the Bostwick Inlet Bay as timber production will adversely affect fishing, gathering, and hunting causing substantial harm to tribal citizens and the surrounding tribal communities; and

WHEREAS, these detrimental changes will impact our tribal sovereignty and a heartbreaking loss to the practice of customary and traditional harvesting of food for a tribal community dependent upon Bostwick Inlet; and

WHEREAS, it is particularly significant and critical to continue to fish, hunt, harvest, and gather in an accessible customary and traditional site for the revitalization and continuity of tribal Native culture and to carry on our traditions in Bostwick Inlet; and

WHEREAS, significant harm will afflict tribal natural and cultural resources from the creation and dissemination of large volumes of timber production creating other forms of pollution across the lands and watersheds feeding into Bostwick Bay; and

WHEREAS, salmon, other fish, wildlife, plants, other natural resources and cultural resources are important parts of our culture, economy, spiritualism, and way of life, and any harm to these harms us; and

WHEREAS, timber production execution in VCU 7630 will displace tribal citizens and have a direct economic and social impact creating a loss of assets or access to assets adversely impacting the tribal citizens' means to a livelihood; and

WHEREAS, scientific findings are not conclusive to the extent or impact timber production will have on the waters and lands at the conclusion of timber harvest and seven generations henceforth; and

WHEREAS, local tribal citizens are unable to devote countless hours to learn about, discuss, and debate land management options, but are aware of the sacredness and significance of Bostwick Inlet's food pantry provisions, and

WHEREAS, the U.S. Forest Service seeks out the promotion of a "collaborative approach" between agencies, partners, tribes, and local public (including tribal citizens) as a strategy on the use of forest lands and the Saxman I.R.A. Council believes its communication by resolution is a part of this approach; and

WHEREAS, the Saxman I.R.A. Council urges the U.S. Forest Service not to marginalize the social, economic, cultural identities of the tribal citizens of the Organized Village of Saxman by further timber harvest and to take positive action to safeguard the watersheds feeding into Bostwick Inlet.

NOW THEREFORE BE IT RESOLVED, the Organized Village of Saxman, Saxman I.R.A. Council hereby requests that the U.S. Forest Service and its officers deem the highest degree of protection for the watersheds feeding into Bostwick Inlet; and

BE IT FURTHER RESOLVED, the Organized Village of Saxman, Saxman I.R.A. Council requests the U.S. Forest Service and its officers to eliminate timber harvest in VCU 7630 and minimize risks to jeopardizing a means of livelihood to tribal citizens; and

BE IT FINALLY RESOLVED, the Organized Village of Saxman, Saxman I.R.A. Council vigorously requests the U.S. Forest Service to protect and preserve all water sheds that feed into Bostwick Inlet, and to re-assign the Value Comparison Unit (VCU) 7630 from Timber Production to Semi-Remote Recreation.

CERTIFICATION:
PASSED and **APPROVED** by a duly constituted quorum of the Saxman I.R.A. Council on the 18th day of July 2006 in Saxman, Alaska by a vote of 3 For, 0 Against, 0 Abstentions and 2 Absent.

Dear Denny Bschor,

The Saxman I.R.A. Council is submitting the enclosed official resolution which was approved at the March 20, 2007 Organized Village of Saxman, Saxman I.R.A. Council Meeting. Please let our resolution serve as the official position on the *Forest Plan Adjustment.* The Saxman I.R.A. Council is pleased to sign this resolution with a strong recommendation to protect and preserve significant cultural/spiritual/life-giving/healthy ecosystems within the Tongass National Forest.

I appreciate the opportunity to provide our tribal resolution for Bostwick Inlet, Yes Bay, Cat Island, and Duke Island. Thank you for defending critical areas of the *Tongass* – and for your commitment and hard work.

Sincerely,

Lee Wallace

RESOLUTION #03-07-104

A RESOLUTION FOR THE ORGANIZED VILLAGE OF SAXMAN, SAXMAN I.R.A. COUNCIL URGING THE U.S. FOREST SERVICE ALASKA REGION TO PROTECT HIGH VALUE AREAS OF BOSTWICK INLET, YES BAY, CAT ISLAND, AND DUKE ISLAND AS IT IMPROVES THE REVISION OF LAND AND RESOURCE MANAGEMENT PLANS (FOREST PLANS) FOR EACH OF THE NATIONAL FORESTS IN THE NATIONAL FOREST SYSTEM.

WHEREAS, the Organized Village of Saxman is a duly constituted Indian Tribe organized pursuant to the authority of the United States Congress by the Indian Reorganization Act, and such legislation of June 8, 1934; and

WHEREAS, the Saxman I.R.A. Council is authorized by the Organized Village of Saxman Constitution and Bylaws approved on October 18, 1940 by the Secretary of Interior, and ratified on January 14, 1941, as the Organized Village of Saxman governing body; and

WHEREAS, the Organized Village of Saxman (OVS) is the federally recognized tribe governed by the Saxman I.R.A. Council, who has the authority to represent and act in all matters that concern the health, education, and welfare of the Native people who reside in the Village of Saxman; and

WHEREAS, the Organized Village of Saxman is a federally recognized Tribe with all powers and responsibilities inherent in a sovereign government; and

WHEREAS, in August 2005, the U.S. Circuit of Appeals for the Ninth Circuit issued a decision in *Natural Resources Defense Council, et al., United States Forest Service, et al., 421 F.3d797 (9th Cir. 2005)* that found deficiencies and inadequacies in the process used to develop the 1997 Forest Plan revision; and

WHEREAS, the U.S. Circuit of Appeals for the Ninth Circuit specifically found deficiencies and inadequacies related to timber demand, the range of alternatives considered relative to timber demand and potential effects on roadless areas, and cumulative effects from activities conducted on non-National Forest System lands; and

WHEREAS, the U. S. Forest Service has specified that a 5 Year Plan Review (completed in January 2005) indicates a need to amend the current Tongass National Forest Land and Resource Management Plan; and

WHEREAS, the Organized Village of Saxman, Saxman I.R.A. Council seeks to preserve and afford protection of biodiversity and healthy ecosystems, wildlife habitat, sea life and fish habitat of Bostwick Inlet, Yes Bay, Cat Island, and Duke Island ensuring seven generations forthcoming will inherit and benefit from these high value areas; and

WHEREAS, the Organized Village of Saxman, Saxman I.R.A. Council strongly supports protection of the biodiversity and healthy ecosystems, wildlife habitat, and sea life and fish habitat of the Tongass National Forest lands and waters, and discourages the present and future environmental threat by timber harvest to the areas of Bostwick Inlet, Yes Bay, and Cat Island; and

Continuation of Resolution 03-07-104, page 2:

WHEREAS, the Organized Village of Saxman, Saxman I.R.A. Council is strongly against continued mineral exploration on Duke Island and firmly maintains that Duke Island be

withdrawn from any further mining claims for the present and future protection of Duke Island because it is an ideal site for numerous migratory birds including geese, and because Duke Island is a significance high use *"crossroads"* area for the Tlingit, Haida, and Tsimshian nations for salmon and bottom fish harvesting, and it possesses a historical link and cultural connection to past ancestors, and lastly the Draft E.I.S. Tongass Land and Resource Management Plan (January 2007) on page 3-280 states: *"Alernatives 4 – 7 would have a somewhat greater, but unknown, potential to contribute to cumulative effects associated with mineral activity."*; and

WHEREAS, the Draft E.I.S. Tongass Land and Resource Management Plan (January 2007) explains that the alternatives are constructed using the LUD allocations defined in the 1997 Tongass Forest Plan as the base, and the Organized Village of Saxman objects to the manner of using the 1997 Tongass Forest Plan as a base for constructing LUD allocations knowing that in 1997 and years prior to 1997, the Forest Service did not engage or establish consultation or cooperation with tribal officials of Saxman when the undertaking and formulation and implementation of the 1997 Tongass Forest Plan was developed; and

WHEREAS, in OVS Resolution 02-02-01 and OVS Resolution 07-06-94 from the Organized Village of Saxman, these resolutions attest to tribal and community member's use and harvest of a significant food supply and life giving nutrition from lands and water of Bostwick Inlet on Gravina Island.

NOW THEREFORE BE IT RESOLVED, that the Organized Village of Saxman urges the U.S. Forest Service to lessen and prevent irreversible harm to Bostwick Inlet, Yes Bay, Cat Island, and Duke Island by eliminating timber harvest and mineral exploration, and for the U. S. Forest Service to ensure a standard and guideline limiting timber harvest and mineral exploration activities that will assure exemplary stewardship for Bostwick Inlet, Yes Bay, Cat Island, and Duke Island for seven generations beyond the present; and

THEREFORE BE IT RESOLVED, the Organized Village of Saxman vehemently requests the U.S. Forest Alaska Region to protect, safeguard, and defend high value areas of Bostwick Inlet, Yes Bay, Cat Island, and Duke Island as it improves the revision of land and resource management plans (Forest Plans) for each of the national forests in the National Forest System.

CERTIFICATION:
PASSED and **APPROVED** by a duly constituted quorum of the Saxman I.R.A. Council on the 16th day of April, 2007 in Saxman, Alaska by a vote of 5 **For**, 0 **Against**, and 0 **Abstentions**.

Sitka Tribe of Alaska

Tribal Government for Sitka, Alaska

RECEIVED APR 19 2007 RA 4-19-07

April 12, 2007

Mr. Forrest Cole, Forest Supervisor
US Forest Service
Alaska Region, Tongass National Forest
648 Mission St.
Ketchikan, AK 99901

RE: Draft Environmental Impact Statement & Draft Proposed Land and Resource Management Plan

Dear Mr. Cole:

The Sitka Tribe of Alaska (STA) is a federally recognized tribal government, and represents over 4,084 tribal citizens based in Sitka. STA is responsible to protect the health, safety, welfare, and culture of our citizens. With this responsibility, Sitka Tribe is reviewing and commenting on your Tongass Land and Resource Management Plan Amendment.

Sitka Tribe of Alaska's customary and traditional territory reflects the lands and waters historically and presently of the Sheet'ka Kwaan, and as such is composed of the western side of Baranof Island, the greater reaches of Peril Strait, southwestern portions of Chichagof Island, and the myriad of islands as well as the waters between these locations.

Sitka Tribe is wary of supporting any of the proposed alternatives listed in the Environmental Impact Statement for the Tongass Land and Resource Management Plan. All of the alternatives contain a Right-of-Way for the Rodman Bay road, which Sitka Tribe strongly opposes. As one tribal member adamantly stated "I am disgusted with the road proposal." There are many in the Tribe who would prefer no option, no development because any development would affect our Customary and Traditional hunting, gathering and fishing sites.

If forced to support an alternative, after reviewing the options Sitka Tribe supports Alternative 1 with the exception of the Right-of-Way for the Rodman Bay road. This alternative would have the least impact on our Customary & Traditional resources and our cultural and sacred sites.

Sitka Tribe would like to address the following areas that are impacted by this plan. Sitka Tribe will not address each alternative and their potential impact because it is understood with each alternative, other than Alternative 1, will substantially affect subsistence, biodiversity, and environmental health. Alternatives 4 through 7 will have devastating impacts on Baranof Island and Sitka Tribe strongly opposes these alternatives.

456 Katlian Street • Sitka, Alaska 99835 • (907) 747-3207 • Fax (907) 747-4915

Land Use Development

Sitka Tribe recognizes the need for economic development, and wants to see economic development that will provide employment or contracting opportunities for our Tribal Citizens. Alternative 1 offers the least disruptive amount of timber harvesting; balancing between moderate and intensive harvesting the total harvest would be 52 million board feet, affecting 1.2 million acres. On Baranof Island deer habitat would receive significant reductions under all alternatives. deer habitat would receive substantial reductions under all alternatives, other than Alternative 1. The magnitude of effect is concentrated particularly on Baranof Island in Alternatives 4 through 7. Under all plans, the harvest on Baranof affects areas that are primary Customary and Traditional hunting and gathering sites.

The Forest Service needs to increase their efforts to manage these stands on Baranof to increase biodiversity. Currently there are four (4) areas on Baranof where the harvest of Sitka deer exceeds 10% of the estimated habitat capability. Without question, any further development will affect the habitat in a negative manner.

Sitka Tribe propose the impact be mitigated by treating the pre-commercial and young growth forest that has developed on the island through past clear cutting by thinning, chipping, and burning slag in place. Thinning is an activity that not only encourages local hire but also will increase the biodiversity of the stands- improving scenic quality, concentrating growth in the fewer larger trees, and improving wildlife habitat.

Steps must be made to remove logging slash that has scarred the habitat on Baranof for decades and rehabilitate the acreage through treatment or reseeding. Sitka Tribe of Alaska encourages the Forest Service to form partnerships with private and public organizations utilizing such organizations such as the Ketchikan Wood Technology Center and other Forest Service Science Centers to address and correct this specific issue. Grants such as Woody Biomass Grants, FS Tribal Granting programs can be utilized in solving the problem of how to utilize low valued material removed from the habitat. Sitka Tribe would commit itself in collaborating with the Forest Service in addressing the forest slash and pre-commercial and young forest growth to improving this environmental and working toward a healthy biodiversity habitat. One Tribal Member in recommending effective slash treatment stated, "In Washington and Oregon the logging companies are required to treat before they wave the logging site, and treating means they burn and spread the ashes of large stumps. The material that can be chipped is spread around once processed, so no piles of debris are left scattered everywhere. These suggestions are a better solution rather than removing the slabs."

Tribal Citizen John Nielsen stated at an STA Cultural Committee meeting, "I've been a resident of Sitka for seventy-seven years. The damage that the Forest Service has done to this country has been devastating. The harvest areas that were clear-cut thirty or forty years ago have been damaged and are subject to mudslides. All the alternatives have the proposed road, and I don't want the road put in place. If the road is put in place, there will be no regulations on vehicles and this would damage the area more. The Tribe should say 'NO' to the proposed road. The previous damage to the habitat ruined fish streams at Nakwasina, Fish Bay, Ushk Bay, Poison Cove, and Fick Cove. Now they want to farm fish and that is not the way to go since it doesn't

make good dry fish. I don't want to see no more clear cutting and no more new roads being built. There should be a way to figure out how to put fish back in the streams."

Trails and Road Development

Sitka Tribe of Alaska was very concerned when the Sitka Access issue came up a few years ago, and Sitka Tribe held a Tribal Citizens' meeting with members of our cultural committee, Customary and Traditional Committee, Herring Committee, and Native Allotment owners, among others. After gathering input from this meeting, Sitka Tribe **opposed** the Rodman Bay alternative. Sitka Tribe supported the Warm Springs route is the least invasive of the roads proposed for "improving" ferry service.

Sitka Tribe is very concerned that *all of the alternatives* contain a Right of Way for the Rodman Bay road. Sitka Tribe is *strongly opposed* to a Right of Way for the Rodman Bay road. Sitka Tribe of Alaska stands opposed to any further road development Again the Tribe reiterates that Sitka Tribe are mandated to protect the hunting, gathering and fishing habitat of our tribal members.

Sitka Tribe is wary of new trails, and would like to be informed of all proposed trails. All trails and roads will impact traditional hunting, gathering and fishing sites, historical and sacred sites to varying degrees. Any trail and road development will increase access to these sites. Increase in access will amplify the impact on the biodiversity of the areas cited for development. A large percentage of the trails and roads proposed will utilize old logging trails that initiated environmental damage to the habitat in the 50s and 60s. Should any development occur, Sitka Tribe propose that in addition to upgrading the trails and roads, funds be utilized for habitat restoration. Examples of habitat restoration Sitka Tribe would like to see include clearing the slags, stumps, rehabilitating the habitat through thinning and other means. Sitka Tribe encourage the Forest Service to develop whatever means possible to restore the clear-cut areas to enhance the biodiversity of the habitat.

Native Allotments:

The land use development plan as well as the trails and roads affect our current and pending allotments. Since time immemorial, Tlingits have utilized this country for settlements, for both summer and winter harvesting campsites. It was not until the middle of the 20th century that an Alaska Native was even allowed to own property. From the beginning of our relationship with the federal government, aboriginal title has been largely ignored until the discovery of oil on the North Slope brought about an immediate need for settlement of aboriginal title. The Allotment Act was instituted but never implemented until "Pence vs. Kleppe" forced BLM to reopen allotment applications that were closed without due process. Due process difficulties have exponentially been made more complicated by time, loss of witnesses, Forest Service removing substandard cabins, etc. Only a fraction of camps will be returned to their rightful owners in the Sheet'ka Kwaan territory.

Many of the allotments awarded have been damaged by clear-cutting and other means. By its definition, allotment land is federal property and as such is the responsibility of the United States Government to protect. The Forest Service by definition is a part of the United States Government. Allotments have been damaged in part due to the misfeasance of the Forest Service. The Forest Service, not unlike the Sitka Tribe of Alaska, the Bureau of Indian Affairs, Park Service and the

Bureau of Land Management, has a responsibility to ensure the protection of the rights of the allottees to enjoy their allotments and realize the full benefits intended in the title.

Native allotments are situated in prime subsistence habitats. All trails, roads, land use development plans will impact some if not all of the allotments (with the possible exception of the Warm Springs road plan). **The Forest Service needs to take affirmative action not only to correct past wrongs but also to prevent future damage to allotments.** Sitka Tribe of Alaska encourages the Forest Service to enjoin a partnership with us to ensure the protection of the allotments and develop sound management to ensure future use to the maximum extent possible.

Sacred Sites:

Sitka Tribe greatly appreciates the efforts of the Forest Service, and specifically John Autrey, to work with the Tribe on drawing up a sacred sites policy. Sitka Tribe is very pleased to see this as part of the Forest Plan. The Forest Service needs to continue acting with continued due diligence in regard to acknowledging and recording sacred sites. The Forest Service will actively ensure that all Forest Service Officers and Line Officers require all employees: 1) Protect tribal cultural and historical information, 2) Consult with Tribes on matters that may affect tribal rights and interests, 3) Work with the Tribes in providing research, transfer of technology, and technical assistance where needed or agreed to concerning cultural and historical information, 4) Ensure that repatriation of Native American human remains and associated funerary objects is done in accordance with the requirements of the Native American Graves Protection and Repatriation Act.

Scientific evidence now embraces the fact that Tlingit have inhabited the Tongass for at least 10,000 years. Baranof Island has been the home to Tlingit since time immemorial. In recent history, Katlian's battle of 1804 has been marked in history as the last armed battle of aboriginal natives of North America against Europeans. It also marked the end of the expansion of the Russians in North America. Ad infinitum, this battle marks the determination and will of all Tlingit to protect their home and its infinite blessings the Tongass gives to its people. Land use development, trails, and roads will not only affect the biodiversity of the habitat but also will directly traverse Native allotments, historical and sacred sites including Katlian's retreat. Any development will require the due diligence and care by the Forest Service in working with the Sitka tribe in identifying and protecting these, sites, camps, villages and trails.

Tribal citizen Duck Didrickson stated at an STA Cultural committee meeting, "This is sacred land. There are many sacred places and the proposed road needs to be opposed now. The previous clear cuts have scarred the land, and people were told that in fifty years the land would be back to normal, which hasn't happened… There should be a plan established for the timber harvest and it should be presented to the Tribe how it's going to be done. There are many sacred places on the proposed road that should be protected. They should use helicopters rather than build a road on the land that the Tlingits have used for thousands of years. If there is timber cut in the proposed areas, the sacred lands will be gone."

In conclusion, Sitka Tribe can support only Alternative 1 *without the Rodman Bay road Right-of-Way*. Sitka Tribe also encourages the Forest Service to emphasize the rehabilitation of areas clear-cut in the Sitka area. Restorative measures need to be emphasized. Sitka Tribe of Alaska needs to be a party in any plan the Forest Service adopts. Sitka Tribe encourage the Forest

Service to adopt local hire and utilize Native hire in its practices that has been exercised in Angoon and Hoonah for maintenance and rehabilitation in the development of trails and roads, cabins and other recreational sites the Forest Service develops. The labor force for the logging and wood products sector in southeast Alaska is comprised of 35% nonresidents. One Tribal member stated "In previous instances, they have hired from down south and met the knowledge of local culture requirement by accepting the statement that they can learn the Native culture. The local and Native hiring policy should be more concrete than a puff of smoke." Sitka Tribe asks that the Forest Service to work cooperatively with the Sitka Tribe and the city of Sitka in reducing the nonresident work force in the logging and wood products industry on Baranof Island to the single digits.

The Tongass Land and Resource Management Plan Amendment while comprehensive is not conducive to thorough review of the developments and or plans that may impact Tribal Customary and Traditional Country. For example in Land Use Designations for timber harvests for each alternative the presentation is on a forest wide harvest. Sitka Tribe would like to see the alternative plans be identified into more specific areas such as Baranof Island where Tribal citizens can have easy access to and discern where the timber production would be, the allowable sale quantity and quality, and the impact designation for Baranof Island through each alternative plan.

In closing, thank you for this opportunity to comment. Sitka Tribe wishes to emphasize the importance of our Customary & Traditional [subsistence] resources and the importance in our cultural sites in *any* alternative considered. If you have any questions, please do not hesitate to contact Helen Dangel Lorrigan, Resource Protection Director for Sitka Tribe at (907) 747-3207.

Sincerely,

Lawrence Widmark

Tongass National Forest
Attention: Forest Plan Adjustment
648 Mission Street
Ketchikan, AK 99901

This letter serves as the Yakutat Tlingit Tribe's official public comment regarding the draft Tongass Land Management Plan (TLMP). The Yakutat Tlingit Tribe has thoroughly evaluated all the Alternatives as well as the Standards and Guidelines, but limited our comments as they apply to the Yakutat Ranger District. We respect other Tribe's and communities opinions with respect to their preferred Alternatives and draft EIS as a whole.

The Yakutat Tlingit Tribe has chosen to modify Alternative 2, in particular the LUD boundaries and designations, to fit with our tribal members' and communities desire for only small timber sales in the Yakutat District. "Just under two-third of residents (61%) also support or strongly support small timber sales" according to the Yakutat Community Opinion Survey: An Analysis of Planning and Development Issues in Yakutat (October 2005, prepared by Sheinberg and Associates for the City and Borough of Yakutat).

You will find an attached map representing the Tribe's wishes to eliminate industrial logging within the Yakutat Ranger District but fulfill small local sawmill and personal use needs by changing the LUD along FS 10 from Timber Production to Modified Landscape designation. All other land outside of this designation have been converted to Semi-Remote LUD.

The boundaries of this LUD were moved outside of the Greater Situk Watershed as significant timber harvest and salvage sales have occurred in this very important area. The Yakutat Tlingit Tribe wishes to protect the Greater Situk Watershed from further timber harvest and salvage in order to sustain a critically important commercial salmon fishery and a world-class sport fishery until it the watershed has been restored. The eastern boundary was lengthened along FS 10 to offer more acres of small timber sales in roaded areas easily accessed by local small sawmill owners. This boundary and LUD change will allow provide approximately 8,984 acres of National Forest for sustainable harvest

Within the Scenic Viewshed and Modified Landscape LUDS we recommend the following changes to TLMP for the Yakutat Ranger District:

1.) Support 200-year rotation with pre-commercial and commercial thinning at logical intervals when needed.
Conversations with local sawmill owners and USFS studies indicate that 200 years is a minimum time span for harvested units to begin producing saw log quality trees and protecting many species (Hanley et al. 2005).

2.) Support selected harvest and small 1-2 acre "patch cuts"
This style of harvest is possible in Yakutat due to the flat topography. Small patch cuts do not open the forest canopy as readily to the wind as does large clear cutting methods. Selected harvest, when done correctly, provides for continuing forest function and remains useful for wildlife, watershed health and the public

3.) Support small sales to meet community needs and create small timber base for value-added wood industry (wood toys, instrument wood, molding, beams, etc.)
The Yakutat Community Opinion Survey conducted in 2005 indicated that 61% of the community is in favor of a small sales program. Only 17% of the community was opposed to this level of logging.

4.) Require research into windthrow patterns for use in harvest planning
On page 3-33 of the West Forelands Landscape Assessment (YRD 2005) the Forest Service, in regard to blowdown damage, states: ***"Almost half the stands adjacent to previous harvest openings had more then 50 percent canopy damage. Over 90 percent of the most severe damage occurred in stands adjacent to harvest openings and about 87 percent of the least damaged stands were in isolated patches".*** Since past management of the USFS has already opened up the Yakutat Foreland Forests to increased blow down intensity, the FS should be responsible for stabilizing the existing unites through research and action.

5.) Require above grade/overlay on all constructed logging roads. Establish a BMP for temporary road construction that prohibits altering the natural seasonal flow of surface or groundwater.
Often logging roads are cut below grade resulting in diverted surface and groundwater. Many streams intersect these below grade roads leading to fry dying when the below grade road surface water dries. To avoid this, roads must be planned with annual flooding in mind.

6.) Require funds generated from sale of timber be set aside for post harvest thinning treatments, silvicultural research, and restoration work.
When problems arise due to management actions by the Forest Service it should be incumbent that money is set aside for mitigation in a timely manner.

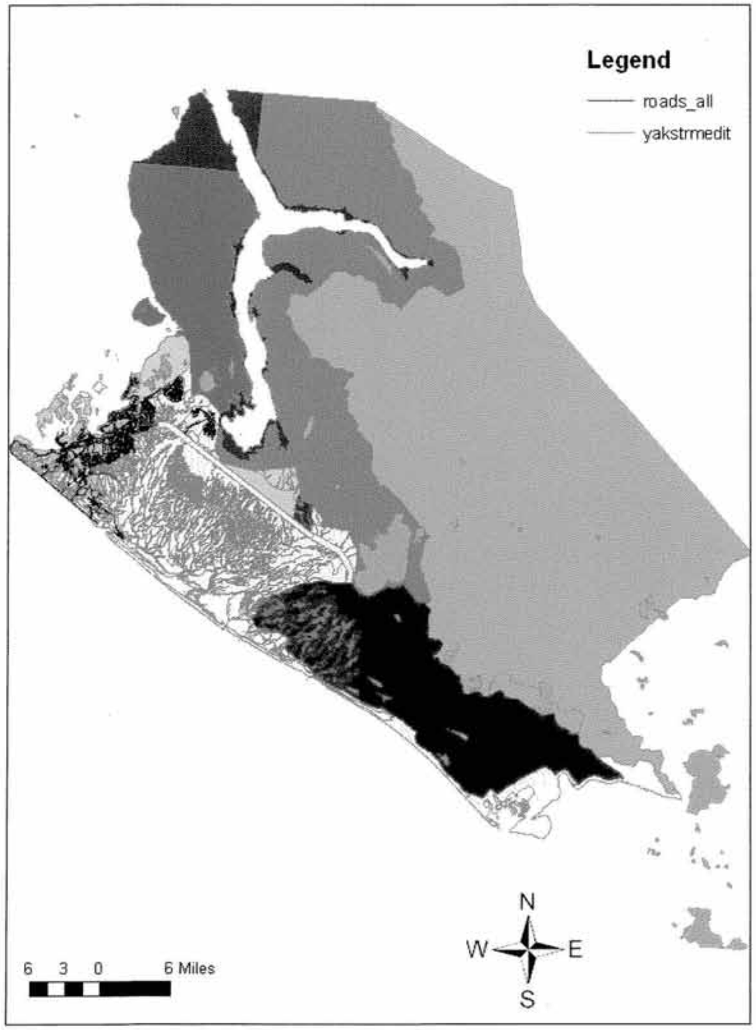
7.) Increase stream buffers from 200 to 500 feet depending on channel type and width. The 500 foot buffer was suggested in the USFS report entitled <u>Scientific Information and the Tongass Land Management Plan: Key Findings from the scientific literature, species assessment, resource analysis, workshop, and workshop risk assessment panels. (1996)</u>

The Yakutat Tlingit Tribe would like the lands surrounding Yakutat to be managed to provide fish and wildlife habitat to support our subsistence foods, tourism, and commercial fishing, sustainably harvest and locally-used lumber and firewood without risking significant damage to our forest and habitat, and a healthy forests for future generations.

Sincerely,

Victoria L. Demmert
President

Alternative 2 Modification



City of Coffman Cove
Resolution 07-14

A RESOLUTION IN SUPPORT OF ALTERNATIVE 7 OF THE DRAFT LAND RESOURCE MANAGEMENT PLAN FOR THE TONGASS NATIONAL FOREST

WHEREAS, Coffman Cove is located in the Tongass National Forest, and

WHEREAS, the residents of Coffman Cove have an abiding respect for the forest, lakes, rivers and wildlife, and

WHEREAS, the need to have a diversified economy with year round jobs with benefits is essential, and

WHEREAS, the Tongass National Forest can support resource development and recreation while maintaining the integrity of the forest for wildlife and fish habitat, and

WHEREAS, the timber industry should be maintained at a level to provide quality jobs and encouraging development of new markets and industry, and

WHEREAS, a stable timber is essential to maintain a timber industry, and

WHEREAS, at the current level of 300 million board feet the Forest Service is only able to supply less than 60 million board feet of timber per yard due to lawsuits and injunctions, and

WHEREAS, 60 million board feet is not adequate to encourage development or maintain a good job market.

NOW THEREFORE IT BE RESOLVED the City of Coffman Cove supports alternative 7 for the revised Tongass Land Management Plan.

CITY OF CRAIG ALASKA

April 6, 2007

RECEIVED APR 18 2007 4-18-07

Mr. Forest Cole
Forest Supervisor
Tongass National Forest
648 Mission Street
Ketchikan, AK 99901

Dear Mr. Cole:

The City of Craig supports Alternative 7 of the proposed draft Land and Resource Management Plan for the Tongass National Forest. This alternative alone provides a balance of recreational, industrial, environmental, and cultural uses of the forest. Alternative 7 meets this balance by providing 5.9 million acres of wilderness areas, 5.8 million acres of natural setting, 1.7 million acres of moderate development, and 3.4 million acres designated as intensive development.

Prince of Wales Island is an excellent example of how the forest can be managed to accommodate all users. The island supports: the timber, sport fishing, trapping, and tourism industries; recreational users of the forest; a strong commercial fishing industry; facilities that provide clean and renewable hydroelectricity; an extensive public road system; a healthy and flourishing population of terrestrial fauna; municipal watersheds; and other resources. The island also contains approximately 147,000 acres of wilderness, 169,000 acres of LUD II set-aside areas, miles of river corridor reserves, and twelve distinct communities. These wide ranging activities demonstrate the compatibility of many uses within the forest.

The City of Craig believes that one goal of the new TLMP should be to seek a more diverse economy in Southeast through the restoration of a healthy timber industry. In order to accomplish that goal, it is imperative that an adequate, reliable supply of economic saw log-quality timber be provided from the Tongass Forest. Only Alternative #7 approaches the needed annual timber supply needed for the industry.

The Tongass Forest has a biological potential of providing an annual timber harvest of 1.3 billion board feet. Only about 1.5 million acres from the 5.7 million acres of commercial timberland on the Tongass must be managed for multiple-use in order to sustain a 360 million board foot timber supply. Since the 1.5 million multiple-use acres can include most of the existing 2nd-growth acreage, about 75% of the Tongass old-growth will be untouched in perpetuity. This modest harvest from the National Forest needs to be clearly pointed out in the FEIS and reflected in the final amended plan.

In addition, based on updated science and a decade of field implementation experience with the 1997 TLMP, the current conservation measures that should be excluded from the final amended plan are:

(907) 826-3275 • Fax (907) 826-3278 P.O. Box 725, Craig, Alaska 99921

1. The marten and goshawk standards.
2. The 100-foot buffers on each side of all Class III, non-fish streams.
3. The large, medium, and small Habitat Conservation Areas (HCA) and the old-growth reserve strategy.
4. The 1000-foot beach and estuary buffers (reduce to 500-feet, except in 2[nd] growth areas where the buffer would be 100-feet).

In addition to the above four problematic conservation measures contained in the 1997 plan, the proposed addition of a Legacy Forest Structure guideline in the amendment calling for the retention of old growth timber stand characteristics within all harvest units should be excluded. This requirement would further hamper the economics of timber sales, would create safety hazards during harvest, would leave large trees subject to future wind damage and would increase the costs of sale planning and layout.

Once the planning is completed and these changes are in place, I would ask the US Forest Service to immediately begin preparing sufficient timber sales to allow for the investment necessary to sustain a fully integrated manufacturing industry.

As you are aware the US Forest Service has worked recently with the Nature Conservancy on what are commonly called restoration projects on Prince of Wales Island. The City of Craig supports these efforts and asks the US Forest Service to continue a program of restoration work here, and if possible continue its cooperative relationship with the Nature Conservancy on these projects.

The forest offers many resources to the public. As it decides which forest plan alternative to adopt, the Forest Service should attempt above all else to provide access to all the various resources in the forest. While this approach will likely mean that no one user group gets a development plan that suits its needs only, such a result is not a reasonable expectation for any one group to hold. In the final analysis the Forest Service should adopt the alternative that provides meaningful access to all user groups within the 17 million acre Tongass National Forest, and Alternative 7 meets that test.

Subject: Draft EIS for the Tongass Forest Plan amendment

Greetings!

The Assembly of the City and Borough of Juneau adopted attached Resolution 2408(b), A Resolution Expressing Assembly Support of the Tongass Futures Roundtable, at its meeting of Wednesday, April 25, 2007.

The resolution expresses the CBJ Assembly's strong support for the forest industry as an important component of the Southeast Alaska Economy. The Assembly commends to the Forest Service the principles adopted by the Tongass Futures Roundtable, and supports the efforts of the Tongass Futures Roundtable to achieve through consensus a "long-term balance of healthy and diverse communities, vibrant economies, responsible use of resources – including timber, while maintaining the natural values and ecological integrity of the forest."

This comment and the attached resolution were e-mailed to: r10_tongass_juneau_rd_plan_adjustment@fs.fed.us on Thursday, April 26, 2007.

Thank you for the opportunity to comment.

Sincerely,

Laurie Sica, CMC
Municipal Clerk
City and Borough of Juneau, Alaska

Presented by: Mayor Botelho
Introduced: 04/25/2007
Drafted by: J.W. Hartle

RESOLUTION OF THE CITY AND BOROUGH OF JUNEAU, ALASKA

Serial No. 2408(b)

A Resolution Expressing Assembly Support of the Tongass Futures Roundtable.

WHEREAS, Southeastern Alaska provides the setting for the Tongass National Forest, the nation's largest national forest at nearly 17 million acres. A 500 mile long archipelago of fjords, glaciers, ridges, jagged peaks, forests, and wetlands, the Tongass forest comprises much of the largest temperate rainforest remaining on Earth; and

WHEREAS, the Forest Service is an agency of the U.S. Department of Agriculture and manages public lands in national forests and grasslands through management plans; and

WHEREAS, the Forest Service originally adopted the current Tongass Forest Plan in 1997 and it has been amended many times since then; and

WHEREAS, additional adjustments and updates of the Forest Plan (officially called a Forest Plan Amendment) are intended to comply with an August 2005 Ninth Circuit Court of Appeals decision and to respond to the findings of the recently completed Tongass Forest Plan 5 Year Review; and

WHEREAS, the Assembly believes that a diverse economy in Southeast Alaska includes a healthy timber industry; and

WHEREAS, the Assembly has supported efforts of the Tongass Futures Roundtable a diverse group of stakeholders, including members of the forest industry, long involved in the Tongass to discuss how to incorporate Southeast Alaska's economic, cultural and ecological values in public policy issues throughout the region; and

WHEREAS, the Tongass Futures Roundtable has identified the following five principles as areas of significant common interest regarding the Tongass Land Management Plan amendments:

1. Protect intact watersheds with important values;
2. Manage timber lands to provide a steady, reliable, and predictable supply of timber to the industry;
3. Transition from old growth to second growth;
4. Promote, support and fund a forest and riparian restoration program; and
5. Provide sufficient, economic timber to support an integrated manufacturing industry.

NOW, THEREFORE, BE IT RESOLVED BY THE ASSEMBLY OF THE CITY AND BOROUGH OF JUNEAU, ALASKA:

Section 1. The Assembly of the City and Borough of Juneau expresses its strong support for the forest industry as an important component of the Southeast Alaska economy.

Section 2. That the Assembly commends to the Forest Service the principles adopted by the Tongass Futures Roundtable.

Section 3. That the Assembly supports the efforts of the Tongass Futures Roundtable to achieve through consensus a "long-term balance of healthy and diverse communities, vibrant economies, responsible use of resources - including timber, while maintaining the natural values and ecological integrity of the forest."

Section 4. Effective Date. This resolution shall be effective immediately upon adoption.

Adopted this 25th day of April, 2007.

Merrill R. Sanford for
Bruce Botelho, Mayor

Mr. Forrest Cole, Forest Supervisor
USDA Forest Service
Tongass National Forest
Federal Building
Ketchikan, AK 99901

Dear Mr. Cole,

Reference is made to the Tongass Land and Resource Management Plan Amendment DEIS January 2007.

The following are the Ketchikan Gateway Borough's concerns relating to this plan amendment:

As you are aware the Ketchikan Borough experienced a serious loss of yearlong family wage jobs with the closure of the pulp mill and then the veneer plant in Ward Cove. One of the key reasons for these closures was lack of an available timber supply along with market conditions and related business decisions. We have pursued an operator for several years for the veneer plant and we believe the new owners will reopen the veneer plant. They have completed a test run of the veneer plant with positive results. Full production of the mill will require a wood supply from the Tongass National Forest. Absence of an adequate timber supply for the veneer plant and other mills in SE Alaska will be devastating to our already fragile economy, and will result in hundreds of jobs leaving the community.

The Forest Service controls 92.9 % of the land within Tongass National Forest; with only 1% being private lands - with the balance of land being owned by the state, local governments, or native corporations. Clearly only a balanced multiple use management plan for the Tongass National Forest lands will provide for the economic health and well being of SE Alaska communities.

A 2000 report by the McDowell Group stated "*Since 1990, volume of timber harvested from the Tongass National Forest has dropped from 470 million board feet to 120 million board feet annually, a 75 percent decline. Timber industry employment is at its lowest point in over 30 years, now directly accounting for only about 670 jobs. At its peak, in the 1970s, the Tongass generated 4,000 timber industry jobs in Southeast Alaska.*" Further on the report states "*Total employment and payroll in Ketchikan are down by 12 percent since 1995. The community has suffered a net decline of 950 jobs and $30 million in annual payroll. Real payroll (adjusted for inflation) has dropped 16% since 1995.*"

Since the 2000 report, the timber harvested on the Tongass has declined another 60%. The few remaining sawmills are struggling to secure enough timber to maintain at least a single-shift operation so they can stay in business and maintain some key employees until an adequate timber supply is restored.

In 2000, Congress passed the Secure Rural Schools Act. This Act provided a safety-net of payments in lieu of the boroughs and unorganized areas of Southeast Alaska's share of timber receipts from the

Tongass. That legislation expired in 2006 and, unless the Act is reauthorized, the boroughs and local governments in Southeast Alaska will again be reliant on the stumpage receipts. At current harvest levels, the loss to Southeast Alaska communities will be about $9 million per year. This amounts to approximately $400,000 that the Ketchikan Gateway Borough relies upon to help fund our borough school system. This is in addition to the lost jobs and lost economic activity from the timber sale program. This loss of funding will mean the local governments will need to raise local taxes to provide funding for schools and roads at current service levels.

The Ketchikan Gateway Borough supports the restoration of the timber industry in Southeast Alaska. The industry, the Southeast Conference, the State of Alaska, the Alaska Congressional Delegation and many others envision a fully integrated timber manufacturing industry in Southeast Alaska. The experts agree that about 360 million board feet of economically harvestable timber is the minimum volume that is needed to enable that vision to become a reality. Since alternative #7 in the Draft Environmental Impact Statement for the Tongass Plan Amendment is the only alternative that seems to satisfy that minimum requirement, we recommend that alternative #7, or one that provides a similar timber supply, be adopted in the final forest plan.

We are also concerned about the issue of timber sale economics on the Tongass. Our understanding is that several of the management prescriptions that were developed for the 1997 land management plan are the primary reason that over half of the timber sales prepared in recent years have been uneconomic, in other words, the cost of accessing, harvesting and processing the timber exceeds the value of the products produced. This situation is even more troubling when one recognizes that wood product prices have been at very high levels in recent years.

<u>Access and Harvest Costs</u>
Both the timber industry and Forest Service District timber sale planners blame most of the high construction and logging costs on four of the 1997 management prescriptions:

1. Mandatory buffer strips on non-fish streams. The Alaska Forest Practices Act requires 100-foot buffers on each side of all anadromous fish streams and high-value resident fish streams whereas the 1997 land management plan requires the 100-foot buffers on all anadromous and resident fish streams and all Class-3 non-fish streams. The requirement to maintain these 200-foot wide strips on the abundant non-fish streams is terribly costly and of questionable value. We agree with the industry that these non-fish stream buffers should be required on a case by case basis and only when absolutely necessary.

2. 1,000-foot no-cut buffers on all beach fringes. The State Forest Practices Act does not require these buffers and prior to the 1997 plan, only 500-foot buffers were required. Consequently, we support much smaller beach fringe buffers such as called for in alternative #7. Also, since the beach fringe buffers were added for old-growth habitat, we support using a much smaller buffer in existing 2nd-growth areas. Managing as much of the existing 2nd-growth as possible for timber production will lessen the need to harvest old-growth timber in other areas.

3. The old-growth reserve strategy sets aside about a million acres of large, medium and small tracts of the highest volume, lowest harvest cost timber stands. Too often the remaining timber stands in each area have such low volumes and high harvest cost that they are not operable once the old-growth parcels are removed. The old-growth reserve strategy is unnecessary because only 1.5 million acres of commercial timberland are needed to sustain the 360 million board foot harvest level. That leaves about 4.2 million acres of old-growth timber on commercial

4. timberland well distributed across the Tongass. Surely leaving ¾ of the old-growth timber untouched in perpetuity is adequate without the imposition of the old-growth reserve strategy.

5. Marten and Goshawk partial cuts. Requiring partial cutting on cable harvesting units is both dangerous and extremely costly. It is also unnecessary for a region that has more than ¾ of its commercial timberland preserved in an old-growth timber status. Furthermore, the guidelines fc protection of these wildlife species are not well founded in science.

The high operating costs associated with the four above guidelines would be further exacerbated if the Legacy Forest Structure guideline as proposed in alternatives #1-6 were adopted. It calls for maintenance of old growth forest structure in all harvest units. Such practices would increase sale design, layout and harvest costs, while creating additional safety hazards. We oppose the inclusion of the above mentioned standards in any of the alternatives.

Manufacturing costs

The cost of manufacturing forest products is higher than necessary because the timber supply has been so severely constrained for so long. The few remaining mills cannot make the necessary investments to remain optimally competitive when they are struggling to maintain a single-shift operation. Further, the sawmill operators are compelled to saw many logs that would more appropriately go to a veneer plant, a fiberboard plant or some other type of processing facility. Sawing these unsuitable logs lowers both the productivity in the mills and the value of the lumber that the mills produce. As a consequence the manufacturing cost is higher than necessary.

Many of the Borough's citizens depend upon subsistence of fish and wildlife resources for their families The Borough does not believe the harvesting and growing of timber under Alternative #7 will be detrimental to the fish and wildlife resources. In fact, we believe species such as deer can and will be more plentiful if Alternative 7 is selected and indeed implemented.

This DEIS is in response to a Ninth Circuit court ruling. Three key issues have been identified: 1) protecting high-value roadless areas, 2) providing a sufficient timber supply to meet market demand and maintain a vibrant economy, 3) protecting wildlife habitat and biodiversity. The Ketchikan Gateway Borough fully believes that Alternative 7 with suggested changes will completely meet and fulfill these key issues.

Summary

The Ketchikan Gateway Borough urges you to adopt an alternative like #7 with whatever changes are needed to insure a suitable land base of 1.5 million acres that provides at least 360 million board feet of economic timber sales offered for sale every year. The industry needs a reliable supply of timber and the 360 million board foot operating level can be provided from a small portion of the Tongass.

These comments were approved by vote of the Ketchikan Gateway Borough Assembly on April 2, 2007

Sincerely,

Joe Williams
Mayor

To Whom It May Concern:

At its regular meeting of April 5, 2007, the Ketchikan City Council unanimously approved Resolution No. 07-2190 supporting a sustainable annual economical timber harvest in Southeast Alaska. This resolution reaffirms the position the City Council has strongly supported for several years: the timber industry is essential to the economic health of Southeast Alaska, and a key component of a healthy and diversified economy in Ketchikan.

The Ketchikan City Council continues to believe that the Tongass National Forest should be managed through the Tongass Land Management Plan and local forest planning efforts. Please consider this resolution as part of the comment record regarding this issue.

Sincerely,

Bob Weinstein

RESOLUTION NO. 07-2190

A RESOLUTION OF THE CITY OF KETCHIKAN, ALASKA SUPPORTING A SUSTAINABLE ANNUAL ECONOMICAL TIMBER HARVEST; RECOGNIZING THE IMPORTANCE OF THE TIMBER INDUSTRY TO SOUTHEAST ALASKA; AND ESTABLISHING AN EFFECTIVE DATE

WHEREAS, the USDA Forest Service is requesting public comment on the Draft Environmental Impact Statement (DEIS) and the proposed Tongass Land Management Plan (TLMP) Amendment; and

WHEREAS, 5.7 million acres of the ten million acre Tongass National Forest are classified as "productive timberland;" and

WHEREAS, approximately 1.5 million acres, inclusive of those areas previously logged, are necessary to sustain a viable economical timber supply in Southeast Alaska; and

WHEREAS, the timber industry in Southeast Alaska has long been a cornerstone of many local economies throughout the region; and

WHEREAS, sustainable timber harvest is consistent and compatible with Ketchikan's interests and goals related to a healthy and diversified economy.

NOW, THEREFORE, BE IT RESOLVED by the Council of the City of Ketchikan, Alaska as follows:

Section 1: The Council of the City of Ketchikan, Alaska expresses support for the public comment process relative to the Draft Environmental Impact Statement (DEIS) and the proposed Tongass Land Management Plan (TLMP) Amendment.

Section 2: The Council of the City of Ketchikan affirms that there are approximately 10 million forested acres in the Tongass National Forest and of that, only 5.7 million acres are currently classified as "productive timberland."

Section 3: Of the 5.7 million acres that are currently classified as "commercial timberland," the Council of the City of Ketchikan urges the USDA Forest Service approve a Tongass Land Use Management Plan (TLMP) Amendment that makes available 1.5 million productive forested acres, inclusive of those acres previously logged, to sustain a viable economical timber supply in Southeast Alaska.

Section 4: The Council of the City of Ketchikan affirms its support of a sustainable economical timber harvest as a component of healthy local and regional economies within Southeast Alaska.

Section 5: This resolution shall become effective immediately upon adoption.

CITY OF KUPREANOF
P.O. BOX 50
PETERSBURG, ALASKA 99833

April 23, 2007

To: Chris Savage, Acting Petersburg District Manager

Subject: Forest Plan Revision, Tongass National Forest

Dear Mr. Savage,

Please enter into public comments Resolution #05-1 from the City of Kupreanof regarding Land Use Designations for the acquired land parcel known as the Petersburg Creek Land Acquisition. This property adjoins the City of Kupreanof and the Petersburg Creek Duncan Salt Chuck Wilderness. A copy of this Resolution is attached.

When the Forest Service makes a decision regarding the Forest Plan Revision and the Petersburg Creek Land Use Designation the City of Kupreanof wishes to restate its strong community desire that the "Tongass National Forest use WILDERNESS designation on all lands within the Petersburg Creek water shed and the remaining lands within the Petersburg Land Acquisition be designated as REMOTE RECREATION".

Thank you for your consideration,

Robert Dolan

Mayor, Robert Dolan

FOREST SERVICE

RESOLUTION #05-1

A RESOLUTION OF THE CITY OF KUPREANOF, ALASKA REQUESTING THAT THE PETERSBURG RANGER DISTRICT, TONGASS NATIONAL FOREST USE A COMBINATION OF WILDERNESS AND REMOTE RECREATION AS THE LAND USE DESIGNATION FOR THE ACQUIRED LAND PARCEL KNOWN AS THE PETERSBURG CREEK LAND ACQUISITION.

WHEREAS, this acquired property is either adjacent to or contained within the City boundaries of the City of Kupreanof and/or borders the Petersburg Creek/Duncan Salt Chuck Wilderness; and

WHEREAS, the entire Petersburg Creek drainage, except these lands, is already designated wilderness; and

WHEREAS, the Kupreanof Policy Plan has a stated goal to "Preserve a roadless community"; and

WHEREAS, the Kupreanof Policy Plan has a policy that states "The City of Kupreanof shall oppose all road construction within its boundaries"; and

WHEREAS, Remote Recreation and Wilderness designations would best protect the purity of potable water sources for Kupreanof residents; and

WHEREAS, it is contained in the City of Kupreanof City Code of Ordinances, Ordinance 76-2 Section 1, "All motorized land vehicles will be prohibited within city limits except on private property". Remote Recreation designation would best support the City of Kupreanof's use policies and the character of the surrounding lands.

THEREFORE, BE IT RESOLVED THAT THE City of Kupreanof strongly requests that the Petersburg Ranger District, Tongass National Forest use WILDERNESS designation on all lands within the Petersburg Creek water shed and the remaining lands within the Petersburg Creek Land Acquisition be designated as REMOTE RECREATION.

Passed and approved by the duly constituted quorum of the City Council of the City of Kupreanof, Alaska on this 10th day of April, 2005.

CITY OF PELICAN
RESOLUTION 2007-7

A RESOLUTION FOR THE CITY OF PELICAN, ALASKA URGING THE UNITED STATES FOREST SERVICE TO MANAGE TONGASS FOREST RESOURCES IN A SUSTAINABLE AND BALANCED MANNER.

WHEREAS, the residents of the community of Pelican, Alaska are heavily dependent on the resources of the Tongass National Forest for our food, health, livelihoods, and lifestyles; and

WHEREAS, Pelican's economy is inextricably linked to the health of the fisheries resource; and

WHEREAS, Pelican residents rely heavily on subsistence foods; and

WHEREAS, road building, according to the Draft Environmental Impact Statement, poses the "greatest risk to fish resources; and

WHEREAS, the projected market demand in all the proposed alternatives greatly exceeds current market demand; and

WHEREAS, the City of Pelican supports small mills and their sustainable and value-added operations in the Tongass; and

WHEREAS, none of the alternatives provided adequately address climate change and global warming issues nor provide for adequate game corridors; and

WHEREAS, it is in Pelican's best interest that old growth watersheds remain intact to provide habitat, subsistence, fishing, hunting, recreation, and tourism opportunities.

NOW, THEREFORE BE IT RESOLVED that the City Council of Pelican, Alaska urges the Forest Service to provide funding for restoration of damaged culverts that block fish passage on existing roads; and

RECEIVED APR 30 2007 4-30-07

BE IT FURTHER RESOLVED that the Forest Service manage, rehabilitate and offer sales in second-growth forests to meet the needs of small mill operators and set harvest levels consistent with recent market demands; and

BE IT FURTHER RESOLVED that the City Council of Pelican, Alaska urges the Forest Service to manage the forest in a sustainable manner that will provide for varied and healthy ecosystems and an economy that allows sustainable use of subsistence, fisheries, timber, and tourism resources.

PASSED, APPROVED AND ADOPTED THIS 30th DAY OF APRIL, 2007.

RESOLUTION 07-02

WHERE AS the residents of Port Alexander are heavily dependent upon the Tongass Forest for our water, health, livelihoods and lifestyles, and

WHERE AS the days of slash clearcutting have gone the way to be replaced to a large degree by a value added forest products mentality, and

WHERE AS most of these products have evolved into a potential second growth sourced manufacturing process, and

WHERE AS so many of the other industries of the Tongass base, such as fisheries, tourism, fishing and hunting charter operations, personal recreation and scenic majesty have also evolved into a multifaceted shared resource. Therefore,

BE IT RESOLVED the City of Port Alexander would recommend that the Forest Service take steps to finally eliminate the utilization of the old growth forests for the timber industry; that the Forest Service take steps to assist the current level of forest product manufacturers in transitioning from the old growth to the second growth primary resources.

RE: City of Wrangell comments on TLMP/DEIS

Dear Supervisor Cole:

The City of Wrangell would like to offer the following comments on the Tongass Land Management Plan Amendment and Draft Environmental Impact Statement.

Wrangell fully supports the restoration of a healthy timber industry to improve the economy of Southeast Alaska and our own community. In order to accomplish this, it is imperative that an adequate, reliable supply of economic timber be provided from the Tongass National Forest.

As you are aware, the City of Wrangell experienced a serious loss of direct yearlong family wage jobs when the mill closed and the subsequent loss of population. Over ten years later, Wrangell is still feeling the decline in the economy due to continued loss of population and the economic staying power to help build businesses and encourage support and service industries. Full production of the Wrangell sawmill will require an economically viable wood supply from the Tongass National Forest. The absence of an adequate timber supply will devastate the large and small mills in SE Alaska and further impact our already fragile economy, resulting in hundreds of additional jobs leaving the region and the less than 75 direct jobs Wrangell has now employed in the timber industry, not to mention other businesses and jobs relying on the employees of the industry for their direct and indirect income.

The US Forest Service controls 92.9% of the land within the Tongass National Forest with only 1% being private lands and the balance of land being owned by state, local governments or native corporations. A balanced *multiple use* management plan for the Tongass National Forest, that includes timber harvesting, can provide economic health and well being for Southeast Communities. It appears that optimistic or unrealistic assumptions were used previously when defining the ability of the state and private lands to annually supply timber. The vast majority of commercial timberland in southeast Alaska is within the National Forest. Much of the non-federal timberland is now in 2nd-growth timber that will not be mature and again commercially harvestable for about another 30-40 years. Thus, the timber supply must come from the Tongass National Forest.

To assure that the Tongass Land Management Plan provides sustained employment for the region, Wrangell offers the following comments:

- The management of the Tongass National Forest must be based on a balanced multiple use plan that provides the employment, goods and services needed by SE Alaska communities both in the short and long term. Economies of SE Alaska must be weighed heavily during consideration.

- When calculating and analyzing economic impacts, examine the impacts on a community-by-community basis and do not claim that the benefits from a growing community that does not depend on the timber industry somehow offset the negative impacts on communities that do depend on the timber industry.

- The areas scheduled for harvest should be concentrated in intensive management blocks so that fewer roadless and high value areas will be impacted.

- Four of the conservation management measures that were developed for the 1997 TLMP are the primary reason that over half of the timber sales prepared in recent years have been uneconomically viable, in other words, the cost of accessing, harvesting and processing the timber exceeds the value of the products produced. This situation is even more troubling when one recognizes that wood product prices have been at very high levels in recent years. Harvests should be designed and managed so that all of the usable wood is taken and used in some form of value-added manner.

1. Mandatory buffer strips on non-fish streams. The Alaska Forest Practices Act requires 100-foot buffers on each side of all anadromous fish streams and high-value resident fish streams whereas the 1997 land management plan requires the 100-foot buffers on all anadromous and resident fish streams ***and*** all Class-3 non-fish streams. The requirement to maintain these 200-foot wide strips on the abundant non-fish streams is terribly costly and of questionable value. We agree with the industry that these non-fish stream buffers should be required on a case by case basis and only when absolutely necessary.
2. 1,000-foot no-cut buffers on all beach fringes. The State Forest Practices Act does not require these buffers and prior to the 1997 plan, the buffers were not required. Smaller beach fringe buffers could be possible on a case by case basis. The all encompassing beach fringe buffers were added for old-growth habitat, but smaller buffers in existing 2nd-growth areas could be permitted for future sustainable harvest areas. Managing as much of the existing 2nd-growth as possible for timber production will lessen the need to harvest old-growth timber in other areas.

3. The old-growth reserve strategy sets aside about a million acres of large, medium and small tracts of the highest volume, lowest harvest cost timber stands. Often the remaining timber stands in each area have such low volumes and high harvest cost that they are not operable once the old-growth parcels are removed. In stead of the old-growth reserve strategy, if the USFS could identify 1.5 million acres of commercial timberland needed to sustain a healthy industry managed for second growth harvesting, that leaves about 4.2 million acres of old-growth timber on commercial timberland that would not be harvested well distributed across the Tongass. Surely leaving ¾ of the old-growth timber untouched in perpetuity is adequate without the imposition of the old-growth reserve strategy.
4. Marten and goshawk partial cuts. Requiring partial cutting on cable harvesting units is both dangerous and extremely costly and would be unnecessary for a region that has more than ¾ of its commercial timberland preserved in an old-growth timber status.

- Establish sale design on the basis of the resources needing protection and otherwise try to maximize production.

- Provide sufficient, economic timber to support an integrated manufacturing industry and do so at an economy of scale that allows the Southeast Alaska timber industry to harvest and process timber competitively with other regions in the world.

- Manage the forest for multiple uses, one of them being timber harvest. Expanding already developed areas, extending existing roads, and staying out of other higher value areas can concentrate harvest to select areas. But some of the standards and guides would need to be relaxed to allow more harvesting in these already developed areas and road extensions. Enough land for a long term sustainable 2nd growth forest could be developed.

In summary, the City of Wrangell urges the Forest Service to fairly evaluate all portions of the alternatives and select a preferred alternative that allows an annual harvest level to maintain full employment and use of the existing mills as well as permit job growth and manufacturing growth opportunity in the wood manufacturing component. The City also urges the Forest Service to provide flexibility with the conservation management measures in order to more intensely manage harvest areas for timber harvesting.

Once the planning is completed and these changes are in place, we would like the U.S. Forest Service of the Tongass National Forest to immediately begin preparing sufficient timber sales to allow for the investment necessary to restore a fully integrated timber manufacturing industry and healthy economies.

CITY OF WRANGELL, ALASKA

RESOLUTION NO. 04-07-1081

A RESOLUTION OF THE COUNCIL OF THE CITY OF WRANGELL, ALASKA, COMMENTING ON THE TONGASS LAND MANAGEMENT PLAN AMENDMENT AND DRAFT ENVIRONMENTAL IMPACT STATEMENT AND SUPPORTING A SUSTAINABLE TIMBER HARVEST

WHEREAS, the City of Wrangell fully supports the restoration of a healthy timber industry to improve the economy of Southeast Alaska and our own community; and

WHEREAS, the City of Wrangell has continued to see a decline in the local economy due to the loss of jobs directly related to the timber industry and indirectly from the continued loss of support and service industry jobs to the community from the declining population; and

WHEREAS, the Southeast Conference has been analyzing the Draft Environmental Impact Statement (DEIS) and proposed Tongass Land Management Plan (TLMP) Amendment and made initial comments to the US Forest Service; and

WHEREAS, unless the problematic conservation measures are adequately addressed and sufficient acres are dedicated to intensive timber management as SEC recommends, there will not be an adequate, reliable supply of economically harvestable timber available to restore an integrated industry and support the many timber dependent communities in Southeast.

NOW, THEREFORE, BE IT RESOLVED BY THE COUNCIL OF THE CITY OF WRANGELL, ALASKA, is on record supporting the Southeast Conference's comments on the 2007 Tongass Land Management Plan Amendment and Draft Environmental Impact Statement and encourages the U.S. Forest Service to work with communities and Southeast Conference to seek solutions in achieving economic diversification and social well-being of Southeast Alaska by developing a sustainable timber harvest within the Tongass National Forest.

To: Tongass National Forest
Attention: Forest Plan Adjustment
648 Mission Street
Ketchikan, AK 99901

The following letter is submitted by the City and Borough of Yakutat Assembly as official public comment regarding the upcoming adjustments to the Tongass Land Management Plan (TLMP). The attached map illustrates the desires of the community of Yakutat regarding land use designations on National Forest within our borough boundaries. This map has been endorsed by the Yakutat Tlingit Tribe, the Yakutat Salmon Board and The Yakutat Planning and Zoning Commission.

We have modified Alternative 2 in regards to Intensive Development, Modified Landscape, Scenic Viewshed and Semi-Remote Recreation Land Use Designations (LUDS).

We have eliminated all intensive development LUD acreage and converted 4,798 acres to modified landscape to allow small timber sales and free-use while encouraging select harvest and small one to two acre "patch cuts". We have reduced the Scenic Viewshed LUD along forest highway 10 to 4,197 acres. The reduction of the Scenic Viewshed LUD is based on its proximity to the Situk River on the Western end of FH10 and the low grade cottonwood/spruce forest on the Eastern end. This alteration will allow for sustainable harvest on 8, 984 acres of National Forest Land.

All remaining lands outside of these designations have been converted to Semi-Remote Recreation LUD. The one exception, which appears to be a FS clerical oversight, is the redesignation of the LUD surrounding Tanis Lake in the Brabazons. This should be redesignated as remote recreation in place of semi remote recreation to match the surrounding LUD. The former timber harvest LUDS redesignated for semi-remote recreation includes the clearcuts along Tawah Creek and the Lost River and the entirety of the federally owned portions of the West Fork Situk, Upper Situk and Old Situk HUC3 Watersheds. Harvest in these watersheds has exceeded sustainable levels. Furthermore, the two major growth industries in Yakutat remain commercial fishing and tourism. We feel that by increasing acreage managed for recreation and subsistence, the USFS will restructure the focus of their budgets by funding tourism infrastructure and planning, and research of fisheries and wildlife resources that community depends on.

Below are specific recommendations for alterations to the TLMP. These comments are made for the geographical area of Yakutat only. However, some of these recommendations may be applicable to the Tongass National Forest as a whole.

Within the Scenic Viewshed and Modified Landscape LUDS we recommend the following changes to TLMP for the Yakutat Ranger District:

1.) Support 200 year rotation with precommercial and commercial thinning at logical intervals when needed.

Conversations with local sawmill owners indicate that 200 years is a minimum time span for harvested units to begin producing saw log quality trees.

2.) Support selected harvest and small 1-2 acre "patch cuts"

This style of harvest is possible in Yakutat due to the flat topography. Small patch cuts do not open the forest canopy as readily to the wind as does large clear cutting methods. Selected harvest, when done correctly, provides for continuing forest function and remains useful for wildlife, watershed health and the public

3.) Support annual small sale program to meet community needs and create small timber base for value added wood industry (wood toys, instrument wood, molding, beams, etc.)

A community survey conducted in 2005 indicated that 61% of the community is in favor of a small sales program. Only 17% of the community was opposed to this level of logging.

4.) Require research into windthrow patterns for use in harvest planning

On page 3-33 of the West Forelands Landscape Assessment (YRD 2005) the Forest Service, in regard to blowdown damage, states*:" **Almost half the stands adjacent to previous harvest openings had more then 50 percent canopy damage. Over 90 percent of the most severe damage occurred in stands adjacent to harvest openings and about 87 percent of the least damaged stands were in isolated patches"***. Since past management of the USFS has already opened up the Yakutat Foreland Forests to increased blow down intensity, the FS should be responsible for stabilizing the existing unites through research and action.

5.) Require all logging roads be constructed above grade. Establish a BMP for temporary road construction that prohibits altering the natural seasonal flow of surface or groundwater.

The attached photos illustrate how roads divert surface and groundwater. To avoid this, roads must be planned with annual flooding in mind.

6.) Require funds generated from sale of timber be set aside for post harvest thinning treatments, silvicultural research, and restoration work.

When problems arise due to management actions by the FS it should be incumbent that money is set aside for mitigation in a timely manner.

7.) Increase stream buffers from 200 to 500 feet depending on channel type and width. The 500 foot buffer was suggested in the USFS report entitled <u>Scientific Information and the Tongass Land Management Plan: Key Findings from the scientific literature, species assessment, resource analysis, workshop, and workshop risk assessment panels. (1996)</u>

The attached photo shows a riparian buffer failure off the end of a USFS 2000 acre clearcut. This buffer was 300 feet wide.

What the majority of Yakutat Residents want is to have, in essence, a community woodlot that is managed sustainably and at low intensity. We want the timber lands managed so that they can be used by all residents for lumber and firewood, provide habitat for wildlife and fish, a place to hunt and trap, and a landscape that shows visitors good stewardship practices. The rest of the non-timber National Forest land is presently providing well managed commercial fishing, guiding, and subsistence opportunities for Yakutat's citizens and the public of the United States. We commend this management and encourage the Forest Service to focus on these activities as the planning team rewrites TLMP.

Sincerely,

Dave Stone, Mayor

February 2005 Yakutat Salvage Sale II Road

May 2004 – blowdown harvest road on private land adjacent to National Forest

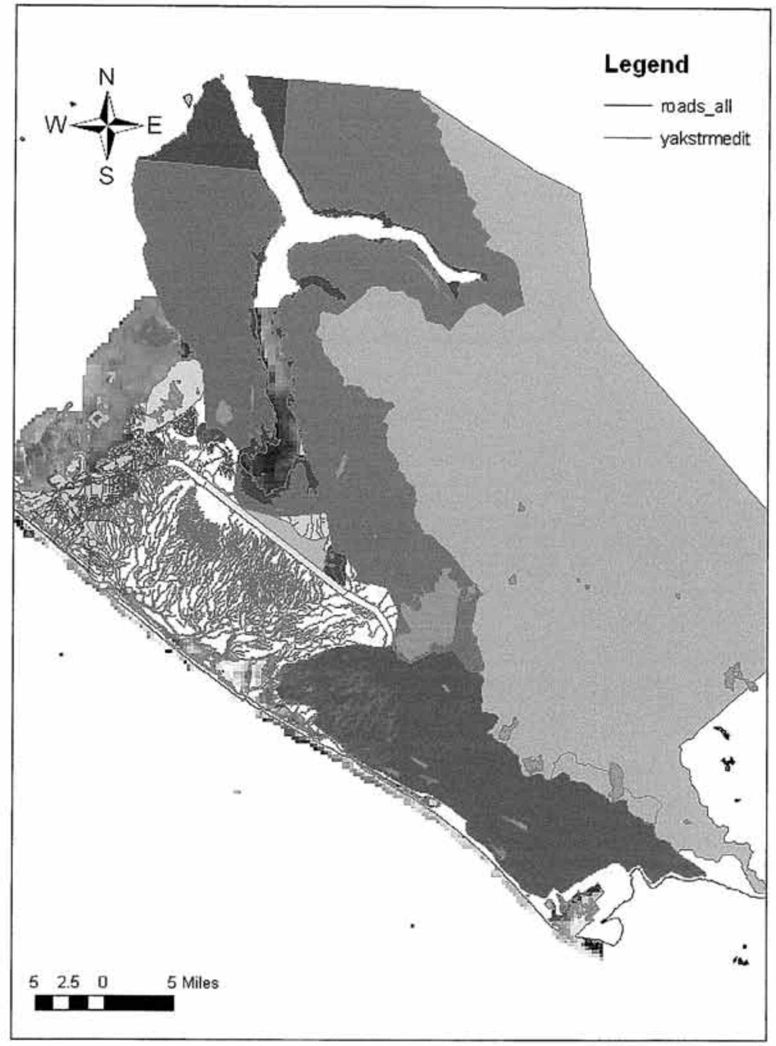
Alternative 2 Modification



H-A101

Land Use Designations

WILDERNESS AND NATIONAL MONUMENT

Wilderness and Wilderness National Monument- Preserve essentially unmodified areas to provide opportunities for solitude and primitive recreation. Limit motorized access.

Non-Wilderness National Monument - Facilitate the development of mineral resources in a manner compatible with the National Monument purposes.

MOSTLY NATURAL SETTING

LUD II - Maintain the wildland characteristics of these congressionally-designated unroaded areas. Permit fish and wildlife improvements and primitive recreation facilities.

Old-Growth Habitat - Maintain old-growth forests in a natural or near-natural condition for wildlife and fish habitat.

Research Natural Area - Manage areas for research and education and/or to maintain natural diversity on National Forest System Lands.

Semi-Remote Recreation - Provide for recreation and tourism in natural-appearing settings where opportunities for solitude and self-reliance are moderate to high.

Remote Recreation - Provide for recreation in remote natural settings outside Wilderness, where opportunities for solitude and self-reliance are high.

Municipal Watershed - Manage municipal watersheds to meet State water quality standards for domestic water supply.

Special Interest Area - Preserve areas with unique archaeological, historical, scenic, geological, botanical, or zoological values.

Wild, Scenic, or Recreational River - Maintain and enhance the outstandingly remarkable values of river segments which qualify the river to be classified as a Wild, Scenic, or Recreational River.

MODERATE DEVELOPMENT

Scenic Viewshed - Maintain scenic quality in areas viewed from popular land and marine travel routes and recreation areas, while permitting timber harvest.

Modified Landscape - Provide for natural-appearing landscapes while allowing timber harvest.

Experimental Forest - Provide opportunities for forest practices research and demonstration.

INTENSIVE DEVELOPMENT

Timber Production - Manage the area for industrial wood production. Promote conditions favorable for the timber resource and for maximum long-term timber production.

Minerals - Encourage mineral exploration and development of areas with high mineral potential.

Re: Tongass Land Management
Plan (TLMP) Comment

Greetings U.S. Forest Service,

Thank you for your time. Craig Community Association is a federally recognized Tribe; with 672 qualified and enrolled Tribal members.

This letter is in regards to the comment that is requested for the Tongass Land Management Plan (TLMP). As a federally recognized Tribe, we support "Alternative 1".

"Alternative 1" takes a lot of economic stress that our forest might not be able to handle anymore. The 20th Century was "The easy way out". In the end, our lands are paying for our mistakes. We must protect and preserve our precious forest. Keeping our logging to a minimum is crucial to the survival of the 21st Century. Southeast Alaska is nothing without our forest.

Alternative 1 will provide a mix of National Forest uses and activities, but would give much additional emphasis to maintaining inventoried roadless areas, associated fish and wildlife values, and unroaded recreation, tourism, and subsistence opportunities, relative to the current Forest Plan. Timber would be managed primarily within the roaded land base and the vast majority of inventoried roadless areas would remain in a natural condition. A total of 1.2 million acres of the Tongass would be in Development LUDs and 15.6 million acres would be in Non-development LUDs.

The 21st Century is full of opportunity- capitalize. We need to get our 20th Century thought and applications out of the stream and start to apply 21st Century consequences with our future actions. We must not make the same mistake again.

The data presented in your EIS shows a decline in the amount of timber being harvested within the TNF; as well as an increase in recreational and subsistence activities. The data presented should be considered in making your decision. We are suggesting that recreation, subsistence and "sacred sites" be put in the front, and set timber sales to a gradual halt.

We understand that up to 450 employees in Southeast Alaska depend on the timber industry (5%). Please take into consideration how many other employees that can be implemented to a National Forest that supports recreation, tourism, and subsistence; not to mention how much wildlife will be enhanced (62% natural resource based). More employees will benefit this "New Horizon", with the interagency protection of our "Sacred Sites".

More areas of great concern are the protection of our subsistence rights, and the conservation and monitoring of our "sacred sites" that are located within the TNF. Sacred Sites are valuable to indigenous people of the TNF. These areas should be protected and monitored under Tribal/USFS interagency supervision. These sacred areas need special attention and will require sensitive monitoring from both governmental agencies. This action will provide balance- a much needed ingredient in today's economy.

Tourism has spiked since the 1990's and will continue to grow. Tourists will not travel to come and see a land that "Once thrived". Tourists are eager to see the true meaning of "The Last Frontier".

Our environment- this is the largest concern in our Draft EIS for the Tongass Land Management Plan. With the increase in the Industrial Age and in global population, a lot of weight is being put on natural resources. Once again, balance is the key ingredient missing in this recipe.

The introduction of noxious or invasive animal and plant species in our forests is drawing more concern with each new initiation. They present no natural predators to control this silent outbreak. Interagency attack is an effective "first-step" to remediation. The Forest Service and Tribes must work together.

Global climate change has scientific based proof that Alaska's overall temperature is increasing faster than any area in the world. Our trees and plants have the balancing effect to help neutralize such worldwide events from happening. We must protect our future today.

We thank you for your time and consideration.

Respectfully,

Dennis Nickerson
Environmental Coordinator
Craig Community Association

April 17, 2007

Mr. Forest Cole
Forest Supervisor
Tongass National Forest
648 Mission Street
Ketchikan, AK 99901

RECEIVED
APR 18 2007
RAS 4-18-07

Dear Mr. Cole:

The Prince of Wales Community Advisory Council supports Alternative 7 of the proposed draft Land and Resource Management Plan for the Tongass National Forest. This alternative alone provides a balance of recreational, industrial, environmental, and cultural uses of the forest. Alternative 7 meets this balance by providing 5.9 million acres of wilderness areas, 5.8 million acres of natural setting, 1.7 million acres of moderate development, and 3.4 million acres designated as intensive development.

POWCAC is an association of communities on Prince of Wales Island (POW) dedicated to improving the quality of life on Prince of Wales. POWCAC achieves this goal by acting in an advisory capacity to State and Federal agencies concerning issues that affect Prince of Wales communities.

Prince of Wales Island is an excellent example of how the forest can be managed to accommodate all users. The island supports: the timber, sport fishing, trapping, and tourism industries; recreational users of the forest; a strong commercial fishing industry; facilities that provide clean and renewable hydroelectricity; an extensive public road system; a healthy and flourishing population of terrestrial fauna; municipal watersheds; and other resources. The island also contains approximately 147,000 acres of wilderness, 169,000 acres of LUD II set-aside areas, miles of river corridor reserves, and twelve distinct communities. These wide ranging activities demonstrate the compatibility of many uses within the forest.

POWCAC believes that one goal of the new TLMP should be to seek a more diverse economy in Southeast through the restoration of a healthy timber industry. In order to accomplish that goal, it is imperative that an adequate, reliable supply of economic timber be provided from the Tongass Forest. Only Alternative #7 approaches the needed annual timber supply needed for the industry.

PARTICIPATING COMMUNITIES:
Coffman Cove, Craig, Hollis, Hydaburg, Kasaan, Klawock, Naukati, Thorne Bay, Whale Pass

The Tongass Forest has a biological potential of providing an annual timber harvest of 1.3 billion board feet. Only about 1.5 million acres from the 5.7 million acres of commercial timberland on the Tongass must be managed for multiple-use in order to sustain a 360 million board foot timber supply. Since the 1.5 million multiple-use acres can include most of the existing second growth acreage, about 75% of the Tongass old growth will be untouched in perpetuity. This modest harvest from the National Forest needs to be clearly pointed out in the FEIS and reflected in the final amended plan.

In addition, based on updated science and a decade of field implementation experience with the 1997 TLMP, the current conservation measures that should be excluded from the final amended plan are:

1. The marten and goshawk standards.
2. The 100-foot buffers on each side of all Class III, non-fish streams.
3. The large, medium, and small Habitat Conservation Areas (HCA) and the old growth reserve strategy.
4. The 1000-foot beach and estuary buffers (reduce to 500-feet, except in 2nd growth areas where the buffer would be 100-feet).

In addition to the above four problematic conservation measures contained in the 1997 plan, the proposed addition of a Legacy Forest Structure guideline in the amendment calling for the retention of old growth timber stand characteristics within all harvest units should be excluded. This requirement would further hamper the economics of timber sales, would create safety hazards during harvest, would leave large trees subject to future wind damage and would increase the costs of sale planning and layout.

Once the planning is completed and these changes are in place, the US Forest Service should begin immediately preparing sufficient timber sales to allow for the investment necessary to sustain a fully integrated manufacturing industry.

As you are aware the US Forest Service has recently worked with the Nature Conservancy on what are commonly called restoration projects on Prince of Wales Island. POWCAC supports these efforts and asks the US Forest Service to continue a program of restoration work here, and if possible continue its cooperative relationship with the Nature Conservancy on these projects.

The forest offers many resources to the public. As it decides which forest plan alternative to adopt, the Forest Service should attempt above all else to provide access to all the various resources in the forest. While this approach will likely mean that no one user group gets a development plan that suits its needs only, such a result is not a reasonable expectation for any one group to hold. In the final analysis the Forest Service should adopt the alternative that provides meaningful access to all user groups within the 17 million acre Tongass National Forest. Alternative 7 meets that test.

Thank you for considering our comments.

Sincerely,

Jon Bolling
POWCAC Chairman

Dear sirs,

H-A104

The Southeast Regional Advisory Council (SERAC) met in Kake, Feb. 26 through Mar. 1, 2007. SERAC represents all southeast subsistence communities including Yakutat. The Council is authorized by the Alaska National Interest Lands Conservation Act (ANILCA) and chartered under the Federal Advisory Committee Act to provide recommendations to the Federal Subsistence Board concerning regulatory and land management actions that may affect subsistence uses of fish and wildlife. ANILCA and the charter also recognizes the Council's authority to "initiate, review and evaluate proposals for regulations, policies, management plans, and other matters related to subsistence uses of fish and wildlife on public lands within the region" and to "provide a forum for the expression of opinions and recommendations…..(on) any matter related to the subsistence uses of fish and wildlife on public lands within the region." Our 13 Council members come from 11 Southeast Alaska communities. They are very well informed concerning the effects of timber management in the region. The Council provided comments on the Tongass Land Management Plan Revision on Nov. 11, 1997 (appended); many of our comments at made at that time remain valid today.

At our recent meeting, Council members reviewed the Tongass Land and Resources Management Plan Amendment, Draft Environmental Impact Statement (DEIS). The Council wishes to acknowledge the attention paid to the review of this plan by Council members Bangs, Hawkins, Hernandez, and Wallace. The following are the Council review comments. Overall, the Council is concerned that the DEIS does not adequately recognize the importance of the subsistence use taking place in the Tongass National Forest, that it does not provide sufficient protections for this use, and that it does not provide enough information to evaluate the foreseeable effects of proposed timber

management, increased levels of tourism and non-subsistence consumptive use, and of global warming on subsistence uses.

1. **Purpose and need**. The Council questions the treatment of the DEIS of market demand. While the Tongass Timber Reform Act may direct Forest Service to meet market demand, Forest Service may have interpreted "market demand" incorrectly. The best indicator of market demand is current and past harvest levels actually achieved. Over the past decade, actual harvests from Federal public land have generally been under 100 mmbf per year. This recent recorded harvest provides an accurate metric for "market demand." The Council believes that the DEIS should use this figure or a slightly higher figure allowing for incremental growth of existing harvesting businesses as the basis for market demand.

   The Council strongly objects to setting market demand to meet the possible demand from industries or businesses that may one day choose to operate in Southeast Alaska. We do not believe that Forest Service needs to meet the fictional demand of businesses that exist only as ideas or proposals. Should viable industrial plans to use Tongass NF timber come close to implementation in the future, the plan may be amended to accommodate these new uses.

2. **A Revision or an Amendment**? The Council is unclear why Forest Service has chosen to undertake an amendment rather than a plan revision. We believe that the ecological situation on the Tongass NF has changed sufficiently, human uses and demands put on the forest have changed, global warming is upon us, and that new management perspectives have emerged since the plan was first approved. This argues for a full plan revision and not an amendment. The main changes we note are:

   a. Virtual collapse of the large scale industrial timber industry in the region. Presently, small producers are the main timber harvesters. Note that the Council supports these local Alaskan business endeavors.
   b. Tourism has grown exponentially since the plan was approved. The charter fishing industry is part of this growth and impacts subsistence directly.
   c. Management perspectives identifying the critical need to restore and rehabilitate clear cut areas of the Tongass NF have come to the fore.
   d. The consensus from scientific and Traditional Econological Knowledge is that the Tongass NF is being and will be profoundly affected by climate change. This effect on the forest and on subsistence uses needs to be fully evaluated in a new forest plan.

3. **Subsistence land use designation**. The Council continues to be concerned about the lack of an appropriate land designation for subsistence. In 1997 we wrote, "Although the Plan included 19 land use designations for purposes such as logging, recreation, research, and municipal watersheds, it included no

designations to protect the most important subsistence use areas of rural communities." To the extent that the DEIS considers subsistence at all, it looks at the effect of other uses on subsistence. We believe that subsistence is a prime use of Tongass NF natural resources and that it should be designated as such. The DEIS must plan **FOR** subsistence rather than merely see the effect of plan activities upon subsistence uses.

4. **Subsistence studies.** The original TLMP identified the need to conduct periodic harvest assessments and other studies of subsistence to provide the data needed by management and to assess whether ANILCA Sec. 810 protections were insuring a continuance of subsistence uses. The Council notes that this provision appears to have been dropped from the DEIS.

   The Council believes that periodic assessment of subsistence harvests and other documentation of subsistence characteristics needs to take place. Projects conducted through the Federal Subsistence Program have led to development of tribal and community capacity to successfully undertake management studies of this type.

5. **Conservation strategy**. Council members reviewed the joint statement of peer review committee members concerning the adequacy of conservation measures proposed for wildlife in the DEIS. The Council agrees with the conclusions that:

   a. The habitat reserves identified are inadequate to provide for viability of wildlife species on the Tongass NF.
   b. There is not enough connectivity between old growth reserves. Key areas for connectivity are:
      i. Cleveland Peninsula
      ii. Bay of Pillars-Port Camden-Three mile arm to Tebenkof Wilderness area on Kuiu Island
      iii. Whale Pass and Honker Divide on Prince of Wales Island
      iv. Hoonah Sound-Port Frederick-Tenakee Inlet on Chichagof Island
      v. Portage Bay-Duncan Salt Chuck on Kupreanof Island.
   c. There is too much fragmentation of wildlife habitat.
   d. In areas where there are wolves, fragmentation results in increased wolf predation and increased pressure on deer.

6. **Viability as a standard**. The DEIS emphasizes species viability and distribution as a standard that needs to be met. In the Council's view mere viability is not an appropriate standard. Subsistence users need to be able to harvest the wildlife and fish they need for subsistence within their normal community hunting and fishing areas, generally those areas where they have recognized customary and traditional use of the species in question. A better standard would be "sustainable and normally distributed" if this were taken to mean that fish and wildlife populations would be maintained in sufficient abundance and in locations where subsistence

harvests may take place.

7. **Habitat rehabilitation and restoration (R&R)**. Some restoration and rehabilitation projects aimed at recovering the original biological productivity of clear cut areas have been begun on Prince of Wales Island. The DEIS needs to greatly expand the scale and scope of R&R to address all clear cut and second growth areas on the Tongass NF. The stewardship responsibility of the Forest Service for areas that have had active timber management includes planning to restore areas to their natural condition.

8. **Impacts on fish and fisheries**. The Council believes that the DEIS inadequately reviews the impact on the region's fish populations and fisheries. Is it really plausible that there is ***no effect*** anywhere from the aggressive timber harvesting program pursued on public lands over that past 30 years? The Council would like more thorough discussion of effects on stream flow, stream temperature, transport of nutrients and feed from headwaters to fish rearing habitat, and the influence of large wood and beaver dams on fish productivity.

   The Council is concerned that known problems with culverts obstructing fish passage, with siltation from forest roads, and with detritus at log transfer facilities are not competently addressed. We need to know when and how these problems will be remedied.

   Steelhead should be listed as a species of concern .

9. **Competition for resources**. The DEIS needs to address the effects of competiton on subsistence uses. Increased road building for timber production would lead to more competition for fish and wildlife resources. Trout and steelhead are particularly vulnerable to over exploitation when there is road access to streams. Subsistence use areas on Gravina Island, Prince of Wales island, Kupreanof island, Wrangell island, Mitkof island, Baranof island, and Chichagof island all have ferry access, making them prone to competition from non subsistence hunters and fishers.

   An increase in timber production would require more logging camps in remote areas. This would greatly increase competition in some presently used subsistence areas.

10. **Climate change**. The DEIS needs a much fuller discussion of climate change and how the DEIS will respond to our best prediction of what lies ahead. Climate change and it's effects on the health of the forest ecosystem essential to wildlife and fish habitat is of great concern to the Council. The Council believes that maintaining diversity of forest flora is very important in a changing climate. Large scale changes to the landscape as a result of intensive logging minimizes diversity. Climate change as stated in the draft report will result in more severe weather which will cause more blowdowns, landslides, and siltation, impacting

streams. Summers could also be hotter and drier. Resulting insect infestation leading to loss of forest could effect stream temperatures. Cedar decline as a result of climate change is also resulting in loss of tree cover for winter range and stream shading.

11. **Maintenance of cultural practices**. In addition to cultural values mentioned in the draft report, the Council also believes that maintaining remote areas where subsistence activities take place is important. A certain amount of solitude is a valuable aspect of the subsistence way of life.

12. **Community assessments**. The council disagrees with the draft plan's blanket conclusion that their will be no impacts to subsistence fisheries for any communities in the Tongass forest. The Council notes that the community assessments do list many impacts to subsistence deer hunting. Given the importance to the rural economy of subsistence hunting, we think impacts on subsistence should be heavily weighted when deciding on an alternative.

13. **ANILCA Sec**. 810. Most or all of the alternatives proposed "may significantly restrict subsistence uses." The DEIS needs to show the relative level of impact from the different alternatives proposed. The alternatives directing large timber harvests have decidedly greater restrictions on subsistence uses than alternatives that direct less calamitously large harvests. Timber harvests in areas documented to be particularly important to subsistence users will have more effect than timber harvests that are less productive for subsistence harvesters.

The Council understands that, "No withdrawal, reservation, lease, permit, or other use, occupancy or disposition of such lands which would significantly restrict subsistence uses shall be effected until the head of such Federal agency--:

1) Gives notice to the appropriate State agency and the appropriate local committees and regional councils established pursuant to section 805;
2) Gives notice of, and holds, a hearing in the vicinity of the area involved; and
3) Determines that (A) such a significant restriction of subsistence uses is necessary, consistent with sound management principles for the utilization of the public lands; (B) the proposed activity will involve the minimal amount of public lands necessary to accomplish the purposes of such use, occupancy, or other disposition, and (C) reasonable steps will be taken to minimize adverse impacts upon subsistence uses and resources resulting from such actions.

The Council is primarily concerned with 3) above. We do not believe that the DEIS has demonstrated that the restrictions on subsistence uses that would occur from timber harvest levels above those of the past 10 years is "necessary" as intended in Sec. 810. Such excessive harvest would not be consistent with sound management of the Tongass NF. Further, the Council is not convinced that the

DEIS has demonstrated that the proposed actions would involve the minimum amount of land necessary. The DEIS also has not demonstrated specifically how adverse impacts to subsistence uses and resources would be minimized.

Please address any questions with this letter either directly to me or through Dr. Robert Schroeder, Subsistence Management Coordinator, U. S. Forest Service, Alaska Region, Box 21628, Juneau, AK 99802-1628, 1 800 586 7895, fax 907 586 7860, rschroeder@fs.fed.us.

Sincerely,

/S/

Dr. Michael P. Dombeck, Chief of the Forest Service
USDA Forest Service
PO Box 96090
Washington, DC 20090-6090

11/17/97

Dear Chief Dombeck;

The Southeast Alaska Federal Subsistence Regional Advisory Council (the Council) is a FACA chartered committee that has responsibility under Title VIII of the Alaska National Interest Lands Conservation Act (ANILCA) to make recommendations concerning issues and actions that may impact subsistence uses of wild renewable resources in the Region. The Council is comprised of citizens from across the Region, both Native and non-Native people selected for their extensive experience and knowledge concerning subsistence and non-subsistence resources and their uses. The members are appointed jointly by the Secretaries of the Interior and Agriculture.

At their recent public meeting in Yakutat (September 30 - October 2, 1997), the Council considered many issues, including the potential impacts of the Tongass Land Management Plan (TLMP). The Council is concerned about the reduction of subsistence opportunities that will occur as a result of the TLMP and unanimously passed a motion to write this letter in support of the Appeal to TLMP submitted to you by five Federally recognized Tribes in Southeast Alaska.

Five major Tlingit Indian Tribes of Southeast Alaska appealed the Revision of the TLMP, arguing that the Plan fails to protect customary and traditional uses of wild fish and game resources for subsistence purposes, as required by section 810 of ANILCA. The appellants are the federally recognized Indian Tribes from the four largest primarily Tlingit villages in the region: Hoonah, Angoon, Kake, and Klawock. The fifth appellant is the Tribal government for Sitka, the largest community in Southeast Alaska defined as "rural" under Title VIII of ANILCA. The Tribes make the following points in their appeal:

- Customary and Traditional uses of fish and game retain vital importance to these villages. Economically, they provide a substantial portion of the villages' food supply. Even more importantly, however, traditional harvest of wild fish and game is the foundation of Native culture.
- Clearcut logging of Tongass old growth harms subsistence uses primarily by destroying essential winter deer habitat. The Forest Service admits that implementation of the Plan will significantly restrict subsistence uses of deer. The agency projects that the areas of the Forest most heavily used for subsistence by rural communities will lose up to half of their deer habitat capability.
- This restriction to subsistence uses is not "necessary," as required by ANILCA section 810. There are no legal or contractual requirements that compel the Forest Service to take actions that restrict subsistence uses.
- The Forest Service illegally concluded that clearcut logging approved as part of a general "multiple use" balancing process justified any restrictions to subsistence uses. Congress enacted ANILCA section 810 specifically because the agencies were not adequately protecting subsistence uses under existing authorities such as "multiple use." Congress intended heightened protection for subsistence uses, not reduced opportunity.
- Although the Plan included 19 land use designations for purposes such as logging, recreation, research, and municipal watersheds, it included no designations to protect the most important subsistence use areas of rural communities.
- None of the standards and guidelines in the Plan provide meaningful protection for subsistence uses, but rather place a priority on timber production. The agency dropped the only standard that could have protected deer habitat in the most heavily use subsistence areas, falsely claiming that it would be "difficult to administer."

The Southeast Alaska Federal Subsistence Regional Advisory Council agrees with the Tribes' points outlined above and offers this letter in support of their appeal.

Sincerely,

Mim McConnell for William C. Thomas

Re: TLMP Adjustments

This letter is submitted on behalf of the Yakutat Salmon Board. The Yakutat Salmon Board is an advisory committee to the City and Borough of Yakutat. These comments are only reflective of Yakutat Salmon Board staff and should not be construed as City & Borough of Yakutat comments except when referenced.

We have a lot of experience with the timber aspect of TLMP in Yakutat. Over 1 billion board feet have been exported from East Yakutat. In addition, all economical timber in West Yakutat has been harvested and the timber operations are leaving this year. Given that Sitka Spruce Forests grow slowly in the North Tongass it is likely that we won't see 1
large scale timber production in our borough for at least another 100 years. In 1903 large tracts of land were harvested for railroad, fish plant and housing construction. The regrowth of this 104 year old forest averages around 10-12 inch dbh which is unsuitable for saw log production. Our community is in favor of small sales. The proposed map includes all small sale units proposed by the Yakutat District.

Our community relies on recreation and commercial fishing for the bulk of its economy. I feel the proposed land use changes illustrated by the enclosed map reflect the economic reality of our town. I also believe that non-local U.S. citizens using the Tongass in 2
Yakutat would agree that fishing, hunting and wildlife viewing is the best use of this public land. If there is a demonstrated need to prove this we can apply for survey money to statistically back this claim.

I strongly encourage the USFS to accept our proposed modifications to alternative 2, which were passed unanimously by the Yakutat Tlingit Tribal Council, The Yakutat Salmon Board, The Yakutat Planning and Zoning Commission and the City and Borough of Yakutat Assembly. I would like to see an increase in spending for Fisheries, Wildlife and Recreation projects on the district.

Sincerely,

Bill Lucey
Director, Yakutat Salmon Board

October 2005

9.0 Timber

Residents were asked how much they supported future timber harvest activities in Yakutat, which could occur on Forest Service, State, or Borough lands or a combination.

This question generated some controversy because the question told residents to assume that all timber harvest could stimulate local value added production and local jobs, that timber harvest would meet State and Federal environmental regulations, and that it could be designed to attempt to stabilize stands from future wind throw. Some suggested this wording was misleading because in their judgment it is the inability of timber sales to achieve these matters that has led to recent controversy and legal action. Residents answered the question as it was written and results indicate:

- Just under two-third (61%) of residents support or strongly support small timber sales.
- 18% support no timber harvesting while over half (56%) do not agree with this option.
- Just under half (46%) are against large timber sales, while one-third (33%) support them.
- 21-26% are neutral on all timber harvest options.

What Residents Say about Timber Harvest

	Net support	Strongly support	Support	Neutral	Against	Strongly against	Net against
Larger timber sales (1- 30 million board feet).	33%	15%	18%	21%	18%	28%	46%
Only small sales (less than 1 million board feet) and continuation of the free use program to fill local needs.	61%	23%	38%	21%	5%	12%	17%
No timber harvest at all.	18%	11%	7%	26%	26%	30%	56%
